Results: The current study reports on descriptive data from parent/caregiver assessment results in a sample of 38 (male=28, Female=10) individuals with ASD or other developmental disorders. The average age was 21.4 year (SD=12.89). In this sample, study participants sought help for a variety of concerns with agitation, aggression and moodiness as most prominent (See Table 1). Results showed that use of Antidepressant and Antipsychotic medication was high in this sample (both at 65.8%) and previous diagnosis of bipolar disorder was lower in females (10.0%) than males (17.9%). Data for each of the assessed conditions are reported in Table 2. With respect to psychiatric conditions identified in the current sample, high occurrences of depression (81.7%) and anxiety (94.7%) were present. In contrast, lower levels of psychosis (28.9%) were found relative to other conditions assessed. The current study found high levels of Sleep (60.5%) and GI (76.3%) concerns. The study also found relatively high levels of Dental (28.9%) concerns. Dental concerns are particularly noteworthy given that these are not routinely explored in psychiatric visits.

Conclusions: The current project documents initial results of a measure designed to support medical providers in caring for minimally verbal adolescents and adults with ASD or developmental disorders. These findings highlight the need to assess a variety of psychiatric and medical/physical conditions in medical visits. Given the current reliance on anti-psychotic medications for treating agitation and aggression in the population, the current findings underscore the need to appropriately assess the individual to properly plan medical treatment.

415.112 *(Poster)* Speech Characteristics of Young Children with ASD

M. Eni[1,2], *M. Ilan*[1,3,4], *A. Gorodetski*[1,2], *I. Menashe*[5], *G. Meiri*[6], *Y. Zigel*[1,2] *and* ***I. Dinstein***[1,3], *(1)National Autism Research Center of Israel, Ben Gurion University, Beer Sheva, Israel, (2)Biomedical Engineering, Ben Gurion University, Beer Sheva, Israel, (3)Psychology Department, Ben-Gurion University of the Negev, Beer Sheva, Israel, (4)Preschool Psychiatric Unit, Soroka Medical Center, Beer Sheba, Israel, (5)Public Health, Ben-Gurion University of the Negev, Beer Sheva, Israel, (6)Preschool Psychiatric Unit, Soroka University Medical Center, Beer Sheva, Israel*

Background: Social communication difficulties may be apparent in speech recordings of children with ASD. Previous manual and automated analyses of speech recordings from children with ASD have revealed a variety of abnormalities in both prosodic features of speech such as pitch and energy, and in features of conversation structure such as the length of speech segments and the number of responses. For example, children with ASD have been reported to exhibit excessive pitch variability, which may be related to excessive neural variability that has also been reported in ASD. Here we used signal processing techniques to analyze recordings of speech from ADOS assessments that were part of the initial ASD diagnosis. We quantified several prosodic and structure characteristics in individual children and examined their relationship with ASD severity.

Objectives: To quantify speech abnormalities in 2-7-year-old children from recordings of their initial ADOS assessments and determine their relationship to ASD severity.

Methods: Audio recordings of 65 children with ASD (57boys), 2-7-years-old, were extracted from ADOS assessments that were performed at the National Autism Research Center of Israel (www.autismisrael.org). The recordings were manually annotated to identify segments of the child's speech and the clinician's speech during the ADOS assessment. Vocal islands of the child's speech were then identified by their energy and a variety of prosodic features including pitch, energy, jitter, formants, and spectral slope were calculated in 40ms windows within each of the vocal islands. The mean and variance of each feature was computed across the vocal islands of each child. In addition, we quantified the total number of speech segments, their average length, and the number of segments where the child responded to the clinician. Each of the measures were correlated with individual ADOS scores.

Results: Significant negative correlations were found between the social affect scores of the ADOS assessment and measures of speech structure including the total number of vocal islands (r=-0.37, p=0.002), their rate (r=-0.39, p=0.001), and the number of responses (r=-0.41, p<0.001). Significant positive correlations were found between the repetitive and restricted behavior scores of the ADOS and the magnitude of energy variability (r=0.27, p=0.027), mean pitch (r=0.28, p=0.026), and pitch variability (r=0.36, p=0.004).

Conclusions: These results demonstrate that recordings of the child's interaction with the clinician during the initial ADOS assessment hold important information regarding the children's ASD severity that can be extracted using speech processing techniques. Furthermore, specific features are associated with specific symptoms domains as demonstrated by selective correlations with either social or repetitive and restricted behaviors scores. These results highlight the potential clinical utility of speech analysis for estimating ASD symptom severity at very young ages.

415.113 *(Poster)* Stability of the Mullen Scales of Early Learning As a Clinical Outcome Assessment for Clinical Trials in Phelan-Mcdermid Syndrome

B. Britvan[1]*, I. Giserman-Kiss*[2]*, J. Weissman*[1]*, D. Halpern*[1]*, J. Zweifach*[1]*, J. Buxbaum*[3]*, A. Kolevzon*[1] *and P. M. Siper*[1]*, (1)Seaver Autism Center, Department of Psychiatry, Icahn School of Medicine at Mount Sinai Hospital, New York, NY, (2)University of Massachusetts Boston, Brookline, MA, (3)Department of Psychiatry, Icahn School of Medicine at Mount Sinai, New York, NY*

Background: Phelan-McDermid Syndrome (PMS) represents a common single-gene cause of autism spectrum disorder (ASD) and intellectual disability (ID), making the cognitive domain a critical target for treatment. Clinical trials in PMS are hindered by limited knowledge about the stability of cognitive assessments in the absence of treatment changes during typical clinical trial periods.

Objectives: To investigate the stability of the Mullen Scales of Early Learning (MSEL) over a 12-week interval in children with PMS compared to children with idiopathic ASD (iASD) and ID. Greater variability is expected in the more heterogeneous iASD group.

Methods: Eleven children with PMS (6 females, m= 6.8 years) and 11 children with iASD and ID (2 females, m= 6.4 years) between the ages of 2-12, were evaluated using the MSEL at baseline and week 12. Data was collected as part of a larger study examining the stability of a battery of clinical outcome assessments (COAs). The MSEL measures early cognitive development across five scales: Visual Reception, Receptive Language, Expressive Language, Fine Motor, and Gross Motor. The MSEL is validated in children from birth to 68 months, and is commonly used in older children with ID. Intraclass Correlation Coefficients (ICCs) were calculated to examine absolute agreement in raw scores between baseline and week 12 for each MSEL scale.

Results: In the PMS group, ICCs were significant (p's <.001) for all scales except the Gross Motor scale (p=.057). ICCs for individual scales were as follows: Visual Reception ICC = .99 (95% Confidence Interval (CI) [.94, 1.00]), Receptive Language ICC =.97 (95% CI [.89, .99]), Expressive Language ICC = 1.00 (95% CI [.99, .1.00]), Fine Motor ICC = .99 (95% CI [.97, 1.00]), and Gross Motor ICC=.65 (95% CI [-.24, .90]).

In the iASD group, ICCs were significant for all scales (p's = .025 (Gross Motor) - <.001). ICCs for individual scales were as follows: Visual Reception ICC = .93 (95% CI [.77, .98]), Receptive Language ICC =.85 (95% CI [.47, .96]), Expressive Language ICC = .91 (95% CI [.65, .98]), Fine Motor ICC = .86 (95% CI [.47, .96]), and Gross Motor (n=7) ICC=.82 (95% CI [.11, .97]).

Conclusions: The MSEL is highly stable over a 12-week interval in individuals with PMS. Greater variability was observed in an iASD group reflecting gains made during the study period. In both groups, results indicated that the Visual Reception scale, a proxy of nonverbal cognitive functioning, is highly stable. The Expressive Language scale showed the greatest stability in the PMS group, although not in the iASD group as evidenced by a large CI. Gross motor skills were most variable for both groups. Overall, results suggest improvement in MSEL scores in the context of PMS clinical trials may be considered a meaningful indicator of treatment response. Data collection is ongoing to further examine the stability of the MSEL and other COAs in larger samples.

415.114 *(Poster)* Stigma As a Moderator for the Relation between Race and ASD Diagnoses

S. L. Johnson[1]*, R. A. Lindsey*[1] *and T. D. Barry*[2]*, (1)Washington State University, Pullman, WA, (2)Psychology, Washington State University, Pullman, WA*

Background: Past research has indicated that minority racial and ethnic groups in the United States face more barriers to accurate and timely autism spectrum disorder (ASD) diagnoses than their white counterparts (Mandel et.al., 2009). Research attributes this finding to cultural factors, different presentation of symptoms in minority children, and high stigmatization in minority communities of developmental delays and disorders (Mandel et.al., 2009).

Objectives: This research project is designed to determine if stigma moderates the relation between race and the time lapse between symptom onset and ASD diagnosis.

Methods: Data were collected from 152 parents of children with an ASD diagnosis. Parents were asked to report at what age their child began showing signs of ASD and what age the child was officially diagnosed with ASD. The age reported was converted to months if the parent reported in years, then a new variable was added by subtracting the age in months at time of symptom onset from age in months at time of diagnosis. Parents also completed a demographic questionnaire, including the child's race which was dichotomized as white and non-white. Finally, parents completed the Affiliate Stigma Scale which measured their own affective, behavioral, and cognitive stigma. The Total Stigma Scale score was used, with higher scores representing more stigma.

Results: An independent samples t-test indicated that the time lapse between symptom onset and diagnosis did not significantly differ between white and non-white participants. Furthermore, the time lapse between symptom onset and diagnosis did not significantly relate to the Total Stigma Scale score. However, a moderated multiple regression analysis indicated that the stigma score moderated the relation between race and the time lapse between symptom onset and diagnosis when comparing white participants (n = 123, M = 21.63, SD = 17.36) to non-white participants (n = 29, M = 17.66, SD = 18.86) p = .02. A post-hoc plot was conducted to examine the nature of the interaction (Figure 1), discussed further below.

Conclusions: These data suggest that race and stigma do play a significant role in how long it takes a child to receive an ASD diagnosis, but the findings are counterintuitive. Although neither race nor stigma individually related to the time lapse between symptom onset and diagnosis, their interaction was significant. Unexpectedly parents of minority children who reported experiencing higher levels of stigma also reported the shortest time lapse between symptom onset and diagnosis. Potential explanations for this finding could be over-pathologizing minority children's behaviors or possibly lower socioeconomic status providing access to free early intervention for minority children, either of which may have led to earlier diagnosis. Further research in this area is warranted to establish if this finding is replicated and to determine what may contribute to these varying outcomes.

415.115 *(Poster)* Study on Sensory Hypersensitivity in 5-Year-Olds with or Suspected of ASD Characteristics -Based on a Study Group of Parents and Childcare Workers Aiming for Reasonable Accommodation at School-

S. Sasaki[1]*, A. Hoshiyama*[2]*, M. Kondo*[3]*, C. Kobayashi*[4]*, A. Yagi*[5]*, Y. Ito*[6]*, N. Haniu*[2] *and M. Hoshiyama*[2]*, (1)Teikyo University, hachioji, Japan, (2)Meisei university, Hino, Japan, (3)Teikyo junior university, Shibuya, Japan, (4)Yugimusashino kindergarten, Hachioji, Japan, (5)INARI Kindergarten, Kita Ward, Japan, (6)Yokohama City Seibu Habiritation center, Yokohama, Japan*

Background: Research is being conducted on the relationship between infants' ASD characteristics and sensory hypersensitivity(Bromley,et al.2004). In recent years, Japan has begun to consider support tailored to sensory hypersensitivity. However, how to share information about how to use ASD characteristics and hypersensitivity for reasonable accommodation at school is still insufficient.

Objectives: The purpose of this study is to examine the ideal way of support aimed at reasonable accommodation at school for ASD characteristics and sensory hypersensitivity of a 5-year-old child.

Methods: We conducted a survey of infants' sensory hypersensitivity perceived by parents and childcare workers, and shared information between parents and childcare workers. The Japanese version of the SP Sensory Profile was used as an evaluation tool for sensory hypersensitivity. Next, we held a study meeting with parents and childcare workers who were in charge of each child how parents would tell school teachers about their children's sensory hypersensitivity when they at school. The subjects of the survey were four parents of five-year-old children attending kindergarten and two childcare workers in charge of the infants. This research has been approved by the Research Ethics Committee of Meisei University. There are no conflicts of interest in this study.

Results: The ratings of 4 parents and 2 childcare workers differed (Figure 1). We realized that infants appear differently in group life and at home as sensitive. Next, parents examined how to communicate to school teachers at the time of enrollment, and they gave consideration to obtaining photos inside and outside the school in advance as a measure of sensitivity to visual information. In addition to clarifying who can be relied upon when in trouble, we also examined how to rely on those who can be relied on for young children. Through these considerations, parents were able to obtain a method that would prevent their children from becoming anxious when transitioning to school. This effort has also helped parents feel safe.

Conclusions: The reasons why parents and childcare workers are differently evaluated are the individual factors of individual subjects and environmental factors such as homes and gardens. (Sasaki, et al. 2019). This time, there were differences in the results of parents and childcare workers in all four cases. As an environmental factor, it was speculated that the appearance of infants in the homes and the gardens are different. For this reason, it is speculated that when parents communicated only the appearance of infants in their homes to school teachers, it is difficult for teachers at school to know what to show in group life. In addition, we found it important to convey information about sensory hypersensitivity to teachers when transitioning to school. In the future, it will be necessary to introduce content of sensory hypersensitivity to the support program at the time of transition to school, and to consider reasonable accommodation methods for school children.

415.116 *(Poster)* The Associations between Age at Diagnosis, Motor Skills, and Severity of Autism Spectrum Disorder

A. Kniola*, C. Gelep, K. Tuohy and S. Char, Mailman Segal Center for Human Development, Nova Southeastern University, Ft. Lauderdale, FL*

Background: Research shows that as children with autism spectrum disorder (ASD) age, they may demonstrate different severity scores in relation to communication, socialization, and daily living skills (Baghdadli et. al., 2011). Motor skills are another area of adaptive functioning that are commonly delayed in children with ASD and could also be related to age. Additionally, research suggests overall severity of ASD changes as children age (Clark, Barbaro, & Dissanayake, 2017).

Objectives: It is hypothesized that children's age at diagnosis will be positively correlated with motor abilities and negatively correlated with overall severity of ASD. This relationship is expected due to some participants receiving prior diagnoses and services.

Methods: The sample included 87 participants diagnosed with ASD (males n =67, females n = 20) with an average age of 49.03 months (SD = 19.89 months). Data was collected over a three-year period from a community-based developmental assessment clinic. Participants consisted of 29.9% Caucasian, 28.7% Latino, 20.7% Black, 11.5% Biracial, and 3.4% Asian individuals. The remaining 1.1% of the sample selected 'other' in relation to ethnicity. Participants were assessed utilizing the *Vineland Adaptive Behavior Scales, Second and Third Edition, Parent/Caregiver Rating Form (Vineland-II, 3)* and the *Autism Diagnostic Observation Schedule, Second Edition (ADOS-II).*

Results: As hypothesized there was a significant negative correlation found between child's age at diagnosis and severity of ASD (r = -.533, p< 0.0001). However, contrary to hypotheses, age at diagnosis was not significantly correlated with motor skills (r = -.147, p = .175).

Conclusions: Older children in this sample appear to have lower severity of ASD. This relationship could be due to older children having prior diagnoses and services potentially improving some symptomatology. Age at diagnosis may not have been correlated with motor skills due to the Vineland -II and 3 not assessing children's motor skills after a specific age.

415.117 *(Poster)* The Clinical Global Impressions-Severity (CGI-S) Scale: Measuring Severity of Social Communication Impairment Among Minimally Verbal Children with Autism

A. J. Schlink *and C. Kasari, University of California, Los Angeles, Los Angeles, CA*

Background: Minimally verbal children with autism (MV) have been shown to respond to intensive interventions targeting joint attention (JA) (Mundy, Sigman, & Kasari, 1990). However, there is a dearth of valid assessment instruments that are specifically designed for MV children (Kasari et al., 2013). One promising approach to address social communication measurement among this population is the Clinical Global Impressions- Severity Scale (CGI-S; Guy, 1976). The CGI-S was originally used as a brief, observation-based, clinician-rated tool to measure the global severity of psychiatric disorders within NIMH clinical trials (Busner & Targum, 2007). Its protocol considers information from a variety of naturalistic contexts to yield a more accurate assessment of functioning. The CGI-S structure has been validated with existing instruments measuring symptomatology of complex disorders such as schizophrenia (Haro et al., 2003) and bipolar disorder (Spearing et al.,1997), but has not yet been validated in an autism population.

Objectives: This present study aimed to explore the validity of the CGI-S scale, a rating instrument designed to better assess social communication within MV children.

Methods: Participants included 54 MV children (M_{age}=6.05 years) in an intervention study whose purpose was to improve unique, spontaneous language.

At the beginning of treatment study, CGI-S ratings were conducted by blinded interventionists and were scored on a 1-7 scale. Higher ratings indicated more severe social communication impairment. To yield meaningful interpretations, CGI-S scores were dichotomized into two groups: the "less-severe" group (ratings 1-5) and "more-severe" group (ratings 6 & 7).

Nonparametric Wilcoxon rank-sum tests were used to determine if there was a statistically significant difference between "less-severe" and "more-severe" CGI-S groups across the Early Social Communication Scale (ESCS) and Repetitive Behavior Scale- Revised (RBS-R) scores. Next, two logistic regressions were used to model the odds of getting a "less-severe" CGI-S rating for every additional increase in specific JA behaviors as measured by ESCS variables after controlling for repetitive behaviors.

Results: Rate of JA initiations and percent of JA responses both differed significantly across groups (W=171, p=0.003, r=0.41; W=124, p< 0.001, r=0.50). Alternatively, RBS total scores did not differ significantly between the groups (W=224.5, p= 0.10).

Logistic regressions indicated a one unit increase in the frequency of JA initiations increased the odds of belonging to the "less-severe" group by a factor of 1.19, 95% CI (1.04-1.44). Additionally, a one percent increase in responses to JA bids increased the odds of belonging to the "less-severe" group by a factor of 1.07, 95% CI (1.03-1.12).

Conclusions: This CGI-S was the first instance a global impression framework had been applied to an autism population to measure social communication, which is often the primary target area for improvement in early behavioral interventions (Howlin et al., 2009). Accurately assessing the social communication skills before the start of intervention is an important first step to determine if a child is making appropriate progress within that mode of treatment. Ultimately, this study suggests the CGI-S could be used as a clinically meaningful and easily interpretable adjunct measure of social communication for MV children.

415.118 *(Poster)* The Development and Psychometric Evaluation of the Theory of Mind Inventory-Self Report-Adult Measure (ToMI-SR-Adult)

T. Hutchins[1]*, P. A. Prelock*[2]*, L. Lewis*[3] *and A. Brien*[2]*, (1)UVM, Burlington, VT, (2)Communication Sciences & Disorders, University of Vermont, Burlington, VT, (3)University of Vermont, Burlington, VT*

Background: Although self-report is being more widely used to assess a variety of characteristics in autism spectrum disorder (ASD) (e.g., anxiety, depression, systemizing, internalizing), self-assessment of social cognition remains a woefully understudied topic. This study reports on the development and preliminary psychometric evaluation of a new self-report measure to assess social cognition in autistic adults: The Theory of Mind Inventory: Self-Report - Adult (ToMI-SR-Adult). The ToMI-SR-Adult consists of 60 statements intended to tap the most advanced aspects of social cognition (e.g., metalinguistics, humor, deception, empathy, emotion blends) as they are presented in real world samples of behavior. The content of the ToMI-SR-Adult was guided by the social cognition literature in typical development and autism and refined through statistical analyses to retain the best performing items.

Objectives: Our objective was to evaluate the psychometric properties of the ToMI-SR-Adult in a sample of typically developing (TD) and autistic (ASD) adults who were diverse in their autism severity and diagnostic comorbidity.

Methods: An international sample of 300 fluent English speakers (111 with ASD and 189 TD; ages 18 - 72) completed the ToMI-SR-Adult online. From this sample, 80 cases were systematically excluded to create ASD and TD groups matched on sex and socioeconomic status. The ASD group was comprised of 111 adults (56 males; 55 females) from nine countries/regions. The TD group was comprised of 109 adults (54 males; 55 females) from five countries/regions.

Results: For the combined (ASD and TD) groups, Cronbach's alpha was .98 and was not improved by removing any items, suggesting that all contributed to the assessment of a unitary construct. When examined separately, the ASD and TD groups evidenced an alpha of .97 and .95 respectively, again indicating a high degree of internal consistency. Contrasting-groups validity was also performed to examine group differences (ASD vs. TD) at the composite score and item level. Significant between-group differences in the expected directions were found for all comparisons at $p < .001$. Moreover, effect sizes (Cohen's d) ranged from 0.60 to 1.86 which are medium to very large. Analyses for accuracy of classification revealed that 92.72% of females and 82.14% of males with ASD were captured by the measure. Positive predictive validity was 83.61% for females and 80.70% for males. Negative predictive validity was 91.84% for females and 81.13% for males. The overall accuracy of identification was 87.27% for females and 80.90% for males. Finally, we examined receiver operating characteristics and area under the curve. The ToMI-SR-Adult achieved a value of 0.95 for females and 0.89 for males. The overall value was 0.92 which is considered excellent.

Conclusions: We found preliminary support for the reliability and validity of the ToMI-SR-Adult. This justifies further development and validation of the measure and supports the notion that autism does not preclude self-awareness and that often, autistic adults may be the best judges of their own subjective social-cognitive experiences.

415.119 *(Poster)* The Effects of Gender and Race/Ethnicity on DSM-5 Criteria of Autism Spectrum Disorder

B. Cauley[1]*, K. J. Tepper*[1]*, J. Schuttler*[1] *and R. Jamison*[2]*, (1)Pediatrics, University of Kansas Medical Center, Kansas City, KS, (2)Center for Child Health and Development, Pediatrics, University of Kansas Medical Center, Mission, KS*

Background: Autism spectrum disorder (ASD) occurs more frequently in males than females (Kogan et al., 2009; Lai et al., 2015; Rynkiewicz et al., 2016). Previous research suggests that males and females may have different symptom presentations based on endorsed DSM criteria for ASD (Hiller et al., 2014). In addition, there are racial/ethnic disparities in parent reported concerns of ASD (Donohue et al., 2019) and age of diagnosis (Dickerson et al., 2017; Ratto et al., 2015). A better understanding of how race/ethnicity and gender may influence diagnosis and presentation of ASD could inform screening, referral, and assessment processes.

Objectives: This study sought to identify potential differences in the likelihood of meeting DSM-5 criteria for ASD based on gender (i.e., males and females) and race/ethnicity (i.e., White or racial/ethnic minorities). Further, we examined whether gender or racial/ethnic differences emerged in presentation of symptoms among children who received a diagnosis of ASD, focusing on restricted, repetitive behaviors or interests (Category B), as endorsement can vary within diagnosis for these behaviors.

Methods: A retrospective analysis of deidentified data included 1,444 children and adolescents who were referred for and completed an interdisciplinary evaluation for autism spectrum disorder at an academic medical center in the Midwestern United States (mean age = 6.37 years, SD = 4.16). The sample was primarily White (66.4%; 33.6% racial/ethnic minority) and male (73.5%; 26.5% female); 58.7% of the sample received a diagnosis of ASD. Chi-square tests were used to identify differences in presence of symptom criteria based on race/ethnicity and gender. Standardized residuals were examined to determine group differences.

Results: Among all individuals referred for evaluation (regardless of eventual diagnosis), race/ethnicity was significantly related to likelihood of meeting individual DSM-5 diagnostic criterion for autism, including deficits in nonverbal communication (A2; $p = .001$) and stereotyped behaviors (B1; $p < .001$). Specifically, a significantly lower proportion of racial/ethnic minorities did not meet criteria for A2 or B1 compared to Whites. In addition, a higher proportion of racial/ethnic minorities met criteria for B1 compared to Whites. Regardless of eventual diagnosis, gender was significantly related to meeting criteria for insistence on sameness (B2;$p = .001$) and restricted interests (B3; $p < .001$). Specifically, a significantly higher proportion of females did not meet criteria for B2 compared to males, and a significantly lower proportion of females met criteria for B3 compared to males.

Looking more specifically at children who received a diagnosis of ASD, there were no significant differences by race/ethnicity for any of the Criteria B symptoms. However, gender was significantly related to meeting criteria for RRB symptoms, such that a higher proportion of females with an ASD diagnosis did not meet criteria for either B2 ($p = .004$) or B3 ($p = .001$) compared to males with ASD.

Conclusions: Findings from this study demonstrate differences in DSM-5 symptom presentation based on race/ethnicity and gender. Our findings are consistent with previous research that males and females differ in ASD symptom presentation and suggest implications for referrals, assessment, and diagnosis of ASD in diverse groups of children.

415.120 *(Poster)* The Efficacy of a DSM-5 Specific Symptom Checklist in Identifying Children with an Autism Spectrum Disorder (ASD) Diagnosis Using Cluster Analysis

R. Lieb *and D. T. Pulsipher, NeuroDevelopmental Science Center, Akron Children's Hospital, Akron, OH*

Background: ASD screening tools infrequently correctly identify those with true ASD. For example, although the M-CHAT has an excellent negative predictive value (~100%), its positive predictive value for ASD specifically is as low as 26.3%. Additionally, the wait time for formal ASD diagnostic assessment has grown, with families typically waiting 3.5 years for a diagnosis. Therefore, it is important to improve screening processes to more accurately identify those truly at risk for ASD.

Objectives: Evaluate the efficacy of a DSM-5 specific ASD symptom checklist.

Methods: Data were reviewed from 320 ASD evaluations at a midwestern children's hospital (mean child age=65 months, SD=25). Upon initial referral, caregivers completed an intake questionnaire including sociodemographic information and a 24-item DSM-5 symptom checklist (e.g., "*Trouble looking people in the eyes/making eye contact, Not showing interest in interacting or making friends with other children, Difficulty with change in routine, Sensory sensitivity to noises, smells, touch/texture"*. Parents rated each item *never, sometimes, often,* or *very often*. Zero-17 months later, in-person evaluations were completed, including clinical interviews, the Autism Diagnostic Observation Schedule, 2nd Edition (ADOS-2), Adaptive Behavior Assessment System, 3rd Edition (ABAS-3), and Social Communication Questionnaire (SCQ). Statistical analyses were conducted using SPSS 26. For questionnaire data reduction, Principal Component Analysis (PCA) and symptom clustering using DSM-5-based scores were each used. Two-step cluster analysis was implemented separately for each set of scores. If more than one cluster was identified, clusters were compared on age, sex, race, interval between intake and evaluation ("time"), provision of ASD diagnosis (and severity level), and ADOS-2, ABAS-3, and SCQ scores. Dichotomous variables were compared using Chi-square tests, and continuous variables were compared using Mann-Whitney U tests after examining variable distributions using Shapiro-Wilk's analyses.

Results: The sample was predominantly male (78.8%) and Caucasian (80%). 55.6% received an ASD diagnosis. PCA identified five separate components, but usage of component scores indicated one cluster; therefore, those components provided no meaningful discriminating information. Two-step cluster analysis using DSM-domain scores identified two clusters (Cluster 1 n = 113, Cluster 2 n = 207) of fair-good quality (0.5). These clusters did not differ significantly by sex, race, ASD level, age, time, and ADOS-2 scores (p's=0.14-0.997). Cluster 2 had significantly higher parental education, ABAS-3 and SCQ scores, and more children with ASD (Cluster1 = 54%, Cluster 2 = 56%). However, the effect size was very small (Cramer's $V = 0.011$), rendering this difference clinically meaningless.

Conclusions: Neither statistical nor theoretical groupings of caregiver-completed DSM-5 symptom checklists produced unique clusters that differed on ADOS-2 scores. While theoretically-derived domain scores produced groups that significantly differed regarding ASD diagnosis, the effect size was extremely small. This suggests that, despite a need for more sensitive screening tools, even explicitly asking caregivers questions based on DSM-5 diagnostic criteria does not improve diagnostic accuracy and does not appear to be a suitable substitute for behavioral observations and formal assessment by trained clinicians. Identification and/or development of sensitive and specific screening tools remain an important area of research to facilitate more accurate and efficient diagnosis.

415.121 *(Poster)* The First Five Minutes with a Toddler on the Spectrum: When Do Clinicians Know It's Autism, and What Makes Them Sure?

A. de Marchena[1]*, A. T. Wieckowski*[2]*, S. J. Fernandes*[2]*, L. Nichols*[2]*, L. B. Adamson*[3]*, S. Dufek*[4]*, D. A. Fein*[5]*, A. C. Stahmer*[6] *and D. L. Robins*[2]*, (1)University of the Sciences, Philadelphia, PA, (2)A.J. Drexel Autism Institute, Drexel University, Philadelphia, PA, (3)Psychology, Georgia State University, Atlanta, GA, (4)Psychiatry, University of California, Davis, Sacramento, CA, (5)Psychological Sciences, University of Connecticut, Storrs, CT, (6)Psychiatry and Behavioral Sciences, University of California at Davis MIND Institute, Sacramento, CA*

Background: Diagnosing clinicians report that autism is immediately apparent in some, but not all, children ultimately diagnosed (de Marchena & Miller, 2017; McDonnell et al., 2019). Clinicians' initial diagnostic impressions have significant implications for accurate final diagnoses (Hedley et al., 2016); however, little is known about the differences between children whose autism is and is not immediately apparent. In addition, very little is known about how confident clinicians are in these critical first impressions, and why.

Objectives: The objectives of this study were: (1) to compare toddlers with autism whose diagnosis is vs. is not immediately apparent, and (2) to investigate predictors of expert clinicians' *confidence* in their initial diagnostic impression.

Methods: Participants (n=87) were toddlers with autism, referred for an evaluation as part of primary care screening studies. Evaluating clinicians with expertise diagnosing autism in toddlers recorded their immediate diagnostic impression five minutes into the evaluation, which typically included greeting the parent and child and observing the child during consent or developmental testing. Clinicians recorded (1) if they believed the child would meet criteria for autism or not following a complete evaluation, and (2) their confidence, on a scale of 1-5, regarding that impression.

Results: First impressions were accurate 64% of the time (i.e., True Positives); 36% of the time (i.e., False Negatives), clinicians initially believed the child did *not* have autism, but ultimately diagnosed autism. Autism severity (p=.01), child age (p=.03), and clinician confidence (p=.02) were higher in the True Positive group vs. False Negative group; groups were comparable on race and sex ratio, M-CHAT score, and developmental level (Table 1).

Predictors of clinician confidence were tested by entering child characteristics and clinician first impression into a regression, with the interaction between first impression and ADOS-2 scores as a second step (Table 2). In Model 1 (p=.006), adaptive behavior skills and race were independent predictors: clinicians were more confident in their first impressions when children were more delayed, and when children were White. In Model 2 (p=.002), the interaction between ADOS-2 scores and first impression group was also significant; for True Positives, clinicians were more confident when children had higher ADOS-2 scores, $r(55)$=.32, p=.02, whereas for False Negatives, ADOS-2 scores were unrelated to confidence, $r(28)$=-.16, p=.41.

Conclusions: For the majority of toddlers ultimately diagnosed with autism, expert clinicians accurately suspected an autism diagnosis within the first five minutes. For about a third of cases, the diagnosis did not become clear until more data was gathered during the evaluation. Clinicians were more likely to immediately suspect autism in older, more symptomatic toddlers, but clinicians' first impressions were equally accurate across sexes. Clinicians were more confident in their first impressions when children were more delayed. Race uniquely appears to be related to the *confidence*, but not the *accuracy* of clinicians' first impressions. The True Positive and False negative groups were also quite similar, suggesting that clinicians' first impressions may be driven by subtler, more nuanced child factors that were not specifically tested here, such as vocal prosody or motor behavior.

415.122 *(Poster)* The Impact of Executive Functioning on Adaptive Behavior in Children with ASD

A. K. Jordan[1] *and L. A. Oakes*[2]*, (1)University of Rochester Medical Center, Rochester, NY, (2)The Ernest J. Del Monte Institute for Neuroscience, University of Rochester Medical Center, Rochester, NY*

Background: Adaptive behavior deficits are well-documented in children with autism spectrum disorder (ASD; Lee & Park, 2007), and greater deficits are noted in children with comorbid attention-deficit/hyperactivity disorder (ADHD) symptomology (Yerys et al., 2019). Given that executive functioning (EF) skills are one component of ADHD symptomology and are teachable, it is important to examine their impact on adaptive behavior in children with ASD (Bertollo & Yerys, 2019). Previous research has shown that EF abilities are strongly related to adaptive behavior in ASD (Gardiner & Iarocci, 2018), and explain the variability in adaptive behavior above and beyond combinations of age, sex, Nonverbal IQ, Full Scale IQ (FSIQ), and ASD symptomology (Bertollo & Yerys, 2019; Pugliese et al., 2015). To date, studies have either examined the predictive role of broad ADHD symptoms on specific adaptive behavior subscales (Uljarevic et al., 2019), or have examined the role of EF specifically, compared to broad behavioral measures (Gardiner & Iarocci, 2018). Given the nuances within EF and adaptive behavior, it is important to further examine the relationships between specific domains within each, as this could have clinical implications.

Objectives: The aim was to explore the utility of the Behavior Rating Inventory of Executive Functioning (BRIEF) in predicting differences in adaptive behavior (measured by the Vineland Adaptive Behavior System, Second Edition [VABS-II]) in a sample of children with ASD. It was hypothesized that global EF deficits would explain variability in adaptive behavior, above and beyond age, FSIQ, and ASD symptom severity. Exploratory analyses investigated EF subdomains.

Methods: Fifty-two children with ASD, ages 6 to 12 years (M=9.68,SD=1.86) and with FSIQs from 51 to 129 (M=92.79, SD=19.53) were assessed on measures of EF (BRIEF) and adaptive behavior (VABS-II). Hierarchical regression examined the relationship between EF (Global Executive Composite) and individual differences in adaptive behavior (Adaptive Behavior Composite), after accounting for age, FSIQ, and ASD symptom severity. Exploratory hierarchical regression examined the role of Metacognition and Behavioral Regulation.

Results: As hypothesized, EF skills explained variability in adaptive behavior, after controlling for age, FSIQ, and ASD symptom severity (β = -0.34, *p*= 0.01). Greater difficulties in EF indicated lower adaptive functioning. Neither Metacognition (β = -0.25, *p*= 0.09) nor Behavioral Regulation (β = -0.11, *p*= 0.46) contributed significantly individually.

Conclusions: The results show that parent-reported EF skills can predict adaptive functioning abilities in a diverse sample of children with ASD. Since EF skills can be taught through direct instruction, this suggests that interventions designed to improve executive functioning abilities may be an important component of adaptive functioning skill building, regardless of whether a child has ADHD symptoms. While neither of the EF domains was a significant contributor to adaptive functioning overall, results may have been limited by the sample size. Further investigation with a larger sample could help to illuminate the potential contribution of these individual domains and findings could be used to further tailor therapies.

415.123 *(Poster)* The Impact of a Previous Diagnosis on Parental Reporting of Adaptive Functioning

***C. Gelep**, K. Tuohy, A. Kniola and S. Char, Mailman Segal Center for Human Development, Nova Southeastern University, Ft. Lauderdale, FL*

Background: When a child obtains a diagnosis from a health provider in order to ensure their child receives the necessary services, parents may sometimes overreport symptoms or behaviors. Parental objectivity is important when a child is being formally assessed for a developmental disability. Although several of the assessments utilized in the diagnostic process of autism spectrum disorder (ASD) are based on parental report, it should not be the sole tool used in diagnosing. In truth, a combination of parental report measures and direct observation is recommended (Falkmer, Anderson, Falkmer, & Horlin, 2013).

Objectives: The current study investigated whether having a prior diagnosis would impact parental report of adaptive functioning. It was expected that the individuals who possessed a prior diagnosis would obtain a lower Adaptive Behavior Composite (ABC) score as measured on the *Vineland Adaptive Behavior Scales, Second or Third Edition Parent/Caregiver Rating Form (Vineland-II, 3)*.

Methods: Participants included 227 children (Males n = 175, Females n = 52) evaluated at a community-based developmental assessment clinic, over the span of three years, which is the reason why certain participants received the *Vineland-II* or *Vineland*-3. Ages of participants ranged from 19 to 253 months (μ= 69.04 months) and they were assessed using the *Vineland-II or Vineland-3* and whether or not the child possessed a previous diagnosis prior to the evaluation. The sample consisted of 30.4% Caucasian, 26.9% Latinx, 18.9% African American, 11.9% biracial, and 2.6% Asian Americans participants. It is important to note that 2.2% selected 'other' in relation to ethnicity. All participants were at-risk for ASD, as determined by a phone screening method. However, not all participants were ultimately diagnosed with ASD.

Results: As hypothesized, there was a significant difference between the *Vineland's* ABC scores between individuals who possessed a previous diagnosis (μ = 73.49, *s* = 13.01) and those who did not (μ = 78.63, *s* = 13.31), t(225) = 2.938, p = .004).

Conclusions: These results suggest that the responses from parents/caregivers yielded lower ABC scores on the *Vineland* when their children had a previous diagnosis of ASD. These results should be interpreted with caution considering that parents may unintentionally be overreporting behaviors on the *Vineland* scores to ensure their child receives the necessary services. Such findings are crucial as they can help to determine how different sources of information should be considered in the evaluation process.

415.124 *(Poster)* The Influence of the ADOS-2 E-Codes on the Assessment and Classification of Autism Spectrum Disorder

***M. R. Ledoux**[1], M. Heyman[2], Y. Bolourian[3], K. K. Stavropoulos[4] and J. Blacher[4], (1)Graduate School of Education, University of California, Riverside, Riverside, CA, (2)UC Riverside, Riverside, CA, (3)University of California - Riverside, Riverside, CA, (4)Graduate School of Education, University of California Riverside, Riverside, CA*

Background: Though individuals with autism spectrum disorder (ASD) experience similar core symptoms, the presentation of behavioral phenotypes vary significantly (Gotham, Risi, Pickles, & Lord, 2007). The ADOS-2 is a "gold standard" observational assessment to determine the classification of ASD. The final section of the ADOS-2 consists of E-codes, targeting behaviors consistent with anxiety, overactivity, and tantrums/aggression. Little research has been conducted to explore the role of the E-codes in the assessment of ASD.

Objectives: This study explored whether significant differences exist on the E-codes between children who qualify for ASD and those who do not on the ADOS-2, and to test whether clinical observations of behaviors during the ADOS-2 related to parent reports (i.e., Child Behavior Checklist).

Methods: Participants included children (*n* = 347, 72.6% male, *M* = 6.30 years *SD* = 3.33) who received screening for ASD. Participants were assessed using the ADOS-2. Chi-square analyses were conducted comparing the ADOS-2 E-codes for anxiety, tantrums/aggression, and overactivity from Modules 1, 2, and 3 by ASD classification (ASD versus non-Spectrum). Correlations were conducted between E-codes and behavioral measures (e.g., CBCL).

Results: Module 1. Within overactivity, there was a significant difference on scores of 2 between ASD groups, $X^2(1)=11.18$, $p=.001$. Score of 2: All (100.0%) classified as ASD. Module 2. Within Anxiety, there was a significant difference on scores of 0 between ASD groups, $X^2(1)=7.20$, $p=.007$. Score of 0: 34.9% classified as ASD versus 65.1% as non-spectrum. No significant differences were observed between ASD groups on Module 3. Across modules, no significant differences were found within Tantrums/Aggressions. No significant correlations were observed between Module 1 Overactivity and Module 2 Anxiety with CBCL Externalizing and Internalizing scales, respectively.

Conclusions: Results indicate differences on E-codes for Modules 1 and 2 between ASD classification groups. On Module 1, children who met criteria for ASD were more likely to show markedly high levels of activity (i.e., overactivity); in fact, all 17 participants who scored a 2 were classified as having ASD. This may point to the variability in ASD symptom presentation and/or the presence of a phenotype associated with ADHD. On Module 2, children who did not meet criteria for ASD were more likely to show marked signs of anxiety compared to those with ASD. As some symptoms of anxiety appear similar to symptoms of ASD (e.g. lack of eye contact, social withdrawal, nervous fidgeting), our findings may reflect the parental concerns that prompt a screening for ASD. Results also revealed no significant correlations between parent-reported symptoms on the CBCL and direct observations on E-codes for Modules 1 or 2. This has important implications for the source of information and time limits for behavioral observations on the ADOS. Although preliminary, these findings point to some important differences in E-codes for children who meet criteria for ASD, compared to children who do not, in the domains of anxiety and hyperactivity. Further analyses may help to interpret scores on the ADOS-2 E-codes, and suggest other behavioral concerns (e.g., ADHD, behavior problems, anxiety) that should be assessed.

415.125 *(Poster)* The Presence (or not) of Parent Concerns before Universal Autism Screening in Primary Care

J. S. Miller[1], *K. Fleming*[2], *W. Guthrie*[1], *K. E. Wallis*[3], *M. Gerdes*[2], *M. Udhnani*[1] *and A. Bennett*[3], *(1)Center for Autism Research, Children's Hospital of Philadelphia, Philadelphia, PA, (2)Children's Hospital of Philadelphia, Philadelphia, PA, (3)The Children's Hospital of Philadelphia, Philadelphia, PA*

Background: The US Preventive Services Task Force indicated that for ASD screening to be recommended for all children, more evidence is needed about whether screening identifies children before they are of concern to parents or providers. Since publication of the Task Force report, several large-scale primary care studies have reported relatively low sensitivity of the M-CHAT-F and M-CHAT-R/F, the most widely used parent report screening tools. While troubling, universal screening with imperfect measures could still contribute to earlier detection and intervention, if at least some children accurately screen positive before their parents or providers are concerned. In ASD, many parents report in retrospect that they were concerned about their child long before the diagnosis was made. Unfortunately, there is very little prospective research on whether and when parents actually raise concerns to their primary care providers, which limits our ability to understand how parent concerns can contribute to early detection. This type of research is especially limited in low-risk, population-based primary care settings with a universal screening program in place.

Objectives: We set out to determine the extent to which parents raised any concerns to their primary care providers before the child screened positive through universal ASD screening.

Methods: We reviewed 25,999 children from a universal screening program who were followed to at least age 4 years (Guthrie et al., 2019). From this population, we identified 176 children who both screened positive on the M-CHAT-F and were later diagnosed with ASD (an additional 278 with ASD screened negative). We categorized parent concerns into the following groups: ASD-specific, Development (speech, motor, general development); Behavior (sensory, emotion dysregulation, unusual behaviors); or No Concerns. We also determined whether the concerns were resolved before age 15 months, or were present between the ages of 15 months and the age of first M-CHAT-F administration.

Results: Of the 176 children with ASD who screened positive, 22% had No Concerns documented in the electronic health record at the time of screening (13% had no concerns since birth). 39% had non-ASD-specific concerns about both Development and Behavior; 26% had concerns about Development only; 13% had concerns about Behavior only. Only 12% of parents were specifically concerned their child might have ASD before screening. When parents were specifically concerned about ASD, they were also concern about Development, Behavior, or both; and often had an older sibling already diagnosed with autism (representing 8 of the 10 known infant siblings). Across individual concerns, the most common were speech delay (59%), sensory dysfunction (40%), gross motor delay (35%) and repetitive behaviors (25%).

Conclusions: Despite imperfections in the M-CHAT-F, our results suggest universal autism screening did identify children before they were of concern to their parents. Work is underway to examine parent concerns in children with ASD who screened negative, as well as children with ADHD and Language delay from this same cohort of 25,999 (and will be presented). Understanding the type and timing of concerns parents raised during primary care will help us improve early detection and intervention for children with ASD.

415.126 *(Poster)* The Relationship between Anxiety and Sensory Subtype in School-Aged Children with Autism

R. Lange[1], *S. J. Lane*[2], *T. Johnson*[3], *L. Rowlandson*[3], *G. Easey*[3], *U. Schall*[3], *L. E. Campbell*[4], *A. J. Woolard*[5] *and* ***A. E. Lane***[6], *(1)University of Newcastle, Newcastle, NSW, Australia, (2)Occupational Therapy, Colorado State University, Fort Collins, CO, (3)University of Newcastle, Callaghan, NSW, Australia, (4)School of Psychology, University of Newcastle, Newcastle, Australia, (5)University of Newcastle, Australia, Callaghan, Australia, (6)University of Newcastle, Callaghan, Australia*

Background: Anxiety disorders and sensory issues are common in children with Autism Spectrum Disorder (ASD; Green & Ben-Sasson, 2010). Previous studies have identified that anxiety is closely associated with the severity of sensory symptoms (Uljarević, Lane, Kelly & Leekam, 2016). Recently, several groups have identified patterns of sensory symptoms in ASD referred to as sensory subtypes (Ausderau et al. 2014; Lane et al. 2014). In Lane's sensory subtype model, subtypes are posited to be related to two latent constructs – sensory reactivity and multi-sensory integration (Hand et al. 2017). Understanding of the relationship between sensory subtypes and their latent constructs with co-morbid symptom sets such as anxiety, may assist in identifying the most optimal approach to intervention (Lane, Molloy & Bishop, 2014). To date, there is no research examining the relationship between anxiety and sensory subtype in school aged children with ASD.

Objectives: This study aims to further examine the relationship between anxiety and sensory subtype in autism by focusing on school-aged children, and utilising both parent report and physiological measures.

Methods: The data utilised in this study was drawn from a larger study investigating the effectiveness of the Alert Program on self-regulation in children with ASD. The screening and baseline data collected as a part of the Alert Program study was analysed and utilised. Participants were children aged from six to twelve years with ASD and an IQ>70 (n=19) and their caregivers. Caregivers completed the Short Sensory Profile (Dunn, 1999) to establish sensory subtype and the Spence Children's Anxiety Scale (Spence, 1998). Respiratory Sinus Arrhythmia (RSA) and impedance (IMP), were collected via a seven-lead electrocardiogram (ECG) during a clinician administered sedentary sensory assessment.

Results: There was no correlation found between sensory reactivity and the average RSA score (r= -0.07, p= 0.77). We did, however, observe a strong and significant negative correlation (r= -0.56, p= 0.02) between average RSA score and multi-sensory integration. A moderate but non-significant association was also observed between sensory reactivity and anxiety (r= 0.42, p = 0.08). Despite the past literature identifying that cardiac measures are an appropriate reflection of anxiety (Chalmers, Quintana, Abbott & Kemp, 2014; Sharma, Balhara, Sagar, Deepak & Mehta, 2011), no relationship was found between RSA and scores on the Spence Children's Anxiety Scale (r= -.15,p= .58).

Conclusions: We found preliminary evidence to support the relationship between physiological arousal and sensory symptoms consistent with subtypes where difficulties are focused in multi-sensory integration. Contrary to expectations, there was no relationship, however, between physiological arousal and sensory reactivity or parent-reported anxiety. Further research is needed to confirm this finding in a larger sample.

415.127 *(Poster)* The Role of Lightness in Color Discrimination Among Adults with Autism

***H. Choi**, Centrummottagningen (psychiatric clinic for autism and psychosis), Stockholm, Sweden*

Background: There is a growing body of evidence that Autism Spectrum Disorder (ASD) entails diverse vision alterations, which, in turn, may lead to many behavioral symptoms of ASD. A handful of studies have focused on color vision, reporting unanimously atypical color discrimination in this group. Despite its importance in visual perception, very little is known about the role of lightness in color vision in ASD. This study aimed to examine whether color discrimination in varying lightness is atypical among adults with ASD.

Objectives: Our objective is to address the following research question: does lightness discrimination capability differ in ASD as compared to TD counterparts? Considering prior studies, we hypothesize that the ability to discriminate colors differing in lightness is hampered among individuals with ASD. We operationalize the question via three tests, each addressing one of the following sub-questions: (1) Does the finest threshold in lightness discrimination differ between these two groups? (2) Does the presence of multiple stimuli varying in lightness affect lightness discrimination ability? (3) Is discrimination ability affected by motion in the stimuli?

Methods: A computer-based test battery with three test blocks was developed for carrying out this study. The blocks consisted of (1) single static stimuli for estimating lightness discrimination threshold, (2) multiple static stimuli for measuring the effect of the presence of other stimuli with similar lightness, (3) cardinal motion stimuli for measuring the ability to detect motion determined by variation in lightness. Six colors were tested, namely, red, green, blue, yellow, cyan and magenta. 15 adults with Asperger syndrome (AS) and 15 typically developing adults (TD) were recruited and administered the test during fall 2018. Three of the participants in the former group were also diagnosed with ADHD. Mann-Whitney U tests were conducted on number of errors, size of errors, and reaction time. Spearman's rank correlation tests were performed on current and AS diagnosis age.

Results: This study found (1) that the AS group performed as well as the TD group in most tested color categories; (2) significant positive correlation between reaction time, size of errors and age in the red color category in the AS group; and (3) in the blue color category, individuals with ADHD outperformed the others in the AS group, and in some cases even those in the TD group.

Conclusions: While it is common for autism assessment studies to focus on children, our study focused on adults, and a wider than usual age span (22 to 54). Our analysis reveals that autism may lower the ability, as age advances, to discern differences in lightness in the red color category. Also, our study included participants with both AS and ADHD. The data revealed that ADHD may mitigate the otherwise poorer performance in lightness discrimination in the blue color category. This latter finding is interesting in light of previous results (Banaschewski et al., 2006) showing that individuals with ADHD perform poorly in chromatic (as opposed to lightness) discrimination tests in the blue-yellow color axis.

415.128 *(Poster)* The Social Skills Improvement System (SSIS) – Teacher Report in Children with ASD Compared to a Clinical Non-ASD Sample

***A. Milgramm**, K. V. Christodulu and M. Rinaldi, Center for Autism and Related Disabilities, Albany, NY*

Background: The *Social Skills Improvement System* (*SSIS)* is a norm-referenced measure that is often included in comprehensive evaluations for autism spectrum disorder (ASD; Gresham & Elliott, 2008). The *SSIS – Teacher Report* provides information regarding children's social skills and problem behaviors within a classroom setting, and directly links the assessment results to intervention tools (Gresham, Elliott, Vance, & Cook, 2011). Despite its many benefits, the utility of the *SSIS – Teacher Report* for differentiating children with autism from other clinical vulnerabilities has yet to be studied.

Objectives: To examine differences between teacher-reported social skills and problem behaviors on the *SSIS* between children with ASD and an age-matched clinical sample.

Methods: Participants included 61 elementary school-aged children who received a comprehensive evaluation for ASD through a university-affiliated autism center (M_{age} = 7.4 years). 33 children received a diagnosis of ASD (54.1% of sample). The remaining 28 children either received no diagnosis (17.8%), or received a diagnosis of ADHD (60.7%), anxiety (17.9%), or OCD (3.6%). As part of the evaluation, teachers completed the *SSIS* (Gresham & Elliott, 2008). The Social Skills domain consisted of seven subscales: Communication, Cooperation, Assertion, Responsibility, Empathy, Engagement, and Self-Control. The Problem Behaviors domain consisted of five subscales: Externalizing, Bullying, Hyperactivity/Inattention, Internalizing, and Autism Spectrum. Behavioral levels were assigned to indicate whether each child was below average, average, or above average on each domain and subscale. Independent samples t-tests and Mann-Whitney U tests were conducted to examine group differences on overall domains and subscales, respectively.

Results: Means for both diagnostic groups were in the below average range on social skills (ASD: M = 80.9; non-ASD: M = 84.0) and above average range on problem behaviors (ASD: M = 115.9; non-ASD: M = 117.0). There were no differences between the ASD and non-ASD groups on overall social skills ($t(57) = -.84$, $p = .40$) or problem behaviors ($t(58) = -.25$, $p = .80$). Children with ASD had significantly lower assertion compared to the non-ASD group ($U = 627$, $z = 2.71$, $p < .01$), but did not differ on the other six social skills subscales (p's > .01). There were no differences between groups on the five problem behaviors subscales (p's > .01).

Conclusions: Compared to the *SSIS* standardization sample, teachers reported on average reduced social skills and elevated problem behaviors in children referred for an ASD evaluation. With the exception of assertion, teachers did not perceive differences in the social skills or problem behaviors of children with ASD and other clinical vulnerabilities. These findings suggest that while the *SSIS – Teacher Report* may be sensitive to social and behavioral difficulties that prompt an ASD evaluation in school-aged children, it may lack diagnostic utility. Furthermore, our finding that teachers report reduced assertion in children with ASD warrants further research, given the role of assertion in bullying prevention (Smith & Low, 2013).

415.129 *(Poster)* Toe Walking in Young Children with Autism

*R. Seijo, M. Valicenti-McDermott and **L. Shulman**, Rose F. Kennedy Center, Children's Evaluation and Rehabilitation Center; Montefiore Medical Center, Bronx, NY*

Background: Toe walking in particular has been a motor finding long associated with Autism Spectrum Disorder (ASD), affecting 20% to 63% of children compared to 5% in the general population. Few studies have looked at the relationship between age of diagnosis, autistic characteristics, and severity in children with ASD who toe walk compared to those who do not.

Objectives: To assess prevalence rate of toe walking in a clinical population of young children receiving an initial ASD diagnosis and the association of toe walking with age of ASD diagnosis, clinical features, and autism severity, in an ethnically diverse population.

Methods: Review of all children receiving an initial diagnosis of ASD from 2003 to 2012 at a University Affiliated Developmental Center. Data included demographic and clinical characteristics, including autistic characteristics, based on the Diagnostic and Statistical Manual of Mental Disorders (DSM-IV) and Childhood Autism Rating Scale (CARS). Toe walking was based on observation during pediatric neurodevelopmental evaluation. Statistics included chi-square, t-test and non parametrics and logistic regression

Results: We identified 512 children, M/F 400/112, 16% White, 47% Hispanic, 26% African-American, 38% bilinguals. Toe walking was observed in 155 children (30%). In terms of demographics, children with toe walking were more likely to be diagnosed with ASD earlier (33±13 m. vs. 42±16 m. $p<0.001$), and to be referred by the pediatrician than family or other agencies (referral source: pediatrician 45%, family 34%, other agencies 21% $p=0.007$) . In terms of clinical characteristics, children with toe walking were more likely to be preoccupied with parts of objects (55% vs. 39% $p=0.005$), to have more hypersensitivities to smell, touch and taste (19% vs.10% $p=0.03$) and the CARS total score was higher (36±5 vs. 34±5 $p=.001$) than in children without toe walking. Children with toe walking were more likely to lack interest to share (62% vs. 43% $p=.001$) and to present delayed language skills (87 % vs. 76 % $p=0.01$) than children without toe walking, but this association did not remain significant after adjusting for age. There were no differences in adaptive behaviors or cognitive testing between the groups. The association between toe walking and preoccupation with parts of objects and hypersensitivities remained significant after adjusting for age.

Conclusions: In this sample, children with ASD who engaged in toe walking were diagnosed earlier, more likely to be referred by their pediatrician, and demonstrated greater severity of social impairment. In this diverse population toe walking may serve as a clearly observable sign that helps children find their way to an earlier diagnosis. The association with autism symptom severity and sensory sensitivities may help to identify a meaningful clinical subgroup of children with autism for further study from etiologic and treatment perspectives.

415.130 *(Poster)* Towards a Data Driven Approach to Screen for Autism Risk at 12 Months of Age

S. S. Meera[1], *K. Donovan*[2], *J. Wolff*[3], *L. Zwaigenbaum*[4], *J. T. Elison*[3], *K. Truong*[2], *M. D. Shen*[5], *H. C. Hazlett*[5], *A. Estes*[6], *L. R. Watson*[7], *G. T. Baranek*[8], *M. Swanson*[9], *T. St. John*[10], *C. A. Burrows*[11], *R. T. Schultz*[12], *S. R. Dager*[13], *K. Botteron*[14], *J. Pandey*[12] *and J. Piven*[15], *(1)National Institute of Mental Health and Neurosciences, Bangalore, India, (2)Gillings School of Global Public Health, University of North Carolina, Chapel Hill, NC, (3)University of Minnesota, Minneapolis, MN, (4)University of Alberta, Edmonton, AB, Canada, (5)University of North Carolina, Chapel Hill, NC, (6)Speech and Hearing Sciences, University of Washington, Seattle, WA, (7)Department of Allied Health Sciences, University of North Carolina at Chapel Hill, Chapel Hill, NC, (8)Chan Division of Occupational Science and Occupational Therapy, University of Southern California, Los Angeles, CA, (9)University of Texas at Dallas, Richardson, TX, (10)University of Washington, Seattle, WA, (11)Pediatrics, University of Minnesota, Minneapolis, MN, (12)Center for Autism Research, Children's Hospital of Philadelphia, Philadelphia, PA, (13)Radiology, University of Washington, Seattle, WA, (14)Washington University School of Medicine, St. Louis, MO, (15)*Co-senior author, University of North Carolina, Chapel Hill, NC*

Background: While measures have been developed to screen for ASD in the second or third year of life, e.g. M-CHAT, there remains need for development of cost-effective screening measures (e.g. parent report) for identifying elevated ASD risk during the autism prodromal period in the first year of life. Currently available tools to screen infants at 12 months of age are limited either by sample size and/or screening accuracy (e.g. sensitivity). In addition, none of these studies to date, have employed a cross validation (CV) approach to prediction to accurately estimate how the stated values of performance (e.g. sensitivity) will generalize to an independent dataset.

Objectives: This study aimed to develop a classifier for infants at 12 months of age based on a parent-report measure (the First Year Inventory; FYI v2.0), to: (1) classify infants at elevated risk, over and beyond that attributable to familial risk status for ASD; and, (2) serve as a starting point to refine an approach for risk estimation in population samples.

Methods: A total of 237 subjects from a prospective, longitudinal study of infants at high familial risk for autism from the Infant Brain Imaging Study (IBIS) with complete FYI data participated in this study. Subjects were divided into two groups; 54 high familial risk (HR) infants later diagnosed with ASD (HR-ASD) and 183 HR infants not diagnosed with ASD at 24 months of age (HR-Neg). The FYI is a 63-item parent questionnaire that was designed to identify 12-month-olds at risk for ASD.

Analytical approach: We used Random Forest machine learning algorithm to develop a classifier based on the raw scores of the individual FYI items. To construct and test the accuracy of the classifier, we conducted 5-fold cross validation (CV) stratified by diagnosis (HR-ASD vs HR-Neg) and repeated 50 times.

Results: The FYI had an estimated sensitivity of 0.71 (95% CI: 0.50, 0.91), i.e. 71% of infants with ASD were correctly classified as ‘at-risk’ for ASD at 12 months of age, specificity of 0.72 (95% CI: 0.49, 0.91). Other measures of predictive accuracy are presented in Table-1.

Conclusions: Measurement of risk at age 12-months is complicated by the variable timing and pattern of emergence of clinically observable behaviors. However, even on the background of these complicating factors, we report higher than previously reported sensitivity. In addition, we demonstrate that the positive predictive value of the classifier (0.44) provides a 91% increase in the number of infants correctly identified as ASD positive, compared to the percentage of those identified solely by high familial risk status (~23%).The classifier demonstrates the potential to improve current screening for ASD risk at 12 months of age in infants already at elevated familial risk for ASD, increasing opportunities for clinical surveillance and research on intervention during the prodromal period in the development of ASD symptoms. In addition, these findings serve as proof-of-principle that parent-report measures combined with machine learning approaches may be clinically useful for screening ASD risk, prior to emergence of the defining diagnostic characteristics, in the general population.

415.131 *(Poster)* Tracking the Influence of Basic Research on Applied Research: A Pilot Study of Research Funded in the US to Improve ASD Identification

P. Doehring*, ASD Roadmap, Chadds Ford, PA*

Background: While concerns about ASD's prevalence and delays in diagnosis have mobilized significant investments in research in the US, recent reports indicate persistent gaps in timely and accurate identification. In presentations last year at IMFAR, we used a research roadmap to capture potential progress from basic to applied research, and to imagine downstream impacts on practice, policy, and outcomes. Application of this roadmap to all major, competitive research grants funded in the US between 2008 and 2015 and focused on improving ASD identification revealed that only 14% of funding was directed to applied research. These findings also raise important questions about the potential impact of the significant investments in basic research. How often do scientists undertaking basic research expect their work to have important implications for clinical practice? Can we trace a path from their findings to specific applied research projects, and increased clinical knowledge?

Objectives: To pilot methods for documenting the routes by which basic research influences applied research, through analyses of basic research funded to improve ASD identification, and publications which result.

Methods: We downloaded information from the Autism Research Database on all projects addressing ASD identification between 2008 and 2016 . We coded principal aims from each grant description according to type of research (Basic, Applied, or Other) and Focus (Improved clinical identification or Other). For projects with aims exclusively involving Basic Research, we also selected those stating implications for improved clinical identification.

To trace the knowledge impact, we are undertaking literature searches followed by abstract/full-text reviews to identify relevant publications; i.e., peer-reviewed publications that describe original research produced by Principal Investigators (PIs) of projects listed above that report findings specifically linked to principal aims. For this pilot, we are identifying all relevant publications for Applied Research projects, and 20 Basic Research projects with at least one relevant publication. We document routes of influence by aligning grants and relevant publications of PIs undertaking basic research with those in their own applied research or that of their collaborators. Then we evaluate evidence that findings of basic research shaped the focus or design of related applied research.

Results: Of 426 projects between 2008 and 2016 funded for almost $300 million to address questions of screening and diagnosis, fewer than 30% had applied research aims or stated implications for improving clinical identification of ASD. PI's of basic research appear more likely to influence the subsequent work of a collaborator than to integrate related basic and applied research aims into a single project or their own successive projects. Consistent with earlier reviews presented at IMFAR, significant publication gaps and lags limit the knowledge impact. Analyses to date suggest that the impact of specific basic research projects on the genesis of other, potentially related applied research projects is very difficult to clearly document.

Conclusions: By documenting how basic research might shape applied research to result in new clinical knowledge, these methods can help policymakers set funding priorities to maximize the impact of investments in research.

415.132 *(Poster)* Updates for a "Hands-on" Developmental-Behavioral Pediatric Rotation: Teaching Pediatric Residents to Diagnose Autism in Primary Care

J. F. Hine[1]*, R. Goode*[2]*, L. Wagner*[1]*, A. S. Weitlauf*[3]*, V. L. Rodrigues*[4]*, J. M. Negron*[5] *and Z. Warren*[1]*, (1)Vanderbilt University Medical Center, Nashville, TN, (2)Developmental Medicine, Vanderbilt University Medical Center, Nashville, TN, (3)Vanderbilt Kennedy Center, Vanderbilt University Medical Center, Nashville, TN, (4)The Vanderbilt Treatment and Research Institute for Autism Spectrum Disorders (TRIAD), Nashville, TN, (5)Pediatrics, Vanderbilt University Medical Center, Nashville, TN*

Background: The AAP has rightly adopted guidelines wherein pediatricians are encouraged to "screen-and-refer" children for ASD at 18- and 24-months of age. However, without also giving pediatricians explicit competence and ownership over being able to diagnose ASD within practice when clearly discernible symptoms are present, this wide-scale identification of general neurodevelopmental risk—and reliance upon specialty tertiary care diagnostic centers—creates a bottleneck for patients and providers alike. When asked about barriers to providing this type of care, pediatricians report factors such as lack of clear tools, discomfort, difficulty navigating follow-up services, and uncertainty around communicating with families and other providers. Pediatricians-to-be within our residency program reported an overall lack of hands-on, applied learning opportunities to strengthen their competence in recognizing ASD in young children and caring for these patients. Thus, if we do not provide wide-scale training in the basics of ASD recognition, diagnostic triage, and post-diagnostic care coordination to future pediatric medical providers, then "screen-and-refer" will continue to lead to lengthy waits for diagnostic confirmation and service initiation, maintaining the current mean age of diagnosis as after four years of age, and postponing access to the early intervention services.

Objectives: To provide updates and new data assessing a service system intervention for training residents in within-practice ASD diagnosis and care. To assess feasibility/acceptability of integrating enhanced curricular components within our existing developmental-behavioral pediatrics (DBP) rotation.

Methods: Our curriculum was designed to improve upon previously passive shadowing experiences within young child ASD clinics by integrating procedural, physician-tailored training in within-practice diagnostic identification and care coordination. In addition to multiple web-based procedural learning activities (including an interactive tutorial teaching administration/scoring of the Screening Tool for Autism in Toddlers and Young Children [STAT]), residents were required to actively participate in evaluations under direct supervision of an attending provider. Using online completion metrics and pre/post-rotation surveys, we analyzed data on completion of curriculum components and changes in comfort level for a range of practice behaviors.

Results: Of the first 90 residents to complete the enhanced rotation activities, 91% completed new training requirements and 85% performed STAT activities during their DBP rotation. Participants reported increased comfort with identifying symptoms/risk for ASD, distinguishing between ASD and other concerns, and making a formal diagnosis. They also reported increased comfort providing feedback about diagnostic decision and effectively connecting families with services. After exposure to new curriculum, 94% of residents reported that they felt comfortable providing primary care for children with ASD, which was an increase from 59% pre-rotation. Updated results will be reviewed in depth.

Conclusions: In line with other residency training programs across the country, DBP rotations often present very few opportunities for active resident participation that would translate into skills relevant for future independent practice. This represents a tremendous training gap that, in turn, is also an opportunity for service system intervention. This project reflects the first step in advancing incorporation of ASD training into pediatric residency programs, thus increasing access to services and information for children with concerns for ASD and their families.

415.133 *(Poster)* Using the ICF Core Sets to Describe Functioning for Young Children with, or at Risk of, Neurodevelopmental Conditions; A Case Study

*K. Evans[1], **E. D'Arcy**[2], A. Chamberlain[3], M. Hayden-Evans[4], S. J. Girdler[5], B. T. Milbourn[5], S. Bolte[6], A. O. Whitehouse[7], V. Eapen[8] and J. Wray[9], (1)Telethon Kids Institute, University of Western Australia, Perth, Western Australia, Australia, (2)Cooperative Research Centre for Living with Autism (Autism CRC), Brisbane, Australia, (3)Autism Research Team, Telethon Kids Institute, Perth, Australia, WA, Australia, (4)School of Occupational Therapy, Speech Pathology and Social Work, Curtin University, Perth, WA, Australia, (5)School of Occupational Therapy, Social Work and Speech Pathology, Curtin University, Perth, WA, Australia, (6)Center of Neurodevelopmental Disorders (KIND), Centre for Psychiatry Research; Department of Women's and Children's Health, Karolinska Institutet, & Stockholm Health Care Services, Region Stockholm, Stockholm, Sweden, (7)Telethon Kids Institute, University of Western Australia, Perth, WA, Australia, (8)Cooperative Research Centre for Living with Autism (Autism CRC), Long Pocket, Brisbane, Australia, (9)State Child Development Service, Western Australia Department of Health, Perth, Western Australia, Australia*

Background: The World Health Organization's International Classification of Functioning, Disability and Health (ICF) and its associated "Core Sets" for neurodevelopmental conditions (NDCs) are valid and established frameworks for understanding functioning for people with autism and other NDCs. Existing assessment of functioning tools do not holistically or comprehensively assess functioning for individuals with NDCs. The ICF Core Sets for autism, attention deficit hyperactivity disorder and cerebral palsy ('ICF Core Sets for NDC') have not been operationalised into clinical assessments. Young children (<six years) may not yet have a formal NDC diagnosis and a broad assessment may be more applicable.

Objectives: To use the ICF Core Sets to describe functioning for young children with, or at risk of, NDCs.

Methods: To describe functioning using the ICF Core Sets for NDC, a case study design was chosen to triangulate qualitative and quantitative information from multiple sources. The sources used to collect information about each child included a parent-reported card sort, semi-structured observations, standardised tools, and case history. The items from the comprehensive ICF Core Sets for NDCs were used as the framework to integrate the data and describe the overall functioning of the child using the existing ICF rating scales on a Documentation Form and caregiver-reported strengths. These items covered body functions, activities and participation, and environmental factors. Data were analysed using descriptive statistics (medians and ranges) and calculating relative weaknesses / strengths through comparing ratings. Assessments were completed for a sample of n>17 Australian children aged under 6 years with various NDCs.

Results: Preliminary results suggest that approximately 30% of items from the comprehensive ICF Core Set for NDCs were considered not applicable to at least one child, however, less than 5% of items were found not applicable to all children. Ratings were also compared to the relevant diagnosis-specific Core Set (if available) for validation purposes. Preliminary analysis did not indicate any clear themes in relation to body functions. The activity and participation chapters where the most difficulties were reported emerged as 'interpersonal interactions and relationships' and 'community, social and civic life', whilst relative strengths were associated with 'mobility' and 'learning and applying knowledge'. The 'services, systems and policies' chapter of environmental factors presented the greatest barrier for the children in the preliminary analysis, whilst the 'support and relationship' chapter was the strongest reported facilitator for functioning (these items had the widest range of scores, both as facilitators and barriers, suggesting this area is very variable depending on the individual).

Conclusions: This project has made important first steps in translating the WHO's ICF and ICF Core Sets into clinical practice and being able to describe functioning comprehensively and holistically for young children with NDCs. However, more work is needed to refine and develop the tool before it is ready for widespread clinical use.

415.134 *(Poster)* Validating the Contextual Assessment of Social Skills in Children with Autism Spectrum Disorder

***C. J. Zampella**, K. Bassanello, A. Pomykacz, M. L. Cola, V. Petrulla, A. Riiff, J. Pandey, R. T. Schultz and J. Parish-Morris, Center for Autism Research, Children's Hospital of Philadelphia, Philadelphia, PA*

Background: The Contextual Assessment of Social Skills (CASS; Ratto et al., 2011) is an observational assessment initially validated for verbal older adolescents and young adults with ASD (ages 16-22). It consists of two loosely structured three-minute conversations with different naïve confederates; in the first, the confederate demonstrates interest and engagement in the conversation, while in the second s/he acts bored and disengaged. Conversations are coded from videotapes. While a few published studies have used CASS procedures with younger ages, it has not yet been formally validated for children.

Objectives: To evaluate CASS as a measure of social skill in children with ASD across a range of ages.

Methods: CASS was administered to 47 children with ASD and 34 typically developing (TD) children, aged 7-17. Groups were matched on age [$M(SD)_{ASD}$=12.2(2.9); $M(SD)_{TD}$=11.4(3.0); p=.22], sex (M:F_{ASD}=44:14; M:F_{TD}=24:10, p=.97), and verbal cognitive ability [$M(SD)_{ASD}$=105.0(12.3); $M(SD)_{TD}$=104.9(12.7), p=.98]. Original procedures from Ratto and colleagues were followed with a few exceptions: (1) confederates were young adult research staff and thus not peers, as training child peers to administer the task with fidelity was impractical; (2) confederates were not required to be of the opposite sex; (3) the prompt to initiate conversations was modified slightly to be appropriate for children. Interested and Bored conditions were coded by two raters trained to 80% agreement with developer Ratto on training videos before rating study videos. 20% of study videos were coded by both raters for reliability analyses and consensus. Primary analyses focused on four codes: Asking Questions, Topic Changes, Overall Involvement, and Overall Quality of Rapport, which were each analyzed via 2x2 mixed ANOVA.

Results: See Table for codes, reliabilities, and means. Interrater reliability (*ICCs)* generally fell in the good to excellent range, particularly for primary variables. Overall internal consistency was good for the Interested condition (α=.81) and acceptable for Bored (α=.77). Significant group (ASD/TDC) by condition (Interested/Bored) interactions (ps<.01) emerged for Asking Questions and Topic Changes, with the TD group showing greater increases from Interested to Bored than the ASD group. Overall Involvement and Overall Quality of Rapport yielded main effects of group (ps<.001), with TD scoring higher than ASD. Overall Quality of Rapport also yielded a main effect of condition (p<.001); scores for Interested were higher than for Bored. A total score was calculated for each condition by summing z-scores across codes. Higher total scores were associated with lower ADOS-2 Calibrated Severity Scores in the ASD group in both conditions (Interested: r=-.54, p<.001; Bored: r=-.57, p<.001).

Conclusions: The pattern of results for this child sample mirrored findings in the young adult development sample, supporting CASS's utility for assessing social skills in children. CASS discriminated between children with and without ASD across codes, and also demonstrated less change in children with ASD across Interested and Bored conditions, suggesting poorer recognition of and adaptation to different social contexts. Moreover, correlations with ADOS-2 within the ASD group suggest that this 6-minute, ecologically-valid assessment may offer a potent snapshot of ASD symptom severity.

415.135 *(Poster)* Validating the Social Responsiveness Scale for Korean Preschool Children with Autism Spectrum Disorder

J. Chun[1], *G. Bong*[2], *J. Kim*[3], *J. Kim*[3], *Y. A. Kim*[4] *and H. Yoo*[5], *(1)Psychiatry, Seoul National University Hospital, Seoul, Korea, Republic of (South), (2)Psychiatry, Seoul National University Bundang Hospital, Seungnam, Korea, Republic of (South), (3)Psychiatry, Seoul National University Bundang Hospital, Seongnam, Korea, Republic of (South), (4)Department of Psychiatry, Seoul National University Bundang Hospital, Seongnam, Korea, Republic of (South), (5)Psychiatry, Seoul National University Bundang Hospital, Seongnam, Korea, The Republic of*

Background: The Social Responsiveness Scale (SRS) has been a widely used screening questionnaire for Autism Spectrum Disorder (ASD) worldwide. Given that SRS was originally developed based on the US population, several studies have investigated its international psychometric properties along with localized best-estimate-cut-off scores.

Objectives: This study aims to examine the psychometric property of SRS in Korea for the first time, and to determine the best-estimate-cut-off scores for diagnosis of ASD in Korean preschool children.

Methods: Children between the age of 10 to 42 months were recruited. Albeit the original SRS preschool version is intended to examine children above the age of 30 months, we also included subjects below the age of 30 months to seek out the validity of SRS in this age group. All subjects were assessed by full diagnostic instruments including the Korean versions of the Autism Diagnostic Observation Schedule (K-ADOS) and the Autism Diagnostic Interview-Revised (K-ADI-R), and diagnoses were ascertained based on DSM-5^{TM} diagnostic criteria by clinical best estimates of a multidisciplinary research team. All children and their parents completed the SRS, the Korean version of Social Communication Questionnaire (K-SCQ), and the Korean version of Childhood Autism Rating Scale (K-CARS). The discriminative validity of SRS was tested by conducting t-test and analysis of covariance to compare the score difference between ASD and non-ASD groups. The convergent validity of SRS with other diagnostic instruments including K-CARS and K-SCQ was examined by using Pearson's correlation. Finally, we conducted a receiver operation characteristic curve analysis to test the sensitivity and specificity of SRS, and to determine the best-estimate-cut-off scores for screening ASD in Korean preschool children.

Results: Among total of 477 children recruited, 181 subjects were diagnosed as having ASD (mean=77.07, SD=27.72), and 296 were classified as non-ASD (mean=37.14, SD=18.61), which include subjects with typical development and with developmental delay. There were significant differences in total scores of SRS between ASD and non-ASD group, and the significance remained in analyses of two subgroups, for children over 30 months and below (Table 1). The differences were significant even after adjusting the subject's age in all groups (Table 1). SRS scores were significantly correlated with K-CARS ($r=0.74$, $p<0.01$) and K-SCQ ($r=0.80$, $p<0.01$) total scores. The significant correlations remained in all subgroup analyses. The best-estimate cut-off scores of SRS to screen ASD in the age group below the age of 30 months was 48.5 (AUC=0.82, sensitivity 74.00%, specificity 73.78%). In the group above the age of 30 months, it was 55.5 (AUC=0.90, sensitivity 83.97%, specificity 84.09%). There was a significant correlation between the SRS scores of all the children and their mother ($r=0.23$, $p<0.01$).

Conclusions: SRS is a valid and reliable instrument to screen and to aid the diagnosis of ASD in Korean preschool children. The validity, however, was weakened in the age below 30 months, thus requiring further verification in larger sample. Notably lower cut-off scores, compared to the original U.S. version, should also be further clarified in a larger sample with a wide age range.

415.136 *(Poster)* Variables Predicting Age of Autism Spectrum Disorder Diagnosis

R. Saban-Bezalel[1], *D. A. Zachor*[2] *and E. Ben-Itzchak*[3], *(1)Communication disorders, Ariel university, Ariel, Israel, (2)The Autism Center/ALUT, Pediatrics, Tel Aviv University /Shamir (Assaf Harofeh) Medical Center, Zerifin, Israel, (3)Bruckner Center for Research in Autism, Communication Disorder, Ariel University, Ariel, Israel*

Background:

Early diagnosis of autism spectrum disorder (ASD) is crucial, as it leads to early intervention, resulting in superior long-term outcomes. Demographic, environmental, personal, clinical, and familial characteristics have been found to be associated with ASD diagnosis. However, research findings are occasionally inconsistent and most of the studies with a large population did not use direct observation or standard clinical measurements. The present study examined children's personal, familial, and clinical characteristics evaluated with common standard measurements to assess their relative contribution in explaining the variability of age of diagnosis. Identifying variables that are associated with age of diagnosis may help clinicians to identify children at high risk for later diagnosis of ASD.

Objectives: The current study aims to examine the relative contribution of familial (parental age and education, number of siblings, familial hierarchy) personal (sex, cognitive ability, autism severity, adaptive skills) and clinical (medical history, previous diagnosis) variables to the variability of ASD diagnosis age.

Methods: The study included a large cohort of children (n=530, 66 females) diagnosed with ASD, with an age range of 16-120 months. All the children underwent comprehensive assessment that included evaluation of possible ASD using the Autism Diagnosis Interview-Revised (ADI-R; Lord, Rutter, and Le Couteur, 1994), the Autism Diagnostic Observation Scales (ADOS; Lord, Rutter, DiLavore, Risi, S., 1999),clinical judgement based on the DSM IV (APA, 2000) or DSM-5 (2013) ; cognitive assessment using age-appropriate standardized tests; adaptive skills using the Vineland Adaptive Behavior Scales (VABS; Sparrow et al. 1984; Sparrow et al., 2005). In addition, comprehensive medical, developmental and familial histories were obtained from the parents.

Results:

To evaluate the relative contribution of the above variables to age of diagnosis, a hierarchical linear regression analysis was performed with age of diagnosis as a dependent variable. Among the examined personal and clinical variables, later diagnosis age was associated with higher IQ levels, having a previous non-ASD diagnosis, and more severe ASD symptoms, specifically ADOS social affect (SA) and ADI Restricted, Repetitive, and Stereotyped Behaviors (RRIB). Familial variables associated with later ASD diagnosis age were generally having more siblings and older parents. In total, the regression model explained 37.4% of the age of diagnosis variability. Children with a previous diagnosis were diagnosed with ASD an average of 20 months later compared to children with no previous diagnosis. Children with higher IQ (i.e. IQ >70) tended to be diagnosed an average of 17 months later compared to children with IQ <70. Significantly higher ASD severity levels were associated with ADOS Module 3, as compared to Module 2 and Module 1. Participants' gender, birth order, medical history and parental education did not associate with diagnosis age.

Conclusions:

Having a previous diagnosis, higher IQ scores, more severe ASD symptoms and having more siblings and higher maternal age point to later age of ASD diagnosis. In addition, the findings imply different levels of complexity among the ADOS SA modules. Clinicians and parents should be aware of factors which may delay ASD diagnosis.

415.137 *(Poster)* Visual Performance and Nonverbal Reasoning in Autism Spectrum Disorder

T. Kamensek[1]*, I. Oruc*[1] *and G. Iarocci*[2]*, (1)Ophthalmology and Visual Sciences, University of British Columbia, Vancouver, BC, Canada, (2)Psychology, Simon Fraser University, Burnaby, BC, Canada*

Background: Studies on visual perception in ASD have reported strengths in various detail-oriented tasks compared to non-autistic controls (Happé & Frith, 2006; Mottron et al., 2006). For example, superior performance in visual search is oft-cited as a widely established finding in ASD research. It has been suggested that these visual atypicalities can be attributed to enhanced perceptual functioning (EPF) (Mottron et al., 2006). Mixed findings in the literature have yet to conclude whether enhanced low-level spatial frequency processing may be a source of EPF. Whereas the majority of research indicates that spatial frequency sensitivity is similar in autistic and non-autistic people (Behrmann et al., 2006; Guy et al., 2016; Jonge et al., 2007; Koh et al., 2010; Simmons et al., 2009), a research study from Keita et al. (2014) found increased sensitivity in ASD at 8 cycles per degree (cpd). Another group found that autistic as compared to non-autistic participants performed more accurately in an object recognition task when presented with higher spatial frequency (4 cpd) stimuli earlier (Caplette et al., 2016). One possible explanation for the mixed findings in the literature is that EPF in ASD may not be a characteristic of the entire spectrum, but rather, a characteristic of a sub-set of people who excel at the Wechsler block design subtest (BDT) (Caron et al., 2006; Shafai et al., 2015).

Objectives: To examine how spatial frequency processing is related to BDT performance in autistic and non-autistic adult participants matched on age-, gender-, and IQ.

Methods: We measured contrast sensitivity across a broad range of spatial frequencies (1-24 cpd) using a 2-interval forced choice detection paradigm. Twenty autistic participants (mean age = 23.8 years; SD = 6.36; 6 females) and 20 non-autistic participants (mean age = 27.9; SD = 6.96; 7 females) had their IQs assessed using the Wechsler Abbreviated Scale of Intelligence II (WASI-II) and completed an eye exam by a licensed optometrist. WASI-II full-scale IQ scores in ASD ranged from 87 to 150 (M = 116.15; SD = 15.64) and from 103-136 in controls (M = 115.7; SD = 7.88).

Results: Contrast sensitivity thresholds did not indicate any enhanced spatial frequency processing in autistic as compared to age-, gender-, and IQ-matched non-autistic participants. However, exploratory analysis based on an expected association between BDT scores and EPF revealed a subset of the ASD group with superior sensitivity at 4 cpd. A systematic analysis via BDT score sweeps revealed that the ASD group consisted of two distinct clusters. One cluster, characterized by higher BDT scores, had better sensitivity at 4 cpd than non-autistic participants, while the other, with lower BDT scores had lower sensitivity than non-autistic participants.

Conclusions: These findings suggest that enhanced low-level visual processing is not a source of EPF for all autistic people. Instead, EPF may be a feature of a sub-population of autistic people, specifically those who excel at the block design test. We propose that performance on the BDT may be one factor that helps reveal a distinct sub-type within the heterogenous ASD population.

415.138 *(Poster)* What Happens after a Positive Autism-Specific Screen? Predictors of Completing an Evaluation and Receiving an Autism Diagnosis

J. L. Kuhn[1]*, J. Levinson*[2]*, M. Udhnani*[3]*, K. E. Wallis*[4]*, E. Hickey*[5]*, A. Bennett*[4]*, A. Fenick*[6]*, E. Feinberg*[2] *and S. broder-Fingert*[5]*, (1)Pediatrics, Boston Medical Center, Boston, MA, (2)Boston University School of Public Health, Boston, MA, (3)Center for Autism Research, Children's Hospital of Philadelphia, Philadelphia, PA, (4)The Children's Hospital of Philadelphia, Philadelphia, PA, (5)Boston Medical Center, Boston, MA, (6)Yale University, New Haven, CT*

Background: Universal ASD-specific screening with consistent diagnostic evaluation referral for those who screen positive is currently considered to be critical for achieving widespread timely and equitable identification and treatment of ASD. However, these practices are limited both by lack of follow-through on diagnostic evaluation referrals post-screening and by poor accuracy from the screening tools in diverse populations.

Objectives: Families, service providers, and service systems would all benefit from expanded knowledge regarding the following questions that this study addresses: 1) after a positive screen on a universally administered Autism-specific screener, who is most likely to follow-through on a recommendation for a diagnostic evaluation; and, 2) of those who screen positive, who is most likely to be diagnosed with ASD?

Methods: This study was a secondary analysis of data collected in a larger multi-site randomized controlled trial evaluating the impact of family navigation on diagnostic ascertainment and linkage to treatment. Participants included 310 predominantly low-income and racially/ethnically diverse parent-toddler dyads who screened positive on the MCHAT-R/F. Baseline data on family factors and child adaptive functioning were collected at the time of primary care referral for a diagnostic evaluation. Families were followed via electronic medical record review to determine whether they completed a diagnostic evaluation and if so, what diagnoses were conferred. Generalized estimating equations were used to fit models of predictors for each of the two binary primary outcomes: completing the diagnostic evaluation and receiving an ASD diagnosis upon evaluation.

Results: The best-fit model for completing a diagnostic evaluation identified the following significant independent predictors: younger child age at screen, older parent age at screen, lower child communication adaptive functioning, receiving Early Intervention, and non-Hispanic ethnicity. Significant predictors for receiving an ASD diagnosis upon evaluation included: male sex of child, lower child communication adaptive functioning, no use of interpreter for MCHAT-R/F screening, White and non-Hispanic parent race/ethnicity, and no parent history of a depressive or bipolar disorder.

Conclusions: Children whose parents were younger or Hispanic, and who are not yet involved in Early Intervention were least likely to access diagnostic services, possibly due to lower awareness of developmental problems or acceptance of referral for services. Parents of older children with higher communication functioning were also less likely to follow-through on diagnostic care; this may be because parents of such children feel less concerned about their child's development. Families with these characteristics may benefit from interventions aiming to enhance parent engagement and address barriers to care. Findings regarding sociodemographic predictors of receiving an ASD diagnosis corroborated prior research indicating problems with MCHAT-R/F accuracy among minority populations and females. Use of an interpreter for screening predicted decreased likelihood of a true ASD diagnosis, suggesting issues with the language interpretation process within parent checklist screening approaches. Finally, lower communication adaptive functioning skills of the toddlers predicted receiving an ASD diagnosis, suggesting that such information may be useful to collect early in the screening and referral process as part of efforts to increase efficiency of care.

415.139 *(Poster)* The Expert Eye: Autism Experts Read out Autism-Discriminative Information from Visual Kinematics

N. Pretti[1], *A. Crippa*[2], *A. Cavallo*[1,3], *F. Battaglia*[1,4], *C. Ansuini*[1], *S. Panzeri*[5], *M. Molteni*[2], *L. Nobili*[4] *and C. Becchio*[1], *(1)Cognition, Motion and Neuroscience, Istituto Italiano di Tecnologia, Genova, Italy, (2)Scientific Institute, IRCCS Eugenio Medea, Bosisio Parini, Italy, (3)Department of Psychology, University of Turin, TORINO, Italy, (4)IRCCS Istituto Giannina Gaslini, Ospedale Pediatrico, Genova, Italy, (5)Neural Computation Laboratory, Istituto Italiano di Tecnologia, Rovereto and Genova, Italy*

Background: Over the past 20 years, retrospective coding of home videos by experienced examiners has proved useful for assessing qualitative aspects of sensorimotor behavior early in the development of autism spectrum conditions (ASC). However, the specific sensorimotor features detected by experienced examiners are unknown. How sensitive is the expert eye? Are examiners with extensive experience in the assessment of ASC children able to detect kinematic features invisible to non-experts? The present study was designed to provide quantitative answers to these questions.

Objectives: To evaluate the extent to which clinical examiners with an extensive experience in ASC assessment are able to pick-up significant information from subtle differences in movement kinematics.

Methods: Participants were clinical examiners with extensive experience in the assessment of ASC children (ASC experts), clinical examiners with no experience in the assessment of ASC (no ASC experts), and participants with no clinical expertise (controls). ASC-related expertise was defined based on the number of ADOS administered during the previous 12 months (at least 20). All participants completed two tasks: an autism discrimination task and an intention discrimination task. Each task consisted of a series of trials displaying reach-to-grasp actions towards a bottle either with the intent to pour or place. Actions were performed by either TD or ASC children. In the group discrimination task, we asked participants to indicate whether the observed action was performed by a TD or an ASC child. In the intention discrimination task, we asked participants to predict whether the observed action was performed with the intent to pour or to place. For each task, we presented 120 videos selected to contain both group-specifying information and intention-specifying information.

Results: Preliminary results were analyzed in the framework of Signal Detection Theory (SDT). Sensitivity (d') and criterion (c) were computed separately for the Group task and the Intention task in ASC experts, no ASC experts, and controls. While all three groups performed well above chance in the intention discrimination task, only ASC experts were able to discriminate whether observed actions were performed by TD versus ASC children. Preliminary results were analyzed in the framework of Signal Detection Theory (SDT). Sensitivity (d') and criterion (c) were computed separately for the Group task and the Intention task in ASC experts, no ASC experts, and controls. While all three groups performed well above chance in the intention discrimination task, only ASC experts were able to discriminate whether observed actions were performed by TD versus ASC children.

Conclusions: To the best of our knowledge, this is the first study to examine the influence of clinical expertise on the ability to extract discriminative information from action observation in the field of autism research. Our preliminary results demonstrate the potential significance of kinematic readout for clinical expertise and suggest that clinical examiners with extensive experience in assessing ASC develop a selective ability to pick-up ASC-discriminative kinematic features.

Drug Discovery and Development

POSTER SESSION — DRUG DISCOVERY AND DEVELOPMENT

416.001 *(Poster)* Assessing the Effects of Fluoxetine, Itraconazole, and Rifampicin on Balovaptan Pharmacokinetics in Healthy Volunteers

M. Derks[1], *C. Wandel*[2], *A. Young*[1], *S. Bolt*[1] *and C. Meyenberg*[2], *(1)Roche Products Ltd, Welwyn Garden City, United Kingdom, (2)F. Hoffmann-La Roche AG, Basel, Switzerland*

Background: People with autism spectrum disorder (ASD) often take several medications. Balovaptan – a novel, potent and selective vasopressin 1a receptor antagonist investigated for the treatment of the core symptoms of ASD – is mainly metabolized by cytochrome P450 3A4 (CYP3A4) and to a much lesser extent by CYP2D6.

Objectives: The objectives of these studies were to assess the potential of balovaptan to undergo CYP3A4- and CYP2D6-mediated pharmacokinetic (PK) interactions with concomitant medications.

Methods: Three phase 1, open-label, two-period studies assessing the effect on the single-dose or steady-state PK of balovaptan and its major plasma metabolites (M2, M3) of a strong CYP2D6 inhibitor (fluoxetine; Study 1; NCT01967979), a strong CYP3A4 inhibitor (itraconazole; Study 2; NCT03579719), and a strong CYP3A4 inducer (rifampicin; Study 3; NCT03586726) were conducted. In all studies, healthy volunteers received balovaptan alone in Period (P)1 and balovaptan in combination with fluoxetine, itraconazole, or rifampicin in P2 (see **Table**). Modulators of CYP3A4 activity (including nutrients/foodstuffs) were restricted within studies. The maximum observed plasma concentration (Cmax) and area under the plasma concentration-time curve (AUC) of balovaptan (and M2/M3) were derived by standard non-parametric/non-compartmental methods from validated liquid chromatography-tandem mass spectrometry analyses of serial blood samples collected in Studies 1 (Day [D]1/P1 and D6/P2), 2 (D10/P1 and D20/P2), and 3 (D10/P1 and D16/P2).

Results: Each study included 14–16 adult volunteers (80–100% male). In Study 1, co-administration of a single dose of balovaptan (12 mg) at D6 of escalated dosing with fluoxetine resulted in a modest 11% increase in balovaptan Cmax (geometric least square means ratio [GLSMR; 90% CI], 1.11 [1.04–1.18]) and 6% increase in balovaptan AUC (GLSMR, 1.06 [0.96–1.16]), and a similarly modest 6% increase in M3 Cmax (GLSMR, 1.06 [1.01–1.12]) and AUC (GLSMR, 1.06 [0.98–1.15]), versus single-dose balovaptan alone. In Study 2, co-administration of itraconazole (200 mg QD) with balovaptan (5 mg QD) for 15 days resulted in approximately 4–6-fold increases in balovaptan Cmax (GLSMR [90% CI], 4.46 [4.06–4.90]) and AUC (GLSMR, 5.57 [5.00–6.21]), versus balovaptan alone; along with approximately 30–40% decreases in M2 Cmax (GLSMR, 0.69 [0.60–0.79]) and AUC (GLSMR 0.68 [0.59–0.78]) and a 40% increase in M3 Cmax (GLSMR, 1.43 [1.32–1.55]) and AUC (GLSMR 1.42 [1.30–1.55]). In Study 3, co-administration of rifampicin (600 mg QD) with balovaptan (10 mg QD) for 10 days resulted in an approximately 90% reduction in balovaptan Cmax (GLSMR [90% CI], 0.14 [0.12–0.15]) and AUC (GLSMR, 0.07 [0.06–0.07]) versus balovaptan alone; along with an approximately 65% decrease in the Cmax and AUC of M2 (GLSMR [90% CI]: Cmax, 0.37 [0.34–0.40]; AUC, 0.34 [0.31–0.36]), and an 80–90% reduction in M3 (GLSMR [90% CI]: Cmax, 0.22 [0.20–0.24]; AUC, 0.13 [0.12–0.14]).

Conclusions: Co-administration of balovaptan with strong inducers or inhibitors of CYP3A4 is likely to significantly alter balovaptan PK and requires caution. By contrast, strong CYP2D6 inhibitors, such as fluoxetine, are less likely to have clinically significant PK interactions with balovaptan.

416.002 *(Poster)* Catching up to the Hype: Strategies to Optimize Collaboration in Cannabinoid Research

***P. E. Cervantes**, G. Conlon, R. Shalev, T. Gomez-Alemany and F. X. Castellanos, Department of Child and Adolescent Psychiatry, NYU Langone Health, New York, NY*

Background: Despite widespread public enthusiasm, we lack rigorous evidence of the potential therapeutic benefits of cannabinoids for autism spectrum disorder (ASD). This is concerning, as the pursuit of cannabinoid treatments is resource-intensive and opaque, given the substantial mislabeling of readily available products and the largely unknown adverse effects and target outcomes. Determining whether cannabinoids will provide therapeutic options targeting core and/or associated symptoms for some or many individuals with ASD and accelerating the typical drug development timeline are urgent priorities. Because the field of cannabinoid therapeutics for ASD is in its infancy, it is uniquely positioned to advance collaborative methodologies that may serve as a model for psychopharmacology broadly.

Objectives: To identify strategies to improve methodology in pharmacological research, including (1) harmonizing outcome measurements across research efforts and (2) integrating the intensive design into intervention trials.

Methods: An analysis of ClinicalTrials.Gov and a review of the literature were conducted to understand current practices and identify promising approaches. First, we analyzed all entries on ClinicalTrials.gov, using the search terms “autism” and “drug,” to evaluate trends in ASD pharmacological research and estimate convergence in strategies. Data collected included trial design, intervention type, primary targets, and outcome measures. Next, inspired by Klein’s (2008) essay in JAMA on “The Loss of Serendipity in Psychopharmacology,” we examined the prevalence of intensive designs (also known as single-case or N-of-1 designs) in ASD drug development and evaluation. A comprehensive literature review was conducted using a variety of search terms to capture terminology differences across disciplines, collecting data on the above-noted variables and on trial results.

Results: We identified 301 ClinicalTrials.Gov entries. The number of registered drug trials posted has increased steadily since inception of the registry, as has the number of complementary and alternative medications studied (e.g., dietary supplements, oxytocin). Most frequent primary behavioral targets included core ASD symptoms (*n*=173), followed by challenging behavior/irritability (*n*=68) and language/communication (*n*=45). Noteworthy was the incongruence in outcome measurement. Although several measures were highly represented (Aberrant Behavior Checklist, *n*=232; Clinical Global Impression Scales, *n*=155) in the search, over 90% of measures evaluating psychiatric/behavioral targets were used in fewer than 10 studies, and a majority were just once or twice. With regard to study designs, literature review revealed the use of intensive designs, while historically always low, has decreased (e.g., 12 studies in 1997-2008, one in 2008-2018).

Conclusions: The lack of outcome harmonization impedes comparison of results across intervention trials and delays the already slow and arduous drug evaluation process. Nascent efforts to enhance harmonization with input from patients and families should be embraced. The near extinction of methodologically rigorous intensive designs is also regrettable, as standard parallel-group approaches are poorly suited for the heterogeneity of ASD. We encourage reconsideration of intensive designs in ASD therapeutics, particularly with respect to determining the therapeutic pros and cons of cannabinoids – a field in which uncontrolled n-of-1 experimentation is occurring rapidly, without safeguards or generalizable information regarding benefits and risks.

416.003 *(Poster)* No Clinically Relevant Effect of Balovaptan on Electrocardiography, Heart Rate or Blood Pressure in Healthy Volunteers

***M. Derks**[1], C. Wandel[2], L. Squassante[2], P. Jordan[2], S. Scoon[1], A. Young[1] and S. Bolt[1], (1)Roche Products Ltd, Welwyn Garden City, United Kingdom, (2)F. Hoffmann-La Roche AG, Basel, Switzerland*

Background: The neuropeptide vasopressin is implicated in modulating the brain circuitry regulating social behavior and the vasopressin 1a (V1a) receptor has emerged as a potential target for treatment of the core symptoms of autism spectrum disorder (ASD). Balovaptan, a potent, selective V1a antagonist in phase 3 development for ASD, has been well tolerated at single doses up to 76 mg and multiple doses up to 52 mg/day.

Objectives: To investigate, as part of a comprehensive safety assessment, the cardiac safety of balovaptan with respect to QT prolongation and other electrocardiography (ECG) parameters, heart rate, and blood pressure.

Methods: This was a single-center, multiple-dose, double-blind, placebo- and positive (moxifloxacin)-controlled, crossover study (NCT03808298) randomizing healthy adult volunteers to one of 12 three-treatment sequences separated by a 13–20-day washout. Treatment A administered a therapeutic balovaptan dose (10 mg/day), and treatment B a supratherapeutic dose (50 mg/day), each for 14 days plus single-dose moxifloxacin placebo on Days 2 and 15; treatments C and D administered balovaptan placebo for 14 days, plus single-dose moxifloxacin 400 mg on Day 2/moxifloxacin-placebo on Day 15 (treatment C), or placebo Day 2/moxifloxacin Day 15 (treatment D). Six sequences included treatments A, B, and C; and six A, B, and D. ECG data were extracted from continuous 12-lead Holter recordings pre-dose and up to 24 hours post-dose on Days 1, 2, 14, and 15 of each period. The primary endpoint was the placebo-corrected change from baseline in the least-squares mean (LSM) Fridericia-corrected QT interval (ddQTcF), derived from a linear mixed model with baseline QTcF as the covariate and gender, period, sequence, time, and treatment as fixed effects. Other endpoints included placebo-corrected LSM changes from baseline in the PR and QRS intervals and heart rate (ddHR), and in mean ambulatory blood-pressure data (systolic [ddSBP], diastolic [ddDBP], and mean arterial [ddMAP] pressure) assessed periodically between 9.00AM and 5.30AM on Days –1 (baseline) and 12. Assay sensitivity was confirmed if ≥1 moxifloxacin ddQTcF from 1–4 hours post-dose was significantly >5 msec (Hochberg-adjusted $p<0.05$).

Results: ECG data were available for 52 placebo/moxifloxacin, 55 balovaptan 10 mg, and 52 balovaptan 50 mg participants. Observed balovaptan plasma concentrations ranged up to 1130 ng/mL. Assay sensitivity was confirmed. There was no clinically relevant effect of balovaptan on ddQTcF at either Day 1 or at steady-state (Day 14), and no apparent time or dose dependency (**Figure**). There were no relevant effects on other ECG parameters (not shown) or on heart rate or blood pressure: steady-state ddHR, ddSBP, and ddDBP are shown in the **Table**; ddMAP on Day 12 was –0.2 mmHg (90% CI –1.65; 1.19) for 10 mg balovaptan, and 0.2 mmHg (–0.97; 1.40) for 50 mg balovaptan. Balovaptan was generally well tolerated, with unremarkable adverse event and laboratory profiles at both doses. There was one discontinuation (neutropenia).

Conclusions: Balovaptan did not show clinically relevant effects on the QT interval, heart rate, or other ECG or blood pressure parameters at multiple doses of 10 mg or 50 mg daily.

Early Development (< 48 months)

PANEL SESSION — **EARLY DEVELOPMENT (< 48 MONTHS)**

209 - Identifying ASD Risk in Infancy: Clinical and Ethical Implications

Panel Chair: Katherine MacDuffie, *Speech and Hearing Sciences, University of Washington, Seattle, WA*

Discussant: Joseph Piven, **Co-senior author, University of North Carolina, Chapel Hill, NC*

Accumulating evidence suggests that brain changes in infants at high familial risk for ASD precede the consolidation of symptoms into diagnosis and allow accurate prediction of which infants will go on to develop ASD. These predictive approaches hold great potential for presymptomatic detection and pre-emptive ASD intervention during a period of rapid brain and behavior development in the first year of life. If replicated, we anticipate that these predictive methods will be incorporated into the clinical assessment of risk and treatment planning for infants with a family history of ASD. Efforts to develop pre-emptive interventions are ongoing, and will be facilitated by predictive approaches that can precisely identify which infants will go on to develop ASD such that only those at highest risk are targeted for intervention. The rapid pace of this research also raises critically-important ethical questions about returning predictive results to parents while the evidence base for presymptomatic interventions is still being built. This symposium will discuss methodological, procedural, clinical, and ethical considerations for presymptomatic identification and treatment for ASD, and identify open questions that remain to be tackled in the next phase of this research.

209.001 *(Panel)* The Presymptomatic Prediction of ASD Using Infant MRI

J. Pruett, **Co-senior author, **For the IBIS Network, Washington University School of Medicine, St. Louis, MO*

Background: Consensus in the field and emerging data suggest that early intervention will improve outcomes in autism spectrum disorder (ASD). Infants who develop ASD begin to manifest disorder-specific behaviors in the second year. As such, there are no first-year-of-life behavioral features that allow for accurate prediction of later ASD. We know from other neuropsychiatric conditions, e.g. Parkinson's disease, that brain-based changes often precede the development of disorder-specific behaviors. With this in mind, it is possible that MRI scans during the presymptomatic period in the first year of life could identify brain-based changes that later contribute to and accurately predict the development of ASD.

Objectives: To test whether multiple independent MRI modalities, in the first year of life in infants at high familial risk for ASD (due to an affected sibling), could produce clinically actionable predictions (e.g., >= 80% positive predictive values) about a later diagnosis of ASD.

Methods: Investigators in the Infant Brain Imaging Study (IBIS) network acquired structural and functional MRI scans from naturally sleeping infants at six and 12 months old, and clinical best estimate diagnosis of ASD was determined at 24 months. Presymptomatic diagnostic outcome prediction utilized fully cross-validated machine learning approaches.

Results: We can predict ASD at 24 months from MRI scans acquired in the first year of life, during the presymptomatic period, using independent MRI modalities – structural MRI scans at 6-12 months and functional connectivity MRI scans at 6 months – with potentially clinically actionable (>= 80%) positive predictive values.

Conclusions: Our predictive outcome classification findings point to the future possibility of randomized, presymptomatic intervention trials for HR infants. These initial results need to be replicated, and we are now funded to do so in a new sample of 250 HR infants, where we will also test the ability of first-year-of-life MRI to predict quantitatively measured levels of later ASD-associated behaviors. The above findings raise important clinical and ethical questions that will be discussed here and in subsequent talks in this panel, concerning: prospects for replication, residual uncertainty, consideration of return-of-results in an ongoing study, extension of positive results from HR infants to the general population, and parent and provider preferences regarding knowledge about accurate predictive information given the current lack of validated presymptomatic interventions. Recruitment for our new study is now underway, and we will provide a brief update about progress.

209.002 *(Panel)* Pre-Symptomatic Prediction of ASD in High Risk Infants with Scalable EEG Methods

S. Jeste *and A. H. Dickinson, University of California, Los Angeles, Los Angeles, CA*

Background: The neurobiological changes associated with autism spectrum disorder (ASD) include alterations in neuronal activity, synchrony and connectivity that begin well before behavioral symptoms emerge (Quesnel-Vallieres et al, 2019).These changes may impact an infant's ability to learn from and engage with environmental inputs, cascading over early childhood into the more complex impairments in social interaction that define ASD (Piven et al, 2018). Measurement of these early brain changes with a scalable, clinically accessible tool—spontaneous (resting-state) electroencephalography (EEG)—can improve timing of risk identification and facilitate closer monitoring and intervention for those infants at highest likelihood to develop ASD

Objectives: (1) To examine EEG patterns of atypical development and predictors of ASD in two distinct risk groups [Tuberous Sclerosis Complex (TSC) and infant siblings], with focus on EEG phase coherence and peak alpha frequency. (2) To place these findings in the context of prior resting-state EEG studies of high-risk infants, discussing methodological and conceptual convergence and variance, and introduce new study designs that may mitigate some of the challenges presented.

Methods: High density EEG was collected as a part of two separate longitudinal studies of development in TSC (ages 12, 18, 24 months) and infant siblings (ages 3, 6, 9, 12 months), with ASD symptoms assessed at 18 months and full diagnostic assessment performed at 36 months. After cleaning using independent component analysis, EEG data were transformed into current source density estimates using a Laplacian transform. Alpha phase coherence and peak alpha frequency were quantified using methods previously published (Dickinson et al, 2018a, 2018b). Two data-driven approaches were applied to examine predictors of ASD, including nonparametric permutation testing, with FDR correction, and support vector regression (SVR) algorithms. Non-parametric Kendall's tau correlation was employed to examine relationships between cognitive function and peak alpha frequency.

Results: Infants with TSC show reduced interhemispheric connectivity compared to controls at 12 months ($p<0.01$), with coherence reduced most significantly in infants who later developed ASD ($p<0.01$). Across all infants and within the TSC group alone, peak alpha frequency at 24 months was associated with verbal and non-verbal cognition at 36 months (0.314, $p=0.020$ for full group, 0.389, $p=0.016$ for TSC group). In infant siblings, significant differences in alpha phase coherence in several networks that represented reduced long-range connectivity and increased frontal cortical connectivity were identified between the ASD+ and ASD- groups as early as 3 months ($R=0.81$, $p<0.01$).

Conclusions: EEG is a promising, scalable method to identify the earliest changes in brain development and function in infants prior to the diagnosis of ASD. Despite heterogeneity in genetic risk and medical comorbidities, EEG changes in long range connectivity can differentiate infants who will develop ASD as early as 3 months, while peak alpha frequency relates to cognitive function. These studies necessitate larger scale collaborations, replication in independent samples, parallel testing of different risk groups, examination of change with early intervention, and concurrent collection of MRI and EEG to understand the structural underpinnings of these functional patterns; ongoing studies to address these challenges will be discussed.

209.003 *(Panel)* Progress in Intervention for Infants with ASD Symptoms

S. J. Rogers[1]*, S. Dufek*[2] *and M. R. Talbott*[3]*, (1)Department of Psychiatry and Behavioral Sciences, The Medical Investigation of Neurodevelopmental Disorders (MIND) Institute, UC Davis School of Medicine, University of California Davis, Sacramento, CA, (2)Psychiatry, University of California, Davis, Sacramento, CA, (3)Psychiatry and Behavioral Sciences, University of California at Davis MIND Institute, Sacramento, CA*

Background: A recent rigorous intervention trial (Whitehouse et al., 2019) found no effects on parent or infant behaviors for symptomatic infants; yet other studies have demonstrated positive parent and infant responses (Steiner et al, 2013; Koegel et al., 2013; Rogers et al., 2014). Studies of symptomatic infants are challenged by the low incidence of such infants in any individual community and lack of validated approaches. Four factors motivate continued study: (1) the plasticity of infant neural and behavioral development, (2) the stress experienced by parents who perceive autism symptom in their infants, (3) the resulting potential alterations in parent-infant interactions, and (4) the promise of effective intervention for minimizing symptoms and supporting development.

Objectives: Provide 1) a brief review of the arguments for and against intervening before diagnosis; 2) a review of published studies involving infants under 12 months; 3) findings from a new single-subject component analysis telehealth infant intervention study.

Methods: A multiple-subject counter-balanced component analysis design to examine effects on parent behavior and infant symptoms of three treatment techniques: Step into the Spotlight, Imitate, and Talking to Baby. Six infants 6-12 months of age exhibiting early signs of ASD and their primary caregiver participated for 3 months. Infants were referred by their parents. Infants were assessed and qualified for the study using a novel telehealth protocol of symptoms administered by parents. Telehealth intervention sessions occurred three times per week for one month. One treatment technique was introduced each week to the caregiver and covered for 3 sessions to allow for caregiver coaching and practice. Interventionists were certified ESDM parent coaches and followed a manualized protocol. Coach's fidelity, caregiver fidelity of implementation (FI) of treatment techniques, and child ASD-specific behaviors were coded from 10-minute caregiver-child dyad intervention video-recorded probes.

Results: Based on initial coding of half the sample, the telehealth assessment approach resulted in high inter-rater agreement on infant symptom presentation and valid assessment of developmental status. Coaches delivered the intervention at 90% fidelity to standards. Caregivers learned each intervention technique to mastery, with interobserver agreement (IOA) of 88% overall. Once learned, parent skills were generally maintained at elevated levels. Parent behaviors regarding each technique tended to remain at baseline until that specific technique was targeted: thus, each technique changed parent behavior in the specific skill area targeted. Parents were highly satisfied with the intervention.

Conclusions: Parents experience great worry and often seek help when they perceive autism symptoms in their infants. This study identified three intervention techniques that contributed independently to improvements in parent intervention skills, the necessary first step to constructing an efficacious parent-delivered intervention. Telehealth procedures provided the opportunity to reach families quickly regardless of distance and to both assess and treat infant symptoms. Infant change demonstrated in single subject studies supports continued efforts to construct effective interventions for this group of infants and parents. Recommending such interventions for nonsymptomatic infants identified with ASD risk based on brain-based or related characteristics raises multiple concerns including ethics, cost, and possible unwanted effects that require careful consideration.

209.004 *(Panel)* Is Presymptomatic Prediction of Autism Spectrum Disorder Ethically Justified?

K. E. MacDuffie[1,2]*, A. Estes*[1] *and B. Wilfond*[2]*, (1)Speech and Hearing Sciences, University of Washington, Seattle, WA, (2)Treuman Katz Center for Pediatric Bioethics, Seattle Children's Hospital, Seattle, WA*

Background: As prior talks on this panel have demonstrated, emerging methods could potentially shift the timing of ASD detection and intervention into the first year of life, accelerating neuroscientific investigations into the early pathogenesis of ASD and enabling targeted enrollment into research trials of presymptomatic interventions. The evidence base for presymptomatic interventions is still being built, however, with consensus on "best practice" for interventions delivered in infancy still likely years away. These circumstances raise an important ethical question for presymptomatic ASD research that has been widely debated in the genomics literature: is disclosure of a predictive diagnosis to parents justified when there is no immediate treatment available? Prior to 2005, international guidelines and position papers on genetic testing offered ambiguous or inconclusive recommendations about whether predictive testing should be offered for childhood-onset disorders with no proven intervention (Borry et al., 2006).

Objectives: The goal of the current project was to review current recommendations from the genomics literature for predictive testing in children and evaluate their applicability to the brain-based prediction efforts described in this panel.

Methods: A review of international consensus statements/guidelines on predictive genetic testing in children was conducted to update a prior review published by Borry and colleagues (2006). Each guideline included in the prior review was revisited and those that had been updated since 2005 were included in the analysis. Statements related to genetic testing for childhood-onset disorders with no proven intervention were extracted; illustrative examples are shown in Table 1.

Results: In the last 15 years, international guidelines and consensus statements have shifted towards allowing parents more discretion in decisions about whether to pursue predictive testing for their children. Parental discretion is advised most strongly in the context of familial disorders, where the uncertainty of whether a child will develop symptoms can be a source of worry and anticipatory distress. Statements in favor of a more discretionary set of policies argue that the benefits of predictive information for families often go beyond strictly *clinical* utility (i.e., enabling access to available, proven treatments) to include a more inclusive and subjective notion of *personal* utility (Garrett et al., 2019).

Conclusions: The results of our literature review suggest that research efforts to develop and evaluate a presymptomatic test for ASD are—in our opinion—ethically justified. The only way to understand the risks and benefits of predictive testing is to study it (Tarini et al., 2011). Our ongoing research efforts aim to understand the perspectives of parents, to whom will fall decisions about whether to pursue presymptomatic testing for a given child. Further work to incorporate perspectives of other stakeholders (clinicians, adults with ASD, disability advocates) on predictive testing is warranted. Resulting evidence will inform future deliberations about whether predictive testing for ASD offers sufficient benefit to justify widespread clinical use.

PANEL SESSION — EARLY DEVELOPMENT (< 48 MONTHS)
210 - New Avenues of Research Reveal Novel Genomic, Functional and Structural Knowledge about Early ASD Brain Development

Panel Chair: Eric Courchesne*, Neuroscience, UC San Diego Autism Center of Excellence, San Diego, CA*

Discussant: Eric Courchesne*, Autism Center of Excellence, Neurosciences, University of California, San Diego, La Jolla, CA*

ASD begins in fetal life and disrupted molecular and neural development continues into the first years. It is therefore of the utmost importance to elucidate the neural functional and structural patterns of developmental change and the underlying molecular dysregulations at the earliest stages of postnatal life, namely, in infants, toddlers and young children with ASD. That knowledge would then enable discovery of early-age neurofunctional and genomic biomarkers that accompany symptom onset, convey prognostic clinical and treatment information, and indicate disorder subtypes and the role of gender. Research and knowledge in this vital area has accelerated in recent years and much new work is underway in many laboratories. Here we present four important examples of investigations using novel designs, methods and concepts to advance genomic, functional and structural knowledge of ASD across early development. Successful work by a variety of investigators in this field enables future research to improve early identification and intervention, reduce uncertainty in objectively identifying subjects for inclusion in treatment trials, and identify brain-behavior and genomic-imaging subtypes to allow for individualized treatment.

210.001 *(Panel)* Altered Resting-State Functional Connectivity Networks in Preschool Age Males and Females with Autism Spectrum Disorder

J. K. Lee[1]*, C. W. Nordahl*[1]*, S. Ozonoff*[2]*, M. Solomon*[1]*, D. S. Andrews*[1] *and S. J. Rogers*[1]*, (1)Department of Psychiatry and Behavioral Sciences, The Medical Investigation of Neurodevelopmental Disorders (MIND) Institute, UC Davis School of Medicine, University of California Davis, Sacramento, CA, (2)Psychiatry and Behavioral Sciences, University of California at Davis, MIND Institute, Sacramento, CA*

Background: Little is known about how Autism Spectrum Disorder (ASD) manifests during early childhood, a period of rapid brain development. Initial evidence in males suggests the early presence of altered amygdala resting-state functional (rsfMRI) connectivity, but alterations in other rsfMRI networks have not been examined within this age group. Much less is known about rsfMRI alterations in females with ASD, or the degree to which alterations in ASD are sex specific.

Objectives: To examine diagnostic and sex differences in amygdala rsfMRI connectivity and in ten rsfMRI connectivity with ten canonical brain networks (Smith et al., 2009) in a cohort of males and females with ASD and typically development (TD) in early childhood.

Methods: Resting-state functional connectivity was examined in 156 ASD (50 female) and 78 TD children (38 female) aged 2 to 6 years during natural sleep. Diagnostic assessments for ASD were carried out by expert clinicians using the ADOS and ADI-R. Resting state images were preprocessed using the Configurable Pipeline for the Analysis of Connectomes (C-PAC; Craddock et al., 2013). Volumes with frame-wise displacement greater than .25 mm were scrubbed. Whole-brain connectivity maps with left and right amygdala seeds were computed. Dual regression (Beckmann et al., 2009) was also performed to estimate participant-specific connectivity maps with canonical rsfMRI networks (Smith et al., 2009). Two analytical strategies were employed. First, multivariate distance matrix regression (MDMR) assessed global diagnostic differences across each network. Second, univariate general linear models identified focal regions with significant mean connectivity differences within each network with cluster-based correction for multiple comparisons using Gaussian Random Field theory ($Z > 2.70$, pGRF<.005).

Results: MDMR analysis revealed significant diagnostic group differences across sexes in several networks, including the default mode, left frontoparietal, and right frontoparietal networks (Figure 1, A, B, and C). However, sex-specific diagnostic differences in left amygdala and cerebellar rsfMRI connectivity networks were observed (Figure 1, D and E). Univariate analysis revealed similar diagnostic differences across sexes between left and right amygdala and the superior temporal sulcus and supramarginal gyrus, as well as with multiple canonical networks, including medial/occipital visual and left and right frontoparietal networks. However, sex-specific diagnostic differences were observed for the left and right amygdala, and in connectivity with several canonical networks, including the cerebellar, sensorimotor, frontoparietal networks.

Conclusions: Altered network connectivity differences were observed in ASD across multiple networks in both males and females with ASD at the age of first diagnosis. However, networks also exhibited sex-specific diagnostic differences.

210.002 *(Panel)* Neural Correlates Underlying Reduced Social-Emotional Speech Engagement in Toddlers with ASD

Y. Xiao[1]*, L. Kupis*[2]*, L. Eyler*[3]*, T. H. Wen*[1]*, D. Goel*[1]*, M. V. Lombardo*[4]*, K. Pierce*[1] *and E. Courchesne*[1]*, (1)Autism Center of Excellence, Neurosciences, University of California, San Diego, La Jolla, CA, (2)University of Miami, Miami, FL, (3)Univeristy of California, San Diego, La Jolla, CA, (4)Center for Neuroscience and Cognitive Systems, Laboratory for Autism and Neurodevelopmental Disorders, Istituto Italiano di Tecnologia, Rovereto, Italy*

Background: It is well-established that typically developing (TD) babies attend to and prefer “motherese”, which is a strongly emotional mode of speech used by parents towards infants and toddlers in nearly all cultures. Saint-Georges et al. (2013) state that motherese “is part of an interactive loop {between mother and infants} that may play an important role in infants’ cognitive and social development.” Motherese enhances joint social attention, language acquisition, and affect and emotion development and regulation. Behavioral preference for motherese may be markedly deficient in infants with ASD. Absent, however, are fMRI studies of motherese that coincide with initial clinical signs of ASD in infants and toddlers. Here we analyze fMRI activations in ASD toddlers responding to neutral, moderately prosodic, or motherese speech and compare them to TD subjects.

Objectives: We investigated fMRI responses to speech with varying levels of social-emotional prosody from typical to motherese in ASD and TD toddlers and whether functional activation to different levels of prosodic speech is behaviorally relevant.

Methods: We scanned 27 ASD toddlers (23 males, 29.07±9.65 months, range 14–55 months) and 17 TD toddlers (11 males, 26.12±6.47 months, range 17–38 months) during natural sleep while presenting the following paradigms: Typical Prosody, Moderate Prosody, and Motherese (recorded female voices reading phrases from storybooks or typical infant-directed utterances presented in a block design; different paradigms exhibit increasing levels of emotional intonation). ASD and TD groups were equivalent on age and gender. For each paradigm, multi-echo fMRI data from separate runs were collected. Structural scans were also obtained from participants.

Data preprocessing was performed using the ME-ICA approach with meica.py tool (Kundu et al., 2013) in AFNI (Cox, 1996); functional images were normalized to an age-matched toddler template (Shi et al., 2011). Head motion was quantified with framewise displacement (Power et al., 2012) and didn't show group differences across tasks. GLM analyses were conducted using SPM12 (https://www.fil.ion.ucl.ac.uk/spm/software/spm12/). Percent signal change (Speech > Rest) was calculated for each task based on language regions from Neurosynth (i.e., bilateral temporal regions) (Yarkoni et al., 2011). For all three paradigms, we examined group differences in brain activation and characterized the relationship between brain activation and social abilities as measured by the Vineland Adaptive Behavior Scales (Sparrow et al., 2005).

Results: In TD toddlers, strong bilateral temporal responses were observed for all levels of prosody; brain activation and social abilities were positively related in the Moderate Prosody and Motherese tasks (see Figure). Compared to TD, ASD toddlers showed hypoactivation to all speech stimuli (Cohen's d ranging from 0.73–1.05) and absence of correlations with social abilities (see Figure).

Conclusions: Consistent with the literature that motherese enhances joint social attention, language acquisition, and affect and emotion development and regulation, we found that Moderate Prosody and Motherese enhanced temporal cortex activation in TD is in strong concordance with social ability. The absence of this at the early age of clinical onset in ASD may be a biomarker of foundational dysregulation of social-emotional development that could underpin development of associated social cognitive functions.

210.003 *(Panel)* Different Large-Scale Associations between Blood Leukocyte Gene Expression and Surface Area or Cortical Thickness in ASD Toddlers with Good Versus Poor Early Language Outcome

M. V. Lombardo[1]*, L. Eyler*[2]*, T. Pramparo*[2]*, J. Seidlitz*[3]*, R. A. Bethlehem*[4]*, N. Bertelsen*[1]*, K. Pierce*[5] *and E. Courchesne*[5]*, (1)Center for Neuroscience and Cognitive Systems, Laboratory for Autism and Neurodevelopmental Disorders, Istituto Italiano di Tecnologia, Rovereto, Italy, (2)Univeristy of California, San Diego, La Jolla, CA, (3)National Institute of Mental Health, Bethesda, MD, (4)Autism Research Centre, Department of Psychiatry, University of Cambridge, Cambridge, United Kingdom, (5)Autism Center of Excellence, Neurosciences, University of California, San Diego, La Jolla, CA*

Background: Understanding of the 'living' biology behind heterogeneous types of autisms (ASD) is the next frontier for autism research (Courchesne et al., 2019, *Molecular Psychiatry*). In prior work, we found that ASD good versus poor early language outcome subtypes show distinct types of large-scale associations between distributed neural systems response to speech measured with fMRI and widespread gene expression patterns in blood leukocytes (Lombardo et al., 2018, *Nature Neuroscience*).

Objectives: Examine whether there are ASD subtype-distinctive associations between gene expression and neuroanatomical features (e.g., surface area (SA) and cortical thickness (CT)).

Methods: n=76 ASD toddlers (ASD Poor n=38, mean age=29.01 months; ASD Good n=38, mean age=29.02 months) and n=47 typically-developing (TD) toddlers (mean age=25.91 months at MRI scan) were scanned with MRI during natural sleep and donated a blood sample for gene expression analysis. Early language outcome subtype stratifications (ASD Poor vs ASD Good) were made according to past work (Lombardo et al., 2015, *Neuron*). Freesurfer estimated SA and CT from parcels determined based on patterns of regional genetic correlations from prior twin studies (Chen et al., 2013, *PNAS*). Weighted gene co-expression network analysis (WGCNA) clustered blood leukocyte gene expression into 21 gene co-expression modules. Partial least squares (PLS) analysis was utilized to find multivariate associations between module eigengene expression and SA or CT. A permutation test (10,000 permutations) was used to evaluate statistical significance of latent variable (LV) pairs and bootstrapping (10,000 resamples) was used to compute 95% confidence intervals to identify co-expression modules with 'non-zero' associations and bootstrap ratios (BSR) to assess regions of importance to each LV.

Results: For SA, we identified 1 LV pair with a statistically significant association (d=3.99, p=9.99e-5), while for CT there were 2 LV pairs that passed FDR q<0.05 (LV1 d=4.30, p=9.99e-5; LV2 d=3.09, p=9.99e-5). CT LV1 showed significant overlap in the non-zero modules for TD and ASD Good (63%, OR=29.75, p=0.01), indicating common associations for these groups. However, in all other LVs, no statistically significant overlap between-groups existed (<33% overlap, all p>0.26), indicating that there are distinct associations specific to each group. Non-zero co-expression modules of importance to LV1 in SA or CT were mainly restricted to TD and ASD Good groups. However, in CT LV2, the ASD Poor group drove most of the non-zero associations with co-expression modules. Finally, the pattern of association across brain regions for SA and CT LV1 followed anterior-posterior (A-P) and ventral-dorsal (V-D) cortical gradients respectively and recapitulate gradients found in twin studies (Chen et al., 2013). Genes from SA and CT LV1 non-zero modules are also enriched for genes that drive similar A-P or D-V gene expression gradients observed during midgestational periods of prenatal brain development (OR>2.39,p<1.35e-21) (Li et al., *2018, Science*).

Conclusions: Different functional genomic mechanisms in ASD language outcome subtypes are linked to early postnatal neuroanatomical development and overlap with similar mechanisms affecting midgestational periods of prenatal brain development. Early structural and functional brain development in ASD toddlers with poor versus good early language outcome is likely driven by distinctive early biological mechanisms.

210.004 *(Panel)* Salience Network Connectivity in 6-Week-Old Infants Predicts Later Development of Social Attention and Autism Symptomatology

M. Dapretto*, Dept of Psychiatry and Biobehavioral Sciences, University of California, Los Angeles, Los Angeles, CA*

Background: Infants who develop ASD show altered developmental trajectories characterized by reduced attention to social information and heightened awareness of non-social sensory input.The neurobiological mechanisms underlying these altered attentional biases that may give rise to autism-related symptoms remains unknown. Examining early brain connectivity offers a promising lens for investigation as neuroimaging studies have consistently implicated atypical brain network dynamics in ASD, with recent evidence indicating that 6-month-olds who later develop ASD already exhibit significant differences in whole-brain functional connectivity.

Objectives: To examine functional connectivity in the Salience Network (SN) – an early-emerging neural network involved in orienting attention to the most salient aspects of one's internal and external environment – as well as its association with subsequent ASD symptomatology (i.e., atypicalities in sensory processing, communicative development, and visual social attention to faces) in 6-week-old infants at high (HR) and low (LR) familial risk for ASD.

Methods: 8-min rs-fMRI scans were collected during natural sleep (N=53). Preprocessing was performed using FSL with ICA-AROMA used to correct for head motion. The SN was identified using the right anterior insula as the seed. The Autism Observation Scale for Infants (AOSI,) the Early Social Communication Scale (ESCS), and the Infant/Toddler Sensory Profile (ITSP) were used at 12 months to assess core ASD symptoms, nonverbal social-communication, and sensory sensitivities, respectively. To capture developmental trajectories in social attention to faces, eye-tracking was conducted at 3-, 6-, 9-, and 12-months while infants viewed videos depicting social interactions.

Results: Compared to LR infants, HR infants showed stronger SN connectivity with sensorimotor regions as well as weaker SN connectivity with prefrontal regions associated with higher-level processing and attentional control. Notably, infants with higher connectivity with sensorimotor regions had lower connectivity with prefrontal regions, suggesting a direct tradeoff between attention to basic sensory versus socially-relevant information. In HR infants, greater SN connectivity with primary sensory processing regions predicted higher sensory hypersensitivity whereas stronger SN connectivity with regions involved in implicit learning and reward processing predicted fewer ASD risk markers on the AOSI. In LR infants, stronger SN connectivity with prefrontal regions predicted increased social attention to faces over the first year; similarly, greater SN connectivity with both prefrontal and subcortical regions associated with reward and learning predicted higher rates of initiating joint attention, indicating that normative SN connectivity patterns in early infancy support attention to socially-relevant stimuli, scaffolding the development of social communication skills.

Conclusions: These results demonstrate that aberrant patterns of SN connectivity can be detected in infants at high risk for ASD as early as 6 weeks of age and that these alterations predict subsequent development of ASD symptomatology. Importantly, these findings provide empirical support for recent theoretical frameworks positing that initial deviations in attentional biases and/or sensorimotor processing may account for the emergence of ASD-related behaviors by altering the experience-dependent brain maturation that typically subserve social development. Identifying atypical brain connectivity early in infancy may pave the way for timely interventions that can effectively redirect attention to socially-relevant input and thus stir development along optimal developmental trajectories.

ORAL SESSION — EARLY DEVELOPMENT (< 48 MONTHS)
311 - Early Identification and Development

311.001 *(Oral)* Early Autism Screening in a Community Sample: Preterm Infants on the First Years Inventory 3.1

E. Choi[1], *J. Sideris*[2], *Y. J. Chen*[1], *E. Campi*[1], *A. M. Wiles*[1], *V. H. Vera Carrasquero*[1], *C. Holland*[1], *H. Lee*[1], *L. R. Watson*[3], *E. Crais*[3] *and G. T. Baranek*[1], *(1)Chan Division of Occupational Science and Occupational Therapy, University of Southern California, Los Angeles, CA, (2)Frank Porter Graham Child Development Institute, Chapel Hill, NC, (3)Department of Allied Health Sciences, University of North Carolina at Chapel Hill, Chapel Hill, NC*

Background: Preterm infants are at higher likelihood for an eventual diagnosis of ASD and atypical development across multiple domains. Thus, ASD screening tools that may be used in the preterm population should be tested for factorial invariance (i.e., testing whether latent variables are measured equivalently across groups). Additionally, though standard assessment practice is to use adjusted age for a minimum of 12 months post birth, specific recommendations may vary across measures and should be justified through data analyses.

Objectives: We sought to use confirmatory factor analysis to test whether the First Years Inventory version 3.1 (FYI 3.1) performed equivalently across preterm and full-term infant groups from a community sample.

Methods: We analyzed 27 core items on the FYI 3.1, a parent-report questionnaire designed to identify infants at risk for an eventual diagnosis of ASD. We conducted invariance testing to determine whether social communication (SC) and sensory regulatory (SR) domain items loaded similarly for preterm (n=400) and full-term infants (n=4,568). We ran separate analyses for two preterm infant groups: “9-month” adjusted (8-10 months adjusted; n=219) and “12-month” adjusted (11-13 months adjusted; n=181). We first tested for configural (structural) equivalence across groups as the baseline model followed by metric, scalar, and residual models with varying constraints on factor loadings and thresholds. Model fit was evaluated using chi-square estimates, comparative fit index (CFI), and root mean square error of approximation (RMSEA). CFI>.90 and RMSEA<.08 (Hu & Bentler, 1999) were considered to be good fit. We assessed chi-square differences between invariance models to test whether assumptions of invariance constraints were violated.

Results: Models were invariant at the most restrictive level for 9-month groups: factor loadings, item thresholds, and item residuals were equal across both groups on both domains. There were small but non-significant differences in SC and SR variances and significantly higher mean scores in SC for the preterm group. Factor loadings for 12-month groups were equal, but there was partial invariance (i.e., some parameters were allowed to be unequal) at threshold and residual levels. The model indicated significantly more variance in SC for the preterm group and no significant differences in SC or SR means.

Conclusions: Our results show that parents of preterm and full-term infants in our sample interpreted the FYI’s SC and SR questions similarly. This provides preliminary evidence supporting the use of the FYI 3.1 in the preterm population. The presence of partial invariance for the 12-month group of preterm infants on both SC and SR reflects differences in average levels of responses (on a scale of “never” to “always”) as a function of prematurity, suggesting potential bias in parent responses in the 12-month group. We will examine these response differences and further explore variance in scale scores across adjusted and unadjusted preterm infant groups to determine whether there is an age at which variances are no longer significantly different. That is, through comparisons between variance across preterm and full-term groups, we will determine whether there is an age group for which the use of unadjusted age is warranted.

311.002 *(Oral)* Aberrant Cortical Thickness and Cortical Surface Area in Auditory and Premotor Cortices in Toddlers and Preschoolers with Autism Spectrum Disorders

B. Chen[1], *A. C. Linke*[2], *M. C. Arcadio Arce*[1], *I. A. Martindale*[3], *J. S. Kohli*[3], *L. Olson*[4], *S. R. Peña*[1], *L. Ringlee*[1], *T. Pinhassian*[1], *M. Sereno*[1], *R. A. Mueller*[2], *R. A. Carper*[3] *and I. Fishman*[2], *(1)San Diego State University, San Diego, CA, (2)Brain Development Imaging Laboratories, San Diego State University, San Diego, CA, (3)Brain Development Imaging Laboratories, Department of Psychology, San Diego State University, San Diego, CA, (4)Joint Doctoral Program in Clinical Psychology, SDSU/ UC San Diego, San Diego, CA*

Background: Early brain enlargement has been consistently reported in young children with autism spectrum disorders (ASDs), with some initial evidence from longitudinal prospective studies of high-risk infants suggesting that accelerated cortical surface area expansion in the first year of life precedes and underlies brain volume overgrowth. Specifically, early surface area expansion appears to be most robust in regions involved in visual processing. However, given the scarcity of imaging data in young children with ASDs, further evidence is needed to determine whether these findings apply to all sensory modalities.

Objectives: To examine cortical thickness and surface area for primary sensorimotor networks (i.e., visual, auditory, somatosensory, motor) in toddlers and preschoolers with ASDs as compared to typically developing (TD) peers.

Methods: Participants wereyoung children with ASDs (age: 42±14 months, 18-69 months) and TD children (41±14 months, 18-65 months) enrolled in a longitudinal study of early brain markers of autism. ASD diagnoses (or clinical best estimates for youngest participants) were established based on the DSM-5 criteria, supported by the Autism Diagnostic Observation Schedule (ADOS-2). The Mullen Scales of Early Learning were administered to assess visual reception, motor, and language skills. T1-weighted MPRAGE scans acquired in 60 toddlers (32 ASD, 28 TD) during natural sleep were included. Data quality, inspected by multiple raters, was equivalent in both groups. Cortical thickness (CT) and surface area (SA) were calculated using FreeSurfer in 58 regions of interests within visual, auditory, somatosensory, and motor networks from the Human Connectome Project parcellation. Group differences in CT were examined with two-sample t-tests. ANCOVA was used to compare group differences in SA, with total SA as a covariate.

Results: Increased SA was detected in the ASD group in regions involved in higher-order auditory processing, including area TA2 and anterior superior temporal gyrus (STGa) in the left hemisphere, as well as in the right premotor eye field. Increased CT was identified in left STGa, while decreased CT was found in premotor area 6v and cingulate motor area 24d in the right hemisphere (all results at $p<0.05$, uncorrected). Mullen Fine Motor (FM) Age Equivalent (AE) scores were positively correlated with CT of right area 6v in children with ASDs (r=.53), but negatively in TD children (r=-.44), with significant FM by diagnosis interaction, controlling for age (Fig. 1). Similarly, CT of right dorsal area 24d was negatively correlated with Mullen FM AE in TD (r=-.54), but not in ASD (r=-.04) children, controlling for age (Fig. 2).

Conclusions: Increased cortical surface area was detected in young children with ASDs, particularly in higher-order auditory regions and premotor cortex, but not in visual cortices. This was accompanied by increased cortical thickness in higher-order auditory cortex, but decreased CT in premotor/motor cortices. Critically, reduced CT in premotor/motor regions was associated with greater fine motor skills in TD children, but this relationship was reversed or absent in children with ASDs, suggesting an atypical brain and behavioral maturation of motor circuits in the first years of life in ASDs.

311.003 *(Oral)* M-CHAT-R/F Performance in Low Mental Age: Autism Spectrum Disorder Versus Global Developmental Delay

R. P. Thomas[1], *S. Milan*[1], *L. B. Adamson*[2], *D. L. Robins*[3] *and D. A. Fein*[1], *(1)Psychological Sciences, University of Connecticut, Storrs, CT, (2)Psychology, Georgia State University, Atlanta, GA, (3)A.J. Drexel Autism Institute, Drexel University, Philadelphia, PA*

Background: Existing screening measures, such as the Modified Checklist for Autism in Toddlers, Revised, with Follow-Up (M-CHAT-R/F; Robins et al., 2014), are influenced by developmental stage, and may flag children with significant delays but not Autism Spectrum Disorder (ASD), because their developmental delay precludes the development of age-typical social interaction. Existing diagnostic tools have been shown to classify some children with a mental age under 12 months (low MA) at risk for ASD when their clinical diagnosis was Global Developmental Delay (GDD; Miller et al., 2019). Identification of specific behaviors that lead to true or false positives for ASD in very delayed children may help clinicians better estimate a child's risk for ASD.

Objectives: There is evidence that the ASD-low MA symptom profile is a unique phenotype, and that children in this group should perform differently from GDD groups on screening and diagnostic instruments (Hinnebusch et al., 2017; Miller et al., 2019). The current project aims to identify screening items that differentiate or fail to differentiate children with ASD-low MA from those with GDD.

Methods: Children (n=60) between 12 months and 34 months of age participated in a multi-site study of early detection in ASD. The ASD-low MA group (n=30) had age equivalents <12 months on MSEL language and nonverbal subtests, and met diagnostic criteria for ASD. The GDD group (n=30) consisted of children who met DSM-5 criteria for Global Developmental Delay. The groups were matched on Expressive Language and Visual Reception Mullen Scales of Early Learning (MSL) age equivalents, but were significantly different on chronological age ($F(1,57)=6.128$, $p=.016$) and race ($t(51)=2.432$, $p=.019$). The ASD-low MA group was significantly older (M=20.4 months, SD=5.5) than the GDD group (M=17.6 months, SD=3.0), and fewer GDD families identified as White. Maternal education differences were not significant between the groups ($t(55)=-.376$, $p=.57$).

Results: Chi-square analyses were conducted to identify the percentage of each group that failed each M-CHAT-R/F item (Table 1). Five of the 20 items differed by diagnostic group. These indicated that parents of children in the ASD-low MA group were more likely to indicate that their child does not follow a point, show interest in children, display social smiling, or imitate others, compared to the GDD group. Parents of children in the GDD group were more likely to indicate that their child does not walk, compared to the ASD group. In logistic regressions with race as a covariate, and setting $p<.01$ for multiple comparisons, only following a point (AOR 7.526, 95% CI: 1.659-34.144) and interest in children (AOR 5.889, 95% CI: 1.068-32.458) remained significantly more likely in the ASD-low MA group.

Conclusions: There may be "key" items to differentiate ASD-low MA from GDD when screening children with known significant delays for possible ASD. Following a point, interest in peers, imitation, and social smiling may be the most robust behaviors that differentiate between these two groups when cognitive level is below one year. Current results suggest that these core autism signs are valid diagnostic markers even with very low developmental status.

311.004 *(Oral)* Sex Differences in the Prediction of Language Development By Patterns of Social Visual Engagement in Children with and without ASD

D. Parmaksiz[1], *S. Koirala*[2], *A. Klin*[3], *S. Shultz*[3], *W. Jones*[3], *L. A. Edwards*[3] *and S. Yuan*[4], *(1)Marcus Autism Center, Atlanta, GA, (2)Department of Pediatrics, Emory University School of Medicine, Marcus Autism Center, Atlanta, GA, (3)Marcus Autism Center, Children's Healthcare of Atlanta and Emory University School of Medicine, Atlanta, GA, (4)Emory University School of Medicine, Marcus Autism Center, Atlanta, GA*

Background: Autism Spectrum Disorder (ASD) diagnoses are about 4 times more common in males than females. Although research on sex differences in language development in ASD remains limited (Lai et al., 2015), females with ASD but without intellectual disability have been found to exhibit more developmentally-appropriate language skills than males with ASD (Messinger et al., 2015). Studies of early social visual engagement (SVE) suggest that females with ASD demonstrate increased attention to faces relative to ASD males under socially-lean conditions (Chawarska et al., 2016), and point to an association between SVE to faces and expressive language (Young et al., 2009). While TD infants increase attention to mouth over infancy, followed by a return to focus on the eyes by two years (Hunnius & Geuze, 2004; Frank et al., 2011), this pattern of SVE has not been shown in autism. Sex-and diagnosis-based divergences in trajectories of SVE over development may hence explain differential language outcomes in ASD.

Objectives: This study examines sex-based differences in the associations between SVE at the beginning of the first and second years of life, and language development and social disability at the end of the second year of life, in a longitudinally-followed cohort of ASD and TD infants.

Methods: Eye-tracking measures of SVE were collected during early infancy (N_{ASD}=40(10 female), $M_{age,male}$=5.13, $M_{age,female}$=5.08, N_{TD}=93(44 female),$M_{age,male}$=5.15,$M_{age,female}$=5.13) and the second year of life (N_{ASD}=45(12 female), $M_{age,male}$=15.20, $M_{age,female}$=15.28, N_{TD} =80 (34 female), $M_{age,male}$=15.28, $M_{age,female}$=15.12) while children watched scenes of naturalistic caregiver interactions. At 24 months, the Mullen Scales of Early Learning and the Autism Diagnostic Observation Schedule (ADOS) were administered as part of clinical best estimate diagnostic procedures. Eye-tracking measures were quantified as percentage of visual fixation to regions-of-interest (eyes, mouth, body or object), and associations between these measures and language/social ability were tested via Spearman correlations.

Results: Eye-looking during early infancy positively predicted Mullen receptive language scores at 24 months in the TD group regardless of sex (r_{female}=0.2981,p_{female}=0.0494; r_{male}=0.3085,p_{male}=0.0305), while increased mouth-looking during the second year of life was a significant positive predictor of Mullen expressive language scores at 24 months in TD females only (r_{female}=0.3771,p_{female}=0.0279). Patterns of SVE to the face were unrelated to later language in the ASD group, but eye-looking negatively predicted ADOS total scores; this association was driven by ASD females (r_{female}=-0.6728,p_{female}=0.0330; r_{male}=-0.1163,p_{male}=0.5406). In ASD females only, mouth-looking positively predicted ADOS total scores (r_{female}=0.7784,p_{female}=0.0080).

Conclusions: Preliminary results indicate that increased attention to distinct areas of the face during the first two years of life predicts language development in typical development. Notably, sex differences were observed in the strength of the association between SVE and expressive language in toddlerhood. In ASD, visual fixation patterns to the face were related to later social disability in females only. These findings suggest that visual fixation has differential adaptive value in ASD, and by sex. Future work will include the investigation of sex-based trajectory differences in SVE to the face and relationships to later language outcomes.

POSTER SESSION — EARLY DEVELOPMENT (< 48 MONTHS)
417 - Early Development (< 48 months) Posters

417.001 *(Poster)* A Comparative Study of Developmental Trajectories in Minimally Verbal and Verbal Children with Autism from 2- to 4-Years of Age

R. H. Cliffe[1], *C. Dissanayake*[2] *and J. Barbaro*[3], *(1)Olga Tennison Research Centre, BUNDOORA, VIC, Australia, (2)Olga Tennison Autism Research Centre, La Trobe University, Melbourne, Australia, (3)Olga Tennison Autism Research Centre, La Trobe University, Melbourne, VIC, Australia*

Background: Despite approximately 30% of children with autism remaining minimally verbal, there has been a paucity of research examining the early development of this group over time. The window of opportunity to develop spoken language decreases after the age of five, with those children who do not develop verbal language having poorer long-term outcomes. Thus, it is important to understand the very early developmental trajectories of minimally verbal children in order to target interventions on individuals with the greatest need.

Objectives: The aim in this study was to compare the very early developmental trajectories of minimally verbal and verbal children with autism across a period of two years.

Methods: The community-based cohort comprised 72 children (22 female) diagnosed with Autism Spectrum Disorder, with baseline assessments conducted at 2 years of age (M = 25.55 months) and follow-up assessments undertaken two years later, at 4 years (*M* = 49.78 months). Minimally verbal was defined as having a very small (< 20 functional words) repertoire of spoken words or fixed phrases that are used communicatively; 23 children were classified as minimally verbal at follow-up (32%; Minimally Verbal Group). All children were assessed with the Autism Diagnostic Observation Schedule and the Mullen Scales of Early Learning at baseline and follow-up.

Results: A 2 (Group: Minimally Verbal; Verbal) x 2 (Time: Baseline; Follow-up) repeated measures ANOVAs revealed that while the Verbal Group significantly increased their verbal developmental quotient (VDQ) from baseline to follow-up, VDQ remained stable in the Minimally Verbal Group. In contrast, the ANOVA showed that Non-verbal DQ in the Verbal group remained stable over time while it decreased in the Minimally Verbal Group. As well as having lower DQ's, the Minimally Verbal Group also had significantly higher symptom severity scores, with both groups showing a significant decrease in Social Affect symptoms over time. Restricted and Repetitive Behaviours (RRBs), on the other hand, increased in both groups from ages 2- to 4-years, with no group difference in RRBs.

Conclusions: Children who were minimally verbal had different developmental trajectories to their verbal peers. They made fewer gains in cognition over time, and had more severe social affect symptoms, although, like the verbal group, these symptoms decreased over time. As expected for their young age, both groups showed few RRBs at age 2, which increased by age 4 years. The findings indicate that minimally verbal children require targeted intervention to increase their language abilities and prevent loss of non-verbal skills in order to facilitate positive long-term outcomes.

417.002 *(Poster)* A Profile of Children with Early Diagnosis of ASD in Puerto Rico

*A. Diaz[1] and **F. Ruiz-Alfaro**[2], (1)HOPE, San Juan, PR, (2)Psychology, University of Puerto Rico, San Juan, PR*

Background: The PR Health Department has established a uniform evaluation protocol that ensures best practices for ASD early identification and diagnosis. The prevalence of children diagnosed with ASD in Puerto Rico is 1 in 62 for 4- 17 age group and 1 in 125 for 0-17 age group (Marazzi-Santiago.; Rodriguez-Ayuso, I.R., 2014).Public Policy (BIDA Law) has developed strategies such as an Autism Registry that provides demographic and diagnostic data in order to produce an accurate profile of ASD population. In addition, the Autism Registry was created, in order to link families with the services available in the community as well as obtaining information related to the population with ASD that facilitate the planning of services to establish policy post in the future.

Objectives: Provide a profile on socio-demographics characteristics of children with an early diagnosis of ASD in Puerto Rico.

Methods: A statistics revision of the 2018 official report of the Timon Committee for the BIDA Law was done to analyze the ASD population in Puerto Rico. During March 2017 until February 2018, 173 children were assessed. Out of that 156 were diagnosed with ASD. Each yearly report shows an increased number of children with ASD in Puerto Rico. The researchers are completing an actualization of these records at the Puerto Rico Autism Center located in San Juan, a government clinic of the Health Department that provides early detection and intervention of ASD to these young children.

Results: Until February 2018, based in the official report produced by the Autism Registry: 90% of children registered was diagnosed with ASD. 94% of assessed children were between 2 to 3 years of age. Out of the children diagnosed, 84% were male and 16% were female showing a prevalence of 5:1 male to female ratio. Regarding the level of severity reported in the diagnostic impression a 48% presented a level 3 of severity in both areas. Regarding comorbidity, 79% of the children also had a diagnosis of communication delay and 69% had a clinical presentation of a sensory processing disorder. A 30% of the children showed gastrointestinal issues and 31% had low muscular tone. These findings will be compared with the actualization of these records at the Puerto Rico Autism Center in San Juan.

Conclusions: An increasing number of children referred at an early age with high suspicion of ASD in PR, documents the need to provide adequate and accurate assessments. The high prevalence of children diagnosed with ASD increases the need for evidence based early interventions that provides targeted stimulation for a developing brain. This profile emphasizes on the need for further studies such as longitudinal research which evaluates the stability in the diagnostic impression at an early stage in life documenting the early intervention results. Future research can compare this outcome with that of groups of older children who were diagnosed later in their youth will provide valuable information for an accurate ASD profile in Puerto Rico.

417.003 *(Poster)* Associations between Local Cortical Gyrification, Age, and Symptom Severity in Toddlers and Preschoolers with Autism Spectrum Disorders

***I. A. Martindale**[1], B. Chen[2], J. S. Kohli[1], A. C. Linke[3], L. Olson[4], R. A. Mueller[3], R. A. Carper[1] and I. Fishman[3], (1)Brain Development Imaging Laboratories, Department of Psychology, San Diego State University, San Diego, CA, (2)San Diego State University, San Diego, CA, (3)Brain Development Imaging Laboratories, San Diego State University, San Diego, CA, (4)Joint Doctoral Program in Clinical Psychology, SDSU/ UC San Diego, San Diego, CA*

Background: Emerging evidence from prospective studies of high-risk infants and from a few studies in young children diagnosed with autism spectrum disorders (ASDs) indicates that neuroanatomical abnormalities, such as increased cortical volume, thickness, and surface area, are present in the first years of life. The local gyrification index (LGI; reflecting the ratio between pial surface and cortical hull) has been suggested to be more sensitive to group differences in cortical morphology than other surface-based measures. In typical development, cortical gyrification – influenced by expansion of cortical layers – increases across early childhood, followed by a gradual decline from adolescence into adulthood. One study reported greater LGI in dorsomedial prefrontal and cingulate cortices, along with an accelerated longitudinal trajectory of increasing LGI in right inferior temporal and inferior frontal gyri in 3-5 years old boys with ASDs, compared to typically developing (TD) boys. Given the scarcity of early childhood data in ASDs, however, further investigation of LGI will be needed for firmer conclusions.

Objectives: To examine cortical morphology, with focus on LGI, in toddlers and preschoolers with ASDs compared to TD children.

Methods: T1-weighted anatomical MRI data were acquired in 38 toddlers with ASDs (mean age: 38.3±12.9 months; range: 17-66 months; 28 males) and 31 TD children (37.6±14.2 months; range: 17-64 months; 17 males) during natural sleep. Clinical best estimates of ASD diagnoses were established according to DSM-5 criteria, supported by the Autism Diagnostic Observation Schedule (ADOS-2). FreeSurfer v.5.3.0 was used for cortical surface reconstruction and to calculate LGI. Vertex-wise analyses were conducted using general linear models to examine group, age, and group-by-age interaction effects on LGI. Vertex-wise correlations also probed associations between ADOS-2 Total scores and LGI within the ASD group. Total brain volume was used as a covariate in all analyses, and results were corrected for multiple comparisons using Monte Carlo simulations.

Results: We observed significant positive main effects of age bilaterally in orbitofrontal regions, along with left precentral and right middle temporal clusters, with LGI increasing with age in both groups. There was also a significant group effect with increased LGI in the ASD group in a cluster extending across the right precentral and postcentral gyri. There were no significant group by age interaction effects. Additionally, LGI was negatively correlated with ADOS-2 Total scores in the ASD group in bilateral clusters extending from the middle to inferior frontal gyri, such that greater LGI was associated with fewer ASD symptoms.

Conclusions: As expected, positive age effects were observed for LGI in this sample of young children with and without ASDs. However, in at least one cluster spanning the sensorimotor cortices in the right hemisphere, LGI appeared to be atypical in children with ASDs, possibly reflecting onset of atypical growth trajectories in infancy. The relationship between ADOS-2 Total scores and LGI suggests that decreased cortical folding in frontal regions may play a role in autistic symptomatology in the first years of life.

417.004 *(Poster)* Associations between Socioeconomic Variables and Language Network Functional Brain Connectivity in Toddlers and Young Children with Autism Spectrum Disorders

L. Olson[1,2]*, A. C. Linke*[2]*, B. Chen*[1,2]*, C. Ibarra*[2]*, L. Ringlee*[2]*, S. R. Peña*[2]*, R. A. Mueller*[1,2] *and I. Fishman*[1,2]*, (1)Joint Doctoral Program in Clinical Psychology, SDSU/ UC San Diego, San Diego, CA, (2)Brain Development Imaging Laboratories, San Diego State University, San Diego, CA*

Background: Socioeconomic status (SES) is associated with language and social development in early childhood in typical development (e.g., Johnson et al., 2016). The degree to which these associations are present in children with ASD is less understood. However, previous work from our lab has shown that SES variables positively correlate with language skills in young children with autism, over and above the effect of diagnosis on language skills (Olson et al., 2019). It remains unknown to what extent SES variables are associated with brain correlates of emerging language skills in children with ASD during sensitive periods for language development.

Objectives: To examine associations between socioeconomic variables and brain functional connectivity patterns in language regions in toddlers with ASD.

Methods: 27 young children with ASD (ages 17-45 months, mean age: 31±8 months), a subset of participants enrolled in a longitudinal study of early brain development in autism, completed developmental and diagnostic assessments as well as an MRI scan conducted during natural sleep. Clinical best estimate ASD diagnoses were established based on DSM-5 criteria, supported by the Autism Diagnostic Observation Schedule (ADOS-2). Receptive and expressive language skills were assessed using the Mullen Scales of Early Learning. Caregivers provided demographic information, including household income, parental education, and racial/ethnic identity. Family median income was also estimated based on postal code, a neighborhood-based SES variable. Nine regions of interest (ROIs) were selected from an ALE meta-analysis of language fMRI studies in autism (Herringshaw et al., 2016) and applied as 10mm spherical masks to denoised BOLD time series. Averaged time courses from each ROI were correlated with each other, resulting in a matrix of 36 ROI-ROI connectivities for each participant. Associations between socioeconomic indices and language network functional connectivity were tested with Spearman's correlations.

Results: Income-to-needs ratio was positively associated with functional connectivity between the right superior temporal gyrus (STG, or Heschl gyrus) and left middle temporal gyrus (MTG) ($r = 0.53$, $p = 0.01$). Connectivity between these regions was also positively associated with expressive language, although not significantly ($r = 0.27$, $p = 0.2$).

Conclusions: These findings suggest that functional connectivity between regions involved in speech perception (rSTG) and action perception, as part of mentalizing network (lMTG), is stronger with increased access to resources (i.e., Income-to-needs ratio). This association suggests that for children with autism, experiences associated with low family income in early childhood may be linked with weaker connections between networks involved in understanding others. Future analyses will include a larger sample of young children with and without autism, and analyses controlling for age and other language variables (e.g., bilingualism). These findings highlight the necessity for targeted intervention and effective implementation strategies for children with ASD from low-resource households and communities, and for policies designed to improve learning opportunities and access to services for these young children and their families.

417.005 *(Poster)* Canonical Babbling at 6 and 12 Months Differentiates Infants at High- and Low-Risk for ASD

L. D. Yankowitz[1]*, V. Petrulla*[1]*, S. S. Meera*[2]*, S. Plate*[1]*, J. Pandey*[1]*, M. Swanson*[3]*, J. Pruett*[4]*, M. Edwards*[1]*, L. Moshiro*[1]*, A. Laver*[5]*, C. Bourneuf*[1]*, T. Jaung*[1]*, B. Tunc*[1]*, W. Guthrie*[1]*, L. A. Wang*[6]*, N. Marrus*[7]*, H. C. Hazlett*[8]*, K. Botteron*[7]*, J. N. Constantino*[7]*, S. R. Dager*[9]*, A. Estes*[10]*, L. Zwaigenbaum*[11]*, J. Piven*[12]*, R. T. Schultz*[1]*, J. Parish-Morris*[1] *and .. The IBIS Network*[8]*, (1)Center for Autism Research, Children's Hospital of Philadelphia, Philadelphia, PA, (2)National Institute of Mental Health and Neurosciences, Bangalore, India, (3)University of Texas at Dallas, Richardson, TX, (4)*Co-senior author, **For the IBIS Network, Washington University School of Medicine, St. Louis, MO, (5)Psychology, Children's Hospital of Philadelphia, Philadelphia, PA, (6)Center for Autism Research, The Children's Hospital of Philadelphia, Philadelphia, PA, (7)Washington University School of Medicine, St. Louis, MO, (8)University of North Carolina, Chapel Hill, NC, (9)Radiology, University of Washington, Seattle, WA, (10)Speech and Hearing Sciences, University of Washington, Seattle, WA, (11)University of Alberta, Edmonton, AB, Canada, (12)*Co-senior author, University of North Carolina, Chapel Hill, NC*

Background: Canonical babbling – producing syllables with a mature consonant, full vowel, and smooth transition between them – is an important developmental milestone that typically occurs in the first year of life, and babbling delays have been associated with later delays in word production (Oller et al., 1999). Some studies indicate delayed or reduced canonical babbling in infants at high familial risk for ASD or who later receive an ASD diagnosis (e.g., Patten et al., 2014; Paul et al., 2011). Further study of the development of canonical babbling during the first year of life is necessary to evaluate its utility as a clinically useful bio-behavioral marker of later language and diagnostic outcomes.

Objectives: This study aims to test: 1) group differences in canonical babbling ratio at 6 and 12 months between infants at low familial risk of ASD (LR) or high familial risk who either did (HR-ASD) or did not (HR-Neg) develop ASD themselves, 2) group differences in the onset of canonical babbling at each age, and 3) the cross-sectional relationship between canonical babbling and language ability.

Methods: Participants (n=110) were selected from the multi-site Infant Brain Imaging Study (Table). Two trained and reliable raters segmented children's speech-like vocalizations produced at 6 and/or 12 months during the Communication and Symbolic Behavior Scales (Wetherby & Prizant, 2002) or Autism Observation Scale for Infants (Bryson et al., 2008). Vocalizations were coded for canonical and non-canonical syllables, with discrepancies resolved through consensus.Canonical babble ratio (CBR) was calculated by dividing the number of canonical syllables by the number of total syllables, and infants were considered to have achieved the canonical babbling milestone if CBR>0.15 (Oller et al., 1999). Outliers (CBR>3 standard deviations above the timepoint's mean) were excluded from analysis (2 HR-Neg infants at 6 months). Expressive language was measured using the Mullen Scales of Early Learning standard score (Mullen, 1995).After controlling for site, cross-sectional generalized linear models predicted CBR, with Tukey-corrected pairwise comparisons of estimated marginal means. Odds ratios of reaching the canonical babbling milestone were calculated.

Results: (1) At 6 months, HR-ASD produced a significantly lower CBR than HR-Neg (estimate: -0.04,p<0.01), with no difference from LR (estimate: 0.004, p=0.9). At 12 months, HR-ASD produced a significantly lower CBR than HR-Neg (estimate=-0.06, p<0.01) and LR (estimate=-0.05, p<0.01). (2) Too few infants had achieved canonical babbling at 6 months to calculate an odds ratio (5 total). No significant group differences in the odds of achieving the canonical babbling milestone were detected at 12 months. (3) At 12 months, CBR significantly predicted current expressive language ability, with a small-to-moderate effect size.

Conclusions: Canonical babbling is an important developmental milestone that could serve as a bio-behavioral marker of later language ability and diagnostic outcomes. These data provide preliminary evidence of canonical babbling differences in 6-month-old infants who go on to receive an ASD diagnosis compared to those who do not. With additional annotation (ongoing), we aim to increase our power to detect early differences, and model longitudinal trajectories of growth in canonical babbling.

417.006 *(Poster)* Changes in Psychophysiological Arousal in Toddlers with ASD and TD Toddlers Following Exposure to Parent Social Activities

D. M. Tagavi[1]*, A. R. Bordofsky*[1]*, S. Chau*[1]*, E. F. Ferguson*[2] *and T. W. Vernon*[3]*, (1)University of California, Santa Barbara, Santa Barbara, CA, (2)The Center for Autism Research/CHOP, Philadelphia, PA, (3)University of California Santa Barbara, Santa Barbara, CA*

Background: Physiological indicators of responsiveness can serve as a quick, objective measure of engagement or give information about an individual's comfort level in a social interaction (Feldman, 2012). Because of the important role that physiological processes play in the development of appropriate socialization and regulation skills, there has been an increased interest in examining these constructs in the ASD population. Emerging evidence indicates that children with ASD have different physiological responses than their TD peers to social stimuli (Lydon et al., 2016). Because of this, it has been postulated that psychophysiology can be used as a characterization strategy, especially as it relates to engagement and socialization. Understanding the specific differences in physiological response between these groups is crucial to be able to characterize children with ASD from their TD peers.

Objectives: This study examined the difference is physiological responses between toddlers with ASD and their TD peers across a set of standardized play situations with and without their parents.

Methods: A sample of 13 participants (8 toddlers with ASD, 5 TD toddlers) and their parents were examined as part of a larger intervention study. Parent and child dyads were presented with a standardized set of toys and asked to engage in three different play scenarios (child playing alone with toys [T1], parent and child playing together with toys [T2], and parent and child playing together without toys [T3]). Dyads were video recorded and data on heart rate (HR) and electrodermal activity (EDA) were collected using non-invasive wristband biosensors. Effect sizes (Cohen's *d*) were calculated to determine the magnitude of difference in physiological response between scenarios for each group due to the small sample sizes and high variability between data in this pilot examination.

Results: Results indicate that, on average, TD children demonstrated larger increases in EDA when transitioned to more social activities (ASD T1 to T2 d=1.77; TD T1 to T2 d= 2.77; ASD T1 to T3 d=3.44; TD T1 to T3 d=6.44). However, similar patterns were not seen across HR data (ASD T1 to T2 d=0.49; TD T1 to T2 d= 0.22; ASD T1 to T3 d=1.06; TD T1 to T3 d=-.41). Changes across situations were not statistically significant when examined with an independent samples t-test, however, additional participants are currently being enrolled in this experimental paradigm, which will yield the needed increase in statistical power.

Conclusions: The present study found that children with ASD have differing EDA responses when transitioned from a solitary play situation to a social one, indicating inherent differences in how they respond in social situations. Though the same patterns were not seen with HR, the sample size of the present study was quite small, so further inspection of these trends is warranted. Through continuing to measure and examine psychophysiological data, researchers may be able to determine more objective measures of engagement that can be utilized to understand the specific social characteristics of children with ASD. Future directions will examine psychophysiology in a larger population, as well as examine this construct as a diagnostic indicator.

417.007 *(Poster)* Characterizing Early Parent Concerns in Infants at Increased Risk for Developing Autism Spectrum Disorder

A. Tran[1]*,* ***M. Del Rosario***[2]*, E. Nosco*[3]*, N. M. McDonald*[4] *and S. Jeste*[5]*, (1)David Geffen School of Medicine at UCLA, Los Angeles, CA, (2)Medicine, David Geffen School of Medicine at UCLA, Los Angeles, CA, (3)UCLA, Los Angeles, CA, (4)UCLA Center for Autism Research and Treatment, Los Angeles, CA, (5)University of California, Los Angeles, Los Angeles, CA*

Background: The American Academy of Pediatrics encourages primary care providers to listen and respond to parent concerns for autism and developmental delays, with parent concerns alone being enough to trigger further evaluation (Johnson and Meyers, 2007). Prospective studies have shown that parent concerns differentiate children with autism spectrum disorder (ASD) from typically developing children as early as 6 to 12 months of age (Ozonoff et al. 2009, Sacrey et al. 2015), with reported differences in sensory and motor skills at 6 months differentiating high-risk children who did and did not develop ASD (Sacrey et al. 2015). However, little is known about parent concerns prior to 6 months of age or how these very early concerns relate to developmental outcomes.

Objectives: (1) To examine parent concerns at early ages (1.5, 3 months), particularly with respect to motor and sensory domains. (2) To track the developmental outcomes of children for whom parents had the earliest concerns.

Methods: Participants included infants with an older sibling with ASD (familial risk; n = 41) and infants with no family history of ASD (low risk; n=35). At 36 months, toddlers were classified into outcome groups of ASD (n=15), other concerns (n=11), or typically-developing (TD; n=50, 20 familial risk TD, 30 low risk TD) based primarily on information from the Mullen (Mullen, 1995), ADOS-2 (Lord et al., 2012), Vineland-II (Sparrow et al., 2005), and clinical judgment. Parents were asked if they had any concerns about their child at 1.5, 3, 6, 9, 12, 18, 24, and 36 months of age. Statements were subsequently classified into 8 domains adapted from Ozonoff et al. (2009): No concerns, Speech, Social, Restricted and Repetitive Behavior, Motor/Sensory, Medical, Behavior/Temperament, Developmental/Other. Two coders established reliability on 20% of the sample with good to excellent reliability (ICC of .886, with a 95% confidence interval between .830 to .923). The distributions of parent concerns are presented.

Results: Among all parents, medical and motor/sensory concerns were reported most frequently at earlier time points (1.5-9 months), while speech concerns became more prominent starting at 6 months of age (Figure 1). Parents of infants who developed ASD reported a higher percentage of motor/sensory concerns within the first year of life as compared to parents of TD children, with some parents reporting these concerns as early as 1.5 months (Figure 2). Of the parents who reported concerns about their infant at 1.5 months (n=10), 5/10 of the children were characterized as having neurodevelopmental atypicalities at 36 months of age (2 ASD, 3 other concerns).

Conclusions: Our findings are consistent with the literature that atypical sensory and motor behaviors may be prodromal signs of ASD (Yirmiya and Charman, 2010). Parent report of concerns as early as 1.5 months may indicate additional risk for atypical development, particularly among infants who are already at heightened risk for ASD. Clinicians should take heed of these very early parent concerns, especially in motor and sensory domains.

417.008 *(Poster)* Cognitive Ability Gains Predicted By Adaptive Behaviors in Toddlers with ASD

J. W. Yang[1]*, M. Pizzano*[2]*, A. Gulsrud*[3] *and C. Kasari*[1]*, (1)University of California, Los Angeles, Los Angeles, CA, (2)Education, University of California, Los Angeles, Los Angeles, CA, (3)UCLA Semel Institute for Neuroscience & Human Behavior, Los Angeles, CA*

Background: Adaptive functioning deficits are prevalent in individuals with ASD throughout the lifespan and evident as early as toddlerhood (Paul, Loomis, & Chawarska, 2014). While adaptive behavior assessments (e.g, Vineland Adaptive Behavior Scale (VABS) increase the clinician's diagnostic accuracy of ASD by 9%, from 75% (fair) to 84%(good) (Tomanik, Pearson, Loveland, Lane, Bryant Shaw, 2007), it is not clear the extent to which adaptive behaviors may affect children's performance on cognitive assessments. Previous studies have found adolescent cognitive skills to predict adaptive functioning skills later on in life, but less is known about the role of adaptive functioning on cognitive development in toddlers with ASD, the aim of this study.

Objectives: This study aims to investigate the relationship between adaptive functioning and changes in cognitive abilities following a parent mediated intervention for toddlers with ASD.

Methods: This study is a secondary analysis of a randomized controlled trial of a parent-mediated social communication intervention (JASPER; Kasari, Gulsrud, Paparella, Hellemann, & Berry, 2015). 86 toddlers (mean age = 31.5 months) and their primary caregivers participated in this study. Toddlers cognitive abilities were assessed with the Mullen Scale of Early Learning (Mullen,1995) at entry and 6 month follow up. Difference scores were calculated on all domains of the Mullen to analyze the change from entry to follow up. Parents also completed the Vineland II adaptive behavior scale parent survey (Sparrow, Cicchetti, & Balla, 2005) at entry only. Linear regression models were used to test the predictive quality of Vineland II scores at entry on the changes in Mullen domains and total score from entry to follow up. The regression models controlled for treatment group assignment.

Results: Linear regressions predicting cognitive change and controlling for treatment group, found that higher Vineland II domains of Daily Living skills ($b = 0.477$, $p < .01$) and Communication ($b = 0.385$, $p < .01$) scores at entry predicted greater changes on average in total Mullen scores from entry to follow up. Examining the individual subscales of the Mullen, Vineland II domains of daily living skills ($b = 0.229$, $p < .01$) and communication ($b = 0.174$, $p < .01$) at entry also uniquely predicted changes in the Mullen receptive language domain at follow up.

Conclusions: Toddlers adaptive functioning, specifically in the domains of communication and daily living skills, predicted change in total Mullen IQ score and Mullen receptive language scores. Toddlers with higher adaptive communication and daily living skills at entry were more likely to have greater gains in overall cognitive abilities and receptive language at follow up. These findings emphasize the importance of adaptive functioning skills and receptive language in toddlerhood. This study also suggests a bidirectional relationship between cognitive abilities and adaptive functioning skills.

417.009 *(Poster)* Comparison of Pre- and Full-Term NICU Infants on ASD Assessment Measures: Are Full-Term NICU Infants an(other) ASD Risk Group?

H. T. T. Phan*, A. Gordon, P. M. Kittler, J. M. Gardner and B. Z. Karmel, Infant Development, NYS Institute for Basic Research in Developmental Disabilities, Staten Island, NY*

Background: Research has established that pre-term infants are at higher risk for ASD. A recent meta-analysis reported a prevalence rate of 7% (Agrawal, et al., 2018). Also, elevated risk scores on ASD assessment measures have been documented in this population (Guy, et al., 2015). Although pre-term births account for the majority of NICU admissions, 48% of NICU admissions are full-term infants (Edwards, 2018), However, little specific attention has been directed to ASD risk in full-term NICU graduates.

Objectives: To compare ASD risk in full- and pre-term high medical risk NICU graduates using scores on the ADOS, AOSI and MCHAT.

Methods: Data from a subset of participants in a longitudinal study of high medical risk NICU infants were analyzed. All participants in the larger study who completed an ADOS at 18 or 24 months of age were included in the current analyses (N=111; 51% male). Twenty-one infants were full-term; and 90 were pre-term (50 were < 33 weeks gestational age (GA), and 40 were 33-36 GA). Assessments of ASD risk included the AOSI at 13 months; the MCHAT at 18 months; and the ADOS at 18 or 24 months of age. All participants were administered the ADOS, and the majority of them also had AOSIs (N=85) and MCHATs (N=74).

Results: The ADOS Toddler Module algorithms were used to calculate the ADOS overall total scores, which in turn were used to determine three levels of concerns for ASD (little or no concern; mid-to-moderate concern; and moderate-to severe concern). In total, 41 infants (37%) scored in the range of some concern, with 21 (19%) scoring moderate-to-severe concern. There were no significant differences in the ADOS level of concern across groups ($X^2_{(4, N=111)}$=6.862, p<0.143). Sex differences in ADOS level of concern were noted ($X^2_{(2, N=111)}$=13.119, p<0.001). The male to female ratio ranged from 2:1 to 4:1 in the groups with concern for ASD. Across assessments, AOSI and MCHAT scores moderately correlated with ADOS severity scores.

Conclusions: High medical risk full-term NICU graduates' scores on ASD assessments presented a level of concern equal to that for pre-term infants. ASD risk in pre-term infants is well studied, but this is less the case for full-term NICU graduates. This preliminary finding has implications for developmental monitoring of NICU full-term infants in relation to detection of ASD risk and timelier intervention

417.010 *(Poster)* Data-Driven Analysis of Two Large Samples of Infants with and without a Familial History of Autism Shows That Atypical Development of Attentional Control Associates with Later Adaptive Functioning, Autism and ADHD Traits

A. Hendry[1]*, E. J. Jones*[2]*, R. Bedford*[3]*, L. andersson Konke*[4]*, J. Begum Ali*[2]*, S. Bolte*[5]*, K. Brocki*[6]*, E. Demurie*[7]*, M. H. Johnson*[2]*, H. Roeyers*[7]*, T. Charman*[8] *and &. Eurosibs Team*[9]*, (1)Department of Experimental Psychology, University of Oxford, Oxford, United Kingdom, (2)Centre for Brain and Cognitive Development, Birkbeck, University of London, London, United Kingdom, (3)King's College London, London, United Kingdom, (4)Uppsala University, Uppsala, Sweden, (5)Center of Neurodevelopmental Disorders (KIND), Centre for Psychiatry Research; Department of Women's and Children's Health, Karolinska Institutet, & Stockholm Health Care Services, Region Stockholm, Stockholm, Sweden, (6)Department of Pyschology, Uppsala University, Uppsala, Sweden, (7)Department of Experimental-Clinical and Health Psychology, Ghent University, Ghent, Belgium, (8)Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, United Kingdom, (9)Birkbeck, University of London, London, United Kingdom*

Background: Despite the heritability of autism, attempts to find a single genetic or cognitive account of autism have largely failed; likely due to heterogeneity within the spectrum, and to high co-occurrence with other conditions, such as ADHD. A more-fruitful approach to understanding the etiology of autism, and the strengths and difficulties shown by autistic people, may be to focus on developmental pathways within particular functional domains; such as those outlined within the Research Domain Criteria. This approach moves beyond diagnostic boundaries to consider intermediate phenotypes; quantifiable processes that are interposed between gene and clinical phenotype and which may contribute to multiple conditions.

Objectives: To investigate early development of attentional control as an intermediate phenotype of autism and ADHD.

Methods: Parent report of attentional control was collected using the Duration of Orienting scale of the Infant Behavior Questionnaire-Revised (10 and 15 months), the Attentional Focus and Attention Shifting scales of the Early Childhood Behavior Questionnaire (25 months), and the Attentional Focus scale of the Children's Behavior Questionnaire (36 months). At 36 months, autism traits were assessed with the Social Responsiveness Scale Preschool Form, ADHD traits with the Child Behavior Checklist for ages 1½-5, and adaptive functioning with the Vineland Adaptive Behavior Scales.

Latent Class Analysis was used to derive data-driven subgroups from attentional control scores at 10-25 months. Subgroups with Attentional Focus scores significantly below the normative score at 36 months were identified as showing atypical development of attentional control. We then tested whether atypical development of attentional control was predictive of more-pronounced autism and ADHD traits, and lower adaptive functioning, at 36 months.

This analysis was run with a discovery sample of 294 UK-based infants (212 with a familial history of autism), and a replication sample of 412 infants (261 with a familial history of autism) from Sweden, Belgium, the Netherlands, and the UK.

Results: In the replication sample, 64% of infants showed a normative profile of increases in attentional control scores between infancy and toddlerhood. Three groups showed atypical development of attentional control: 9% showed plateaued attention development between 10 and 25 months, 13% showed consistently-low attentional control and 5% showed low attentional focus coupled with high attention shifting at 25 months. The remaining 10% showed consistently-high attentional control.

Consistent with pre-registered hypotheses, low attentional control and plateaued attention development groups had significantly (p<.05) higher autism and ADHD traits, and lower adaptive functioning at age 3 years, than the normative class. Infants later diagnosed with autism were more likely than their peers to show plateaued attention development. Nevertheless, the majority of autistic children showed a typical profile of attention development.

Data-driven profiles explained more variance in adaptive functioning and autism and ADHD traits (Cohen's d=.36-.52) than single time-point attention scores (Cohen's d=.01-.11).

Conclusions: This study illustrates the heterogeneity in attentional control development amongst children with and without a familial history of autism. Atypical development of attentional control appears to be an intermediate phenotype of autism and ADHD, which is associated with lower adaptive functioning by age 3 years.

417.011 *(Poster)* Deconstructing Overlap between Quantitative Autistic Traits and Callous Unemotional Traits in Early Childhood

K. Lineback[1]*, Y. Zhang*[2]*, A. L. Glowinski*[3]*, N. Marrus*[4] *and J. N. Constantino*[4]*, (1)Washington University School of Medicine in St. Louis, St. Louis, MO, (2)Washington University School of Medicine, Saint Louis, MO, (3)Washington University in St. Louis, St. Louis, MO, (4)Washington University School of Medicine, St. Louis, MO*

Background: Studies characterizing early relationships between heritable quantitative autistic traits (QAT) and social domains implicated in other psychopathology can clarify mechanisms specific to the ontogeny of autism spectrum disorder (ASD). Here we attempted to differentiate early manifestations of *asocial* behaviors observed in ASD from *antisocial* behaviors representing callous-unemotional traits (CUT), a feature of disruptive behavioral disorders, in a genetically informative, general population twin sample encompassing the full range of variation in these social domains.

Objectives: A) To quantify early associations between QAT and CUT. B) To characterize relationships between CUT symptom structure and QAT, including testing for genetic influences on CUT symptoms. C) To compare CUT-QAT relationships with relationships between CUT and social motivation, a hypothesized causal factor for ASD, and CUT and externalizing, a behavior commonly associated with elevated QAT or CUT.

Methods: Participants included 111 twin pairs ascertained from the general population and a clinical cohort with ASD (n=16). When children were ages 36-48 months, parents completed the Social Responsiveness Scale, which indexes QAT; a 10-item subset from the Inventory of Callous-Unemotional Traits; and the Child Behavior Checklist, which contains an externalizing subscale. A *Social Motivation* Composite, derived for twins at age 18 months, was comprised of face valid items for social motivation (Chevallier et al., TICS, 2012) selected from parent-report measures including the video-referenced rating scale of Reciprocal Social Behavior, the Modified Checklist for Autism in Toddlers, and the Brief Infant Toddler Social Assessment. Principal component analysis (PCA) examined CUT symptom structure on its own and in conjunction with QAT, *Social Motivation*, or *Externalizing*. Comparison of intraclass correlations between monozygotic (MZ) and dizygotic (DZ) twins tested evidence for heritability.

Results: Higher levels of QAT and CUT were observed in toddlers with ASD ($t(15)=-6.71$, $p<.001$), and QAT and CUT were strongly correlated in twins ($\rho = .523$, $p < .001$, Figure 1). PCA identified three CUT components: "social conscientiousness," "unemotionality," and "shamelessness" (Table 1). In separate PCAs, both QAT and *Social Motivation* showed the strongest loading on "unemotionality," while *Externalizing* primarily loaded on "shamelessness." Higher concordances for MZ versus DZ twins suggested genetic influences for *Social Motivation* and *Externalizing* in both sexes and for "social conscientiousness" and "unemotionality" in males only. "Shamelessness" did not show evidence of heritability.

Conclusions: QAT and CUT, two social dimensions implicated in child psychopathology, show partial phenotypic overlap in early childhood. This overlap is largely attributable to an "unemotionality" component of CUT, demonstrating the distinction between early *asocial* and *antisocial* behavior. Evidence of heritable CUT components specifically in males suggests sex differences in causal influences for this trait overlap. Association of "unemotionality" with QAT and earlier *Social Motivation* is consistent with *Social Motivation's* hypothesized causal role in ASD, while the association of "shamelessness" with *Externalizing* but not QAT supports distinct underpinnings for QAT and disruptive behavior. Future longitudinal, developmental studies quantifying genetic and environmental influences on QAT and CUT could importantly clarify mechanisms specific to ASD versus other disorders entailing social impairment, thereby advancing early assessment and intervention.

417.012 *(Poster)* Development of Early Screening for Communication and Social Skills (ESCoMS) Instrument: Sensitivity and Specificity

D. Swaminathan[1], *K. Iyengar*[2], *D. Purkayastha*[2], *M. Lewin*[3], *F. Naaz Fathima*[4], *T. Agrawal*[4], *V. Raman*[2] *and A. M. Visweswariah*[5], *(1)Psychiatry, St. John's Medical College Hospital, Bangalore, India, (2)Psychiatry, St John's Medical College Hospital, Bangalore, India, (3)Pediatrics, St John's Medical College Hospital, Bangalore, India, (4)Community Medicine, St John's Medical College Hospital, Bangalore, India, (5)CARE-ADD, Unit of Hope, Department of Psychiatry, St John's Medical College Hospital, Bangalore, India*

Background: Studies have shown that symptoms of autism begin during infancy and can be identified in those as young as 6 months of age. Early identification of autism features helps facilitate early intervention and provide better outcome. No measures exist for screening for autism spectrum disorders in infancy in the Indian context.

Objectives: We intended to develop a questionnaire to screen infants between 9-18 months for Autism Spectrum Disorder (ASD) using mixed methodology design.

Methods: The study was divided into three phases – 1 Develop items through qualitative methods 2. Discriminant validation and instrument consolidation 3. Explore predictive validation. In this paper we present results of phase 1 and phase 2 (Phase 3 is currently in progress).

Phase 1 included two parts: 1. Collation of items from literature and conducting interviews with professionals 59 from Bangalore and 11 from other parts of the country from different disciplines with over 10 years of expertise in working with children with autism. Broad themes and codes were elucidated from these data. A list of 27 items was finalized. In Phase 2, all these items were administered to children who between 2-5 years, with a clinical diagnosis of autism (n=250) and typically developing children (n=220). Children with autism were drawn from centers across the city. Parents were asked to answer the 27 polar questions based on recollection of the children's behavior when they were below 18 months. The collated data was analysed using Statistical Package for Social Science (SPSS) and Receiver Operating Characteristic Curve (ROC).

Results: All the 27 items were analysed and three items which did not have significant statistical difference between the two groups were eliminated from the final instrument. For the 24 items which were validated, the cut off score was set as 14 with 90% specificity and 90% sensitivity. Further those with any history of regression in motor and cognitive milestones are deemed to be positive regardless of their endorsement of other items.

Conclusions: Literature indicates very late identification of children with autism in India. It is expected that this tool can help identify children at risk for this diagnosis early leading to very early intervention programs that can plausibly improve the prognosis. We are currently exploring the predictive validity of this tool in phase 3 of the study.

417.013 *(Poster)* Developmental Cascades during the First Year after Diagnosis in a Prospective Cohort of Young Children with Autism Spectrum Disorder (ASD)

T. Bennett[1], *E. Duku*[2], *S. Georgiades*[2], *P. Mirenda*[3], *I. M. Smith*[4], *T. Vaillancourt*[5], *J. Volden*[6], *L. Zwaigenbaum*[6], *M. Elsabbagh*[7], *W. J. Ungar*[8], *A. Zaidman-Zait*[9], *P. Szatmari*[10] *and C. M. Kerns*[3], *(1)Offord Centre for Child Studies, McMaster University, Hamilton, ON, CANADA, (2)McMaster University, Hamilton, ON, Canada, (3)University of British Columbia, Vancouver, BC, Canada, (4)Dalhousie University / IWK Health Centre, Halifax, NS, CANADA, (5)University of Ottawa, Ottawa, ON, Canada, (6)University of Alberta, Edmonton, AB, Canada, (7)McGill University, Montreal, QC, Canada, (8)University of Toronto / The Hospital for Sick Children, Toronto, ON, Canada, (9)Tel-Aviv University, Tel-Aviv, Israel, (10)The Hospital for Sick Children, Toronto, ON, Canada*

Background: The rate at which individuals with ASD develop skills in one developmental domain may affect the rate of acquisition of other domains both directly and indirectly. Furthermore, research suggests that other child- and family-level characteristics, identifiable at time of diagnosis, may support early "head starts" in language and social development among young children. Elaborating these dynamic processes is crucial to developing and tailoring more effective, developmentally sensitive interventions.

Objectives: We aimed to model dynamic interactions between social competence (SOC) and structural language (LANG) trajectories and determine how child and family sociodemographic factors may influence their development.

Methods: Data for 365 2- to 4-year-olds were obtained from the “Pathways in ASD Study” — a prospective inception cohort study of preschoolers diagnosed with ASD. Children were assessed at time of diagnosis and 6 and 12 months later using the Vineland Adaptive Behavior Scales II (Socialization subscale) and the Preschool Language Scale 4. Latent growth curve models were developed to measure the associations between initial levels (intercepts) and rates of change (slopes) of SOC and LANG and child- and family-level covariates.

Results: Children showed significant growth in SOC and LANG over 12 months as a group, with significant variability between individual rates of change across both domains. The intercept of LANG predicted rate of change of SOC; however, the converse was not true. Rates of change were moderately correlated between domains over the 12 months after baseline assessment. Children’s participation in language intervention prior to diagnosis was associated with increased improvement in SOC (but not LANG)Younger age at time of diagnosis was linked to increased improvement in LANG. Child age and cognitive ability, but not sex, were positively associated with baseline SOC and LANG. Higher family income was positively associated with baseline SOC and higher level of caregiver education was linked to higher baseline LANG.

Conclusions: Language ability as measured shortly after time of diagnosis was more predictive of change in social competence in young children with ASD, than vice versa. The two domains were moderately coupled. Child IQ, age at diagnosis, engagement in services, and family characteristics such as income and primary caregiver education appeared to influence social and language trajectories during the preschool years in this cohort. Broadening the scope of ASD assessment to include supportive identification of family and other contextual strengths and challenges, as well as children’s skills and abilities should be considered and evaluated as part of an equitable and individualized model of care. Service models should address contextual factors known to affect the development of children with ASD, including additional support for families struggling with low socioeconomic status, in addition to core child ASD symptoms, language and other key developmental skills.

417.014 *(Poster)* Developmental Regression in ASD: A Pilot Study in Chongqing, China

P. Zhou[1,2,3,4,5,6], *T. Yang*[1,2,3,4,5,6], *Q. Li*[1,2,3,4,5,6], *B. Peng*[7], *J. Chen*[1,2,3,4,5,6], *T. LI*[1,2,3,4,5,6] *and L. Chen*[1,2,3,4,5,6], *(1)Growth, Development and Mental Health Center for Children and Adolescents, Children's Hospital of Chongqing Medical University, Chongqing, China, (2)Ministry of Education Key Laboratory of Child Development and Disorders, Chongqing, China, (3)National Clinical Research Center for Child Health and Disorders (Chongqing), Chongqing, China, (4)China International Science and Technology Cooperation base of Child development and Critical Disorders, Chongqing, China, (5)Children’s Hospital of Chongqing Medical University, Chongqing, P.R China., Chongqing, China, (6)Chongqing Key Laboratory of Child Health and Nutrition, Chongqing, China, (7)Department of Statistics, Chongqing Medical University, Chongqing, China*

Background: Autism spectrum disorder (ASD) is a neurodevelopmental disorder, and the number of ASD combined with developmental regression—loss of previously acquired skills— reported by parents is increasing.

Objectives: This study described the basic information of ASD children with regression, sought to explore the influencing factors of regression, provide references for the diagnosis, and make a proposal for health care system improvement and social support for families with autism.

Methods: Of a total of 110 ASD children from Chongqing, China, comprehensively identified through clinician records, questionnaire investigation, and telephone consultation, 57 of them had concomitant regression. The data was analyzed by SPSS 19. The relationship between history of rescue at birth, history of postnatal disease and regression, which was considered as dependent variable, was taken by logical regression analysis respectively, age for first concerned of autistic symptoms by parents, ASD combined with regression by two–sample t–test. Wilcoxon rank sum test was conducted to assess the correlation between regression and the family's economic burden—proportion of expenditure on rehabilitation treatment for autism to total household income.

Results: In this study, the ratio of male to female was 4.78 :1 (91/19) for total of ASD, 4.18:1 (46/11) for ASD combined with regression. The average age for first concerned of autistic symptoms was 2. 00 ± 0.67 years old. 8 patients were unsure of the onset age for regression. The average age of the rest was 2. 21 ± 0.98 years old, mainly in the form of language (89.47%), followed by interest and social skills (49.12%), gross motor/fine motor (8.77%), and others (33.33%). The logical regression model b= -0.26, OR = 0.77 (0.24 ~ 2.47), P=0.66 (>0.05) was for history of rescue at birth and regression, b = -0.20, OR = 0.82 (0.34 ~ 2.00), P = 0.66 (>0.05) was for history of postnatal disease and regression. T = -1.18 and P = 0.24 (>0.05) were for the difference between onset age of autistic symptoms and regression by two–sample t–test. There was no statistical significance between ASD combined with regression and ASD combined without regression on onset age of autistic symptoms. The median on family financial burden proportion for ASD combined with regression was 0.80 (0.60 – 1.00), for ASD without regression was 0.70 (0.50 – 1.00). P = 0.94 (>0.05) was for the difference between regression and ASD without regression on family financial burden by Wilcoxon rank sum test.

Conclusions: In this study, there was no significant relationship between developmental regression and history of rescue at birth, postnatal disease and onset age of autistic symptoms. These factors couldn't be early predictors of regression in ASD children. The proportion of family financial expenditures wouldn’t be significantly influenced by regression, but the overall cost of rehabilitation for such subtype is quite high. Government should further improve the social health care system for ASD patients, and strengthen economic investment for families with ASD children.

417.015 *(Poster)* Developmental Trajectory and Prediction of Intellectual Disability in Children with Global Developmental Delay, with and without Autism

L. V. Gabis[1], *O. Leon Attia*[2], *R. Rosenan*[3] *and S. Shefer*[4], *(1)Pediatrics, Sheba Medical Center, Rehovot, ISRAEL, (2)Child developement Center, Sheba Medical Center, Tel Hashomer, Israel, (3)Bar-Ilan University, Tel Aviv, ISRAEL, (4)Shild Development Center, Sheba Medical Center, Tel Hashomer, Israel*

Background: A diagnosis of Global Developmental Delay (GDD) is given to children younger than five years of age when there is clear evidence of developmental delay compared to expected function (according to chronological age), or dysfunction that can't be categorised yet to a specific diagnosis. Significant GDD as assessed before five years of age, is considered to be a preliminary marker of subsequent Intellectual Disability (ID).

Objectives: The purpose of the current study was to examine the stability and the correlation of developmental tests to subsequent IQ testing among GDD with ASD population, as compared to children with GDD and without ASD.

Methods: We compared the early initial DQ scores of children referred for an evaluation of developmental delay at the age of 1-3years to subsequent case by case achievements on IQ tests after the age of 3 years. The children that were subsequently diagnosed with ASD were compared to the children who did not receive such a diagnosis. The study included the data of 80 children (55 boys and 25 girls) that were diagnosed at the Weinberg Child Development Center at two time points between the years 2000-2009. First, the children received a diagnosis of GDD before the age of 42 months. Second, the same children returned for a re-evaluation after the age of 48 months using standardised IQ tests.

Results: Average MDI score among 80 children that were included in this study was M=56.10 (SD=8.23) and the score range was 49-74.

Follow-up analysis of the data revealed a cutoff point in MDI scores which has a significant effect on later IQ scores. Children with MDI score lower than 65 (high to moderate risk) have lower IQ (M=70-82, SD=15-19) than children with MDI score higher than 65 (M=100, SD=19).A statistically significant positive correlation was found between the MDI and IQ scores in the ASD group r_p=0.681, p<.00 (R^2=46%). Correlation between MDI and IQ scores was not significant in the GDD no ASD group.

Conclusions: A positive correlation was found between lesser degrees of developmental delay as measured by MDI to subsequent higher achievements on IQ in both groups, meaning that less delay predicts a higher IQ, as expected. It was found that scores of MDI below 65 highly predict intellectual disability in both groups.

The additional finding of a higher predictive value and stability among children with diagnoses of *both* GDD and ASD as opposed to children with GDD and *without* ASD, elutes to the heterogeneity and the significant motor involvement in GDD without ASD which precluded a more accurate assessment of GDD for those children.

417.016 *(Poster)* Differential Adaptive Value of Social Visual Engagement in Subgroups of Children with ASD at Different Levels of Social Impairment

S. Yuan[1], *S. Koirala*[2], *D. Parmaksiz*[3], *A. Klin*[4], *S. Shultz*[4], *W. Jones*[4] *and L. A. Edwards*[4], *(1)Emory University School of Medicine, Marcus Autism Center, Atlanta, GA, (2)Department of Pediatrics, Emory University School of Medicine, Marcus Autism Center, Atlanta, GA, (3)Marcus Autism Center, Atlanta, GA, (4)Marcus Autism Center, Children's Healthcare of Atlanta and Emory University School of Medicine, Atlanta, GA*

Background: Heterogeneity in autism spectrum disorder (ASD) presents obstacles in identifying causes of the disorder and designing targeted interventions to increase social functioning. Measures capturing the core underlying features of ASD, such as reduced interest in socially adaptive stimuli, may provide a means for parsing phenotypic-heterogeneity in ASD. According to a recent study, the adaptive value of where school-aged ASD children looked when viewing social scenes differed significantly based on their cognitive profiles (Rice, Moriuchi, Jones & Klin, 2011). Given the developmental nature of ASD, such findings call for further investigation into whether ASD subjects diverge in their social visual engagement strategies even in the earliest years of life, and whether such divergences reflect or predict distinct adaptive strategies and outcomes within the ASD population.

Objectives: This study aims to examine whether social visual engagement in the first 2 years of life differs, and has differential adaptive value for language development, between subgroups of ASD subjects characterized by different levels of social disability.

Methods: 59 ASD subjects (42 males) contributed eye-tracking measures of social visual engagement over the first 2 years of life, and received 24-month language assessments (Mullen expressive (EL) and receptive (RL) scales) and clinical best estimate diagnoses. Subjects were divided into subgroups based on their 24-month ADOS social affect (SA) scores. The high-ADOS group encompassed 33 ASD subjects with SA≥10 (24 males; M_{SA}=13.58, SD_{SA}=2.62); the low-ADOS group comprised 26 ASD subjects with SA<10 (18 males; M_{SA}=5.69, SD_{SA}=2.54). Between-group differences in percent fixation to regions of interest (ROIs) were assessed using repeated-measures ANOVA. Within-subgroup correlations were tested for associations between fixation to ROIs and 24-month Mullen RL and EL age equivalent scores.

Results: High-ADOS group subjects looked less at the eyes and more at the mouth, body, and objects than those in the low-ADOS group, and these differences reached statistical significance in the second year of life (M_{age}=18.56months, group*ROI F=3.62, p=0.0145). While social visual engagement was unrelated to 24-month language outcomes in the high-ADOS group, in low-ADOS subjects higher levels of eye-fixation in the first and second years of life predicted higher EL outcomes at 24 months (M_{age}=4.07, r=0.625, p=0.0042; M_{age}=24.73, r=0.504, p=0.0073, respectively); conversely, in low-ADOS subjects mouth-looking in the first and second years of life negatively predicted 24-month EL (M_{age}= 4.07months, r=-0.466, p=0.0441; M_{age}= 24.73months, r=-0.417, p=0.0306, respectively).

Conclusions: Less socially impaired infants with ASD look more at the eyes throughout early development, and show increased social adaptive value of eye-looking, compared to more socially impaired ASD infants. This suggests that fundamentally different social learning processes may be at play within subgroups of individuals with ASD, from the first years of life. Future work will use longitudinal modelling procedures to examine trajectories of social visual engagement as predictors of language and social outcomes within these subgroups of children with ASD.

417.017 *(Poster)* Discrepancy between Parent Report and Direct Assessment of Development in Toddlers with ASD: Does Child Gender Matter?

S. James[1], *S. Hallur*[1], *E. Bacon*[2], *C. J. Smith*[1] *and K. Pierce*[2], *(1)Southwest Autism Research & Resource Center, Phoenix, AZ, (2)Neurosciences, University of California, San Diego, La Jolla, CA*

Background: Underdiagnosis of females is thought to contribute to male bias in ASD prevalence (Ferri et al., 2018). Underdiagnosis may result from: (1) gender differences in the presentation of core and associated symptoms, and (2) gender differences in parental concerns and expectations (Halladay et al., 2015). Gold standard ASD diagnostic evaluations incorporate both parent-report and direct assessment of child behavior. Although there is good overall convergent validity at the group level between parent-report and direct observation measures (Le Couteur et al., 2008; Miller et al., 2017), gender effects have yet to be examined. Examining whether agreement between reporters varies as a function of child gender may shed light on differences in autism detection.

Objectives: To examine if agreement between parent report and direct assessment of language and fine motor abilities varied by gender in toddlers with ASD.

Methods: Data were collected as part of a larger study designed to lower the age of autism diagnosis and treatment. Analyses focused on a sample of toddlers diagnosed with autism (n = 100, mean age 24.32 months), matched on age, gender, and visual reception. Data on language and fine motor abilities were collected through parent report and direct assessment (i.e. VABS and MSEL age equivalent scores for receptive language, expressive language, and fine motor abilities). Two (data source: VABS/MSEL) by two (gender) mixed factorial ANOVAs were used to assess differences.

Results: There were significant main effects of data source on receptive language scores, F (1, 97) = 14.13, p < .001, η^2_p = .13, and fine motor scores, F (1, 98) = 6.40, p = .01, η^2_p = .06. Specifically, parent-report scores (i.e., VABS) were significantly lower than direct assessment scores (i.e., MSEL) in females for both receptive language (p < .001, d = .50) and fine motor abilities (p = .03, d = .32). No significant differences emerged for males. There were no significant main effects of gender on any developmental domain, but there was a significant data source by gender interaction for expressive language scores, F (1, 98) = 9.84, p = .002, η^2_p = .09. Specifically, parent-report expressive language scores were significantly higher than direct assessment scores in males (p = .04, d = .33). In contrast, parent-report scores were significantly lower than direct assessment scores in females (p = .02, d = .31).

Conclusions: Parents of female toddlers with ASD rated receptive language, expressive language, and fine motor abilities significantly lower than what was observed through direct assessment. Interestingly, parents of male toddlers rated expressive language significantly higher than what was observed through direct assessment. Significant main effects of gender were not observed on the VABS or MSEL. This pattern of findings may indicate that parental expectations for development differ by gender. Consequently, gendered expectations may influence parent interpretation and reporting of language and fine motor abilities. Given that gender-based differences may vary as a function of child age, it is important for future research to assess inter-rater agreement throughout the lifespan.

417.018 *(Poster)* Early Developmental Trajectories of Children with Autism from Multiplex and Simplex Families

C. Dissanayake[1], *G. Christou*[2] *and L. P. Lawson*[3], *(1)Olga Tennison Autism Research Centre, La Trobe University, Melbourne, Australia, (2)La Trobe University, Melbourne, VIC, Australia, (3)Olga Tennison Autism Research Centre, La Trobe University, Melbourne, VIC, Australia*

Background: Research has indicated that Multiplex (MPX; two or more affected individuals per family) and Simplex (SPX; only one affected individual per family) autism represent separate subgroups associated with distinct etiological mechanisms, and which may represent separate phenotypes. While some phenotypic differences in the cognitive and behavioural profiles between MPX and SPX children have been found, no study to date has compared the developmental trajectories over time between these groups. Given the heterogeneity evident in early developmental trajectories in autism, it is important to delineate the development of MPX and SPX subgroups over time.

Objectives: The first study aim was to compare the early developmental trajectories of young children with MPX and SPX autism over the period of one year. A second aim was to examine the relationship between baseline autism symptom severity and cognition at follow-up one year later in each group, to further inform any developmental differences in MPX and SPX children.

Methods: Assessment data at baseline and follow-up one year later on autism symptomatology (Autism Diagnostic Observation Schedule; Social Communication Questionnaire), cognition (Mullen Scales of Early Learning) and adaptive behaviour (Vineland Adaptive Behaviour Scales) from a sample of 147 (115 males) children diagnosed with Autism Spectrum Disorder attending a community-based early intervention centre was utilised to address the study aims. Children in both MPX (n = 47) and SPX (n = 100) groups were of similar ages at baseline (Mean = 34 months) and follow-up one year later (Mean = 45 months).

Results: 2 (Group: MPX; SPX) x 2 (Time: Baseline; Follow-up) repeated measures ANOVAs revealed significant effects of Time with both MPX and SPX groups showing similar increases in cognitive and adaptive functioning, and a reduction in symptom severity, over the period of one year. The only significant Group difference was that SPX children had more severe autism symptoms than MPX children at baseline. Both groups showed similar levels of cognition and adaptive behaviour at baseline and follow-up. In the MPX group (but not the SPX group) higher baseline autism severity scores predicted poorer outcomes in verbal and non-verbal cognition, after controlling for baseline cognition; no significant relationships were found in the SPX group.

Conclusions: Few phenotypic differences were revealed between young MPX and SPX children with autism with both groups showing similar developmental trajectories over time in cognition and adaptive behaviour. However, given the pattern of correlations between groups on baseline autism severity (with the SPX group showing more severe symptoms) and cognition at follow-up, it appears that development may be influenced by different factors in the MPX and SPX groups. It is therefore important that future research continue to examine differences in causal factors in the development of MPX and SPX.

417.019 *(Poster)* Early Executive Function Is Associated with Adaptive Functioning in Very Young Children with ASD

H. de Vries[1], *K. Means*[1], *T. St. John*[2], *A. Estes*[3], *S. R. Dager*[4], *H. C. Hazlett*[5], *K. Botteron*[6], *R. T. Schultz*[7], *L. Zwaigenbaum*[8], *J. Piven*[9] *and .. The IBIS Network*[5], *(1)University of Washington Autism Center, Seattle, WA, (2)University of Washington, Seattle, WA, (3)Speech and Hearing Sciences, University of Washington, Seattle, WA, (4)Radiology, University of Washington, Seattle, WA, (5)University of North Carolina, Chapel Hill, NC, (6)Washington University School of Medicine, St. Louis, MO, (7)Center for Autism Research, Children's Hospital of Philadelphia, Philadelphia, PA, (8)University of Alberta, Edmonton, AB, Canada, (9)*Co-senior author, University of North Carolina, Chapel Hill, NC*

Background: Impairments in executive function (EF) in individuals with ASD may emerge as early as 24 months, are present throughout the life span, and are associated with worse adaptive functioning (AF). EF has been associated with the AF subdomains of Socialization, Communication, and Daily Living Skills. Well-developed AF is essential to independent functioning and obtaining real world skills. However, to date, the relationship between EF and AF in children with ASD under 3 years old has not been reported.

Objectives: To investigate the relationship between EF at 12 months and AF at 24 months in children at high familial risk for ASD who do (HR-ASD) and do not (HR-NonASD) develop ASD, and a comparison group of children who are at low familial risk for ASD (LR).

Methods: This longitudinal sample consisted of participants (HR-ASD n=21, HR-NonASD=100, LR n=46) from all Infant Brain Imaging Study (IBIS) sites (UNC, CHOP, WUSTL, UW). All participants, a subsample from IBIS, had complete data at 12 and 24 months and a clinical-best-estimate diagnosis at 24 months. The A-not-B was used to assess EF at 12 months (total correct/total trials). The Vineland-II, used to assess AF at 24 months, yields 5 standard scores (Adaptive Behavior Composite [ABC]; Communication; Daily Living Skills [DLS]; Socialization; and Motor Skills). Overall cognitive development from the Mullen Scales of Early Learning Composite (ELC) at 12-months was used as a covariate in all analyses.

Results: Linear regression analysis revealed that group (HR-ASD>HR-NonASD, LR) moderated the relationship between 12-month EF and 24-month ABC (ΔR^2=.03, p=.03;ΔR^2= .04, p=.02 respectively; see Tables 1 and 2). Follow-up regression analysis of the ABC subdomains was conducted (see Tables 1 and 2) and showed that group moderated the relationship between 12-month EF and 24-month Communication (HR-ASD>HR-NonASD, LR;ΔR^2=.04, p=.01;ΔR^2= .05, p=.01 respectively) and 24-month Socialization (HR-ASD>HR-NonASD;ΔR^2=.03, p=.04; LR=ns). Group did not moderate the relationship between 12-month EF and 24-month Motor Skills and therefore was dropped from the model. Re-analysis without the interaction term revealed a significant relationship between 12-month EF and 24-month Motor Skills across group (F(3,147)=5.66, p=.001). There was no association between 12-month EF and 24-month DLS. Moderation effect of group on 12-month EF and 24-month ABC, Socialization, and Communication did not survive correction for multiple comparisons (α=.006).

Conclusions: This data provides some of the earliest evidence of associations between EF and AF. Trends in the current data are consistent with prior studies of older children with ASD. However, unlike prior studies, no significant association between EF and DLS was found, suggesting self-help skills in toddlers rely less heavily on EFs. On the other hand, the results of the current study suggest that earlier developing EF may be related to development and functional use of motor skills in a toddler's daily environment. These results provide important considerations for service providers who implement early intervention designed to increase adaptive skills in young children with ASD.

417.020 *(Poster)* Early Identification of ASD in Males and Females: Sex-Specific Behavioral Phenotypes in Toddlers Assessed with the STAT, RITLS, and PDMS-2

J. Gattuso[1]*, L. Mulford*[2]*, Y. Li*[3]*, S. C. Bauer*[4]*, A. Devonshire*[5] *and V. Nanclares-Nogues*[6]*, (1)Pediatric Developmental Center at Advocate Illinois Masonic Medical Center, Advocate Children's Hospital, Chicago, IL, (2)Advocate Children's Hospital, Pediatric Developmental Center at Illinois Masonic Medical Center, Chicago, IL, (3)Advocate Center for Pediatric Research, Advocate Children's Hospital, Oak Lawn, IL, (4)Pediatric Developmental Center, Advocate Children's Hospital, Chicago, IL, (5)The Chicago School of Professional Psychology, Chicago, IL, (6)Pediatric Developmental Center, AIMMC, Advocate Children's Hospital, Chicago, IL*

Background: Recent research suggests that a two-tiered screening method utilizing the STAT shows strong positive predictive value and sensitivity as well as a reduction in the false positive rates of diagnosis. Previous research at our clinic examining sex-specific behavioral phenotypes in toddlers on the STAT revealed patterns of stronger play skills in girls with ASD, lending a lower overall total score on the STAT. This is consistent with existing literature on girls with ASD suggesting more age and gender-appropriate interests and play. A lower score on the STAT could potentially lead to girls missing the threshold on the STAT and being less likely to receive early intervention. As such, examining other areas of development, including cognitive functioning, language, and, and motor skills, may give further insight into a broader behavioral phenotype to better identify males and female toddlers at risk for ASD.

Objectives: This study aims to examine sex differences in toddlers assessed by clinicians using the Screening Tool for Toddlers and Young Children (STAT), Rosetti Infant-Toddler Language Scale (RITLS), and the Peabody Developmental Motor Scales, 2nd Edition (PMDS-2) to further refine potential diagnostic markers for the early identification of ASD in males and females.

Methods: This retrospective record review examines 281 children aged 19 to 36 months (median age 33) who were assessed through a multidisciplinary medical diagnostic evaluation utilizing the STAT, RITLS, and PMDS-2. A receiver operating characteristic curve analysis was used to identify overall diagnostic performance in the sample population. Non-parametric methods (Spearman correlation and Mann-Whitney U tests) were also used to compare and correlate STAT items by sex. A Youden's J was used to identify optimal cutoffs by sex. Future item analysis will be conducted to provide insight into trends across sexes on STAT items.

Results: In a preliminary analysis, boys (N=225, 80.1%) displayed a higher median score (3.00 vs 2.75 in girls, p=0.06) on the STAT, indicating greater severity of symptomatology associated with ASD. Furthermore, a lower cutoff score of 1.9 was indicated in females versus 2.1 in males to obtain the same level of sensitivity (89%), suggesting that females may be missed with the recommended STAT cutoff of 2.0, which would have lower sensitivity for diagnosing females (71%) than for males. When additional development results of cognitive, language, and motor testing were examined, preliminary analysis revealed that there are no sex differences among language, motor, or cognitive abilities for children diagnosed with ASD. Further analysis of performance on different developmental measures will be conducted to examine impact on STAT performance.

Conclusions: There are not identifiable differences between males and females in cognitive, language, or motor abilities during early diagnostic evaluations in toddlers. However, STAT scores suggested borderline statistical difference among males and females with females receiving a lower median score. This suggests that despite some similar behavioral phenotypes, identifying specific social communication differences on a second-tier screening tool is imperative to early, accurate diagnosis.

417.021 *(Poster)* Early Impairments in Social Attention Skills Detect and Predict Toddlers' Risk for Autism

P. Ni[1]*, H. Shao*[2] *and J. He*[1]*, (1)Department of Psychology and Behavioral Sciences, Zhejiang University, Hangzhou, China, (2)The First Affiliated Hospital of Wenzhou Medical University, Wenzhou, China*

Background: Although there are lot of efforts to detect autism spectrum disorders (ASD) during toddlerhood, many ASD children remain undiagnosed until school age, because caregivers in daily life or paediatricians in time limited visits may miss their early signs of ASD. These phenomena are very pervasive in rural areas of China. Considering the importance of early intervention, it is of great importance to find quick and easy ways to detect early signs of ASD.

Objectives: This study examined whether some social attention skills tasks can detect children with autism risk and predict their later diagnosis, in order to provide a better understanding of social attention impairments in ASD.

Methods: Three groups of toddlers participated in the study: 30 toddlers with high autism risk, 23 toddlers with development delay, 22 typical developing toddlers. Participants were matched by their intellectual ability measured by cognitive subscale of Bayley Scales of Infant Development and social adaptive ability measured by Infant-adolescent Social Adaptive Scale (ISAS) ($p = 0.1$; $p = 0.09$ accordingly). When entering the current study, the three groups differed in autism risk measured by Autism behavior Checklist (ABC) (F（2,72）=150.1； p ＜0.001), with autism risk group had higher scores than other two groups. All participants took part in four social attention tasks: attention to self in mirror, attention to human faces, attention to others' distress, and attention to social sounds. Toddlers' ABC and ISAC scores were collected again three months later.

Results: Toddlers with autism risk had poorer performance than the other two groups in attention to self in mirror (F（2, 72） = 4.51; $p = 0.014$), attention to others' distress (F（2, 72）= 3.72; $p = 0.029$), and attention to human faces tasks (F（2, 72） = 4.13; $p = 0.02$). More importantly, toddlers performance in the attention to others' distress and to human faces tasks significantly correlated with their ABC scores three months later (r = －.352, p = .004; r = －.344, p = .005 accordingly), and their performance in attention to others' distress and to social sounds tasks correlated with their ISAS scores three months later (r = －.289, p = .019; r = －.271, p = .029 accordingly).

Conclusions: Early impairments in social attention skills, especially attention to others' distress, can distinguish toddlers with high risk for autism from others. More importantly, such impairments could reliably predict toddler's autistic traits and social adaption in later development. Though these tasks would not be sufficient to result in a diagnosis of ASD, they could raise parental and paediatricians' concerns and signal the need for further developmental assessments.

417.022 *(Poster)* Early Patterns of Social Visual Engagement Predict Later Language Outcome in Typical Development but Not in Autism Spectrum Disorder

S. Koirala[1]*, D. Parmaksiz*[2]*, S. Yuan*[3]*, S. Shultz*[4]*, A. Klin*[4]*, W. Jones*[4] *and L. A. Edwards*[4]*, (1)Department of Pediatrics, Emory University School of Medicine, Marcus Autism Center, Atlanta, GA, (2)Marcus Autism Center, Atlanta, GA, (3)Emory University School of Medicine, Marcus Autism Center, Atlanta, GA, (4)Marcus Autism Center, Children's Healthcare of Atlanta and Emory University School of Medicine, Atlanta, GA*

Background: Infants' patterns of social visual engagement to faces change over the first two years of life. While typically developing (TD) infants tend to fixate on a speakers' eyes, they shift their attention to the mouth at around 8-10 months, a developmental time point at which canonical babbling emerges (Lewkowicz et al., 2012), and again during the second year of life, when first words are spoken (Hillairet de Boisferon et al., 2018). These shifts in attention between the eyes and mouth have been shown to predict language outcomes in TD infants. For example, attention to the mouth and gaze-following at 12 months positively predicted vocabulary at 24 months (Tenenbaum et al., 2015). In contrast, infants later diagnosed with autism spectrum disorder (ASD) show atypical patterns of social visual engagement to faces, with early and prolonged declines in eye-looking over the first two years of life. Mouth-looking in infants with ASD increases during the same time, but the relationship between these patterns of early looking and later language abilities is not well understood.

Objectives: The present study examines the relationship between social visual engagement at the beginning of the first and second years of life, and language development at the end of the second year, in a longitudinally-followed cohort of ASD and TD infants.

Methods: Eye-tracking measures of social visual engagement were collected at the beginning of the first and second years of life, from infants at high and low familial risk for ASD. At 24 months, language development was measured using the Mullen expressive and receptive language scales, and clinical best estimates confirmed diagnoses of ASD (n=58) in the high-risk cohort and TD (n=119) in the low-risk cohort. Eye-tracking data were quantified as percentage of time spent visually fixated on regions of interest (ROIs). Between-group comparisons measured levels of fixation to ROIs in ASD and TD infants. Within-group Pearson correlations tested whether infants' early patterns of visual fixation predicted language scores at 24 months.

Results: In TD and ASD groups, the adaptive value of fixation patterns differs: TD infants' eye-looking at the beginning of the first year of life (M_{age}= 5.14mo) positively predicted receptive language (r=0.312, p=0.002), and mouth-looking during the second year of life (M_{age}=15.21mo) trended towards positive prediction of expressive language scores at 24 months; in contrast, in infants later diagnosed with ASD, patterns of visual fixation were unrelated to language scores. Instead, ASD infants' early (M_{age}= 5.12mo) eye-looking and later (M_{age}= 15.23mo) object-looking predicted ADOS total scores at 24 months (r=-0.346, p=0.029; r=0.384, p=0.009, respectively).

Conclusions: Increased visual attention to eyes at the beginning of the first year of life is adaptive in TD infants, positively predicting later receptive language. In infants with ASD, these patterns of visual fixation were unrelated to 24 months language outcomes. Instead, patterns of social visual engagement predicted levels of social disability at 24 months in infants with ASD. Future analyses will investigate longitudinal trajectories of social visual engagement as predictors of language outcome in both ASD and TD infants.

417.023 *(Poster)* Early Pregnancy Placental Markers in Maternal Serum and Autistic Traits in the Children

A. Tsompanidis[1]*, R. Holt*[1]*, E. Aydin*[1]*, T. Austin*[2] *and S. Baron-Cohen*[1]*, (1)Autism Research Centre, Department of Psychiatry, University of Cambridge, Cambridge, United Kingdom, (2)University College London, London, United Kingdom*

Background: Males are more likely to be diagnosed with autism despite greater awareness of under-diagnosis or misdiagnosis of autism in females (Lai, Lombardo and Baron-Cohen, 2014). Sexual dimorphism in the prenatal endocrine environment may be a contributing factor. Several sex steroid hormones, including androgens and estrogens, are elevated in the fetal circulation of males with autism (Baron-Cohen et al., 2019). The placenta could be contributing in elevated steroidogenesis, as it synthesizes the majority of estrogens. Human choriogonadotropin (hCG) and pregnancy-associated plasma protein A (PAPP-A) are two placental proteins that are routinely measured in maternal serum in the 1st trimester, since their atypical levels may indicate developmental conditions affecting the brain, such as trisomy 21. Both very high and very low levels of HCG in maternal serum have been previously associated to autism likelihood (Windham, Lyall, Anderson, & Kharrazi, 2016).

Objectives: To investigate if the levels of hCG and PAPP-A in maternal serum:

1. correlate to steroid hormone levels
2. predict the number of autistic traits in the children
3. mediate their effects on neurodevelopment via changes in brain growth, as measured in ultrasound (U/S)

Methods: Following informed consent, clinical records were collected to ascertain values of 1st trimester human choriogonadotropin (hCG) and pregnancy-associated plasma protein A(PAPP-A) in the serum of n=196 pregnant women, taking part in the Cambridge Ultrasound Siblings and Parents (CUSP) study. Hormone median-of-means (MoM) values were calculated by standardizing for gestational age and maternal age according to international norms. Maternal serum samples were also collected as part of the National Prenatal Screening Programme (n=126). Concentrations of the following steroids and peptides were measured: Testosterone (T), Estradiol (E2), Dehydroepiandrosterone sulphate (DHEAS), Progesterone (P), Insulin-like Growth Factor 1 (IGF1), sex hormone-binding globulin (SHBG), via targeted immunoassays. Fetal brain development was assessed at two time-points by measuring head circumference and transcerebellar diameter via ultrasound (U/S) at 20-22 and at 26-30 weeks of gestation. Expectant mothers were also asked to complete the Quantitative Checklist for Autism in Toddlers (Q-CHAT) online when their infant was between 18- and 20-months old.

Results: PAPP-A MoM levels did not correlate to Q-CHAT scores. Preliminary analysis suggested that a binomial, U-shaped association between 1st trimester hCG MoM values and Q-CHAT scores of the children was statistically significant, with infant sex and the child's age at the time of assessment as covariates in the model (p=0.015). This effect was largely driven by females, as it was not significant in males after stratifying for sex. Increases in transcerebellar diameter in the 2nd trimester (20 to 22 weeks gestation) partly mediated the linear effect of hCG on Q-CHAT (ACME=0.31, p=0.04). hCG levels were also significantly associated with testosterone levels via linear Pearson's regression (p=0.038). There was insufficient power to detect potential associations of steroid hormones with Q-CHAT scores, as these measures were obtained in different subsets of the original cohort.

Conclusions: Atypical hCG levels may be an early indicator in the development of autistic traits and has relevance for the prenatal sex steroid and brain overgrowth theories of autism.

417.024 *(Poster)* Early Vocalization Trajectories Predict Which High-Risk Infants Develop ASD

S. Plate[1,2], *V. Petrulla*[1], *L. D. Yankowitz*[1], *M. L. Cola*[1], *N. Yacoub*[3], *N. D. Ede*[1], *C. Ya*[1], *A. Bennett*[1], *W. Guthrie*[1], *B. Tunc*[1], *J. Pandey*[1], *M. Swanson*[4], *S. S. Meera*[5], *A. Estes*[6], *N. Marrus*[7], *S. Paterson*[1], *J. Pruett*[8], *H. C. Hazlett*[9], *S. R. Dager*[10], *J. N. Constantino*[7], *T. St. John*[11], *K. Botteron*[12], *L. Zwaigenbaum*[13], *J. Piven*[14], *R. T. Schultz*[1], *J. Parish-Morris*[1] *and .. The IBIS Network*[9], *(1)Center for Autism Research, Children's Hospital of Philadelphia, Philadelphia, PA, (2)Department of Psychology, University of Pittsburgh, Pittsburgh, PA, (3)Center for Autism Research, Philadelphia, PA, (4)University of Texas at Dallas, Richardson, TX, (5)National Institute of Mental Health and Neurosciences, Bangalore, India, (6)Speech and Hearing Sciences, University of Washington, Seattle, WA, (7)Washington University School of Medicine, St. Louis, MO, (8)*Co-senior author, **For the IBIS Network, Washington University School of Medicine, St. Louis, MO, (9)University of North Carolina, Chapel Hill, NC, (10)Radiology, University of Washington, Seattle, WA, (11)University of Washington, Seattle, WA, (12)Psychiatry (Child) and Radiology, Washington University School of Medicine, St. Louis, MO, (13)University of Alberta, Edmonton, AB, Canada, (14)*Co-senior author, University of North Carolina, Chapel Hill, NC*

Background: Recent research has identified patterns of early vocalization development that differentiate infants at high familial risk for autism from infants at low risk (Paul, Fuerst, Ramsay, Chawarska, & Klin, 2011; Northrup & Iverson, 2015), but little is known about which high-risk infants will develop ASD. Significant heterogeneity in language development in high-risk infants has made it difficult to identify specific linguistic markers of enhanced autism risk. Recently, there has been a push to use naturalistic language sampling to characterize language development in ASD, rather than (or in addition to) standardized assessments and parent-report questionnaires (Barokova & Tager-Flusberg, 2018). However, prospective naturalistic vocalization sampling has yet to be used to identify markers of elevated autism risk in samples of infants already at high familial risk for ASD.

Objectives: This study utilizes a data-driven, latent class approach to (1) identify trajectories of language development from 6-24 months in a large sample of infants at high familial risk of ASD, and (2) assess the relative likelihood of being diagnosed with ASD in each pathway.

Methods: Infants at high familial risk of developing ASD (N=232) were assessed at 6 (AOSI; Bryson, Zwaigenbaum, McDermott, Rombough, & Brian, 2008), 12 (AOSI or CSBS; Wetherby & Prizant, 1993), and 24 (CSBS) months as a part of the multi-site Infant Brain Imaging Study, with diagnostic assessment at 24 months. Trained and reliable coders identified speech-like vocalizations (non-vegetative or affective) from videos. Vocalizations (count per 10 minutes) were entered into a general latent class mixed model fitted using maximum likelihood. The optimal number of classes was detected using goodness-of-fit statistics (BIC). Posterior classification probabilities and class membership by diagnosis are reported; class was used to predict diagnosis in a logistic regression.

Results: The optimal number of classes in this dataset is 2 (BIC=4599.64; Table). Class 1 (58.19%) showed steep growth in the production of speech-like vocalizations from 6-24 months (Figure). Class 2 (41.81%) demonstrated an attenuated slope, with large class differences by 24 months. Class significantly predicted diagnostic group (b=-1.27, z=-3.96, p<0.001); high-risk infants in class 2 (slow growth) were more likely to be diagnosed with ASD at 24 months than high-risk infants in class 1 (OR=3.57).

Conclusions: Wide variability in the phenotypic profiles of infants at high familial risk for ASD renders it challenging to identify early markers that confer likelihood of diagnosis. This study utilized data driven methods to identify two latent classes of speech-like vocalizing that were associated with differential likelihood of developing ASD. Infants with attenuated growth in speech-like vocalizations were 3.57 times more likely to be diagnosed with ASD than infants showing steeper growth. Infants in the steep growth class had a rate of diagnosis similar to rates seen in other populations of infant siblings (14.81%; Ozonoff et al., 2015) whereas the class with slower growth had a diagnosis rate of 38.14%. Class assignment did not identify 100% of infants later diagnosed with ASD, but could be utilized to identify infants who should be prioritized for diagnostic assessment and early intervention.

417.025 *(Poster)* Establishing the Early Intervention System at a Age of 12 to 24 Months in a Japanese Community Applying Esdm

T. R. Haramaki*, Osaka University, Osaka, JAPAN*

Background: The effectiveness of the Early Intervention for ASD has been stressed from research, but the EBPs for young children with ASD cost a lot, so the Japanese local authorities are hesitant to move forward. Saga city and Taku city that have the low population areas have build the 18 months check up system and started trying to establish the E.I.System for the resident. They chose the ESDM(Early Start Denver Model), and tried to put the budget to train the Public nurses as Early Detection materials, and train the professionals as certified ESDM therapist.

Objectives: Establishing the Early detection System on ASD before 2 yr old in a local community and apply the effective E.I. System locally.

Methods: Training the Public nurses for Early Detection, and the children who were screened as ASD were provided the ESDM once a week and for a year. Pre- post examining of the effectiveness of the children made the progress by ESDM were carried out, with New Kyoto Developmental test, Vineland2 and ADOS2. And the mothers were given the BDI-2.

Results: Once the training of the Public Nurses finished, the young children who are suspected as ASD at the age of 18 to 20 months are increased. Pre- Post examining showed the good progresses in all areas of all the tests and mothers' BDI2 were progressed.

Conclusions: It is a preliminary community study. Even the poor resources of the local communities, training for the nurses were effective to become the Early Detection, and providing the ESDM as an EI made the good progress in children's development.

417.026 *(Poster)* Examination of the Developmental Relationships between Social Motivation, Initiation of Joint Attention, and Language in Infants at Risk for Autism

L. Jia[1], *N. Marrus*[2], *D. J. Povinelli*[3], *J. T. Elison*[4], *A. Estes*[5], *S. Paterson*[6], *M. R. Swanson*[7], *S. S. Meera*[8], *J. Parish-Morris*[6], *J. Piven*[9] *and J. Pruett*[10], *(1)Washington University in St. Louis, Saint Louis, MO, (2)Washington University School of Medicine, St. Louis, MO, (3)University of Louisiana at Lafayette, Lafayette, LA, (4)University of Minnesota, Minneapolis, MN, (5)Speech and Hearing Sciences, University of Washington, Seattle, WA, (6)Center for Autism Research, Children's Hospital of Philadelphia, Philadelphia, PA, (7)The University of Texas at Dallas, Dallas, TX, (8)National Institute of Mental Health and Neurosciences, Bangalore, India, (9)*Co-senior author, University of North Carolina, Chapel Hill, NC, (10)*Co-senior author, **For the IBIS Network, Washington University School of Medicine, St. Louis, MO*

Background: Joint attention, the coordinated orienting of two individuals toward an object, has been linked to later language capabilities in children with typical development and with autism spectrum disorder (ASD). Early social motivation, the disposition to preferentially orient to social stimuli and to seek, like, and maintain social engagement, has also been hypothesized to promote language development. However, no prior research has examined whether social motivation and joint attention are necessary for the emergence of specific language abilities.

Objectives: We hypothesized that a minimal threshold of social motivation (SM) at 6 months (M) and the presence of initiation of joint attention (IJA) at 12M are each necessary but not sufficient for the later development of language at 24M. For our study, we examined specific aspects of language ability (verbal-utterance, symbolism, inference) by abstracting items from language subscales of standard developmental assessments. "Language" in our study was operationally defined as having a score>0 on items that indexed all 3 components (our "language pillars"). We then tested whether quantitative scores of earlier SM behavior at 6M and IJA at 12M correlated with 24M language abilities and language complexity scale scores (combined ceiling scores of the Receptive and Expressive subscales of both the Vineland II and MSEL).

Methods: Analyses involved 426 participants in the Infant Brain Imaging Study, a multisite, prospective study of infants at high and low familial risk for ASD. Measures included Expressive and Receptive subscales of both the Mullen Scales of Early Learning and the Communication Domain of the Vineland II (language); Question 7 of the Communication and Symbolic Behavior Subscales (IJA); and a composite Social Motivation Index (social motivation), derived from specific items in the Vineland II, Autism Observation Schedule for Infants, and Infant Behavioral Questionnaire-revised. Based on linguistically informed criteria, individual language items were assigned to novel language pillar subscales measuring verbal-utterance, symbolism, and inference. Items common across SM and language, and IJA and language were excluded. Additional items that indexed multiple language pillars were categorized under combination subscales (e.g., symbolism + verbal-utterance), with items fulfilling all 3 pillars deemed as measures of language. Correlations were computed between SM scores at 6M and language scores at 24M, and between IJA at 12M and language scores at 24M. These were followed by binomial probability tests to evaluate the necessity of threshold levels of 6M SM and 12M IJA for 24M language proficiency.

Results: 6M SM scores were significantly correlated with verbal-utterance, symbolism+verbal-utterance, inference+symbolism, and inference+symbolism+verbal-utterance scale scores at 24M ($p<0.005$). 12M IJA scores were significantly correlated with all language subscale scores at 24M ($p<0.005$). None of the binomial tests of probability achieved significance ($p>0.9$).

Conclusions: These findings provide novel evidence for links between early SM and later language. They also extend previously described associations between IJA and later language through the examination of associations between IJA and linguistically informed subscales measuring specific language capabilities. The failures of tests for necessity suggest that, while these domains interact, SM and IJA are not, by themselves, necessary developmental prerequisites for language.

417.027 *(Poster)* Executive Function at Two Years Is Associated with Executive Function at School Age in Children at High and Low Familial Risk for ASD

T. St. John[1], *A. Estes*[2], *S. R. Dager*[3], *K. E. MacDuffie*[2], *J. T. Elison*[4], *H. C. Hazlett*[5], *K. Botteron*[6], *R. T. Schultz*[7], *L. Zwaigenbaum*[8], *J. Piven*[9] *and .. The IBIS Network*[5], *(1)University of Washington, Seattle, WA, (2)Speech and Hearing Sciences, University of Washington, Seattle, WA, (3)Radiology, University of Washington, Seattle, WA, (4)University of Minnesota, Minneapolis, MN, (5)University of North Carolina, Chapel Hill, NC, (6)Washington University School of Medicine, St. Louis, MO, (7)Center for Autism Research, Children's Hospital of Philadelphia, Philadelphia, PA, (8)University of Alberta, Edmonton, AB, Canada, (9)*Co-senior author, University of North Carolina, Chapel Hill, NC*

Background: Impairments in executive function (EF) are present in individuals with ASD and their relatives. EF differences may emerge by 2 years of age in siblings of children with ASD. Working memory and inhibition of prepotent responses are among the first EFs to emerge and are present in typically developing infants by 12 months. EF increases in complexity and capacity with age and encompasses cognitive, emotional, and behavioral responses and actions. However, it remains unclear how early-emerging EFs relate to later EFs in younger siblings of children with ASD.

Objectives: To investigate the association between emerging EF at age 2 and EF at age 8-11 years in children at high familial risk (HR) and a comparison group of children with no family history of ASD (low risk; LR).

Methods: Participants are from the on-going, longitudinal, multisite (UNC, CHOP, WUSTL, UW) Infant Brain Imaging Study. To date, HR (n=31) and LR (n=18) participants with EF data at 2 years and school-age (8-11 years) have been evaluated. EF at age 2 was assessed using the A-not-B (total correct/total trials) and school-age EF with the BRIEF-2. The BRIEF-2 provides a Global Executive Composite score (GEC) and three index scores; (Behavior Regulation Index [BRI], Cognitive Regulation Index [CRI], and Emotion Regulation Index [ERI]). Higher scores on the BRIEF-2 indicate more impairment. IQ, assessed at school-age with the DAS-2, was a co-variate in the analyses.

Results: There was a significant main effect of EF at age 2 on school-age GEC ($F(3,38) = 3.62$, $p = 0.02$) and ERI ($F(3,38) = 2.95$, $p = 0.05$) controlling for IQ and group, but not on BRI and CRI. Interaction (group x EF at age 2) for GEC, ERI, and CRI was non-significant. However, group (HR vs. LR) moderated the relationship between EF at age 2 and BRI ($F(1, 37) = 2.71$, $p = 0.04$), controlling for IQ, such that better EF at age 2 was associated with lower scores on BRI in the HR group only (Figure 1). Follow-up analysis of the BRI subscales showed that group moderated the relationship between EF at age 2 and Self-Monitor ($F(1, 37)=2.98$, $p=0.03$), controlling for IQ. In the HR group, better EF at age 2 was associated with lower Self-Monitor scores, with the opposite pattern evident for the LR group (Figure 2). There were no significant main effects or interactions on the Inhibit subscale.

Conclusions: EF at age 2 was associated with overall EF and emotion regulation at school-age for both HR and LR children. EF at age 2 was also associated with behavior regulation at school-age (specifically self-monitoring), but only for HR children. EF is related to school readiness and academic success and has been linked to better outcomes later in life. These findings suggest that EF intervention may be warranted in HR children as young as 2 years of age when EF difficulties are present. Future studies are needed to evaluate whether EF intervention in very young children lead to better outcomes in school-age.

417.028 *(Poster)* Expressed Affect in Infants at High- and Low-Risk for ASD during an Emotion Eliciting Task

V. L. Armstrong[1]*, J. A. Brian*[2]*, S. E. Bryson*[3]*, S. Raza*[4]*, L. A. Sacrey*[5]*, I. M. Smith*[6] *and L. Zwaigenbaum*[4]*, (1)IWK Health Centre, Halifax, NS, Canada, (2)Holland Bloorview Kids Rehabilitation Hospital, Toronto, ON, Canada, (3)Dalhousie University, Halifax, NS, Canada, (4)University of Alberta, Edmonton, AB, Canada, (5)Autism Research Centre, Glenrose Rehabilitation Hospital, Edmonton, AB, CANADA, (6)Dalhousie University / IWK Health Centre, Halifax, NS, CANADA*

Background: Children diagnosed with ASD have early histories of increased negative affect, decreased positive affect, and lower levels of behaviour regulation compared to children without ASD (e.g., Clifford et al., 2009; Garon et al., 2009; 2016). A better understanding of the development of these temperament traits is warranted given the implications for early detection and intervention. We aim to extend these findings based on parent-report questionnaires to behavioural observation. Here we focus on expressed affect in infants at high familial risk for ASD using a task designed to elicit positive and negative affect.

Objectives: To determine if affect expressed at 6, 12, and 18 months of age during the emotion eliciting task is related to ASD symptoms at 24 months.

Methods: Participants were 63 high-risk (HR) infants with an older sibling with ASD and 20 low-risk (LR) controls. Infants were assessed at regular intervals beginning at 6 or 12 months of age. The emotion task consisted of short sub-tasks in this order: neutral baseline video (BL), bubbles, BL2, toy play, toy removal, blank mask, cow mask, brush hair, wash face, BL3. The task was video-recorded and coded offline using Noldus Observer. Expressed affect was coded, blind to group, in 5 s intervals based on facial and vocal cues on a scale from -2 to 2 (negative to positive affect; 0 = neutral). At 24 months, infants were assessed with the Autism Diagnostic Observation Schedule, 2nd ed. -Toddler module (ADOS-T). For each age and group, we used *t*-tests to compare mean affect for each subtask to 0 (neutral), in order to determine if subtasks elicited the expected affective valence. For each age, we used Pearson correlations to determine if overall mean affect (all tasks combined) was related to 24-month ADOS-T scores.

Results: At each age, the valence in affect generally matched expectations for probed affect, especially at 12 and 18 months. In particular, mean affect for bubbles was consistently positive, with differences from neutral significant at 18 months for LR infants, and at 12 and 18 months for HR infants ($p < .002$). Face washing was consistently negative across all ages and groups (p's $< .005$ except for controls at 12 months). Pearson correlations indicate that overall mean affect at 6 months was negatively correlated with ADOS-T scores at 24 months ($p = .03$), with this relationship driven by the ADOS-T social affect score ($p = 007$).

Conclusions: The emotion task suitably elicited a range of infant affect displayed facially and vocally. Findings that 6-month-olds with lower mean affect on the emotion task have higher scores on the ADOS-T indicates that behavioural observation is sensitive to the relationship between early expressed affect and later ASD symptoms. A better understanding of this relationship could inform the development of very early intervention for infants at risk for ASD.

417.029 *(Poster)* Eye-Blink Entrainment in Infant-Caregiver Dyads

Z. M. Ammar[1]*, W. Jones*[2]*, A. Klin*[2] *and S. Shultz*[2]*, (1)Neuroscience Program, Emory University, Atlanta, GA, (2)Marcus Autism Center, Children's Healthcare of Atlanta and Emory University School of Medicine, Atlanta, GA*

Background: Typically-developing infants engage in contingent interactions with their caregivers, continuously modifying and being modified by the behavior of their social partners (Fogel 1993). For example, caregivers and infants coordinate their vocalizations, eye gaze, and facial expressions, providing a critical foundation for social learning. In addition to the coordination of these overt facial and vocal signals, previous studies of adults show that even subtle behavioral signals, such as posture, breathing, and eye-blinks, are synchronized between interacting partners. For example, eyeblinks are synchronized between communicative partners at attentional breakpoints, an entrainment phenomenon that may reflect a shared understanding of the unfolding narrative and facilitate successful communication (Nakano et al., 2010). Interestingly, eye-blink entrainment is not observed in adults with Autism Spectrum Disorder (ASD), highlighting deficits in interactional synchrony that may both reflect and contribute to the social communication deficits characteristic of ASD (Nakano et al., 2011). Investigating when eye-blink entrainment emerges in typical development and whether it is disrupted in infants later diagnosed with ASD will shed light on implicit aspects of interactional synchrony that provide an important foundation for successful communication and social learning.

Objectives: To determine if eye-blink entrainment is: (1) present in typically developing (TD) infants and (2) disrupted in infants with ASD.

Methods: Eye-tracking data were collected from: (1) 4- to 6-month-old TD infants (n=20) during a 70 second interaction with their caregiver; and (2) a pilot sample of 3- to 5-month-old infants with ASD (n=9) during a 30 second interaction with their caregiver (Figure 1). Blinks and lost data were hand coded at each frame (data sampled at 30 frames per second). Peristimulus time histograms (PSTHs) were used to quantify change in rate and timing of infant eye-blinks relative to moments when their caregiver blinked. Permutation testing was used to test the null hypothesis that the timing of infant eye-blinks was unrelated to the timing of caregiver eye-blinks. Over 1000 iterations, each infant's binary time series of blink data was circularly shifted by a random number and the 95th percentile across all permuted data served as a threshold for statistically significant blink entrainment ($p<.05$).

Results: Preliminary analyses reveal that both TD and ASD infants show eye-blink entrainment, with TD infant blink rate peaking 600 ms *before* the blinks of their caregivers (Figure 2A), and blink rate of infants with ASD peaking 150 ms *after* the blinks of their caregivers (Figure 2B).

Conclusions: Our results provide the first demonstration that eye-blink entrainment, a critical aspect of interactional synchrony, is already present in the first months of life. Preliminary findings from a small pilot sample of infants with ASD show that the timing of eye-blink entrainment may be delayed in ASD, a difference that may reflect disruptions in attunement to others' behavior. Immediate next steps include replicating findings in a larger sample size of age-matched infants, investigating the time-scale (within an interaction) over which infant-caregiver eye-blink entrainment emerges, and investigating the conditions under which infant-caregiver eye-blink entrainment is observed.

417.030 *(Poster)* Factors Related to Retention in a Prospective Longitudinal Study of Infants at Risk for Autism

A. M. Hill[1]*, G. S. Young*[2]*, K. Ashley*[3]*, M. M. Hill*[4] *and S. Ozonoff*[5]*, (1)UC Davis MIND Institute, Sacramento, CA, (2)University of California at Davis, MIND Institute, Sacramento, CA, (3)College of Medicine, California Northstate University, Elk Grove, CA, (4)Psychiatry and Behavioral Sciences, University of California, Davis, MIND Institute, Sacramento, CA, (5)Psychiatry and Behavioral Sciences, University of California at Davis, MIND Institute, Sacramento, CA*

Background: Previous studies have examined cohort recruitment practices and retention in longitudinal study designs. In a premature infant clinical trial, birth weight and maternal age interacted with treatment in predicting dropout (Constantine et al., 1993)**.** A longitudinal study of general child development found participants with greater psychosocial risk were less likely to be retained to outcome (Woolfenden et al., 2016). Cohorts in longitudinal samples do not remain fixed over time and should be evaluated for representativeness based on recruitment strategies and participant retention. Biased patterns of retention can create threats to external validity. This has not yet been examined in longitudinal studies of infant siblings at risk for autism spectrum disorder (ASD).

Objectives: We explored factors that could influence participant retention in a longitudinal sample of infants at low and high risk for ASD by examining differences between participants who were and were not retained in a study protocol that spanned 2.5 years.

Methods: Non-retention was defined as having attended at least one study assessment but dropping out prior to the outcome assessment at 36 months old. The retained (N = 327) and not retained (N= 64) groups were compared on ten factors that may be related to retention (see Table 1), including recruitment group (low or high risk for ASD), demographics, travel distance, and pre-existing parental concerns captured at intake. We hypothesized that variables associated with family stress, feasibility of participation, and likelihood of an ASD diagnosis would predict retention patterns.

Results: Significant differences were found between the retained and not retained groups in family income and maternal education using the asymptotic linear-by-linear association test, with the retained group having significantly higher income ($z= -2.29$, $p =.02$) and significantly higher maternal education level ($z= -2.40$, $p = 0.017$). T-tests showed a significant difference for maternal age ($t=-3.18$, $p = 0.002$) where mothers in the retained group were significantly older. The not retained group had significantly longer travel distance than the retained group (Mann Whitney $U=10{,}000$, $p = 0.05$). There were no other significant group differences (Table 1).

Conclusions: In this infant sibling study sample, the retained group differed from the not retained group on three demographic variables. The retained group was more likely to have higher family income, higher maternal education, and higher maternal age. The retained group also lived closer to the research institute where the study took place. These findings can help researchers predict families most likely to drop out of a longitudinal study and develop procedures that can reduce dropout rates. Importantly, recruitment group and existing parental concerns, variables that could influence participant outcomes, ASD risks, and ASD recurrence rates and thus create serious threats to external validity, were not significantly different between groups. This suggests that the study findings from the retained group should be largely generalizable.

417.031 *(Poster)* Familial Genetic Liability for Autism and Brain Development in Infant Siblings

J. B. Girault[1], *H. C. Hazlett*[1], *K. Donovan*[2], *E. Forsen*[3], *M. D. Shen*[1], *M. Swanson*[4], *S. H. Kim*[1], *J. Wolff*[5], *J. T. Elison*[5], *G. Gerig*[6], *J. Pandey*[7], *T. St. John*[8], *K. Botteron*[9], *A. Estes*[10], *L. Zwaigenbaum*[11], *S. R. Dager*[12], *R. T. Schultz*[7], *M. Styner*[13] *and J. Piven*[14], *(1)University of North Carolina, Chapel Hill, NC, (2)Gillings School of Global Public Health, University of North Carolina, Chapel Hill, NC, (3)University of North Carolina at Chapel Hill, Chapel Hill, NC, (4)University of Texas at Dallas, Richardson, TX, (5)University of Minnesota, Minneapolis, MN, (6)New York University, New York, NY, (7)Center for Autism Research, Children's Hospital of Philadelphia, Philadelphia, PA, (8)University of Washington, Seattle, WA, (9)Washington University School of Medicine, St. Louis, MO, (10)Speech and Hearing Sciences, University of Washington, Seattle, WA, (11)University of Alberta, Edmonton, AB, Canada, (12)Radiology, University of Washington, Seattle, WA, (13)Psychiatry and Computer Science, University of North Carolina, Chapel Hill, NC, (14)*Co-senior author, University of North Carolina, Chapel Hill, NC*

Background: Inherited polygenic variation is thought to account for the vast majority of ASD cases, yet it is currently unknown how familial genetic liability for ASD contributes to individual differences in brain development. Recent work from our group (Girault et al., under review) has demonstrated that autistic traits in older siblings with ASD (probands) are associated with recurrence risk in their younger siblings, suggesting that proband ASD traits may serve as an important presymptomatic index of genetic liability for ASD in later born siblings. Here we investigate associations between proband autistic traits and sibling brain development in the first two years of life. We focus on three well-established brain phenotypes associated with ASD: total surface area (TSA), total cerebral volume (TCV), and extra-axial cerebrospinal fluid volume (EA-CSF).

Objectives: Define associations between proband ASD traits – as a potential presymptomatic index of genetic liability for ASD – and brain structural phenotypes at 6, 12, and 24 months in their younger siblings at high familial risk (HR) for ASD.

Methods: Participants included 346 pairs of probands and siblings from the Infant Brain Imaging Study. ASD probands (mean age 5.5 years, range 1.7 to 15.5 years) were phenotyped using the Social Communication Questionnaire (SCQ). Infant siblings underwent magnetic resonance imaging at 6, 12, and 24 months of age. T1 and T2-weighted images were used to generate measures of TSA, TCV, and EA-CSF. Siblings received a clinical best estimate diagnosis at 24 months using DSM-IV-TR criteria. Proband SCQ scores were evaluated as predictors of brain phenotypes at 6, 12, and 24 months in their younger siblings (n = 76 with ASD, n = 270 without ASD).

Results: Visual investigation and bi-variate Pearson's correlations revealed significant associations between proband SCQ scores and infant sibling TSA and TCV at 12 (TSA: r = 0.40, p = 0.011; TCV: r = 0.36, p =0.024) and 24 months (TSA: r = 0.41, p = 0.004; TCV: r = 0.35, p = 0.015) in infants who go on to develop ASD (HR-ASD); proband SCQ scores explained 16.8% and 12.3% of the variation in HR-ASD sibling TSA and TCV at 24-month diagnosis, respectively. No associations were found between proband SCQ and EA-CSF ($-0.02 \leq r \leq 0.20$, all $p \geq 0.203$). Longitudinal mixed models identified significant associations between trajectories of both TSA (beta = 0.44, p = 0.002) and TCV (beta = 0.40, p = 0.002) and proband SCQ scores in HR-ASD siblings.

Conclusions: This study reports quantitative associations between proband SCQ scores and brain development in infant siblings later diagnosed with ASD, building upon recent evidence to suggest that proband ASD trait level may serve as an important presymptomatic index of genetic liability for ASD in later born siblings. Further, these associations were specific to brain volume and surface area phenotypes, but not EA-CSF, suggesting distinct pathogenic mechanisms. Our findings suggest familial characteristics should be captured and included in prediction frameworks designed to parse heterogeneity in ASD and identify individualized early treatment targets.

417.032 *(Poster)* Improved Personality Flexibility Trait through Conducted Parent Early Start Denver Model (P-ESDM) Enhanced Parenting Effectiveness from Taiwan: A Pilot Study

S. Fan*, Taipei Medical University Hospital, Taipei, Taiwan*

Background: Various researches report the parents of children with autism spectrum disorder (ASD) experience high levels of stress and a specific negative impact on their life quality. Parent implemented-early start Denver model (P-ESDM) program have been indicated effectiveness in Western and Asian culture (Rogers et al., 2012; Estes et al., 2014; Zhou et al., 2018）. As we know, the parent would be a good coach for the first life. The benefit of the parent coach could reduce stress and improve parenting. However, there is seldom the reasearch to figure out the personality trait associated with parenting courses.

Objectives: The first aim of this study is to provide an effective parent program and try to find the correlation between parent personality phenotype and parenting skills changed. The second purpose we also expect that parenting efficacy will increase after P-ESDM.

Methods: Three single-subject designs had conducted. We collected three different age levels (20m, 34m, and 41m) to learn the P-ESDM. All participants have assessed their cognitive/language abilities by Mullen scales of early learning. Autistic symptoms were measured by the Screening Tool for Autism in Toddlers & Young Children (STAT) and Childhood Autism Rating Scale–Second Edition (CARS-2) inventory. Individual ten treatment goals were set up for the next 12 weeks via the ESDM curriculum. P-ESDM was performed by a certified ESDM therapist who also completed the P-ESDM three-day workshop without certified for P-ESDM. Parent stress status from parent stress inventory (PSI), parenting sense of competence scale (PSCS), and board autism phenotype (BAP) were also measured.

Results: We found that parent fidelity increased after 12 weeks and maintain after three months and parenting sense of competence. The abilities based on curriculums improved across different developmental domains. And the parent phenotype was indicated to develop the decrease extent of aloof and rigid subscales, respectively.

Conclusions: In conclusion, we could find similar improved children's ability and parenting skills as previous studies. Moreover, the exciting things which indicated parent could be more flexible to conduct the joint activity routines with various themes of the play and daily life routines after training. These may also improve their personality trait phenotype. Parents implemented ESDM not only to decrease life/ parenting stress but also enhanced the parenting satisfaction associated with passion and flexible personality style.

417.033 *(Poster)* Investigating Early Attention to Non-Social and Social Stimuli and Underlying Mechanisms of Language in a Prospective ASD and ADHD Infant-Sibling Study.

M. A. Agyapong[1], *E. J. Jones*[2], *T. Charman*[1], *M. H. Johnson*[2,3] *and &. The BASIS Team*[1,2], *(1)Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, United Kingdom, (2)Centre for Brain and Cognitive Development, Birkbeck, University of London, London, United Kingdom, (3)Department of Psychology, University of Cambridge, Cambridge, United Kingdom*

Background: Language impairments have been frequently observed in Autism Spectrum Disorder (ASD). Prospective studies have found a greater frequency of language delay and lower distributions of language scores for infant siblings at elevated-likelihood (EL) of ASD compared to those at typical-likelihood (TL). While ASD and attention deficit hyperactivity disorder (ADHD) frequently co-occur, there is limited evidence for language impairments in ADHD. Twin studies report impaired language skills in individuals with elevated ADHD traits; however, there is a dearth of developmental language research in ADHD. Early attention to underlying social communication cues from facial features (like the eyes or mouth) may inform the development of language abilities in ASD and/or ADHD.

Objectives: To investigate attention to underlying features of language, and its relation to language development in infant siblings at typical- and elevated-likelihood of ASD and/or ADHD.

Methods: This study included 93 five-month old infants (51 males) from the British Autism Study of Infant Siblings, Studying Autism and ADHD Risks (STAARS; staars.org). 25 TL controls, 42 EL-ASD, 14 EL-ADHD and 12 EL-ASD+ADHD infants completed an eye-tracking paradigm ('Frequency Task'). Ten-second videos of non-social stimuli (checkerboard pairs) and of social stimuli (face pairs) were presented to the infants. Three trials were presented for each condition, respectively. In both non-social and social conditions, each stimulus in the pair alternated at a different frequency; either 6Hz (i.e. the frequency of human syllabic speech), 1Hz or 10Hz.

Results: There was an effect of frequency on looking at checkerboards (F (1.78, 158.79) = 136.13, $p < .001$, $\eta_p^2 = .61$) and faces (F (1.95, 163.50) = 11.45, $p < .001$, $\eta_p^2 = .12$). This was significant for both checkerboards and faces when 10Hz was compared to 6Hz, and for checkerboards when 6Hz was compared to 1Hz (see Table 1 & Figure 1a). There was a marginal effect of EL-ASD on looking at checkerboards (F (1, 89) = 3.65, p = .059, $\eta_p^2 = .04$), while there was no effect of likelihood status on any other non-social or social analyses.

Infants looked more at the lower-face region of social stimuli that alternated at 10Hz compared to 6Hz ($p = .001$, $\eta_p^2 = .12$), and there was an interaction between EL-ADHD and frequency (F (1.87, 156.98) = 3.51, $p = .035$, $\eta_p^2 = .04$). Infants at TL-ADHD looked more than EL-ADHD at 6Hz compared to 1Hz, while EL-ADHD looked more than TL-ADHD at 10Hz compared to 6Hz lower-face regions (Figure 1b). Other two- and three-way interactions were not significant.

Conclusions: Young infants do not show an innate preference for stimuli within the frequency range of syllabic speech. Irrespective of likelihood status, infants preferred higher frequencies of non-social and social stimuli, generally showing a 10Hz>6Hz>1Hz looking pattern. These findings contribute to the literature on language development in TL and EL infants, suggesting that 5-months may be too young for infants to show perceptual tuning to underlying frequencies of language. Attention to other facial features such as the eyes may be more socially informative at this early stage of development.

417.034 *(Poster)* Investigating Gender Differences in the Early Markers of Autism Spectrum Conditions (ASC) in Infants and Toddlers

J. Barbaro[1,2] *and N. C. Freeman*[3], *(1)Olga Tennison Autism Research Centre, La Trobe University, Melbourne, VIC, Australia, (2)Cooperative Research Centre for Living with Autism (Autism CRC), Long Pocket, Brisbane, Australia, (3)Faculty of Education, Monash University, Melbourne, VIC, Australia*

Background: Many females on the autism spectrum are diagnosed later, missed, or mis-diagnosed, leading to lost opportunities for early intervention, supports, and services that can enhance quality of life. Research into the very early presentation of Autism Spectrum Conditions (ASC) in females is therefore critical.

Objectives: The primary objective of this study was to investigate gender differences in the early signs of ASC in infants and toddlers identified through primary care. A secondary aim was to examine gender ratio trends from 12- to 24-months of age.

Methods: A cross-sectional sample of 197 infants and toddlers aged 12- to 24-months (44 female, 153 male) at "high likelihood" for ASC were assigned to the following groups following gold standard assessment using the Autism Diagnostic Observation Schedule-Toddler (ADOS-Toddler) and Autism Diagnostic Interview-Revised (ADI-R): 1) Female-ASC; 2) Male-ASC; 3) Female Non-ASC; and 4) Male Non-ASC groups. Their early social-communication behaviours (e.g., eye contact, protodeclarative pointing, use of gestures, joint attention, showing, etc.) were then compared at 18 and 24 months of age, using the Social Attention and Communication Study-Revised (SACS-R; Barbaro & Dissanayake, 2010, 2013, 2018) tool. Comparisons were not conducted at 12-months due to small sample sizes in the female groups (both $n = 1$). The first author coded these behaviours via observation of videotapes of their diagnostic assessment using the ADOS-Toddler. A second rater, blind to diagnostic status, recoded 20% of the SACS-R behaviours, with overall percentage agreement of .96.

Results: No differences in the early markers of autism were found between females and males in both the ASC and Non-ASC groups at 18- and 24-months of age. However, the ratio of females to males with ASC decreased over time, with a ratio of 1:15 at 12-months, 1:3.8 at 18-months, and 1:3.2 at 24-months; the overall ASC gender ratio was 1:3.7.

Conclusions: The discrepant gender ratio between 12- and 24-months of age, with significantly fewer females at 12 months, suggests that females need to be closely monitored between 12 and 18 months when conducting screening and developmental surveillance for ASC. Furthermore, the lack of differences found between the groups on the early markers of autism indicates that future studies should continue to focus on the early autism phenotype in community-based samples, to assist with modification or development of female specific screening tools at these early ages.

417.035 *(Poster)* Is Effortful Control Related to Social Competence in Toddlers with Autism Spectrum Disorder?

E. Yhang*, D. M. Goncalves Fortes, N. Powell, C. Nutor, C. D. Gershman, K. Joseph, M. Butler, H. Feiner, S. Macari, A. Vernetti and K. Chawarska, Child Study Center, Yale University School of Medicine, New Haven, CT*

Background: Effortful control (EC), a key aspect of self-regulation, is critical to the development of social competence in children. In typically-developing preschoolers, EC was found to be positively related to social competence, with this association being stronger for children with higher negative affectivity (Eisenberg et al., 2014; Eisenberg et al., 2010). While a similar relationship was reported in both preschoolers with ASD (Jahromi, Bryce, & Swanson, 2013) and typically-developing toddlers (Spinrad et al., 2007; Mathieson & Banerjee, 2010), the association remains unclear for toddlers with ASD. As self-regulatory and social impairments are considered hallmarks of ASD, addressing this gap in research on affected toddlers can contribute insight into early intervention practices targeting social competence.

Objectives: To characterize the magnitude of the association between parent-reported effortful control and social competence in toddlers with and without ASD, and to investigate the role of negative affectivity in this association.

Methods: Parents of 136 toddlers (Mean age=21.71 months, SD=3.45) with ASD (n=82) and of chronological age-matched typically-developing (TD; n=54) toddlers completed the Early Childhood Behavior Questionnaire (ECBQ; Putnam, Gartstein, & Rothbart, 2006) and the Vineland Adaptive Behavior Scales (VABS-2; Sparrow et al., 2005). Autism symptom severity and nonverbal skills were concurrently characterized using the Autism Diagnostic Observation Schedule (ADOS-2; Lord et al., 2012) and the Mullen Scales of Early Learning (MSEL; Mullen, 2005), respectively.

Results: Toddlers with ASD scored lower on ECBQ-EC (d=-1.05, p<.001) and VABS-2 Socialization standard score (VABS-2 SOC; d=-2.08, p<.001) compared to TD toddlers. However, there was no difference in ECBQ Negative Affectivity (ECBQ-NA) scores (d=-0.05, p=0.775). A multivariable regression model computed for each group separately controlling for ECBQ-NA and Nonverbal DQ scores found no association between ECBQ-EC and VABS-2 SOC in either group (B_{ASD}=1.86, R^2=0.106, p=0.078; B_{TD}=2.29, R^2=0.223, p=0.441). A significant association was, however, found between ECBQ-NA and VABS-2 SOC in both groups (B_{ASD}=-2.23, R^2=0.106, p=0.029; B_{TD}=-6.92, R^2=0.229, p=0.016).

Conclusions: The present study found that parent-reported effortful control did not significantly predict social competence in toddlers with and without ASD. While negative affectivity has been reported to moderate the relationship between effortful control and social competence, our findings suggest that in the second year of life, negative affectivity may itself be a significant predictor of social competence. The increased relevance of negative affectivity may be a result of the younger age of our sample, as effortful control is thought to still be emerging at this stage. Our results thus suggest that the relationship between parent-reported effortful control, negative affectivity, and social competence may change across development. Future longitudinal studies should address the age-dependent factors shaping the emergence of social competence in the context of both ASD and typical development.

417.036 *(Poster)* Language Profiles in Toddlers with Autism Spectrum Disorders and Developmental Delay: A Function of Assessment Tools?

***C. D. Gershman**, H. Feiner, M. Lyons, N. Powell, C. Nutor, K. Joseph, M. Butler, D. M. Goncalves Fortes, A. Vernetti, S. Macari and K. Chawarska, Child Study Center, Yale University School of Medicine, New Haven, CT*

Background: Language and communication deficits are hallmarks of the autism phenotype. Studies on typical language development show that toddlers develop language in a "receptive-better-than-expressive" pattern. However, language studies in toddlers with Autism Spectrum Disorder (ASD) often demonstrate an opposite "expressive-better-than-receptive" pattern (Nevill et al. 2019; Weismer, 2017). To measure language profiles, expressive-to-receptive discrepancy scores are calculated across measures. It has been noted that this expressive-better-than-receptive pattern holds for some standardized language and development measures, but not others, though studies often include children with wide age ranges, small samples, and varying diagnostic techniques. Evaluating the role of assessment tool in profiling language is imperative for early and accurate diagnosis of ASD and other developmental disorders and atypical symptoms (ATP). (Kwok, 2014, Nevill et al., 2019).

Objectives: 1) To examine if the Receptive – Expressive (R-E) discrepancy scores differ significantly from zero across diagnoses. R-E > 0 score denotes receptive-better-than-expressive pattern, and R-E < 0 denotes expressive-better-than-receptive pattern. We hypothesize that expressive-better-than-receptive profiles will hold true across measures for the ASD group, while typically developing (TYP) and ATP groups will express the opposite pattern.

Methods: 84 toddlers with ASD (M_{age}=22.3,SD=3.2), 48 ATP (M_{age}=21.4,SD=3.9), and 36 TYP (M_{age}=21.9,SD=3.7) were administered the Mullen Scales of Early Learning (MSEL) and Preschool Language Scales, 5th edition (PLS-5). Using standard and t-scores, E-R discrepancy scores were calculated across measures, yielding positive scores for receptive-better-than-expressive and negative for expressive-better-than-receptive. One-sample t-tests were run to evaluate if the E-R indices were different from zero.

Results: Please see Figure 1 for the R-E discrepancy scores for ASD, ATP, and TYP groups based on the MSEL and PLS-5 measures. On the MSEL, ATP (t(47)=2.29,p=.026) and TYP (t(35)=2.15,p=.038) groups showed significantly greater than 0 R-E scores, suggesting the receptive-better-than-expressive pattern. In the ASD group, the R-E score was negative, but it did not differ significantly from 0 (t(83)=-1.23,p=.22). However, on the PLS-5, in the ASD group, the R-E score was significantly lower than 0 suggesting the expressive-better-than-receptive pattern (t(83)=-2.58,p=.012). In the ATP and TYP groups the R-E score was not significantly different from 0 (t(47)=1.46,p=.14), t(d35)=-0.95,p=.35, respectively).

Conclusions: Consistent with prior work, language profiles differed based on language measures. Although there was an expected trend toward the expressive-better-than-receptive pattern for the ASD group on the MSEL measure, the PLS-5 had a more pronounced and statistically significant effect, as it more specifically targets language skills and relies on more recent and extensive national norms. As expected, the new norms in the PLS-5 resulted in minimizing the previously reported receptive-better-than-expressive effect in children with developmental delays and typical development. These findings hold clinical importance regarding selection of language measure for assessing toddlers with suspected social disability. When investigating language profiles, the PLS-5 holds greater promise to identify atypical language profiles in very young children with ASD. Using a more sensitive, language specific measure that better represents ASD populations is important in early screening, diagnosis, and the design of individualized intervention plans for affected children.

417.037 *(Poster)* Longitudinal Patterns of Objectively Measured Activity Level Among Infants Developing ASD and Diagnostic Concerns for ADHD

R. Reetzke[1], *C. Tanase*[2], *L. De La Paz*[3], *A. Chuang*[3], *B. Hatch*[3], *E. Shoham*[3], *E. P. Hanzel*[3], *S. Ozonoff*[3] *and M. Miller*[3], *(1)Center for Autism and Related Disorders, Kennedy Krieger Institute, Baltimore, MD, (2)University of California, Davis, Sacramento, CA, (3)Psychiatry and Behavioral Sciences, University of California, Davis, MIND Institute, Sacramento, CA*

Background: Elevated symptoms of attention-deficit/hyperactivity disorder (ADHD), including high levels of activity, are frequently observed in children with autism spectrum disorder (ASD) (Antshel et al., 2016), increasing risk for delayed or inaccurate diagnosis (Miodovnik et al., 2015). Despite this, little is known about developmental patterns of overactivity in infants who develop ASD versus diagnostic concerns for ADHD by 3-years of age. Understanding similarities and differences in the developmental time-course of overactivity is critical to improve early detection of both ASD and ADHD.

Objectives: Using accelerometry, an objective measurement of motion-based activity, we examined longitudinal patterns of activity in infants at high and low familial risk for ASD or ADHD.

Methods: Participants included 127 infants at high and low familial risk for ASD or ADHD. Continuous motion-based activity was recorded using tri-axial accelerometers worn on participants' ankles at 12-, 18-, 24-, and 36-months of age during structured developmental testing and the administration of the Autism Diagnostic Observation Schedule. At 36-months, participants were categorized into one of three outcome groups: ASD (n = 19; met *DSM-5* criteria), ADHD Concerns (n = 16; elevated ADHD symptoms based on examiner, parent, and teacher report), and a Comparison group without ASD or ADHD Concerns (n = 92) (Table 1). Two measures of motion-based activity were calculated from the accelerometer data recorded during each assessment ($M_{duration}$ = 120 min; $SD_{duration}$ = 30 min): the mean number of movements (mean activity) and the mean intensity of activity (mean intensity). Differences in longitudinal patterns of activity were assessed using generalized estimating equations (GEE).

Results: For both measures of activity level, there were main effects for outcome group [χ^2 (2) = 22.0, $p < .001$] and age [χ^2 (3) = 177.6, $p < .001$], as well as a significant interaction between group and age [χ^2 (6) = 21.6, $p = .001$] (Figure 1). Post-hoc analysis for the interaction between outcome group and age indicated that at 12-months of age the three outcome groups did not exhibit significant differences in mean activity or mean intensity of activity (all ps $\geq$ 0.64). Over time, both the ADHD Concerns and ASD outcome groups exhibited significantly higher activity levels relative to the Comparison group, with significant differences first observed at 18-months of age (ASD vs. Comparison [t (14.01) = 2.87, p = 0.01]; ADHD Concerns vs. Comparison [t (13.43) = 2.62, p = 0.02]), persisting through 24- and 36-months of age (all ps $\leq$ 0.05). No significant differences in activity level were observed between the ASD and ADHD Concerns groups at any age (all ps $\geq$ 0.07).

Conclusions: Infants developing ASD and ADHD concerns exhibited higher frequency and intensity of motor activity by 18-months of age compared to infants developing typically. While the findings suggest that symptoms of overactivity may be an overlapping marker of atypical development in infants/toddlers developing ASD and diagnostic concerns for ADHD, it is possible that there are different mechanisms mediating activity level in infants/toddlers developing ASD (e.g., social avoidance behaviors) and ADHD Concerns (e.g., general dysregulation).

417.038 *(Poster)* Maternal Trauma History As Risk Factor for Infant ASD Behaviors in the Chatterbaby Autism Risk Survey

S. J. Poulhazan[1], *J. A. Estabillo*[2], *C. Kasari*[3], *M. Dapretto*[4], *S. Jeste*[3], *J. Parga*[5], *B. H. Dang*[6], *S. Zhang*[3], *A. Razzak*[3], *S. Yoon*[3], *P. Kaur*[3], *Y. Quezada*[3] *and A. Anderson*[3], *(1)Molecular, Cell and Developmental Biology, University of California, Los Angeles, Los Angeles, CA, (2)Psychiatry, UCLA Semel Institute for Neuroscience & Human Behavior, Los Angeles, CA, (3)University of California, Los Angeles, Los Angeles, CA, (4)Dept of Psychiatry and Biobehavioral Sciences, University of California, Los Angeles, Los Angeles, CA, (5)Division of Neonatology, CHOP, Philadelphia, PA, (6)Department of Neuroscience and Psychiatry, UCLA, Los Angeles, CA*

Background: Maternal trauma refers to a traumatic event that occurs during pregnancy which damages a woman's physical or mental health. The role of maternal trauma is particularly interesting in the placenta/fetal unit, where the hormonal interaction between the mother and developing fetus is regulated. Consequently, trauma occurring to the mother during pregnancy may significantly impact this regulation and the subsequent development of the child. The underlying mechanisms that lead to developmental delays, specifically autism spectrum disorder (ASD) remain unclear. Because maternal trauma may lead to higher exposure to cortisol levels and inflammation in the developing brain, the possible relationships between maternal trauma and presence of developmental delays in infants were explored. This analysis was largely motivated by previous findings that have shown that acute maternal stress during pregnancy increased the rate of neurodevelopment disorders in the offspring (e.g. schizophrenia).

Objectives: The purpose of the study was to examine the relationships between maternal trauma history and ASD-associated behaviors in infants.

Methods: Data were collected as part of a voluntary survey completed by any user of the infant cry translation app, ChatterBaby (n = 1798, infant age M = 1.23 years, mother's delivery age M = 30.41 years). The "ChatterBaby Autism Risk Survey" obtains participants' consent for their information to be used in research and queries demographic information, including maternal trauma history. These categories were based on traumatic experiences outlined by the National Traumatic Stress Network. Of the total participants, 14.6% of mothers reported experiencing a traumatic event during pregnancy. Mothers additionally responded to questions related to their child's development which were based on CDC developmental milestones. Of these questions, behaviors which indicated ASD concern were examined To examine the general relationship between maternal trauma and ASD-associated behaviors, trauma scores (sum of all traumas) and behavioral-risk-scores were calculated for each individual participant and then fitted to two linear regression models. Model 1 fitted behavioral-risk-score with mother's delivery age, mother's education, infant's age, infant's sex, and ASD family history. Model 2 added maternal trauma scores. An ANOVA test was then used to determine significance. To examine specific relationships between types of maternal trauma and ASD-associated behaviors, a Pearson correlation coefficient was used to correlate maternal trauma types with each behavior.

Results: Findings did show significant relationships between the presence of maternal trauma and infant ASD-associated behaviors in either model ($p < 0.05$). Male gender and increased maternal education were associated with increased behavioral risk. However, trauma-scores had an inverse relationship with behavioral risk; increased trauma was associated with a reduction in ASD-associated behaviors. Contrary to our hypothesis, results indicated significant negative correlations between trauma type and ASD-associated behaviors.

Conclusions: Trauma-scores did predict ASD-associated risk scores. However, the direction of this relationship was contrary to our hypothesis: increased trauma scores were found to be associated with reduced ASD-associated risk scores. These findings oppose previous research conducted on trauma and schizophrenia risk. Given various factors related to maternal trauma and development of ASD, additional research further examining these relationships is needed.

417.039 *(Poster)* Negative Emotional Reactivity, Effortful Control, and Self-Regulatory Strategies in Toddlers with ASD

***N. Powell**, M. Butler, E. Yhang, C. Nutor, C. D. Gershman, K. Joseph, D. M. Goncalves Fortes, H. Feiner, K. K. Powell, S. Macari, A. Vernetti and K. Chawarska, Child Study Center, Yale University School of Medicine, New Haven, CT*

Background: The ability to inhibit and regulate emotional responses, actions, and cognition (Effortful Control, EC) is a leading predictor of overall well-being (Eisenberg et al.,2014). Individuals with Autism Spectrum Disorder (ASD) experience marked challenges in self-regulation and increased intensity of negative emotionality (Jahromi, Bryce, & Swanson,2013). Negative emotions and poor coping skills in combination likely contribute to the increased comorbidity of psychiatric disorders among those with ASD (Mazefsky,2014). Compared to their peers, toddlers with ASD exhibit increased negative emotionality (Macari et al.,2018) and deficits in EC (Macari et al.,2017). However, little is known about the relationship between self-regulatory capacity and negative emotional reactivity during frustrating situations in toddlers with ASD.

Objectives: (1) To examine whether toddlers with ASD exhibit elevated anger during frustrating tasks compared to atypically-developing (language delay, global delay: ATP) and typically-developing (TYP) toddlers; (2) To examine if toddlers with ASD exhibit impaired self-regulatory capacity as measured by parent report and direct observation; (3) To examine the association between self-regulatory capacity and intensity of anger in response to everyday challenges.

Methods: Participants included 220 toddlers (Mage=21.4mo, SD=3.60; 84 ASD, 71 ATP, 65 TYP). Toddlers underwent anger-inducing standardized probes adapted from the Laboratory Temperament Assessment Battery (LabTAB; Goldsmith & Rothbart,1999). Intensity of emotional expressivity (iEE) through facial, vocal, and bodily channels and the presence of social (looking to parent, physical comfort seeking) and nonsocial (gaze aversion, self-stimulatory, tactile exploration) self-regulatory strategies during LabTAB were coded offline by blinded coders. Parents reported EC using the Early Childhood Behavior Questionnaire (ECBQ; Putnam, Gartstein, & Rothbart,2006). Autism severity was quantified using the Autism Diagnostic Observation Schedule-2 Toddler module (ADOS-2, Lord et al.,2012).

Results: The analyses revealed that toddlers with ASD showed higher iEE of anger compared to TYP toddlers [p<.001, d=0.60] but no other differences were found between groups (all ps>.075). Toddlers with ASD used fewer social self-regulatory strategies during anger probes than their ATP [p=.038, d=.32] and TYP [p<.001, d=.68] peers. However, their employment of nonsocial self-regulatory strategies was comparable to the other groups (all p>.455). Parents of toddlers with ASD reported lower EC compared to ATP (p=.004, d=0.48) and TYP (p<.001, d=1.06) groups. Finally, iEE of anger was negatively correlated with nonsocial regulatory strategies in each group (ASD: r(84)=-.32, p=.004, ATP: r(71)=-.26, p=.029, TYP: r(65)=-.27, p=.030) but not with EC nor social regulatory strategies.

Conclusions: As expected, parents of ASD toddlers reported greater vulnerabilities in effortful control. When faced with frustrating tasks, toddlers with ASD showed significantly more negative emotionality and used fewer social regulatory strategies (e.g., looking toward parent) than their peers but were comparable in their use of nonsocial regulatory strategies (e.g., gaze aversion or disengagement from frustrating stimulus). Children who employed fewer nonsocial regulatory strategies exhibited greater intensity of negative emotions in all three groups. The study emphasizes the complex link between enhanced negative emotionality and self-regulation in autism, which requires further examination for the early identification of children with ASD at greatest risk for comorbid psychiatric disorders.

417.040 *(Poster)* Neural Responses to Audiovisual Speech in Infants at-Risk for Autism Spectrum Disorder: An ERP Pilot Study

***K. Dunham**[1], B. Keceli-Kaysili[2], A. Golden[1], P. Santapuram[1], J. I. Feldman[1] and T. Woynaroski[3], (1)Vanderbilt University, Nashville, TN, (2)Hearing and Speech Sciences, Vanderbilt University Medical Center, Nashville, TN, (3)Hearing & Speech Sciences, Vanderbilt University Medical Center, Nashville, TN*

Background: Speech is inherently a multisensory process, wherein highly synchronized visual cues from the moving mouth complement the dynamic acoustic stream. Past research has shown typically developing (TD) infants “tune in” to multisensory speech, looking to the mouth of their communication partners by midway through the first year of life, presumably to access the audiovisual cues that facilitate speech processing and language learning.

Objectives: This study aims to determine a) whether visual cues increase the efficiency of speech processing as indexed via event-related potentials (ERPs) in infants at low risk for ASD (infant siblings of TD children; Sibs-TD), and (b) whether infants at high risk for autism spectrum disorder (i.e., infant siblings of children with ASD; Sibs-ASD) display a lesser boost in speech processing efficiency with access to multisensory versus unisensory cues compared to Sibs-TD?

Methods: Forty 6-18 month old infants (20 Sibs-ASD; 20 Sibs-TD matched on sex and chronological age) are being recruited. Participants view videos of a female speaker saying syllables in audiovisual (auditory speech + synchronous visual mouth movements) and auditory only (auditory speech + still image of the face) conditions. Data are collected using NetStation and 128-channel Geodesic sensor net (Net Amps 400 amplifier, Hydrocel GSN 128 EEG cap, EGI Systems Inc.). The raw EEG signal is sampled at 1000 Hz and referenced to the vertex (Cz). The amplitude of the N1 (i.e., defined a priori as occurring between 100 ms and 140 ms post-stimulus onset) and P2 (i.e., defined a priori as occurring between 160 ms and 340 ms) as measured at a centrally located electrode site (Cz) are extracted from the grand average waveform of each participant and manually reviewed.

Results: Preliminary results for data processed to date (7 Sibs-TD; 4 Sibs-ASD) suggest infants across groups display an *increased* P2 amplitude in response to audiovisual relative to auditory only speech at 8 and 10 months (the developmental window wherein typically developing infants begin to increase looking to the moving mouth of their communication partners) and display a *decreased* or suppressed P2 amplitude in response to audiovisual versus auditory only speech between 12-18 months of age (the developmental window wherein they have perceptually narrowed to their native language and tend to shift their gaze from the mouth towards the eyes of their communication partners). On average, Sibs-ASD display reduced differentiation of audiovisual versus auditory only speech as indexed by the P2 amplitude compared to Sibs-TD.

Conclusions: Findings from this work will provide new insights into the developmental trajectories of multisensory speech processing in infants at high and relatively lower risk for autism. Preliminary results suggest differential processing of audiovisual speech may emerge within the first year of life, marked by a brief period associated with increased processing demands followed by subsequent facilitation of processing when typically developing infants have access to multisensory versus unisensory speech cues. Infants at heightened familial risk for ASD appear to show reduced differentiation of multisensory versus unisensory speech that may prove clinically useful for predicting ASD and related symptomatology.

417.041 *(Poster)* Nonverbal Prediction across Toddlers with Autism, Language Delay, and Typical Development

***T. Liu**, V. A. Munoz, M. Watson, O. Boorom and M. D. Lense, Vanderbilt University Medical Center, Nashville, TN*

Background: Successful navigation of a complex and dynamic world involves extracting regularities from incoming sensory inputs, developing predictions regarding the timing and nature of upcoming events, planning and executing subsequent behaviors, and flexibly updating predictions based on error signals. Accurate prediction and prediction updating are important for learning: Verbal and nonverbal prediction skills are associated with language abilities in typically developing (TD) children. Difficulties with updating predictions (D'Cruz et al., 2013), perhaps due to a high and inflexible precision of prediction errors (Van de Cruys et al., 2014), are observed in ASD. This impairment may contribute to deficits in social and communicative functioning in individuals with ASD. However, we know little about prediction skills and their relationship with language and social communication during early development including in toddlers with or at-risk for ASD and language delay (LD).

Objectives: Examine nonverbal visual prediction in toddlers with or at-risk for social communication and language impairments versus TD toddlers, and examine if nonverbal visual prediction relates to language and social communication skills.

Methods: Preliminary data is collected from 25 participants 15-32 months of age (13 TD, 12 with or at-risk for social communication impairments and/or LD); data collection is ongoing (anticipated total n=60). Of the 12 participants in the clinical/at-risk group, 6 have ASD, 3 have LD, and 3 have an older sibling with ASD. Participants completed an eye-tracking task adapted from Reuter et al. (2018) in which a central audiovisual stimulus was followed by a peripheral audiovisual target to one side of the screen for the first eight trials (Block 1; 200 ms delay between stimuli), and then to the opposite side of the screen (novel location) for the subsequent eight trials (Block 2). We compared overall number of anticipatory eye movements (AEMs) to either peripheral location (i.e., prediction quantity) and proportion of correct AEMs in Block 2 (prediction updating) between groups.

Results: Data analyses are ongoing. Preliminary analyses suggest no differences between TD and clinical/at-risk groups in regard to number of trials with AEMs both across both blocks (regardless of correctness), as well as separately in Block 1 and Block 2 (p's > 0.5), suggesting similar profiles of attention to the task and disengagement frequency from the central stimulus. However, TD toddlers had a significantly greater proportion of correct AEMs to the novel location in Block 2 (M=0.77) compared to those in the clinical/at-risk toddlers (M=0.45), $t(23)=-2.91$, $p=0.008$.

Conclusions: Preliminary findings suggest that TD toddlers are more successful at updating their predictions than participants with or at-risk for social communication or language impairments. These results are consistent with prediction updating difficulties observed in older children/adults with ASD and may provide a framework to examine links between prediction and communication development in toddlers with ASD and related language/communication challenges. Further analyses on the full sample will examine relationships between nonverbal prediction, language and social engagement, as well as differences between subgroups of the clinical/at-risk group (e.g., ASD vs. non-ASD LD vs. at-risk but no clinical diagnosis).

417.042 *(Poster)* Parent Perception of Social Communication Behavior in the Autism Screening Process: A Review of the STAT-Q

***L. Mulford**[1], J. Gattuso[2], S. C. Bauer[1], Y. Li[3], A. Devonshire[4] and V. Nanclares-Nogues[5], (1)Pediatric Developmental Center, Advocate Children's Hospital, Chicago, IL, (2)Advocate Children's Hospital, Pediatric Developmental Center at Illinois Masonic Medical Center, Chicago, IL, (3)Advocate Center for Pediatric Research, Advocate Children's Hospital, Oak Lawn, IL, (4)The Chicago School of Professional Psychology, Chicago, IL, (5)Pediatric Developmental Center, AIMMC, Advocate Children's Hospital, Chicago, IL*

Background: Parents' perception of their child's behavior plays a critical role in the screening process for Autism Spectrum Disorder (ASD). Most research on sensitivity and specificity of parent - reported screening tools for infants and toddlers (e.g., M-CHAT,) focuses on the first tier of screening. Recent research suggests that a two-tiered screening method shows strong positive predictive value and sensitivity as well as reduces the false positive rate of diagnosis. The STAT is a second-tier screening tool with a parent questionnaire (STAT-Q) to help identify risk for ASD. Given the importance of early identification and intervention, an improved understanding of parents' perceptions of child behavior during the screening process, particularly within the second tier of screening, is necessary to understand the utility of the tool as well as support parents in the diagnostic process.

Objectives: This study aims to examine parents' perception of their child's behavior using the STAT-Q. This study will further identify its utility as a diagnostic tool including specificity and sensitivity of the tool, as well as identify differences in responding based on sex and language spoken in the home.

Methods: Children between 19 and 36 months (N=281), were assessed through a multidisciplinary clinic utilizing the STAT and STAT-Q. A receiver operating characteristic curve analysis was used to identify overall diagnostic performance in the sample population. Non-parametric methods (Spearman correlation and Mann-Whitney U tests) were also used to compare and correlate STAT-Q items across sex and caregivers' languages.

Results: The STAT-Q showed strong specificity across caregivers (82.4% mothers; 82.8% fathers). In addition, a Positive Predictive Value of 86.8% for mothers and 91.4% for fathers was obtained. However, this tool does not have strong sensitivity (58% mothers; 61.2% fathers). Specific differences were noted across sex and language used in the home among questions endorsed on the STAT-Q. Both mothers' and fathers' STAT-Q, predict an ASD diagnosis better among boys (mothers AUC=0.73, fathers AUC=0.81) than among girls (mothers AUC=0.55, fathers AUC=0.59). Fathers' responses on individual items related to following directions (rho=0.43) and pointing (rho=0.40) were more strongly correlated with an ASD diagnosis than the overall STAT-Q score (rho=0.37). Additionally, English speaking mothers of children diagnosed with ASD, obtained more severe scores than did Spanish speaking mothers on items related to shared social engagement ($p<0.05$). Whereas Spanish speaking mothers reported more severe ratings related to items including nonverbal communication and following directions ($p<0.01$).

Conclusions: While the STAT-Q does not have strong sensitivity, it does have a strong positive predictive value and shows strong specificity. Further, different perspectives across caregivers and cultural backgrounds may impact responses on the STAT-Q. Improved understanding of parents' perceptions of their child's behavior using the STAT-Q may improve a clinician's use of clinical judgment to support the diagnostic process for individuals with ASD and their families across cultures. The tool's optimal utility may be to better understand the parents' view of their child and autism related symptoms during the diagnostic decision-making process.

417.043 *(Poster)* Parent-Reported Social Communication Skills of Children with Autism, Language Delay, and Typical Development Early and Late in the Second Year of Life

***J. L. Hooker**, A. Delehanty and A. Wetherby, Florida State University Autism Institute, Tallahassee, FL*

Background: Individuals with autism spectrum disorder (ASD) exhibit wide variability in their communication and cognitive profiles that can complicate efforts in early detection. Because delays in social communication can be observed in children at risk for ASD in the second year of life (Delehanty et al., 2018; Reinhardt et al., 2015), continued examination of this domain may help inform the development of improved screening tools. There is limited research examining parent report measures in characterizing the social communication of young children with ASD as well as differentiating this population from children with language delays (LD) and typical development (TD). Utilization of valid parent report measures of early social communication could help to lower the age of identification of children at risk for ASD.

Objectives: The purpose of this study was to explore differences on a parent report measure of social communication in a community-ascertained sample of children with ASD with and without global developmental delay (GDD), children with LD, and children with TD early and late in the second year of life.

Methods: Participants included 156 children recruited from archival database of the FIRST WORDS® Project (Delehanty et al., 2018; Dow et al., 2017; Wetherby et al., 2008). Children were given a best-estimate diagnosis of ASD (n = 45), ASD with GDD (n = 27), LD (n = 24), or TD (n = 60) at a M_{age} of 33.61 months (SD =7.69). Parents completed the CSBS Caregiver Questionnaire (Wetherby & Prizant, 2002) regarding their child between 12-16 months (Time Point 1; M=14.48, SD=1.43) and again between 18-22 months (Time Point 2; M=19.67, SD=1.41).

Results: Results of oneway ANOVAs indicated a significant main effect of group at each time point across all composites (all *p*s < .05). At time point 1, children with ASD evidenced significantly lower scores on the social composite compared to the TD group (M_{diff}=1.73), but differences across the other composites (speech and symbolic) were nonsignificant (*p*s >.05). At time point 2, children with ASD showed significantly lower scores across all composites and the total score compared to the TD group (M_{diffs}=1.58-2.89 and M_{diff}=10.67, respectively). The ASD group did not differ from the LD group on any of the composites or the total score at either time point (*p*s >.05). Children with ASD and GDD evidenced significantly lower scores on all composites and the total score than children with TD at both time points (M_{diffs}=2.07-4.99 and M_{diffs}=15.19-23.91, respectively).

Conclusions: Results provide preliminary support for the utility of the Caregiver Questionnaire in distinguishing children with ASD from children with TD under the age of 24 months. Increasingly, individuals diagnosed with ASD do not have co-occurring delays in language and cognitive domains. Early and late in the second year of life, it may be critical to supplement parent report of early social communication milestones with autism-specific questions to distinguish children with ASD from those with other developmental delays. The Caregiver Questionnaire is one of few parent report measures examining early social communication skills in the second year of life.

417.044 *(Poster)* Paternal Speech Directed to Young Children with Autism Spectrum Disorders with and without Intellectual Disability and Typical Development

*S. De Falco[1], S. Perzolli[2], G. Bertamini[3], **A. Bentenuto**[4] and P. Venuti[4], (1)University of Trento, Trento, Italy, (2)University of Trento, Rovereto, Italy, (3)Department of Psychology and Cognitive Science, University of Trento, Rovereto, Italy, (4)Psychology and Cognitive Science, University of Trento, Rovereto, Italy*

Background: The functional aspects of speech – that pertain its purposes – can be considered especially salient, as they seem to reflect more general parenting purposes of scaffolding child cognitive development within an affective framework (Bornstein at al. 1992). Research on the specific features of parent pragmatic speech directed to children with ASD is still limited and, in particular, paternal speech is almost completely unexplored (Flippin & Watson, 2015 ; Konstantareas, Mandel, Homatidis, 1988; Wolchik, 1983).

Objectives: Considering the urge of involving fathers of children with ASD in research and clinical practice, the main purpose of this study was to investigate paternal speech directed to children with ASD, with and without intellectual disability (ID), compared to that of fathers of language-age matched TD children. Moreover, we aimed to analyse how fathers' language was associated to children with ASD' severity of cognitive and linguistic impairments and of autistic symptoms.

Methods: To this aim, we coded multiple functional aspects of speech produced by fathers during 10-min of naturalistic dyadic play interactions with their pre-school children. Fathers language was firstly verbatim transcribed using the standardized format of the CHAT system (MacWhinney, 2000).Then, the transcripts were coded in terms of the primary function of each speech unit. Forty fathers and their children participated in this study: 20 were fathers of children with ASD (Chronological age: M =42.55, SD = 8.56, n = 20; Language age: M =24.83, SD = 14.11; 8 = females) and 20 were fathers of language age-matched TD children (Chronological age: M =23.45, SD = 3.82; n = 20; Language age: M = 23.45, SD = 3.82;12 = females).

Results: Results showed that fathers of children with ASD, essentially independently from child co-occurent ID, used a peculiar child-directed language that seems to reflect the effort to sustain a challenging social interaction, while providing enhanced scaffolding and reduced demands. In general, information-salient speech was used more often than all other speech main categories in both groups. A significant effect of group on affective-salient speech emerge, revealing that fathers of children with ASD used more affective-salient speech than fathers of TD children, $F(1, 36) = 9.35$, $p < .01$, $\eta 2 = .20$. Moreover, fathers of children with ASD called their child name more often than fathers in the TD group, $F(1, 36) = 4.74$, $p < .05$, $\eta 2 = .11$. Descriptions were used more often by fathers of children with ASD than fathers of TD children, $F(1, 36) = 7.71$, $p < .01$, $\eta 2 = .08$. Fathers of children with ASD referred more to child internal state, $F (1, 36) = 5.34$, $p<.05$, $\eta 2 = .13$, than did those of TD children. Moreover, fathers adapted aspects of their information-salient speech to the severity of specific child impairments.

Conclusions: Results of the present study expand the limited literature on fathering children with ASD. Our findings confirm the often-claimed urge to include fathers in early developmental intervention programs for children with ASD, by underlining fathers' spontaneous adaptation to their children needs.

417.045 *(Poster)* Responding to Joint Attention As a Mediator of the Relationship between Temperament and Symptom Severity in Infants at Risk of Autism Spectrum Disorder

S. Raza[1], *L. A. Sacrey*[2], *L. Zwaigenbaum*[1], *V. L. Armstrong*[3], *J. A. Brian*[4], *I. M. Smith*[5] *and S. E. Bryson*[6], *(1)University of Alberta, Edmonton, AB, Canada, (2)Autism Research Centre, Glenrose Rehabilitation Hospital, Edmonton, AB, CANADA, (3)IWK Health Centre, Halifax, NS, Canada, (4)Holland Bloorview Kids Rehabilitation Hospital, Toronto, ON, Canada, (5)Dalhousie University / IWK Health Centre, Halifax, NS, CANADA, (6)Dalhousie University, Halifax, NS, Canada*

Background: Prospective research on the early development of autism spectrum disorder (ASD) has shown that infants at risk for ASD have an early temperament profile characterized by reduced positive affect, high negative affect, low regulation, and poor attentional and behavioral control (Garon et al., 2009, 2016). As temperament affects the development of social behavior and interpersonal relationships, the possible links between temperament, social-communication, and ASD are of interest. Indeed, early temperament may play a critical role in the development of later social-communicative skills (i.e., joint attention; Vaughan et al., 2003; Nichols et al., 2005). How these developmental processes interact longitudinally to predict emerging ASD symptomatology warrants examination.

Objectives: The purpose of this study was to examine whether joint attention mediates the relationship between early temperament and subsequent ASD symptom presentation in high-risk infant siblings.

Methods: *Participants:* 42 high-risk (HR) infants with an older sibling diagnosed with ASD. Infants were assessed at 12, 18, and 24 months of age. *Temperament*: At 12 months, caregivers completed the Infant Behavior Questionnaire (IBQ; Rothbart, 1981) to index caregiver perception of infant temperament. Three constructs were measured: Surgency/Positive Emotionality, Negative Affectivity, and Regulation. *Joint Attention:* At 18 months, infants were assessed on an adapted version of the Early Social Communication Scales (ESCS; Mundy et al., 2003), which examines an infant's ability to initiate and respond to social presses with an examiner during toy play. Initiating joint attention (IJA) and responding to joint attention (RJA) were coded. *ASD Symptom Severity:* At 24 months, the Autism Diagnostic Observation Schedule – 2nd ed. – Toddler Module (ADOS-T) was administered. Symptom severity was measured using total algorithm score. *Analytical Approach:* The mediator role of joint attention was assessed using the PROCESS macro for SPSS (Hayes, 2018). The ability of the IBQ to predict subsequent ADOS-T total score was examined using three separate models with IBQ constructs (Surgency, Negative Affectivity, and Regulation) as independent variables, and IJA and RJA as mediators.

Results: The total direct effect of IBQ Surgency was a significant predictor of ADOS-T score ($t(39) = -2.10$, $p = 0.04$). The mediation process showed that RJA, controlling for Surgency, was significant ($b = -2.65$, $t(39) = -2.10$, $p = 0.04$). Controlling for the mediator RJA, Surgency was a significant predictor of ADOS-T total score ($b = -0.12$, $t(39) = -4.38$, $p = 0.04$). There were no significant direct or indirect effects involving IBQ Negative Affectivity or IBQ Regulation on ASD symptom severity, nor did IJA mediate these relationships when included in the models.

Conclusions: RJA mediates the longitudinal relations between HR infants' temperamental Surgency and ASD symptom presentation. The results suggest that, in addition to aspects of temperament, RJA may be related and contribute to individual differences in the emergence of ASD. These findings highlight that interrelationships among temperament, joint attention, and symptom expression may be important to consider when investigating developmental outcomes and intervention mechanisms in children with ASD.

417.046 *(Poster)* Screen Time in 36-Month-Olds at Increased Risk for ASD and ADHD

M. M. Hill*, D. N. Gangi, M. Miller and S. Ozonoff, Psychiatry and Behavioral Sciences, University of California, Davis, MIND Institute, Sacramento, CA*

Background: The amount of time children spend viewing electronic media has increased dramatically in the last two decades. The latest screen time recommendations issued by the American Academy of Pediatrics suggest that children between 2 and 5 years of age limit the use of screen media to no more than 1 hour per day. Previous studies have found that preschoolers who engage in screen time more than 2 hours a day demonstrate significantly more emotion dysregulation (Stiglic & Viner, 2019), inattention, and hyperactivity (Tamana et al., 2019), as well as lower language (Byeon & Hong, 2015) and prosocial behavior, relative to those viewing less than two hours per day. Associations between screen time and such negative developmental outcomes may be especially relevant to children at risk for behavioral difficulties and/or developmental delays, such as those with a family history of Autism Spectrum Disorder (ASD) or Attention-Deficit/Hyperactivity Disorder (ADHD).

Objectives: We examined the relationship between video-based media viewing (screen time), behavioral outcomes, and language development in a sample of 36-month-olds including children at increased familial risk for ASD or ADHD.

Methods: Participants included 120 36-month-olds at high risk for either ASD (n = 62) or ADHD (n = 30) or at low risk for either disorder (n = 28) based on family history. Parents reported average daily hours of screen time viewed by the child. Examiners unaware of familial risk status conducted a standardized diagnostic evaluation including a language assessment. Participants were assigned to an outcome group of either ASD (n = 20), ADHD Concerns (n = 14; children exhibiting increased *DSM-5* symptoms of ADHD), or Comparison (n = 86; did not meet criteria for ASD or ADHD Concerns).

Results: Analysis of variance showed a significant effect of outcome group on screen time, $F(2, 117) = 7.50$, $p = .001$. Post hoc analyses indicated that the mean hours of screen time for the ASD group ($M = 2.03$, $SD = 0.94$, $p = 0.01$) and ADHD Concerns group ($M = 2.33$, $SD = 0.94$, $p = 0.001$) were significantly greater than the mean hours for the Comparison group ($M = 1.49$, $SD = 0.85$). There was no significant difference in screen time between the ASD and ADHD Concerns groups (see Figure 1). Regression analyses, controlling for outcome group, showed that screen time significantly predicted language development across groups, with both receptive (β = -0.32, standard error (SE) = 0.94, $p < .001$) and expressive language scores (β = -0.28, SE = 0.92, $p < .001$) decreasing with increased screen time (see Table 1 for parameter estimates).

Conclusions: The findings demonstrate an association between increased screen time, ASD, increased ADHD symptoms, and diminished language development at 36 months of age. Future longitudinal studies are needed to determine the direction of effects and causality. Children with or at risk for ASD or ADHD may be especially vulnerable to the negative effects of excess screen time on development and providing families with strategies to help reduce the use of screen time may be beneficial.

417.047 *(Poster)* Screening for Autism Symptomology in Infants Identified with Fragile X

***A. M. Edwards**, A. Wheeler and K. C. Okoniewski, Center for Newborn Screening, Ethics, and Disability Studies, RTI International, Research Triangle Park, NC*

Background: Individuals with *FMR1* mutations are at risk for a spectrum of involvement including autism symptomology. However, with an average age of diagnosis of 38 months, there is very limited understanding of the earliest signs of autism, when they emerge, and how they progress from early infancy in infants with Fragile X[1]. As part of an innovative screening research pilot program in North Carolina, Early Check is offering parents the opportunity to screen their infant for *FMR1* full and pre mutations and participate in comprehensive follow-up procedures through three-years-of-age. Given the high prevalence of co-morbid autism spectrum disorder (ASD) in individuals with the full mutation as well as subthreshold symptoms in individuals with a premutation, assessment of autism symptomology is a necessary aspect of follow up in order to provide adequate surveillance. In order to assess the earliest signs of autism symptomology in infants identified through Early Check with the full or premutation of Fragile X, the Autism Observation Scale for Infants (AOSI) is administered, providing valuable insight to the social communicative development of these young children.

Objectives: To characterize and monitor autism symptomology in infants from 6 months of age identified with an *FMR1* mutation.

Methods: Parents of infants identified with an *FMR1* full or premutation are offered the opportunity to participate in follow-up developmental assessments at baseline (approx. 3-months), 6- and 12-months of age. At 6- and 12-months, participants are administered the Autism Observation Scale for Infants (AOSI)[2], a semi-structured 20-minute play observation designed to identify putative signs of autism in infants aged 6–18 months.

Results: To date, three infants with a premutation (all female) and three with a full mutation (one female and two males), have completed the 3- and 6-month follow-up assessments. A preliminary review of AOSI results suggest that 6-month old infants with an *FMR1* mutation display a range of behaviors thought to be indicative of autism; with infants with the full mutation exhibiting more of these behaviors than infants with a premutation. These behaviors include difficulty with disengagement of attention, orienting to name, imitation of actions, social babbling, and motor control and behavior.

Conclusions: Monitoring behaviors associated with autism from early infancy may contribute to the identification of "risk factors" for ASD in infants with Fragile X. Continued longitudinal assessments in infants identified pre-symptomatically with the full and premutation may help determine the stability of symptoms in young infants with Fragile X, and the efficacy of the AOSI as a predictive tool for ASD with these infants.

417.048 *(Poster)* Sex Differences in Autistic Symptoms of Toddlers and Young Children

***J. Kim**[1], D. Y. Song[1], G. Bong[2], S. Y. Kim[3], J. M. Kim[4] and H. Yoo[5], (1)Psychiatry, Seoul National University Bundang Hospital, Seongnam, Korea, Republic of (South), (2)Psychiatry, Seoul National University Bundang Hospital, Seungnam, Korea, Republic of (South), (3)Lynch School of Education, Boston College, Chestnut Hill, MA, (4)Department of Psychiatry, Seoul National University Bundang Hospital, Seongnam, Seongnam, Korea, Republic of (South), (5)Psychiatry, Seoul National University Bundang Hospital, Seongnam, Korea, The Republic of*

Background: There are differences in the mean age of diagnosis and prevalence rates between males and females with autism spectrum disorder (ASD) (Petrou et al., 2018). However, previous studies examining sex differences in the phenotypic presentation of ASD have yielded conflicting results across wide age groups. While autistic symptoms may present differently across the developmental trajectory, there is still a lack of investigation exploring whether sex differences of core autistic characteristics appear early on to be detected in toddlers and young children and explore how such results may compare to their peers.

Objectives: The purpose of this study is to investigate sex differences in autistic symptoms of toddlers and young children with ASD, as compared with their typically developing (TD) and developmental delay (DD) peers.

Methods: A total of 473 Korean toddlers and young children, aged 10-42 months, comprised of 180 subjects with ASD (141 males, 39 females), 221 with typical development (TD, 130 males, 91 females) and 72 with developmental delay (DD, 43 males, 29 females) participated in the study (Table 1). A comprehensive evaluation using the Autism Diagnostic Observation Schedule (ADOS-2), Autism Diagnostic Interview-Revised (ADI-R), Social Responsiveness Scale (SRS), and Vineland Adaptive Behavior Scales (VABS) was administered. Domain scores of ADOS and ADI-R were used to examine autistic symptoms across diagnostic groups. Univariate analyses of covariance (ANCOVA), covarying for VABS scores were used to assess the main effects of sex on ADOS, ADI-R, and SRS scores. Further ANCOVA analysis was conducted by age groups (18-23, 24-35, and 36-48 months) to see whether age could have an effect.

Results: The social interaction (SI) domain in ADI-R revealed a statistically significant effect of sex ($F(1,177)=7.257$, $p=0.008$) in subjects with ASD where females showed higher scores (M=15.79, SD=5.488) than males (M=14.39, SD=4.736), while ADOS showed no significant differences in both sexes. SRS scores found an effect of sex only in the TD group ($F(1,218)=5.195$, $p=0.024$) with lower scores in females (M=45.37, SD=4.948) than males (M=47.67, SD=6.934). Both TD and DD group exhibited significantly higher scores in the restricted and repetitive behavior (RRB) domain of both ADOS (TD: $F(1,218)=4.598$, $p=0.033$; DD: $F(1,69)=4.592$, $p=0.036$) and ADI-R (TD: ($F(1,218)=5.717$, $p=0.018$; DD: $F(1,69)=7.780$, $p=0.007$) (Table 2). When broken down into age groups, only the DD group revealed a statistically significant effect of sex on ADI-R RRB scores across 18-23 months ($F(1,8=10.993)$, $p=0.011$) and 24-35 months ($F(1,31)=5.124$), $p=0.031$), with higher scores in males (18-23 months: M=3.40, SD=2.074; 24-35 months: M=2.25, SD=1.517) than females (18-23 months: M=1.00, SD=0.894; 24-35 months: M=1.21, SD=0.893).

Conclusions: The results suggest that female toddlers and young children with ASD experience increased dysfunction in the SI domain when compared to male toddlers and young children with ASD. RRB domain scores are consistently higher in male in the TD and DD groups, suggesting that there might be an effect of sex in behavioral characteristics in subjects without ASD. Further research is needed to examine whether specific items are responsible for such differences in sex.

417.049 *(Poster)* Social Communication Profile in High-Familial Risk Infants Who Go on to Have Autism

S. Ravi[1], *S. S. Meera*[2], *J. Parish-Morris*[3], *L. D. Yankowitz*[3], *S. Paterson*[3], *A. Estes*[4], *L. Zwaigenbaum*[5], *H. C. Hazlett*[6], *K. Botteron*[7], *S. R. Dager*[8], *R. T. Schultz*[3], *J. Pandey*[3], *C. A. Burrows*[9], *T. St. John*[10], *J. Piven*[11] *and M. Swanson*[12], *(1)Communication Sciences and Disorders, University of Texas at Dallas, Richardson, TX, (2)National Institute of Mental Health and Neurosciences, Bangalore, India, (3)Center for Autism Research, Children's Hospital of Philadelphia, Philadelphia, PA, (4)Speech and Hearing Sciences, University of Washington, Seattle, WA, (5)University of Alberta, Edmonton, AB, Canada, (6)University of North Carolina, Chapel Hill, NC, (7)Washington University School of Medicine, St. Louis, MO, (8)Radiology, University of Washington, Seattle, WA, (9)Pediatrics, University of Minnesota, Minneapolis, MN, (10)University of Washington, Seattle, WA, (11)*Co-senior author, University of North Carolina, Chapel Hill, NC, (12)University of Texas at Dallas, Richardson, TX*

Background: Social communication deficits often emerged around the first birthday in infants who go on to have autism (Ozonoff et al., 2010; Zwaigenbaum et al., 2005). Toddlers with autism who had better social communication skills at 21 months also had better verbal and nonverbal skills and less severe autism symptoms at 36 months (Wetherby, Watt, Morgan, & Shumway, 2007). Since early social communication skills are a harbinger for later development, investigating these skills during infancy may help shed light on early risk markers and treatment targets for infants who go on to have autism.

Objectives: The main objective of this study is to examine group differences in social communication skills measured with the Communication and Symbolic Behavior Scales (CSBS; Wetherby & Prizant, 2002) at 12 and 24 months of age across three groups: low familial risk typically developing infants (LR-Neg), high familial risk infants without autism (HR-Neg), and high familial risk infants with autism (HR-ASD).

Methods: Infant participants were assessed longitudinally, using the CSBS at 12 and 24 months. Inclusion criteria included the completion of at least one CSBS assessment and diagnostic outcome at 24-months (N=537). Eighty-seven high familial risk infants met clinical best-estimate criteria for autism using the DSM-IV-TR (HR-ASD), and 295 did not meet criteria for autism (HR-Neg). The 155-low familial risk (LR-Neg) infants in this study did not meet criteria for autism or language delay (MSEL ELC >85, Table 1). Dependent variables included raw scores for the CSBS total, social composite, speech composite, and symbolic composite. Raw scores were used due to floor effects in standard scores at the 12-month time point. The statistical model included the effects of group, time (chronological age), group*time. Sex of the infant was a covariate.

Results: Analyses using general linear models indicated significant main effects for group ($p<.01$), time ($p<.0001$), and group*time ($p<.0001$) for all CSBS scores (Table 1). HR-ASD infants had fewer gains in social communication from 12-24 months when compared to HR-Neg and LR-Neg infants (Figure 1). Cross-sectional analyses (Table 1) indicated that HR-ASD infants had lower CSBS total scores at 12 and 24 months when compared with the HR-Neg and LR-Neg groups. At 12 months the HR-Neg group had lower CSBS total scores when compared to the LR-Neg group. However, at 24 months, the HR-Neg and LR-Neg group did not significantly differ from one another. Results from follow up tests of subscale scores revealed a similar pattern of results (Table 1).

Conclusions: Our results indicate that HR-ASD infants demonstrate difficulties with social communication at 12 and 24 months that can be captured using standardized assessments. Interestingly, HR- Neg infants demonstrated a lag in social communication at 12 months when compared with LR-Neg infants. However, by 24 months these two groups did not significantly differ in social communication abilities with the exception of symbolic skills (Table 1). At 24-months HR-Neg infants scored lower on this subscale when compared to the LR-Neg infants. These findings have important implications for identifying and remediating early social communication difficulties in toddlers with ASD.

417.050 *(Poster)* Social Spectrum: Longitudinal Comparison of Social Skill Development Amongst Infants at High and Low Risk for Autism

A. C. Dowd[1], *A. Massa*[2], *N. Brane*[1], *M. Pileggi*[1], *A. Wetherby*[3] *and C. Klaiman*[1], *(1)Marcus Autism Center, Children's Healthcare of Atlanta and Emory University School of Medicine, Atlanta, GA, (2)Cincinnati Children's Hospital Medical Center, Cincinnati, OH, (3)Florida State University Autism Institute, Tallahassee, FL*

Background: Autism Spectrum Disorder (ASD) is a neurodevelopmental disorder characterized by deficits in social communication and interactions. Although social functioning is recognized as existing along a spectrum (Social Spectrum), little is known about the early development of social functioning across the full spectrum from typically developing children (TD) to children with ASD. Existing research has also indicated that females tend to demonstrate more social skills than males on clinician-based measures. Alternatively, parent rated measures tend to indicate more autistic traits. However, there is a paucity of research regarding potential gender differences in the social development trajectories for children, including how and when different skills for both males and females develop. Understanding when skills are developing and when developmental differences first emerge is crucial for informing early intervention services.

Objectives: This study evaluated the developmental progression of three types of social skills from 9 to 24 months of age. Additionally, this study examined if and how social development varies across the Social Spectrum and across gender.

Methods: High-risk (*N*= 108) and low-risk (*N*= 125) infants (Male= 150, Female= 83) were assessed at 9, 12, 18, and 24 months. Weighted raw scores for three skill categories (Emotion/Eye Gaze, Communication, and Gestures) that comprise the Social domain of the Communication and Symbolic Behavior Scales (CSBS; live observation of social and communicative interactions) were analyzed to assess for skill development over time. The sum of parent ratings (Not Yet/Rarely, Sometimes, or Often) on 22 items related to Social Interacting & Communicating at 9 months was used as a measure of Social Spectrum, with higher scores depicting greater impairment in social functioning. LME models were conducted separately for each skill with Visit, Gender, and Social Spectrum as predictors. Non-significant interactions and main effects were removed from the models when the AIC was lower.

Results: Results indicated a significant Visit by Social Spectrum interaction on Emotion and Eye Gaze (Figure 1) and Communication (Figure 3) development. Significant main effects for these variables were indicated in the prediction of Gesture development (Figure 2). There was also a significant effect of Gender for both Communication and Gestures (Figure 4).

Conclusions: Social skills related to emotion and eye gaze, communication, and gestures are developing from 9 to 24 months of age. Additionally, the development of these social skills varies depending on infants' social functioning at 9 months of age. Results related to gender differences are also consistent with extant literature regarding females typically demonstrating better social abilities. Early identification of trajectories and factors impacting development are imperative to better understand developmental pathways across the Social Spectrum as it relates to ASD. Such an understanding will help in the provision of individualized early invention services for children with varying degrees of social impairment. Upcoming research conducted by the authors is further examining potential differences in the developmental pathways of the individual skills (e.g., joint attention, types of gesture use) that comprise these broader social skill domains.

417.051 *(Poster)* Spontaneous Imitation and the Emerging Autism Phenotype in at-Risk Infants

T. Cohenour[1]*, N. Libster*[2]*, A. Gulsrud*[3] *and C. Kasari*[1]*, (1)University of California, Los Angeles, Los Angeles, CA, (2)UCLA Center for Autism Research and Treatment, Los Angeles, CA, (3)UCLA Semel Institute for Neuroscience & Human Behavior, Los Angeles, CA*

Background: Imitation is an early-emerging skill that facilitates infant social interaction, creating optimal conditions for learning. Imitation deficits are both pervasive and specific to ASD (Rogers et al., 2003). Existing literature on spontaneous imitation in ASD is focused on older children and has yielded inconsistent findings. While it remains unclear when the developmental trajectory of spontaneous imitation is derailed in ASD, the current study may shed light on the developmental sequelae of imitation deficits observed at later ages in ASD by characterizing imitation abilities and concurrent predictors thereof in a community-referred sample of infants with emerging ASD.

Objectives: Specific aims include (1) determining whether specific domains of spontaneous imitation are differentially impacted in infants with emerging ASD, and (2) examining the relationship between imitation ability and early social-communication skills.

Methods: Participants include N=65 infants between age 12-23 months (M=17.75, 78.5% male) who completed imitation tasks as part of a larger behavioral intervention RCT for infants showing behavioral features of ASD (NICHD P50-HD-055784, Project PI: Kasari). Spontaneous imitation was assessed using a semi-structured, nine-item battery yielding total, gross motor, and object imitation scores (Ingersoll, 2008; Rogers et al., 2003; Stone et al., 1997). Imitation tasks were embedded within a play interaction during which the assessor modeled each task without providing verbal prompts. Tasks were scored on a 0 to 4 scale to reflect accuracy of imitation responses. Hypothesized predictors of spontaneous imitation include autism symptoms, initiation and response to joint attention (IJA, RJA), expressive language, and play level as measured at study entry.

Results: At-risk infants performed significantly better on object tasks than on gross motor tasks ($t=5.511$, $p<.0001$; Figure 1). Results reveal that joint attention was a consistent predictor of spontaneous imitation performance (Figure 2). Linear regressions controlling for NVDQ demonstrate that IJA is a significant predictor of total imitation ($\beta=0.014$, $p=0.005$) and object imitation ($\beta=0.014$, $p=0.008$), and approached significance for gross motor imitation ($\beta=0.014$, $p=0.061$). RJA approached significance in the model predicting object imitation ($\beta=0.407$, $p=0.058$). No other social-communication skills of interest were found to predict imitation.

Conclusions: At-risk infants demonstrated poor performance on tasks of spontaneous imitation, and these weaknesses were particularly pronounced in gross motor tasks. Initiation of joint attention, but not developmental level or other social-communication skills, was predictive of imitation performance. Shedding light on this relationship early in development is critical given imitation and joint attention have a social function (e.g., sharing attention) and a learning function (e.g., imitating functional play) which facilitate the development of more complex skills (Ingersoll, 2008). The relationship between these skills and subsequent social development may be "gated" by joint engagement, an area of weakness for children with ASD and a common mechanism underlying imitation and joint attention (Kasari et al., 2008). The findings from the current study highlight weaknesses in foundational social-communication skills among infants at risk, and underscore the criticality of developing interventions that are specific to the emerging ASD phenotype and target the basic skills necessary for the development of more sophisticated forms of social-communication (e.g., language).

417.052 *(Poster)* Testability Developmental Paths in Young Autistic Children: A Longitudinal Study Using Conventional and Strength-Based Assessment.

D. Girard[1]*, V. Courchesne*[2] *and I. Soulieres*[1]*, (1)Département de Psychologie, Université du Québec à Montréal, Montréal, QC, Canada, (2)Autism Research Group, CIUSSS du Nord-de-l 'Île-de-Montréal, Montréal, QC, Canada*

Background: Intellectual assessment in autistic children at the age of diagnosis bears many challenges which decrease testability in this population. A number of untestable autistic children are often excluded from studies and are presently underrepresented in the literature. It would be important to address this bias.

Objectives: We aim to document the variation of testability (i.e. the number of sessions required to complete a test) from the age of diagnosis (T0) until a year later (T1) and two years later (T2) in a group of young autistic and typically developing (TD) children. WPPSI-IV and Raven Coloured Progressive Matrices (RCPM) were used as conventional and strength-based assessment respectively.

Methods: A cohort of autistic and TD children aged 30-70 months were assessed using WPPSI-IV and RCPM at the age of diagnosis (T0), a year (T1) and two years (T2) later. Data from 60 children (20 autistics; 40 TD) who were testable on 2 out of 3 time points were used in the analyses (including dropouts or children having failed to complete the tests). Multilevel linear model (MLM) were used as they allow the use of all available data without the deletion of entire cases; they estimate the parameters using the available data. MLM are optimal for conservative analyses in clinical trials. Both groups were matched on age at baseline (*p*s > .05). Age in months at T0 was included as a covariable: [T0($M_{\text{Autistics}}$=50.3±11.0; M_{TD}=47.4±10.1), T1($M_{\text{Autistics}}$=66.1±8.7; M_{TD}=59.9±11.3), T2($M_{\text{Austistics}}$=80.1±9.4; M_{TD}=73.7±10.9)].

Results: Almost all TD children assessed with the WPPSI or the RCPM were able to complete the tests across time points (WPPSI: T0=87%, T1=100%, T2=97%; RCPM: T0=88%, T1=100%, T2=100%). In the autistic group, the proportion of children able to complete the WPPSI or the RCPM increased with time (WPPSI: T0=46%, T1=71%; T2=88%; RCPM: T0=44%, T1=78%, T2=93%). MLM analyses using testability on WPPSI as the dependent variable indicated a main effect of Group, $F(1, 62.96) = 32.20$, $p < .001$: the TD group (M=1.41±0.09) needed less sessions in average to complete the WPPSI compared to the autistic group (M=2.27±.012). There was also a main effect of Time [$F(2, 54.41) = 3.60$, $p = .034$]: both groups needed less sessions in average to complete the WPPSI at T2 (M=1.64±.0.14) compared to T0 (M=2.15±.15). MLM analyses using testability on RCPM as the dependent variable revealed a Group x Time interaction, $F(2, 52.56) = 4.02$,p= .024. Posthoc analyses revealed that autistic children needed less sessions in average from T0 (M=1.77±0.17) to T1 (M=1.11±0.65), $p = .002$ to complete the RCPM, and stabilized from T1 to T2(M=1.59±0.12), $p = .051$. TD children needed a similar number of sessions to complete the RCPM across time (T0: M=1.28±0.11; T1: M=1.06±0.05; T2: M=1.05±0.12), all *p*s > .05.

Conclusions: Our results confirmed that testability significantly increases with time in autistic children. Next steps will include (1)testing whether visual abilities or the presence of certain behaviors at T0 could predict the gain in testability, (2)investigating whether testability at T0 predicts cognitive level at T1 or T2 and (3) comparing the testability between different cognitive tests.

417.053 *(Poster)* The Accuracy of a Digitally-Administered M-CHAT in a Diverse Community Sample: Preliminary Findings

C. Nutor[1]*, K. Joseph*[1]*, N. Powell*[1]*, C. D. Gershman*[1]*, E. Yhang*[1]*, D. M. Goncalves Fortes*[1]*, M. Butler*[1]*, H. Feiner*[1]*, A. Vernetti*[1]*, K. Chawarska*[1]*, F. Shic*[2] *and S. Macari*[1]*, (1)Child Study Center, Yale University School of Medicine, New Haven, CT, (2)Center for Child Health, Behavior and Development, Seattle Children's Research Institute, Seattle, WA*

Background: The Modified Checklist for Autism in Toddlers (M-CHAT) is the most widely used autism screener (Johnson et al, 2007). Its recent revision, the M-CHAT-R/F, incorporates a follow-up interview (FUI) that improves accuracy (Dumont-Mathieu, 2017). However, the FUI is not consistently administered (Guthrie et al., 2019; Khowaja et al., 2015). A digitally-administered M-CHAT-R/F automatically includes the FUI, decreasing rates of false positive screening (Campbell et al., 2017; Harrington et al., 2013). Parents with less-than-average education report increased risk on the M-CHAT (Chiang et al., 2018; Fujiwara, 2014) and are less likely to be up-to-date with pediatrician visits (Bishop-Fitzpatrick, et al., 2017; Mandell et al., 2009). This study aims to examine the impact of maternal education level on M-CHAT-R/F screening when it is digitally administered to an ethnically-diverse sample.

Objectives: (1) To examine positive screening rates before and after FUI via digitally-administered M-CHAT-R/Fs and the effect of maternal education on these rates in a community sample. **(2)** To examine preliminary accuracy of the M-CHAT-R/F in relation to diagnostic outcomes ascertained by electronic medical record (EMR) review. **(3)** To examine sociodemographic factors affecting the likelihood of having up-to-date pediatric visits.

Methods: 231 parents completed the M-CHAT-R/F on a tablet during their toddlers' 18-, 24-, and 30-month well-child pediatric visits. Toddlers (63% male; Mage=23mo, SD=4.843) were minorities: 48% Black, 23% Mixed-Race, 3% Asian, and 46% Hispanic. Maternal education consisted of: 14% less than high school, 46% high school, 28% some college, 4% college, and 10% graduate school. M-CHAT-R/Fs categorized as medium-risk (3-7 failed items) were automatically administered the corresponding FUI. Diagnostic outcomes for 192 (83%) of the children were available via EMR review (Mage=35mo; ASD: 4%; developmental delays: 16%; typical development: 64%).

Results: (1) Of the 231 participants, 84% initially screened negative (scores 0-2), while 16% initially screened positive (scores ≥3). After FUI, 9% screened positive and 91% screened negative. Maternal education was not related to initial ($\chi2(4,231)=2.01$,p=.721) or final risk classification ($\chi2(4,231)=3.38$,p=.497). **(2)** For the 192 children with known diagnostic outcomes, the positive predictive value for ASD was 44% and the negative predictive value was 99%. Overall accuracy was 95% (sensitivity=0.958; specificity=0.875). **(3)** The 39 children without updated visits in the EMR did not differ from children with updated EMR outcomes by risk classification or racial/ethnic groupings (p-values>.336), but did differ by maternal education ($\chi2(4,231)=12.95$,p=.012). The "some college" and "graduate school" groups were more likely to have unknown outcomes.

Conclusions:

Contrary to previous findings, there were no significant differences in initial or final M-CHAT risk by maternal education. Our positive screening rates were higher than those in population studies (Robins, 2014; Stenberg, 2014), but are comparable to those reported for minorities (Khowaja, 2015; Rea, 2019). Maternal education affected the likelihood of having a current visit and thus a diagnostic outcome in the EMR. Future research should clarify this relationship. Although results regarding accuracy are limited by the small sample size and short length of follow-up to outcome, this study provides preliminary support for the use of digitally-administered M-CHAT-R/F in diverse populations.

417.054 *(Poster)* The Association between Esdm Fidelity and Child's Response

***H. K. Rinn**, A. Zitter, A. GuhaRay, D. L. Robins and G. Vivanti, A.J. Drexel Autism Institute, Drexel University, Philadelphia, PA*

Background: The Early Start Denver Model (ESDM) is a comprehensive evidence-based intervention for toddlers (12-48 months) with Autism Spectrum Disorder (ASD). ESDM draws its principles from developmental and behavioral science with a focus on cognitive, social-emotional, and language development (Rogers & Dawson, 2010). Adherence to manualized procedures in ESDM is measured using the ESDM fidelity checklist, which includes 13 items. Despite initial evidence for efficacy of the ESDM (Dawson et al., 2010; Rogers et al., 2019), response to intervention is variable, and knowledge is limited on the role of treatment fidelity on intervention response.

Objectives: We examined the association between fidelity of ESDM implementation and child's learning in response to ESDM, focusing on both overall fidelity and item-level contributions.

Methods: Participants were receiving ESDM in an ongoing clinical trial. Twenty videotaped sessions of 10 toddlers (18-36 months) with ASD who received ESDM from 10 therapists at different stages of their ESDM training were randomly selected. Sessions were coded to derive (a) fidelity of implementation across the 13 items of the ESDM fidelity checklist and overall fidelity score, and (b) child's performance in response to the use of the ESDM techniques. Each of the 13 ESDM fidelity items were operationalized on a Likert scale between 1-4 (1 = absence of fidelity and 4 = best example of fidelity) based on guidelines by Rogers & Dawson (2010). Scores were specific to each individual fidelity item. Child learning was operationalized as instances of the child emitting the targeted behavior in response to therapist's instruction. Inter-rater reliability between three independent coders was above 80% across all variables of interest. Associations between child learning and fidelity across each item as well as overall fidelity were first examined using Pearson Product Moment Correlation Coefficients. Linear regression analyses were then conducted including fidelity variables that had significant correlations with child learning.

Results: Average fidelity scores across the 13 items ranged from 2.2 to 3.9. Children's learning was positively correlated with overall fidelity score; (r = .69, p < .001). Additionally, 8 of the 13 fidelity items were significantly correlated with the child's response (r's ranges = .45-.73; all p's < .05). A linear regression showed that overall fidelity contributed to approximately 25% of the variance in child's learning above and beyond variance explained by child's age and IQ (*R Square change*=.25, *F Change p*<.01). A second linear regression showed that no single fidelity item contributed to child's learning above and beyond the contribution of the other fidelity items, with the exception of "management of child attention", which explained approximately 20% of the variance in child's learning above and beyond variance explained by child's age and IQ and all the other fidelity items significantly associated with child's learning (*R Square change*=.19, *F Change p*<.05).

Conclusions: Variations in treatment fidelity contribute to variations in children's learning in response to ESDM. The therapist's ability to manage the child's attention plays a particularly important role on a child's intervention response.

417.055 *(Poster)* The Development of Gestures in Children with Autism Spectrum Disorder and Its Relationship with Other Abilities

***Q. Ye**, L. Liu, S. Lv and H. Deng, Child Developmental & Behavior Center, Third Affiliated Hospital of SUN YAT-SEN University, Guangzhou, China, Guangzhou, Guangdong, China*

Background: Autism spectrum disorder (ASD) is a neurodevelopmental disorder, with impairments in social interaction and communication, and restrictive and repetitive behaviors as its main symptoms. Gesture is a form of nonverbal communication and acts as the preamble of language. Studies have found that typically developing children (TD) begin to consciously use gestures to communicate with their caregivers at 7-9 months. Furthermore, gestures have an important impact on information processing, language acquisition, cognition, and memory. Atypical manifestations and/or defects in gestures have been found in early development of ASD, and are an early sign of impairments in social interaction and communication.

Objectives: 1. To explore the differences in gestures between TD and ASD from the aspects of quantity, quality, communication purpose and specificity. 2. To find the relationship gesture has with language, social ability, intelligence, symbolic behaviors and adaptive behaviors.

Methods: Participants were split into two groups: 24 TD (12-36 months, 7 females; 17 males) and 37 ASD (24-48 months, 7 females, 30 males). Gestures were coded from a 10-20 minutes video recording a standardized semi-structured gesture assessment adapted from Autism Diagnosis Observation Scale (ADOS). All children were assessed by the Chinese Communicative Development Inventory (CDI), ADOS, Bayley Scales of Infant development (BSID) or Wechsler Intelligence Scale for Children (WISC), Infant-Toddler Checklist (ITC), Adaptive Behavior Assessment System (ABAS).

Results: (1) Compared with TD, ASD displayed gestures fewer in quantity, worse in quality, and more specific, as well as more naive gesture communication purpose (GCP). (2) For minimally verbal children (i.e. speak single or no words), ASD has fewer gestures than TD, and ASD GCP is more naive, meanwhile the quality of ASD gesture is worse. The difference is reduced in children with phrase speech. No statistical difference was found in the number of gestures between ASD and TD, but ASD GCP remains more naive and gesture quality is still worse. (3) In ASD, children with phrase speech are better at integrating gesture and language than those who are minimally verbal, and their GCP is more mature. TD children with phrase speech are more accomplished in integrating gestures in voice or language than minimally verbal TD children, but their GCP is not significantly different. (4) In both ASD and TD groups, gestures are correlated to language, social ability, intelligence, symbolic behaviors and adaptive behaviors. ASD gestures have more relevance to language, intelligence, social ability and symbolic behavior, while TD has more relevance to adaptive behavior.

Conclusions: In early development, the differences in gestures between ASD and TD are significant which might help differentiate ASD and TD in early life. We found that these differences may be affected by speaking ability. And unlike TD, ASD speaking ability might not only affect the ability to integrate language with gestures, but also affect GCP. Lastly, future research can explore whether gestures can be an effective indicator for early assessment of ASD functional levels, as gestures are significantly correlated to other abilities.

417.056 *(Poster)* The Development of Play in Very Young Children with Elevated Likelihood for Autism Spectrum Disorder

F. Moerman[1]*, P. Warreyn*[2]*, E. Demurie*[2] *and H. Roeyers*[2]*, (1)Departement of Experimental, Clinical and Health Psychology, Ghent University, Ghent, Belgium, (2)Department of Experimental-Clinical and Health Psychology, Ghent University, Ghent, Belgium*

Background: There is accumulating evidence for atypical play development of young children with elevated likelihood (EL) for autism spectrum disorder (ASD) who develop ASD in comparison to EL-children who do not (Campbell et al., 2018). However, longitudinal studies on this matter are scarce and focus only on younger siblings of children with ASD. Nevertheless, preterm children are another important EL-group (e.g., Agrawal, Rao, Bulsara, & Patole, 2018).

Objectives: This study examined play skills at 10- (T1) and 14 months (T2) in both younger siblings of children with ASD and premature children (<30 gestational weeks) and its relationship with ASD characteristics at T2 and 24 months (T3).

Methods: As part of a longitudinal study, play skills of EL-children (n=30) were assessed at T1 and T2 using diverse measures. First, the relative duration of functional play was coded in videos of a semi-structured play observation. Secondly, the subscale Object Use of the Communication and Symbolic Behavior Scales-Developmental Profile Caregiver Questionnaire (CSBS-DP CQ, Wetherby & Prizant, 2002) assessed parent-reported play skills. ASD symptoms were observed with the ADOS-Toddler (ADOS-T, Lord et al., 2012) at T2 and T3.

Results: A repeated measures ANOVA determined that parent-reported play skills of 30 infants included up to date, increased significantly between T1 and T2 ($F(1,21) = 22.458$, $p < .0001$). Moreover, functional play was only observed in two children at T1, in contrast to 22 children at T2. Preliminary analyses showed no significant differences in play skills between the two EL-groups. As reported by parents at T1 ($\rho(23)= -0.56$, $p = .004$) and T2 ($\rho(24)= -0.39$, $p= .047$), and as observed at T2 ($\rho(26)= -0.44$, $p = .021$), play skills were negatively related to restricted and repetitive behaviour (RRB) scores on the ADOS-T at T2. The relative duration of functional play at T2 was marginally significantly lower in EL-children with an elevated concern for ASD according to the ADOS-T scores (n=7) in comparison to EL-children who scored within the range of little to no concern ($U=40$, $p= .073$). Finally, there was no significant agreement between presence of parent-reported functional play and presence of observed functional play at T1 ($\kappa = .018$, $p = .869$) and T2 ($\kappa = - 0.016$, $p = .932$). Since the study is still ongoing, results of a much larger sample and associations between play skills at T1 and T2, and ADOS-T scores at T3 will be presented at the meeting.

Conclusions: This prospective study provides information on the association between early play skills and ASD-characteristics in two EL-groups, which has been examined in only a few studies. Overall, no significant differences in play skills were found between the two EL-groups. Furthermore, these preliminary results indicate increasing play skills between T1 and T2, consistent with studies of play in typically-developing children. In addition, our findings show that play skills are associated with RRB and not with social-affect symptoms. Lastly, it is important to emphasize the use of both parent-report and observational measures to map the early development of play as complementary methods.

417.057 *(Poster)* The Impact of Socioeconomic Status on Early Vocal Development in Infants at Risk of ASD

D. Dragovic[1]*, C. Klaiman*[2]*, S. P. White*[3]*, M. Edwards*[4]*, M. Pileggi*[2]*, N. Brane*[2] *and G. Ramsay*[1]*, (1)Marcus Autism Center, Children's Healthcare of Atlanta, and Emory University School of Medicine, Atlanta, GA, (2)Marcus Autism Center, Children's Healthcare of Atlanta and Emory University School of Medicine, Atlanta, GA, (3)Department of Pediatrics, Emory University, Atlanta, GA, (4)Marcus Autism Center, Emory University, Atlanta, GA*

Background: Socioeconomic status (SES) is known to impact many aspects of child development, including language acquisition, but the mechanisms by which different SES factors may interact with ASD risk to affect severity of outcome are not well understood. It is unclear whether two main factors, access to resources (household income) and parental environment (education and occupation), show profiles that differ for ASD, and whether any such differences are significant in relating core features of autism to language.

Objectives: The goal of this study was to test whether indices of socioeconomic status measuring parental income and education at birth predict early trajectories of vocal development over 0-24 months and later language outcome at two years, in autism and typical development.

Methods: As part of an NIH Autism Center of Excellence, we tracked vocal development in 45 high-risk siblings and 35 low-risk controls. Using a recording device (LENA) worn by each child, we made audio recordings of each child's language environment from 0-24 months. Using speech recognition technology, we counted the number of vocalizations per hour for child and adult, as well as the rate of contingent interactions. Using Functional Data Analysis, we calculated developmental trajectories for each child. We modeled each trajectory as an exponential curve with scale and exponent parameters to separately characterize overall dosage and change over time. Receptive and expressive language scores from the Mullen Scales of Early Learning were collected from children who completed clinical assessments at 24 months. Based on parent questionnaires, we calculated the Hollingshead Four-Factor Index from caregiver education and occupation, together with household income quantized into $25K intervals.

Results: Comparing the joint distribution of the two SES indices, we found significant differences between risk groups; both showed the expected correlation between income and education, but the high-risk group scored lower on both. We found significant correlations between both income and education factors and expressive and receptive language scores overall, but no significant difference between risk groups, indicating that SES impacts language outcome regardless of autism risk. We found significant correlations between education and income factors and the scaling parameter of the adult vocalization rate trajectories, but not with any other parameters, suggesting that SES affects the overall amount of parental input, but does not affect either child volubility or vocal contingency, or change over time. In contrast, our previous research showed that rate of change over time in vocal contingency, rather than adult and child volubility, is the main predictor of diagnosis and language outcome in high-risk infants. This suggests that the mechanism by which SES influences language outcome is common across risk groups and unrelated to autism.

Conclusions: Consistent with previous studies, we found that SES is correlated with parental input and language outcome. Although there are differences in SES between high-risk and low-risk infants, this research suggests that early differences in parental input, generally associated with socioeconomic status, do not resemble early deficits in infant-caregiver social interaction specifically associated with autism, indicating that these are separate compounding factors impacting language outcome.

417.058 *(Poster)* The Importance of Maternal Responsiveness: The Association between Social Communication and Disruptive Behaviors in Toddlers with Autism Spectrum Disorder

H. L. Fipp-Rosenfield*, R. S. Levy, J. Grauzer, Y. S. Stern and M. Roberts, Communication Sciences and Disorders, Northwestern University, Evanston, IL*

Background: One in three toddlers with ASD display clinically significant disruptive behaviors (Hartley, Sikora, & McCoy; 2008). Although there is empirical support for the association between: (a) disruptive behaviors and social communication (Park, Yelland, Taffe, & Gray, 2012), and (b) child social communication skills and maternal responsiveness in children with ASD (Gros-Louis, West, King, 2014), the extent to which maternal responsiveness mediates the association between disruptive behaviors and social communication skills remains unknown (Baptista et al., 2019; McDoniel & Buss, 2018). Maternal responsiveness may mediate this association because children who demonstrate fewer disruptive behaviors may allow for more responsive parent-child interactions.

Objectives: The current study aims to examine the (1) association between children's disruptive behaviors and social communication skills and (2) extent to which maternal responsiveness mediates the association between children's behaviors and social communication skills in toddlers with ASD.

Methods: The current study included 89 mother-child dyads of toddlers with ASD (Range: 19.02-48.95 months, M = 33.22, SD = 6.22). Standardized 10-minute mother-child interactions were transcribed and micro-behavior coded using Mangold InterACT software (Mangold, 2015). Maternal responsiveness was defined as the percentage of utterances that were temporally and topically contingent on the child's previous communicative act. Children's social communication was measured using the Total Weighted Raw Score from the Communication and Symbolic Behavior Scales Developmental Profile Infant-Toddler Checklist (CSBS DP; Wetherby & Prizant, 2002). Children's behaviors were measured using the Infant-Toddler Social Emotional Assessment, a parent-report that examines four domains of behavior: Externalizing problems, Internalizing problems, Dysregulation, and Competence (ITSEA - Parent form; Carter & Briggs-Gowan, 2006).

We conducted a series of linear regressions to determine the relationship between disruptive behaviors and social communication, controlling for child age and nonverbal cognition (MSEL; Mullen, 1997). We planned to test for mediation of disruptive behaviors on social communication through maternal responsiveness, using a Sobel test (Baron & Kenny, 1986).

Results: Multiple linear regressions revealed the ITSEA Competence Domain positively predicted CSBS score ($B = 23.40$, $t = 2.46$, $p < 0.05$). More competent behaviors were predictive of higher social communication scores. The remaining ITSEA behavior domains were not significant predictors of CSBS score (see Table 1). Given child competence was also predictive of maternal responsiveness ($B = 0.26$, $t = 4.17$, $p < 0.001$), we were able to test for mediation (see Table 2). Results revealed the effect of competent behaviors on children's social communication abilities was partially mediated through maternal responsiveness (indirect effect = 17.63 (5.76), $p < 0.01$).

Conclusions: The presence of children's positive behaviors, rather than the absence of disruptive behaviors, may allow mothers to be more responsive, and as such provide optimal linguistic input to facilitate children's social communication development. These findings support the use of intervention strategies targeting the increase of competent behaviors and the decrease of disruptive behaviors in toddlers with ASD. Future research should consider (1) the relationship between children's disruptive behaviors and more nuanced language measures and (2) which specific types of competent behaviors are most related to social communication and maternal responsiveness.

417.059 *(Poster)* The Parental Report Early Motor Questionnaire Can Detect Early Motor Abnormalities in a High-Risk Population for ASD

A. Caruso[1]*, L. Gila*[1]*, M. Puopolo*[2]*, T. Salvitti*[1]*, F. Fulceri*[1] *and M. L. Scattoni*[1]*, (1)Research Coordination and Support Service, Istituto Superiore di Sanità, Rome, Italy, (2)Department of Neuroscience, Istituto Superiore di Sanità, Rome, Italy, Istituto Superiore di Sanità, Rome, Italy*

Background: There is evidence that motor abilities predict the later development of social communication skills. Motor impairments are among the earliest signs of autism spectrum disorder (ASD). The Italian Network for early detection of ASD (NIDA), the largest Italian cohort of infants at high risk for ASD (HR: siblings of children with a diagnosis of ASD, small for gestational age, and premature newborns), is actually applying a multi-observational protocol from birth to 36 months in the entire Italian territory. The protocol includes the evaluation of spontaneous movements at 10 days, 6, 12, 18, and 24 weeks of age and the comprehensive clinical assessment of several areas of development at 6, 12, 18, 24 months. To date, NIDA has enrolled 247 HR siblings and 114 low-risk infants.

Objectives: To evaluate whether early motor performances predict developmental outcomes in a cohort of siblings of children with a diagnosis of ASD.

Methods: We prospectively evaluated the fine and gross motor development of a subgroup of HR infants enrolled in the NIDA Network. The HR infants were subdivided into three groups based on their clinical outcome at 24-36 months: 6 HR diagnosed with ASD (HR-ASD); 8 HR diagnosed with NDDs (HR-NDDs) and 16 HR with typical development (HR-TD). Each child completed a range of motor, cognitive, and diagnostic assessments through parental reports and direct observational measures. The motor assessment included the Griffiths fine and gross motor subscales and the Early Motor Questionnaire (EMQ), a parent-report measure of motor development organized into three sections: gross motor, fine motor, and perception-action integration skills. Statistical analyses were carried out on data from 12 and 18 months. The Pearson correlation coefficients were computed to define the concurrent validity of the two tests at 12 and 18 months. Differences between clinical groups were analyzed using repeated-measures ANOVA (12 and 18 months) in the subset of HR infants with available data.

Results: EMQ and Griffith's motor subscales resulted correlated: EMQ gross motor and Griffiths locomotor subscale at 12 months (r= 0.465, p= 0.005) and at 18 months (r= 0.373, p= 0.042); EMQ fine motor and Griffiths eye-hand coordination subscale at 18 months (r= 0.422, p= 0.020); EMQ perception-action and eye-hand coordination subscale at 18 months (r=0,482 p=0.006). At 18 months, HR-ASD and HR-NDDs children showed lower EMQ scores in perception-action integration skills than HR-TD (p< 0.026; p< 0.028). HR-NDDs and HR-TD significantly differed in the EMQ gross motor skills (p< 0.029). No between group differences emerged at 12 months.

Conclusions: Early motor development may provide crucial clues to anticipate social delays in HR infants. Indeed, HR infants later diagnosed with ASD or NDDs showed reduced perception-action integration skills at 18 months of life, long before the diagnosis. Our findings suggest the EMQ questionnaire can provide an affordable, easy-to-apply, and informative assessment for evaluating early motor divergences and predict abnormal outcomes in HR infants. The ongoing NIDA enrolment will overcome the current small sample size.

417.060 *(Poster)* The Relationship between Early Autism Symptoms and Maternal Pitch Contours within Infant-Directed Speech

A. J. Woolard[1]*, T. Benders*[2]*, L. E. Campbell*[3]*, F. Karayanidis*[4]*, V. Murphy*[5]*, L. Korostenski*[6]*, D. Barker*[7]*, C. A. Mallise*[8]*, O. Whalen*[1]*, J. Mattes*[9] *and A. E. Lane*[10]*, (1)University of Newcastle, Australia, Callaghan, Australia, (2)Linguistics, Macquarie University, Sydney, Australia, (3)School of Psychology, University of Newcastle, Newcastle, Australia, (4)Psychology, University of Newcastle, Australia, Callaghan, Australia, (5)Medicine and Public Health, University of Newcastle, Australia, Callaghan, Australia, (6)John Hunter Children's Hospital, Newcastle, Australia, (7)University of Newcastle, Newcastle, Australia, (8)The University of Newcastle, Callaghan, Australia, (9)University of Newcastle, Callaghan, NSW, Australia, (10)University of Newcastle, Callaghan, Australia*

Background: Mother-infant interactions during the first year mediate development and comprise the infant's sensory environment. The communication between the mother and infant is a central component of early interactions, and the infant-directed speech (IDS) the mother uses is crucial to many aspects of development. The prosodic elements of IDS, in particular pitch contours, can encourage infant language learning and social communication. There is little research, however, investigating maternal pitch contours in relation to infants showing deficits in socio-communicative, sensory regulation and language development, such as those displaying early symptoms of Autism Spectrum Disorder (ASD).

Objectives: The aim of this study was to explore the relation between pitch contours used by mothers when interacting with their 12-month-old infants displaying early symptoms of ASD.

Methods: 105 mother-infant dyads (44f, 59m) participated in a 15-minute recorded interaction. Infants were assessed for early ASD symptoms using the parent-report First Year Inventory (FYI; Reznick, Baranek, Reavis & Crais, 2007) and the observer-rated Autism Detection in Early Childhood assessment (ADEC; Young, 2007). Pitch contours used by mothers in the interaction (n=36,128) were analysed and classified into contour type (rising, bell, sinusoidal, u-shape, slow-fall, rapid-fall/rise, flat, or complex). 10 infants scored as 'at-risk' for receiving a diagnosis of ASD on the FYI and on the ADEC, respectively. Spearman's rank correlation coefficient was used to determine relations between the contours and the infant's FYI and ADEC scores.

Results: Maternal pitch contours used during the interaction were related to both the FYI and the ADEC. Mothers made fewer utterances (r= -.30, p=.005), and used fewer sinusoidal contours (r= -.31, p= .003) when their infants displayed more early autism behaviours as indicated by FYI total risk scores. Mothers of infants displaying more early ASD behaviours were observed to use more flat (r= .22, p= .03) and slow-fall contours (r= .22, p= .03), however. These associations were most strongly associated with sensory regulation symptoms on the FYI. Mothers used less sinusoidal (r= .32, p=.002), and more flat (r=.23, p=.03) and slow-fall contours (r= .21, p= .05) with infants displaying higher scores (more dysregulated) in sensory regulation. In terms of the ADEC, mothers used less bell (r= .40, p= .05) and flat contours (r= .48, p= .02) as infants score increased (indicating more ASD behaviours present).

Conclusions: These data provide initial support for the notion that mothers of infants displaying early ASD behaviours, use different patterns of IDS. Patterns of IDS appear to be particularly related to sensory regulation features in the infants. Early interactions are likely to be bi-directional in nature, with both the infant and mother active participants. Future research is needed to determine the nature of IDS within the early sensory environment, and whether the mother is modifying her behaviour in response to infant feedback, which could help inform early intervention involving interactions with infants showing early ASD behaviours.

417.061 *(Poster)* The Relationship between Gaze to the Mouth and the First Word Milestone in Typical Development and in Autism Spectrum Disorder

E. Kushner[1]*, S. Shultz*[2]*, A. Klin*[2]*, W. Jones*[2] *and L. A. Edwards*[2]*, (1)Emory University, Marcus Autism Center, Atlanta, GA, (2)Marcus Autism Center, Children's Healthcare of Atlanta and Emory University School of Medicine, Atlanta, GA*

Background: Successful social functioning relies upon the ability to identify and learn from salient aspects of one's environment. In typical development (TD), infants show increased attention to the eyes early in life; this facilitates social learning in TD children and those with Autism Spectrum Disorder (ASD) (Klin et al., 2003). As infants acquire new skills, different aspects of the environment become salient, and attention is reallocated accordingly. Within the second year of life TD infants demonstrate a shift in preferential looking from eyes to the mouth. This shift occurs at ages that coincide with word learning and is associated with later vocabulary (Tenenbaum et al., 2015). However, past findings are variable regarding the adaptive value of mouth-looking for children with ASD, depending on the age and developmental level of a given sample. In both TD and ASD, it is also unclear whether and to what extent mouth-looking is specifically related to the first word milestone.

Objectives: The present study explores the adaptive value of mouth-looking during the period of early word learning in TD and ASD groups. We hypothesize that mouth-looking will be directly associated with language ability only at key points of word learning; specifically, we predict a significant relationship between mouth-looking and language at the onset of word learning, for both TD and ASD groups.

Methods: Chronologically age-matched ASD (n=48; M_{age}(SD)=14.85 (4.348) months) and TD (n=109; M_{age}(SD)=13.01(3.001) months) children were assessed using the MSEL expressive and receptive language scales and eye-tracking measures of visual engagement (quantified as percentage of time spent fixated on different facial regions of interest (ROIs)). Children were classified into four groups based on their early word learning status (MSEL item 11scale: no words (n=39), one word (n=31), two-to-seven words (n=57), and eight-or-more words (n=25). Within each category of word learning, we tested for between-group differences in visual fixation to eye and mouth regions, and within-group associations between visual fixation and concurrent expressive and receptive language.

Results: Once children with ASD reached eight-or-more words, they displayed significantly less mouth-looking than TD children in the same stage (p=0.049); there were no other differences in amount of eye- or mouth-looking between groups. TD children without words exhibited a positive association between mouth-looking and concurrent receptive language (r=0.654, p<0.001), and an inverse relationship between eye-looking and expressive language (r=-0.564, p=0.002). Those closest in time to the first word milestone (one word) exhibited a positive association between mouth-looking and concurrent expressive language (r=0.448, p=0.036). Eye- and mouth-looking were unrelated to language in ASD children at all stages of word learning.

Conclusions: These findings suggest that for TD children, the adaptive value of mouth-looking changes around the first word milestone: specifically, mouth-looking positively predicts receptive language ability before word onset, then positively predicts expressive language ability during the immediate period following word learning. These patterns were not observed in children with ASD. Future analyses will explore associations between visual fixation and language in a cohort followed longitudinally across the first word transition, and potential heterogeneity in this relationship within ASD.

417.062 *(Poster)* The Relationship between Joint Engagement, Joint Attention, and Cognition in Infant-Toddlers at Risk for Autism Spectrum Disorder

M. Tafolla Magana[1]*, K. Sterrett*[2]*, A. Gulsrud*[3] *and C. Kasari*[4]*, (1)UCLA, Los Angeles, CA, (2)University of California Los Angeles, Los Angeles, CA, (3)UCLA Semel Institute for Neuroscience & Human Behavior, Los Angeles, CA, (4)University of California, Los Angeles, Los Angeles, CA*

Background: Deficits in joint attention (JA) are well documented in individuals with autism spectrum disorder (ASD; Mundy et al., 1990), and interventions targeting joint engagement (JE) have a positive and sustained effect on JA (Kasari et al., 2010). Furthermore, JA is a precursor to important developmental milestones, such as language (Mundy et al. 1990), and is known to be influenced by cognitive ability (Mundy et al. 2007). However, little is known about how cognition influences the relationship between JA and JE in infants-toddlers at-risk for ASD.

Objectives: To analyze the association between joint engagement and joint attention in infants at-risk for ASD and whether it is influenced by non-verbal cognitive ability (NVIQ).

Methods: This analysis includes baseline data from 80 infants with ASD (MAge= 17.66 months, 54% non-white, 80% Male) enrolled in a clinical trial of JASPER for children at risk for ASD. Children met for mild-moderate concern on the ADOS Toddler Module (Luyster et al., 2009). Children's NVIQ was assessed using the receptive language and visual receptive domains on the Mullen Scales of Early Learning. The Early Social Communication Scales (ESCS) measured children's percentage of responding to joint attention (RJA) and frequency of initiating joint attention (IJA). JE was coded from a 10-minute parent child, free play interaction using a scheme adapted from Adamson and colleagues (2009). First, a negative-binomial regression was fit with IJA gestures as the dependent variable and age, time spent jointly engaged, NVIQ and the interaction between NVIQ and JE as mean centered, independent variables. Next, multiple linear regression was used with RJA as the dependent variable and age, time spent in joint engagement, NVIQ and their interaction as the independent variables.

Results: In the IJA model, for every 1 standard deviation (SD) increase in JE the frequency of IJA is expected to increase by 10% and for every 1 SD increase in NVIQ the frequency of IJA is expected to increase by 109%. However, the interaction term indicated that the effect of NVIQ decreases by approximately 60% for each SD increase in JE. In the RJA model there were main effects of JE and NVIQ on RJA and the interaction term for the RJA model was significant, t(55)= -2.61, p <.01 indicating that increases in joint engagement had a more positive association with RJA in those with low NVIQ.

Conclusions: Decisions about what goals to prioritize in very young children with autism remains a critical area of interest for clinicians and early intervention researchers. Consistent with other samples, in our sample, lower cognitive ability was strongly related to fewer initiations of joint attention (Mundy et al., 2007). However, we found that infants' ability to maintain periods of joint engagement with their parents appears to protect against this effect. Those children with more joint engagement had more initiations of, and responses, to joint attention, regardless of their cognitive ability. Overall, these data reiterate the importance of joint engagement as a foundation to teach joint attention skills, particularly in those infants with more global developmental delays.

417.063 *(Poster)* The Relationship between Motor Skills, Gestures and Language Development in Children with an Elevated Likelihood of ASD

M. Mues[1]*, E. Bruyneel*[2]*, S. Boterberg*[3]*, E. Demurie*[3] *and H. Roeyers*[3]*, (1)Experimental, Clinical and Health Psychology, Ghent University, Gent, Belgium, (2)Department of Experimental-Clinical and Health Psychology, Ghent University, Gent, Belgium, (3)Department of Experimental-Clinical and Health Psychology, Ghent University, Ghent, Belgium*

Background: Early motor skills are known to correlate with language development in typically developing (TD) and ASD populations. In TD groups however, this relationship has been found to be mediated by representational gesture frequency. Although gestures have also been shown to be a predictor of language development in children with (elevated likelihood (EL) of) ASD, the relationship between motor skills, gestures and language development remains understudied in these groups. More insight into this relationship is necessary given the prevalence of impairments in these domains in children (with EL of) ASD.

Objectives: To provide more insight into the potentially mediating role of gestures on the relationship between motor skills and language development in a population at risk for impairments in these domains.

Methods: As part of a longitudinal study we investigated gestures, motor and language skills in 40 children. 26 children were siblings of children with ASD, thus with an EL for ASD (EL group). The control group (TL) consisted of 14 children. At fourteen months, early and late gestures were examined with the Dutch version of the MacArthur-Bates Communicative Development Inventory. Fine and gross motor skills were observed with the Mullen Scales of Early Learning (MSEL). The MSEL was also used to obtain scores for receptive and expressive language at 36 months. Intercorrelations were assessed using Spearman's rho and group differences were assessed with Wilcoxon signed-rank tests while correcting for multiple comparisons. Mediation analyses were executed using regression analysis and bootstrapping with 1000 iterations. Early and late gestures were investigated as possible mediators on the relationship between gross and fine motor skills on the one hand and receptive and expressive language on the other.

Results: We observed medium to high significant correlations (ranging from .34 to .69.) between variables, except between early gestures and gross motor skills. Group differences were only observed for expressive language and late gestures, with the TL group scoring better on all variables (all p's <.008). The EL group showed substantial within-group variance in all variables. Regression analyses evaluating the influence of gross motor skills on receptive language showed no significant effect for either group separate. When assessing this influence on the continuous sample however, the analysis yielded a significant effect. For the EL group only we found a significant effect of gross motor skills on expressive language and this effect was fully mediated by late gestures (p = .01). However, when adjusting for multiple comparisons, the effect did not survive.

Conclusions: Our results show a trend suggesting that late gestures do indeed mediate the relationship between gross motor skills and expressive language in a population at risk for impairments in these domains. This suggests that it could be important for clinical practice to pay closer attention to the gesture use of children with an increased likelihood of ASD given their potential influence on language outcome. More research however is needed to confirm this finding, given the limited sample size of the current study.

417.064 *(Poster)* The Weak Link- Hypotonia in Infancy and the Autism Spectrum

L. V. Gabis[1,2], *M. Shaham*[3], *M. Daloya*[3], *O. Leon Attia*[4], *S. Shefer*[5], *R. Rosenan*[6] *and A. Halevy*[3], *(1)Pediatrics, Sheba Medical Center, Rehovot, ISRAEL, (2)Pediatrics, Sheba Medical Centre, Tel-Hashomer, Ramat Gan, Israel, (3)Statistics, University of Haifa, Haifa, Israel, (4)Child developement Center, Sheba Medical Center, Tel Hashomer, Israel, (5)Shild Development Center, Sheba Medical Center, Tel Hashomer, Israel, (6)Bar-Ilan University, Tel Aviv, ISRAEL*

Background: Since the diagnosis of ASD is clinical, the age by which diagnosis is given- is influenced by the presented symptoms and concerns. Recently it was recommended that the evaluation should be performed at a younger age, and that a diagnosis made during the second year of life is stable. The earlier the intervention, the more effective it is in improving functioning. Accurate identification of easy to recognize, measurable and reliable "red flags" is paramount to the improved outcome.

Objectives: We suggest that low muscle tone- hypotonia, is a sign that meets the above criteria of consistency and reliability, and may serve as an early "red flag" to prompt neurodevelopmental evaluation and autism diagnosis.

Methods: Comparing age distributions and testing for significance of rates of ASD in the presence of muscle-tone indicators, as reported in the Keshet database. A machine learning algorithm was used to construct a predictive model in order to further enhance the significance of the observation to ASD diagnosis.

Data set:

Keshet center database of children diagnosed at the child developmental center from 2010 to 2018. A machine learning algorithm was used to construct a predictive model. Data was cut off at 2 years of age, in order to facilitate a condition where the sum of diagnoses given to an individual is un-known after 2 years, making an attempt to predict based only on diagnoses given up to that point.

Results: A dataset of 5280 children (75% less than 12years old), 1659 with ASD, 207 of them diagnosed before age of two years. Examining the full dataset reveals that while the mean age of ASD diagnosis in the absence of hypotonia is around 5 years for males and 4 for females, it will decrease significantly in the presence of hypotonia, by an average of 2 years for males and 1.5 years for females.

Distributions of age at first ASD diagnosis and significance:

Since the actual diagnosis of hypotonia is transient by nature and decreases with age, we further cut the overall data set to children diagnosed before age seven. The age for first diagnosis remained consistently lower for both males and females by one year and in ½ year respectively in the presence of hypotonia. Similarly, a predictive model showed 90% confidence to a significant difference in males for the probability of ASD in the presence of hypotonia and torticollis, if diagnosed before the age of 2 years.

Conclusions: Early signs and symptoms such as lack of eye contact can be recognized during the first year of life, and motor gaps such as head lag, hypotonia and motor asymmetries should prompt a more extensive evaluation.

We proved that low muscle tone is a recognizable marker of ASD. It is also a marker of severity, since it adds delay in motor milestones to the language and communication delays so children with ASD and hypotonia are more likely to present with global developmental delay, and subsequent Intellectual Disability, which accounts to more severe ASD.

417.065 *(Poster)* Understanding the Development of Large-Scale, Automatically Identified White Matter Tracts in Typically Developing Infants

L. Li[1], *M. Zeydabadinezhad*[2], *A. Klin*[3], *W. Jones*[3] *and S. Shultz*[3], *(1)Marcus Autism Center, Children's Healthcare of Atlanta, Emory University, Atlanta, GA, (2)Emory University, Decatur, GA, (3)Marcus Autism Center, Children's Healthcare of Atlanta and Emory University School of Medicine, Atlanta, GA*

Background: Establishing growth curves of white matter tract development in typical infancy is critically needed for identifying deviations therefrom in infants later diagnosed with autism spectrum disorder (ASD)[1]. Diffusion tractography is the only available method for mapping infant white matter development non-invasively and longitudinally[2]. However, traditional methods of delineating infant white matter tracts suffer from several limitations: (1) it is time consuming to delineate tracts in a large cohort; (2) it requires extensive expertise in neuroanatomy; (3) large inter- and intra-experimenter variability exists; (4) only about a dozen major fiber tracts can be feasibly studied using manual delineations and (5) tractography performed in the template space can be limited by the complexity of models supported by the template data. Due to these limitations, we implemented a framework to automatically delineate a large number of fiber tracts in infants without the need for manual interventions. This approach will accelerate our understanding of early white matter development in infants with and without ASD.

Objectives: The objective is to implement an automatic framework to derive large number of fiber tracts in infants without neuroanatomy expertise and manual interferences.

Methods: *Participants:* 33 typical developing infants (age = 113(54) days; 10 females) were enrolled. *Longitudinal Data Sampling:* DTI data were collected from each infant at three pseudorandom time points between birth and 6 months, yielding a total of 63 scans. *Data Acquisition*: Data were collected on a 3T Siemens Trio system with 32-channel head coil. Multiband MRI sequences that simultaneously acquire several slices of data[3] were used. DTI parameters are: TR/TE of 6200/74ms, a multiband factor of 2 combined with a GRAPPA factor of 2, FOV of 184×184, spatial resolution of 2mm isotropic, b=0/700 s/mm^2, 61 diffusion directions. *Data Processing*: Data were preprocessed for susceptibility and eddy-current distortions using FSL. A two-tensor with Unscented Karman Filter method was used to delineate whole-brain tractography in each infant's diffusion space[4]. After whole-brain tractography was derived, these tracts from infants were mapped onto a fiber atlas. 800 fiber clusters were automatically derived and then grouped into 58 deep fiber tracts and 198 superficial fiber tracts[5]. Microscopic properties of these tracts were indexed by tensor-derived scalar measure, fractional anisotropy(FA).

Results: Unlike the registration of anatomical T1 and T2 images in which white matter and gray matter in infants younger than 6 months tend to have reversed imaging contrasts compared to older infants, whole-brain tractography in infants remain similar in terms of morphology as that in adults, resulting in less challenges in aligning whole-brain tracts. 58 deep white matter tracts were identified to form anatomically meaningful tracts in each infant's original space. Subsidiary association fibers with protracted development such as SLF III can be probed and studied for their developmental changes (Fig.1).

Conclusions: Aimed to overcome many issues that plagued white matter connectivity studies in infants using conventional methods, the current novel and automatic framework can perform tractography analysis on large infant cohorts, studying both deep and superficial white matter tracts and without the need for manual interventions.

417.066 *(Poster)* What Are the Odds?: Predicting the Likelihood of Negative Episodes in Toddlers with ASD Using Parent and Child Behaviors

A. M. Dimachkie[1]*, K. Sterrett*[2]*, A. Gulsrud*[3] *and C. Kasari*[4]*, (1)Human Development and Psychology, UCLA, Los Angeles, CA, (2)University of California Los Angeles, Los Angeles, CA, (3)UCLA Semel Institute for Neuroscience & Human Behavior, Los Angeles, CA, (4)University of California, Los Angeles, Los Angeles, CA*

Background: Individuals with ASD exhibit deficits in emotion regulation (ER) (Konstantareas and Stewart, 2006). These impairments can result in poorer response to intervention and treatment (Jahromi et al, 2012). Thus, preventing challenging behaviors and negative episodes may help to improve children's intervention outcomes. It is known that parents play an important part in co-regulating their toddlers with ASD (Gulsrud et al., 2011), but there have been no attempts to describe how parent and child co-regulation strategies interact to increase or decrease the likelihood of negative or disruptive behavior in real time.

Objectives: This study aims to identify specific parent and child behaviors that make a negative episode more or less likely to occur within parent child interactions.

Methods: 71 toddlers with ASD (24 – 36 months) completed a 3-minute distress task at entry into the study based upon the Lab-TAB distress task used with typically developing preschoolers (Goldsmith, Reilly, Lemery, Longley, & Prescott, 1999). Toddlers were given a locked toy box and a ring of keys and encouraged by parents to open the box. Videos of the task were coded in 10-second intervals for child negativity, child ER strategies and parent co-regulation strategies. Each child had a total of 17 intervals leading to 1207 total intervals across children. Each interval was considered a unique measurement period. Mixed effects logistic regression was used to account for the nested structure of the data (intervals within child) with child ER strategy, parent co-regulation strategy and parent responsiveness entered as categorical predictors of the presence of negativity in the following interval (i.e. interval 2 strategies predicting interval 3 negativity) while controlling for cognitive ability (MSEL). All results are reported in terms of odds-ratios.

Results: The full table of results including estimates and confidence intervals is provided below. Overall, the confidence intervals for the estimates were large. Children's use of tension release (i.e: high energy behavior with no instrumental purpose such as hand-flapping or kicking legs) was 3 times more likely to occur preceding a negative episode. In contrast, parental use of emotion regulation strategies and children's use of distraction reduced the likelihood of a negative child episode by 34% and 39%, respectively, although the confidence interval for these two estimates crossed 1. Lastly, parental non-responsiveness was almost twice as likely to precede an episode of child negativity compared to parental responsiveness (5.5 and 2.75 increased likelihood respectively).

Conclusions: Several notable findings emerged from these analyses. Firstly, the use of tension release appeared to be an antecedent of dysregulation, rather than an emotion regulation strategy. Additionally, children's use of distraction and parents' co-regulation strategies decreased the likelihood of dysregulation, although the large confidence interval speaks to the variability in the sample. Lastly, parents categorized as non-responsive were 2 times more likely to have a child have a negative episode in the following interval than parents who were categorized as responsive. These findings indicate the need for a targeted, parent-mediated intervention for parents and their young children with ASD.

417.067 *(Poster)* "Differentiation Time Window" and Different Pattern of Gesture Use in Infant Siblings of ASD

L. Liu[1], *H. Deng*[1], *S. Lv*[2] *and Q. Ye*[1], *(1)Child Developmental & Behavior Center, Third Affiliated Hospital of SUN YAT-SEN University, Guangzhou, China, Guangzhou, Guangdong, China, (2)Child Development and Behavior Center, Third Affiliated Hospital of SUN YAT-SEN University, Guangzhou, China*

Background: Researches have found significant group differences of gestures between infant siblings of autism spectrum disorder (ASD) and infants with no family history of ASD, with high-risk infants (HRA) producing fewer gestures compared to their low-risk peers (LRA). Based on these differences, fewer gestures at 12-14 months of age may be an early sign of ASD.Considering a few previous studies suggest that the quality of early gesture in HRA is also different from LRA and remains unclear, the analysis of more fine-grained communicative gestures, may lend deeper insight into the earliest emerging communicative differences.

Objectives:

1. To explore the "differentiation time window" of early gestures between HRA and LRA from both quantity and quality perspectives.
2. To explore the different pattern of gesture use at the differentiation time.

Methods: This study includes three cross-sectional analysis of gesture use at 9 months old (N_{HRA}=17, 10 males; N_{LRA}=12, 5 males), 12 months old (N_{HRA}=20, 16 males; N_{LRA}=12, 7 males), 15 months old (N_{HRA}=16, 13 males; N_{LRA}=9,3 males). There were no significant group differences of age. Gestures were examined using an observational measure adapted from the Communication and Symbolic Behavior Scales Behavior Sample (CSBS-BS; Wetherby & Prizant,2002) and a new coding manual was developed. All Infants were assessed by The *Griffiths* Mental Development Scales-*Chinese* (GDS-C) across six separate subscales: Locomotor, Personal-social, Language, Eye-hand co-ordination, Performance.

Results: We found that there were no significant group differences in GDS-C results at 9、12、15 months old and in gestures at 9 and 12 months old. The group differences of gestures are detectable at 15 months old ($p<0.05$, Table 1). Among these different gestures, overall gesture frequency, BR gesture, integration gesture and compliant gesture have strong positive correlations with personal-social Score and language Score($r>0.6$, $p<0.05$) in HRA. While language Score only has strong positive correlations with gestures integrating verbalization in HRA($r>0.6$, $p<0.05$).

Conclusions: Our findings show that the potential differentiation time window of early gesture ranges from 12 to 15 months old, at which time the differences of motor, Social, language skills between HRA and LRA may yet not appear. Our findings show different pattern of gesture use in HRA at 15 months old: low frequency (overall frequency and frequency of behavioral regulation) and poor communication quality (less initiative, less integration with Vocalization or verbalization, less compliant), and is related to personal social and language skills. Compared to LRA, this gesture pattern of HRA may be more relevant to language. By implication, risk group differences have been informative in suggesting that gesture may be a risk factor for ASD, early gesture use should be closely monitored and assessed in high-risk infants to identify those who will be diagnosed as ASD ASD at a later age.

Early Phase Drug Discovery

POSTER SESSION — **EARLY PHASE DRUG DISCOVERY**
418 - Early phase drug discovery Posters

418.001 *(Poster)* Dopamine D1 Receptor Antagonism Influences Social Behaviour and Locomotion in Juvenile Zebrafish

L. Westberg*, Department of Pharmacology, University of Gothenburg, Gothenburg, Sweden*

Background: Autism spectrum disorder (ASD) is a neurodevelopmental disorder severely affecting the life of 1% of the population and substantially increases the risk of other psychiatric conditions. Social deficits are a hallmark for autism, and although there are promising findings suggesting that the neuropeptide oxytocin and a handful of other drugs may reduce this core symptom there are no established pharmacological treatment options available. The overall goal of our research is to identify pharmacological tools for reversing social deficits in animal models with validity for autism. Zebrafish offers a great in-vivo model to run high-throughput phenotypic screens for potential drug therapies. To date, most high-throughput studies in zebrafish measures locomotion or anxiety-like behavior in very young larvae. High-throughput drug screens for social interaction are needed to provide better possibilities for finding drugs that can improve social abnormalities seen in autism and related disorders. While social interaction in zebrafish is a good model to study etiology and treatment of such disorders, raising fish to adulthood has significant time and cost associated with it. Zebrafish larvae show robust social interaction at 3-weeks of age and we are using a paradigm that allows efficient and higher-throughput testing of social interaction in larval fish. Moreover, we have recently shown that deficient oxytocin signalling decrease social preference in zebrafish. This study aims to investigate to what extent dopamine receptor D1 modulates social preference behavior in young zebrafish. Dopamine is known to play a prominent role in social reward and has been suggested to be relevant for the social deficits seen in ASD patients. Previous studies have shown that a dopamine D1 receptor antagonist (SCH-23390) can reduce social preference in adult zebrafish.

Objectives: In this study, we investigate if SCH-23390 may alter social behaviour in three-week-old juvenile zebrafish.

Methods: The behavioural experiments were performed in arenas flanked by social (fish stimuli) and non-social compartments (empty). Test fish were treated with 0, 1 or 10 mg/L of SCH-23390 for either 30 or 60 minutes. Time and location in the arenas were scored and a social preference index was calculated. A separate control test for studying movement, vision and motivation was performed by addition of artemia. We used t-tests or repeated-measures multi-variate ANOVAs as appropriate to determine statistical significant ($p < 0.05$) differences between the comparison groups.

Results: Fish treated with 10 mg/L preferred the social stimulus side less than control fish and those treated with 1 mg/L of SCH-23390 after both 30 and 60 minutes exposure. Moreover, a decrease in the distance travelled was observed in both drug-treated groups compared to the control group. However, there was no correlation between distance moved and social preference index. The control test showed an increase in movement after addition of artemia in all treatment groups, which indicates that the fish can detect and react to food stimuli also when dopamine D1 receptor signalling is inhibited.
Conclusions: Our results suggest that dopamine D1 receptors may regulate, independently of one another, social preference and locomotion in developing zebrafish.

Education

PANEL SESSION — **EDUCATION**
211 - Parents and Teachers: Collateral Benefits for Children with ASD

Panel Chair: Lisa A. Ruble, *University of Kentucky, Lexington, KY*

Discussant: Brian Boyd, *Juniper Gardens Children's Project, University of Kansas, Kansas City, KS*

At the conclusion of early intervention, children with autism spectrum disorder (ASD) transition to school with all of its requisite challenges, such as getting along with peers and teachers. Although about 40% of children with ASD are included in general education classrooms, their teachers may not have received the training to accommodate them and their parents. Parent-teacher communication quality has implications for both coordination of educational goals for school and at home, as well as for the development of optimal student-teacher relationships. Four papers address aspects of parent and teacher interaction that have positive, collateral effects on children. The first paper reports on a parent-to-parent program (Parents Taking Action) to help urban, low income Black parents understand ASD and to better prepare them and their children for school (Dababnah et al.). The second paper involves parents and teachers (K-5) working more effectively with each other as part of the Partners in School model (Azad et al.). The third paper examines whether parent-teacher relationships have any bearing on student-teacher relationships (Losh et al.). The final paper presents the first phase of the development of an IES-funded intervention to improve student-teaching relationships (Smooth Sailing; Bolourian et al.).

211.001 *(Panel)* A Feasibility Study of a Peer-to-Peer Parenting Program for Urban Black Families Raising Children with Autism
S. Dababnah[1], *W. E. Shaia*[2], *I. Kim*[3] *and S. Magaña*[4], *(1)University of Maryland, Baltimore, Baltimore, MD, (2)Social Work Community Outreach Service, University of Maryland Baltimore, Baltimore, MD, (3)School of Social Work, University of Maryland, Baltimore, Baltimore, MD, (4)Steve Hicks School of Social Work, University of Texas at Austin, Austin, TX*

Background: While racial and socioeconomic disparities in autism diagnoses and treatment in the U.S. have been well-documented, there is a dearth of intervention research focusing on low-income families of Black children with autism.
Objectives: We will report the results of a feasibility trial of an adapted version of a peer-led, 14-week manualized program, *Parents Taking Action* (PTA), among urban caregivers raising Black children with autism in low-income neighborhoods. PTA aims to increase autism knowledge, improve advocacy skills, build social support, reduce parenting stress, and manage challenging child behavior.
Methods: We used a mixed-methods approach to adapt, implement and evaluate PTA. We formed an advisory board composed of local parents, providers, and other stakeholders to recommend program adaptations. We trained four Parent Leaders (caregivers of Black children 9 years and older with autism) to deliver the in-home program to caregivers of Black children ages 8 and younger with or at-risk for autism. Social workers provide case management for material needs. Participants complete measures on service use, parenting stress, depression, autism knowledge, family functioning, and child behavior before, mid (session 7), and after the 14-week program. Parent Leaders submit fidelity checklists weekly. Additionally, researchers observe the Parent Leaders twice during the 14-week program for fidelity.
Results: We will present preliminary results on program feasibility and participant baseline results. Parent Leaders have delivered the program sessions to seven mothers with a high level of fidelity. All participants have significant concrete needs, such as homelessness and food insecurity. The average time between sessions is three weeks, with the primary reasons for session cancellations related to meeting these material needs.
The average participant age is 32.6 years (SD=5.1). Approximately 29% of the participants are single; the remaining are married (29%) or living with a partner (43%). 80% of participants have annual incomes lower than $40,000. The average child age is 5.7 years (SD=1.4). The average child age when parents had first developmental concerns was 14.6 months (SD=8.2) and the average age of autism diagnosis was 3.9 years (SD=1.4). About 66% of participants indicated they were stressed and 57.1% of participants reported they were depressed at pre-intervention assessment. At baseline, 43% of participants indicated they understood their child's strengths, needs and abilities and about 30% of participants indicated they had access to local autism resources and supports. Approximately 14% of parents reported they had support systems, knew their rights, and advocated for their child at pre-intervention assessment.
Conclusions: We describe our efforts to culturally and contextually adapt an intervention aimed at families living in low-income urban neighborhoods, with significant input from a community-based advisory board. Parent Leaders can deliver the program as intended in the PTA manual. At baseline, participants on average reported experiencing high levels of stress and depression, and limited access to local autism services and supports. Delivering the program on a weekly basis is challenging due to participants' other needs. Our findings can inform current and future efforts to better serve communities experiencing the multiple effects of poverty.

211.002 *(Panel)* Partners in School: An Implementation Strategy to Optimize Parent-Teacher Communication for Children with Autism Spectrum Disorder

G. F. Azad[1]*, K. Minton*[2]*, Y. Jang*[2] *and R. Landa*[2]*, (1)Department of Mental Health, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, (2)Center for Autism and Related Disorders, Kennedy Krieger Institute, Baltimore, MD*

Background: Effective communication is essential to ensure that parents and teachers are addressing pervasive concerns and implementing the same interventions across settings (i.e., problem-solving), as well as for sustaining high quality relationships. However, little is known about what communication skills parents and teachers need to successfully work together.

Objectives: To examine key areas for optimizing parent-teacher communication in the *Partners in School* model. In this implementation strategy, parents and teachers: (1) identify a mutual concern, (2) define mutually agreed upon evidence-based interventions to address the concern, and (3) implement those steps at home and school. We examined the communication skills that parents and teachers reported needed training in, and the extent to which those communication skills were related to problem-solving and relationship quality.

Methods: Participants were 21 teachers and 36 parents of children with ASD. Parents were mothers (72.2%) and averaged 35.6 (SD = 7.5) years of age. They identified as white (44.4%), black/African American (41.7%), American Indian/Native Alaskan (5.6%) and Asian (8.3%). Almost a third (36.1%) reported an annual income of less than 45K (36.1%). Teachers were all female, with an average age of 33.5 years (SD = 10.3). Approximately 86.1% of the teachers were white, 16.7% were black/African American, and 2.8% were Asian. Teachers reported teaching for 6.8 years (SD=7.4); 70% reported no training in working with parents. The students were in pre-kindergarten through 5th grade, and were on average 5.4 years (SD = 2.5). Parents and teachers completed the Participation in Problem-Solving Scale. Relationship quality was assessed with two subscales (joining and communication to the other) on the Parent-Teacher Relationships Scale.

Results: On average, teachers reported needing communication training in information exchange (1.81; SD=.51), time management (2.00; SD=.68), and identification of problems (2.15; SD=.47). Linear regression models suggested that teachers with better time management also reported more problem-solving with parents (B= 2.92, p= .007). Age and time management were related to relationship quality. More specifically, older teachers reported more joining (i.e., partnership) with parents (B= 2.23, p= .034) and more positive communication with them (B= 2.33, p= .027). The extent to which teachers managed their time was also related to joining with parents (B= 2.26; p= .032) and communicating more effectively with them (B= 2.59, p= .015). On average, parents reported needing communication training in intervention adherence (2.20; SD=.54), time management (2.36; SD=.49), and shared decision-making (2.45; SD=.46). For parents, older age was also associated with more joining with teachers (B= 2.77, p= .010). The better parents managed their time, the more effective their communication was with teachers (B= 2.41, p= .023).

Conclusions: These results highlight the communication skills that parents and teachers need to more effectively work together, and sustain positive relationships with each other. Our findings also indicate that age and time management skills are essential to consider in parent-teacher communication. This information was used to develop parent-teacher communication training as part of the *Partners in School* model.

211.003 *(Panel)* The Impact of Parent-Teacher Relationships on Student-Teacher Relationship Development for Young Students with ASD

A. Losh[1]*, A. Eisenhower*[2] *and J. Blacher*[1]*, (1)Graduate School of Education, University of California Riverside, Riverside, CA, (2)University of Massachusetts Boston, Boston, MA*

Background: Student-teacher relationship (STR) quality in early elementary is a key predictor of later academic, social, behavioral, and emotional functioning (Zeedyk et al., 2016). In addition to facing unique challenges during the transition into early school due to social communication barriers and commonly co-occurring behavioral challenges, students with autism spectrum disorder (ASD) have poorer-quality STRs (i.e., higher conflict and lower closeness; Blacher et al., 2014). Specific risk factors for poorer-quality STRs include externalizing behaviors, autism symptom severity, and parent intrusiveness, whereas protective factors include IQ and language skills (Caplan et al., 2016). Parent-teacher relationships (PTRs), which have been found to predict student engagement and socio-behavioral functioning among typically developing (TD) students, may be another key predictor of STRs (Kim et al., 2013). Externalizing behavior problems are a risk factor for poorer-quality PTRs (Garbacz et al., 2016), thus, students with ASD may be at compounded risk for poorer academic, social, and behavioral outcomes via lesser-quality PTRs and STRs. Although child risk and protective factors are emerging, the conjunction of PTRs and child factors in STR development for young students with ASD remains unexplored.

Objectives: The present study examined whether PTR quality predicted change in STR quality over the course of one school year for young students with ASD, above and beyond child background predictors of STRs.

Methods: Participants were 135 students with ASD (4-7 years) who were enrolled in a longitudinal study examining early school transition for students with ASD (see Table 1). At the beginning of the school year (Time 1), their teachers completed the Parent-Teacher Relationship Scale (PTRS) and Student-Teacher Relationship Scale (STRS), their parents completed the CBCL and SRS, and students completed the WPPSI and CASL. At the end of the same school year (Time 2), teachers again completed the PTRS and STRS (see Table 1).

Results: Bivariate Pearson correlations between PTRS Time 1 scores, child characteristics (WPPSI, CASL, CBCL externalizing, SRS), and STRS Time 2 scores revealed significant correlations between STRS Time 2 and the following: (a) PTRS Time 1, (b) WPPSI, (c) CASL, and (d) STRS Time 1 (see Table 2). In order to assess whether PTRS scores significantly predicted change in STRS over the school year above and beyond WPPSI and CASL, multiple regression analysis was conducted using STRS Time 2 as the outcome and STRS Time 1 as a covariate. The model explained 34% of the variance in STRS Time 2, but only PTRS significantly predicted outcomes alongside the covaried STRS Time 1 (see Table 2).

Conclusions: Findings indicate that PTR quality at the beginning of the school year predicted change in STR quality over the remainder of the school year for students with ASD, above and beyond child predictors of STR quality. Because STRs are critically important for student outcomes across several domains, and young students with ASD are at risk for poorer-quality STRs, future research should explore specific key characteristics of positive and negative PTRs and aim to develop teacher interventions to promote proactive, positive PTRs in this at-risk student population.

211.004 *(Panel)* Smooth Sailing: Iterative Development of a Teacher-Directed Intervention

Y. Bolourian[1]*, N. Hamsho*[2]*, A. Eisenhower*[3] *and J. Blacher*[4]*, (1)Graduate School of Education, University of California, Riverside, Riverside, CA, (2)Department of Psychology, University of Massachusetts, Boston, Boston, MA, (3)University of Massachusetts Boston, Boston, MA, (4)Graduate School of Education, University of California Riverside, Riverside, CA*

Background: Funded by IES, the *Smooth Sailing* study involves general education teachers, grades K-2, in the iterative process of developing a teacher-directed professional development (PD) intervention to improve teacher readiness to work with students with autism spectrum disorder (ASD), including their ASD-specific knowledge, their self-efficacy to teach students with ASD, and the quality of their relationships with students with ASD. The intervention contains three components (i.e., educational modules, coached parent-teacher interviews, and semi-structured student-teacher interactions). The current study presents data from initial focus groups conducted with partnering general education teachers to obtain their perceptions and input on their experiences with children with ASD in their classrooms, including a description of the initial iterative development process of the PD program.

Objectives: Primary aims of the focus group were to understand general education teachers' perspectives of (1) autism, (2) pedagogical practices for including students with autism in the classroom, and (3) strategies for building positive relationships with these students. Ultimately, these perspectives were utilized in the iterative development of the intervention, particularly in the development of the student-teacher relationship-building component of the program, the *Time2Connect* sessions.

Methods: Cross-site focus groups were conducted with participating teachers (*n*=8, California; n=10, Massachusetts). Teachers were from schools that served culturally and socioeconomically diverse populations. Three prompts were pre-determined to address the objectives of the focus group. Participants engaged in a series of guided activities (i.e., free-listing, ranking, and pile-sorting). In response to prompts, teachers were asked to write down words/phrases on individual cards. Next, they reviewed their cards and the cards of other participants to individually rank responses. Saliency scores were calculated (Grinker et al., 2015; Miguel & Cohen, 2018), with higher scores indicating greater consensus across participants. Finally, participants were asked to sort cards under a single category and label them based on determined categories. Pile-sorting helped determine which responses were similarly perceived.

Results: When asked what words/phrases came to mind when thinking about their student with ASD, recurring themes included Social Communication Difficulties; Restrictive, Repetitive Behaviors and Sensory Issues; Emotion-Regulation Difficulties; and Strengths (e.g., charming, uniquely talented). The theme with the highest saliency score was Social Communication Difficulties; lowest saliency score was associated with Strengths and Positive Attributes. The same procedures for developing saliency scores will be used for analyzing inclusion practices and relationship-building strategies.

Conclusions: Findings indicate that teachers recognized difficulties associated with ASD, but did not consistently identify positive attributes of ASD. Findings also reflect a high level of awareness around ASD among participating teachers, given that two out of the four emerging themes in their perceptions of ASD align with the core DSM-V diagnostic criteria. Next steps include conducting a single case research design (SCRD) study to collect observation data and determine the effects of the intervention in the classroom. A description of the iterative development process as well as preliminary findings from this SCRD will be presented. We expect the *Smooth Sailing* program to lead to improved student-teacher relationship quality between young students with ASD and their general education teachers.

ORAL SESSION — **EDUCATION**
312 - Autism in the Schools: Contexts and Supports

312.001 *(Oral)* Making on and Off the Spectrum: An Inclusive, Strength-Based Program to Support STEM Interests and Related Skills in Middle-School Students

Y. L. Chen[1]*, K. P. Koenig*[1]*, W. Martin*[2]*, R. Vidiksis*[2] *and K. Murthi*[1]*, (1)Occupational Therapy, New York University, New York, NY, (2)EDC, New York, NY*

Background: Students on the spectrum have strengths well-suited to STEM careers, such as the ability to engage in systemizing thinking and excellent attention to detail (Baron-Cohen et al., 2009). However, their challenges in social interaction and a lack of opportunities to engage in engineering practices may hinder their achievement of full potential. To support their STEM career preparation in inclusive education, this project collaborated with STEM education program developers and autism educators to develop an inclusive engineering design program, the "Maker Club". The program features a strength-based approach that utilizes students' interests in hands-on engineering practice.

Objectives: To investigate the feasibility of the Maker club program in public middle-schools and its effectiveness on engineering practice and peer engagement.

Methods: The program was implemented in three public middle-school in a large urban area by eight teachers in those schools. A total of 150 students (60 with autism and 90 without) participated in the program over 2017-2019. Data collection included:

- Field observations of every program session in 2017 (n=55)
- Mid-year focus group with all teachers (n=2) and post-implementation focus groups with the teachers at each school (n=15)
- Program implementation logs from teachers (n=41)
- Parent interviews in two schools during student presentations
- Video-based social behavior observation over 14 45-min program sections in one school. Trained observers coded each social initiation, its purpose (social/functional), and type (seeking/ sharing/ attending/ offering/ joking), and each social response and its quality (topic-extending/ topic-relevance/ tangent).

Results: Participating teachers successfully implemented the Maker Program without assistance after the first-year piloting. Field observation and teacher report showed high-level student engagement, with all students with autism completed the entire curriculum and created individual design projects. Teachers reported that students with autism required less additional support then in typical classes, such as visual demonstration of complex steps and assistance with manual dexterity. Further, we observed that students spontaneously integrated individual interests in engineering practice and showed great self-determination in creating individual designs. Parents reported that students were highly motivated by the program and showed increased knowledge and interest in engineering.

Positive peer engagement was also observed. Teachers reported observing increased peer interaction in students with autism during the program than in regular classes, including conversing about their projects and helping each other. Structured behavior observation showed no significant differences in rates of social initiation (p=0.11) and response (p=0.11) between students with and without autism (Fig.1). Patterns of social behaviors between students with and without autism were similar, except for initiation purposes (Fig.2, p=0.02). Ratios of initiation types and response qualities were similar between groups (initiation type: p=0.30; response quality: p=0.59). Both groups initiated interaction primarily by sharing and seeking (Fig.3) and responded to peers with more topic-relevant and extending responses (Fig.4).

Conclusions: The Maker Club was a feasible extracurricular engineering practice program that can be sustainably implemented in autism inclusion public middle-schools. Demonstrating promising outcomes on engineering practice and peer engagement, the program is supported by the National Science Foundation for expansion to broader schools and grade-levels.

312.002 *(Oral)* School-Based Professionals' Knowledge and Selection of Evidence-Based Practices for Students with Autism

K. L. Morin[1]*, A. Sam*[2]*, B. Tomaszewski*[3,4,5]*, V. Waters*[6] *and S. Odom*[3]*, (1)Lehigh University, Bethlehem, PA, (2)Frank Porter Graham Child Development Institute, Carrboro, NC, (3)Frank Porter Graham Child Development Institute, University of North Carolina at Chapel Hill, Chapel Hill, NC, (4)Psychiatry, University of North Carolina at Chapel Hill, Chapel Hill, NC, (5)TEACCH Autism Program, University of North Carolina at Chapel Hill, Chapel Hill, NC, (6)Frank Porter Graham Child Development Institute, University of North Carolina at Chapel Hill, Carrboro, NC*

Background: In response to the national focus on evidence-based practices, the National Professional Development Center on ASD (NPDC) conducted a large-scale, systematic review to identify effective interventions for students with autism (Wong et al., 2015). As a result, the NPDC identified 27 evidence-based practices for students with autism which they have translated into user-friendly online modules to teach practitioners how to implement the practices. As of May 29, 2019, AFIRM had 78,031 registered users from 179 countries and this number has continued to increase since the modules were launched in 2015 (Sam et al., 2019). Although AFIRM has a wide user base, the majority of users are school-based professionals. Given the large amount of data that are generated from school-based users, researchers and administrators have the opportunity to learn about the selection of, and knowledge about, evidence-based practices for students with autism. This has implications for researchers interested in how to effectively design a socially valid professional development model for school-based professionals.

Objectives: The purpose of this study was twofold: to analyze (1) school-based AFIRM user data to determine if there are differences in the selection of evidence-based practices by occupation, and (2) pre-test scores for each evidence-based practice to determine if there are differences in the pre-test knowledge of school-based professionals by occupation.

Methods: Data for this study came from a total of 22,775 unique AFIRM users who identify as a school-based professional and completed a total of 67,546 pre-tests across the 27 modules. Overall usage data were analyzed with descriptive statistics, and a one-way ANOVA was conducted to examine the differences in pre-test knowledge of evidence-based practices for school-based professionals by occupation. Post-hoc comparisons were examined using the Games-Howell test due to unequal sample sizes across occupations, using a Bonferonni correction for multiple comparisons ($p < .003$). Effect sizes were calculated as partial eta squares (η^2). Correlations were examined using Spearman's rho correlations among average pre-test knowledge of evidence-based practice and the average use of the evidence-based practices per month.

Results: Overall, there were significant differences in average pre-test knowledge across evidence-based practices by occupation, $F (5, 22{,}769) = 167{,}55$, $p < .001$, $\eta^2 = .04$. Post-hoc comparisons indicated that the average pre-test knowledge of evidence-based practices for related service providers was significantly higher than all other occupations. Additionally, when considering the mean number of modules for which school-based professionals completed pre-tests, paraprofessionals selected to learn about the most evidence-based practices.

Conclusions: This study provides an important first step in increasing our understanding about the pre-test knowledge and selection of evidence-based practices for students with autism. By analyzing user data for the AFIRM modules, valuable insight is gained into which practices school-based professionals have more or less knowledge about and which practices are being selected more or less frequently. Although specific occupations had a higher pre-test knowledge of some practices than others, the average pre-test knowledge was generally low across all occupations and indicates school-based professionals continue to need training in evidence-based practices for students with autism.

312.003 *(Oral)* The Effects of Embedding Circumscribed Interest in Activities on the Engagement and out-of-Seat Behaviors of Children with Autism Spectrum Disorder

G. Kim[1]*, S. Lee*[2] *and J. R. Martinez*[1]*, (1)University of Kansas, Lawrence, KS, (2)Special Education, Ewha woman's Univ., Seoul, Korea, Republic of (South)*

Background: Engagement in academic and social activities within early childhood settings is critical for young children to achieve academically as well as for them to develop appropriately socially and emotionally (Hojnoski & Missall, 2010; Williford, Whittaker, Vitiello, & Downer, 2013). Young children with autism spectrum disorder (ASD) often exhibit challenging behaviors (e.g., out-of-seat behavior) that makes it difficult for them to engage in academic and social activities (McWilliam & Bailey, 1995). As a means to decrease the negative developmental outcomes associated with lack of engagement and challenging behaviors, efforts to address these behaviors in children with ASD and improve these children's engagement in academic and social activities within early childhood settings are necessary. The Division of Early Childhood (DEC) of the Council for Exceptional Children recommends practitioners to identify and use children's preferences to promote engagement in active learning, which in turn, can decrease challenging behaviors (DEC, 2016). For children with ASD, this can be achieved by incorporating circumscribed interest within classroom activities.

Objectives: The purpose of this study was to examine the effects of embedding circumscribed interests in large group activities on engagement and out-of-seat behaviors for young children with ASD in early childhood settings.

Methods: Three children (ages 3-5 years) with ASD exhibiting low levels of engagement and high frequency of out-of-seat behavior during large group activities in inclusive early childhood classrooms participated in this study. Prior to the implementation of the intervention, the participants' general education teachers, along with a special education teacher and the participants' caregivers, identified the circumscribed interest for each participant. The general and special education teachers collaboratively developed circumscribed interest embedded activity plans, which were implemented by the general education teachers in each participant's classroom. A multiple baseline experimental design across participants was used to examine the functional relation between circumscribed interest embedded activity and the engagement and out-of-seat behaviors. Each experimental session was videotaped for data collection purposes and the behaviors were measured using a partial interval recording system.

Results: Data across participants are displayed in the attached graphs. For all three participants, a functional relation was established between the intervention and increases in the levels of engagement in the target activities. Moreover, a functional relation was established between the intervention and decreases in the challenging behaviors exhibited by all three participants. The effects of the intervention generalized across stimuli and maintained after the intervention was discontinued. Interobserver agreement (IOA) data were collected on 25% of the randomly selected experimental sessions across all participants, for both target behaviors. Procedural fidelity data were collected on 35% randomly selected intervention sessions across participants. The mean IOA for engagement behavior was 99%, out-of-seat behavior was 100%, and the mean fidelity was 92%.

Conclusions: The results of this study illustrate the effectiveness of incorporating circumscribed interest into large group activities in early childhood general education classrooms on engagement and out-of-seat behaviors for young children with ASD. Data will be presented and discussed in terms of their implications for research and practice.

312.004 *(Oral)* Inclusion of Children with Autism Spectrum Disorder: Toward an Alignment between Teachers' Practices and Evidence-Based Models

I. Russo[1]*, F. Agrillo*[2]*, C. D. Zierhut*[3] *and P. Aiello*[4]*, (1)Dipartimento di Scienze Umane, Filosofiche e della Formazione, University of Salerno, Fisciano, Italy, (2)Dipartimento di Scienze Umane, Filosofiche e della Formazione, Università degli Studi di Salerno, Fisciano (SA), Italy, (3)Early Days Autism Center and Every Child, 510(c)3, Sacramento, CA, (4)Dipartimento di Scienze Umane, Filosofiche e della Formazione, University of Salerno, Fisciano (SA), Italy*

Background: In many countries worldwide Education Systems have attempted to implement Evidence Based Practices (EBPs) for children with Autism Spectrum Disorder (ASD) in inclusive settings. However, no single educational intervention is effective for all, and the diverse nature of abilities in the autism diagnoses requires general educators in inclusive classrooms to learn a range of skills and knowledge to be able to respond to the variety of needs of pupils with ASD. While the research community is increasing attention toward educators training on ASD and EBPs, teachers in inclusive schools face the challenges to maintain the focus both on individual needs of children with ASD and the rest of their peers.

Objectives: Our implementation research project in Sacramento, California was established to develop a training program on the Group-based Early Start Denver Model (G-ESDM) by Vivanti et al. (2017) while ensuring the educational inclusion of learners with autism in a community-based preschool. In the first exploration phase of this study, which utilizes the Active Implementation Frameworks by Fixsen, et, al. (2005), we explored possible alignment between teachers' practices and G-ESDM core components. In collaboration with teachers, the objective of this study was to assess the fit and examine the innovation of the G-ESDM in the school culture, organization, and structure.

Methods: Participants were early childhood educator in a community-based preschool: lead teachers (TE=8), instructional assistant (IA=13), and the director (DI=1). This study was conducted at baseline, before the G-ESDM in-service training commenced, and it utilizes quantitative and qualitative methods to identify specific enablers and barriers to the model. We assessed the fit and the innovation by comparing three core components of the G-ESDM with those of the school: curriculum program; daily schedule; and teachers' roles. Second we assessed teachers' skills at the baseline with ESDM and G-ESDM fidelity tools (Dawson, Rogers, 2010; Vivanti et al., 2017) in order to create a training program and to identify G-ESDM ingredients that teachers naturally implement in their practices. Third we analyzed teachers' tools for measuring child progress toward desired outcomes(Desired Results Developmental Profile) with the ESDM Curriculum Checklist.Teachers' perspectives on the G-ESDM, potential use of the G-ESDM as a classroom strategy, and barriers were identified through a questionnaire and guided discussions.

Results: Overall, teachers found G-ESDM valuable, but they identified some challenges. We found inhibiting factors, in the organization and culture of the school such as teachers retention to the training; teachers' reluctance to adapt specific part of the program, teachers' perception on their abilities to play with children with ASD.

Conclusions: Our study describes a process of obtaining quanti-qualitative information and feedbacks from frontline stakeholders who face the challenges of individualized programs for pupils with ASD and ensure the educational attainment of the class. Our implementation study provides a generalizable model for researchers to build community-based collaborations and promote an optimally use of the G-ESDM in mainstream classrooms. Future efforts should concentrate on developing training programs, which are feasible for teachers, whilst aligning, translating and applying EBP's to their educational practices.

POSTER SESSION — **EDUCATION**
419 - Education Posters

419.001 *(Poster)* ASD in the Classroom: Teacher Strategies Supporting High-Quality Student-Teacher Relationships.

M. Feldman[1]*, R. O. Rubin*[1]*, M. Hagler*[1]*, A. Eisenhower*[1] *and J. Blacher*[2]*, (1)University of Massachusetts Boston, Boston, MA, (2)Graduate School of Education, University of California Riverside, Riverside, CA*

Background: Children with autism spectrum disorder (ASD) are at risk for poor student-teacher relationship quality (STRQ). This trend is concerning because high-quality relationships with teachers promotes academic and social engagement (Eisenhower et al., 2015). Researchers have identified child factors that predict STRQ for children with ASD but have rarely examined the impact of teacher characteristics and behaviors. Teachers' use of structure and emotional support predict STRQ for children with ASD (Manti et al., 2013), as do teachers' level of experience and education (Caplan et al., 2016). Researchers have called for investigation of a wider range of teacher factors and examination of differences between general education and special education settings (Eisenhower et al., 2015).

Objectives: The current study sought to determine whether specific teaching strategies and aspects of teachers' professional preparedness promote or hamper STRQ and academic engagement. We also examined whether factors associated with these outcomes differ between general education and special education settings.

Methods: The sample included 122 young children (18% female; M_{age} = 5.5 years) who had confirmed ASD diagnoses and their teachers. Children were entering pre-K, kindergarten, or first grade at enrollment; 57% were in general education classrooms (43% special education). Data were collected in spring of two consecutive school years. Teachers reported on their professional preparedness (years taught, highest degree, professional training in ASD, self-perceived preparedness to teach children with ASD), use of specific teaching strategies (praise, proactive strategies, parental engagement, limit-setting, and punitive strategies), students' academic engagement (emotional and behavioral), and STRQ (closeness and conflict). Children also rated STRQ. Multiple linear regressions were used to predict teacher- and student-rated STRQ as well as students' behavioral and emotional engagement in school, controlling for students' STRQ and academic engagement at the end of the previous school year. Missing data were handled using FIML.

Results: In both general and special education settings, parental engagement predicted higher teacher-rated relational closeness. In special education (but not general education) settings, praise was positively associated with student-rated STRQ, and punitive strategies were negatively associated with student-rated STRQ. In general education (but not special education) settings, punitive strategies were negatively associated with students' behavioral engagement. Teachers' years of experience and self-perceived ASD preparedness were positively associated with student- and teacher-rated STRQ in special educational settings. Contrastingly, in general education settings, self-perceived preparedness was negatively associated with teacher-rated relational closeness, and years of experience was negatively associated with behavioral engagement.

Conclusions: This study found that the factors that promote or undermine STRQ and academic engagement differ significantly across general and special education settings, although parental engagement emerged as universally important for STRQ. Although punitive strategies appear to increase risk for negative outcomes in both settings, they appear to impact different outcomes. Contrary to study hypotheses, perceived ASD preparedness and years of experience were associated with better STRQ and engagement in special education classrooms but were negatively associated with these outcomes in general education classrooms. Teachers, particularly in general education, may benefit from support around the use of appropriate strategies with students with ASD.

419.002 *(Poster)* Achievement Emotions and Math Performance: The Role of Math Anxiety across Learning Contexts for Students with Autism

K. Howard[1]*, C. Labonté*[1]*, L. Trafford*[1]*, E. Gaudet*[2]*, N. Denomey*[1]*, R. Del Colle*[3]*, A. Lee*[1] *and H. M. Brown*[1]*, (1)Educational Psychology, University of Alberta, Edmonton, AB, Canada, (2)Educational Psychology, University of Alberta, Edmonton, AB, CANADA, (3)University of Alberta, Edmonton, AB, Canada*

Background: Among typically developing (TD) populations, a link between the role of achievement emotions (i.e., emotions connected to achievement activities and outcomes) and math performance exists (Pekrun, 2006). Since individuals with autism spectrum disorder (autism) experience challenges regulating their emotions (Samson et al., 2015), achievement emotions are likely to impact their performance in math as well. Studies examining mathematical performance in children with autism have focused primarily on cognitive and linguistic abilities as predictive factors (Miller et al., 2017), while the role of achievement emotions has received less attention. Additionally, there is a high comorbidity of autism and clinically-elevated anxiety (Lopata & Thomeer, 2014). Among TD children, research has associated math-related anxiety with poor math outcomes (Lichtenfeld et al., 2012). Researchers have demonstrated a similar relationship between test anxiety and math performance among students with autism (Oswald et al., 2016), however, the nature of this relationship across academic contexts remains unknown. Understanding how students with autism experience anxiety in math across learning contexts can help teachers better meet the emotional needs of these students.

Objectives: In the present study, the researchers explore how achievement-related anxiety across academic contexts predicts mathematical performance among students with autism through the following question: How does math-related anxiety in the contexts of class time, homework completion, and test writing predict math performance among students with autism above and beyond predictors of cognitive ability and expressive language ability?

Methods: Recruitment is ongoing, with a projected *N* expected to exceed 45 by April, 2020. Presently, 32 students diagnosed with autism aged 6 to 15 (*M*=10.24 yrs) completed the Basic Concepts composite of the *KeyMath-3 Diagnostic Assessment* to assess math performance. Participants also completed the Formulated Sentences subtest of the *Clinical Evaluation of Language Fundamentals, Fifth Edition* to assess expressive language ability, and age-appropriate versions of *Raven's Progressive Matrices* to assess non-verbal cognitive ability. Lastly, participants completed the *Achievement Emotions Questionnaire, Elementary School* (AEQ-ES), which measures achievement emotions in math, including anxiety, across academic contexts (i.e., class time, completing homework, and test writing).

Results: Using current data, we conducted a regression analysis with the anxiety scale of the AEQ-ES. Hierarchical regression models demonstrated that cognitive ability and expressive language explained 66.9% (p<.001) of the variance in math performance, while overall math anxiety explained an additional 10.3% (p=.024). In the second model, where cognitive ability and expressive language were controlled, math anxiety experienced during class was the only unique contributor (=-.243, p=.048), while homework-based math anxiety approached significance as a second unique contributor (=-.254, p=.058). Math test anxiety made no unique contribution.

Conclusions: Preliminary results suggest math performance of students with autism is grounded in cognitive and linguistic skills—however, anxiety towards math is another factor that may affect performance. Specifically, anxiety experienced during math learning activities (i.e., class time and homework) may impact math understanding and, consequently, the math performance of students with autism. The results suggest that educators need to support students with autism by implementing strategies designed to reduce anxiety inside and outside of the classroom.

419.003 *(Poster)* An Exploratory Study into Parental Perceptions of the Diagnostic Process of Girls with ASD in Australia

J. Wator[1] *and P. Paradis*[2]*, (1)Faculty of Education, Monash University, Clayton, VIC, Australia, (2)Krongold Clinic, Monash University, Monash University, Clayton, VIC, Australia*

Background: Girls with autism spectrum disorder (ASD) are less likely to receive a timely diagnosis and experience a longer diagnostic process compared to boys with ASD (Dukevot et al., 2016). Girls are often misdiagnosed or diagnosed later than boys due to gender differences in presentation (Dworzynski, Ronald, Bolton & Happé, 2012). Girls tend to present with a less severe expression of ASD characteristics and develop coping strategies to mask their difficulties in social environments (Lai, Lombardo, Auyeung, Chakrabarti, & Baron-Cohen, 2015). Recent research suggests that professionals do not have enough gender-specific knowledge on girls with ASD that is needed to reliably diagnose girls at an early age (Gibbs et al., 2019). This has resulted in girls and their families experiencing heightened stress due to a lack of information, professional support and access to timely therapeutic interventions (Crane, Chester, Goddard, Henry, & Hill, 2016).

Objectives: To explore parental experiences of the diagnostic process and support needs following a diagnosis for girls with ASD in Australia.

Methods: This current study consisted of 188 Australian parents who have a daughter with ASD aged between 4 to 17 years. Parents completed a detailed online questionnaire that included the Strengths and Difficulties Questionnaire – parent report (SDQ) to assess girls' complexity of needs and the Kessler Psychological Distress Scale (K10) to assess perceived parental stress. Thematic analysis was conducted to interpret parents' experiences of the diagnostic process based on responses in relation to initial concerns, information/support provided by professionals, and current information/support needs following a diagnosis for girls with ASD.

Results: The findings of this current study reveal that initial concerns were raised at approximately five years of age (M = 4.52, SD = 3.02). The diagnostic process spanned two years and two months (M = 2.13, SD = 2.25) from when initial concerns were raised until the point of diagnosis at nearly seven years of age (M = 6.65, SD = 3.40). Parents reported experiencing a difficult and stressful diagnostic process. Professionals showed a lack of knowledge on girls internalised ASD symptoms and consequently, parental concerns were disregarded or disbelieved. Due to a diagnosis of ASD being provided past the early intervention cut-off age in Australia, parents reported experiencing financial difficulty due to the high cost of therapies and having limited access to funding. Australian parents currently seek face-to-face parent support groups to ease the perceived isolation experienced from parenting girls with ASD and mentorship/social support groups for girls with ASD.

Conclusions: This current study identified a diagnostic timeline for girls with ASD in Australia and factors impacting upon parents' lived experience of the diagnostic process. Numerous professional practice recommendations were provided to assist in the identification of symptoms for girls with ASD. There is a need for clearer information to be provided to parents in terms of the impact of ASD on development and methods to access support. This study shows that more support is required to assist girls with ASD and their families in preparation for future difficulties.

419.004 *(Poster)* An Overview of University Accommodations and Supports for Autistic Students: A Cross-Institutional Survey Study

A. Riccio[1]*, S. K. Kapp*[2]*, E. Cage*[3]*, J. Vincent*[4]*, D. DeNigris*[5]*, A. Jordan*[6]*, J. Delos Santos*[7]*, P. Dwyer*[8]*, B. Kofner*[9]*, J. Solomon*[10]*, M. Hossain*[11] *and K. Gillespie-Lynch*[12]*, (1)Department of Psychology, The Graduate Center, City University of New York (CUNY), New York, NY, (2)Department of Psychology, University of Portsmouth, Portsmouth, United Kingdom, (3)University of Stirling, Stirling, United Kingdom, (4)York St. John University, York, United Kingdom, (5)Psychology & Counseling, Fairleigh Dickinson University, Madison, NJ, (6)CUNY, Staten Island, NY, (7)Hunter College, City University of New York, New York, NY, (8)Department of Psychology, University of California, Davis, Davis, CA, (9)CUNY, NY, NY, (10)Job Path NY, New York, NY, (11)Psychology, Pace University, New York, NY, (12)Department of Psychology, College of Staten Island; CUNY Graduate Center, Brooklyn, NY*

Background: In the past decade, the number of autistic students entering and expecting to enter higher education (HE) has increased significantly (Bakker et al., 2019). There have been reports of poor postsecondary outcomes for autistic adults, especially compared to those with other disabilities, concerning HE attendance and employment (Shattuck et al., 2012; Roux et al., 2013) and a growing literature examines challenges faced by autistic HE students, highlighting co-occurring mental health conditions and interrelated difficulties with social interaction, self-advocacy, and executive functioning (e.g., Anderson et al., 2017; Elias & White, 2017; Jackson et al., 2018). Studies have recently reported notable strengths of autistic university students in areas of college writing (under review) and academic examination grades (Bakker et al., 2019) compared to non-autistic peers. Some universities have implemented mentorship programs or other services but very few have been systematically evaluated and many charge a fee in addition to tuition (Barnhill, 2016).

Objectives: This study aims to characterize services provided to and utilized by autistic university students and their helpfulness/satisfaction with services in a cross-institutional study.

Methods: Participants (n=71, $Mage$=24.4, 43.7% male, 67.6% White, 70.4% undergraduates; representing 8 countries and 48 universities) completed an online survey assessing accommodations and supports available to and utilized by students and their relative helpfulness/satisfaction. Participants were also asked how services at their university could be improved. Open-ended responses were coded by two independent coders.

Results: Participants used extra time (64.8%) and alternate testing environments (53.5%) accommodations most often. Participants reported the accommodations they received to be helpful 74.8% of the time. When reporting on more general supports, participants used one-on-one meetings with professors (64.8%), social supports from friends (63.4%), general accessibility services (57.7%), and social support from family (52.1%) most often. Overall, 63% of participants who reported using general accessibility services at university found them to be helpful, the lowest of any support discussed (Table 1).

When asked how supports at their university could be improved (Table 2), most participants reported the need for more group-based supports (51.8%) such as autism-specific social groups (14.1%). Participants also cited the need for increased autism awareness or training for faculty/staff (18.8%) and fellow students (10.6%). On a five-point agreement scale, participants were most satisfied with one-on-one mentorship (M=4.1 out of 5) and group meetings which involved autistic people (M=4.1) and least satisfied with available employment-related supports (M=3.1) and mental health supports (M=3.3).

Conclusions: This research provides an overview of services used by autistic university students and their relative helpfulness in a sample of university students across institutions. Overall, the results point to participant satisfaction with accommodations and supports but the desire for autism-specific group supports and spaces is noteworthy. A larger, more diverse sample is needed to conclusively confirm these findings. However, university staff should consider these findings when providing and designing services for autistic students to better serve their needs.

419.005 *(Poster)* Anxiety and Wellbeing in Autistic Children during School Transition: Individual Differences and Group Comparisons.

M. Ashworth[1]*, E. Burchell*[2]*, O. Palikara*[3] *and J. Van Herwegen*[4]*, (1)Centre for Research in Autism and Education, UCL Institute of Education, University College London, London, United Kingdom, London, United Kingdom, (2)The University of Roehampton, London, United Kingdom, (3)The Univeristy of Warwick, Coventry, United Kingdom, (4)Institute of Education, University College London, London, United Kingdom*

Background: Previous research has suggested that autistic people experience higher levels of anxiety and may have worse well-being compared to typically developing individuals or other developmental disorder groups (e.g. Down syndrome) (Cribb, Kenny & Pellicano, 2019). However, most studies have examined anxiety and well-being cross-sectionally, using participants across a wide age-range, and thus it is unclear how the different individual experiences may impact on anxiety and well-being in autistic children.

Objectives: This current study included autistic children who were at the end of primary school in England and who were about the transition to secondary school. Inclusion of this specific age group allowed examination of individual differences and whether these individual differences were similar and predicted by the same factors as children with other developmental disorders, namely Williams syndrome and Down syndrome.

Methods: During their final year at primary school, parents and children completed a range of questionnaires that measure anxiety and wellbeing, including *Spence Children's Anxiety Scale SCAS-P (Spence, 1999)*, Strength and Difficulties Questionnaire (Goodman, 1997), Sensory Profile Questionnaire (Dunn, 2014), Social Responsiveness Scale **(***SRS-2 ; Constantino & Gruber, 2012)***,** *Health-Related Quality of Life Questionnaire (Kidscreen-10 Index, HRQOL)*, and Kids Coping Scale (Maybery et al., 2009). Data was obtained for 23 autistic children (mean age 11;04 years old), 23 children with Down syndrome (mean age 11;06 years old), and 18 children with Williams syndrome (age 11;03 years old).

In first instance group differences were explored using ANOVA's for overall scores and Chi-Square was used to see if there were any differences between the groups for the number of children that reached cut-off criteria for clinical diagnosis. Secondly, correlations and regression analyses were run to explore relationships between anxiety and wellbeing.

Results: Across all three groups a significant number of children experienced higher anxiety before making a school transition. However, in each groups there was large variability in the overall anxiety children experience. There were no differences between the three groups for overall levels of anxiety. However, looking at the different types of anxiety, autistic children experienced more anxiety that relates to repetition or OCD. However, there was also considerable overlap in the different types of anxiety across the different groups. In addition, in all three groups anxiety correlated with SDQ scores and SRS scores. Regression analyses showed further group differences.

Conclusions: This study's findings highlight some important parallels between the groups in the nature of the anxiety (i.e. physical injury and pain) but also group differences. A better understanding of these group and individual differences in anxiety and wellbeing allows the development of better group and individual specific interventions to help tailor support and prevent long-term suffering.

419.006 *(Poster)* Artea – Artistic Practices with Children in the Autism Spectrum

M. L. Nogueira[1] *and* ***J. Sander***[2]*, (1)Universidade Federal de Minas Gerais, Belo Horizonte, Brazil, (2)Universidade Federal de Minas Gerais, Belo horizonte, Brazil*

Background: Brazil doesn't have robust epidemiological data on prevalence of ASD. Our education has worked from the perspective of inclusive education since 1994, but the law that regulates this model was only enacted in 2016. In 2007, official data from the city's municipal education office in Belo Horizonte, Minas Gerais, pointed only 38 children with autism in early childhood education (0 to 60 months). In 2008, this number rises to 68; and in 2016, 140 students. However, in 2018, we identified (through document analysis) 12 children diagnosed with ASD in only one of the 131 schools in the network.

Children at this age spend between 20-38h weekly at school. Knowing the importance of children's time quality, the importance of early intervention, and knowing the lack of knowledge of those teachers on ASD, we built a pilot project called ArTEA (art-ASD, in portuguese), using art-education as main tool.

Objectives: To present ArTEA as a tool to expand the range of possibilities for offering ASD care in the context of early childhood education in Brazilian context;

Identify if artistic practices can be useful for early intervention and sensitization of Early Childhood teachers;

Reflect on the potential of using methodologies to work with art education in the field of inclusion, as well as the importance of interdisciplinary work in addition to health and education courses, including Visual Arts, Dance, Music and Theater.

Methods: Pilot Project with a group of Municipal Unit of Early Childhood Education-UMEI: 20 children aged 4/5 years, 2 with ASD, 2 teachers and 2 auxiliaries of inclusion (paraprofessionals, with no professional licensure and almosto no training in ASD);

20 4-hour meetings of artistic workshops, focusing on group corporal movement experimentation, aiming at inclusive activities, that instill the corporality of all in the activity. We used some principles of the Early Star Denver Model (ESDM) as a coadjuvant, namely: following child leadership, reciprocity (being play partners), and positive affect. We also use sensory-body and rhythmic proposals, using different materials (percussive musical instruments, tissues, hula hoops, balloons, etc.);

10 training meetings with teachers, coordination and paraprofessionals;

Application of post interview and questionnaire (with Likert scale) pre and post project for teachers.

Results: We note inclusive power of artistic work when performed in conjunction with typical children, especially in aspects of relational improvement among pairs and play repertoire expansion of childrens in the spectrum. We observe the importance of planning activities based on elements children in the spectrum bring - preferences, focus of attention, etc.

Teachers feel more secure and interested after participating in the workshops, although the school hasn't been able yet to schedule the theoretical training sessions.

Conclusions: The project is situated in a frontier territory between art, education and clinic. Artistic practices, even though they are neither therapeutic nor educational in their origin, place us face multiple possibilities of encounter. It is important that new practices and research be done, filling the gap of methodological and experiential knowledge about the arts with children with ASD and early childhood education.

419.007 *(Poster)* Assessing Social Validity of Parent-Implemented Function-Based Intervention: Mixed-Methods Study

M. Y. Chung[1] *and H. Meadan*[2]*, (1)Education, Stonehill College, Easton, MA, (2)University of Illinois, Champaign, IL 61820, IL*

Background: The term *social validity* was developed from anecdotal reports of concerns about the social meaningfulness of interventions in ABA-based research (Wolf, 1978). In the ABA field, conducting research that is "socially important" is the primary purpose (JABA, 2016). Two articles, the first by Wolf (1978) and the second by Kazdin (1977), responded to these concerns and defined the concepts of how to measure "social importance," which is now considered under the rubric of social validity. Since 2005, measuring social validity became one of the quality indicators in single-case research (Horner et al.). However, according to the reviews of the literature, in single-case research, there are several limitations of measuring social validity: (a) social validity assessments have not been well conducted within single-case design research, (b) the reviewed studies contain insufficient information about how researchers conducted social validity assessments and what they measured, and (c) the reported results are insufficient to infer that studies are socially valid. One way to overcome the limitations of social validity assessment is to apply a mixed-methods; multiple data sources will capture a different dimension of the social validity in a certain intervention.

Objectives: We conduct a mixed methods study to assess the social validity of the intervention we previously delivered to three parents who have children with disabilities and challenging behaviors.

Methods: The purpose of the previous intervention was to evaluate the effectiveness of a parent training and coaching program, delivered via telehealth, for implementing functional communication training (FCT) with their children. We used single-case design to demonstrate the intervention effectiveness by observing parents' and children' behaviors change. The intervention demonstrated a functional relation between parent training and coaching program and parents' fidelity of behavioral strategy. Also, the intervention showed decreases in children's challenging behaviors. In the current study, to assess whether the intervention was socially valid to the participated family members, first, we conduct pre- and post-intervention interviews with parent implementers and other family members. As a secondary data sources, we survey blind professional raters to evaluate the acceptability and effectiveness of the previous parent-implemented FCT. By mixing all those data, we evaluate whether the intervention was socially valid to the participants and related stakeholders.

Results: The preliminary finding from the interviews indicate that the outcome of the function-based intervention exceeded their expectations and agreed it was effective to decrease their children's challenging behaviors. Parent interventionists all agreed the social validity goal was met, and they also gave some suggestions for improving study procedures of a future replication. The blind raters' survey data collection is completed, and analysis is currently in progress.

Conclusions: Preliminary findings showed some degree of evidence of socially valid parent-implemented FCT. By mixing multiple data sources, various aspects of social validity will be evaluated. Study limitations and future implications will be discussed.

419.008 *(Poster)* Autism Preschool Education Services: Does Parent Preference Matter?

M. Maye[1]*, A. S. Nahmias*[2]*, J. Smith*[3]*, S. R. Crabbe*[4] *and D. S. Mandell*[5]*, (1)University of Massachusetts Boston, Boston, MA, (2)Psychiatry and Behavioral Sciences, University of California at Davis MIND Institute, Sacramento, CA, (3)HealthCore Inc., Wilmington, DE, (4)University of Pennsylvania, Philadelphia, PA, (5)Center for Mental Health, University of Pennsylvania, Philadelphia, PA*

Background: In the United States, schools must include parents in developing their child's individual education plan (IEP; IDEA, 2006). Inclusive preschool classrooms, autism specific classrooms, and home-based interventions are some of the most common special education services preschool-aged children with an autism spectrum disorder (ASD) use. Little is known about the degree to which parent preferences drive placement – nor whether child or family characteristics increase the likelihood that parent preferences match a child's placement.

Objectives:

1. We examined the association between parent preference for child special education placement and placement of child in special education services.
2. We examined whether child or family characteristics predicted an increased match between parent preference and their child's special education placement.

Methods: The sample included 48 preschool aged children with autism receiving community-based services. Participants completed developmental and diagnostic assessments (i.e., Mullen Scales of Early Learning, Autism Diagnostic Observation Schedule – 2) and parents completed demographic and developmental forms (i.e., child race, child gender, mother's education, Adaptive Behavior Assessment System [ABAS]). Parents also completed a survey regarding their preferences regarding preschool placement. We also reviewed children's IEPs. We completed descriptive statistics (Objective 1) and employed forward selection logistic regression (Objective 2) to examine the association between child and family characteristics and agreement between parent preference and placement.

Results: Parent reported preferences were as follows: 41.7% autism-only, 22.9% mixed disability, 33.3% inclusion, and 2.1% home. Approximately 48% of parents had children in the placement that was their stated preference. Maternal education, child race, child gender, and ADOS severity score did not predict match between parent preference and child placement. However, lower adaptive behavior scores as measured by the ABAS (p= .03, CI: .82-.99) predicted an increased likelihood that parent preference matched IEP placement.

Conclusions: Approximately half of the children in our sample received special education services in the setting their parent preferred. Demographic variables often associated with oppression (i.e., race, maternal education) were not significant predictors of match between parent preference and child special education placement. Worse adaptive behavior skills were significantly associated with match between parent preference and child special education placement, even after controlling for other covariates. This finding may indicate that parents and the IEP team are more likely to agree on the most appropriate child placement if the child has clear functional difficulties that are best supported in less inclusive environments where a child may receive more individualized support.

419.009 *(Poster)* Autism Severity Changes in Young Children with Autism Are Similar across Distinct Educational Settings

M. Ilan[1,2], *M. Faroy*[3], *L. Manelis*[4], *A. Michaelovski*[5], *H. Fluser*[3], *H. Binoun-Chaki*[3], *R. Segev-Cojocaru*[3], *O. Dotan*[3], *I. Menashe*[5,6], *I. Dinstein*[1,5] *and G. Meiri*[5,7], *(1)Psychology Department, Ben-Gurion University of the Negev, Beer Sheva, Israel, (2)Preschool Psychiatric Unit, Soroka Medical Center, Beer Sheba, Israel, (3)Soroka Medical Center, Beer Sheba, Israel, (4)Negev Autism Center, Ben Gurion University of the Negev, Beer Sheva, Israel, (5)National Autism Research Center of Israel, Ben-Gurion University of the Negev, Beer Sheva, Israel, (6)Public Health, Ben-Gurion University of the Negev, Beer Sheva, Israel, (7)Preschool Psychiatric Unit, Soroka University Medical Center, Beer Sheva, Israel*

Background: In Israel and other western countries children with autism are eligible for placement in either special education (i.e., small classes with relatively large well-trained staff) or regular education (i.e., regular class with a minimally-trained educational assistant). In 2018, approximately one third of children with autism in Israel, ages 3-21, were placed in regular education settings and two thirds were in special education settings. There are several advantages and drawbacks to each educational setting. For example, placement in special education is twice as expensive as inclusion in a regular education setting. Remarkably few studies have compared the developmental outcome of children across the two educational settings, which differ dramatically in their structure, content, and cost.

Objectives: The aim of the current study was to compare longitudinal changes in ADOS scores of 2-5-year-old children who were placed in special education versus those placed in regular education.

Methods: We examined longitudinal data from 122 children, who were recruited at the National Autism Research Center of Israel (www.autismisrael.org). All children were 11-65-months old (mean age = 33.25 months) at the time of their autism diagnosis. ADOS scores, cognitive scores, and socio-demographic data was collected twice: once during the initial diagnosis and again 12 to 24 months later during a follow-up assessment. Longitudinal differences in each measure were calculated for each of the children. Measures were compared across groups using t-tests and relationships across measures were examined using Pearson's correlations.

Results: ADOS comparison scores decreased (i.e., improved) slightly over the 1-2-year period between assessments (Mean = -0.7, Std = 2.1). Differences in ADOS comparison scores were similar across educational settings and did not differ ($t(120) = -1.1$, $p = 0.29$). There was a significant correlation between the age of diagnosis and improvement in ADOS scores ($r(122) = 0.279$,$p = 0.002$). Children in the two educational settings did not differ significantly in terms of age of diagnosis ($t(120) = 0.852$,$p = 0.396$) nor in their initial ADOS scores ($t(120) = -0.81$, $p = 0.41$). Children placed in special education did exhibit significantly lower socio-economic level ($t(120) = 2.6$, $p = 0.01$), poorer initial cognitive abilities ($t(86) = 2.79$, $p = 0.006$) and their mother's level of education was lower ($t(97) = 3.21$, $p = 0.002$).

Conclusions: These finding support previous findings regarding the importance of early diagnosis and treatment for longitudinal improvement in ADOS scores. Placement in either special education or regular education settings, however did not have an overall impact on longitudinal changes in ADOS scores. These initial findings suggest that young children with autism develop similarly in terms of social abilities in both setting. Additional comparisons of changes in cognitive abilities, adaptive behaviors, language abilities, and other measures of development are highly warranted for assessing the efficacy of each setting for specific autism cases.

419.010 *(Poster)* Autism and the Right to Education in the European Union

R. van Kessel[1] *and A. Roman-Urrestarazu*[2], *(1)Maastricht University, Maastricht, Netherlands, (2)University of Cambridge, Cambridgeshire, United Kingdom of Great Britain and Northern Ireland*

Background: Research into the effects of inclusion of children with autism in education has surged in recent years and specially after the surge at the international level of the policy that autistic children with special education needs (SEN) should be included in education instead of separated into special schools and that best practices should be applied when addressing these children. However, as of yet, there has not been any large-scale report on how these initiatives have been translated into national policy.

Objectives: To investigate all 28 European Union (EU) Member States' SEN and autism policy; aiming to create a comparative policy analysis that will culminate into one report of the differences that are observed in autism educational policy across the EU. The work carried out in this project aimed to first map international, EU and national autism policies in the field of education across these 28 countries.

Methods: We used an analysis of policy path interdependency that drew on past and current international, EU, and national policies in the field of SEN and autism from 1948 up to date. Path dependence approaches allow the identification of policymaking patterns and establish influences and interrelations among policies in linear layers of temporality. It also enabled policy process-tracing, which (1) aims to explain what factors are present in critical policy junctures, (2) aims to create a reference framework and depict how decision processes come to conclusions, and (3) aims to describe how behaviour that takes place in different stakeholders as a response to external factors affects different institutional. We used a timeline to show connection and overlap between policies to enable further analysis. This enabled the interpretation of policy creation as historical sequences and patterns and allowed for the identification of path dependence.

Results: The values of the Universal Declaration of Human Rights and the Convention on the Rights of Persons with Disabilities have been closely translated into the respective education systems of the countries under study, offering special education needs services and support in mainstream education with the aim of including as many children into mainstream education as possible, regardless of the vast differences in education systems.Additionally, fragments of a segregated system are still in place across the EU in order to account for the development of children with SEN that are unable to attend mainstream education due to their condition. Proper teacher training was found to play a significant role in addressing SEN adequately in classrooms, while family involvement was generally limited to social support of the child.

Conclusions: All countries under study have incorporated the values of the international documents in their respective education systems, while emphasising the need to include as many children in the mainstream system as possible.Remnants of a segregated system ensure the inclusion of all children with autism in the education systems of the EU.

419.011 *(Poster)* Bullying Victimization Experiences of High Schoolers with ASD

R. Anderson[1]*, J. McNeill*[2]*, B. Tomaszewski*[3,4,5]*, J. R. Steinbrenner*[3] *and K. Hume*[3]*, (1)University of North Carolina at Chapel Hill, Chapel Hill, NC, (2)School of Education, University of North Carolina, Chapel Hill, NC, (3)Frank Porter Graham Child Development Institute, University of North Carolina at Chapel Hill, Chapel Hill, NC, (4)Psychiatry, University of North Carolina at Chapel Hill, Chapel Hill, NC, (5)TEACCH Autism Program, University of North Carolina at Chapel Hill, Chapel Hill, NC*

Background:

A growing body of research suggests that youth with autism spectrum disorder (ASD) are more likely than their typically developing peers to experience bullying victimization. Although specific rates are difficult to ascertain due to varying definitions and measurement procedures, a meta-analysis of 17 studies estimates that 44% of youth with ASD have been victims of bullying (Maïano, Normand, Salvas, Moullec, & Aimé, 2016) with a range of 7% to 80% of youth with ASD being bullied. Compared to the U.S. Department of Education's indication that 20.8% of the general population of middle and high schoolers report being bullied at school (Lessne & Yanez, 2016), this rate within the ASD student population is alarming. However, the known heterogeneity of symptomology and experiences of individuals with ASD presents a challenge for understanding potential risk and protective factors against victimization within schools. The existing research variably addresses individual and contextual heterogeneity related to school factors, associated diagnoses, and adaptive skills.

Objectives:

1. Determine the rate of teacher-reported victimization for high school students with ASD
2. Examine whether victimization rates vary based on individual characteristics (i.e. race, cognitive ability, ASD symptom severity, adaptive behavior, comorbid mental health diagnoses) or school experiences (i.e. time spent in general education classroom, educational program quality).

Methods:

This secondary data analysis included 136 students (age 13-22) in 30 high schools in North Carolina, California, and Wisconsin participating in a larger ongoing study of high school programs. The dependent variable of interest was teacher report of victimization experiences (physical verbal, social, or cyber). Potential predictor variables were based upon special education classification of autism and time spent in general education, parent-reported demographics and other diagnoses, and standardized measurements of symptom severity (Social Responsiveness Scale), adaptive behavior (Vineland-II), nonverbal IQ (Leiter-3), and program quality (Autism Program Quality Rating System). Analysis included descriptive statistics of victimization frequency and group comparisons between victimized and non-victimized students using t-tests and chi-squared tests.

Results:

The secondary data analysis revealed 14% of the student sample had experienced some type of victimization within the last four weeks. For students experiencing victimization, 2.2% experienced physical bullying, 9.6% experienced verbal bullying, 10.3% experienced social bullying and 0.7% experienced cyber bullying. In total, 47.4% of student experienced more than one type of bullying. Victimized and non-victimized groups did not differ significantly on any individual characteristics or school experiences.

Conclusions:

This study indicated a lower prevalence of victimization experiences among students with ASD than has been reported by others. This may reflect improvements in anti-bullying initiatives and inclusion of students with ASD, but could also signify underreporting by teachers. Additionally, previous research has suggested links between victimization and higher-functioning ASD, mental health comorbidities, and general education settings, none of which appeared in this analysis. Such lack of associative findings may relate to the complexity and heterogeneity of the autism spectrum, suggesting that individual variables cannot adequately capture differences in risk. Future studies should consider differences in teacher, parent, and self-report of victimization and use larger samples for more complex analysis.

419.012 *(Poster)* Characterization of Schooling of a Sample of Preschoolers Diagnosed with ASD in Uruguay in Low and Middle Class Patients

C. Amigo[1]*, N. Orrico Rocca*[2] *and G. Garrido*[3]*, (1)Clinica de psiquiatria pediátrica Facultad de medicina, UDELAR, Montevideo, Uruguay, (2)Montevideo, Centro Hospitalario Pereira Rossell Asociación Española, Montevideo, Uruguay, (3)Universidad de la República, Montevideo, Uruguay*

Background: In recent years, reflections and debate regarding the right to quality education for everyone, moving from a view based on access to schools from one based in the quality of the learning achievements has deepened. In Uruguay, legislation meant to guarantee access to quality education to persons with disabilities exists. However, various difficulties in access to schooling is frequently noted in clinical practice. Moreover, teachers lack necessary supports to ensure successful educational inclusions. Education in Uruguay is mandatory as from 4 years of age, however it is an extended practice in our culture that children are schooled early in development, commonly around two years of age. The increase in early diagnosis of Autism Spectrum Disorders (ASD), together with the aforementioned paradigm changes towards inclusive education, bases the importance of deepening research in this area.

Objectives: Determine the frequency of preschoolers with ASD who attend and don´t attend school, number of hours of those schooled

Determine the amount of hours preschoolers of hour sample attend school.

Look for association between different variables, such as social class, severity of ASD, Access to language and presence of challenging behaviors and access to school.

Methods: a cross-sectional, descriptive and exploratory study, of two different settings public hospital and private office a child psychiatrist who specializes in ASD. Subjects: 34 preschoolers aged between 2 and 5 years of age who were referred to the outpatient clinic specialized in ASD at Centro Hospitalario Pereira Rossell in the period august 2018 august 2019 and receive an ASD diagnosis base on clinical evaluation and ADOS administration. A sample of preschoolers of the same age range referred during the same period to a psychiatrists private office is currently being analyzed.

Instruments: Data were taken from clinical records, if necessary telephone interviews were conducted. Information considered was the one obtained during the first visit. Data wew anlyzed using Excel . Ethical aspects were considered.

Results: More than half (68%) of preschoolers with ASD in the low socio economic sample are under-schooled, the reasons are diverse, predominantly lack of resources in the school and comorbidity with challenging behaviors as reported by parents. The average number of school hours in that sample is 2.2 hours per day. Given the low number of children who were with the personal assistant resource (n=7), the incidence in the adaptation process could not be assessed. Results in the middle class sample are being processed. We expect to see if there are differences in the aspects considered in the middle class sample.

Conclusions: In low class sample access to school in children with moderate and severe ASD is highly compromised. Reasons for this are varied, focusing in lack of resources as well as challenging behaviors not part of ASD core symptoms. Children with mild ASD have better access to school, but still tend to have reduced schedules and poor support. . We expect to conclude if there are differences in access to school in the private and public setting and possible reasons.

419.013 *(Poster)* Child and Family Predictors of the Emergent-Literacy Skills of Children with Autism

***J. Dynia**, The Ohio State University, Columbus, OH*

Background: There is an emerging body of research on emergent literacy and its role in the acquisition of conventional literacy skills for children with autism. Children with autism tend to have a discrepant profile of strengths in code-related skills (i.e., alphabet knowledge) but meaning-related skills that seem to lag behind their peers. However, there is significant variance in emergent-literacy skills for children with autism. The heterogeneity in emergent literacy has been found to be related to autism severity, oral language, and nonverbal cognition. It is unclear whether other child variables (gender, age, race, preschool attendance) or family SES variables (education, income) are related to the variability in children with autism's emergent-literacy skills.

Objectives: Therefore, we examined three research questions: (1) are there differences in the emergent-literacy skills of children with autism in comparison to children with language impairment (LI) and children who are typically developing (TD)?, (2) What are the child and family predictors of gain in emergent-literacy skills for children with autism?, and (3) what are the child and family predictors of gain in emergent-literacy skills for children with autism in comparison to children with LI and children who are TD?

Methods: Data for the current proposal represent children with autism (n = 33), children with language impairment (n = 93), and children who are typically developing (n = 503) from the larger sample. Measures of emergent-literacy skills included four subtests from the Phonological Awareness Literacy Screener (PALS; Invernizzi et al., 2004): uppercase letters, lowercase letters, book and print awareness, and name writing.

Results: Results indicated that children with autism had similar scores on alphabet knowledge tasks (uppercase and lowercase letters) in both the fall and spring of preschool as children with LI and children who were TD. However, there were significant differences for the book and print awareness and name writing tasks, such that children with autism were lagging behind both children with LI and children who are TD in both the fall and spring. None of the child or family variables were significant predictors of children with autism's residualized gains in any of the emergent-literacy skills. However, for both book and print awareness and name writing results indicated that children with autism were scoring about 3 points lower than their peers on the book and print awareness task and 2 points lower than their TD peers on the name writing task when controlling for child and family variables.

Conclusions: First, when examining the descriptives, the findings from this sample align with much of the previous research on children with autism's emergent-literacy skills – strength in alphabet knowledge and a weakness in print knowledge. In addition, children with autism also seemed to lag behind their peers in name writing. Second, child and family variables do not seem to be related to children with autism's gains in emergent-literacy skills; however, when controlling for child and family variables autism status was a significant predictor of book and print awareness and name writing.

419.014 *(Poster)* Comparison between Strategies in Expository Text between Children with ASD and Typical Development

***Y. Kimhi**[1,2], I. Kemper[2] and N. B. Bauminger-Zviely[3], (1)Levinsky College of Education, Tel Aviv, Israel, (2)Bar Ilan University, Ramat Gan, Israel, (3)School of Education, Bar Ilan University, Ramat Gan, Israel*

Background: Reading comprehension (RC) is the ability to extract meaning from a written text. Understanding RC in ASD is vital since, according to recent studies, 65–73% of school-age children with ASD have RC difficulties.

Objectives: Only one study to date compared reading strategies within ASD, and only a few examined strategies that facilitate expository text RC. The purpose of this study was to compare two reading strategies (main idea [MI] or graphic organizer [GO]) to see which would enhance expository-text RC abilities within ASD. The study is novel in three significant aspects: a) examination of group improvement (ASD/TD) of RC abilities following the use of RC strategies;b) comparison between two expository text RC strategies and c) comparison of open-ended /close-ended comprehension questions.

Methods: Participants: 56 third-grade children from central Israel: 28 ASD (2 girls, 26 boys); 28 TD (11 girls, 17 boys). There were fewer female participants in ASD, following the uneven gender ratio in ASD. All participants had VIQ of 75 or above (PPVT-III; Dunn & Dunn, 1997). Participants were matched for VIQ and SES.

RC was assessed via two expository texts, which were matched on the complexity level. Four questions examined explicit knowledge (two open-ended and two close-ended questions), and four questions examined implicit knowledge (two open-ended and two close-ended questions). Half of the participants were taught the MI strategy, and half were taught the GO strategy.

Results: Without strategy: significant group difference for implicit knowledge $F(1,52)=4.98$, p=.03, $\eta^2=.09$.

Improvement with strategy: No significant group effect. The effect without the strategy score retained a negative trend, with a regression to the median. Children who had a lower RC score without strategy improved more than the children who had a higher RC score, beyond group (ASD / TD)

Comparison between the two strategies (MI / GO) for improvement measures.

A significant effect only for GO beyond group (ASD/TD(was found for:

improvement of understanding implicit knowledge $F(1,51)=6.48$, p=.01, $\eta^2=.11$; answering close-ended questions $F(1,51)=7.02$, p=.01, $\eta^2=.12$; and for the general reading comprehension score $F(1,51)=4.45$, p=.04, $\eta^2=.08$.

Comparison between the two strategies (MI / GO) within groups.

ASD group: only with GO significant improvement in close-ended questions (b=-1.58, p=.007); in general RC score (b=-1.49, p=.03); and close to significant improvement in implicit information (b=-.97, p=.06)

TD group: non-significant improvement.

Conclusions: The findings before the strategy use highlight the complexity of understanding expository texts within ASD. The study's findings expand empirical evidence concerning RC strategies specific for expository texts and can be implemented into daily practice in educational settings for children with ASD. GO strategies significantly improved RC abilities for ASD, giving strong support to the recommendation to teach RC skills through GO strategies. This finding has substantial practical educational bearing since RC interventions need to be designed according to students with ASD unique needs. A further contribution is the comparison of question format, which influences RC abilities. The improvement found may be due to the activation of more efficient search behaviors activated following the use of the strategy.

419.015 *(Poster)* Effectiveness of an Online Program Using Manga to Change Japanese High School Students' Attitudes Toward Individuals with Neurodevelopmental Disabilities

M. Torii[1]*, F. Someki*[2]*, Y. Nishio*[3]*, M. Umeda*[4]*, H. Ogawa*[5]*, T. Kondo*[6] *and Y. Shikibu*[1]*, (1)Graduate School of Human Development and Environment, Kobe University, Kobe, Japan, (2)Department of Educational Studies, College of Staten Island, City University of New York, Staten Island, NY, (3)Faculty of Education, Kio University, Kitakaturagi-gun Koryo-cho, Japan, (4)Miyagi Gakuin Women's University, Sendai, Japan, (5)Graduate School of Education, Hyogo University of Teacher Education, Kobe, Japan, (6)Research Center for Advanced Science and Technology, The University of Tokyo, Tokyo, Japan*

Background: The World Health Organization (2001) has presented the International Classification of Functioning, Disability, and Health (ICF) as a more comprehensive model of disability. Based on the ICF, stigma from others is one of the environmental factors and a barrier to participation for students with neurodevelopmental disabilities (ND); hence, we have to develop not only interventions for individuals with ND, but also educational programs for other students.

Furthermore, knowledge about Autism Spectrum Disorder (ASD) was shown to be an important factor in decreasing stigma toward ASD. We found that educational programs, a face-to-face program for high school students (Torii et al., 2016), and online training for undergraduates (Someki et al., 2018), decreased the misunderstanding and stigma associated with ASD.

In this study, we developed an online educational program to decrease stigma in high school students using manga, which is very popular in Japanese culture. For example, "With the light," a famous manga about ASD, has been changing knowledge of ASD all over the world. Therefore, we think an online program using manga could be useful in decreasing the stigma toward ND in high school students.

Objectives: To investigate the effects of the online educational program "Understanding Neurodevelopmental Disability -Introductory Course" (UND-IC) on high school students

Methods: Participants: A total of 476 high school students, comprising 181 males and 285 females (10 unspecified). Their grade levels were K10 (336), K11 (58), and K12 (82).

Materials: The online questionnaire consisted of 2 items on previous experiences with people with disabilities, 13 items on knowledge about ND, 6 items on social distance toward ND, and 6 items on their interest/behavior toward people with ND. The UND-IC consisted of 69 slides in which a Japanese high school student explained his Attention-Deficit/Hyperactivity Disorder (ADHD) disability, ASD disability, another ND, and the social model of disability.

Procedure: The introduction and questionnaire were posted on the SurveyMonkey website. Participants took a pre-test and a post-test with the UND-IC. All of these contents were shown on the website.

Results: About 206 students had positive experiences with people with ND, whereas 25 students had negative experiences; 192 students had neither positive nor negative experiences.

Many students answered "I have no idea" about items on knowledge of ND (symptoms, difficulties, development and course). Before the UND-IC, 65.8% of students had no experience of volunteer activities, 68.9% did not invite peers with ND to participate in activities, and 47.3% did not watch TV programs or news about ND or talk about ND with their friends or family. However, after UND-IC, over 70% of students changed their interest/behavior, although the knowledge score did not change.

Conclusions: For high school students, it was difficult for them to understand knowledge regarding ND, its symptoms, difficulties, development and course. However, an online program using manga could help them empathize with their ND peers. Explaining ND using manga characters aided high school students to develop empathy toward individuals with ND. In this study, we found that knowledge had no direct effect on decreasing stigma toward ASD.

419.016 *(Poster)* Effects of Peer-Mediated Intervention Strategy to Increase the Social Interactions of a Kindergartener with Autism Spectrum Disorder

K. Railey *and M. J. Ault, University of Kentucky, Lexington, KY*

Background: Research has examined the role peers play in promoting social-emotional and play skill development in young children with autism spectrum disorder (ASD; Sperry et al., 2010). Peer-mediated interventions (PMIs) provide environments to promote the development of joint interactive play (JIP), which is an appropriate, functional behavior for students with ASD as play with peers helps improve social, emotional, language, academic, and cognitive abilities (Coolahan et al., 2000). Traditionally, most PMIs involve formal peer and teacher training to promote the successful engagement in positive social interactions between peers and students with ASD (McGrath et al., 2003). However, research is limited on the effects of PMIs without formal peer training related to the interactions between typical peers and students with ASD.

Objectives: The purpose of the study was to investigate the effects of a PMI strategy to increase JIP between a Latina kindergartener with ASD (Camila) and a typically-developing peer (Kate).

Methods: A withdrawal design (Gast, Ledford, & Severini, 2018) was used to evaluate the effectiveness of a PMI procedure for increasing percent engagement in JIP and/or attempts to engage in JIP. Prior to the intervention, neither Kate nor Camila received any training, and only one brief 30 min teacher training was needed to achieve reliable implementation of the PMI strategy. The intervention involved a teacher verbally prompting Kate to interact with Camila only in the instance that one minute passed without the occurrence of JIP or an attempt from Camila to interact with Kate. Data was collected on the following variables: percent engagement or attempts to engage in JIP, number of verbal prompts, and number of praise statements. The investigator and reliability data collectors gathered interobserver agreement and procedural fidelity data.

Results: Researchers evaluated the level, trend, variability, consistency, overlap, and immediacy of effects within and between baseline and intervention conditions. Figure 1 shows the percent of intervals of JIP during baseline and intervention conditions. The results indicated a functional relation between the use of the PMI strategy and an increase in JIP. Comparing the first baseline and intervention phases, an increase of 31.77% percent engagement in JIP was observed. When the intervention was withdrawn, engagement in JIP decreased to an average of 21.34% during the second baseline before increasing to an average of 47.77% during the second intervention phase.

Conclusions: Results of the current study provide a unique contribution to the literature by extending minimal research available on implementing PMIs without peer training. Findings highlight the effectiveness of an efficient, easy-to-implement PMI strategy. This is especially relevant in general education settings where teacher and instructional time is predominantly focused on academic instruction, with instruction on social-communication skills receiving lower priority. Given that teachers report limited time to plan and implement interventions as a barrier to implementation of classroom-based interventions (Wilson & Landa, 2019), it is important to identify strategies, like the one used in the current study, that are both efficient and involve others (e.g., peers) in the promotion of the social-communication of students with ASD.

419.017 *(Poster)* Emergent Literacy Profiles of Kindergarten Children with ASD: Implications for Educational Practice

A. R. Henry[1]*, E. J. Solari*[2]*, R. Grimm*[3] *and M. C. Zajic*[3,4]*, (1)University of California at Davis, Davis, CA, (2)Curriculum, Instruction, and Special Education, Curry School of Education University of Virginia, Charlottesville, VA, (3)University of Virginia, Charlottesville, VA, (4)University of California at Davis MIND Institute, Davis, CA*

Background: There is evidence that children with autism spectrum disorder (ASD) may exhibit heterogeneous abilities in reading and reading-related skills. Though many studies have concluded that many children with ASD may conform to a “hyperlexic” profile of reading (e.g., average phonological awareness and word-reading abilities coupled with poor comprehension abilities), there is also evidence that many students with ASD demonstrate concurrent phonological awareness disturbances alongside comprehension deficits. Early precursor skills such as phonological awareness and alphabet knowledge are predictive of later reading development. Therefore, understanding emergent literacy heterogeneity in children with ASD will help inform intervention and educational practices to better support these students in their early elementary years.

Objectives: The goal of this study was to identify unique profiles of emergent literacy skills in a sample of kindergarten children with ASD.

Methods: This study uses data from *N*=626 students with ASD who were assessed using the Phonological Awareness Literacy Screening (PALS), which is a statewide screener for difficulties in phonological awareness and other emergent literacy skills (i.e., rhyme, beginning sound, alphabet knowledge, concept of word and developmental spelling). Utilizing LPA, empirically derived profiles of emergent literacy at kindergarten entry will be presented.

Results: Many of the children in this sample demonstrated below average abilities in the emergent literacy constructs, though initial results support the emergence of four distinct profiles based on discrepancies across constructs. This model allows for an examination of similarities and differences in the profile-specific performance levels across skills.

Conclusions: There is evidence that supports different emergent literacy profiles in a large sample of young children with ASD. To develop the most effective reading interventions for students with ASD, we must acknowledge that these instructional methods must be tailored to meet the specific reading needs of individual students. These findings allow for a better examination in the relationships between emergent language and reading skills in children with ASD that will be crucial in developing targeted literacy interventions to support these students.

419.018 *(Poster)* Emergent Literacy Profiles of Kindergarten Children with ASD: Implications for Educational Practice

A. R. Henry[1]*, E. J. Solari*[2]*, R. Grimm*[3] *and M. C. Zajic*[3,4]*, (1)University of California at Davis, Davis, CA, (2)Curriculum, Instruction, and Special Education, Curry School of Education University of Virginia, Charlottesville, VA, (3)University of Virginia, Charlottesville, VA, (4)University of California at Davis MIND Institute, Davis, CA*

Background: There is evidence that children with autism spectrum disorder (ASD) may exhibit heterogeneous abilities in reading and reading-related skills. Though many studies have concluded that many children with ASD may conform to a “hyperlexic” profile of reading (e.g., average phonological awareness and word-reading abilities coupled with poor comprehension abilities), there is also evidence that many students with ASD demonstrate concurrent phonological awareness disturbances alongside comprehension deficits. These findings allow for a better examination in the relationships between emergent language and reading skills in children with ASD that will be crucial in developing targeted literacy interventions to support these students.

419.019 *(Poster)* Emergent Writing and Reading Profiles of Preschool-Age Children with Autism Spectrum Disorder

M. C. Zajic[1]*, E. J. Solari*[2]*, R. Grimm*[1] *and A. R. Henry*[3]*, (1)University of Virginia, Charlottesville, VA, (2)Curriculum, Instruction, and Special Education, Curry School of Education University of Virginia, Charlottesville, VA, (3)University of California at Davis, Davis, CA*

Background: Children with autism spectrum disorder (ASD) exhibit heterogeneous development in reading and writing skills across the school-age years. However, few large-scale empirical studies have examined how their earlier emergent literacy skills support later reading and writing skills. Examining these skills is important to understand both later reading-writing development as well as to develop appropriate, targeted literacy interventions across the school-age years that meet the literacy needs of children with ASD.

Objectives: This study used latent profile analysis (LPA) to empirically derive profiles of emergent literacy skills (i.e., early reading and writing skills) in a large, state-wide representative sample of preschool children diagnosed with ASD. This study also sought to examine how profiles differed on later 3rd-grade performance in reading and writing on state-wide Standards of Learning (SOL) assessments.

Methods: Data for this study come from de-identified, state-level data of approximately 600 children with ASD from a southeastern state in the United States. Data were collected as part of the state-wide Phonological Awareness Literacy Screening (PALS) assessment that screens for difficulties in and monitors progress across phonological awareness and emergent literacy development in children in preschool through 3rd grade. The accessed de-identified, archival data used in this study were approved under the university's Institutional Review Board. The PALS Preschool (PALS-PreK) assessment battery assesses emergent literacy skills in both early writing (name writing) and early reading (alphabet knowledge, beginning sound awareness, print and word awareness, rhyme awareness, and nursery rhyme awareness). SOL tests in reading and writing are annual assessments that measure how well students are meeting the state's expectations for learning and achievement. Pass/fail rates for reading and writing SOL tests at 3rd grade were examined in this study. LPA was used to examine if subgroups of children demonstrate varying levels of strengths and challenges across early writing and reading skills. Profiles were then compared on their pass/fail rates on 3rd-grade SOL tests.

Results: Initial results support the emergence of multiple distinct profiles based on differential performance across reading and writing skills. Findings will be discussed reflective of profile-specific performance levels across reading and writing skills to examine to what extent derived profiles differed in individual reading and writing skills. Profile comparisons on later 3rd-grade reading and writing SOL performance will be further discussed during the presentation.

Conclusions: Little empirical research has examined emergent reading and writing skills. Most prior studies have focused on individual literacy skills or relied on small, limited samples. This study drew from state-level data and supports the need for increased research in understanding the heterogeneous development of early reading and writing skills in children with ASD. Findings are beneficial to both researchers interested in understanding the relationships between language, reading, and writing in children with ASD and to educators developing and implementing instructional practices to support reading, writing, and broader literacy development in children with ASD.

419.020 *(Poster)* Estimating the Prevalence of Autism Among Postsecondary Students in the United States

B. E. Cox[1]*, C. B. Francis*[2] *and C. Kepple*[2]*, (1)Educational Leadership and Policy Studies, Florida State University, Tallahassee, FL, (2)Florida State University, Tallahassee, FL*

Background: How many postsecondary students have autism? Although this question is seemingly simple and straightforward, the current literature does not provide adequate evidence to provide a solid answer to this most basic of questions. To date, only two studies (Wei et al., 2015; White et al., 2011) appear to have attempted an answer, both of which have critical limitations that prevent either from yielding an authoritative figure. Extrapolation from these studies to estimate the total number of college students in the United States have autism would yield results that range from fewer than 80,000 to nearly 400,000, both of which likely underestimate the real number of students. Without a trustworthy estimate, it will remain hard to convince college administrators or policymakers that this population has reached a critical mass warranting our collective attention.

Objectives: This study's ultimate goal is to generate trustworthy estimates regarding the prevalence of autism among college students in the United States.

Methods: This study reviewed information from nationally representative federal datasets, reports from assessment instruments widely administered to college students, and empirical data presented in scholarly publications. In reviewing these sources, we examined data derived from any of four distinct approaches from which we might estimate the prevalence of autism among postsecondary students in the United States: 1) tracking autistic students after they leave high school, 2) screening for autism or requesting self-disclosure from a cross-section of college students (not just those known to have autism), 3) identifying the frequency of postsecondary attendance among a cross-section of autistic adults, and 4) asking campus disability service offices about the number of students who formally disclose an ASD diagnosis to their institution.

Results: Our examination of wide ranging data sources and employing multiple approaches to data collection reveals the paucity of empirical evidence from which we may generate plausible estimates of autism's prevalence in postsecondary education. Fewer than 20 of the 390 journal articles we screened appear to pursue any of the four approaches from which we could derive national estimates. Moreover, the vast majority of those articles draw from small or idiosyncratic samples that make them unsuitable for extrapolation. Only 1 of the 12 student surveys asked questions that would allow the disaggregation of autism from other disabilities. Among federal datasets, beyond the widely cited NLTS-2, only one USDOE study offers any data that might yield viable estimates; none of the Census Bureau's data sources appear to hold any such potential. Forthcoming analyses of these sources will allow us to generate context-specific and empirically grounded estimates of autism's prevalence in higher education.

Conclusions: Limitations affecting previous studies limit the utility of estimates derived exclusively from individual datasets. However, by combining evidence from multiple data sources--federal datasets, college student surveys, and scholarly publications--we can generate plausible estimates of autism prevalence among college students. These estimates may be critical to ensuring that the growing population of college students with autism receives appropriate attention, support, and resources from their postsecondary institutions.

419.021 *(Poster)* Evaluating the Effectiveness of a Psychoeducational Training Video for Improving Recognition of Autism

*K. Warren, K. Langley and **C. R. Jones**, Wales Autism Research Centre, Cardiff University, Cardiff, United Kingdom*

Background: Understanding of autism in both the general population and in frontline clinical, social and educational services is often limited (e.g. Heidgerken et al., 2005; Tipton & Blacher, 2004). This partly relates to the complexity of autism; the signs of autism vary between individuals and can often be subtle. Training has been shown to effectively increase knowledge of autism (e.g. Obeid et al., 2015). However, training packages are not often evidence-based and empirical testing of their effectiveness is rarely conducted. In response to this, our group developed an 18 minute training video, The Birthday Party (see www.autismchildsigns.com). The film integrates the 14 most discriminating items (Carrington et al., 2015) from the Diagnostic Interview for Social and Communication Disorders (Leekam et al., 2002; Wing et al., 2002), supplemented by information from the UK National Institute for Clinical Excellence guidelines on autism. The film highlights five 'SIGNS' (**S**ocial interaction; **I**magination; **G**estures; **N**arrow interests; **S**ensory responses) of autism and focuses on three autistic children (two boys and one girl) attending a birthday party.

Objectives: To assess the effect of The Birthday Party psychoeducational training video on the recognition of autism in undergraduate students.

Methods: Seventy-one undergraduate students participated (55 female; mean age = 19.15 years, SD = 1.56). Half (N = 36) were shown The Birthday Party film and half (N = 35) were shown an educational film about dyslexia. At baseline, groups were matched on previous knowledge of autism (Autism Awareness Survey; Gillespie-Lynch et al., 2015; Tipton & Blacher, 2014) and previous contact with autistic people (Level of Contact Report; Holmes et al., 1999). Following video presentation, we assessed recognition of autism by presenting participants with ten clinical vignettes that described four autistic children, four children with other childhood disorders, and two with no disorder. Participants had to identify the correct diagnosis for each vignette as well as indicate confidence in their judgement.

Results: Participants who watched The Birthday Party film were significantly better at recognising autistic children from clinical descriptions compared to participants who watched the control film. The group that watched The Birthday Party film were specifically more confident than the control group in making decisions about the autistic children, although there was no overall group difference when all vignettes were considered.

Conclusions: Training materials are commonly used to support autism education, but few have an evidence-base or have their effectiveness tested empirically. Our data establish that The Birthday Party has a significant impact on the ability of undergraduate students to recognise autism, which was reflected in elevated confidence in judgments. The film is freely available film available in six languages and has been used in 12 countries to date. Future research should investigate the effect of the film on improving knowledge of frontline professionals, as well as empirically examine the effect of the film in changing attitudes about autism.

419.022 *(Poster)* Evaluating the Effects of a Commitment Emphasis Consultation Model to Increase Teacher Implementation of Autism Specific Assessment

***B. Bronstein**[1], D. S. Mandell[2], M. Tincani[3], A. Gilmour[3] and J. Boyle[3], (1)University of Pennsylvania, Philadelphia, PA, (2)Center for Mental Health, University of Pennsylvania, Philadelphia, PA, (3)College of Education, Temple University, Philadelphia, PA*

Background: There are several effective treatment methods and evidence based practices (EBP) for teaching children with Autism Spectrum Disorders (ASD). It is often overwhelming for teachers to identify and implement available best practices with fidelity in the absence of ongoing training and support (Alexander, Ayres & Smith, 2015). One way to affect teacher implementation and behavior change is through different consultation styles, including performance feedback or a commitment emphasis approach. Performance feedback is a widely used and effective method to improve teacher implementation and treatment fidelity (Burns, Peters & Noell, 2008). A commitment emphasis model is a social influence strategy, which also shows continuing support for teacher behavior change (Noell et al. 2005).

Objectives: To compare a performance feedback model with a commitment emphasis plus prompt model of consultation to increase teachers' completion of a curriculum-based student assessment for students with ASD.

Methods: Participants consisted of 29 new K-5 autism support teachers in an urban school setting, receiving 13, 1.5 hour consultation visits over the course of the school year. Participants were randomly assigned using a between group design. The study consisted of a control group which included teachers being coached using a performance feedback approach and given initial prompts to complete the Student Learning Profile (SLP), a curriculum based assessment, and an experimental group where teachers were coached using a performance feedback model plus commitment emphasis and given prompts throughout their consultation to complete the SLPs. All coaches followed a standardized script and met procedural fidelity. Coaches used an implementation checklist based on teacher's needs and pre-established consultation approach. Two types of outcomes were collected, assessment completion and time to completion at beginning and middle of the school year.

Results: Findings indicate a significant effect for teacher SLP completion at time-point one for teachers' in the experimental group using a commitment emphasis model. Students of teachers in the treatment group had, on average, 25.8 times the odds of SLP completion than students in the control group (*logit*=3.25; $p<.05$). Results also indicated that t teachers in the control group took 1.2 times as long to complete their students' SLPs than teachers in the treatment group.

Conclusions: The use of behavioral consultation strategies in classroom-based settings has continued to show efficacy throughout many studies. Recent research has explored the use of approaches including social influence strategies such as commitment emphasis and prompts (Noell et al. 2005). The current study shows preliminary results to support the work by Noell and colleagues, which shows the use of social influence strategies as an effective approach to changing teacher behavior, including the use of intervention implementation and assessment completion. The use of EBPs for individuals with ASD is imperative to the success of students as well as the teachers in classroom-based settings and should be a priority of all clinicians, researchers and educators and policy makers.

419.023 *(Poster)* Examining Idiographic Approaches for Monitoring IEP Goal Progress in Children with ASD across Ages

M. Yee[1]*, L. A. Ruble*[2] *and J. H. McGrew*[3]*, (1)Educational, School, and Counseling Psychology, University of Kentucky, Lexington, KY, (2)University of Kentucky, Lexington, KY, (3)Psychology, Indiana University - Purdue University Indianapolis, Indianapolis, IN*

Background: Children with ASD have shared difficulties in social, communication, and learning skills. Progress monitoring and outcome assessment is a challenge faced by special educators. Often, we measure the progress of goals with nomothetic assessment; however, nomothetic approaches may be less sensitive in observing different levels of baseline performance, intervention plans, and intervention outcomes, compared to idiographic measures.

Objectives: One objective of the study is to determine the relationship between parent and teacher report of child progress on IEP objectives and an objective assessment of the same goals from an independent observer using goal attainment scaling (GAS). Another objective of the study examines whether the relationship between parent, teacher, and an independent observer remain stable across age groups.

Methods: Data were collected from a secondary analysis of two RCT's of the Collaborative Model for Promoting Competence and Success (COMPASS). COMPASS consists of a parent-teacher consultation and four coaching sessions. A shared decision-making approach is used for goal selection and intervention planning. At the end of the year, parents and teachers completed both nomothetic and idiographic measures of IEP progress.

Parents and teachers assessed IEP goal progress with a Likert-type scale questionnaire. Parents and teachers were asked to think of where the student was at the beginning of the school year with the specific goal and rate how much progress had been made to date using a 5-point scale for each goal. Informants' judgments of goal progress were internally consistent across the three goals for the parent measure (α = .81) and the teacher measure (α = .69).

Psychometrically equivalence tested goal attainment scaling (PET-GAS) was used to evaluate IEP progress by an independent evaluator. Each GAS used a 5-point rating scale: -2 = *student's present levels of performance*, -1 = *progress*, 0 = *expected level of outcome by the end of the school year*, +1 = *somewhat more than expected*, +2 = *much more than expected*. PET-GAS pre- and post-treatment ratings were based on video demonstrations, work samples, and/or data collected.

Results: Data were analyzed using partial correlations controlling for group assignment. Significant correlations were found between parent report and independent evaluator's report on student's progress in communication and learning goals, not social goals (See Table 1) for children ages 3-8. For the same age group significant correlations were found between teacher report and independent evaluator's report on student's progress for all three goals (See Table 1). Sample size differs for each group. Data regarding transition age students will be analyzed at a later date.

Conclusions: Results indicate significant correlations between the majority of GAS ratings and teacher /parent ratings, and there is evidence supporting the use of idiographic measures for children with ASD in early childhood. Results examining transition age children will be analyzed and compared to make conclusions regarding idiographic measures across age groups.

419.024 *(Poster)* Examining the Effectiveness of a Multimodal ASD Training Program for Medical Students

A. Friedman*, B. O'Hagan, L. Bartolotti, P. Sonikar, S. King and M. Augustyn, Developmental and Behavioral Pediatrics, Boston Medical Center, Boston, MA*

Background: Autism Spectrum Disorder (ASD) is a neurodevelopmental disability characterized by core deficits in social communication and restricted, repetitive behaviors[1]. Individuals with ASD have been found to utilize healthcare services at a higher rate than their typically developing peers[2–4]. However, healthcare providers have also reported a lack of knowledge on how to best interact with patients with ASD[2–4], suggesting a need for additional training for medical professionals[5]. To address this gap, The Autism Program at Boston Medical Center (BMC) integrated and delivered a 90-minute "Autism 101" training into third-year medical student curriculum at the Boston University School of Medicine during their psychiatric rotations.

Objectives: To increase self-reported familiarity with: ASD, techniques for accommodating patients, comfort examining patients, and communicating with patients.

Methods: 205 third-year medical students participated in monthly "Autism 101" trainings throughout 2018-2019, which includes a parent panel that provides critical insight into patient and family experiences. Topics covered include definition, presentations, and associated diagnostic criteria of ASD; barriers faced by patients with ASD and families in the hospital; and strategies to facilitate interactions with patients with ASD. Medical students were asked to complete a pre-training and post-training survey, consisting of quantitative and qualitative items. The survey was developed to assess the training objectives, by asking students to rate statements on a 5-point Likert Scale (1 = not at all familiar/comfortable, 5 = very familiar/comfortable) on all four aims: familiarity with ASD, techniques for accommodating patients, comfort with exam, and comfort with communication.

Results: An independent-samples t-test was conducted to compare students' familiarity with ASD, techniques for accommodating patients, comfort-level in examining patients, and communicating with patients with ASD. There were statistically significant differences in responses to all four survey items before and after the training (Table 1). In addition, medical students also provided positive qualitative feedback for the training, such as "[this training] is an invaluable resource...as we prepare to be the individuals on the other side of the bed caring for patients and their families", and requested that the training be kept "every year" for medical students.

Conclusions: Medical students found the "Autism 101" training helpful in improving their familiarity and comfort-level with ASD. Integration of ASD education and training into general medical student curriculum nationwide may be beneficial. More research is needed to further evaluate how their familiarity and comfort impacts future behavior.

419.025 *(Poster)* Examining the Practices and Experiences of General Education Teachers Including a Student with Autism

K. Oliver[1], *D. Christy*[2] *and A. Stahmer*[3], *(1)Koegel Autism Center, Santa Barbara, CA, (2)UC Davis MIND Institute, Sacramento, CA, (3)Psychiatry and Behavioral Sciences, UC Davis MIND Institute, Sacramento, CA*

Background: The number of students with autism included in general education (GE) has been steadily increasing. However, considerable work still needs to be done to address the multiple barriers to effective inclusion for most students with autism. GE teachers consistently report a lack of adequate training, knowledge, and resources to effectively educate students with autism. GE teachers often perceive students with autism to be difficult to teach and in need of specialized instruction that cannot be provided in GE. Linking evidence-based practices for autism to existing training initiatives is one way to address these barriers while minimizing additional burden on teachers. For example, Universal Design for Learning (UDL) is a nation-wide educational initiative with the potential to positively influence inclusion due to the many commonalities with Classroom Pivotal Response Teaching, an evidence-based approach for autism. Understanding strategies GE teachers already use that fit current GE initiatives, such as UDL, and that also overlap with autism-specific evidence-based practices may be a helpful jumping off point for successfully designing professional development opportunities that support inclusive classrooms.

Objectives: This study provides an in-depth examination of GE teacher perceptions and experiences related to including a student with autism in their classroom. We asked teachers about the strategies, tools, and modifications they used to support students with autism. Additionally, we aimed to gain more insight on GE teacher's perceptions and use of UDL and CPRT components.

Methods: Twelve GE teachers participated in focus groups conducted via Zoom, a HIPAA-compliant web-based discussion forum. Recruitment continued until we reached saturation of themes. Focus groups lasted approximately one hour, were co-facilitated by the first two authors, and included one to four GE teachers per group. Teachers taught kindergarten through grade five, had taught at least one student with autism, and represented public, private, and charter schools. We gave teachers brief information about UDL and CPRT with vignettes of hypothetical students with autism so participants had the same reference for discussion, though teachers were encouraged to share their personal experiences. The facilitators used an interview guide to ask teachers about strategies they used to support their students with autism, their perceptions and application of UDL and CPRT strategies, and challenges they encountered or anticipated when using these strategies. We transcribed focus groups and used thematic analysis guided by a grounded-theory approach to identify themes.

Results: Teachers reported using a variety of strategies, include those with a strong evidence-base, to facilitate communication, self-regulation, social interaction, and academic engagement with their students with autism. Most teachers had limited to no direct training in CPRT or UDL but still reported generally positive perceptions, with some negative responses regarding certain CPRT components. Feedback on UDL components was positive overall.

Conclusions: Many GE teachers report using research-supported educational approaches for autism. An important next step for teacher training is to link teacher's pre-existing knowledge and experiences to specific evidence-based strategies for autism to maximize teacher buy-in and minimize burden. This could help ensure good contextual fit of intervention strategies in the inclusive GE classroom.

419.026 *(Poster)* Exceptional Skills in School-Age Autistic Children – Perceptions of Parents and Teachers

T. R. Clark[1,2,3], *J. M. Roberts*[4], *V. Gibbs*[1], *P. Howlin*[5], *J. Jung*[6], *K. P. Haas*[1] *and M. Clark*[7], *(1)Aspect Research Centre for Autism Research, Autism Spectrum Australia (Aspect), Sydney, NSW, Australia, (2)Institute for Educational Research, Griffith University, Brisbane, NSW, Australia, (3)Autism Spectrum Australia (Aspect), Seven Hills, Australia, (4)Graduate Intitute of Educational Research, Griffith University, Meadowbrook, QLD, Australia, (5)King's College London, London, United Kingdom, (6)Education, University of New South Wales, Sydney, NSW, Australia, (7)Graduate Institute of Educational Research, Griffith University, Brisbane, Australia*

Background: Autism is commonly described in terms of deficits, with most outcome research indicating that autistic individuals have poorer quality of life than "neurotypical peers" of comparative cognitive ability. Nevertheless, the research also indicates that most autistic individuals demonstrate one or more exceptional skills. Using a strengths-based approach to educating autistic children with exceptional skills may equip them to use these skills in ways that foster greater inclusion and a better quality of life in adulthood. To assist educators develop such programs, a better understanding of the exceptional skills of autistic students is needed.

Objectives: This study aimed to examine the (1) rates of exceptional skills in autistic school-aged children: (2) associations between exceptional skills (and skill type) with autism severity and intellectual disability; correlations between parents/carers and teacher reports of exceptional skills.

Methods: Parents and teachers of 74 students attending autism-specific schools in Australia completed an online exceptional skills questionnaire. To provide a measure of autism, parents also completed the Social Responsiveness Scale. The questionnaire gave descriptions and examples of three types of exceptional skills - savant, relative strengths and giftedness. Giftedness refers to high-level abilities i.e. in the top 10% of all children of their age. Parents who had identified their child as having one or more exceptional skills (n=30) were then interviewed by a clinical psychologist to gain further insight and assign a final rating of exceptional skills according to the study criteria. Descriptive statistics identified the numbers of children reported by parents and/or teachers as having one or more exceptional skills. The Kappa coefficient was used to assess agreement between parent and teacher reports, and between parent/teacher reports and clinician ratings. The relationship between the presence of exceptional skills and a diagnosis of intellectual disability was examined using a chi-square test of independence; independent t-tests examined the relationship between skills and autism severity.

Results: Thirty parents (39.5%) and thirteen (17.1%) teachers reported their child/student had at least one exceptional skill. There was poor agreement between parent and teacher reports (Kappa=.175, p=.074). In comparison, 28.9% of the children/students were rated as having at least one exceptional skill by the clinician; the most commonly reported exceptional skills were in memory and reading. No students were rated by the clinician as displaying giftedness. For further analyses, children rated by the clinician as having savant skills or relative strengths were combined into one group. There was no significant difference in autism severity scores or diagnosis of intellectual disability for those with and without exceptional skills.

Conclusions: Parental reports confirm the presence of exceptional skills in around one third of autistic school-age students as reported in previous studies. Although there were no reports of giftedness as rated by the clinician, this may be a result of the sample only comprising students in special education schools, rather than from mainstream settings. The poor agreement between parents and teacher reports warrants further examination.

419.027 *(Poster)* Experiences of Paraprofessionals in Public School Settings

K. L. Morin[1]*, S. W. Nowell*[2]*, J. R. Steinbrenner*[3]*, A. Sam*[4]*, V. Waters*[5] *and S. Odom*[3]*, (1)Lehigh University, Bethlehem, PA, (2)University of North Carolina - Chapel Hill, Chapel Hill, NC, (3)Frank Porter Graham Child Development Institute, University of North Carolina at Chapel Hill, Chapel Hill, NC, (4)Frank Porter Graham Child Development Institute, Carrboro, NC, (5)Frank Porter Graham Child Development Institute, University of North Carolina at Chapel Hill, Carrboro, NC*

Background: Paraprofessionals play a vital role in the instruction of students with disabilities, with more paraprofessionals employed in preschool through high school settings than special education teachers (U.S. Department of Education, 2018). Given the importance of paraprofessionals, adequate preparation and training are critical for students to achieve the best outcomes (Brock & Carter, 2013). Unfortunately, many paraprofessionals do not receive preparation or training for their roles, which can lead to low quality instruction for students with ASD (Jones et al., 2012). Professional development is needed for paraprofessionals serving students with ASD to be more successful in their roles, but first it is important to know what responsibilities paraprofessionals currently have in order to teach content that is relevant. Additionally, professional development providers need to know what barriers prevent paraprofessionals from engaging in training.

Objectives: The purpose of this study was to gather information that could serve as the foundation of the development of a professional development program for paraprofessionals working in special education. Specific research questions addressed include: (1) What are the roles and responsibilities of paraprofessionals in school settings? (2) What types of professional development result in applied knowledge for paraprofessionals? (3) What are the barriers to professional development? Secondary research questions explored whether paraprofessionals' responses to these questions differed by the setting (i.e., general education or special education) or grade level (i.e., preschool/elementary or middle/secondary) in which they primarily worked.

Methods: To answer our research questions, we designed and distributed a survey to registered AFIRM users (affirm.fpg.unc.edu) who identified as a paraprofessional working with students with autism in a PreK-12 grade public school setting. Data reflect responses to 16 questions by 325 paraprofessionals who responded to the survey. We conducted descriptive analyses on paraprofessionals' responses to each survey question, and post-hoc analyses to determine if there were differences in paraprofessionals' survey responses by grade level and setting. To correct for the multiple comparisons, we applied the Bonferroni-Holm method.

Results: Paraprofessionals engaged in the following tasks daily: providing (a) academic support, (b) self-help instruction, (c) support in instructional settings, (d) support or supervision related to behavior, and (e) supervision for non-instructional times. Paraprofessionals working in special education settings reported spending significantly more time planning and preparing for student lessons and providing self-help instruction than paraprofessionals working in general education. The major barriers to professional development included a lack of (a) employer support, (b) resources, and (c) money.

Conclusions: Information on the roles and responsibilities that paraprofessionals of students with ASD engage in on a regular basis can help professional development providers design relevant training that is socially valid. Because teachers supervise paraprofessionals on a daily basis, they are naturally the most suited for providing training to paraprofessionals. The information in this study can help researchers planning on designing a model of professional development to be implemented by teachers in school settings for paraprofessionals of students with ASD. Such a model is needed and has the potential to improve the outcomes of school-aged students with ASD (Walker & Smith, 2015).

419.028 *(Poster)* Exploring Autistic Students' Experience of Using Social Network Maps to Address Social Changes When Transitioning to University

J. Lei[1]*, C. Ashwin*[2]*, M. Brosnan*[3] *and A. Russell*[4]*, (1)Centre for Applied Autism Research, University of Bath, Bath, United Kingdom, (2)University of Bath, Bath, United Kingdom of Great Britain and Northern Ireland, (3)Centre for Applied Autism Research, University of Bath, Bath, United Kingdom of Great Britain and Northern Ireland, (4)Psychology/Centre for Applied Autism Research, University of Bath, Bath, United Kingdom*

Background: For many autistic students, adapting to a novel social environment at university can be especially challenging. Providing information about the different aspects and functions of social networks may help autistic students carefully consider the purpose of maintaining or establishing new relationships during transition to university.

Objectives: 1) Develop a workshop to generate student discussions about different aspects of SNS in relation to accessing support.

2) Evaluate (mixed-methods) students' experience of using network maps to plan for social transitions when going to university.

3) Gather feedback about the workshop.

Methods: The goal of the workshop was to provide information about *what* a social network is, *why* networks are important for accessing support, and *how* networks might change at the time of university transition. Individualised social network maps for each student were created based on self-reported relationships over the past 3 months (Figure 1). Three groups of 8-10 students (total N= 29) participated in the one-hour workshop. Information was delivered through didactic teaching. Students completed exercises to identify key network members who provided them with support pre-university, and how they would like their social network to change during university transition. Students rated the accuracy of, and satisfaction with their own social network maps on a 5-point Likert scale, and provided written feedback about the workshop. Twenty-seven students (Age: M(SD) = 17.86(2.82) years; 18 Male) completed the personal social network exercises, and two students completed a neutral (non-personal) exercise.

Results: 59% of students rated family to be one of the most important sources of social contact based on their network map, and 40% identified at least one close friend. Students felt neutral (M(SD) = 3.37(1.04)) regarding network satisfaction (p = .097) and found their networks to be somewhat accurate (M(SD) = 3.57(0.98); p = .021). Around 60% of students reflected on losing existing friendships and seeking new peer support when going to university, and 92% expressed wanting to keep some existing relationships, mostly family (44%) and friends (52%) (Table 1a). Students rated the workshop as enjoyable (M(SD) = 3.83(0.76), p <.001) and helpful (M(SD) = 4(0.67), p < .001), especially for social transition planning in preparation for university (M(SD) = 4.07(0.77), p < .001). Students found visualising relationships through network maps both appealing and useful. 52% of students found network maps helped improve their understanding of social relationships between different groups of people within their networks. However, around 14-17% of students found the material confusing, and difficult to be confronted with the paucity of social connections in their network (Table 1b).

Conclusions: Our pilot workshop showed that social network maps allow autistic students to visualise how they access support from different network members in a clearly structured and succinct way and help them plan for social changes when going to university. Future workshops can improve clarity of information presented to match the diversity of students' learning styles and include exercises to buffer distress experienced by students who had limited social networks.

419.029 *(Poster)* Factors Associated with Academic Attainment for Autistic Individuals within a Population-Based Twin Sample.

V. L. Milner[1]*, E. Colvert*[2] *and F. Happé*[1]*, (1)Social, Genetic and Developmental Psychiatry Centre, Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, United Kingdom, (2)SGDP, Institute of Psychiatry, Psychology and Neuroscience, KCL, London, United Kingdom*

Background: Previous research has shown a large proportion of adults with ASD (diagnosed in childhood) leave school without formal academic qualifications (Howlin, 2000). In the non-autistic population, research has shown that factors such as socioeconomic status (Hedges et al, 1999), sex (Voyer & Voyer, 2014), mental health and behavioural difficulties (Kessler et al, 1995, Loe & Feldman, 2007, Breslau et al, 2008), and IQ (Mayes et al, 2009) have a significant impact on academic attainment.

However, there has been limited research into the effect these factors (SES, sex, mental and behavioural difficulties and IQ) have on autistic individuals' academic attainment in comparison to their non-autistic peers, and whether these factors play an equal role in academic attainment, depending on autism diagnosis, and/or degree of autistic traits.

Objectives: This study explored factors that might influence academic attainment, comparing autistic twins, their non-autistic co-twins, and a non-autistic control group selected for low autism traits.

Methods: Three groups of participants were included from a population-based twin-sample: 55 18-year-old twins who met criteria for a research diagnosis of ASD (83% male); 22 non-ASD co-twins (31% male); 50 comparison twins (64% male). Participants completed team-designed questions about education and academic attainment as part of a wider research assessment.

Multiple regression analyses were run to predict total public exam passes at age 18 from autism severity scores (ADOS calibrated severity scores or CAST scores at aged 8 for the control group), IQ, sex, maternal education, and emotional, conduct, peer, prosocial and hyperactivity (from SDQ) for each group.

Results: For the ASD group, the multiple regression model significantly predicted exam passes, $F(9,45) = 4.864$, $p < 0.00$, adj. $R^2 = 0.392$. The following variables significantly contributed to the model for the ASD group: IQ, ASD severity scores, maternal education, emotional difficulties and prosocial difficulties (all $p<0.05$).

For the co-twin group, the multiple regression model was not statistically significant, $F(7,14) = 1.906$, $p = 0.144$, adj. $R^2 = 0.232$. The small number in this group may have limited statistical power. Exam passes were significantly correlated with ASD severity scores and conduct difficulties ($p<0.05$).

For the control group, the multiple regression model significantly predicted exam passes, $F(9,40) = 4.642$, $p<0.000$, adj. $R^2 = 0.401$. On closer inspection, IQ and gender were the only coefficients that significantly contributed to the model (all $p<0.05$).

Conclusions: Academic attainment was found to be influenced by a range of factors, varying by ASD diagnostic status. The ASD group showed that severity of autistic traits and additional mental health concerns may impact on school attainment, indicting areas for possible intervention in educational settings.

419.030 *(Poster)* Following the Footprints: Making an Autism-Friendly Pediatric Emergency Department (ED) in "the Sweetest Place on Earth"

C. M. Lucas[1]*, A. Brawley*[1]*, B. Otaibi*[1]*, H. Patel*[1]*, R. P. Olympia*[2] *and C. D. Tierney-Aves*[2]*, (1)Penn State College of Medicine, Hershey, PA, (2)Penn State Health Children's Hospital, Hershey, PA*

Background: Children with autism often face negative experiences when accessing healthcare, and autism care plans have been shown to improve patient outcomes. The Autism Spectrum Ambassador Program (ASAP) aims to improve the healthcare experience for children with autism and their families by providing a trained Medical Student Ambassador and Accommodation Plan to facilitate patient-centered care, meeting the child's unique needs in the Emergency Department (ED).

Objectives: To evaluate the utility of this novel program in the ED through the assessment of family, provider, and student experiences.

Methods: Program materials were created by study personnel to educate medical student volunteers to become Ambassadors. The ASAP was initially implemented in the same-day surgery center at Penn State Children's Hospital, and it was adapted for implementation in the Pediatric ED utilizing input from a multidisciplinary team of Child Life Specialists, nurses, providers, and technicians. Parents of children with autism aged 30 months-17 years who present to the ED between 4pm-10pm, Monday-Friday will be consented and provided an iPad to complete an Autism Accommodation Survey (AAS) while in the waiting room. The Accommodation Plan is automatically generated from responses on the AAS and printed as color-coded, provider-specific accommodation cards to be displayed at the bedside (e.g., physicians/APPs, nurses, Child Life, and technicians). A footprint window cling on the patient's door will alert staff to program participation, prompting them to be mindful of the need for making accommodations during the patient encounter. Within three days, all program participants will be emailed a survey to measure program satisfaction. Satisfaction surveys will also be sent to parents of children with autism who did not have a Medical Student Ambassador available during their ED visit, serving as a control group.

Results: The program will officially launch January 2, 2020, and we anticipate preliminary data by March. Although in its infancy, this project has led to increasing the level of acuity at triage if the parent would indicate their child is at risk for aggression with prolonged wait-time as well as new ED-specific accommodations, such as an "If, then" board, social stories, headphones, weighted blankets, sunglasses, and sensory-oriented motivators.

Conclusions: The ASAP continues to work toward improving the healthcare experience for pediatric patients with autism and their families, breaking down barriers that have prevented high-quality patient-centered care through education and advocacy utilizing a multidisciplinary approach. We hope that the ASAP will inspire others to advocate for individuals with disabilities and consider implementing similar programs, following the footprints of the Autism Spectrum Ambassador Program.

419.031 *(Poster)* Heterogeneity in Math and Reading Scores in Students with ASD

J. C. Bullen[1] *and P. Mundy*[2]*, (1)University of California, Davis, Davis, CA, (2)University of California at Davis, Sacramento, CA*

Background: The rate of students with ASD without intellectual disability (IQ > 75; ASD-WoID) has increased in recent years (Baio et al., 2018). As a result, more students with ASD-WoID are spending a majority of their time in general education classrooms (Wagner et al., 2005). However, previous research has pointed to heterogeneity in mathematics and reading performance in children with ASD-WoID and the impact that behavioral and cognitive factors have on achievement (Chen et al., 2018). Further research is needed to understand if these patterns of achievement are reproducible.

Objectives: To examine the heterogeneity of math and reading ability in children with ASD-WoID and the cognitive and behavioral factors that may impact math and reading achievement.

Methods: 121 children participated including 78 children with ASD-WoID (M = 11.33 years, SD = 2.14) and 43 neurotypical controls (M = 11.55 years, SD = 2.27). ASD diagnosis was confirmed with the ADOS-2. Attention symptoms were measured using the Connor's-3, and symptoms of anxiety and depression were measured using the BASC. To gauge academic achievement, participants completed numerical operations and problem solving measures from the WIAT-III and reading fluency and comprehension measures from the GORT-5. Participants also completed measures of verbal, symbolic, and story memory from the WRAML2 and measures of IQ from the WASI2. Participants were clustered on their math and reading scores using hierarchical cluster analysis.

Results: The cluster analysis resulted in a two cluster solution which replicated the clusters of Chen and colleagues (2018). Our two clusters also resulted in a "low achieving" group (LA) and "high achieving" group (HA). The LA group performed below the HA group on all math and reading assessments ($ps < .05$). In both the TD and ASD groups, there were significant differences in IQ between the LA and HA cluster groups, wherein the LA group had significantly lower verbal, performance, and full-scale IQ scores than the HA group ($ps < .05$). In the ASD group, the LA group performed below the HA group on verbal working memory, $t(76) = 4.55$, $p < .01$, symbolic working memory, $t(76) = 5.01$, $p < .01$, and story memory $t(76) = 4.33$, $p < .01$. In the TD group, the groups only differed on symbolic working memory performance, $t(41) = 3.07$, $p < .01$. Behavioral analyses are currently underway.

Conclusions: The findings of this study support those previously reported by Chen and colleagues (2018). There is significant heterogeneity in mathematics and reading performance in students with ASD-WoID. These students can benefit from inclusion in general education classrooms; however, the students in the lower achieving group are at risk for mathematics and reading learning difficulties, possibly related to differences in IQ and working memory. This heterogeneity needs to be anticipated in educational settings. The findings of these studies may help aid educators to identify students who may experience difficulty in mathematics and reading, and to address these issues with appropriate curricular adaptations.

419.032 *(Poster)* Latino Communities, ASD, & Parental Engagement: A Systematic Review of the Literature

J. Miguel*, UC San Diego, San Diego, CA*

Background: Limited research exists on parental engagement among diverse parents of children with autism spectrum disorder (ASD) (Burke, 2013; Burke & Hodapp, 2016). The U.S. Census Bureau's (2017) most recent American Community Survey indicates that individuals of Hispanic origin make up 18% of the U.S. population with 25% under 18 years of age. This paper will utilize a critical sociocultural framework (Holloway, Cohen, & Domínguez-Pareto, 2018) to examine socioeconomic diversity among Latino families whose children are diagnosed with Autism Spectrum Disorder (ASD) within the parental engagement literature.

Objectives: The purpose of this study was to understand the socioeconomic diversity among Latino parents whose children are diagnosed with autism within parental engagement literature.

Methods: The systematic review met six specific qualifications. Participants/articles had to be (1) From Latin American countries (e.g. Central America, Mexico); (2) Have children with ASD; (3) Child participants of elementary age; (4) Results specific to educational engagement; (5) Published in 2008 or later; and (6) Peer reviewed. Keywords using each of the inclusion criteria were used for searching (e.g. Mexican, autism, involvement) across six databases (e.g. ERIC, PsycINFO). From these databases 1,168 total articles were collected, 17 were selected for final review. Each article was examined using the quality appraisal process (Brantlinger, Jimenez, Klingner, Pugach, & Richardson, 2005; Trainor & Graue, 2014), see Table 1. Using the critical sociocultural framework, key demographics were recorded to examine the various cultural communities of participants (see Table 2) and analyzed to understand between group differences.

Results: A total of 1,100 adult and 275 child participants were accounted for. Half of the articles reported differences across language, marriage status, and child's age but less than half included frequency counts. Additionally, over 50% of the articles did not include demographics such as income, age, or education level of adult participants. There were four key demographic findings; (1) 94% of the articles, indicated that only 20% of adult caregivers (e.g. mother, father, grandparents) are male; (2) Latinos made up 44% of all articles reported, 32% identified as Latino/Hispanic, 9% Mexican heritage, 1.3% Caribbean, 1% Central American, and .9% South American; (3) 59% of articles reported the primary language spoken by participants, 16.3% reported a language other than English, 11% indicated they were bilingual (i.e. English/Spanish); (4) 53% of articles indicated that 94% of the participants were married.

Conclusions: This study utilized a critical sociocultural framework to examine the cultural communities in the final articles selected (Holloway, Cohen, & Domínguez-Pareto, 2018). The sociopolitical and cultural factors are particularly important in the field of special education since culture is often conceptualized through overgeneralizations (Holloway et al., 2018). However, sociocultural characteristics, such as immigration, country of birth, and approximate recruitment location were missing from the majority of studies. If the field intends to move away from generalizing ethnic groups, it is important to include these more nuanced characteristics of sociocultural context given that immigration history, income, and access can vary (Cohen & Miguel, 2018; Hausmann-Stabile, Zayas, Runes, Abenis-Cintron, & Calzada, 2011).

419.033 *(Poster)* Mapping out Autism-Specific College Support Programs in the United States

B. R. Nachman[1]*, C. T. McDermott*[2] *and B. E. Cox*[3]*, (1)University of Wisconsin-Madison, Madison, WI, (2)Shrub Oak International School, Lake Mohegan, NY, (3)Educational Leadership and Policy Studies, Florida State University, Tallahassee, FL*

Background: Nationally representative statistics from the United States indicate that fewer than 39% of autistic students who enter college complete their degrees (Newman et al., 2011). To improve students' chances for college success, many scholars and practitioners encourage these students to disclose their diagnosis to their institution's Disability Services Office (DSO) and formally request disability accommodations. Yet, emerging research suggests that the most common accommodations (e.g., in-class note-takers, extended test time) are frequently inadequate for students with autism. In response, some postsecondary institutions have created autism-specific programs that incorporate multiple types of supports (e.g., peer mentors, social skills training, tutoring services). Little research about these programs has yet been conducted.

Objectives: This project used a collaborative, systematic approach to identify autism-specific college support programs in the United States and document both institutional and programmatic characteristics. The results will support three groups. First, students and families can pinpoint potential college options. Second, higher educational professionals can create or adapt programs upon identifying peer institutions featuring similar programs. Third, researchers can draw on this data to better contextualize current autism/higher education scholarship.

Methods: Data are drawn from all 4,567 degree-granting postsecondary institutions in the United States (Carnegie Classification of Institutions, 2015). From August 2018 to August 2019, researchers conducted searches for "autism" and "program" off of search bars on each institution's homepage. Pages returned from this search were examined to determine the existence of autism-specific programs. To ensure accurate results, each institution was examined by two different researchers. Whenever initial results were unclear, the research team sent emails seeking clarification from institutional staff and collectively met to reach consensus. To be included in our list, the program must: 1) exclusively or primarily serve autistic students currently enrolled at a college or university; 2) feature a publicly accessible webpage about the program; and 3) be currently active (e.g., not closed or under development).

Results: Only 78 of the 4,567 (1.7%) of degree-granting postsecondary institutions in the United States host autism-specific college support programs. The distribution of these programs varies dramatically across eight distinct geographical regions in the United States. The greatest concentration of programs occurred in the Mid-Eastern region (NY, NJ, PA, DE, MD, and Washington D.C.) where 24 of 722 institutions (3.3%) hosted programs. In contrast, none of the 260 institutions in the New England region (ME, VT, NH, RI, MA, CT) hosted programs. The vast majority of programs were located at 4-year (83.3%) and at public (73.1%) institutions.

Conclusions: While a number of states offer autism-specific college support programs, these are only found in 29 states and a vast majority of programs are situated in 4-year institutions, despite the prominence of autistic students attending community college (Wei et al., 2014). These findings are concerning because they point to the need for many students to attend programs at institutions located outside their home state (thus increasing costs and the emotional labor of living away from home) and within larger 4-year campuses that may not feel as comfortable to them.

419.034 *(Poster)* Measuring the Effectiveness of the Attention Autism Programme on Improving Social Communication Skills for Primary School Children with Autism.

R. Ferguson[1]*, L. Hynds*[2]*, S. Cross*[3] *and* ***F. Mccaffrey***[4]*, (1)Middletown Centre for Autism, Armagh, United Kingdom of Great Britain and Northern Ireland, (2)Psychology, Belfast Education Authority, Belfast, United Kingdom, (3)Research and Development, Middletown Centre for Autism, Armagh, United Kingdom, (4)Middletown Centre for Autism, Middletown, Co Armagh, United Kingdom of Great Britain and Northern Ireland*

Background: Social skills encompass the essential socially acceptable learned behaviours that enable a person to successfully interact with others (Gresham and Elliott, 1984). For autistic people social communication situations can be challenging (Sutton et al., 2018).

Interventions which focus on developing fundamental skills in play and attention are thought to support social communication skills in all children (Toth et al., 2006). The Attention Autism Programme (AAP) created by Specialist Speech and Language therapist, Gina Davies, is a novel intervention which utilises an irresistible invitation to attend through play. However, AAP has underwent little formal investigation (McKeown, 2015).

Objectives: This study aims to investigate the effectiveness of the AAP on improving social communication skills for children with autism.

Methods: This study compared the social communication skills of 25 autistic children between of 6 – 8 years pre and post participation in a six week AAP. Certified trainers conducted the AAP with 25 children with autism. The effectiveness of the intervention was assessed using the Social Responsiveness Scale (Constantino and Gruber., 2012); The Joint Attention Task (Bean and Eigsti., 2012); and Video Analyses of the duration of attentional behaviours. Education staff were interviewed to ascertain the effect of the AAP on classroom behaviours.

Results: A Wilcoxon signed rank test revealed a statistically significant increase in the participants observed attentional behaviours between week 1 and week 5 of the AAP $z=-4.28$, $p<.001$, with a large effect size ($r = .605$). The mean observed attentional score increased from 64.2 % in week 1 to 80.7% in week 5 indicating that the participants attentional behaviours improved significantly during the AAP. A statistically significant difference in the duration of communication the participants engaged in during the AAP between week 1 ($M = 9.18\%$) and week 5 ($M = 12.8\%$), $z=-2.03$, $p<.05$, with a medium effect size ($r= .287$) was also evident.

A standard multiple regression was carried out to investigate if the participants scores on JTAT and SRS2 could predict the participants attentional scores based on observations of the AAP sessions in week 1. The results of the regression indicated that the model explained 41.1% of the variance and that the model was a significant predictor of observed attentional performance in the AAP, $F (2, 22) = 7.66$, $p= .003$. While scores on the JTAT contributed significantly to the model ($B=.554$, $p= .003$), whereas the SRS2 scores did not ($B=-.264$, $p=.124$). Further exploration of results using hierarchical multiple regression, revealed that neither the age of the participant or the participants school placement impacted on their attentional abilities during the AAP.

Conclusions: The AAP has been shown to be effective in significantly increasing observed attentional behaviours and in duration of communication in 25 autistic children aged 6-8 across educational settings.

419.035 *(Poster)* Promoting Program Quality for Students with Autism through Coaching

A. Sam[1]*, B. Tomaszewski*[2,3,4]*, V. Waters*[5] *and S. Odom*[2]*, (1)Frank Porter Graham Child Development Institute, Carrboro, NC, (2)Frank Porter Graham Child Development Institute, University of North Carolina at Chapel Hill, Chapel Hill, NC, (3)Psychiatry, University of North Carolina at Chapel Hill, Chapel Hill, NC, (4)TEACCH Autism Program, University of North Carolina at Chapel Hill, Chapel Hill, NC, (5)Frank Porter Graham Child Development Institute, University of North Carolina at Chapel Hill, Carrboro, NC*

Background: Federal law requires educators to provide high-quality programs for children with autism. For high school programs, Kraemer et al. (2020) found that program quality was mediocre to poor. However, little is known about program quality for children in elementary schools and the effects of interventions designed to improve quality. A key feature of professional development programs designed to promote program quality is the presence of coaching who provide training and feedback to teachers.

Objectives:

- Describe quality of programs for students with autism enrolled in elementary schools.
- Describe an intervention approach designed to improve program quality.
- Determine how coaching affect changes in program quality across a school year.

Methods: This study took place in 59 elementary schools and was part of a larger randomized control study examining the effects of a comprehensive treatment model. Data were collected in inclusive and non-inclusive programs operating at each school. At the beginning and end of the school year research staff conducted the Autism Program Environment Rating Scale—Preschool/Elementary (APERS-PE) (Odom et al., 2018). The APERS-PE is a 59 item, 5-point rating scale that yields a total mean rating and individual domain scores (across 10 domains). A rating of 5 indicates excellent quality, 3 indicates mediocre quality, and 1 indicates poorest quality.

Results: The internal consistency of the APERS-PE in this study was .93 and .96 for the inclusive and non-inclusive program APERS-PE. Inter-rater agreement checks occurred for 20% of the sample. Interclass corrections between the two raters for the inclusive and non-inclusive programs were .97 and .98 respectively. At pretest there were no differences between the treatment and control groups. For the total group, the mean total scores were 3.10 and 2.96 for the inclusive and non-inclusive programs. A characteristics pattern was for schools to score greater than 3.0 on Environment, Climate, Family and Team, and consistently lower than 3.0 on the intervention domains (Social, Communication, Independence). When changes across the school year were analyzed, the only significant difference was for the social domain in the inclusive programs. However, four of the 11 coaches in the study did not meet expectations for quality of coaching. To determine the impact of coaching on program quality, pre-post APERS effect sizes were calculated for the schools with coaches needing supervision, schools with coaches meeting expectations for competence, and control schools. Consistently, schools with competent coaches had the highest effect sizes across domains, with schools with less competent coaches having effect sizes less than the other treatment schools and often similar to the control schools.

Conclusions: A general finding of this study was that the quality of educational programs for children with autism was mediocre to high for environmental features of the program, but poor for intervention domains. An intervention designed to promote program quality across the school year did not finding consistent difference when compared to the control schools. However, the quality of coaching provided to the intervention schools appears to have a major impact on change in APERS scoring for school in the treatment group.

419.036 *(Poster)* Review of the Use of Immersive Virtual Reality Technologies in Adolescents with Autism

X. Qian*, P. Gu and T. H. Weng, University of Kansas, Lawrence, KS*

Background: Autism affects 1 in 59 children and is about 4 times more common boys than girls (Baio, 2018). Children do not grow out of Autism, thus as a result, there is a critical need to identify interventions targeting the unique needs of the growing population of adolescents and adults with Autism. Technologies related to Virtual Reality has the potential to assist people with Autism in practicing and generalizing social skills that can be transferred into the real world. Research has suggested some prospective benefits of using immersed virtual reality technologies [i.e., virtual reality (VR), mixed reality (MR), and augmentative reality (AR)] to improve educational and practical outcomes for adolescents and adults with Autism (Smith et al., 2014)

Objectives: This review aims to (1) determine the number of empirical studies using VR-related interventions, (2) identify the skills targeted in these interventions, (3) describe technology features used and the overall effects, and (4) analyze scientific rigor of these studies (e.g., types of design, reliability and validity evidence related to dependent and independent variables).

Methods: The databases for PubMed, PsycINFO, CINAHL and Web of Science were searched for relevant paper between 2000 to 2018 published in peer-reviewed journals. We coded the following variables: (1) the technology used to deliver the intervention, (2) types of targeted skill(s), (3) demographics (gender, age, cognitive ability and disability), (4) experimental setting, (5) dependent and independent measures, and (6) quality of research. Three independent researchers coded all the studies and inter-rater reliability was checked for 20% of the articles.

Results: VR technology has been used to train school-aged children with Autism in the areas of social and communication skills, driving skills and employment experience. Statistically significant improvement of targeted skills has been found, indicating positive effect of immersive technology applications on students with Autism. Most studies took place in labs using a small convenient sample and very few studies were conducted in natural settings (e.g., homes and schools). The majority of studies focused on social skills and several examined employment related skills such as interviewing skills.

Conclusions: Although immersive technology, such as VR, AR and MR, has been proved to be effective in helping people with Autism improve their behavioral, cognitive and social skills, most studies focused on individuals with Autism who do not have intellectual disability. Future studies need to examine the application of immersed VR technology on improving quality of life for all students with Autism. Researchers should also examine the degree to which skills trained using VR transfer to other settings. Another suggestion for future researchers and technology designers is teacher and practitioner education about the utilization and launching immersive tools to Autism populations. Current studies focus mostly on learning experience and outcomes of students, and experiment settings are strongly context dependent. The promising effect of the VR technology can be enhanced by the aid of effective and efficient pedagogy and training methods.

419.037 *(Poster)* School-Based Autism Rates By State: An Analysis of Demographics, DSM Alignment, and Differential Identification

***J. Safer-Lichtenstein**, J. Hamilton and L. L. McIntyre, Special Education and Clinical Sciences, University of Oregon, Eugene, OR*

Background: Rates of children served under autism spectrum disorder (ASD) special education eligibilities differ greatly by U.S. state. Previous studies indicate that socioeconomic factors, including caregiver income and education, impact ASD prevalence rates (e.g. Thomas et al., 2011; Sullivan, 2013). Additional factors that may impact these differential rates include influences of statewide policy/decision-making, such as ASD eligibility criteria and state political leanings (Barton et al., 2016; Marmor, 2017). Finally, diagnostic substitution, or use of certain labels over others, may determine how often students are being found eligible under different disability categories (Brock, 2006; Shattuck, 2006).

Objectives: First, we seek to provide updated statistics on school-based ASD rates by states and the number of U.S. states using ASD eligibility criteria aligned with medical criteria. Next, we attempt to determine what state-level demographic factors (i.e., median income, education attainment, state political leanings) predict these rates. Finally, we examine state rates of other disability categories that potentially have shared characteristics with ASD, and thus are considered part of the differential diagnosis/identification process in ASD evaluations.

Methods: Data for this study were collected from the U.S. Department of Education website. The data were analyzed for the 50 U.S. states and Washington D.C. To calculate the proportion of ASD and other disability categories, we chose to focus on the proportion of students with that eligibility out of the total number of students receiving special education in each state.

We obtained data on state-level demographic information, including median state household income and educational attainment (number of years of schooling completed for persons 25+), the American Community Survey. Additionally, we utilized the Cook Partisan Voter Index to determine political leanings of each state. Finally, we searched state department of education websites to find state ASD eligibility requirements and determine what criteria were being utilized.

Results: In terms of overall school-based "prevalence," there were 1 of 81 students nationally receiving special education services under an ASD eligibility. The proportion of special education students being served under an ASD eligibility averaged 9.16% across states, with a range of 1.12% to 14.78%. SES factors of state-level household income and adult education alone accounted for 17% of the total variance in the proportion ASD of special education students, $R^2 = .17$, $F(2, 48) = 4.83$, $p = .012$. After adding in the variable of political leaning, the combination of state-level household income, adult education, and political leanings accounted for 23% of the total variance in the proportion ASD of special education students, $R^2 = .23$, $F(4, 46) = 3.47$, $p = .015$. In looking at differential diagnosis/identification by state, higher rates of ASD were associated with lower rates of Intellectual Disability (ID) and Specific Learning Disability (SLD), and higher rates of Other Health Impairment (OHI).

Conclusions: While all of the factors that impact these differential rates are not fully known, this study provides evidence that state-level demographic factors, including education, income, and political leaning, play a role beyond child characteristics. Diagnostic substitution with other disability categories may also impact ASD rates.

419.038 *(Poster)* School-Based Health Education for U.S. Autistic Students Served By the Special Education System

***L. Graham Holmes**[1], J. Rast[2], A. Roux[2] and P. Shattuck[2], (1)A. J. Drexel Autism Institute, Drexel University, Philadelphia, PA, (2)A.J. Drexel Autism Institute, Drexel University, Philadelphia, PA*

Background: In 2017, 312,000 students aged 12-21 were served by the U.S. special education system. Youth who receive special education services have the right to the same health education as their peers, including school-based sexuality education (SBSE) and substance abuse prevention education (SAPE). Only one previous study has used population representative data to investigate whether youth with autism and other disabilities receive health education. This study, the National Longitudinal Transition Study-2, indicated that autistic adolescents were the least likely to receive SBSE (28.0%) and SAPE (25.3%) across students from all IEP categories. The current study provides an update using the National Longitudinal Transition Study-2012 (NLTS2012) data.

Objectives: (1) Estimate the proportion of autistic students served in special education in public high schools who received SBSE/SAPE compared to students.

(2) Investigate factors associated with receipt of SBSE/SAPE for autistic students.

Methods: The NLTS2012 was designed to yield nationally representative estimates of the characteristics and experiences of U.S. youth receiving special education services. This study examined youth in all IEP categories, with 504 plan accommodations, and students with neither an IEP nor 504 plan. Students were 14 and over, in grades 9-13 or an ungraded class, in a school setting (not home schooled or in an institutional setting), who answered the youth questionnaire on their own behalf (parent proxy respondents were not asked questions about student experiences with SBSE/SAPE). Students were asked 1) whether they received reproductive health or pregnancy services or education, and 2) whether they received SAPE. We present prevalence estimates of the receipt of SBSE/SAPE, group comparisons of receipt of SBSE/SAPE, and multivariable logistic regression for each outcome with each of the three groups (see figure and table for examples). We examined factors relevant to receipt of services (e.g., student participation in IEP meetings, student communication ability).

Results: Less than half of autistic students received SBSE (47.4%) or SAPE (49.6%). Compared to students with no IEP/504, a significantly lower proportion of autistic students received SBSE (p=.001); significant differences were also found for ID (p<.001) and emotional disturbance (ED; p=.008). Additionally, a significantly lower proportion of autistic students received SAPE (p=.029); significant differences were also found for ID (p<.001), ED (p=.004), multiple disabilities (p=.016), and orthopedic impairment (p=.007).

For autistic students, only sex was associated with SBSE: girls received SBSE at 2.26 times the rate of boys when adjusting for age, race, income, IEP meeting attendance, and communication/adaptive skills. For students with other disabilities, inclusion in SBSE/SAPE was associated with youth participation in IEP meetings, less impaired conversation, and greater ability to go places outside of the home; less impaired receptive language predicted SBSE only.

Conclusions: Results suggest that autistic students in public high schools do not consistently receive free and appropriate health education. Given only students who could/were allowed to answer for themselves participated, results likely overestimate the degree to which autistic adolescents receive SBSE/SAPE, increasing their vulnerability for health risks. Findings can inform policy aimed at increasing inclusion of students with autism and other disabilities in health education.

419.039 *(Poster)* Serving Students with Autism in High Need School Districts: The Role of Classroom Quality and Teacher Burnout

***A. S. Nahmias**, M. Matheis and A. C. Stahmer, Psychiatry and Behavioral Sciences, University of California at Davis MIND Institute, Sacramento, CA*

Background: Racial/ethnic disparities in autism spectrum disorder (ASD) identification, access to services, and quality of services have been well documented (e.g., Zuckerman et al., 2017), indicating an urgent need to develop methods to reduce them. More than 90% of children with autism are served in public schools (NCES, 2016). For students with autism from diverse backgrounds and those living in poverty, school may be the only intervention they access (Thomas, Parish, & Williams, 2014). School districts that serve many socially disadvantaged or minority students have been found to have lower quality general (Hirsch et al., 2007) and special education (Fall & Billingsley, 2011).

Objectives: Examine differences in classroom quality for students with autism and teacher burnout in districts serving many socially disadvantaged or minority students to inform our understanding of how to support the dissemination and implementation of evidence-based interventions (EBI) in these high need districts.

Methods: Public educators participating in a hybrid 3 effectiveness trial of Classroom Pivotal Response Teaching (CPRT, Suhrheinrich et al., 2019), an EBI for students with autism, completed the Maslach Burnout Inventory-Educators Survey (Maslach et al, 1986) and an adapted Autism Program Environment Rating Scale Self-Assessment Preschool and Elementary- Revised (National Professional Development Center on ASD, 2011). District indicators (i.e., percentage of minority or socially disadvantaged students) were obtained from the California Department of Education (www.ed-data.org). CPRT training outcomes (e.g., fidelity) will be also be collected. Generalized Estimating Equations were used to assess the association between district indicators and classroom quality and burnout, controlling for covariates (e.g., special or general education, study year, other district indicators) and nesting of teachers within districts. Recruitment is ongoing and data collection will be completed by the conference.

Results: Preliminary results from the 111 educators (98.2% female, 80.2% white, 89.2% special education) enrolled to date indicates district differences in classroom quality. In districts with a larger percentage of socially disadvantaged students, educators reported significantly worse: use of communication systems (B= -0.03), responsiveness to off-task student behavior (B= -0.01), consideration of student social skills (B= -0.02), and data collection on replacement behaviors (B= -0.01; all p-values < .05). In contrast, in districts with a larger percentage of minority students, teachers reported significantly better: lesson planning (B= .01), transition warnings (B= .01), responsiveness to off-task student behavior (B= .01), use of prompting (B= .01), and consideration of student social skills (B= .01; all p-values < .05). In regards to burnout, teacher-reported emotional exhaustion and depersonalization/cynicism were not associated with the percentage of socially disadvantaged or minority students (all p-values > .40).

Conclusions: Districts with a larger percentage of socially disadvantaged students reported poorer classroom quality; teachers working in these districts may need additional support to successfully work with students with autism. That teachers reported better classroom quality in districts with a larger percentage of minority students suggests that districts with many socially disadvantaged students may face different challenges than high minority districts when supporting students with autism. The impact of burnout and district indicators on CPRT training outcomes will be explored.

419.040 *(Poster)* Sexual Behavior and Gender Identity of Youth with Autism Aged 16 to 24: Are They Different from People without Autism?

M. H. Poulin[1], *C. L. Normand*[2], *S. McKinnon*[3], *G. Couture*[4] *and S. M. Fecteau*[5], *(1)Psychoeducation, UQAT, Rouyn-Noranda, QC, Canada, (2)Psychoéducation et psychologie, Université du Québec en Outaouais, Gatineau, QC, Canada, (3)CIUSSS Saguenay-Lac-St-Jean, CISSS Bas-St-Laurent et Côte-Nord, Sept-Îles, QC, Canada, (4)Direction de l'enseignement universitaire, de la recherche et de l'innovation, Centre Intégré Universitaire de Santé et de Services Sociaux de la Mauricie-et-du-Centre-du-Québec, Trois-Rivières, QC, Canada, (5)Psychoéducation et psychologie, Université du Québec en Outaouais, St-Jérôme, QC, Canada*

Background: Autism research on sexual behaviors and related topics began about 20 years ago (Van Bourgondien, Reichle and Palmer, 1997). Certain features of autism spectrum disorder (ASD) could affect how sexuality is experienced. For example, difficulties in decoding nonverbal cues and emotions might make it difficult to interpret another person's sexual attraction (Mintah & Parlow, 2018). Social isolation also tends to limit the sexual education and experiences of autistic youth (Locke, Ishijima, Kasari & Stagg, 2010; Pecora, Mesibov & Stokes, 2016). Individuals with autism report being more comfortable meeting and interacting online (Sallafranque St-Louis & Normand, 2017). Also people with ASD may have a more fluid gender identity and live more homosexuality (Dewinter, De Graaf & Begeer, 2017, Hillier et al., 2019). Sexuality being so personal, it is preferable to ask people directly about their reality, desires and concerns. Too often, information about sexuality in youth is gathered second hand (Hartmann et al., 2019).

Objectives: This presentation aims to describe the romantic and sexual behaviors and experiences of young people with autism compared to non-autistic peers.

Methods: Autistic and non-autistic youth 16 to 24 years of age (M: 18.79, SD: 2.4) were recruited through social media, schools, organizations, and clinics. A total of 172 respondents completed an online questionnaire on sex education, gender identity, romantic relationships, sexual orientation, unpleasant experiences, online sexual activities, socializing and friendships, sexual behaviour, attraction, initial romantic interactions, privacy, sexual exchanges, and concerns. Female respondents being overrepresented, subjects were matched on gender and age, resulting in 48 with ASD (50% female) and 48 without (50% female).

Results: The sexual behaviors of young people with autism between 16 and 24 years of age are comparable to that of their non-autistic peers. However, youth with ASD are more likely than their non-autistic peers to question their gender identity and sexual orientation. We also found that they express a certain lack of interest in sexuality despite their desire to be in a relationship. Even if they are as well informed about sexuality as their non-autistic peers, they complain that the sexual education they received was not adapted to their learning style and had difficulty understanding the concepts they were taught. A greater proportion of autistic youth and young adults say they "never" had online sexual activities such as watching explicit pornographic material or masturbating in front of their screen. In contrast to non-autistic youth, they are more worried about the interpretation of their sexual behavior by others. Finally, they are concerned that others may take advantage of them.

Conclusions: Our study with a matched comparison group allows us to put in perspective the sexual experiences and needs of autistic individuals. It appears that they may not be so different from their peers in late adolescence and young adulthood. More research is needed to investigate whether distinctions are more pronounced in early puberty, especially regarding the issue of gender identity.

419.041 *(Poster)* Social Capital and Professional Development: Investigating the Social Support Networks of Professional Trainers Who Support Special Education Teachers of Children with Autism Spectrum Disorder

E. McGhee Hassrick[1], *A. C. Stahmer*[2], *J. Suhrheinrich*[3], *P. Schetter*[4], *A. S. Nahmias*[2], *M. Melgarejo*[3], *J. Li*[5] *and C. Friedman*[6], *(1)A..J. Drexel Autism Institute, Drexel University, Philadelphia, PA, (2)Psychiatry and Behavioral Sciences, University of California at Davis MIND Institute, Sacramento, CA, (3)San Diego State University, San Diego, CA, (4)UC Davis, Sacramento, CA, (5)UC Davis, Davis, CA, (6)Drexel University A.J. Drexel Autism Institute, Philadelphia, PA*

Background: Social networks in school settings can provide social capital in the forms of trust, expertise and support, (Bryk and Schneider 2002; Coburn 2001; Daly et al. 2010; Frank et al. 2004, 2011) which can improve the implementation of evidence-based practices (EBPs) in the classroom. However, few studies have investigated how social capital might impact the implementation of EBPs for children with Autism Spectrum Disorder (ASD). Special education (SPED) teachers receive instructional support from multiple school, district, county and state-level trainers. However, few studies have investigated if the social networks of professional trainers at the district or state level, with expertise in EBPs for children with ASD, might improve the implementation of EBPs by SPED teachers for children with ASD. This study seeks to address this gap in the literature by investigating the social networks of professional trainers at the district and state level and their performance coaching SPED teachers in EBPs for children with ASD. There is a pressing need for more knowledge about the kinds of social capital professional trainers need to be successful at their job.

Objectives: To test the association between the support networks of professional trainers participating in a state-wide initiative scale up to improve the implementation of evidence-based practices (EBPs) for students with autism and their job performance coaching teachers in EBPs for their students with autism.

Methods: Data were collected via Qualtrics surveys and R programing was used to reconfigure the Qualtrics file into a social network edge list to compute social network measures. R was used to create an analytical database with network variables included in the analysis and conduct descriptive analyses of network variables and Linear Network Autocorrelation Models to test for associations between the support networks of professional trainers and their job performance coaching teachers in EBPs for students with ASD, controlling for years teaching, high EBP knowledge, high authority, district type and district size.

Results: Overall, 407 support network members were identified (Table 1). Support network members provided more types and frequency of coaching supports than financial supports (2.4 types vs 1.98 types; 33.17 days vs. 16.59 days). The most frequent area of coaching support was problem solving about administrators and staff and the most frequently provided financial supports were dedicated time and materials. Support networks for professional trainers were very sparse (overall mean = approx. 1 person). However, findings suggest that trainers' networks were associated with performance. Professional trainers that had support networks performed at significantly higher levels than coaches w/out support networks. Both coaching and financial networks were associated with significantly higher performance.

Conclusions: The support networks of professional trainers can provide key systems level resources for special education teachers of children with ASD. Findings suggest that professional trainers that provide implementation support for special education teachers to use EBPs for children with ASD can significantly improve their job performance if they have coaching and financial support networks.

419.042 *(Poster)* Special School Teachers' Attitudes Towards Adopting a Multi-User Wearable System for Real-Time Monitoring of Students' Mental States: A Feasibility Study

H. T. Chiu[1,2]*, F. N. Y. Ching*[1,2]*, R. H. M. Chan*[3]*, W. K. Shek*[4] *and S. W. H. Wong*[1,2]*, (1)Department of Educational Psychology, The Chinese University of Hong Kong, Hong Kong, Hong Kong, (2)Laboratory for Brain and Education, The Chinese University of Hong Kong, Hong Kong, Hong Kong, (3)Department of Electrical Engineering, City University of Hong Kong, Hong Kong, Hong Kong, (4)Hong Chi Morninghill School Tuen Mun, Hong Kong, Hong Kong*

Background: One of the greatest challenges for special education teachers is to apprehend the mental states of their students during class. For instance, students with autism spectrum disorder (ASD) often struggle to communicate their needs due to deficits in social communication. Their relative "calm" expression may be misinterpreted as a positive sign until they are overloaded by the stressful experience and have an emotional meltdown.

To facilitate teachers in developing a better understanding of their students, we developed a multi-user wearable system that is capable of monitoring and recording the physiological indices of students. The system can analyze the collected physiological indices and provide teachers with moment-by-moment mental state indices, such as attention, relaxation and arousal. Therefore, teachers could observe the changes in mental states in a whole class of students and be aware of students' needs at an earlier stage, prior to occurrences of disruptive classroom behavior.

Objectives: To examine special school teachers' attitudes towards using this technology, and whether this system could facilitate teaching in the classroom by assisting their interaction with students.

Methods: A total of 8 teachers were recruited from a special education school in Hong Kong to participate. The school was a special school for students with mild grade intellectual disability, with over 60% of the students with ASD. A pilot trial was conducted in 3 classes, which included a total of 10 students. Before the trial, teachers were administered a questionnaire that included scales measuring their attitudes towards using wearable technologies and their perceptions of whether the technology can facilitate teaching in the classroom. Teachers were trained to use and implement the system over 3 sessions (each lasting at least 20 minutes). The same questionnaire was administered after 3 sessions. Paired t-tests were run to compare pre- versus post-trial differences in teachers' attitudes of the system.

Results: Apart from mobile device anxiety, none of the measures administered reached significance in terms of differences in the first and second administration. Elevated levels of mobile device anxiety was found among teachers after the trial. Post-hoc feedback indicated that teachers found it challenging to analyze and interpret the data after it was collected by the system. Nevertheless, the other measures indicated an increased trend in positive attitudes towards using the technology and its role in facilitating teaching.

Conclusions: As an exploratory study, providing teachers a tool to monitor real-time indices of students' mental states was shown to be potentially useful for the special education classroom. Other than training for system operation, it is also important to provide training regarding data analysis to ensure that teachers are comfortable in adopting this system when teaching. Future development will integrate further multi-modal measurements (e.g., ECG, skin conductance, blood pressure) and incorporate machine learning algorithms to increase the prediction accuracy of emotional changes in students.

419.043 *(Poster)* Student Voice in Creating Autism Support Initiatives in Higher Education: A Qualitative Study

J. Monahan[1]*, B. Freedman*[2] *and K. Pini*[1]*, (1)University of Delaware, Newark, DE, (2)Center for Disabilities Studies, University of Delaware, Newark, DE*

Background: Despite an increasing number of students identifying as autistic on college campuses, many continue to experience low graduation and employment rates. Many college support models are developed without a full understanding of the unique needs of autistic students on that campus, and do not necessarily consider the full body of autism research. Understanding student experiences and the unique needs of this population can support more rigorous research that identifies evidence-based practices for this community which, in turn, should inform campus-based intervention models. Thus, the University of Delaware (UD) conducted a survey of current autistic students in preparation for developing a comprehensive support system.

Objectives: Participants will:

- Understand barriers in higher education at one university based on survey results from autistic students.
- Discuss solutions to barriers in higher education at one university based on survey results and existing research
- Brainstorm areas for future applied research and creative ways for conducting studies in this unique setting

Methods: The quantitative and qualitative survey was sent to approximately 60 autistic students with 22 student respondents (~36% response rate) at the University of Delaware. Quantitative items were coded, and descriptive statistics were analyzed in SPSS. Qualitative questions were coded through a thematic analysis using deductive and inductive processes (Fereday & Muir-Cochrane, 2006).

Results: All students who responded identified as being on the autism spectrum. The participant ages ranged from 19 to 40, with a mean age of 24.73. Twelve respondents identified as males, eight as females, one as other/non-binary and one chose not to respond. Students rated the helpfulness of universally available resources and services on campus and their confidence in their ability to engage in a variety of academic and social activities. Results showed that most students found universally available supports (i.e. tutoring, academic enrichment, etc.) somewhat helpful, and found the counseling center somewhat unhelpful.

Through thematic content analysis, the following common themes were identified: challenges, factors for success, supports from the university, and things students wish faculty or other students knew. Specifically, students identified environmental factors like noise in residence and dining halls and shared office spaces. Many concerns regarding lack of awareness of autistic characteristics and lack of inclusive teaching practices was also apparent. Students also discussed factors for their success related to their learning, citing common themes, such as: requiring clear and explicit language; clear rubrics for assessments; and faculty acceptance of accommodations.

Conclusions: Some supports (e.g., tutoring) were found to be more helpful than others (e.g., counseling center). Students also identified common challenges (e.g., noise in residence and dining halls) and concerns (e.g., lack of awareness among professors). Opportunities for improved campus collaboration and building stronger support systems appear critical for autism support programs. The design for a new support system which incorporated these factors will be shared, as well as intended next steps for conducting research and evaluation in order to further inform the program and the field.

419.044 *(Poster)* Teachers Professional Competence: Reading Comprehension in Classes for Children with ASD

Y. Kimhi[1]*, O. Sokol*[1] *and R. Hillel Lavian*[2]*, (1)Levinsky College of Education, Tel Aviv, Israel, (2)Kehilat Odesa 12, Levinsky College of Education, Tel Aviv, Israel*

Background: Many teachers of children with ASD report having challenges, particularly in differentiating the curriculum and providing appropriate curriculum access for their pupils. As a result, children with ASD do not receive the required instruction. The teachers often feel incompetent, leading to low feelings of efficacy. In Israel, many pupils with ASD learn in special education classes within regular schools. Most such classes have a special education counselor who assists the teachers in implementing strategies that are ASD specific, thereby enabling relevant and appropriate behavioral, social, and academic interventions.

Objectives: We conducted an intervention study aimed at examining the professional competence of teachers in the context of implementing a specific teaching model for improving reading comprehension within an ASD classroom. The goal of the model was to impart knowledge on strategies for improving pupil's reading comprehension while coping with their learning difficulties. Before developing the model, the teachers were interviewed to understand their professional needs. The model was designed accordingly, based on classroom navigation skills, incorporating strategies to improve reading comprehension which were found to be useful for pupils with ASD: The Reread-Adapt and Answer-Comprehend (Hua et al., 2012); anaphoric cueing (O'Connor & Klein, 2004); and Question-and-Answer Relationships Strategy (Whalon & Hart, 2011).

Methods: The study was designed as a qualitative case study with a participating researcher.

Participants:

- Teachers: six leading teachers in ASD classes, who had been working in special education for several years mainly with students with ASD
- The ASD special education counselor: Orit (second author), a participating researcher studying for her M.Ed. in special education. Her guidance was built into the teachers' weekly routines. After designing the model, she led learning sessions with the teachers.

Assessment Measures: a)Two semi-structured interviews with the teachers. The first was conducted before the model was applied, the second at the final stage of its implementation.

1. b) The participating researcher's reflective research journal.

Data collection was conducted pre-and post-implementation of the model. The data were analyzed in an analysis of interpretative content.

Results: The following themes emerged:

Before the implementation of the model:

- The teachers' basic understanding of their pupils' disability and its manifestation in the class.
- The accommodations and support provided in the class.
- The teachers' ability to cope with reading comprehension units.
- The teachers' feelings of frustration.
- Knowledge gaps between the ability to cope with behavioral, communication and social issues and inability to cope with academic issues.

After the implementation of the model

- Change in teaching formats in literature lessons.
- The pupils' improvement.
- Improvement in teachers' feelings of competence.

Conclusions: The findings underscore improvement in the teachers' sense of competence. They shed light on the change the teachers underwent regarding their feeling of efficacy, and underscore a need for greater access to consultative support and constant professional development for teachers in ASD classes. Disseminating best practices and implementing guidelines can enhance teachers' teaching abilities and promote their sense of competence, thus elevating their perception of self -efficacy.

419.045 *(Poster)* Technology-Based Interventions for Students with Autism: Multi-Disciplinary Professional Perspectives

S. Hurwitz[1]*, A. Asomani-Adem*[2]*, N. Bengert*[2]*, B. Burgess*[2]*, B. Garman-McClaine*[2]*, O. Heck*[2]*, N. Rodriguez*[2] *and A. Thielmeyer*[2]*, (1)Special Education, Indiana University, Bloomington, IN, (2)Indiana University, Bloomington, IN*

Background: The use of technology-aided interventions is on the rise for all children, and students with autism are no exception (Odom et al., 2015). Research supports using technology as a tool to address skill deficits for children with autism in multiple domains, including social problem solving, receptive language, and academics (Grynszpan et al., 2014). One of the newest intervention approaches is a robot-based curriculum that is currently being developed to teach social and communication skills. Although relatively new, school districts from Vancouver to South Carolina have already adopted a program using a robot called Milo, and the approach is spreading. Milo is a humanoid robot that can walk, model human facial expressions, speak, and is used to teach social-communication skills to children with autism. As others have pointed out, the enthusiasm for new technologies can lead to their adoption before understanding what the potential collateral effects might be (Odom et al., 2015). This study asks multi-disciplinary education professionals about their views on implementing a technology-based intervention (Milo) in Midwestern public schools.
Objectives: The purpose of this study was to determine the perspectives of educational professionals on the introduction of Milo for students with autism in K-12 schools in a Midwestern state.
Methods: A focus group was conducted with 10 multidisciplinary professionals from a Midwestern state. Participants included special education faculty, autism leaders and advocates, directors of disability-related institutions, special education district directors, and school principals. Questions explored their views about the feasibility of introducing a robot-based intervention to schools within the state. Participants were asked questions ranging from recruitment and training of teachers, to the logistics of scheduling time for students and facilitators to use the robot. Data was analyzed thematically.
Results: Data analysis indicated that, overall, participants were supportive of initiating the robot-based intervention in their schools. However, they had a number of concerns. A main concern they discussed was related to which school staff would receive training. More specifically, they were interested in the possibility of establishing a train-the-trainer model to increase competencies across school personnel to be more cost-effective. Additionally, focus group participants were apprehensive about the initial costs of training and the requirements for up-to-dates supplemental technologies (e.g., iPads). Furthermore, they were concerned with the amount and quality of external support each school would receive and what would happen to the licensure to use Milo after initial dissemination into the classrooms. Focus group members expressed interest in the possibility of extending the intervention to preschools, alternative settings, middle schools, and other settings.
Conclusions: Based on suggestions from this focus group, the next step for this project is to deploy the robot-based intervention in over a dozen schools in the state. Research will continue with an emphasis on understanding the perceptions of the school personnel who are involved with using the robot before, during, and after implementation of the curriculum, to learn how successful Milo is at improving social outcomes of students with autism in public elementary schools.

419.046 *(Poster)* Territory-Wide School Support Project for Students with Autism in Hong Kong Mainstream Primary and Secondary Schools
H. Tse *and K. Wong, Psychology, The University of Hong Kong, Hong Kong, Hong Kong*

Background: Hong Kong adopted integrated education which allows students with special education needs to attend mainstream schools. The Education Bureau ("EDB") promoted a 3-tier support model (Figure 1) to support their diverse needs.
The rising number of students with Autism Spectrum Disorder ("ASD") presents a great challenge to schools as they often have limited resources and expertise. To facilitate students' school adaptation, with the funding support from The Hong Kong Jockey Club Charities Trust, we collaborated with EDB and 8 non-governmental organizations to launch a six-year JC A-Connect school support project ("Project"), in 2015. The Project aims at enhancing mainstream schools' support to ASD students by:

1. Mobilizing NGOs' professionals to reach out to schools to provide school-based support to ASD students, peers, teachers and parents;
2. Providing Tier-2 small group training to students with ASD on important aspects for school adaptation: social, emotional regulation and learning skills;
3. Building the capacity of teachers and NGOs in supporting students with ASD.

The Project is the first large-scale school-based support programme in Hong Kong with a coverage of more than half of students with ASD population, benefitting 6,375 students in 2019. 503 schools, i.e. over 50% of schools have joined the Project.
The NGOs provided school-based group training to students. Teachers filled in questionnaires to assess the learning, social and emotional skills of the students, and the training objectives are set based on the need reflected. NGOs adopt evidence-based strategies in their trainings. Each group consists of four to six students and at least 18 hours of training each year. A school personnel is required to assist in the group training to facilitate skill transference in schools. The Project also provides support to other important stakeholders including teacher and parent consultations, and peer activities that promote inclusion.
Objectives: Examine the effectiveness of our Project in helping students with ASD to adjust better in school.
Methods: For initial need assessment and continuous monitoring of student's progress, teachers filled in Student Profile Checklist for School Adjustment (EDB, 2016), which consists of learning, social and emotion items (classified into 10 subdomains, see Table 1), before joining the Project and after the Project each year. As students could have improved in 4 years due to developmental changes, we compared the ratings of all participants at the beginning of our Project (i.e., without training) with ratings of all participants collected at the end of the 4th year (i.e., received 1 to 4-years of training) using independent t-test.
Results: Table 1 shows students adjusted significantly better after receiving training in most areas. Effects on primary school students are stronger than that of secondary school students.
Conclusions: Our Project effectively helps primary and secondary school students with ASD better adjust in mainstream school. It also informed policy changes in Hong Kong to regularize the support to them with reference to our service model. Educators from other regions using the 3-tier support model may find our service model useful.

419.047 *(Poster)* The Cognitive and Behavioral Profile of Chinese Autistic Children with Savant Syndrome
Y. Wang[1]*, H. Zhu*[1]*, Y. Li*[1]*, W. Cao*[2] *and X. Zou*[1]*, (1)Child Development and Behavior Center, Third Affiliated Hospital of SUN YAT-SEN University, Guangzhou, China, (2)South China Academy of Advanced Optoelectronics, South China Normal University, Guangzhou, China*

Background: Autism spectrum disorder (ASD) is a type of neurodevelopmental disorder.About 0.6%-10% of autistic children have savant syndrome, and their outstanding skills in a specific field(computation, mechanics, art etc.) may exceed the normal level of ordinary people. However, parents and professionals often pay more attention to their deficiencies and neglect the recognition and support their skills. Therefore, it is necessary to explore the cognitive and behavioral characteristics of the autistic savant.

Objectives: In this context, this research aims to find more clinical features of savant group by comparing the cognitive and behavioral differences between autistic savants and autistic non-savant group.

Methods: 56 autistic individuals (30 savant and 26 non-savant) were included in the current study. All individuals were cases of idiopathic autism. The clinical diagnosis of autistic disorder was assured using the Chinese forms of the Autism Diagnostic Interview-Revised (ADI-R) and/or the Autism Diagnostic Observation Schedule. The most pronounced special abilities in the savant group (ASD-SS group) were memory and calender calculation in 18, musical in 4, arithmetic in 4, reading in 4, highly specialized knowledge in 4, drawing in 3 and machinery in 2. The average age of 30 autistic savants (29 males, 1 female) was 8.43 (S.D.=2.08). The non-savant autistic group (ASD-NSS group) consisted of 25 males and 1 female individuals., and average age of the was 9.03(S.D.=1.61). Age was matched between these two group（t=-1.19，P=0.24).Webster Intelligence Scale, Combined Raven Test, and Empathy /Systemizing Quotient Scale were used to assess the cognitive abilities and styles in different ways. Furthermore, Autism Diagnosis Observation Scale and Repetitive Behavior Scale were to confirm a prior clinical diagnosis and to provide some measure of core deficits of autism. In addition, Adaptive Behavior Assessment System-II Parent Form were filed to assess the adaptive behavior of the children.

Results: There was no significant difference between the savant group and the non-savant group in the Wechsler Intelligence Scale and the combined Raven test scores (P>0.05), but the ASD-SS group got higher score in block design subsets (P=0.02); ASD-SS group has a higher Systemizing Quotient (P=0.00) but lower Empathy Quotient than ASD-NSS group (P=0.00).The groups did not differ on the severity of social communication (P>0.05). And also, there was no significant difference between the ASD-SS group and ASD-NSS group in stereotypes, self-injury behavior, compulsive behavior and ritual behavior (P>0.05)，but ASD-SS group got higher score in interest behavior (P=0.01). In terms of the general adaptive ability, the differences between the two groups were mainly in the aspects of social interaction, communication, health and safety and self-care behavior(P<0.05).

Conclusions: The autistic children with savant syndrome have a specific cognitive and behavioral profile of superior systematizing and poor empathy ability, their narrow interest behavior is more obvious, and also have poorer adaptive ability.

419.048 *(Poster)* The Comparison of Discrete Trial Training with Two Different Error Correction Procedures in Teaching to Children with Autism Spectrum Disorder

D. E. Altun, ***S. Yucesoy-Ozkan*** *and N. Oncul, Anadolu University, Eskisehir, Turkey*

Background: Error correction, which is one of the important components of instruction, is that the teacher corrects the student's error in different ways immediately after the child responds incorrectly or does not respond. There are some different types of error correction procedures in the use of discrete trial training. These are; vocal feedback or error statement, a brief time-out, a model of the correct response, active student response, repeated response, re-present until independent, remove and re-present, and mixed type.

Objectives: In the current study, we aimed to compare the effectiveness and efficiency of the discrete trial training with two different error corrections, a model of the correct response and remove and re-present, in teaching community signs to children with ASD. We also aimed to determine whether children were able to generalize the behavior across materials and identified the acceptability of error correction procedures by peers with typical development.

Methods: Four children participated in the study who attended a segregated special education school. All participants had ASD diagnosis. Their age was seven to 11 years old. One of the participants was female, three of them were male. An adaptive alternating treatments design, one of the single-case experimental research designs, was used. The dependent variable was the percentage of identifying the community sign, and the independent variables were discrete trial training with two different error correction procedures. The percentage of inter-observer agreement was 100% for all participants and all sessions. The percentage of treatment integrity was 100% for all behaviors and participants in all sessions.

Results: Results indicate that discrete trial training with both the model for correct response and the remove and re-present were effective in teaching community signs to children with ASD. There was no significant difference between two discrete trial training procedures. Discrete trial training with a model for the correct response was more efficient for four children in terms of the number of sessions, trials, errors, and total time whereas discrete trial training with remove and re-present resulted in less error only for one child. The findings reveal that while the three children generalized the behavior across materials, a child could not generalize. Findings also show that a model for a correct response as an error correction procedure was more acceptable for peers with typical development.

Conclusions: Discrete trial training with error correction procedure is an effective intervention for children with ASD. In the literature, there is a limited study of error correction. The current study contributes to literature; however, there is also need a future study on comparing the error correction procedure.

419.049 *(Poster)* The Comparison of in-Vivo Modeling and Video Modeling on Teaching Symbolic Plays to Children with Autism Spectrum Disorder in Small Groups

N. Oncul[1] *and I. Cifci-Tekinarslan*[2]*, (1)Anadolu University, Eskisehir, Turkey, (2)Special Education, Bolu Abant Izzet Baysal University, Bolu, Turkey*

Background: Although children with typical development can learn to play on their own in natural environments, children with ASD cannot learn to play themselves on their own. The literature supports that the quality and quantity of play activities in preschoolers with ASD are different from their peers. Children with ASD usually play repetitive and unpurposive plays, prefer to play alone and cannot perform symbolic plays. Because of those reasons, the teachers teach the play behaviors and skills to children with ASD.

Objectives: The purpose of this study is to compare the in-vivo modeling and video modeling in terms of effectiveness and efficiency on teaching symbolic plays to children with ASD in small groups. In the current study, the following questions were sought:

1. Is there any difference between the effectiveness and efficiency of in-vivo modeling and video modeling presented in small group instructional arrangements in teaching symbolic play to children with ASD?
2. Do the children with ASD learn the target plays of their peers by observational learning during instruction sessions?
3. What are the social validity data about the purpose, method, and findings of the research?

Methods: Three children with ASD who were attending the segregated special education school. One of the participants in the study had pervasive developmental disorder diagnosis and two of them had autism diagnosis. The participants were all male at the age of 11. In the study, we used the adaptive alternating treatments design. The independent variables of the study were in-vivo video modeling and video modeling presented by small group instruction; the dependent variables of the study were two different symbolic plays.

Results: The research findings demonstrated that both in-vivo modeling and video modeling presented by small group instruction were effective in teaching, maintaining and generalization of symbolic plays to children with ASD. Video modeling was more effective than in-vivo modeling in acquisition; in-vivo modeling was more effective than video modeling in maintenance; and there was no difference between in-vivo modeling and video modeling in the generalization. The findings also revealed that video modeling was more efficient than in-vivo modeling for two participants, and in-vivo modeling was more efficient than video modeling for one participant. Moreover, observational learning was occurred in both in-vivo modeling and video modeling; and that not only the participants but also the preservice teachers had positive views about the research process.

Conclusions: Both in-vivo modeling and video modeling are effective in teaching symbolic plays to children with ASD. Children with ASD can learn symbolic plays by observing their peers. There is still a need for future research on teaching symbolic play through observational learning.

419.050 *(Poster)* The Effectiveness of the 'Star-Bus' Inclusion Intervention Programme (SIIP) for Enhancing Autism-Knowledge in the Peers of Pupils with Autism

K. Stefanik[1,2]*, M. Molnar-Varga*[1,3]*, V. Németh*[1,2]*, C. Bertók*[1,2]*, Á. Havasi*[1,2]*, T. Oszi*[1,2,4]*, M. Janoch*[1,2,4] *and M. Gyori*[1,3]*, (1)HAS-ELTE 'Autism in Education' Research Group, Budapest, Hungary, (2)Institute of Special Needs Education for People with Atypical Behavior and Cognition, ELTE University, Budapest, Hungary, (3)Institute for the Psychology of Special Needs, ELTE University, Budapest, Hungary, (4)Autism Foundation, Budapest, Hungary*

Background: Autism Spectrum Conditions (ASC) represent a unique challenge for mainstream education. Well-planned and -managed integration can bring about several benefits for all parties, mis-managed integration may have risks and high 'costs'. Research suggests that paucity of autism-knowledge in peers leads to limited understanding of autism-related behaviors, and this can contribute to the occasional rejection by peers and to the exclusion of the child with ASC. Peer education programmes to support autism-understanding and acceptance, therefore, are highly needed, but the available amount and quality of evidence on the effectiveness of the existing pedagogical methods of peer education in autism is limited.

Objectives: We aimed at (1) developing a complex, picture book-based peer education programme in autism for children in primary schools; and (2) evaluating its effectiveness and applicability, using a mixed-method prospective controlled study design. In the present study, we examined whether the programme was able to bring about positive changes in autism-knowledge in the test group of mainstream primary school pupils.

Methods: The intervention programme (the SIIP programme) focuses on primary school children. It includes a two-day preparatory training for teachers, and a detailed teachers' instruction guide with 25 varied and playful activities. Teachers can implement these into their daily classroom work. The main foci are: acceptance of human differences, understanding autism, strategies for relating positively to a peer with autism, strategies to prevent bullying, and raising autism-awareness in the wider public. 283 primary school pupils in 14 second- and third-grade mainstream classes (8 test and 6 control) participated in the effectiveness and applicability study. Data on their general pre- and post-test autism-knowledge were gained by the Pupils' Autism Knowledge Questionnaire (PAKQ), compiled by our research group.

Results: 2x2 (pre-test vs post-test, test vs control group) mixed ANOVA was run on data from the PAKQ. At the beginning of the programme, there was no significant difference between the two groups' knowledge of autism, while the test group showed significantly higher level of knowledge at the end of the programme. Overall, the general autism-knowledge has grown significantly in the total sample from the pre-test to the post test measurements. A significant pre-post X test-control interaction arose, demonstrating the effectiveness of the intervention programme in terms of enhancing autism-knowledge, selectively in the test group.

Conclusions: Results suggest that the SIIP programme is able to enhance knowledge about autism in pupils of mainstream primary schools, and confirm previous studies suggesting that inducing such effects requires systematically constructed and validated programmes, organized in several sessions of colorful and playful activities. Further analyses are underway on the impact of the enhanced autism-knowledge on quality of life, autism-attitudes, and social relationships.

419.051 *(Poster)* The Importance of Parent-Teacher Informant Discrepancy in Characterizing Youth with ASD: A Replication Latent Profile Analysis

E. Kang[1]*, M. D. Lerner*[1] *and K. D. Gadow*[2]*, (1)Department of Psychology, Stony Brook University, Stony Brook, NY, (2)Department of Psychiatry, Stony Brook University, Stony Brook, NY*

Background: Recent research about autism spectrum disorder (ASD) supports variation in symptom presentations across settings (Stratis & Lecavalier, 2015), and there is a growing literature that explicates how this variability may improve characterization of the ASD phenotype. Capitalizing on well-established literature on informant discrepancy as an index of contextual variability (De Los Reyes et al., 2015), research suggests that differing parent and teacher perceptions may impact treatment or special education-related outcomes (Frey et al., 2014; Rosen et al., 2019), and degree of discrepancy between parent and teacher ASD symptom ratings define discrete and clinically meaningful subgroups of ASD (Lerner et al., 2017). However, replication in an independent investigation with larger sample is important in supporting the validity and utility of the subgroups for use in research and practice.

Objectives: We sought to characterize patterns of parent-teacher informant discrepancies among children and adolescents with ASD to (1) determine if discrepancies relate to clinical and functional correlates and outcomes, and to (2) replicate a latent profile analysis (LPA) in a new, independent sample. We hypothesized that parent-teacher discrepancies in ratings of ASD symptom severity would better characterize ASD subgroups and these subgroups would predict clinical and functional correlates and outcomes.

Methods: Parents and teachers of 609 youth (83% male; M_{age} =9.27, SD_{age}=2.84) referred to an ASD specialty clinic completed the Child and Adolescent Symptom Inventory-4 (CASI-4; Gadow & Sprafkin, 2002). Latent profile analyses (LPA; Bartholomew, 1987) were used to determine optimal number and structure of subgroups from best-fitting model for the data. After specifying the classes, one-way multivariate analysis of variance (MANOVA) was used to compare classes for IQ and age, and a series of chi-square tests were conducted to determine if the groups derived from the LPA demonstrated meaningful differences across outcomes (i.e., receiving special education, type of class, currently receiving medication, ever received medication).

Results: Four distinct LPA groups emerged (Figure 1): two discrepancy profiles (Moderate Parent/High Teacher [1] and High Parent/Moderate Teacher Severity [2]) and two agreement profiles (Moderate [3] and High [4] Symptom Severity); these are identical to the previous LPA in this literature (Lerner et al., 2017). Class 2 and 3 participants were older than class 1 and 4 (all p<.02). Class 3 had higher IQ than all three other classes; and class 4 had lower IQ than all three other classes (all p<.004). LPA groups demonstrated significant differences in whether or not receiving special education ($\chi^2(3)=31.31$, p<.001) and type of class ($\chi^2(15)=59.56$, p<.001; Table 1), but not in medication status, either current or ever (both $\chi^2(3)<4.91$, p>.179).

Conclusions: Results from LPA from this large sample supported a four-class model consisting of two agreement profiles and two disagreement profiles, replicating findings from Lerner et al., (2017). Latent class membership differently predicted IQ and age of participants and educational outcomes. Unique, clinically-useful information about the taxonomy and clinical impact of ASD is obtained by considering informant discrepancies in symptom severity ratings, which underscores the importance of considering contextual variability assessed through multiple informants.

419.052 *(Poster)* The Self-Reported School Experiences of Autistic Students in Canada

***C. Lebenhagen**, Calgary Board of Education, Calgary, AB, Canada; University of Calgary, Calgary, AB, Canada*

Background: Commonly autistic students are spoken for or their experiences are re-interpreted by well-meaning non-autistic parents, educators and advocates. While the inclusion of autistic voice in research is improving, insufficient research exists that includes perspectives of speaking and non-speaking autistic individuals. Additionally, systems of education have struggled with clear definitions of inclusive education which has led to uncertainty on how best to support autistic learners in inclusive school settings (Maciver et al., 2017; Majoko, 2016).

Objectives: The purpose of this study is to provide opportunities for speaking and non-speaking autistic students to self-report their inclusive educational experiences within a Canadian context. These self-reports will provide valuable insights into the successes, challenges and priorities of autistic learners, which are often overlooked by non-autistic individuals (Kourti & MacLeod, 2018). Improving our understanding of autistic student experiences within current inclusive education initiatives is fundamental to improving educational outcomes for autistic students and will help to inform future inclusive education design and policy (Makin, Hill & Pellicano, 2017).

Methods: Using a mixed-method interpretive phenomenology (MMPR) research design, autistic students share their unique experiences through the use of Qualtrics, an online research platform. The sequential study design begins with 18 Likert survey questions (QUAN), followed by an option for participants to participate in a follow-up email interview (QUAL). The survey questions are from the Panorama Survey (Harvard School of Education, 2014) and are based on six scales: 1. Pedagogical Effectiveness, 2. School Climate, 3. School Engagement, 4. School Teacher-Student Relationships, 5. School Belonging and 6. School Safety.

Results: Survey Closes November 30, 2019

Conclusions: Analysis and conclusions are expected to be complete by March 2020.

419.053 *(Poster)* The Utility of Classroom Observations As a Tool for Measuring Executive Functioning Skills in Adolescents: Validity and Sensitivity to Treatment Change

***R. Handsman**[1], M. D. Powers[1], L. Kenworthy[1], L. Anthony[2] and C. E. Pugliese[1], (1)Center for Autism Spectrum Disorders, Children's National Hospital, Washington, DC, (2)University of Colorado, Denver, Aurora, CO*

Background: Executive Function (EF) impairments are well-documented in youth with ASD, as evidenced by parent report measures (e.g., Behavior Rating Inventory of Executive Function, Second Edition, BRIEF-2) and neuropsychological tasks (e.g., Block Design, Tower of London). EF problems impact academic success (Petra et al., 2011), but there are no current objective measures focusing on EF impairments in the high school classroom. Such assessment tools could provide a valid measure of behavioral progress and response to intervention. We recently developed a classroom observation measure to assess for change during a high-school effectiveness trial of a cognitive-behavioral EF intervention to improve flexibility, planning, and self-determination in adolescents with ASD. A treatment-masked assessor rated youth on the following behaviors during a 15-minute classroom observation in the general education setting pre/post-treatment: student engagement, initiation, organization, planning, transitioning, flexibility, overwhelm, self-advocacy, social reciprocity, and social appropriateness.

Objectives: To examine convergent/divergent validity of the classroom observation tool in relation to measures of EF, as well as sensitivity to treatment change.

Methods: Participants were 60 teens with ASD aged 14-20 (M=16.3, SD=1.3) with FSIQ≥80 (M=104.5, SD=15.4), who met DSM-5 criteria for ASD supported by the SCQ and/or ADOS-2. Students were recruited from 8 schools and randomized to the EF intervention or treatment-as-usual (TAU). A treatment-masked assessor rated the presence or absence of target behaviors, and a mean classroom observation score was calculated. Students completed task-based measures of EF (Block Design, ToL). Teachers (n=40) rated the severity of classroom behavior problems using the *Swanson, Kotkin, Agler, M-Flynn, and Pelham Scale* (SKAMP; Swanson, 1992) with developmental adaptations for teens, and EF problem interference in daily life was measured using the EF Interference Scale. Parents and students rated EF severity on the BRIEF-2 and EF interference on the Interference Scale. Kuder-Richadson-20 reliability coefficient was calculated for the classroom observation measure to determine its internal reliability. Bivariate correlations assessed associations between baseline observation score, demographic variables, and EF measures. Independent samples t-test were used to assess change in observation mean score pre/post treatment.

Results: The Kuder-Richardson-20 reliability coefficient for classroom observations was .64. Classroom observations were not significantly correlated with age, IQ, sex, or ASD symptom severity. Observations were significantly correlated with teacher report of EF problem severity(SKAMP; r =-.348* p<.05) and interference with daily life (r =-.501**, p<.01). Observations did not correlate significantly with parent- or self-reported EF problems on the BRIEF; or laboratory-based measures of EF. Observations were, however, sensitive to treatment change; youth receiving the EF intervention made greater improvement than the TAU group (t=-3.06, p<.01, d=0.9).

Conclusions: Baseline classroom observations correlated with teacher perception of EF difficulty and functional impairment, and were sensitive to treatment change. Additionally, they were not correlated with age, IQ, or sex. Lack of correlations with youth and parent report may be due to families' greater insight into EF difficulties beyond the classroom. Importantly, classroom observations are masked to treatment conditions whereas teacher report is subjective, making these observations a novel tool to assess EF changes in response to intervention.

419.054 *(Poster)* Training Caregivers with Limited Proficiency in the Majority of Language to Reduce Children Problem Behaviors: A Systematic Review

F. Vargas Londono *and T. S. Falcomata, Special Education, The University of Texas at Austin, Austin, TX*

Background: Parents are the primary source of education for their children, and can become the principal interventionist to prevent and treat their child's problem behavior. The present study reviewed 16 experimental studies that implemented caregiver-training for parents with limited proficiency in the majority language. Families had an offspring that presented problem behavior (e.g., aggression, disruption, drug abuse) and were from a culturally and linguistically diverse background. Adequate parent training can be a challenge with the overgrowth on international migration (258 million in 2017; United Nations, 2017) and the diversity of language spoken worldwide. For instance, just in the US 21.9% of the population speaks a language other than English (American Community Survey, 2017).

Objectives: The present systematic review had 3 purposes, first, determine different types of caregiver-training interventions, for minority families. Second, measure the impact of these interventions on parents' and children's outcome and third, to analyze the various strategies to adapt the interventions to caregivers with limited proficiency in the majority language.

Methods: PRISMA guidelines procedures were followed during the review. A search from 1970 to 2019 was conducted using five electronic databases for peer-reviewed journals. We analyzed the quality of the study in terms of What Works Clearinghouse (WWC) Standards Rating. To measure the impact of the training on parents' and child outcome, effect sizes using Cohens'*d* and a robust variance was conducted to compare the global impact of the interventions across studies.

Results: The overall findings reflected multiple interventions, the most common being "The Incredible Years Parenting Intervention," the "Parent Management Training - Oregon Training," and Family Therapy. The results suggest a non-significant small effect on (a) increasing caregiver positive parenting practices; (b) decreasing caregiver harsh discipline, (c) reducing child problem behavior, and (d) reducing youth drug use. The most prevalent adaptation to the intervention was related to the language of instruction, religion accommodations, community collaboration to adapt the training, training trainers to be culturally sensitive, and reducing access barriers to training (e.g., provide childcare, snacks, transportation, etc.).

Conclusions: Problem behaviors can have serious deleterious consequences for the child's health, social interaction, and family's quality of life. Parent training is an effective intervention to reduce children's problem behaviors. However, more research is necessary to increase the effectiveness of the intervention. Cultural adaptations were socially valid and essential to recruit participants and to reduce the attrition rate. Further analysis of which adaptation has a better outcome with different cultures is necessary to individualize interventions better. Finally, potential directions are caregiver-training for non-native language parents with children with disabilities using other behavioral interventions such as early childhood since there is a lack of research in that area.

419.055 *(Poster)* Training Special Education Teachers and Paraprofessionals to Implement Pivotal Response Treatment for Academic Tasks

S. K. Poyser[1] *and T. W. Vernon*[2]*, (1)University of California, Santa Barbara, Santa Barbara, CA, (2)University of California Santa Barbara, Santa Barbara, CA*

Background: Special education teachers and paraprofessionals face numerous challenges when working with students diagnosed with Autism Spectrum Disorder (ASD). These students can be difficult to engage in academic lessons, may have low motivation to learn, and often display challenging behaviors during structured academic tasks in the school setting (Cowen, Abel & Candel, 2017; Gunn & Delafield-Butt, 2016). Disengagement and challenging behaviors can create disruptions for both students and teachers. Educators may benefit from implementing positive evidence-based practices to support their students. Previous research suggests that educators can be taught to use components of Pivotal Response Treatment (PRT) in their classrooms (Robinson, 2011; Stahmer et al., 2015; Suhrheinrich, 2011). This line of research has led to adaptations of PRT to increase its implementation in the school environment (Stahmer, Suhrheinrich & Rieth, 2016; Suhrheinrich & Chan, 2017), resulting in beneficial student outcomes (Pellecchia et al., 2015). Other studies have applied PRT to structured academic tasks (Koegel, L., Singh, & Koegel, R., 2010), and have shown that students may display increased affect and on-task behaviors when PRT is incorporated specifically with academics. It is not clear, however, how the individual PRT strategies an educator might use with an individual student impact their academic performance and corresponding behavior on a moment-by-moment basis.

Objectives: The present study focused on the examining improvements to interactions between an educator (special education teacher or paraprofessional) and an individual student before, during, and after training in PRT for academic tasks.

Methods: A multiple baseline experimental design was conducted with three educators and three elementary students diagnosed with ASD. All sessions were conducted in an elementary school setting. Following baseline analyzing teacher-student interactions, educators were provided with didactic training in PRT and then received in-vivo coaching and feedback across 2-4 sessions. Videos of teacher-student interactions were scored for PRT fidelity and student challenging behavior, on-task behavior and affect. Additionally, educators completed self-report measures of ASD teaching efficacy and program acceptability/effectiveness.

Results: Preliminary data is reflective of professionals meeting 80% PRT fidelity of implementation by the end of the intervention and during a maintenance session in which no coaching was provided. Specifically the components of child choice (90% fidelity across sessions) and interspersing tasks (90% fidelity across sessions) were implemented with consistent fidelity. Data were also indicative of a significant increase in student interest and on-task behavior and decrease of challenging behavior during academic tasks.

Conclusions: This research may help to understand the interaction between educator and student during PRT implementation. Increasing educator fidelity of PRT implementation and looking at corresponding student behavior may inform the methods used to train teachers and professionals in PRT for academic tasks. Results demonstrated increased teacher self-efficacy, increased on-task behaviors, and higher affect of students. By working directly in the school and incorporating educator's input during intervention sessions, this research contributes to decreasing the research-to-practice gap in school settings.

419.056 *(Poster)* Understanding Student Attentional Profiles to Develop Better Instructional Strategies

A. Riccio[1]*, J. Herrell*[2]*, B. Rosenberg*[3]*, A. Hurst*[4] *and K. Gillespie-Lynch*[5]*, (1)Department of Psychology, The Graduate Center, City University of New York (CUNY), New York, NY, (2)CUNY School of Professional Studies, New York, NY, (3)Technology, Culture, Society, New York University Tandon School of Engineering, Brooklyn, NY, (4)New York University, New York, NY, (5)Department of Psychology, College of Staten Island; CUNY Graduate Center, Brooklyn, NY*

Background: Overlap and divergence in strengths and weaknesses may allow youth with ASD or ADHD to learn from one another when educational contexts are structured to facilitate such learning. Learning from others with disabilities can also promote self-acceptance (Salmon, 2013). Instructional strategies that are designed to provide opportunities for youth with disabilities to learn from diverse peers are highly consistent with the central focus of Universal Design for Learning (UDL) on creating instructional environments where diversity is appreciated. Tech Kids Unlimited (TKU), an informal educational not-for-profit in NYC, provides instruction to students with diverse learning challenges and may benefit from curriculum adaptations based on student attentional profiles and specific strengths.

Objectives: This study aimed to assess how student attentional profiles affect learning preferences in a classroom environment in order to better implement principles of UD and develop curriculum for students with disabilities.

Methods: In 2019, TKU served 74 adolescents (diagnosis available for 95%; 68.5% ASD, 11.1% ADHD, and 11.1% ASD + ADHD; 51% ethnically diverse). Using the AAPE as a measure of emotions (Riccio et al., under review), we conducted four brief engagement probes each week using online surveys to examine students' engagement with targeted instructional strategies: solo work, pair work, group work, hands-on work, discussion, or lectures. Students were invited to complete an attentional profile assessment (DKEFS Color Word Interference Task; n=17) and longer end-of-week surveys assessing learning preferences and goals.

Results: When asked which instructional strategies instructors should use, hands on activities (78%) and choices (67%) were popular while written text was unpopular (39%). More students preferred multiple simultaneous instructional modalities (pictures, text and speech; 36%) to speech and pictures (24%) with the fewest preferring just speech (18%). Students who preferred instructional strategies featuring multiple modalities exhibited *more* errors inhibiting and shifting attention than students with more unidimensional instructional preferences (ps < .01).

Instructional probes with the AAPE (α=.82) revealed that preferring a unidimensional instructional strategy was associated with less positive affect during group work (p=.02). Negative affect toward group activities was associated with a preference for solo activities at the end of the week (p=.008). A repeated measures analysis with difficulty inhibiting attention as a covariate revealed that students experienced the least anxiety during solo work, followed by partner work, and then group work (p=.003) and that heightened anxiety during group work was associated with less difficulty inhibiting attention (p=.003).

Conclusions: Results align with Universal Design recommendations that instructors use multiple modalities to engage diverse learners (e.g., CAST, 2011). These data provide promising initial support for the hypothesis that attentional profiles impact engagement and indicates that difficulties working with others observed among some neurodivergent youth may arise from attentional differences. This study has allowed us to develop an accessible, reliable, and socially valid measures of engagement through collaboration with autistic researchers that has been iteratively polished through feedback from neurodivergent students. Formal and informal educational programs may benefit from adjusting their instructional strategies to better meet the needs of diverse students in the classroom.

419.057 *(Poster)* Usability and Feasibility of an Enhanced Sexual Health Education Program for Individuals with Intellectual and Developmental Disabilities

E. K. Schmidt[1]*, B. N. Hand*[1]*, S. Havercamp*[2]*, C. Sommerich*[3]*, L. Weaver*[1] *and A. Darragh*[4]*, (1)Health and Rehabilitation Sciences, The Ohio State University, Columbus, OH, (2)College of Medicine, Nisonger Center, Ohio State University, Columbus, OH, (3)Health and Rehabilitation Sciences, Ohio State University, Columbus, OH, (4)Division of Occupational Therapy, The Ohio State University, Columbus, OH*

Background: Autistic individuals are at increased risk for experiencing sexual abuse and demonstrate decreased knowledge of sexual health topics (Jones et al., 2012; Spencer et al., 2005; Sullivan & Knutson, 2000), yet they are less likely to receive formal sexual health education (SHE; Barnard-Brak, Schmidt, Chesnut, Wei, & Richman, 2014).

Objectives: The purpose of this study was to: 1) identify the gaps, barriers, and recommendations for SHE as described by individuals with I/DD, parents, health providers, and educators; 2) develop and test the usability of activities that address the gaps and barriers; and 3) assess the feasibility of a five-week SHE program using these activities. This work was conducted in compliance with the guiding policies and principles for experimental procedures endorsed by the National Institutes of Health.

Methods: A grounded theory study design using mixed methods of data collection with the four stakeholder groups was used to identify gaps, barriers, and recommendations for SHE. Focus groups and interviews were analyzed using a constant comparative method to identify gaps and barriers and a thematic analysis was used to identify recommendations. Educational activities that were recommended were developed and/or sourced from available materials. Iterative usability testing confirmed the usability, usefulness, and desirability (UUD) of each activity using a pre-established set of criteria. And finally, feasibility of recruitment, data collection, and treatment protocol was assessed.

Results: Participants in the mixed methods study (n = 37) reported barriers that contribute to current SHE practices that only result from naturally occurring educational opportunities, are provided by multiple stakeholders, and only include relationships, puberty and adolescent development, and safety (Figure 1). These current practices and participants' recommendations contributed to the development of the Accessible Sexual Education Theory that proposes use of a proactive, continuous and formal comprehensive education provided by multiple stakeholders. Educational activities were developed or sourced based on participants' recommendations for videos, visuals, the use of Universal Design for Learning (UDL), and direct, explicit instruction. Seven of the nine activities were found to be acceptable. The remaining two required further revisions and a fourth iteration to confirm acceptability. These activities were incorporated into a five-week community-based SHE program and this program was found to be feasible in terms of recruitment (90%), retention (77.8%), attendance (97%), and assessment completion rates (pretest=77.8%, posttest=100%). The following changes were recommended for future programs: 1) revised treatment protocol including 10-15 minutes for review and reminders, 20-30 minutes for content, 30-50 minutes for learning activities, and 5 minutes for question and answers, 2) an updated schedule (Table 2), and 3) incorporation of UDL into consent documents and the demographics questionnaire.

Conclusions: The findings support the use of a proactive, continuous, formal education provided by multiple stakeholders. Activities were developed or sourced and were found to be accessible to this population. Additionally, the enhanced SHE program was found to be feasible with revisions to the consent procedures, treatment protocol and schedule. Future research is needed to identify the effects of the activities and program among a larger, more diverse sample size.

419.058 *(Poster)* What Autism-Specific Training Do Law Enforcement Officers Receive?: A Systematic Review

K. Railey[1]*, J. M. Campbell*[2] *and A. M. Love*[3]*, (1)University of Kentucky, Lexington, KY, (2)Psychology, Western Carolina University, Cullowhee, NC, (3)Educational, School, and Counseling Psychology, University of Kentucky, Lexington, KY*

Background: The Community Oriented Policing Services model encourages law enforcement officers (LEOs) to build relationships with all people in their communities, especially those who may differ physically, intellectually, emotionally, and socially (Price, 2005). In everyday interactions, LEOs routinely encounter individuals with developmental disabilities (Organization for Autism Research, 2014). Despite known interactions between LEOs and persons with autism spectrum disorder (ASD), research suggests that LEOs are often not knowledgeable about ASD and report concerns about appropriately handling situations involving persons with ASD (Chown, 2009; Crane et al., 2016). In addition, research suggests that LEOs often do not receive specialized training in ASD (Crane et al., 2016; Laan et al., 2013). The lack of appropriate support to individuals with ASD by LEOs could potentially lead to emotional stress, breakdowns in communication abilities, and behavioral regulation difficulties. Given the various reports of negative interactions between LEOs and persons with ASD (Copenhaver & Tewksbury, 2019), formal training on how to recognize and respond to the needs of community members with ASD is needed.

Objectives: Although previous research has focused on training to improve LEOs' awareness and knowledge of people with intellectual disability and learning disabilities, review of the efficacy of ASD-specific law enforcement training is needed. Thus, a systematic review of the literature was conducted to provide up-to-date information regarding training for LEOs related to ASD.

Methods: Adhering to the Preferred Reporting Items for Systematic Reviews and Meta-Analyses for Protocols (PRISMA), we conducted a search of 13 professional databases and 28 journals using search terms related to both ASD and law enforcement training. Two researchers independently reviewed articles during all steps of the screening process to determine article eligibility based on inclusion and exclusion criteria set a priori. In addition, two raters independently completed the McMaster Quantitative Critical Appraisal Tool (Law et al., 1998) to appraise the identified studies.

Results: From 606 articles identified during the initial search, only two articles met inclusion criteria, which suggests that limited research exists that explores ASD and law enforcement training. *Kappa* values for both screening decisions and final inclusion were 1.0. Table 1 summarizes the main findings from both studies, including participant information, training format, content, and outcomes. Both identified studies reported statistically significant improvements in participants' self-reported awareness of ASD and confidence in supporting individuals with ASD (Murphy et al., 2018) as well as knowledge of ASD and confidence in identifying and interacting with people with ASD (Teagardin et al., 2012).

Conclusions: One of the major findings of the review is the scarcity of research concerning ASD-specific trainings for LEOs. Although both identified studies provide promising results, the review highlights the need for more empirical evidence to establish effective training protocols for teaching LEOs to support people with ASD. Findings from the present study serve as a stepping stone to understanding available literature and act as a catalyst for further research in this area.

419.059 *(Poster)* "Sometimes I Can't Keep the Mask to Myself": Social Skills Instruction from the Perspectives of Three Autistic Adolescent Girls.

M. Kofke*, Independent Scholar, Portland, OR*

Background: The social experiences of autistic[1] adolescent girls, and their perspectives of such experiences, has recently become an area of academic scrutiny (Tierney, Burns, & Kilby, 2016). Autism is expressed differently for autistic girls or women (Kirkovski, Enticott, & Fitzgerald, 2013). This study serves as a unique contribution to scholarship on the intersectional effects of experiencing being one of the only autistic girls in a high school social skills (SS) group (Saxe, 2017).

Objectives: The data for this paper was drawn from a larger dissertation study. One research question asked what are the perspectives of adolescent autistic students who identify as female, girl, or young woman, on their experiences with learning and using SS in high school? This paper focuses on desire to learn and generalizability of SS, gender isolation in SS classes and intersectional understandings of gender, and learning to mask autistic traits.

Methods: A qualitative research design using Interpretative Phenomenological Analysis (Smith, Flowers, & Larkin, 2009) and neurodiversity paradigm was applied. The participants were three white autistic girls: Maia, Ninja, and Ernie[1], who were 14/15 years old in 9^{th}/10^{th} grades while attending different public high schools. Each student was identified as having an autism label by contact personnel at their schools. Three one-on-one interviews with each participant were transcribed verbatim and coded for themes. The study was approved by university IRB. Participants had an opt-out option at any time.

Results: The participants wanted to learn SS to fit in better with neurotypical peers and as bullying prevention. Maia had direct instruction on how to mask autism and the others did not. Each student had chosen SS she valued and wanted to learn in order to build better relationships. They independently generalized these SS that were valuable to them. They experienced gender isolation as the female minority in their SS class. Topics salient to the intersection of gender and autism were not covered at school. The students did not know other autistic girls and did not think there was a distinct difference in autism among genders.

Conclusions: Extant SS research suggests autistic students struggle with generalizing SS (Laugeson, et al., 2014), however these autistic adolescent girls independently generalized SS they valued. They did not perceive autism and gender as intersectional. Knowing other autistic girls would support understanding gender differences. Concepts related to gender and the social function of masking should be incorporated into SS classes. Masking is connected to autistic well-being to prevent isolation and increase relationships with non-autistic people. (Milton & Sims, 2016), but also correlated with increased rates of depression and anxiety (Bargiela, Steward, & Mandy, 2016). Masking should be taught with this in mind. School-wide programs should work toward acceptance of autistic students and differences across genders.

[1] The use of identity-first language, with the term autistic, is used throughout this paper as indicative of the neurodiversity paradigm and is the language used by the students in this study to talk about their autistic identity.

[1] The students chose their own pseudonyms

419.060 *(Poster)* "They're like the People That Aren't Exactly, like, Normal Brained.": Neurodiversity from the Perspectives of Three Autistic Adolescent Young Women.

***M. Kofke**, Independent Scholar, Portland, OR*

Background: The school-based experiences of autistic[1] adolescent girls, and their perspectives of such experiences, has only recently become an area of academic scrutiny (Cridland, Jones, Magee, & Caputi, 2013; Jamison & Schuttler, 2015; Tierney, Burns, & Kilby, 2016). Due to the increased social and emotional vulnerability inherent with this population, much still needs to be learned of their experiences (Shefcyk, 2015)

Objectives: The data for this paper was drawn from a larger dissertation study. One of research questions asked: How does the ongoing work of learning social skills (SS) at school, via instruction or otherwise, contribute to the students' perspectives on the development of an autistic identity? This paper focuses on the students' interpretations of neurodiversity and implications for school-based instruction on neurodiversity.

Methods: Interpretative Phenomenological Analysis, a qualitative method (Smith, Flowers, & Larkin, 2009) was applied to this study. The primary participants were three white autistic adolescent girls: Maia, Ninja, and Ernie[1], who were 14/15 years old in 9^{th}/10^{th} grades while attending different public high schools. Each student was identified as having an autism label by contact personnel at their schools. Three one-on-one interviews with each participant were transcribed verbatim and coded for themes. The study was approved by university IRB. Participants had an opt-out option at any time.

Results: Maia read autism books like *Thinking in Pictures* by Temple Grandin where she learned about the term *neurotypical*, but she was not familiar with the term *neurodiversity*. She deduced the meaning of neurodiversity, concluding "They're like the people that aren't exactly, like, normal brained." Maia tried to mask being autistic at school.

Outside of school, Ninja was exposed to autism books from her parents. She said her teacher "...talks more about like, social skills than autism itself." and she would "like it if [teacher] talked more about autism, so I could know more about it." While Ninja identified as autistic, she had not been exposed to concepts or resources that supported learning about autism from the perspectives of autistic people. She did not like being autistic.

Ernie completed a project at school about autism and learned about it from other autistic students in her school. She learned about neurodiversity from autistic people's social media pages online and liked identifying as an autistic person.

Conclusions: Learning about neurodiversity at school has potential to support a positive autistic identity. The deficit perspective Maia and Ninja had can lead to negative effects on well-being. Ernie's autistic identity was more positive and informed by other autistic people. Curricular materials developed from the perspectives of autistic people on how to teach autistic students about neurodiversity and autistic culture need to be available to educators.

[1] The use of identity-first language, with the term autistic, is used throughout this paper as a marker of the neurodiversity paradigm and the language used by the students in this study.

[1] The students chose their own pseudonyms

Emotion

PANEL SESSION — **EMOTION**

212 - Without Addressing Our Daughter's Emotion Regulation Issues, Nothing Else Was Possible: Determinants, Outcomes, and Treatment of Emotion Dysregulation in ASD

Panel Chair: Carla Mazefsky, *Department of Psychiatry, University of Pittsburgh School of Medicine, Pittsburgh, PA*

Discussant: Carla Mazefsky, *Department of Psychiatry, University of Pittsburgh School of Medicine, Pittsburgh, PA*

Emotion regulation (ER) has been steadily gaining attention in autism, with an emphasis on its association with psychiatric symptoms. Less is known about how ER impacts other outcomes, processes that contribute to impaired ER, and its treatment. This session addresses these questions using methods spanning affective neuroscience to a clinical trial. The first presentation examines the stability of ER impairment from kindergarten entry to exit and its association with peer problems and behavior, in ASD and non-ASD kindergarteners. The second presentation establishes that ER impairment, more than ASD or ADHD symptom severity, markedly increases the odds of crisis (e.g., hospitalization, police contact) and outpatient service utilization in large (1000+) non-referred ASD and US census-matched samples. The third presentation highlights autonomic nervous system activity as playing a role in the biology of ER in ASD, finding differences in both physiological and facial responses to emotional stimuli in ASD youth. The fourth presentation will share promising outcomes from a randomized clinical trial of a group-based ER intervention. All panelists consider how characteristics such as gender, age, IQ, and race, may impact ER-related difficulties. Finally, the discussant will highlight themes emerging from this research and important future directions for ER studies.

212.001 *(Panel)* Diagnostic and Gender Differences in Physiological and Facial Reactivity to Positive and Negative Emotional Stimuli

V. H. Bal[1]*, M. Turley*[1]*, N. Morris*[2]*, S. R. Holley*[3]*, H. J. Rosen*[2] *and V. E. Sturm*[2]*, (1)Graduate School of Applied and Professional Psychology, Rutgers University-New Brunswick, Piscataway, NJ, (2)Department of Neurology, University of California, San Francisco, San Francisco, CA, (3)Department of Psychology, San Francisco State University, San Francisco, CA*

Background: Emotions are brief, multi-system responses that are accompanied by rapid changes in autonomic nervous system activity, facial expression and subjective experience. Emotions facilitate adaptive behaviors, helping us to navigate the physical environment and social world. Kanner (1943) suggested an affective basis for social impairments in children with ASD. To date, most studies have focused on emotion recognition (e.g., identification of emotions in others' faces) and regulation (e.g., modulation of one's own emotions). Few studies, however, have examined whether children with Autism Spectrum Disorder (ASD) exhibit aberrant emotional reactivity in response to affective stimuli.

Objectives: 1) To compare autonomic nervous system reactivity and facial behavior in response to emotion-inducing film clips in school-age children with ASD and typically developing controls. 2) To explore the relationship between laboratory-based measures of emotional reactivity and clinical assessments of social behavior and autism symptoms.

Methods: Eighteen children with ASD (*M* Age=11.0 SD=2.3 years, 78% male) and 17 age- and IQ-matched controls (*M* Age=10.8 SD=1.6 years; 41% male) completed a laboratory-based paradigm that included watching film clips that elicit specific negative (sadness, disgust) and positive (amusement, awe, love) emotions. Continuous recordings of autonomic nervous system activity (7 channels measuring cardiac, respiratory and electrodermal responses) were collected using a Biopac system. Standardized change scores (trial – baseline) for each channel were averaged to yield a single measure of autonomic reactivity for each emotion trial. Facial behavior was coded using a modified version of the Emotion Expressive Behavior System (Gross, 1996); intensity scores were summed for each trial to yield composites for negative (anger, disgust, contempt, sadness, fear, concentration) and positive (happiness/amusement) facial expressions. Multivariate ANOVAs were used to explore effects of diagnosis and gender on autonomic reactivity and facial behavior across trials (5x2x2). Linear regression was used to explore whether autonomic reactivity and facial behavior predicted autism symptoms on the Autism Diagnostic Observation Schedule in the children with ASD.

Results: The MANOVA reflected a tendency for ASD participants to be less physiologically reactive to the disgust and sad films (η_p^2=.07 and .09, respectively). Main effects of gender (η_p^2=.57) and diagnosis (η_p^2=.31) were observed for facial behavior. Univariate tests indicated that females showed greater positive facial behavior during the awe (η_p^2=.27) and love (η_p^2=.24) films than the males. The ASD group showed greater positive facial behavior during the disgust film than the controls (η_p^2=.15). Lower physiological reactivity (r_{part}=-.62) and positive facial behavior (r_{part}=-.40) to the disgust film predicted greater autism severity.

Conclusions: Taken together, these results suggest that children with ASD show aberrant responses to negative emotional stimuli, including lower physiological reactivity and context-incongruent facial behavior. Gender differences in physiological reactivity and facial behavior underscore the importance of accounting for the gender imbalance often found in ASD studies. Further analyses will be conducted to identify the specific physiological indices (e.g., cardiac, respiratory) driving the trends for autonomic differences.

212.002 *(Panel)* Exploring Differences, Change, and the Predictive Role of Emotion Regulation in ASD and TD at Kindergarten Entry and Exit

D. Swain[1]*, H. R. Thomas*[1]*, C. B. Klein*[1]*, D. Janvier*[2]*, H. Karamchandani*[3]*, J. Moses*[4] *and S. H. Kim*[1]*, (1)Psychiatry, Center for Autism and the Developing Brain, White Plains, NY, (2)Psychiatry, Weill Cornell Medical College, White Plains, NY, (3)Psychiatry, Weill Cornell Medicine, White Plains, NY, (4)Weill Cornell Medicine, Center for Autism and the Developing Brain, White Plains, NY*

Background: Children with ASD consistently show impairment in emotion regulation (ER), the ability to monitor and modify emotional experiences (Gross, 2013), compared to typically developing (TD) peers (Cibralic et al., 2019). Despite several significant findings linking poor ER to heightened behavioral problems and social difficulties, few studies have explored the longitudinal changes of ER in young children ASD compared to TD.

Objectives: 1) Examine if children with ASD show significantly more impairments in ER compared to TD children after controlling for age, gender, NVIQ at kindergarten entry; 2) Explore if children with ASD demonstrate significant improvements in ER over the kindergarten year; and 3) Examine the effects of school-entry ER on concurrent peer play and behavior in children with ASD.

Methods: Parents of sixty-eight children (30 ASD) completed questionnaires at kindergarten entry (T1) and exit (T2) for the following variables/measures: emotion regulation (Emotion Regulation Index (ERI) and two associated sub-scales (Shift, the ability to respond flexibly to changes in one's environment, and Emotional Control (EC)) from BRIEF-2, Gioia et al., 2000), internalizing and externalizing behaviors (CBCL/6-18; Achenbach, 2009) and peer play behavior (Disruption, Interaction and Disconnect sub-domains from PIPPS, Fantuzzo & McWayne, 2002)). Across groups, children were similar in age, race, and maternal education but significantly different in NVIQ and gender. One-way ANCOVAs were conducted to determine group differences (ASD vs. TD) in ERI while controlling for child clinical and demographic characteristics (see below). A Generalized Linear Mixed Model (GLMM) was used to measure change in ERI over time in ASD only sample. Finally, regressions were run to analyze the predictive nature of ERI subscales on peer play and child behaviors.

Results: At T1, after controlling for age, gender, and NVIQ, children with ASD showed significantly more impairments in ERI (F=16.07,*p*<.001), EC (F=11.45,*p*=.001), and Shift (F=30.84,*p*<.001) compared to TD children. Controlling for age, gender, NVIQ and Calibrated Severity Score (CSS) from the ADOS-2 in an ASD only sample, results from the GLMM showed no significant changes in ER scores over time. For ERI and EC, there was a significant main effect of NVIQ (F=4.12,*p*=.048, and F=5.53,p=.023 respectively), such that higher NVIQ corresponded to better ER abilities at both T1 and T2. For ERI and Shift, a main effect of CSS emerged (F=2.82, *p*=.026, and F=2.49,*p*=.044 respectively), with higher ASD symptomology linked to increased ER impairment. Controlling for age, gender, NVIQ, and CSS, T1 EC significantly predicted T1 Play Disruption (β=.68,*p*=.009) and T1 Externalizing behavior (β=.81,*p*=.001), such that greater difficulty modulating emotions led to more aggressive/antisocial behaviors that interfered with play interactions. Shift was a significant predictor of T1 internalizing behavior (β=.56,*p*=.006).

Conclusions: The current study supports previous findings that children with ASD demonstrate increased difficulty with ER, compared to TD children. These high levels of ER difficulties remained constant after completing Kindergarten and may be exacerbated by lower NVIQ and higher ASD symptomology. Given the predictive nature of ER on social and emotional outcomes, providing interventions that target ER to young children with ASD appears imperative, even before school-entry.

212.003 *(Panel)* Initial Trial Outcomes of Regulating Together: Emotion Regulation Treatment for Children and Teens with ASD in an Intensive, Group, Parent-Assisted Program

R. Shaffer[1]*, R. Adams*[2]*, L. M. Schmitt*[2]*, D. L. Reisinger*[1]*, J. Ruberg*[2]*, S. Randall*[2]*, M. Coffman*[3] *and C. A. Erickson*[2]*, (1)Division of Developmental and Behavioral Pediatrics, Cincinnati Children's Hospital Medical Center, Cincinnati, OH, (2)Cincinnati Children's Hospital Medical Center, Cincinnati, OH, (3)Virginia Tech, Blacksburg, VA*

Background: At age 8, >95% of youth with Autism Spectrum Disorder (ASD) demonstrate co-occurring behavioral and emotional symptoms that are related to negative outcomes throughout their development (Soke et al. 2018). These clinical issues are hypothesized to arise from difficulties in *emotion regulation* (ER,(Mazefsky et al. 2013). Inadequate ER skills in ASD have been linked to higher rates of hospitalizations, school disciplinary action, peer rejection, failed transitions to college and employment, and use of psychotropic medications (Turcotte et al. 2018; Mazefsky et al. 2013). Due to the severity of concerns associated with weak ER skills in ASD, traditional school- and outpatient-based programs are not equipped to deal with this population, and thus children with ASD are often excluded from treatment. Traditional interventions are typically individual-based without caregiver inclusion. Given the lack of empirically-validated interventions to address this impactful issue in ASD, our group developed Regulating Together, a group-based, parent-assisted model utilizing elements of CBT, ABA, and Mindfulness approaches (Shaffer et al. 2018). Pilot data indicated feasibility, acceptability, and positive improvements in participants.

Objectives: We are conducting a 2-year trial of RT for youth ages 8-18 with ASD to investigate the effectiveness of the program using measures of reactivity, irritability, flexibility, and parental confidence for Year 1 of the trial.

Methods: Forty-six children and teens (8-18 years) enrolled in the study with 5 withdrawals (Table 1). By the time of the conference, a total of 70 participants will have completed the study. To test the effects of the intervention, we used a within-subjects-design with a 5-week waitlist control period, 5-week RT treatment, and 10-week follow up. Primary outcome measures include the Aberrant Behavior Checklist-2 Irritability Subscale (ABC-I) and the Emotion Dysregulation Inventory- Reactivity Scale (EDI-R). Secondary outcome measures include the Flexibility Scale and parent confidence in behavior management.

Results: Preliminary analyses were completed for treatment and follow-up measures for the 23 participants that have currently completed the study (see Table 2). For the primary outcome measures, repeated measures ANOVAs found a significant decrease for ABC-I from the pre-intervention time point to the initial post-intervention time point (F(1,20)= 8.68, p<.01; Eta Squared=.30) and at the follow-up time point. At the initial post-intervention time point (ABC-I F(1,12)=12.70, p<.01; Eta Squared=.51), EDI-R was marginally reduced (F(1,20)=3.90, p=.06; Eta Squared=.16), but significantly reduced at the follow-up time point compared to the pre-intervention for both outcome measures (EDI-R (F(1,12)=9.84, p<.01; Eta Squared=.45). For the secondary outcome measures, improvements in flexibility and parental confidence managing behavior were found at the initial post-intervention period and at follow-up.

Conclusions: ER is a critically under-studied and under-treated issue in ASD leading to high rates of hospitalizations and social and academic difficulties. Thus, we developed a short-term parent-assisted group intervention approach aimed at increasing ER skills. Initial findings from year 1 of our 2 year trial indicate promising findings with excellent enrollment, retention, and improvements post-treatment and follow up in ER, irritability, flexibility, and parental confidence in managing their child's behavior.

212.004 *(Panel)* Emotion Dysregulation Drives Utilization of Acute and Outpatient Psychiatric Services in ASD More so Than ADHD or ASD Symptom Severity

C. M. Conner[1]*, J. Golt*[2] *and C. A. Mazefsky*[1]*, (1)Department of Psychiatry, University of Pittsburgh School of Medicine, Pittsburgh, PA, (2)The University of Alabama, Tuscaloosa, AL*

Background: Prior research indicates that youth with ASD require high rates of inpatient hospitalization, police contact, and emergency room visits for psychiatric or behavioral concerns, and that these negative outcomes are likely to co-occur within the same individual[1–3]. Emotion regulation (ER) may be important to consider as a potentially modifiable risk factor given mounting evidence that it is impaired in ASD and associated with a higher likelihood of co-occurring psychiatric problems[4].

Objectives: This study aimed to investigate whether ER impairment increases risk of using acute and outpatient psychiatric services in ASD and non-ASD samples, and to explore whether ER is predictive when accounting for ASD and ADHD symptom severity and demographics.

Methods: Participants were 6-to 18-year-olds recruited via the Interactive Autism Network (IAN; n=1,165) and US-census matched youth (n = 1000). Parents completed the Emotion Dysregulation Inventory (EDI)[5], that produces theta scores (M= 0, SD= 1) for Reactivity (EDI-R; poor ER and high emotional intensity) and Dysphoria (EDI-D) based on autism norms as well as a clinical-cut off score based on a general US sample. The ASD group parents completed the Social Responsiveness Scale (SRS-2)[6] and Child Behavior Checklist (CBCL)[7] ADHD scale. Information regarding lifetime psychiatric hospitalization, recent crisis services (police contact, in-home evaluation, or ER visit), prescriptions (antipsychotic, mood stabilizer, or antidepressant), and participation in therapy (individual or group) was gathered. Logistic regressions were run to predict these outcomes based on group, EDI cut-off scores, and EDI-group interactions. Follow-up analyses in the ASD group explored whether EDI scales were significant when ASD and ADHD symptoms were included. All analyses included age, gender, race, and intellectual disability as covariates.

Results: After controlling for other variables, bivariate odds ratios indicated that those with clinically elevated EDI-R are 4.91 times more likely to have been hospitalized, 8.97 times more likely to use crisis services, 20.39 times more likely to be prescribed psychotropic medication, and 20.01 times more likely to be attending therapy than those below EDI-R clinical cut-offs. Similarly, those with elevated EDI-D were 7.43 times more likely to have been hospitalized, 15.39 times more likely to use crisis services, 6.48 times more likely to be prescribed psychotropic medications, and 7.36 times more likely to be attending therapy. With one exception, group and group-EDI interactions were non-significant, suggesting ER's association with outcomes is transdiagnostic. Other significant covariates varied by outcome and included older age (hospitalization, prescriptions), being non-White (crisis services), and being female (therapy).

Follow-up analyses in the ASD group including ASD and ADHD symptoms further supported the importance of ER. Higher SRS-2 scores were only a significant predictor of hospitalizations, and higher ADHD symptoms only significantly predicted psychotropic prescriptions, whereas higher EDI-R and EDI-D scores significantly predicted all four outcomes.

Conclusions: Results indicate that higher ER impairment is strongly associated with use of acute and outpatient psychiatric services beyond ASD symptom severity and ADHD symptoms in a sample of non-clinically referred youth. ER impairment may be an important treatment target in ASD to reduce service utilization and improve outcomes.

POSTER SESSION — **EMOTION**
420 - Emotion Posters

420.001 *(Poster)* Alexithymia and Perception of Attachment Security to Parents: A Preliminary Study on School-Age Children with High-Functioning Autism Spectrum Disorder

*M. Giannotti[1], P. Venuti[2], **A. Bentenuto**[2] and S. De Falco[3], (1)University of Trento, Rovereto, Italy, (2)Psychology and Cognitive Science, University of Trento, Rovereto, Italy, (3)University of Trento, Trento, Italy*

Background: Alexithymia refers to individual difficulties in identifying, describing and distinguishing one's own feelings, which are often accompanied by an externally oriented thinking. Literature has documented the negative influence of alexithymia on parent-child interaction and interpersonal relationships as well as its frequent co-occurrence with Autism Spectrum Disorder (ASD). However, the majority of the studies on this topic have focused on adulthood and little is known about alexithymia and its impact on child socioemotional outcomes in school-age children with ASD.

Objectives: The general aim of this study is to examine explicit cognitive emotion processing and child attachment in school-age children with High-functioning ASD. In the first place, we explored potential differences between groups with respect to perceived attachment to parents and alexithymia. For this purpose, we also estimated the percentage of children above the normative cut-off of alexithymia. Secondly, in order to investigate which mechanisms intervene in shaping perception of attachment security to parents in ASD, we tested the predictive effect of child age, verbal intelligence and alexithymia.

Methods: This study included twenty-four children with High-Functioning ASD and 24 matched typically developing children (mean age 10 years). We assessed child alexithymia and attachment by using respectively two self-reported measures: the Children Alexithymia Questionnaire (CAQ) and the Inventory of Parent and Peer Attachment (IPPA). Measures of family Socioeconomic Status as well as verbal and non-verbal intelligence were collected. In order to screen children for socio-communicational symptoms we asked the mothers to complete the Social Responsiveness Scale (SRS-2). In addition, the Autism Diagnostic Observation Schedule (ADOS-2) was used to confirm ASD diagnosis in the clinical group.

Results: We observed that ASD children showed higher levels of alexithymia compared to the matched control group. In particular, 27% of children with ASD exceed the alexithymia normative cut-off. By contrast, no difference between groups emerged in the perception of attachment to parents. Moreover, self-reported alexithymia, but not the presence of ASD diagnosis, showed a negative predictive effect on child perception of attachment security to parents. Moreover, data revealed no significant effect of child age and verbal IQ on child outcome.

Conclusions:

Our findings highlighted that alexithymia is more common in school-age children with ASD, whereas perceived attachment to parents was similar between groups. These results are consistent with previous ASD literature on both alexithymia and attachment. With respect to alexithymia predictive value, difficulties in explicit cognitive emotion processing may hamper the development of a positive explicit representation of parent-child attachment relationship. Thus, alexithymia seems to play a crucial role on the way school-age children with and without ASD perceive their relationship with their parents. Limitations and directions for future research are discussed.

420.002 *(Poster)* An Examination of Temperament Traits in School-Age Children with ASD Using Parent-Reported Temperament

*R. Cardy[1], M. Malihi[2], J. Nguyen[1], B. Andrade[3], S. Monga[4], A. Dupuis[5], J. A. Brian[1], E. Anagnostou[1] and **A. Kushki**[6], (1)Holland Bloorview Kids Rehabilitation Hospital, Toronto, ON, Canada, (2)University of Toronto, Toronto, ON, Canada, (3)Centre for Addiction and Mental Health, Toronto, ON, Canada, (4)The Hospital for Sick Children, Toronto, ON, Canada, (5)Biostatistics, University of Toronto, Dalla Lana School of Public Health, Toronto, ON, Canada, (6)Bloorview Research Institute, Toronto, ON, Canada*

Background: Temperament is a biologically-based characteristic that is highly associated with emotional functioning, behavioural adjustment, and psychopathology. While temperament is considered largely stable over time, it can be influenced by development and maturation. Research on temperament in autism spectrum disorder (ASD) has largely focused on early stages of development and has demonstrated a temperamental profile for infants with ASD characterized by lower effortful control, higher negative affect, and lower surgency compared to typically developing (TD) peers. Few studies have assessed temperament profiles in older children with ASD. To address this gap, we examined temperamental traits in school-age children with ASD compared to TD controls using the Temperament in Middle Childhood Questionnaire (TMCQ).

Objectives: To examine the temperament profiles of children with ASD compared to TD, and to explore the relationship between temperament traits and ASD symptoms.

Methods: Fourteen children with ADOS-confirmed ASD (mean age=10.4, 12 males) and fifteen TD (mean age=9.1, 8 males) between ages 8-12 have participated in the study thus far. All participants had IQ >85 ($FSIQ_{ASD}$=104.21±11.11; $FSIQ_{TD}$=117.00±12.21). Parents completed the Social Communication Questionnaire (SCQ), a measure of ASD symptoms, and the TMCQ. The TMCQ is a widely used 17 subscale parent-report measure; however there has been little research on its application in an ASD population. The subscales are clustered into 3 higher-order factors: Effortful Control, representing self-regulation of emotional reactivity, attention and behaviour; Negative Affect, reflecting a capacity for a variety of negative emotions; and Surgency, representing high levels of positive affect and behavioural action. We examined the effect of diagnosis (ASD, TD) on 3 higher-order factors of the TMCQ using t-tests or nonparametric Wilcoxon tests (as appropriate). We then examined the correlations of the SCQ with each of the 3 TMCQ factors: Effortful Control, Negative Affect, and Surgency, using ordinary linear regression.

Results: Scores on two of the higher-order factors differed significantly across groups, revealing higher levels of Effortful Control in the TD group (p<0.001), and higher levels of Negative Affect in ASD (p=0.005). Analyses of associations between ASD symptoms and higher-order temperament dimensions in the ASD group revealed a positive correlation between symptom severity and Negative Affect (R^2=0.29, p<0.05).

Conclusions: Results indicate higher negative affectivity and lower effortful control for the ASD group, consistent with previous research on temperament in infants and toddlers with ASD, and supportive of a unique and stable temperament profile in ASD. If replicated in larger samples, the positive correlation between ASD symptom severity and Negative Affect for the ASD group could suggest an underlying risk factor or brain network similarly influencing both ASD symptomatology and negative affectivity, or possibly that core ASD symptoms inherently resemble negative affectivity. Results of this preliminary analysis support an emerging temperamental pattern in ASD and warrent further investigation of this parent-report measure in a school-age ASD sample.

420.003 *(Poster)* Attention to Fear Signals in Toddlers with ASD

***K. Chawarska**[1], F. Shic[2], A. Vernetti[1], S. Macari[1] and Q. Wang[1], (1)Child Study Center, Yale University School of Medicine, New Haven, CT, (2)Center for Child Health, Behavior and Development, Seattle Children's Research Institute, Seattle, WA*

Background: Toddlers with ASD show diminished *fear reactivity* compared to developmentally delayed and typically developing (TD) controls (Macari et al., 2018), impacting their ability to react to potentially dangerous situations. The factors driving this effect remain unknown. Emotion processing includes constructs of emotional reactivity (i.e., intensity of emotional responses to potential triggers) but also emotional attention (i.e., preferential processing of others' emotional signals). Here we examine whether diminished fear reactivity is driven by limited attention to fear signals from conspecifics, which may prevent toddlers with ASD from learning which stimuli are potentially threatening.

Objectives: We examined (1) if toddlers with ASD and TD controls attend preferentially to fear signals conveyed through facial expressions, body movement, and vocalizations, and (2) whether attention to fear signals is related to fear reactivity measured via parent report and observation.

Methods: Participants were toddlers with ASD (n=67, M_{age}=22.26mo, SD=3.3mo) and TD controls (n=49, M_{age}=20.99mo, SD=3.5mo). Attention to fear signals was tested using the Visual Paired Comparison (PC) paradigm implemented on the eye-tracking platform. Fear signals were conveyed through dynamic facial, bodily (biomotion) and vocal expressions and paired and presented paired with corresponding neutral signals. The preference ratio for fear signals (FearPrefRatio) was computed for each modality. Intensity of fear reactivity was assessed using the Laboratory Temperament Assessment Battery Fear Probes (LabTAB_Fear) and the parent-report Early Childhood Behavior Questionnaire (ECBQ) Fear Scale. We compared FearPrefRatio to a chance level (.50) to determine if fear signals elicited preferential attention. Then, we compared FearPrefRatio across groups and conditions using linear mixed models and examined the relationship between FearPrefRatio and LabTAB_Fear and ECBQ_Fear using Pearson's correlations.

Results: *Fear signal preference.* Both groups preferably allocated their attention to the fear signals regardless of modality (all ps<.001, **Figure 1**). However, toddlers with ASD had lower FearPrefRatio than TD toddlers across all modalities (p<.001). Both groups showed greater FearPrefRatio in the Face condition compared to the Bodily and Vocalizations conditions (ps<.001). The interaction between group and condition was not significant (p=.313). Preferential attention to facial and vocal but not bodily fear signals was associated with lower autism severity in the ASD group (Face: r(54)=-.295, p=.030; Vocalizations: r(63)=-.239, p=.058).

Correlations with intensity of fear reactivity. The associations between FearPrefRatio and parent-reported Fear (ECBQ_Fear)(all ps >.223) as well as intensity of fear expression during LabTAB (LabTAB_Fear) (all ps>.383) were negligible in both groups and in all conditions.

Conclusions: Toddlers with and without ASD attend preferentially to fear signals regardless of the modality through which fear is expressed. However, toddlers with ASD spent less time monitoring fear signals. There was no association between attention to fear signals and intensity of fear reactivity in either group. This suggests that attention to fear signals represents a dimension of emotional processing distinct from behavioral fear reactivity. Future work will need to consider not only the role of attention to fear signals but also what type of information is extracted from the signals, how it is processed, and subsequently used in modulating responses to threat in ASD.

420.004 *(Poster)* Bullying and Suicidal Ideation in Children with Autism Spectrum Disorder

M. C. Hunsche[1], *S. Saqui*[1], *P. Mirenda*[1], *T. Bennett*[2], *E. Duku*[3], *M. Elsabbagh*[4], *S. Georgiades*[3], *I. M. Smith*[5], *P. Szatmari*[6], *W. J. Ungar*[7], *T. Vaillancourt*[8], *C. Waddell*[9], *A. Zaidman-Zait*[10], *L. Zwaigenbaum*[11] *and C. M. Kerns*[1], *(1)University of British Columbia, Vancouver, BC, Canada, (2)Offord Centre for Child Studies, McMaster University, Hamilton, ON, CANADA, (3)McMaster University, Hamilton, ON, Canada, (4)McGill University, Montreal, QC, Canada, (5)Dalhousie University / IWK Health Centre, Halifax, NS, CANADA, (6)The Hospital for Sick Children, Toronto, ON, Canada, (7)University of Toronto / The Hospital for Sick Children, Toronto, ON, Canada, (8)University of Ottawa, Ottawa, ON, Canada, (9)Simon Fraser University, Vancouver, BC, Canada, (10)Tel-Aviv University, Tel-Aviv, Israel, (11)University of Alberta, Edmonton, AB, Canada*

Background: Youth with autism spectrum disorder (ASD) are at elevated risk for suicide (Mayes et al., 2013). Bullying and social exclusion are key risk factors, both in the general population (van Geel et al., 2014) and in adults with ASD (Hedley et al., 2018). Though experiences of bullying are prevalent among children with ASD (Humphrey & Hebron, 2014), no study to date has examined whether bullying is associated with suicidal ideation (i.e., suicidal thoughts with or without plan or intent) in this population. Depression and anxiety are also associated with suicidal ideation in children with ASD (Horowitz et al., 2018; Storch et al., 2013), but whether bullying plays a role in this association is unclear.

Objectives: This study examined whether parent-reported bullying experiences are associated with suicidal ideation (SI) across middle childhood in ASD.

Methods: Data collected from 195 families from the Canadian *Pathways in ASD* study were included in current analyses. Parents completed the *Child Behaviour Checklist 6-18* (CBCL) and a modified version of the *Olweus Bully/Victim Questionnaire* (BVQ) at four time points (T1: 7.3 – T4: 11.9 years). SI was assessed via Item 91 on the CBCL: Talks about killing self, with a rating of 1 “sometimes true” or 2 “often true” at any time point considered endorsement. The most frequent bullying (range: “not at all” to “many times per week”) reported on the BVQ across T1-T4 was used to estimate bullying severity. Mood problems were assessed via *T*-scores on the Anxiety Problems and Affective Problems subscales of the CBCL at T1 (M_{Age}= 7.7 years). All participants had complete data on the CBCL at T1 and BVQ at ≥ 1 time point.

Results: Per parent report, 38.2% children were bullied regularly (1+ times a month) and 9.2% expressed SI at least once across T1-T4. In addition, 10.1% demonstrated clinical levels of depression and 12.3% demonstrated clinical levels of anxiety as measured by the CBCL at T1.

A sequential logistic regression examined the independent contribution of bullying severity to SI in children with ASD, controlling for T1 anxiety and affective problems. In the final model, anxiety problems (β = .10, OR = 1.10, 95% CI [1.03, 1.18]), but not affective problems (β = -.02, OR = 0.99, 95% CI [0.91, 1.06]), were significantly associated with SI. Controlling for these variables, bullying severity was also significantly associated with SI (β = .40, OR = 1.49, 95% CI [1.06, 2.08]).

Conclusions: Findings suggest that bullying severity during middle childhood is significantly associated with SI in children with ASD, even after controlling for anxiety and affective problems at age 7. Additionally, anxiety problems were associated with SI above and beyond the influence of bullying, suggesting that bullying and anxiety represent distinct risk factors for SI in this population. Further longitudinal research is needed to clarify the extent to which bullying and anxiety predict or covary with the emergence and persistence of suicide-related outcomes in youth with ASD.

420.005 *(Poster)* Child Depressive Symptoms and Child Adaptability in Young Children with Autism

E. A. Bisi*, T. M. Rutter, C. E. Quinnett, J. Strom and B. J. Wilson, Seattle Pacific University, Seattle, WA*

Background: Adaptability involves regulating emotion and coping through change and transitions (Sparrow et al., 2005). Adaptability in adolescents has been associated positively with agreeableness and educational achievement, and negatively with peer conflict and neuroticism (Martin et al., 2012). Children with autism spectrum disorder (ASD) often have difficulty adapting readily to unexpected changes in their environments (Lee & Park, 2007). Many children with autism also experience depressive symptoms which may impact their ability to effectively adapt (Hollocks et al., 2014).

Objectives: We sought to examine the differential effect of child depressive symptoms on adaptability in children with ASD and typical development (TD). We hypothesized that depressive symptoms would moderate the relation between child developmental status (ASD vs. TD) and child adaptability. Specifically, we predicted that higher depressive symptoms would predict lower adaptability for both status groups and that this effect would be more pronounced for our ASD group.

Methods: Participants were 31 children between ages 3 and 6, including 20 TD children (60% female) and 11 children with ASD (18% female). Parent ratings from The Behavioral Assessment System for Children--Second Edition (BASC-2; Reynolds & Kamphaus, 2006) were used to measure child depressive symptoms and adaptability.

Results: A moderated multiple regression was conducted to evaluate the relation between child status and parent report of child depression on parent-reported child adaptability. Our overall finding indicated a trend with the total effect (p = .06, B = -.662, CI_{95} = -1.345 to .021), which we explored further by looking at the conditional effects of our predictor at different values of our moderator. These results indicated a significant conditional effect when depressive symptoms levels reached at-risk to clinically significant (t scores = 62 and above; p > .001, B = -17.8, CI_{95} = -29.77 to -5.82). The negative valence means that those with ASD and high depressive symptoms demonstrated, on average, 17.8 units less adaptability than the TD group.

Conclusions: Results supported our hypothesis that at high levels of depressive symptoms, children with ASD would demonstrate more pronounced challenges in adaptability compared to TD peers. Given that our moderator (depressive symptoms) showed a significant conditional effect only at near-clinically significant levels, it may be that ASD children demonstrate unique resilience in adaptability compared to those with TD. That is, among children with ASD, depressive symptoms did not appear to interfere in effectively adapting to environments until depressive symptoms reached near-clinical levels. Future research should prospectively examine adaptability trajectories for children with ASD, particularly as demands increase within school settings. Given that our overall findings trended towards significance, future research should also utilize adequately powered analyses with a larger sample of young children.

420.006 *(Poster)* Children with Autism Spectrum Disorder Show Typical Levels of Accuracy on a Task of Basic Multimodal Emotion Recognition

S. Sivathasan[1]*, H. Dahary*[2]*, J. Burack*[1] *and E. M. Quintin*[1]*, (1)Educational & Counselling Psychology, McGill University, Montreal, QC, Canada, (2)McGill University, Montreal, QC, Canada*

Background: Social and communication challenges central to autism spectrum disorder (ASD) are often thought to be associated with deficits in emotion recognition (ER) skills. In order to study the universality of these disparities, they might best be studied within a modality, such as music, that is of specific interest to children with ASD.

Objectives: The objective was to provide an initial comparison of basic ER skills among children with ASD and typically developing (TD) children across the modalities of face, vocalizations, and music.

Methods: Twenty-five children with ASD and 21 TD children between the ages of 6-13 years (*M*=10.42, *SD*=1.54) completed tasks associated with identifying emotions in faces, vocalizations, and music. Each modality included 8 happy, 8 sad, and 8 fearful emotional expressions from validated stimuli sets for a total of 72 stimuli. After each stimulus was presented on a computer screen for 1.5-2 seconds, the participants selected the verbal label that best described the stimulus from among these three possible expressions.

Results: Overall median accuracy ratings did not differ significantly between the children with ASD (*Mdn* = .86) and TD children (*Mdn* = .85). However, additional analyses revealed differences in emotion recognition accuracy across modalities ($p < .0001$) and emotions ($p < .0001$). Post hoc analyses with Wilcoxon signed rank tests (Bonferroni $p < .017$) revealed that the participants more accurately identified emotions from voices than faces and music, all $ps < .0001$. Across modalities, the participants also more accurately identified happy expressions than fear, and sad expressions than fear, $ps < .005$. No significant difference in overall accuracy was found for identification of happy versus sad emotions, $p = .06$. Further, happy faces and voices, and sad faces and voices were more accurately identified than happy and sad music, respectively, $ps < .01$. Conversely, fearful voices were more accurately identified than fearful faces or music, $ps < .0001$. No differences in accuracy were found for happy faces and voices ($p = .33$), sad faces and voices ($p = .67$), and fearful faces and music ($p = .98$).

Conclusions: The children with ASD and TD children were similarly able to identify emotions from faces, voices, and music in our experimental paradigm. However, significant differences in accurately identifying emotions across modalities were found, as the participants across both groups more accurately identified emotions from voices and faces than from music, and more accurately identified happy and sad emotions than fear. Further, happy emotions were more easily identified via social modalities (faces and voices) than music, but fear was less accurately identified by the participants in facial expressions and music compared to voices. These findings are contrary to the generally accepted literature on reduced emotion recognition capabilities of children with ASD, suggesting a potential for typical patterns of strengths and challenges in ER across modalities and emotions.

420.007 *(Poster)* Clinical Validation of the Emotion Dysregulation Inventory for Autism

K. Breitenfeldt[1]*, C. M. Conner*[2]*, S. W. White*[3] *and C. A. Mazefsky*[2]*, (1)Psychiatry, University of Pittsburgh Medical Center (UPMC), Pittsburgh, PA, (2)Department of Psychiatry, University of Pittsburgh School of Medicine, Pittsburgh, PA, (3)Psychology, The University of Alabama, Tuscaloosa, AL*

Background: Recently, the Emotion Dysregulation Inventory (EDI) was developed and validated as the first parent-report of emotion regulation (ER) impairment for children and adolescents with ASD (Mazefsky et al., 2018).Because the EDI was designed to be useful across the full range of functioning, measures of ER strategy use were not included in the evaluation of its initial psychometrics. Prior research has identified ER strategies that appear to be more commonly reported in ASD (e.g., rumination, suppression) and have shown their association with specific psychiatric symptoms (e.g., depression, anxiety; Cai et al., 2018). It remains unclear how ER strategy use corresponds to observable indicators of emotion dysregulation more broadly.

Objectives: We investigated the associations between ER impairment measured by the EDI and ER strategy use measured by the Response to Social Stress Questionnaire (RSQ) in adolescents and young adults with ASD. We hypothesized that EDI Reactivity would be associated with involuntary engagement (e.g. rumination, sustained arousal), whereas EDI Dysphoria would be associated with involuntary disengagement (e.g., shutting down).

Methods: 68 teens and young adults (12-21 years old) with ADOS-confirmed ASD and verbal IQ scores above 80 were recruited to participate in an open and randomized control trials of the EASE program (Emotional Awareness and Skills Enhancement- a mindfulness-based intervention). Parents completed the EDI and RSQ prior to treatment. The EDI provides scores for Reactivity (intense and poorly regulated negative emotional reactivity) and Dysphoria, and the RSQ measures coping strategies and involuntary stress responses. The EDI also provides clinical cut-offs based on norms from a sample of 1000 general youth matched to the US census.

Results: Higher Reactivity was associated with more Involuntary Engagement, (r=.323, p=.008), which includes strategies such as rumination, intrusive thoughts, emotional arousal, physiological arousal, and impulsive involuntary action. While higher Dysphoria was associated, (r=.295, p=.015), with Involuntary Disengagement (emotional numbing, cognitive interference, inaction and escape strategies). Additionally, higher Dysphoria was associated with less acceptance-focused coping strategies (Secondary Control Coping; r=-.279, p=.022). By means of logistic regression, the use of these positively correlated strategies contributing to the EDI clinical cut offs for reactivity and dysphoria was assessed, while controlling for age and IQ. Higher scores on Involuntary Engagement influenced the chances of meeting criteria for clinical levels of Reactivity on the EDI (p=.016), and exceeding the clinical cut-offs for Dysphoria on the EDI was influenced by increased Involuntary Disengagement (p=.014). Further analyses explored the significance of the subtests within these strategy categories.

Conclusions: These findings provide further validity support for the EDI by demonstrating expected associations between ER strategies and EDI scores. Further, the patterns are generally consistent with prior research on the association between ER strategy use and specific psychiatric symptoms (Cai et al.). This emerging picture suggests largely nonspecific effects of aberrant ER strategy use on a range of poor outcomes. Although longitudinal studies are needed to understand the direction of these effects, these findings could be used to inform future interventions to target the specific strategies that are most maladaptive for emotion regulation in this population.

420.008 *(Poster)* Developing a Multidimensional Visual Scale of Emotions (AAPE) and Autistic Identity through a Research Partnership with Autistic Scholars

A. Riccio[1]*, J. Delos Santos*[2]*, S. K. Kapp*[3]*, A. Jordan*[4]*, D. DeNigris*[5]*, D. S. Smith*[6] *and K. Gillespie-Lynch*[7]*, (1)Department of Psychology, The Graduate Center, City University of New York (CUNY), New York, NY, (2)Hunter College, City University of New York, New York, NY, (3)Department of Psychology, University of Portsmouth, Portsmouth, United Kingdom, (4)CUNY, Staten Island, NY, (5)Psychology & Counseling, Fairleigh Dickinson University, Madison, NJ, (6)College of Staten Island, CUNY, Staten Island, NY, (7)Department of Psychology, College of Staten Island; CUNY Graduate Center, Brooklyn, NY*

Background: Measures that are accessible to individuals across the autism constellation are needed so that a more representative group of autistics may share their experiences using communication methods designed around their abilities and challenges. Given that autism is often associated with visual strengths (Kaldy et al., 2016), picture-based options may increase comprehension of survey items and may allow more diverse autistic individuals, who have traditionally been underrepresented within the autism research literature (Jack & Pelphrey, 2017), to participate in research. Picture-based measures may be especially useful for research concerning autistic identity, a key area where representation of diverse autistic perspectives is greatly needed. Thus, picture-based tools may improve the accuracy and generalizability of findings.

Objectives: We, members of a participatory research group of autistic and non-autistic researchers, developed and evaluated 1) a picture-based measure of autistic identity which depicts experiences common to autistic people and 2) an emotion rating scale including 4 emotional dimensions (AAPE, under review).

Methods: Our participatory research group developed and revised the Multidimensional Scale Assessing Affect, Anxiety, Pride and Energy (AAPE; Figure 1a) guided by pilot testing with autistic high school (*n*=15) and college (*n*=16) students using online surveys. In final testing, autistic university students (*n*=72) rated comprehension of each emotional dimension using both open-ended response and an agreement scale from 1-to-5.

Ten visual representations of autistic experiences (Figure 1b), agreed upon by autistic members of our research group and drawn by an artist, were qualitatively and quantitatively rated by autistic university students (n=72) through an online survey.

Results: Open-ended responses indicated that the AAPE was well-comprehended on dimensions of affect (97.2%), anxiety (79.2%), and energy (84.7%) with potential for improvement in representation of pride (52.8%). Quantitatively, participants agreed that affect (*M*=4.28±.92) and anxiety (*M*=4.29±.86) depicted the intended emotional dimensions, followed by energy (*M*=4.08±1.00) and pride (*M*=3.50±1.20) on an agreement scale from 1-to-5.

Analysis of participant comprehension of ten autistic experiences is presented in Table 1. Depictions of sensory overload, making patterns, and experiencing miscommunication were best understood by participants in this sample. After being informed of the experience depicted, participants generally agreed that experiences were well-represented (Table 1). Cronbach's alphas as a visual autistic identity scale rated on each emotional dimension were somewhat questionable (affect α=.63; anxiety α=.63; pride α=.62; energy α=.67).

Conclusions: The AAPE was well-received by participants and has utility for use in future research studies to assess diverse participants' feelings in various contexts. Cross-checking how participants interpret scales, as we did here, is recommended for all dimensions, but particularly pride. This study took a first step towards developing a picture-based measure of autistic identity rooted in personal feelings about autistic experiences. Alphas were similar to widely used autism knowledge scales (e.g., Campbell et al., 1996), suggesting that the construct "autism" is multidimensional. Quantitative feedback indicates that autistic experiences and emotions were well-comprehended as a multimodal scale including both images and explanatory text.

420.009 *(Poster)* Do Different Aspects of Anxiety Symptomatology Have Differing Impact for Children and Youth on the Autism Spectrum?

D. Adams*, Autism Centre of Excellence, Griffith University, Brisbane, Australia*

Background: Anxiety is recognised as one of the most common co-occurring conditions for individuals with a diagnosis on the autism spectrum, with approximately 40% of children on the spectrum receiving a clinical diagnosis of an anxiety disorder. To date, research has tended to focus upon understanding presentation and evaluating interventions, with little focus on understanding the impact that the anxiety may be having on the individual and their family.

Objectives: This study aimed to describe the profile of scores on a standardised measure of impact of anxiety and investigate which, if any, aspects of parent and child anxiety levels predict the different aspects of parent-reported impact of the child's anxiety in and outside of the home.

Methods: A community sample (*n*= 131) of parents of children on the spectrum completed questionnaires on their child's autism characteristics and anxiety symptomatology (the Anxiety Scale for Children - Autism Spectrum Disorder; ASC-ASD-P) as well as their own levels of anxiety (DASS) and a standardised questionnaire on impact of anxiety; the Child Anxiety Life Impact Scale (CALIS). A series of Hierarchial Multiple Regressions were undertaken, with autism characteristics and anxiety symtomatology subscale scores as the predictor variables and CALIS impact subscales as the outcome variables.

Results: Parents reported that their child's anxiety has the highest impact upon the child doing daily or enjoyable activities, including attending activities or events with their caregiver. A significant proportion (85%) also noted that their child's anxiety impacts their classroom performance at least sometimes. Hierarchical Multivariate Regression models identified that specific aspects of child anxiety as well as parent anxiety predicted different subscales of the CALIS. The child's anxious arousal significantly predicted the impact of anxiety at home, the child's difficulties with uncertainty significantly predicted the impact of anxiety outside the home and the combination of the child's difficulties with uncertainty and parental anxiety significantly predicted the impact the child's anxiety has on the parents.

Conclusions: In order to understand anxiety, researchers need to move beyond just measuring anxiety symptomatology to exploring the impact that this may be having on the individual or on those who live with and/or support them. Identifying the aspects of anxiety which have the biggest impact on the home, school and community has important clinical and research implications, as it may be the interventions and/or supports for these aspects of anxiety should be prioritised. As this study is only based on parent-report, the importance of further work incorporating self-report is explored.

420.010 *(Poster)* Enhanced Anger Recognition in ASD Children with Internalizing Symptoms

***T. M. Rutter**, A. J. O'Connor, E. A. Bisi and B. J. Wilson, Seattle Pacific University, Seattle, WA*

Background: One key inconsistency of facial emotion recognition (FER) investigations is the employment of various paradigms (e.g., static, dynamic, high-intensity, low-intensity, cartoon, face-in-the-crowd). While Bal and colleagues (2010) found that children with autism spectrum disorder (ASD) were less able to detect anger compared to typically developing (TD) controls when viewing dynamic expression videos, other studies demonstrate no significant group differences in static anger recognition (Lacroix, Guidetti, Roge, & Reilly, 2009). Much is left to explore regarding accurate emotion recognition among young children within ecologically valid tasks (e.g., dynamic paradigms). Although individuals with ASD often have concurrent internalizing symptoms (Volker et al., 2010), the role of internalizing symptoms have been understudied in FER investigations. Recent evidence from a longitudinal investigation suggests children with ASD and concurrent internalizing symptoms demonstrate enhanced FER accuracy (Rosen & Lerner, 20016). Given inconsistencies within the anger recognition literature, we sought to clarify these associations in the context of internalizing symptoms in young children with ASD and TD.

Objectives: Our overall objective was to examine factors associated with accurate recognition of anger among young children with ASD. We hypothesized that internalizing symptoms would moderate the relation between developmental status and anger recognition.

Methods: Participants were 151 children (ages 3:0 to 6:11) and their parents. Eighty-four TD children (42% female) and 67 children with ASD (19% female) participated. Parent ratings from the Behavioral Assessment System for Children - Second Edition (BASC-2; Reynolds & Kamphaus, 2004) were used to measure internalizing symptoms. Children completed a dynamic emotion recognition task via laptops in a laboratory setting. Two trials of twenty slides were presented. Scores reflect the mean slide number of first accurate recognition; higher scores indicate slower recognition.

Results: A moderation analysis was conducted using the macro PROCESS (Hayes, 2013) for SPSS 26 to evaluate whether the association between developmental status and recognition of anger was moderated by parent-reported child internalizing symptoms. Children's age and gender were controlled for in the analysis. Results indicated a significant main effect of status on emotion recognition (B = 6.222, CI95 [1.763, 10.681], p = .006). The main effect of internalizing symptoms on emotion recognition was not significant (B = .022, CI95 [-0.048, 0.928], p = .532). The contribution of the interaction between status and internalizing symptoms was significant (B = -0.09, CI95 [-0.176, -0.003], $\Delta R2$ = .022, $F(1,145)$ = 4.251, p = .041. Our model explained 19.32% of the variance in accurate identification of anger.

Conclusions: Overall, children with ASD demonstrated slower recognition of anger. However, as internalizing symptoms increased, the difference between TD children and children with ASD for first identifying anger decreased. This suggests that internalizing symptoms may have a sensitizing effect on anger recognition ability for children with ASD. Internalizing symptoms may be an important factor in anger recognition, possibly accounting for the mixed findings within the literature. Future investigations should focus on examining the role of internalizing problems on the processing of emotions across other facial recognition paradigms in young children with ASD.

420.011 *(Poster)* Evidence of Feasibility and Acceptability of the Parent Mediated Group Intervention Coping with Uncertainty in Everyday Situations (CUES) from Parents Attending a Pilot Randomised Controlled Trial

*J. Rodgers[1], **J. Goodwin**[1], J. R. Parr[2], V. Grahame[3], C. Wright[4], D. Garland[3], M. R. Osborne[5], M. Labus[6], A. Kernohan[7] and M. Freeston[8], (1)Institute of Neuroscience, Newcastle University, Newcastle Upon Tyne, United Kingdom, (2)Population Health Sciences Institute, Newcastle University, Newcastle upon Tyne, United Kingdom, (3)Cumbria, Northumberland, Tyne and Wear NHS Foundation Trust, Newcastle upon Tyne, United Kingdom, (4)Child and Adolescent Mental Health Service, Northumbria Healthcare NHS Foundation Trust, North Shields, United Kingdom, (5)South Tyneside's Kids And Young Adults Klub - Special needs support group (KAYAKS), South Shields, United Kingdom, (6)Research and Enterprise Services, Faculty of Medical Sciences, Newcastle University, Newcastle Upon Tyne, United Kingdom, (7)Institute of Health & Society, Newcastle University, Newcastle Upon Tyne, United Kingdom, (8)Newcastle University, Newcastle upon Tyne, United Kingdom*

Background: Anxiety is common in autistic children. One key mechanism underlying anxiety is intolerance of uncertainty (IU), a tendency to react negatively on an emotional, cognitive, and behavioural level to uncertain situations. We have worked with clinicians and parents to develop a parent-based intervention to assist autistic children to manage uncertain situations more effectively: Coping with Uncertainty in Everyday Situations (CUES© 2016 Newcastle University). We are conducting a pilot randomised controlled trial of this intervention.

Objectives: We aimed to ascertain whether CUES© is feasible to deliver through NHS services by trained therapists, and whether it was acceptable and well-received by families.

Methods: Eight trained NHS therapists facilitated four CUES© groups. Fifty-three families were recruited to the study through clinical services. The children were aged 6 – 16 years, had a diagnosis of ASD, and were experiencing anxiety related to IU. Parents were allocated by chance to either receive CUES© or attend a psychoeducation group in a small group setting. Four months after the programme, parents and therapists completed a semi-structured interview about their experiences of the intervention. The data from the semi-structured interviews were then analysed thematically.

Results: Retention and attendance at the group was good. Feedback from parents demonstrated that taking part in the CUES© group was useful: it allowed parents to understand their child's anxiety, to identify uncertain situations and apply the strategies they learned during the programme. Also, taking part in the study helped parents to feel less isolated, because they were able to connect with other parents in a similar situation. Parents who had a child with intellectual disability found the group helpful, but thought it would be useful to attend a group with others parents whose children had similar abilities. All parents that the reported programme highlighted the role of uncertainty in their child's anxiety and they felt better equipped to manage it.

Therapists reported that they had positive experiences of delivering the CUES© programme. They reported the content was appropriate and well-paced. They observed a particular strength of the programme was that the content built incrementally each week to consolidate the parents' knowledge, as IU was a new concept for them. Most families found the 'homework' useful but not all had the time to complete it depending on individual circumstances.

Conclusions: Our data support the acceptability and feasibility of CUES©. The findings indicate that parents valued a range of aspects of the programme, including the content and pace of the programme, the small group setting which was beneficial for peer support, repetition of concepts to consolidate learning, and the focus on IU, which had face validity for parents. Therapists found the materials to be deliverable and the content appropriate for the families they are working with. Our pilot trial has established parents were willing to be recruited and randomised, the format and content of the groups were feasible and acceptable and the outcome measures were appropriate for use in a future definitive trial.

420.012 *(Poster)* Examining the Effect of Family Functioning on Emotion Regulation in Autism Spectrum Disorder

B. Syed[1], *M. Malihi*[1], *J. Nguyen*[2], *R. Cardy*[2], *B. Andrade*[3], *S. Monga*[4], *A. Dupuis*[5], *J. A. Brian*[2], *E. Anagnostou*[2] *and A. Kushki*[6], *(1)University of Toronto, Toronto, ON, Canada, (2)Holland Bloorview Kids Rehabilitation Hospital, Toronto, ON, Canada, (3)Centre for Addiction and Mental Health, Toronto, ON, Canada, (4)The Hospital for Sick Children, Toronto, ON, Canada, (5)Biostatistics, University of Toronto, Dalla Lana School of Public Health, Toronto, ON, Canada, (6)Bloorview Research Institute, Toronto, ON, Canada*

Background: Emotion regulation difficulties are highly prevalent in autism spectrum disorder (ASD) and have been associated with adverse mental and physical health outcomes. Among the many factors contributing to these difficulties, family functioning may play a key role. In the general population, the family context is suggested to impact children's emotion regulation abilities through observational learning, parenting practices related to emotion management, and the emotional climate of the family (Morris et al, 2007). However, the association of emotion regulation abilities and family functioning has not been explored in children with ASD.

Objectives: To examine the association between family functioning and emotion regulation abilities in children with ASD.

Methods: The study sample consisted of 28 children aged 8 to 12 years who were typically developing (n=15, mean age=9.1, SD=1.2, 8 male) or had a diagnosis of ASD (n=13, mean age=10.5, SD=1.5, 11 male). All children had full-scale IQ greater than 85. Emotion regulation ability was measured using the total score on the Emotion Dysregulation Inventory (EDI), a 64-item parent-reported questionnaire validated in samples of children with ASD, in which a higher score reflects higher emotion dysregulation. Family functioning was measured by the Family General Functioning Scale (FGFS), a 12-item parent-reported questionnaire, on which a higher score indicates poorer family functioning. Wilcoxon-Mann-Whitney tests and linear regression analyses were used to examine group differences and EDI-FGFS associations. respectively.

Results: The ASD group had significantly higher scores than the TD group on all 3 EDI indices namely, short ($p<0.005$) and full ($p<0.005$) reactivity, and dysphoria ($p<0.05$). Over all participants, FGFS was significantly associated with the dysphoria index (Linear Regression, $\beta=2.55 \pm 0.72$, $p<0.005$, $R^2=0.32$). Significant FGFS x diagnoses (ASD/TD) interactions were found for the reactivity indices (full, $F(3,24)=16.86$, $p<0.0001$; short, $F(3,24)=9.42$, $p<0.0005$), suggesting a positive association in the ASD group, but a weak negative association in the TD group (Figures 1 and 2).

Conclusions: Consistent with previous literature, our results showed that children with ASD had significantly greater emotion regulation difficulties when compared to the TD children. Better family functioning was associated with greater emotion regulation abilities across both ASD and TD groups, although our results suggest the nature of this association may be different in ASD. In particular, for the ASD group, poorer family functioning was associated with lower emotion regulation. These results highlight the role of family functioning in emotion regulation. If replicated in larger samples, these results may suggest family functioning as a potential intervention target for emotion regulation difficulties in children with ASD. Future longitudinal studies can help tease out the direction of causality between emotion dysregulation and family functioning.

420.013 *(Poster)* Exploring Sources of Childhood Trauma for Individuals with ASD: Perspectives from Adults on the Spectrum and Caregivers

C. M. Kerns[1], *D. L. Robins*[2] *and S. J. Berkowitz*[3], *(1)University of British Columbia, Vancouver, BC, Canada, (2)A.J. Drexel Autism Institute, Drexel University, Philadelphia, PA, (3)psychiatry, UC School of Medicine, Denver, CO*

Background: Trauma occurs when an event or series events are experienced as physically or emotionally harmful or life threatening and have lasting adverse effects on individual functioning and well-being (SAMSA, 2014). That is, trauma is defined by not only experience, but also an individual's appraisal and ability to cope with what they experience. Given the subjective nature of trauma, it has been hypothesized that the types of stressors individuals with ASD encounter and experience as traumatic may vary from those experienced by neurotypical populations (Kerns, Newschaffer & Berkowitz, 2015).

Objectives: To test this hypothesis, we conducted a qualitative study to describe (1) sources of childhood trauma as identified by adults with ASD and caregivers; (2) agreement between qualitative findings and the results of a standard traumatic events questionnaire.

Methods: Stratified purposeful sampling was used to enroll autistic adults (N=14) and parents of children and adults with ASD (N=15) with varied adverse experiences, functional outcomes and socio-demographic characteristics. ASD was confirmed with standard scales. Participants completed the Trauma History Questionnaire (THQ), standard measures of ASD and mental health symptoms, and qualitative interviews, which were audio-recorded, transcribed and submitted to inductive (e.g.,codes derived from review of interviews) and theoretical (e.g.,premeditated code) thematic analysis through Nvivo. In each interview, participants were asked to describe events and circumstances they considered traumatic given the SAMSHA definition (as above) using a semi-structured protocol. Each transcript was coded by two raters, who met regularly to compare ratings, clarify codes and reconcile inconsistencies.

Results: Participants described a range of both traditional and distinct trauma sources in the lives of people with ASD on both the THQ and qualitative interviews (see Table 1). Cited sources of trauma included neglect, physical, sexual and emotional abuse as well as more chronic traumatic stressors, such as bullying, discrimination/stigma, marginalization, betrayal and experiences that may be more specific to ASD, such as sensory-related trauma, social confusion, seclusion/restraint and social isolation. Distinct sources of trauma bore many hallmarks of traumatic experience, including feelings of helplessness, chaos, and unpredictability. All adults and 87% of parents described sources of trauma (both traditional and distinct) in their qualitative interviews that were not reported on the THQ, though the item “other trauma” was frequently endorsed on this measure (71% adults, 47% parents).

Conclusions: Adults with ASD and caregivers described a varied array of experiences as having a lasting, deleterious impact on their functioning and well-being that were not detected by a standard measure of adversity. Whereas some of these experiences reflect commonly recognized sources of trauma and PTSD, others may reflect particular vulnerabilities associated with having an autism diagnosis. Disclosure and thus comprehensive assessment of potential trauma in ASD may be influenced by the format (i.e. questionnaire, interview) as well as content (traditional v. ASD-related stressors) of inquiry. Results have important implications for the assessment of adverse and potentially traumatic events for individuals with ASD and for inquiries into the potential role of childhood adversities in the high rate of psychiatric comorbidity observed in ASD.

420.014 *(Poster)* Fear Potentiated Startle in Children with Autism: Relationship to Anxiety Symptoms and Development of the Amygdala

D. Hessl[1], *L. Libero*[2], *A. Schneider*[3], *C. M. Kerns*[4], *B. Winder-Patel*[5], *B. Heath*[2], *C. C. Coleman*[6], *M. Solomon*[2] *and C. W. Nordahl*[2], *(1)Department of Psychiatry & Behavioral Sciences, UC Davis MIND Institute, Sacramento, CA, (2)Department of Psychiatry and Behavioral Sciences, The Medical Investigation of Neurodevelopmental Disorders (MIND) Institute, UC Davis School of Medicine, University of California Davis, Sacramento, CA, (3)Pediatrics, MIND Institute, University of California at Davis, Sacramento, CA, (4)University of British Columbia, Vancouver, BC, Canada, (5)MIND Institute, University of California, Davis, Sacramento, CA, (6)Department of Psychiatry & Behavioral Sciences, The Medical Investigation of Neurodevelopmental Disorders (MIND) Institute, University of California, Davis, Sacramento, CA*

Background: The development of biologically meaningful probes of brain function in order to phenotype the behavioral heterogeneity of autism has become a major initiative of modern research in the field. Anxiety disorders have been estimated to affect more than 50% of individuals with autism, yet the presence, severity and mechanisms underlying anxiety has been challenging to characterize. We have been focusing on efforts to diagnose anxiety in autism and to establish biological or physiological biomarkers of increased anxiety. Fear potentiated startle (FPS) is a biobehavioral response mediated by the amygdala that provides an index of fear conditioning and has been associated with anxiety in human and animal studies.

Objectives: The purpose of the present study was to evaluate FPS in a cohort of 8-12-year-old children with autism compared to typically developing controls who are part of the longitudinal Autism Phenome Project, and to examine the association between FPS, amygdala growth and anxiety.

Methods: Participants were 145 children (15 females and 68 males with autism; 23 females and 38 males with typical development) between 9 and 13 years. Children with autism met ADOS and ADI criteria, and had DAS Global Cognitive Composites ranging from 24 to 170 (mean = 79 +/- 31). Anxiety was evaluated by a trained and reliable clinical interviewer with the primary caregiver using the Anxiety Disorder Interview Schedule (ADIS), Autism Spectrum Addendum. Longitudinal structural MRI for determination of amygdala volume were collected throughout early childhood.

The FPS stimuli included an air puff (the US), a burst of air for 200ms at 60psi from tubing pointing at the base of the throat, and an acoustic startle stimulus (SS; 100dB white noise, 50ms) presented in a set of headphones. The conditioning phase consisted of 20 presentations of the CS, a red screen presented on the computer in front of the participant, paired with the US for 50ms, to facilitate fear conditioning. The testing phase included 30 randomized trials of three types: (1) 6 CS-US pairings, (2) 12 CS-SS “threat” trials, (3) 12 SS alone “safe” trials. The startle reflex was measured via electromyographic activity (EMG) recorded using two Ag/AgCl surface electrodes placed under the left eye (orbicularis oculi). The FPS response is analyzed from the 12 “threat” and “safe trials”; potentiation is indicated by a greater response in the threat condition compared to the safe condition, measured as percentage startle potentiation.

Results: Analyses pending will include comparisons of FPS between children with autism and controls, the correlation between severity of anxiety symptoms from the ADIS interview and FPS level in each group. FPS in relation to amygdala growth trajectory and the emergence of clinically significant anxiety in middle childhood also will be examined.

Conclusions: Establishment of links between FPS and anxiety in autism will provide evidence that brain mechanisms known to underlie fear conditioning in animal models and humans generally play an important role in this sub-phenotype of the condition. In addition, FPS may provide a useful objective biomarker for examining response to treatment and target engagement.

420.015 *(Poster)* Fear-Induced Arousal in Toddlers with Autism Spectrum Disorder Depends on the Social Nature of the Situation

A. Vernetti[1], *F. Shic*[2], *S. Macari*[1], *M. S. Goodwin*[3] *and K. Chawarska*[1], *(1)Child Study Center, Yale University School of Medicine, New Haven, CT, (2)Center for Child Health, Behavior and Development, Seattle Children's Research Institute, Seattle, WA, (3)Northeastern University, Boston, MA*

Background: Physiological arousal quantified by the measure of changes in skin conductance levels (ΔSCL) (Vernetti et al., under review), and behavioral responses measured by the intensity of facial and vocal expressions (Macari et al., 2018) have recently shown under-reactivity to nonsocial threat in toddlers with ASD. However, it is not clear if this physiological phenomenon is specific to the (non)social nature of fear-inducing episodes. While, social fear (fear of stranger) in children with and without ASD has widely been studied, the stranger fear as a universal phenomenon has been questioned as it may depend on contexts and developmental level (Rheingold & Eckerman,1974, Lobue et al.,2019). This study aims to examine threat-induced arousal in toddlers with autism in different social, nonsocial and socially-ambiguous contexts.

Objectives: (1) To test whether toddlers with ASD differ from typically developing (TYP) controls in the magnitude of ΔSCL to real-world Nonsocial (mechanical objects), Social (stranger wearing sunglasses/cap), Socially-Ambiguous (person wearing mask/cloak) episodes. (2) To test whether ΔSCL is associated with intensity of behavioral fear reactivity.

Methods: Participants included 40 toddlers with ASD (Mage=22.5mo, SD=3.5) and 34 age-matched TYP controls (Mage=20.8mo, SD=3.6). ΔSCL during the Laboratory-Temperament Assessment Battery (Goldsmith&Rothbart, 1999) using an ankle sensor Affectiva Q-Sensor. ΔSCL was computed between a 10-sec baseline preceding each episode, and the fear-inducing episodes. Peak of intensity of fear expression across facial, vocal, and bodily channels was computed. Autism severity was assessed using the Autism Diagnostic Observation Schedule, 2ndEdition (ADOS-2).

Results: A GLM analysis of ΔSCL indicated a significant diagnosisXepisode interaction ($F(2,123)=5.38, p=.006$). In the TYP group, ΔSCL was not significantly different between Social, Nonsocial and Socially-ambiguous episodes (all $p>.339$). However, in the ASD group, ΔSCL was lower during the Nonsocial ($t=2.55, p=.013, d=.60$) and Socially-ambiguous episodes ($t=2.79, p=.007, d=.65$) compared to the Social episode. ΔSCL in the ASD group was lower compared to the TYP group during Nonsocial ($t=2.78, p=.007, d=.69$) and Socially-ambiguous ($t=2.60, p=.011, d=.62$) but not during Social episodes ($t=1.06, p=.296, d=.29$). In the TYP group, greater ΔSCL was associated with greater intensity of fear expression during Nonsocial ($r(31)=.39, p=.024$)) and Socially-ambiguous ($r(32)=.39, p=.022$) episodes but not in the Social episode. In the ASD group, greater ΔSCL was associated with intensity of fear expression only during the Social episode ($r(27)=.51, p=.005$) (Figure 1).

Conclusions: The social nature of threat moderated arousal response differently in TYP and ASD groups. In the TYP group, increase in arousal was most pronounced in the nonsocial and ambiguously social episodes and the magnitude of increase in arousal was correlated with intensity of behavioral fear reactivity. The stranger episode elicited little changes in arousal. In contrast, toddlers with ASD showed attenuated arousal in response to nonsocial and socially-ambiguous triggers, but their arousal increased in response to the stranger episode. However, as a group, toddlers with ASD did not exhibit elevated physiological response to stranger compared to TYP controls. Given the precursory roles of nonsocial and social fear in the emergence of anxiety in the general population, this study emphasizes the need to further examine the contextual factors influencing fear reactivity in ASD.

420.016 *(Poster)* Going to the Museum Makes You Happy: A PILOT Study at the Teatro Alla Scala Museum.

E. Grossi[1]*, A. Castelnuovo*[1] *and A. Ravagnan*[2]*, (1)Autism Research Unit, Villa Santa Maria Foundation, Tavernerio, Italy, (2)International Council of Museums Italy, MIlano, Italy*

Background: Recent studies have shown that subjects with autism are able to perceive aesthetic stimuli of artistic beauty. Therefore, by making art accessible to the, potential benefits such as greater self-esteem, mental stimulation and greater social interaction may potentially ensue.

Objectives: The aim of this pilot experience is to explore the impact on wellbeing of a special museum and performing arts experience in adolescents with autism.

Methods: Twelve adolescents with autism (age 10-17) took part to this study. The ASD subjects were diagnosed with autism according to the DSM V criteria, confirmed through ADOS-2 and under observation at our Institute. Their mean ADOS severity score was 7.8 (range 4-10). The experience consisted in a guided visit to the Teatro Alla Scala Museum by a cultural mediator with experience in the field of inclusion for people with cognitive disabilities. At the end of the visit, the guests were made to sit in the Exedra hall, which houses the famous Steinway piano that belonged to Franz Liszt. Here a team from the Conservatory "Giuseppe Verdi" in Como presented a special reduction of “The Magic Flute” by Mozart, illustrating the history and individual characters with drawings and objects such as the music box, and singing the famous arias accompanied by piano and flute along with stage movements and dances. The performance lasted about half an hour. The measurement of the impact of this experience on psychological well-being was done by using a special continuous chromatic analogue scale presented as a 10 cm rule. The ruler has a sliding cursor that the subject is invited to position at the level corresponding to his current perceived psychological well-being. Before visiting the museum, well-being measurements were taken for five consecutive days, to establish a basic level of reference by asking subjects to use the ruler to determine the level of their momentary psychological well-being at a given time of day, between 10 a.m. and 11 a.m. On the day dedicated to the theatre experience, the same type of evaluation was carried out at 11 a.m., immediately before the experience, at 12.30 p.m., immediately after the experience, and at 2.30 p.m. on return to the Institute.

Results: Measuring well-being immediately after the aesthetic experience highlighted a strong emotional impact with a 47% increase in the momentary psychological well-being (from 64 mm to 94 mm). The increase resulted similar to that obtained in a control group of twelve adolescent with other forms of neuropsychiatric disorders.

Conclusions: This pilot study confirms that adolescents with autism are keen to receiving enjoyment when exposed to beauty, art and music and that the measurement of their momentary well-being is feasible despite the presence of an important cognitive deficit.

420.017 *(Poster)* How Are Teachers Recognizing and Supporting Anxiety in Students on the Autism Spectrum?

D. Adams[1] *and K. Simpson*[2]*, (1)Autism Centre of Excellence, Griffith University, Brisbane, Australia, (2)Messines Rd, Griffith Univeristy, Brisbane, QLD, Australia*

Background: It is well recognized that anxiety is elevated in students on the autism spectrum. However, the presentation of anxiety symptomatology in students on the spectrum remains debated, with suggestions that traditional checklists do not assess the entire range of symptomatology.

A systematic review (Adams, Young & Keen, 2019) has identified that there is very limited research exploring anxiety in autism in the school setting and the available research to date has tended to report mean scores on broad measures of emotion and behavior, rather than detail the symptoms presenting in the school setting. There is also no research documenting the strategies teachers are using to support or reduce anxiety levels in their students on the spectrum.

Objectives: This study aimed to address the gaps in the previous research by firstly documenting the signs of anxiety noted by teachers of students on the spectrum and secondly explore the strategies that teachers report finding useful to reduce anxiety in students with autism.

Methods: Teachers of 63 students (aged 6-13) on the spectrum were asked a combination of open-ended and closed questions about signs of the student's anxiety as well as a standardised measure of school anxiety (School Anxiety Scale). The data were analyzed using quantitative and qualitative methods (content analysis) in order to document teacher descriptors of the student's anxiety at in the classroom and playground and explore how these may change with student age or gender.

Results: Approximately half of teachers (50.8%) felt their student was anxious in the classroom and a little over a third (34.9%) felt their student was anxiety out in the playground. Teachers most commonly reported increased activity levels as an indicator of anxiety in the classroom and peer interaction difficulties as an indicator of anxiety in the playground. The student withdrawing or hiding was frequently noted as an indicator of anxiety across both the classroom and playground.

When asked about the strategies they find effective to help support/reduce anxiety in the student on the spectrum, teachers most frequently identified simplified, calm communication and a calm, quiet or safe location for the child as effective strategies to reduce anxiety in the classroom. Strategies to support anxiety in the playground were more variable across the cohort.

Conclusions: Through the combination of standardised questionnaires and teacher-led, open-ended responses, this study adds to the small but growing literature base reporting on the presentation of anxiety in students on the spectrum and the ways in which this anxiety is currently being managed or supported in the school setting. Given that anxiety is highlighted as one of the top three factors influencing school performance (Saggers et al., 2019), these results highlight the importance of understanding each student's profile of anxiety symptomatology, which may include behavioral, cognitive and/or emotional indicators. The results also document the variability in strategies being used by teachers both across students and between settings, with few being evidence-based and some being known to increase anxiety in neurotypical children, highlighting the need for more research into this area.

420.018 *(Poster)* Identification of Novel Risk Factors for Depressive Symptomatology in Autism: An Ecological Momentary Assessment Study

A. R. Dallman[1]*, C. Harrop*[1] *and A. Bailliard*[2]*, (1)Department of Allied Health Sciences, University of North Carolina at Chapel Hill, Chapel Hill, NC, (2)University of North Carolina at Chapel Hill, Chapel Hill, NC*

Background: Depression is a commonly reported and concerning mental health comorbidity in autism spectrum disorder (ASD; Mazefsky, Kao, & Oswald, 2011), with estimates as high as 44% (Strang et al., 2012). Despite the US Preventative Services Task (USPSTF) (Siu & Bibbins, 2016) recommendations for universal screening, depression is often overlooked in adolescence who are both typically developing (Leaf et al., 1996) and those with ASD (DeFilippis, 2018). Thus, identification of markers of depressive symptomatology in ASD is an urgent concern.

Objectives: (1) Evaluate the role of ecological momentary assessment (EMA) in identifying individuals with ASD at risk for depression. (2) identify predictors of negative affect (depression risk factors) and positive affect (protective factors) in this population. (3) test the hypothesis that affective instability predicts depressive symptomatology in this population.

Methods: 18 adolescents (ages 11 to 17) and their caregivers were recruited to the study. Of these 18, 17 were eligible to complete based on intelligence quotient (IQ) above 85 and the adolescent has regular access to mobile phone. In addition to several behavioral assessments, adolescents completed an EMA of depressive symptoms (six times per day for seven consecutive days). To analyse the data, we took a data driven approach by generating random forests, inputting all numeric variables as predictors to model the importance of each variable to current positive affect score measure and negative affect score separately. Next, we use influential variables as predictors to fit linear mixed-effects model for momentary mean positive score and momentary mean negative score, with a random effect for intercept added to each participant. We then take a theory driven approach to estimate the importance of mean square successive difference (MSSD) (see Thompson et al., 2012) to parent-reported depressive symptomatology.

Results: Predictor variables level of current social interaction, quality of current social interaction, parent-reported overall health, and parent-reported voice changes have significant effects ($p<.01$) on participants' momentary positive affect. For momentary negative affect score, only the predictor variable *quality of current social interaction* had significant effects on participants' momentary negative affect ($p=.02$). We then examined the effect of overall current pubertal status on momentary positive and negative affect. For momentary positive score endpoint, significant interactive effects ($p <0.05$) are detected on the interaction of level of social interaction and early pubertal stage. Positive affective instability, as calculated by MSSD of positive affect, was significantly related to parent-reported depressive symptomatology ($p=0.02$, $B=6.8$, $SE=2.83$).

Conclusions: First, we identified reduced quality of social interaction as a risk factors that may increase momentary negative affect. For those in the early pubertal stages, higher levels of social interaction (i.e., being around more people) was related to positive affect. Interestingly, though, for children at later pubertal stages, only the quality of social interaction was identified as a significant predictor. This may suggest protective social mechanisms will vary with pubertal status. Our findings also suggest that emotional dysregulation, namely affective instability, may be an important key factor in the phenotype of depressive symptomatology and a potential useful treatment target.

420.019 *(Poster)* Manipulating Identity of Threat in Fear Reactivity Paradigms: Effect of Social Nature of Triggering Stimuli in Toddlers with and without ASD

S. Macari[1]*, A. Vernetti*[1]*, F. Shic*[2] *and K. Chawarska*[1]*, (1)Child Study Center, Yale University School of Medicine, New Haven, CT, (2)Center for Child Health, Behavior and Development, Seattle Children's Research Institute, Seattle, WA*

Background: Atypical fear reactivity in early childhood has been linked to a wide range of later psychopathology. Findings regarding fear reactivity in toddlers with ASD are conflicting. Toddlers exposed to largely nonsocial triggers exhibited lower fear reactivity than TD and developmentally-delayed peers (Macari et al., 2018). However, when exposed to a social threat (Stranger Approach, a task used for decades to study fear in infants and young children (Rheingold & Eckerman, 1974)), preschoolers with ASD exhibited higher fear reactivity compared to Fragile X and TD peers (Scherr et al., 2017). In the current study, we examine, for the first time in the same participants, whether fear reactivity in toddlers with ASD is modulated by the social nature of triggering stimuli.

Objectives: To examine whether the social nature (social, nonsocial, socially-ambiguous) of threatening stimuli affects the intensity of fear expressions in ASD and TD groups.

Methods: Participants were 76 age-matched toddlers (M_{age}=22.1 months; SD=3.6) with ASD (n=42) or typical development (TD; n=34). We administered Fear episodes adapted from the Laboratory Temperament Assessment Battery: Stranger Approach-Social (person wearing sunglasses/cap), Objects-Nonsocial (mechanical spider/dinosaur), and Masks-Socially ambiguous (person wearing mask/cloak). Sessions were coded for intensity of emotion expression (iEE) and mean peak iEE Fear across facial, vocal, and bodily channels was computed.

Results: Linear mixed models revealed significant main effects of group (F(1,73)=5.60, p=.02), episode (F(2, 145)=3.61, p=.03), and a significant interaction (F(2,145)=9.94, p<.001). (Figures 1&2). Within-group comparisons: In ASD, iEE Fear was greater in the Social than in the Nonsocial episode (p=.01), equal in the Social compared to the Socially-ambiguous episode (p=.21), and lower in the Nonsocial compared to the Socially-ambiguous episode (p=.05). In TD, iEE Fear was lower in the Social compared to Nonsocial episode (p=.02), lower in the Social compared to the Socially-ambiguous episode (p<.001), and equal in the Nonsocial versus Socially-ambiguous episode (p=.12) (Figure1). Between-group comparisons: iEE fear was significantly lower in ASD than in TD during Nonsocial (p<.001) and Socially-ambiguous (p=.002) episodes; there was no difference between groups in iEE fear during the Social (p=.36) episode.

Conclusions: This study suggests a divergent response to threats varying in social characteristics in toddlers with ASD compared to TD at the level of emotional expressivity. TD toddlers exhibited the strongest fear reactivity in response to novel nonsocial and ambiguous stimuli – rapidly-approaching mechanical objects and a person dressed in a long dark cloak and scary masks. In comparison, their response to the Stranger was muted. In contrast, toddlers with ASD responded more strongly to the Stranger and socially-ambiguous triggers compared to the objects. But the ASD toddlers' fear reactivity to the Stranger resembled that of TD controls, while their response to socially-ambiguous and nonsocial threat was diminished compared to controls. Taken together, results reveal atypical patterns of fear reactivity in toddlers with ASD that are inconsistent with accounts of either general underreactivity to threat or increased social fear. Careful consideration should be given to design of fear induction tasks as fear reactivity is highly context-dependent and effects vary across populations.

420.020 *(Poster)* Modifying the Emotion Dysregulation Inventory for Use in Young Children with ASD

T. N. Day[1,2]*, A. Wetherby*[3] *and C. A. Mazefsky*[4]*, (1)Florida State University, Tallahassee, FL, (2)Duke University Medical Center, Durham, NC, (3)Florida State University Autism Institute, Tallahassee, FL, (4)Department of Psychiatry, University of Pittsburgh School of Medicine, Pittsburgh, PA*

Background: Early childhood is a formative time for emotion regulation development. However, there is a dearth of measures to characterize the developmentally-normative variation in emotion dysregulation (ED) and, more importantly, when ED deviates from typical development. Previous research has demonstrated that rates of ED are especially high and impairing among those with ASD. To address measurement of ED in school-aged children with ASD, the *Emotion Dysregulation Inventory* (EDI) was designed and validated to optimize sensitivity across a wide range of ED severity, independent of functional ability levels (Mazefsky et al., 2016, 2018). Given that the EDI was created to capture *observable* indicators of ED, extending the original measure to include children ages 2-5 appears to be a promising avenue for measurement of ED in young children.

Objectives: This presentation will describe the creation of items tapping early manifestations of ED in children with ASD, following PROMISÒ guidelines, and their preliminary utility. These represent the initial steps in the development of the *EDI-Young Child* (EDI-YC).

Methods: The EDI-YC item bank development included a 3-stage process: (1) drafting of candidate items; (2) review by experts in early ED; (3) qualitative interviews with 10 parents of 2-5-year-olds with ASD, *M*=3.30yrs, *SD*=1.16yrs, using a combined think-aloud and debriefing methodology (will be detailed further). The final item bank was evaluated in the first author's (TD) dissertation sample of toddlers, range=22-28mo, *M*=25.44mo, *SD*=1.85mo, with ASD diagnosed (*n*=17) or ruled out (*n*=17) via a gold-standard evaluation.

Results: As depicted in Figure 1, items were added, removed, and modified based on input from experts and parents of young children with ASD. The final item bank was 48 items. In the sample for preliminary testing, the EDI-YC appeared sensitive to a wide range of ED with a high degree of variability (range=6-157). Relative to non-ASD toddlers, toddlers with ASD had significantly higher total scores (non-ASD: *M*=26.47, *SD*=16.97; ASD: *M*=62.59, *SD*=35.31) and were rated higher on 34 of the 48 items. Additionally, the total score demonstrated expected correlations with the CBCL emotionally reactive subscale (*r* =0.74) and internalizing (*r*=.64) and externalizing composites (*r*=.70). However, the total score was not related to ADOS-T CSS (*r*=-.05) or Mullen ELC (*r*=.17) in the ASD sample.

Conclusions: The strategy used to develop the EDI-YC was effective in creating an item bank with sufficient content coverage and ease of understanding. Preliminarily, the EDI-YC appears to characterize a range of ED in young children, demonstrate construct validity, and differentiate toddlers with and without ASD. The total score and many items were rated higher in the ASD than the non-ASD sample. Importantly, severity of ED in toddlers with ASD was independent of ASD symptom severity and developmental level. The senior author (CM) plans to conduct psychometric analyses in samples of young children with (*n*=1000) and without ASD (*n*=1000) to establish the factor structure and final items. These steps are in effort to support the EDI-YC's use in characterizing early manifestations of ED and in developing and testing early interventions targeting ED as the mechanism of change.

420.021 *(Poster)* Opposite Developmental Trend in Processing Happy Facial and Bodily Expressions in Children with and without ASD

N. Mazzoni[1]*, T. Del Bianco*[2]*, E. Tonelli*[1]*, A. Bentenuto*[1] *and P. Venuti*[1]*, (1)Psychology and Cognitive Science, University of Trento, Rovereto, Italy, (2)Centre of Brain and Cognitive Development, Birkbeck College, University of London, London, United Kingdom*

Background: One of the core features of Autism Spectrum Disorder (ASD) is a difficulty in processing the emotional expressions. Previous studies in ASD have focused on facial expressions. However, the human body is as important as face in conveying emotional cues. Therefore, the investigation of both emotional face and body processing in ASD is desirable.

The ability to recognize emotions through faces and bodies improves with age in typical developing children (TD). During preschool years, children are increasingly exposed to peer interactions. Deficit in visual exploration of emotional cues could prevent children with ASD to exploit this massive opportunity for social interactions, which in turn may result in a lack of emotion processing's refinement. Thus, the investigation of visual preference for emotional stimuli during development is crucial to understand the origin of the difficulty in interpreting others' emotional signals in ASD.

Objectives: On these premises, we investigated the spontaneous visual preference of pre-school children with and without ASD for facial and bodily expressions of anger and happiness.

Methods: The sample included 20 children with ASD (Mean=5.52, SD=1.9), and 20 chronologically matched children with TD (Mean Age=5.4, SD=1.87).

We used a spontaneous, visual preference paradigm with the technique of eye-tracking. We presented pictures of faces and body postures upright and inverted on the two sides of the screen. Rectangular areas of interest (AOIs) were manually drawn on the upright and inverted stimuli. Time to First Fixation (TTF) and the number of fixations (NF) to the AOIs were used as dependent variables. Analyses of Covariance (ANCOVAs) were performed separately for faces and bodies, with Group as between factor, Emotion and Orientation as within factors, and Age as covariate.

Results: FACE: Overall, we found faster TTFF ($F(1,30)= 9.684$, p-value=0.004) and greater NF ($F(1,30)=10.30$, p=0.003) for upright than inverted faces (i.e., inversion effect). TTFF became faster ($F(1,30)=4.257$, p-value=0.048) and NF increased with age, but only for upright faces ($F(1,30)= 6.487$, p=0.016). Furthermore, NF to happy faces increased significantly with age in the TD group, but not in the ASD group ($F(1,30)=4.27$, p-value=0.048).

BODY: NF to the upright bodies increased with age in children with TD, while it significantly decreased in children with ASD ($F(1,30)= 5.613$, p-value=0.025). Furthermore, NF to happy bodies decreased in the ASD group, while it increased in the TD group ($F(1,30)=5.416$, p-value=0.03).

Conclusions: We found that, differently from TD, children with ASD made fewer fixations to happy faces and bodies with increasing age. This opposite developmental trend in children with TD and ASD may reflect increasing social motivation in TD and a lack of it in children with ASD, which would not sustain further development of emotional and social abilities. Alternatively, it might be a consequence of progressive social isolation that prevent children with ASD from social encounters. Crucially, results showed a cross-modal alterations in the visual preference (both in facial and bodily expressions), suggesting that the difficulty in ASD is not limited to face processing. This have implication for interventions that should hence include facial as well as bodily expressions.

420.022 *(Poster)* Perioperative Program for Children with ASD- the Experience at Boston Children's Hospital

***B. Vlasakova**, Boston Children's Hospital, Boston, MA*

Background: Children with ASD face significant difficulties when in need of different hospital based procedures, studies and visits. Changing their daily routines, being exposed to the loud and bright Hospital environment often tests their coping mechanisms to a great extended. Research has shown that children with ASD need general anesthesia more often to complete simple procedures and exams because of their baseline behavioral anxiety. At Boston Children's Hospital (BCH) we developed a program geared toward improving and streamlining their hospital stays. Objectives: To improve Hospital experiences of patients with ASD and their families.

Methods: Multidisciplinary perioperative team was assembled to address the needs and specifics of our patients with ASD. We reviewed the existent practices and identified areas for improvement based of parental and staff feedback. The fallowing changes were made:

1. Children with ASD are scheduled as first cases in the morning.
2. Their arrival time was decreased to 1h instead of the usual 1.5h to minimize unnecessary wait and decrease perioperative agitation.
3. For children with aggressive or unpredictable behavior an isolated room is available where they are protected from the noise, bright light and personnel traffic
4. Favorite toys, communication devices, comforting items are strongly encouraged and provided based on prior discussion upon patient arrival.
5. Certain changes were made in our NPO guidelines for children with ASD- favorite drinks like soda are now allowed.
6. All necessary discussions about the perioperative plan are performed with caregivers and families outside the patient's room to avoid escalating negative behavior.

We included a child life specialist with expertise in working with children with ASD. The Hospital Behavioral team is involved on as needed base in preparing a patient specific behavioral plan. We reviewed the existing literature and with the help of the Division of Developmental Medicine we prepared social stories that describe the perioperative process in details. The stories are available online with free access given to the families to facilitate the preoperative preparation of the children. We also provide a printed version to be used in the preoperative areas. Structured education to staff was provided by the Division of Developmental Medicine and other specialists with interest and expertise in care for children with ASD.

Results: The changes we made allowed us to build a well structured pathway for the care of children with ASD at BCH. The evaluation of the program is based on families' satisfaction, feedback from perioperative teams and duration of perioperative stay. The diagram (see attached as image) describes the different steps of the program.

Conclusions: Children with ASD present significant challenges to the perioperative teams. Patient specific approach is a recommended way to help them and their families cope with the challenging process. For successful implementation a multidisciplinary approach as well as in advance planning and preparation are of utmost importance.

420.023 *(Poster)* Positive but Not Negative Facial Expressions Modify Behavior in Adolescents with ASD.

A. P. F. Key[1], *D. Jones*[2] *and B. A. Corbett*[3], *(1)Vanderbilt Kennedy Center; Dept. of Hearing and Speech Sciences, Dept, of Psychiatry and Biological Science, Vanderbilt University Medical Center, Nashville, TN, (2)Vanderbilt Kennedy Center, Vanderbilt University Medical Center, Nashville, TN, (3)Psychiatry and Behavioral Sciences, Vanderbilt University Medical Center, Nashville, TN*

Background: Emotional expressions play an important role in social interactions by providing cues that help regulate behavior. Sensitivity to the emotional context may contribute to more adaptive social functioning. Prior studies noted that the ability to detect and label emotional expressions might be altered in persons with autism spectrum disorder (ASD), with emotion processing differences being most apparent in adolescence. However, the question of how emotional expressions affect behavior regulation in ASD remains largely unexplored.

Objectives: The goal of the study was to examine the effect of positive and negative facial emotion expressions on behavioral and neural markers of inhibition (Go/NoGo N200 response) and target detection (target vs. standard P300 response) in 47 adolescents with ASD. Based on published evidence in typical populations, we hypothesized that negative vs. positive emotional expressions will be associated with more successful inhibition of behavioral responses and larger N200 responses, while both positive and negative emotions will elicit larger target P300 responses compared to the standard stimuli.

Methods: Brain responses associated with inhibition and target detection in the context of emotional cues were evaluated using visual event-related potentials (ERPs) in adolescents with ASD (age 10-16 years). Following the procedures of Taylor et al. (2018), all subjects completed the inhibition (Go/NoGo) and target detection (active oddball) blocks where they viewed a series of color photographs depicting unfamiliar young adults with happy (50%) or angry (50%) facial expressions. The subjects were instructed to attend to the color of the stimulus picture frame and respond (target trials) or withhold the response (NoGo trials) to the designated color (blue or purple) only (25% of trials/block). Inhibition was quantified as the amplitude of anterior N200 (200-300ms) response to NoGo trials. Target detection was assessed as the parietal P300 (300-600ms) amplitude to target trials. Behavioral measures included accuracy and reaction time for each block as well as standardized assessments of autism symptomatology (ADOS) and social skills (Social Communication Questionnaire, Social Responsiveness Scale).

Results: Behavioral performance was better than chance (>75%), with no significant differences in accuracy or reaction time between the inhibition and target detection blocks. Contrary to the expectation, increased anterior N200 inhibition responses were present only for the NoGo trials with happy faces. Similarly, increased parietal P300 responses were observed only for the target color frames that contained happy faces. The ongoing work is examining the association between these neural responses and behavioral measures of social functioning.

Conclusions: The findings indicate that adolescents with ASD can successfully regulate behavior based on nonsocial cues (picture frame color). The emotional context of the task affects performance in ASD, but contrary to the prior results in the typical populations, only the positive facial expressions increase neural responses associated with inhibition and target detection. While it is not yet clear whether this pattern of results may be related to difficulties with processing negative emotions in ASD, our findings indicate that positive emotional cues may be particularly effective for regulating behavior in adolescents with ASD.

420.024 *(Poster)* Predictors of Severity and Stability in Emotional Reactivity Among Youth with ASD

J. B. Northrup[1], *M. T. Patterson*[2] *and C. A. Mazefsky*[3], *(1)Department of Psychiatry, University of Pittsburgh, Pittsburgh, PA, (2)Carnegie Mellon University, Pittsburgh, PA, (3)Department of Psychiatry, University of Pittsburgh School of Medicine, Pittsburgh, PA*

Background: Problems with emotional reactivity (ER) are prevalent and disruptive in the lives of individuals with ASD and their families. While ER is common in ASD, it is neither universal nor stable. Understanding what individual features predict both severity and stability in ER is important for treatment planning and may be a first step toward understanding the function of ER in this population.

Objectives: 1) Describe the relationship between severity and stability in ER in two samples of youth, one with ASD and one census-matched community sample. 2) Probe predictors of severity and stability in ER among youth with ASD.

Methods: Participants were 6-18 year-olds recruited from two sources: 1) 1,215 youth with ASD (Mean Age = 12.05) recruited via Interactive Autism Network; and 2) 1,015 US-census matched youth (Mean Age = 12.05) recruited through YouGov, a polling company.

All parents completed the Emotion Dysregulation Inventory (EDI), a caregiver report measure of ER. Items are rated on a 5-point scale based on severity of behavior (0= Not at all to 4 = Very Severe) and on a 3-point scale indicating whether current behavior is worse, the same, or better compared to behavior over the child's lifetime. A measure of stability was created by coding 1 for no change and 0 when a behavior was marked either better or worse, then averaging these responses across items (higher scores = greater stability).

In addition to the EDI, parents filled out the Social Communication Questionnaire (SCQ), a measure of autism symptom severity with scores in Social, Communication, and Restricted, Repetitive Behavior (RRB) domains (higher scores indicate more difficulty). Parents also reported child's verbal ability on a 5-point scale (5 = nonverbal; 1 = meaningful, fluent speech) and presence of intellectual disability (ID; none, mild, moderate-severe).

Linear regressions predicted 1) Mean EDI reactivity (severity); and 2) Mean stability scores, controlling for severity. Predictor variables included age, gender, SCQ domain scores, ID, and verbal ability.

Results: Figure 1 displays density plots describing the relationship between severity and stability in the two samples. As can be seen in the Figure, the ASD sample was much more variable with regards to both severity and stability of ER compared to the community sample.

Table 1 reports results of two regressions predicting EDI severity and EDI stability (controlling for severity) in the ASD sample. As can be seen in the Table, younger age, higher scores on the SCQ social and RRB domains, and presence of moderate-severe ID were all unique predictors of EDI severity. Controlling for severity, younger age, lower scores on the SCQ social domain, higher scores on SCQ RRB, and higher EDI severity scores were predictive of *changing* EDI severity.

Conclusions: Severity of ER was predicted by severity of ASD symptoms in the social and RRB domains, as well as the presence of moderate-severe ID, but not by measures of communication or verbal ability. Individuals with better social skills were more likely to show changing ER, while greater restricted and repetitive behaviors predicted greater stability.

420.025 *(Poster)* Proximity to Threat As an Index of Fear Reactivity in Children with ASD

Q. Wang[1,2], *A. Vernetti*[1], *C. Nutor*[1], *G. Zhu*[2,3], *H. Zhang*[2,3], *D. Macris*[1], *S. Macari*[1] *and K. Chawarska*[1], *(1)Child Study Center, Yale University School of Medicine, New Haven, CT, (2)Key Laboratory of Biomedical Spectroscopy of Xi'An, Xi'an Institute of Optics and Precision Mechanics (XIOPM), Chinese Academy of Sciences, Xi'an, China, (3)University of Chinese Academy of Sciences, Beijing, China*

Background: Recent work (Macari et al, 2018) suggests that children with ASD exhibit reduced emotional reactivity to threat compared to children with and without other developmental disorders as measured by intensity of facial and vocal expressions. Here we examine yet another measure of emotional reactivity, proximity to threat, and evaluate if the Kinect sensor can be used to characterize differences between children with ASD and typically developing (TD) controls in how they, in the context of free exploration, regulate their distance to potential threat and to their parents. We manipulated the nature of threat by including both social and nonsocial conditions.

Objectives: 1) to explore the feasibility of using Kinect to measure the proximity between children and threat stimuli during free exploration; and 2) to examine whether children with and without ASD respond differently to fear-inducing stimuli in social and nonsocial conditions.

Methods: Participants included children with ASD (n=16, Age=48.47mo, SD=12.40) and typically developing (TD) controls (n=11, Age=38.60mo, SD=2.27). Proximity to threat was assessed using the Risk Room probe from the Laboratory Temperament Assessment Battery (LabTAB). The children the in two conditions. In the social condition, a Stranger is prominently present while the child explores the room. In the nonsocial condition, the stranger the by a human-size Gorilla. The child's proximity to threat and the parent was measured using the Kinect sensor placed above the head of the Stranger and Gorilla. Kinect is a depth sensor that can detect 3D positions of 27 joints of a human. The child-threat proximity and child-parent proximity were analyzed using group (ASD vs. TD) s condition (Gorilla vs. Strange) linear mixed model approach.

Results: For the child-threat proximity measure there was a significant effect of condition with children staying closer to the Gorilla than to the Stranger ($F(1,25) = 10.06$, $p = 0.004$) and a significant effect of group, with children with ASD maintaining closer proximity to Stranger and Gorilla than TD controls, ($F(1,24)=5.927$, $p = 0.023$). The group x condition interaction was not significant, ($F(1,25)=2.286$, $p = 0.143$). Age as the covariate was not significant ($F(1,24)=0.008$, $p = 0.931$).

For the child-parent proximity measure there was a significant effect of condition as the children in both groups maintained closer proximity to their parents in the Stranger than in the Gorilla condition ($F(1,25) = 10.987$, $p = 0.003$). There was also a significant effect of the group with TD children maintaining closer proximity to their parents than children with ASD, ($F(1,24)=6.640$, $p =0.017$). There was no interaction between condition and diagnosis ($F(1,25)=1.845$, $p = 0.186$). Age as the covariate was not significant ($F(1,24)=0.342$, $p = 0.94$).

Conclusions: In a context of free exploration young children with ASD maintain closer proximity to novel and potentially threatening stimuli and stay farther away from their parents compared to typically developing controls. The study supports the use of the Kinect sensor for extracting proximity measures between free-moving humans and stationary stimuli.

420.026 *(Poster)* Pupil Dilation Responses in Autism: The Impact of Emotional Category and Intensity

F. Shafai[1], *N. E. Scheerer*[2], *J. I. Feldman*[3], *E. Gateman*[4], *E. Altoum*[4], *G. Iarocci*[2], *T. Woynaroski*[5], *R. A. Stevenson*[6] *and J. T. Montenegro*[7], *(1)The University of Western Ontario, London, ON, Canada, (2)Psychology, Simon Fraser University, Burnaby, BC, Canada, (3)Vanderbilt University, Nashville, TN, (4)University of Western Ontario, London, ON, Canada, (5)Hearing & Speech Sciences, Vanderbilt University Medical Center, Nashville, TN, (6)Western University, London, ON, Canada, (7)Psychology, University of Western Ontario, London, ON, Canada*

Background: Autistic individuals exhibit different pupillary responses to emotional faces than their neurotypical (NT) peers, suggesting differences in autonomic arousal. It has been proposed that altered pupillary responses in ASD are more pronounced for particular emotions, specifically that fear and happiness elicit greater differences in pupillary reactions across autistic and NT individuals. These previous studies of emotion processing have, however, shown mixed results. We suspect that autistic individuals are able to process emotions relatively well when they are extremely salient but may have more difficulty with more subtle displays of emotion.

Objectives: By presenting autistic and NT individuals with dynamic displays of emotion while varying levels of emotional intensity and recording pupil dilations, we aim to assess whether pupillary responses to specific emotions differ between autistic and NT individuals. We also aim to determine whether the intensity of the emotion differentially effects pupillary responses across autistic and NT individuals.

Methods: Autistic (n=16, M=19.0 years, SD=7.73, 6 females) and NT (n=99, M=19.04 years, SD=3.42, 75 females) individuals viewed videos of actors that uttered the phrase "kids are talking by the door". Actors expressed both high- and low-intensity emotions including anger, disgust, fear, happiness, and sadness through both visual facial expression and auditory prosody, as well as a non-emotive control condition. Pupil diameters were collected, and both mean pupillary response and pupillary time courses were compared across emotion, intensity level, and diagnostic groups.

Results: A 5x2x2 (Emotion, Intensity, and Group) mixed-model ANOVA was conducted. An emotion*group interaction demonstrated that autistic individuals showed a different pattern of pupillary responses across emotions than did their TD peers ($F(4,452)=2.852$, $p=0.023$, $\eta_p^2=0.084$). Pupillary responses to fear ($d=0.418$) and happiness ($d=0.632$) showed the largest between-group differences, with the NT group having larger pupillary responses than the ASD group (Figure 1a). An intensity*group interaction approached significance, with autistic individuals showing a greater reduction in pupillary response to low-intensity emotional expressions (Figure 1b; $F(1,113)=2.804$, $p=0.097$, $\eta_p^2=0.024$). Continuing data collection will clarify this trending result.

Conclusions: These data suggest that autistic individuals exhibit differences in autonomic arousal in response to specific emotions. Less pronounced pupillary responses to fear and happy expressions in autistic individuals indicate that responses to both negative and positive valence emotions produce reduced arousal in this group. It is possible that these results are being influenced by altered amygdala activity for fear processing, and less interest in rewarding social interactions for happy expressions. These results are in line with the social motivation hypothesis of autism, which suggests that autistic individuals are less interested in social interactions and find social stimuli less engaging than their NT peers, thereby leading to reduced interactions that allow for the fine-tuning of emotion processing skills throughout development.

Additionally, increased pupil diameter is considered an index of emotional arousal, where the most valent emotions elicit the largest pupillary responses. Autistic individuals showed a larger decrease in pupillary responses with low-intensity emotional stimuli. This suggests that autistic individuals may have more difficulty processing subtle displays of emotion than highly explicit displays of emotion.

420.027 *(Poster)* Relationships between Dysregulation, Intolerance of Uncertainty, and Autism Symptoms in Preschool Children with Autism Spectrum Disorder

R. G. McDonald[1]*, A. Keefer*[2]*, V. Singh*[2] *and R. A. Vasa*[3]*, (1)Center for Autism and Related Disorders, Kennedy Kreiger Institute, Baltimore, MD, (2)Center for Autism and Related Disorders, Kennedy Krieger Institute, Baltimore, MD, (3)Kennedy Krieger Institute, Baltimore, MD*

Background: Dysregulation is characterized by difficulty managing behaviors, thoughts, and affect in different situations (Mick et al., 2011), and is commonly observed in individuals with autism spectrum disorder (ASD; Mazefsky et al., 2018). Dysregulation exacerbates a variety of core ASD symptoms, i.e., social functioning, repetitive behaviors, and sensory responses (Samson et al., 2014; Berkovitis et al., 2016; Joshi et al., 2018; Uljarevic et al., 2018). Additionally, preliminary evidence suggests that dysregulation may contribute to intolerance of uncertainty (IU), a dispositional trait characterized by negative reactions to situations and events that are uncertain (Vasa et al., 2018; Uljarvic et al., 2018). The underlying hypothesis is that children with dysregulation may have difficulty regulating emotional and behavioral responses when confronting uncertain situations. Despite elevated levels of dysregulation in children with ASD, few studies have examined the prevalence of dysregulation, as well as how dysregulation and IU interact to affect ASD symptoms in preschool children with ASD. Understanding these relationships when children are young can inform specific treatment targets that could improve outcomes both short term and potentially in the future.

Objectives: 1) To determine the prevalence of dysregulation in children, 3-5 years old, with ASD. 2) To examine relationships between dysregulation, IU, and ASD symptoms.

Methods: A cohort of 51 children with ASD (*M* = 53.96 months, *SD* = 10.59), who have been rigorously characterized and have a broad range of IQ levels (*M* = 76.5, *SD* = 24.34), have thus far been enrolled in this study, with the plan of enrolling 30 more children by May 2020. The Child Behavior Checklist Dysregulation Profile (CBCL-DP; Althoff et al., 2012) was used to assess dysregulation. The CBCL-DP scale is comprised of the CBCL Attention Problems, Anxious/Depressed, and the Aggressive Behavior subscales. The total score of these three subscales was used to classify children as having mild (T score ³ 179), moderate (T score 180 - 209), or severe (T score £ 210) dysregulation (Althoff et al., 2012). The Response to Uncertainty and Low Environmental Structure Scale was used to assess IU, and the Social Responsiveness Scale-Revised and the Short Sensory Profile -2 were used to assess ASD symptoms. All measures were completed by the parent.

Results: Forty percent of children had moderate (32%) or severe (8%) dysregulation. Strong to moderate correlations were present between dysregulation and social communication (r=.42, p <.01), repetitive behaviors (r = .63, p<.01), sensory over-responsivity (r = .59, p<.01), sensory seeking behaviors (r = .70, p<.01), and IU (r = .60, p <.01). IU was also strongly correlated with overall ASD severity (r = .67, p<.01). Multivariate analyses will be used to examine associations between dysregulation and IU, and how interactions between these variables affect ASD symptoms.

Conclusions: Dysregulation is common in preschool children with ASD and was present in 40% of this sample. Preliminary findings indicate that dysregulation and IU are both associated with ASD symptoms. Targeting these two processes could potentially improve social and behavioral outcomes in young children with ASD.

420.028 *(Poster)* Self-Determination and Emotion Regulation in Adults with Autism Spectrum Disorder: A Possible Mechanism for Change

J. Golt[1]*, E. Goodcase*[1] *and S. W. White*[2]*, (1)The University of Alabama, Tuscaloosa, AL, (2)Psychology, The University of Alabama, Tuscaloosa, AL*

Background: Self-determination (SD) has been defined as the attitude and ability of an individual to make their own choices without undue assistance (Michael L Wehmeyer, 1992), and previous research has shown that individuals with autism spectrum disorder (ASD) demonstrate less SD than their neurotypical peers (M L Wehmeyer & Shogren, 2008). Additionally, research has shown a strong relationship between poor emotion regulation (ER) and greater risk for increased psychopathology(Mazefsky & White, 2014). Improvement in SD and ER have the potential to decrease problems behaviors and increase better life outcomes in individuals with ASD. Perception and understanding of the self, a Research Domain Criteria (RDoC) construct, involves processes related to self-awareness and knowledge, including recognition of one's emotions, behaviors, and cognitions (*fig. 1)*.

Objectives: This study investigates the relationship between SD and ER to better understand if the relationship is stronger than SD with other constructs. Based on the RDoC model of perception and self-understanding, we'd expect to see an association between ER and SD in the perception and understanding of self model. A better understanding of this mechanism could be important when considering future mechanisms for change in intervention research.

Methods: There were a total of *n* = 59 participants with ASD and without intellectual disability. This sample was 81.4% male and 86.4% white with an average age of *M* = 18.84yrs (*SD* = 2.06) and an average IQ of *M* = 104.88 (*SD* = 13.20). Self-report measures were collected within a clinical trial investigating improving college readiness in ASD. This study uses baseline SD, as measured by the AIR-SD (Wolman, Campeau, Dubois, Mithaug, & Stolarski, 1994), to draw relationships to ER, social skills, and goal directed behavior. ER in this study is measured using the Emotion Regulation Difficulties Scale(Gratz & Tull, n.d.) emotion awareness and strategies subscales. A path analysis was used to measure relationships between SD and social skills, ER, and goal-directed behavior while controlling for autism symptomology using the Social Responsiveness Scale (Constantino, 2005).

Results: The path analysis model was fully saturated and therefore model of fit indices could not be obtained. SD was significantly associated with emotional awareness (unstandardized b = -.12, p = .01, standardized β = -.38) and emotional regulation strategies (b = -15, p = .02, β = -.30) while controlling for ASD symptomology. However, self-determination was not significantly associated with social skills (b = 11, p = .17, β = .19) or goal directed behavior (b = -.02, p = .67, β = -.06) while controlling for ASD symptomatology (*fig. 2)*.

Conclusions: Results indicate a significant relationship between SD and ER while SD, social skills, and goal directed behavior were not significantly associated. In this model, greater SD, was associated with less ER related problems. Additionally, these results are aligned with the RDoC construct of SD and self-regulation, which includes ER, as important factors in one's perception and understanding of self. These findings demonstrate the importance of further investigating this relationship as a potential mechanism of change for downstream effects.

420.029 *(Poster)* Similarities and Differences in Emotion Regulation Strategies during a Frustrating Situation in Parent-Child Dyads with and without ASD

M. Gurm *and G. Iarocci, Psychology, Simon Fraser University, Burnaby, BC, Canada*

Background: Emotion dysregulation is hypothesized to be an inherent aspect of ASD (Mazefsky et al., 2013). Previous research comparing preschool children with and without ASD suggests that parents of children with ASD use simpler strategies than parents of typically developing (TD) children, and TD children display a wider variety of emotional expression than children with ASD (Hirschler-Guttenberg et al., 2015). However, little is known about the emotion regulation strategies of parents and school-aged children with and without ASD.

Objectives: The objectives of this study were to 1) examine similarities and differences across groups in emotion regulation behaviour, and 2) examine which parent behaviour is helpful for school-aged children during a frustrating situation.

Methods: Twenty-one children with ASD and 20 typically developing children (age 7-12; IQ > 70) and a parent were recruited as a part of a larger social interaction study. Parent-child dyads participated in a task adapted from Melnick & Hinshaw (2000), where they were asked to build two Lego animals. Pieces were stuck together to make the task frustrating. The dyads' behaviour was coded for two minutes after they noticed the stuck pieces. The presence of the behaviours in every ten second interval was coded: parent or child problem-solving (looking at instructions, using other pieces, persisting to unstick the pieces) or cognitive reappraisal, child venting, child asking for social support, parent praise and encouragement, parent unhelpful behaviour, and parent emotional support. Child emotional expression was also coded in each interval: positive, neutral, or negative.

Results: There were no mean group differences in coded parent behaviour. As presented in Table 1, typically developing children were more likely to *use instructions* (exp(B) = 1.44, Wald χ^2 = 5.43, p = .02), *display positive emotions* (exp(B) = 3.79, Wald χ^2 = 9.75; p = .002), and *vent* (exp(B) = 1.78, Wald χ2 = 3.03, p = .08) compared to children with ASD. For children with ASD, helpful parent strategies (i.e., associated with a decrease in child negative emotion in the next 10 second interval) included working on the stuck Lego pieces (Yule's Q = .24) and cognitive reappraisal (Fisher's Exact Test p = .04, V = .20). For TD children, helpful parenting strategies included emotional support (Fisher's exact test p = .08, V = .23) and focusing on other Lego pieces to solve the problem (Yule's Q = .44). Please see Table 2 for more information

Conclusions: Although parenting behaviours were similar for both groups, different parent strategies were associated with a decrease in negative emotion in children with and without ASD. Typically developing children displayed more variety in their emotion during the task (i.e., more positive expressions and more venting) suggesting that emotion regulation difficulties in school-age children with ASD may not be restricted to a problem with negative emotions. The findings have implications for the design of emotion regulation interventions in identifying common parenting strategies that work for all dyads and those that are especially effective for children with ASD and their parents.

420.030 *(Poster)* Symptom Profiles and Correlates of Anxiety and Depression Among Parents of ASD Girls and ASD Boys

C. F. Sharpley[1] *and V. Bitsika*[2]*, (1)Brain-Behaviour Research Group, University of New England, Armidale, NSW, Australia, (2)University of New England, Armidale, NSW, Australia*

Background: Parents of a child with Autism Spectrum Disorder (ASD) also experience greater anxiety and depression than parents of non-ASD children. To date, no study has directly compared the anxiety and depression levels of parents of ASD boys compared to ASD girls.

Objectives: Four research questions were addressed: 1. Were there any significant differences in the anxiety or depression severity between parents whose ASD child was female versus those whose ASD child was male? 2. Were there any significant differences in the anxiety and depression symptom profile severity of parents whose ASD child was female than those whose ASD child was male? 3. Were age, IQ or ASD severity significant correlates of parental anxiety or depression when examined within child sex subgroups? 4. Were age, IQ and ASD severity significant correlates of the symptom profiles of anxiety or depression for either subgroup of parents, and did those correlations differ across parents of males versus females?

Methods: Fifty-one parents of young ASD males (*M* age = 10.2yr, SD = 2.8yr, range to 6 to 17yr) and 51 parents of ASD females (*M* age = 10.1yr, SD = 2.7yr, range to 6 to 17yr), completed the GAD7 and PHQ9. Their children were matched on age and WASI-II Full Scale IQ, but the girls had significantly higher ADOS-2 scores than the boys. Statistical processes covaried age, IQ and ADOS-2 scores out of the analyses to address Research questions 1 to 4.

Results: Research question 1. There was no significant effect for sex of child, nor any significant univariate effects for GAD7 or PHQ9; Research question 2. There were two significant univariate effects for child's age at the Bonferroni-corrected *p* value of .05/7 = .007. These were *Being so restless it's hard to sit still*, and *I have trouble relaxing*, both of which were medium to large effects; Research question 3. IQ was significantly and inversely associated with the GAD7 total scores of parents of ASD boys but not for ASD girls' parents; Research question 4. The Pearson correlation coefficient between WASI-II FS IQ and the GAD7 item *I have trouble relaxing* for ASD girls' parents was -.022, which was significantly lower than that for the ASD boys' parents.

Conclusions: These data report the absence of widespread differences in the overall global levels of anxiety and depression across parents of ASD boys and ASD girls, although there were some differences in the ways that aspects of the ASD child interacted with their sex to influence specific parental somatic symptoms of GAD and MDD. The findings regarding differential correlates to parents' GAD7 and PHQ9 symptoms are particularly novel, and suggest that (as with non-ASD children) different aspects of their sons' or daughters' age, cognitive ability, and neurological profiles may contribute to different manifestations of some of the key symptoms of anxiety and depression in parents.

420.031 *(Poster)* The Association between Autism Traits and Maladaptive Daydreaming

M. J. West[1]*, E. Somer*[2] *and I. M. Eigsti*[1]*, (1)Psychological Sciences, University of Connecticut, Storrs, CT, (2)School of Social Work, University of Haifa, Haifa, Israel*

Background: Daydreaming is a common and often useful mental activity. Some individuals immerse themselves in elaborate mental narratives and worlds, to the extent that it interferes with daily functioning. “Maladaptive daydreaming” may be more prevalent in those who experience difficulties with social interaction and emotion regulation, and who have stereotyped repetitive behaviors (Somer et al., 2017; West & Somer, 2019). These features are similar to some of the core characteristics of autism spectrum disorder (ASD); However, the overlap in symptoms between these conditions has not been tested. Although deficits in imagination have been reported (e.g., reduced creative fluency), individuals with ASD are reported to generate ideas that are more original and novel compared to individuals with typical development (Best et al., 2015; Liu et al., 2011). More broadly, little is known about the internal mental experiences of individuals with ASD. Here, we theorize that the tendency to fixate on unique thoughts or daydreams is related to autism traits. Daydreaming may serve to supplement difficult real-life relationships in ASD.

Objectives: The current study investigated the association between maladaptive daydreaming and broad ASD traits. Further, we tested whether the association between ASD traits and maladaptive daydreaming was mediated by loneliness, emotion regulation difficulties, and restrictive and repetitive behaviors. Exploratory items probed whether the content and context of daydreaming activity varies with ASD traits.

Methods: Adult participants (N = 386, 278 females; M_{age} = 25), recruited online, completed an online survey consisting of the following previously-validated measures: The Autism-Spectrum Quotient (AQ), Maladaptive Daydreaming Scale (MDS), UCLA Loneliness Scale, Difficulties in Emotion Regulation Scale – short form (DERS-SF), and the Adult Repetitive Behavior Questionnaire-2 (RBQ-2A). We also included novel exploratory questions about daydreams.

Results: All standard measures were significantly positively correlated. The level of ASD traits significantly predicted maladaptive daydreaming symptoms (Figure 1), controlling for demographic variables. Moreover, loneliness and difficulties with emotion regulation were significant mediators of the relationship between ASD traits and maladaptive daydreaming (see Table 1).

Individuals with higher levels of ASD traits reported greater prevalence of violent or tragic content in daydreams compared to individuals with lower levels of ASD traits. However, there were no differences in the level of detail and degree of realism of daydreams, nor in the reasons for or triggers of daydreaming. Participants reported that their most common imagined identities were a “better version” of oneself (63% of the time) or a novel identity (54% of the time), rather than imagining their “real” self (29% of the time), a celebrity (18% of the time), or someone they know (7% of the time). Identities did not differ according to ASD traits.

Conclusions: Results support the hypothesis that ASD traits and maladaptive daydreaming symptoms are associated, and further suggest that the ability to imagine detailed fantasy scenarios is not limited by ASD traits. These two conditions may reflect similar mechanisms, particularly regarding social isolation and emotion regulation difficulties. A fixation on internal narratives may simulate social and emotional needs in those with higher levels of ASD traits.

420.032 *(Poster)* The Differential Impact of Emotion Intensity on Speech and Song-Evoked Emotion Recognition Among Children with ASD and TD

T. Fernandes*, J. Burack and E. M. Quintin, Educational & Counselling Psychology, McGill University, Montreal, QC, Canada*

Background: The commonly accepted dogma of difficulties in inferring others’ emotions from various social cues among persons with ASD needs to be recast in relation to context. For example, the emotion recognition abilities of persons with ASD, like those of others, are highly influenced by factors such as the intensity to which emotions are conveyed and the level of social pragmatic language skills. Emotion recognition also varies across modality. For example, persons with ASD can accurately recognize music-evoked emotions.

Objectives: In order to fine-tune our understanding of emotion recognition in ASD, we examined the relation between specific emotions, emotion intensity, and social pragmatic language skills on the recognition of speech and song-evoked emotions.

Methods: Twenty-six children with ASD (mean age = 10.9 years; VCI = 77.8) and 21 TD children (mean age = 9.0 years; VCI = 101.6) completed a computerized task in which they identified emotions of high or normal intensity from spoken or sung sentences with neutral semantic content. The Verbal Comprehension Index (VCI) of the WISC-V was administered to the participants and caregivers completed three subscales of the Child Communication Checklist-2 measuring quality of initiating social conversations, scripted language, and adapting conversation to different contexts.

Results: A repeated-measures ANOVA with stimuli modality (speech vs. song), emotion (happy, sad, angry), and intensity (high vs. normal) as within-subject factors, participant group (ASD vs. TD) as a between-subject factor, VCI as a covariate, and emotion recognition accuracy as the dependent variable revealed a significant main effect of emotion (p = .046), in which anger was the most easily recognized emotion. VCI, and not participant group, had a significant effect on emotion recognition accuracy. A significant group X intensity interaction (p = .035) indicated that children with ASD, but not those with TD, responded more accurately in recognizing high intensity as compared to normal intensity emotions. A separate repeated-measures ANOVA with response time as the dependent variable revealed a marginally significant group X intensity X stimuli interaction (p = .05) such that the ASD group showed faster response times for high (vs. normal) intensity emotions conveyed in speech but not in song, while the response times of the TD group showed similar response times across intensity and modalities. A regression analysis revealed that a component of social pragmatic skills (i.e., quality of initiating social conversations) was associated with emotion recognition accuracy for the TD group but not for the ASD group.

Conclusions: These findings suggest that emotion recognition among children with ASD is impacted by intensity, particularly for speech-evoked emotions, while an effect was not observed among the children with TD, who performed comparably across intensity conditions and modalities. Findings replicate previous work showing associations between verbal skills and emotion recognition of children with ASD. In contrast, social pragmatic language skills were not related to emotion recognition of children with ASD. These findings suggest that interventions targeting emotion recognition of children with ASD may be ameliorated by first teaching emotions that are intensely conveyed followed by those that are more subtle.

420.033 *(Poster)* The Relationship between Social Anxiety and N170 ERP Responses to Emotional Faces in Young Adults Along the Broader Autism Phenotype

***M. Blottner**, S. C. Taylor, C. L. Dickter and J. Burk, College of William and Mary, Williamsburg, VA*

Background: Autism Spectrum Disorder (ASD) is a neurodevelopmental condition characterized by deficits in communication and social interaction. Trait social anxiety is often co-morbid with ASD. Individuals with ASD show impairments in emotion identification, especially for negative emotions and complex emotions. Adults with social anxiety also show impairments at identifying emotional expressions but attribute more intense emotions to faces than neurotypical adults. Deficits in emotion identification may be related to differences in brain activity necessary for facial recognition. In particular, the N170 event-related potential of electroencephalograph (EEG) is sensitive to the neural processing of faces. Thus, examining N170 activity during face processing may help reveal the neural correlates of early emotion identification in individuals varying in social anxiety and give insight into the neural mechanisms associated with face processing challenges in ASD.

Objectives: The purpose of the current study was to test whether the neural processing of facial expressions differs as a function of levels of social anxiety and task type in individuals along the broader autism phenotype (BAP) in order to better understand emotion processing related to ASD and its co-morbid conditions. The current study uses both full-face and eye region stimuli to control for known behavioral scanning differences and to isolate the resulting impact on neural activity.

Methods: Neurotypical participants varying in autistic traits (n=34) completed an emotion identification task while EEG data were recorded. For each trial, a face depicting an emotion (i.e., happy, angry, fear, surprise) or a neutral expression was presented for 1000 ms; an inter-stimulus interval of 500 ms was used between trials. In half of the trials, participants indicated if the emotion of the face matched that of the face presented before it (matching task). In the other trials, participants indicated if the emotion of the face was positive or negative (valence task). Each participant completed the Social Phobia and Anxiety Inventory (SPAI) to measure their level of social anxiety.

Results: A 5 (Emotion: Angry, Fear, Happy, Neutral, Surprise) x 2 (Task: Valence, Matching) x 2 (SPAI: Low, High) mixed model Analysis of Variance (ANOVA) was conducted and a significant three-way interaction emerged. For the matching trials, there were no significant effects. For the valence task, however, there was a significant Emotion x SPAI interaction revealing an effect for surprise, such that participants with greater social anxiety showed larger N170 amplitudes to surprised faces compared with participants with lower social anxiety.

Conclusions: These results provide a better understanding of neural activity during emotion processing for those on the BAP and add to work investigating the neural underpinnings of emotion processing deficits in individuals with conditions co-occurring with ASD.

Epidemiology/Population Studies

ORAL SESSION — EPIDEMIOLOGY/POPULATION STUDIES
313 - Early and Prenatal Risk

313.001 *(Oral)* Differentiating Pop and DD Controls in Autism Research: New Findings from the Study to Explore Early Development

***R. Fitzgerald**[1], C. Nadler[2], S. M. Kanne[3], L. Eck[1], R. E. Wagner[1] and J. N. Constantino[1], (1)Washington University School of Medicine, St. Louis, MO, (2)Children's Mercy Kansas City, Kansas City, MO, (3)Thompson Center for Autism & Neurodevelopmental Disorders, Columbia, MO*

Background: Studies investigating autism spectrum disorder (ASD) phenotypes rely on contrasting samples of individuals described as typically developing population controls (POP) and/or developmentally delayed *without* ASD (DD). However, this case-control approach presupposes categorical distinctions between these samples and often neglects robust characterization of the control groups, despite evidence that ASD traits are continuously distributed throughout the population (Constantino and Todd, 2003). Investigation of the overlapping distributions of ASD traits and other cognitive/behavioral features of control samples can highlight this issue, and present opportunities to derive meaningful observations that go beyond subtype characterization.

Objectives: Extending Wiggins et al.'s (2015) description of ASD symptomatology in Phase 1 of the Study to Explore Early Development (SEED 1), the objective of this study is to investigate the overlapping phenotypes in SEED 1&2 participants.

Methods: SEED (Schendel et al., 2012) is a multi-site case-control study of children ages 2-5 with well-defined POP, DD and ASD samples. The Social Communication Questionnaire (SCQ) was administered to all participants regardless of recruitment source (clinic, school, population, etc.), and any participant with SCQ >=11 received a comprehensive evaluation. ASD case status was based on Autism Diagnostic Observation Schedule (ADOS) and Autism Diagnostic Interview-Revised (ADI-R) results; participants not meeting the ASD case definition received a final case status based on recruitment source (DD or POP). As a result, the DD comparison group includes a sub-group of children with ASD symptoms. In the current analysis the DD group was sub-divided into DD with and without ASD symptoms. One-way Analysis of Variance was used to asses mean differences in SRS and Mullen scores between groups.

Results: The SEED 1/2 dataset contains 6,222 participants, including those with a final case status of ASD (1,499), DD (602 with ASD symptoms, 1,763 without ASD symptoms) and POP (2,358). Mean SRS total raw scores differed significantly (n=4,136, F=2017.84, p<.01) by group: ASD (M=92.6, SD=29.3), DD with ASD symptoms (M=68.3, SD=27.9), DD without ASD symptoms (M=35.3, SD=21.4) and POP (M=25.5, SD=17.6). A similar statistically significant pattern (n= 5,039, F=1,153, p<.0001) was observed in the Early Learning Composite (ELC) standard score from the Mullen: ASD (M=65.8. SD=20.7), DD with ASD symptoms (M=79.6, SD= 19.1), DD without ASD symptoms (M=88.4, SD= 21.4), and POP (M=102.7, SD=16.6). These results are consistent with those reported by Wiggins et al. (2015) for SEED 1. However, despite significant mean differences on these measures across study groups, the distributions of these measures for the four study groups overlap considerably for both males and females (Figure 1 & 2) and suggest a pathological shift in score distribution for each group as expected by categorical classification.

Conclusions: The POP, DD, and ASD groups derived in SEED 1/2 for case-control purposes demonstrate the expected phenotypic differences, but rigorous phenotyping of the DD group allows for more meaningful characterization of individuals based on symptom profile rather than assigned final case category. The patterns of overlap in the distributions for autistic traits and cognitive abilities are highly homologous, supporting the need to derive profiles based on multiaxial symptom quantification.

313.002 *(Oral)* The Family Morbidity Risk Score for Autism

L. Ejlskov[1]*, J. N. Wulff*[2]*, A. Kalkbrenner*[3]*, C. Ladd-Acosta*[4]*, M. D. Fallin*[4]*, B. K. Lee*[5] *and D. Schendel*[6]*, (1)Economics and Business, National Center for Registry-based Research, Aarhus University, Aarhus, Denmark, (2)Econometrics and Business Analytics, Aarhus University, Aarhus V, Denmark, (3)University of Wisconsin-Milwaukee, Milwaukee, WI, (4)Wendy Klag Center for Autism and Developmental Disabilities, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, (5)Epidemiology and Biostatistics, Drexel University, Philadelphia, PA, (6)Aarhus University, Aarhus, Denmark*

Background: Family morbidity history is an important predictor of autism and likely reflects both genetic and environmental risk factors. However, systematic investigations of different morbidities and family members to elucidate the underlying structure of family morbidity risk for autism are lacking.

Objectives: Identify the optimal family morbidity history model to predict autism risk based on multiple psychiatric, neurologic and somatic disorders across six family member types.

Methods: Using linked Danish national registries, we identified all Danish live births, 1980-2012 (n=1,697,231), their 3-generation family members and morbidity diagnoses reported prospectively for each family member through April 10, 2017. 353 morbidity indicators were included in the analyses. They comprised of 73 mutually exclusive psychiatric, neurologic, cardiometabolic, congenital defect, autoimmune, asthma, and allergy conditions across six family member types (mother, father, full siblings, grandparents, cousins, aunts/uncles). Using a machine learning approach, we tested a variety of competing models to determine the optimal model for predicting autism risk across different algorithms: Random Forest, Extreme Gradient Boosting, the traditional generalized linear model, Neural Networks, Support Vector Machines, K nearest neighbors and three ensemble learning techniques. We calculated a family morbidity risk score (FMRS) based on the best performing model and estimated odds ratios and 95% confidence intervals (95%CI) for the risk of receiving an autism diagnosis adjusting for gender, birth year, birth weight, gestational age and parental ages.

Results: 26,840 (1.6%) cohort members received an autism diagnosis during follow-up. The best model included 41 morbidity indicators and performed better on all investigated performance measures compared to considering parental psychiatric history alone. For example, the FMRS demonstrated a 50% increase in sensitivity and a 27% increase in observed vs predicted accuracy. Table 1 presents an overview of the 41 morbidity indicators in the best performing model. It comprised all family member types, 8 mental morbidities (e.g., neurotic/stress disorders, personality disorders, different child onset disorders,) and 9 somatic morbidities (e.g., obesity, hypertension). We observed a dose-response relationship between the FMRS and autism (see figure 1). On average, 1 in 154 cohort members in the lowest FMRS group had an autism diagnosis vs 1 out of 6 in the highest group. Cohort members in the highest compared to the lowest FMRS group had a 15-fold increase in autism risk (OR: 15.4; 95%CI: 14.0-17.1). In contrast, autism risk was 2-fold (OR: 1.98; 95%CI, 1.97-2.08) considering only parental psychiatric history and 6-fold (OR: 6.1; 95%CI, 5.86-6.38) considering only full sibling autism history. There was no evidence of sex differences in FMRS-based risk estimates.

Conclusions: A machine-learning based FMRS based on 17 morbidities in 6 family member types outperformed traditional, single measures of family morbidity history in terms of associated autism risk and risk prediction. Although individual risk prediction is still poor, these results indicate family morbidity history relevant to autism risk may extend beyond psychiatric conditions in parents and siblings. We view this as one approach to a better understanding of familial morbidity liability patterns underlying autism risk, which may elucidate both autism etiology and future individual risk prediction algorithms.

313.003 *(Oral)* The Association between Birth Order and Clinical Phenotypes at Autism Diagnosis

G. A. Alvares[1]*, P. G. Stevenson*[1]*, M. K. Licari*[1]*, K. Bebbington*[1]*, M. N. Cooper*[1]*, E. J. Glasson*[1]*, M. Uljarevic*[2]*, K. J. Varcin*[1]*, J. Wray*[3] *and A. O. Whitehouse*[1]*, (1)Telethon Kids Institute, University of Western Australia, Perth, WA, Australia, (2)The School of Psychological Sciences, University of Melbourne, Melbourne, VIC, Australia, (3)State Child Development Service, Western Australia Department of Health, Perth, Western Australia, Australia*

Background: Birth order effects have been linked to a wide variety of outcomes, including intelligence, educational attainment, and sexual orientation. Although there is evidence that increasing birth order is associated with decreased intellectual functioning in ASD, effects on other aspects of clinical phenotype are less well understood, and no study has used a whole of population dataset to examine this relationship.

Objectives: In this study, we investigated the association between order of birth and clinical diagnostic phenotypes in large cohort of children diagnosed with ASD in Western Australia.

Methods: Clinical data on cases (n = 5941) were obtained from an ongoing prospectively collected registry (the 'Western Australian Autism Register'), with cases notified to the register by clinicians at the time of diagnosis, between 1999 to 2017. Data reported included demographic characteristics, diagnostic criteria met, IQ, and functional abilities. Information about any siblings, relationship (full/half), sex, and diagnosis of ASD were also recorded. Birth order was calculated by ranking sibling's year of birth against case year of birth to establish order within a family. Due to smaller numbers of cases born fifth or later (<2%), cases were only included for analysis for birth order up to four. Linear regression models were used to test whether birth order predicted adaptive functioning and IQ scores, and generalised linear models used to test associations between birth order and categorical outcomes (having an intellectual disability, being male, having a sibling diagnosed with ASD, having a female sibling diagnosed with ASD). All models were adjusted for age and year of diagnosis, with first-born cases the reference group.

Results: After adjusting for age and year of diagnosis, relative to being First Born, there were significant associations between birth order and adaptive functioning. On average, later born children had lower adaptive functioning scores, which became more pronounced with increasing birth order. For example, Second Born cases on average had a -1.83 (95% CI -2.93, -0.73) reduction in adaptive functioning scores while Fourth Born cases exhibited an average -4.28 reduction (95% CI -6.60, -1.95), relative to those First Born. No statistically significant association was found between birth order and IQ or having an intellectual disability. Increasing birth order was significantly associated with an increased proportion of siblings diagnosed with ASD. 4.8% of First-Born cases had a sibling diagnosed with ASD compared to 13.1% and 17.0% of Second or later-born cases, respectively. There was also a significantly higher proportion of female siblings diagnosed with ASD in later born children (48.1%), compared to those born first (14.8%).

Conclusions: The current study provides convincing evidence in a very large and representative sample that variability in ASD diagnostic phenotypes is associated with an individual's birth order. Children born later have increased adaptive functioning impairments relative to first-born children and are more likely to be in a family with other siblings also diagnosed with ASD. These data have significant implications for understanding underlying mechanisms that contribute to heterogeneity in ASD clinical presentations as a function of birth order and family size.

313.004 *(Oral)* Maternal Peri-Pregnancy Cannabis Use and Problem Behaviors in Children with and without Features of Autism Spectrum Disorder: Study to Explore Early Development (SEED)

C. DiGuiseppi[1], *T. Crume*[2], *C. Ledbetter*[1], *K. R. Sabourin*[3], *G. N. Soke*[4], *L. A. Croen*[5], *J. Daniels*[6], *S. Friedman*[7], *L. C. Lee*[8], *L. Schieve*[4], *L. Wiggins*[4], *G. C. Windham*[9] *and C. Robinson Rosenberg*[10], *(1)Colorado School of Public Health, University of Colorado Anschutz Medical Campus, Aurora, CO, (2)Epidemiology, University of Colorado Anschutz Medical Campus, Aurora, CO, (3)University of Colorado Anschutz Medical Campus, Aurora, CO, (4)Centers for Disease Control and Prevention, Atlanta, GA, (5)Division of Research, Kaiser Permanente, Oakland, CA, (6)University of North Carolina at Chapel Hill, Chapel Hill, NC, (7)Pediatrics, University of Colorado School of Medicine, Aurora, CO, (8)Department of Epidemiology, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, (9)Environmental Health Investigations Branch, California Department of Public Health, Richmond, CA, (10)University of Colorado / JFK Partners, Aurora, CO*

Background: Past-month cannabis (marijuana) use by pregnant women in the US doubled between 2015 (3.4%) and 2017 (7.1%). In several longitudinal studies, prenatal cannabis use adversely affected child behavior and development. Such effects may present differently in children with features of autism spectrum disorder (ASD).

Objectives: Examine associations of maternal peri-pregnancy cannabis use with child behavior and development; explore whether associations are modified by ASD features.

Methods: Participants were children 30-68 months-old, born in 2003-2006 or 2008-2011, and their mothers. "Children with ASD features" (N=2052) either met study criteria for ASD based on standardized diagnostic instruments or had a developmental delay or disorder (DD) and one of the following: previous ASD diagnosis, ASD risk on a standardized screening tool at enrollment, or clinician suspicion of ASD during study evaluation. "Children without ASD features" (N=2966) had a known DD without any criteria noted above or were from the general population. Mothers were asked about their cannabis use from 3 months preconception through delivery ("peri-pregnancy use"). Outcomes were child behavior (including sleep problems) assessed via the Child Behavior Checklist and developmental level via the Mullen Scales of Early Learning. Linear mixed-effects models estimated adjusted mean differences (AMD) in T-scores between offspring of peri-pregnancy cannabis users and offspring of non-users, controlling for study site, maternal education, and prenatal alcohol and tobacco use; likelihood ratio tests were used to assess interaction with ASD features.

Results: Peri-pregnancy cannabis use was reported by 5.4% (n=118) of mothers whose children had ASD features and 4.0% (n=111) of mothers whose children did not. Peri-pregnancy cannabis use was associated with a higher mean aggressive behavior score among children with ASD features (AMD between offspring of cannabis users vs. non-users=2.60 [95%CI:0.97, 4.23]) but not children without ASD features (AMD=0.19 [-1.34, 1.72]; test for interaction, p=0.029). Peri-pregnancy cannabis use was associated with a higher mean sleep problems score among children with ASD features (AMD=2.33 [0.77, 3.90]) but not children without ASD features (AMD=-0.43 [-1.09, 1.04]; test for interaction, p=0.009). Associations between peri-pregnancy cannabis use and attention problems, internalizing behaviors and developmental level did not differ for children with and without ASD features (tests for interaction, p=0.247, p=0.709, p=0.721, respectively). The mean attention problems score was significantly higher among offspring of peri-pregnancy cannabis users (AMD=1.09 [0.04, 2.13]). Mean internalizing behavior score and developmental level did not differ by peri-pregnancy cannabis use.

Conclusions: Maternal peri-pregnancy cannabis use was associated with more aggressive behaviors and sleep problems only among children with ASD features. Several potential explanations warrant further research. Cannabis use may act synergistically with other factors, such as underlying genetic risk or environmental exposures, to amplify regulatory problems in children with ASD features. Alternatively, there may be a common underlying etiology (e.g., genetic predisposition) resulting in mothers using cannabis and having children with ASD features and problem behaviors. Mothers who use cannabis may also differentially report both ASD features and problem behaviors in their offspring. With rising cannabis use among pregnant women, future studies should monitor behavioral outcomes among children with ASD features.

POSTER SESSION — **EPIDEMIOLOGY/POPULATION STUDIES**

421 - Epidemiology/population studies Posters

421.001 *(Poster)* Assessing the Associations between Autism, Autistic Traits and Multiple Risk Behaviours in Adolescence: A Population-Based Birth Cohort Study

A. Ly[1,2]*, J. Heron*[2,3]*, D. Rai*[2,4] *and C. Wright*[3]*, (1)Population Health Sciences, Bristol Medical School, MRC Integrative Epidemiology Unit, Bristol, United Kingdom, (2)Population Health Sciences, Bristol Medical School, Centre for Academic Mental Health, Bristol, United Kingdom, (3)Population Health Sciences, Bristol Medical School, Centre for Public Health, Bristol, United Kingdom, (4)BASS Autism Services for Adults, Avon & Wiltshire Partnership NHS Trust, Bristol, United Kingdom*

Background: Multiple risk behaviours (MRBs), engagement in two or more risk behaviours, typically begin in adolescence, often co-occurring in individuals. Risk behaviours include: smoking, alcohol consumption, cannabis use, illicit drug use, risky sexual behaviour and anti-social/criminal behaviour, among others. Considering the multiplicity and diversity of risk behaviours is of public health importance as MRBs are associated with increased risk of downstream adverse health and social outcomes. There is mixed evidence relating to autism/autistic traits and MRBs. With a dearth of literature on this topic, there is little understanding of the relationships between autism and autistic traits and MRBs, which should be addressed.

Objectives: To investigate whether autism cases and autistic traits predict engagement in MRBs across adolescence in a large cohort study in England.

Methods: ***Study setting and participants***

Data were from child participants in the Avon Longitudinal study of Parents and Children (ALSPAC), a longitudinal birth cohort study, established in Bristol and the surrounding areas in 1991. The sample includes 14,601 children who were alive at 1 year of age.

Exposure measures

Autism diagnosis and severe presentation of four autistic traits were the exposures of interest. Autism diagnoses were identified via a multi-source approach, including clinical record review, educational record review and validation by a consultant paediatrician using the *International Statistical Classification of Disease, 10th revision*. The top 'high risk' decile of each autistic trait distribution in participants who completed questionnaires were also selected. The traits were: social and communication difficulties as measured by the Social Communications Disorder Checklist (SCDC), assessed at 91 months; coherence assessed at 115 months; repetitive behaviours assessed at 69 months and sociability assessed at 38 months.

Outcome measures

Continuous measures of participation in up to 13 risk behaviours at ages ~ 12, 14, 16 and 18 years were derived from participants' responses during ALSPAC data collections.

Statistical analysis

We used structural equation (SEM) modelling approaches to investigate the associations between (i) autism cases and (ii) severe presentation of four autistic traits, and MRB total score at ages ~ 12, 14, 16 and 18 years. SEM approaches included latent growth curve and latent basis growth curve modelling techniques. The latter was used to test non-linearity. We also tested whether these relationships are moderated by sex.

Results: Analysis using both SEM approaches led to similar estimates. As illustrated in Table 1, the results suggest that when compared to population-based controls, social interaction and communication difficulties, repetitive behaviours and coherence issues are all positively associated with MRBs at age ~12 years. Social communication difficulties are also positively associated with MRBs over adolescence. Having an autism diagnosis and reduced social temperament are both negatively associated with MRBs over adolescence. There was evidence for sex-specific differences; males rather than females with autism or autistic traits are at greater risk of MRBs, particularly at ~12 years of age.

Conclusions: The effect of having a diagnosis of autism and autistic traits appears to have different effects on risk of engaging in MRBs during adolescence. These associations are moderated by sex.

421.002 *(Poster)* Association between Neighbourhood Socioeconomic Status and Developmental Vulnerability of Kindergarten Children with Autism Spectrum Disorder across Canada

A. Siddiqua*, E. Duku and M. Janus, McMaster University, Hamilton, ON, Canada*

Background: There is increasing consensus that inequalities in health outcomes of a population may be attributable to factors that operate at an aggregate level, such as neighbourhood characteristics. The relationship between neighbourhood socioeconomic status (SES) and health of children with Autism Spectrum Disorder (ASD) remains poorly understood.

Objectives: To examine the association between neighbourhood SES and developmental vulnerability at the individual level across neighbourhoods, while controlling for individual SES, among kindergarten children with ASD living in Canada.

Methods: This study used data from a population-level database of child development in kindergarten, collected with the Early Development Instrument (EDI). The EDI is completed by kindergarten teachers, includes records of medical diagnoses, and has been administered at the population level in most Canadian provinces and territories. The EDI data provide information on children's developmental status in 5 domains: physical health and well-being, social competence, emotional maturity, language and cognitive development, and communication skills and general knowledge. Scores below a baseline 10th percent cut-off on any of the 5 domains indicate vulnerability. Neighbourhood SES was assessed using an SES index created using 10 variables from the 2011 Canadian Census and 2010 Taxfiler data. Individual SES was assessed using 4 variables from the 2016 Canadian Census data. Multilevel logistic regression analyses were used to examine the association between neighbourhood SES and developmental vulnerability of the child, while controlling for individual SES and demographic characteristics and accounting for clustering of children in neighbourhoods.

Results: Higher neighbourhood SES was associated with lower odds of vulnerability in most domains, but not in all provinces. Specifically, higher neighbourhood SES was associated with lower odds of vulnerability in the Physical Health and Well-Being domain in Ontario (OR: 0.90, 95% CI: 0.83 to 0.98; $p<0.05$); in the Social Competence domain in Ontario (OR: 0.89, 95% CI: 0.81 to 0.98; $p<0.05$), in the Emotional Maturity domain in British Columbia (OR: 0.73, 95% CI: 0.58 to 0.91; $p<0.05$); in the Language and Cognitive Development domain in Ontario (OR: 0.87, 95% CI: 0.79 to 0.95; $p<0.01$), and in Manitoba (OR: 0.73, 95% CI: 0.55 to 0.99; $p<0.05$); and in the Communication Skills and General Knowledge domain in Ontario (OR: 0.85, 95% CI: 0.78 to 0.94; $p<0.01$). In Nova Scotia only, higher neighbourhood SES was associated with higher odds of vulnerability in the Social Competence domain (OR: 2.20, 95% CI: 1.14 to 4.22; $p<0.05$) and in the Communication Skills and General Knowledge domain (OR: 2.27, 95% CI: 1.15 to 4.53; $p<0.05$).

Conclusions: Meaningful associations between higher neighbourhood SES and better developmental health of children with ASD were found for most domains, but not consistently in all Canadian jurisdictions. Children with ASD living in neighbourhoods with higher SES are less likely to demonstrate developmental vulnerability, emphasizing the importance of addressing neighbourhood deprivation to support the development of children with this disorder. The nation-wide implementation of the EDI provides a large representative sample, improving generalizability of study findings.

421.003 *(Poster)* Association of Adverse Birth Outcomes of Parents with Autism Spectrum Disorder in Their Offspring

*J. Xiao[1], Y. Gao[2], Y. Yu[3], Y. Zhang[1], J. Luo[1], Y. Xia[1], J. Olsen[4], J. Li[3] and **Z. Liew**[1], (1)Yale School of Public Health, New Haven, CT, (2)Shanghai Jiao Tong University, Shanghai, China, (3)Clinical Epidemiology, Aarhus University Hospital, Aarhus, Denmark, (4)Aarhus University, Aarhus, Denmark*

Background: Preterm birth and low birth weight in children are considered risk factors for ASD. However, the relationship between adverse birth outcomes of the parents, likely resulted from unfavorable intrauterine growth and development, and ASD risk in their offspring have remained unexplored.

Objectives: We conducted a nationwide register-based cohort study in Denmark of three generations to investigate whether parental preterm birth and/or low birth weight was associated with increased risk of autism spectrum disorder (ASD) in their offspring.

Methods: Danish mothers and fathers born since 1978 who have had singleton live-born offspring registered in Denmark during 1990-2013. We identified 230,180 mother-child pairs and 157,926 father-child pairs for statistical analyses. Information of preterm birth (<37 weeks gestation) and low birth weight (<2500 gram) of parents were obtained from the Danish Medical Birth Register. ASD diagnoses in offspring were ascertained from the Danish Central Psychiatric Registry. We estimated Odds Ratio (OR) and 95% confidence intervals (CI) for offspring ASD according to the parental preterm and low birth weight status, with or without adjustment for grandmaternal sociodemographic factors including age, parity and education level.

Results: Children of mothers with adverse birth outcomes were associated with about 30% higher risk for ASD (low birth weight, OR=1.35, 95% CI: 1.17-1.57; preterm birth, OR=1.31, 95% CI= 1.12-1.55) compared with mothers who were born with normal birth weight or born at term. Paternal adverse birth outcomes were also associated with about 40% elevated risks for ASD in the offspring (low birth weight, OR=1.38, 95% CI= 1.12, 1.55; preterm birth, OR=1.43, 95% CI=1.18, 1.73). These associations were slightly attenuated upon adjustment for grandmaternal sociodemographic factors. A small portion of these associations was found to be mediated through parental health and perinatal risk factors for the offspring.

Conclusions: Offspring of parents born preterm or low birth weight showed slightly elevated risks for ASD. Adverse birth outcomes in parents might act as a proxy that indicates harmful in-utero exposures of parents that transmitted disease risks to the next generations through germlines effect. In addition, parents with adverse birth outcomes could result in poorer overall health and persistent sociodemographic disadvantages that impact their reproductive health and disease risks in their offspring. Transgenerational risks for ASD should be considered in future research of ASD etiology.

421.004 *(Poster)* Association of Grandparental and Parental Age with ASD: A Multi-Generational Cohort Study in Denmark

*Y. Gao[1], Y. Yu[2], J. Xiao[3], Y. Zhang[3], J. Luo[3], Y. Tian[1], J. Zhang[4], J. Olsen[5], J. Li[2] and **Z. Liew**[3], (1)Shanghai Jiao Tong University, Shanghai, China, (2)Clinical Epidemiology, Aarhus University Hospital, Aarhus, Denmark, (3)Yale School of Public Health, New Haven, CT, (4)Shanghai Jiao Tong University School of Medicine, Shanghai, China, (5)Aarhus University, Aarhus, Denmark*

Background: Advanced parental age has been linked with increased risk of Autistic Spectrum Disorders (ASD) in children. However, little is known for the relationship between grandparental age at the time of birth of the parent and risks for ASD in children.

Objectives: We conducted a population-based multigenerational cohort study in Denmark and investigate the associations between parental and grandparental age and ASD risks in children.

Methods: We conducted a linkage study using multiple Danish national health registers. We first constructed a parental age cohort and evaluated the association between parental age and ASD risks in 1,476,783 singleton children born from 1990 to 2013 with available information on parental age. We additionally constructed a multigenerational cohort to study grandparental age by following 362,438 fathers and 458,234 mothers born from 1973 to 1990 whose information on grandparental age were available and evaluated the risks of ASD in grandchildren. Exposures of interests were parental age at childbirth and grandparental age at the time of the birth of the parent. Diagnoses of ASD in children were obtained from the Danish Psychiatric Central Research Register (1994-2017) based on the International Classification of Disease, Tenth Revision. Logistic regression was used to estimate the associations between parental or grandparental age and ASD in children.

Results: Advanced paternal or maternal age over 30 years was monotonically related to increased ASD risks among children. We additionally observed U-shaped relationships between paternal grandparental age and ASD risks in the grandchildren e.g. about 12-40% elevated risks of ASD in children of fathers born to younger (≤19 years) or older (≥40 years) grandparents, compared to children of parents born to grandparents between age 25 to 29 years. Moreover, children with young maternal grandparents (≤19 years) also had 50-68% elevated risks for ASD, but no apparent associations were observed for older grandparental age.

Conclusions: Our study corroborated previous findings that advanced parental age was independently related to increased ASD risks in children. We additionally observed that children with young maternal grandparents, and children with young and old paternal grandparents had elevated ASD risks. Our findings suggested possible transmission of ASD risks across generations, which should be considered in future etiological research on ASD.

421.005 *(Poster)* Association of Maternal Plasma Biomarkers of Oxidative Stress with Autism Related Traits in the EARLI Study

E. M. Kauffman[1], *N. Snyder*[1], *S. Melnyk*[2], *S. J. James*[3], *C. Salafia*[4], *I. Hertz-Picciotto*[5], *L. A. Croen*[6], *M. D. Fallin*[7], *C. J. Newschaffer*[8] *and K. Lyall*[1], *(1)A.J. Drexel Autism Institute, Drexel University, Philadelphia, PA, (2)Arkansas Children's Research Institute, Little Rock, AR, (3)University of Arkansas for Medical Sciences, Little Rock, AR, (4)Institute for Basic Research, Staten Island, NY, (5)University of California at Davis, Davis, CA, (6)Division of Research, Kaiser Permanente, Oakland, CA, (7)Wendy Klag Center for Autism and Developmental Disabilities, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, (8)College of Health and Human Development, Pennsylvania State University, University Park, PA*

Background: Oxidative stress is known to induce cellular effects including protein oxidation, lipid peroxidation, and DNA damage, each of which have been related to dysregulated fetal brain development. Glutathione (GSH) is an antioxidant important in preventing damage due to reactive oxygen species. The oxidized form of GSH, glutathione disulfide (GSSG), is increased when cells are experiencing oxidative stress. The ratio of GSH:GSSG, a marker of oxidative stress, decreases during periods of oxidative stress. Though oxidative stress is a key mechanism hypothesized in the etiology of autism spectrum disorder (ASD), studies examining biomarkers of oxidative stress during critical windows of neurodevelopment are lacking.

Objectives: To examine whether maternal prenatal levels of oxidative stress biomarkers are associated with later ASD traits in children.

Methods: Participants were drawn from the Early Autism Risk Longitudinal Investigation (EARLI) study, an ASD enriched-risk cohort that enrolled pregnant mothers who already had a child with ASD, and then followed the subsequent child to age three. Biomarkers of oxidative stress, including GSH and GSSG, and 3-nitrotyrosine were measured in 3rd trimester plasma samples from 183 mothers with outcome information available in their children. Continuous ASD traits were measured using the Social Responsiveness Scale (SRS) preschool version and the Mullen Scales of Early Learning (MSEL) at 36 months. Least squares regression was used to assess the association between maternal oxidative stress biomarkers and child outcomes, including adjustment for potential confounders.

Results: In crude models, we observed a positive association (β=0.492, p=0.024, 95% CI 0.06-0.92), between the ln-transformed ratio of GSH:GSSG and ln-transformed SRS, meaning that for a 10% increase in the ratio of GSH:GSSG (and thereby a decrease in oxidative stress), the SRS total score is estimated to increase by 4.8% (increase in ASD-related traits). In adjusted models accounting for child sex, maternal age, maternal race and ethnicity, maternal education, and pre-pregnancy BMI, the association persisted and strengthened (β=0.529, p=0.012, 95% CI 0.12-0.94). GSH and GSSG examined individually yielded positive and negative associations with SRS, respectively, consistent with the direction found for GSH:GSSG ratio, although individual marker associations were not statistically significant. Parallel analyses examining associations with the Early Learning Composite score of the MSEL demonstrated no significant associations, though estimates were in a plausible direction. No significant associations were observed with 3-nitrotyrosine.

Conclusions: We observed an inverse association between oxidative stress measured in the 3rd trimester of pregnancy via the GSH:GSSG ratio and offspring SRS at age three. The paradoxical association between increased ASD traits and decreased oxidative stress emphasizes the need for further investigation into the role oxidative stress plays in ASD and neurodevelopment. Future analyses will examine potential modifiers and non-linear associations, which may help to explain these findings, as well as investigate other oxidative stress biomarkers involved in lipid peroxidation and DNA damage.

421.006 *(Poster)* Association of Placental Morphology with Autism-Related Traits in the EARLI Study

C. Zhong[1], *E. M. Kauffman*[2], *R. Shah*[3], *C. Salafia*[4], *L. A. Croen*[5], *M. D. Fallin*[6], *I. Hertz-Picciotto*[7], *C. J. Newschaffer*[8] *and K. Lyall*[2], *(1)Department of Epidemiology and Biostatistics, Drexel University, Philadelphia, PA, (2)A.J. Drexel Autism Institute, Drexel University, Philadelphia, PA, (3)Placental Analytics, LLC, New Rochelle, NY, (4)Institute for Basic Research, Staten Island, NY, (5)Division of Research, Kaiser Permanente, Oakland, CA, (6)Wendy Klag Center for Autism and Developmental Disabilities, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, (7)University of California at Davis, Davis, CA, (8)College of Health and Human Development, Pennsylvania State University, University Park, PA*

Background: Placental morphologic features may yield important insights into factors influencing prenatal fetal development. Previous work has suggested differences in placental morphology between families enriched for autism spectrum disorder (ASD) and those from the general population, but how such features associate with ASD-related outcomes in enriched-risk families is not yet well characterized.

Objectives: To examine whether placental morphologic features are associated with ASD-related outcomes in families with enriched-risk for ASD.

Methods: Participants were drawn from the Early Autism Risk Longitudinal Investigation (EARLI) study, a multisite prospective autism enriched-risk cohort study, which enrolled pregnant mothers who had already had a child with ASD, and followed the subsequent child through the age of three. Analyses here include mother-child pairs with data on placentas and offspring outcome data (n=129, including 21 children with a diagnosis of ASD at age 3). Outcomes examined include ASD clinical diagnosis, Social Responsiveness Scale (SRS) scores (preschool version), and Mullen Scales of Early Learning (MSEL) Early Learning Composite scores. Placental morphologic features, including placental weight, thickness, eccentricity, perimeter, area, radius, and umbilical cord parameters were examined in association with these outcomes using multivariable linear regression models adjusting for maternal demographic factors, body mass index, and the child's sex. We also explored use of principal components analysis (PCA) to create groupings of a wider set of placental morphology features, and examined these components in association with our outcomes as well.

Results: Although unadjusted analyses showed some associations of placental morphologic features with SRS and MSEL scores, these did not persist after adjusting for factors noted above. Results from PCA identified 3 main components, summarizing 83.4% of the variance in these data; these were related to placental shape/cord location, placental surface size, and variance in disc thickness. The z-score of the component summarizing placental shape and cord location (capturing placental radius, umbilical distance from center, and umbilical cord eccentricity, with higher values on the component indicative of a larger placenta and more eccentric cord features) was significantly positively associated with SRS scores in analyses (Beta=6.76, 95% CI 0.08 – 13.45) adjusting for maternal demographic factors and placental weight, but not following adjustment for maternal BMI and child sex (Beta= 6.18, 95% CI -1.10 – 13.47). Other parallel analyses examining associations with the Early Learning Composite score of the MSEL and ASD diagnosis demonstrated no consistent or significant associations.

Conclusions: Our preliminary analyses did not reveal strong associations between placental morphologic features and child ASD-related outcomes, though our sample size was small. Further analyses will examine placental vascular measures and explore other variable reduction and grouping techniques. Given the placenta is the key interface between the mother and the developing fetus, a better understanding of how placental features may relate to ASD is needed.

421.007 *(Poster)* Association of Prenatal Phthalate Exposure with Autistic Traits: Exposure Measurement in Maternal Urine & Meconium

L. Mathew[1,2]*, N. Snyder*[1]*, K. Lyall*[1]*, B. K. Lee*[2]*, H. E. Volk*[3,4]*, M. D. Fallin*[3,4]*, L. A. Croen*[5]*, I. Hertz-Picciotto*[6] *and C. J. Newschaffer*[7]*, (1)A.J. Drexel Autism Institute, Drexel University, Philadelphia, PA, (2)Epidemiology and Biostatistics, Drexel University, Philadelphia, PA, (3)Wendy Klag Center for Autism and Developmental Disabilities, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, (4)Mental Health, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, (5)Division of Research, Kaiser Permanente, Oakland, CA, (6)MIND Institute, University of California, Davis, Sacramento, CA, (7)College of Health and Human Development, Pennsylvania State University, College Park, PA*

Background: Phthalates are endocrine disrupting chemicals suspected to adversely affect fetal neurodevelopment. Several epidemiologic studies have linked prenatal phthalate exposure to fetal neurodevelopment in a sexually dimorphic manner. In these studies, phthalate metabolites were measured in maternal urine from pregnancy, reflecting maternal exposure given temporal variability. Meconium, the first stool of the neonate, may be a better biosample to measure fetal exposure as it is more proximal to the fetus than maternal urine.

Objectives: To evaluate the association between phthalate metabolites measured in 3rd trimester maternal urine or in baby's meconium with a quantitative measure of autism-related traits assessed at 36 months in a cohort of children at high risk for Autism Spectrum Disorder (ASD).

Methods: We quantified 14 phthalate metabolites in third trimester maternal urine samples and 13 metabolites in meconium samples collected from children born to mothers in the Early Autism Risk Longitudinal Investigation (EARLI) study, a pregnancy cohort of mothers with an older child already diagnosed with ASD. Phthalate metabolites were measured using liquid chromatography-mass spectrometry. Molar sum of di-2ethylhexl phthalate (DEHP) metabolites, and an anti-androgenic (AA) score using mono-isobutyl phthalate (MiBP), mono-n-butyl phthalate (MnBP), mono benzyl phthalate (MBzP), and DEHP metabolites were computed. Autism-related phenotype was measured at 36-months using the Social Responsiveness Scale (SRS). Among children with available SRS and maternal urine samples, and among those with SRS and meconium samples, we evaluated the association of log-transformed phthalate metabolites with log-transformed SRS total raw score, using linear regression models adjusted for *a priori* selected covariates. Quadratic terms were used to explore non-linear associations and interaction terms between child sex and phthalate metabolites were used to explore effect modification.

Results: Eleven metabolites were detected in over 90% of maternal urine samples and only six were detected in over 90% of meconium samples. Two maternal urine metabolites were positively associated with increasing SRS, MnBP, β= 0.19 (95% CI 0.01, 0.38), and mono-3-hydroxy-n-butyl phthalate (MHBP), β= 0.18 (0.02, 0.36), as was the AA score, β= 0.19 (0.02, 0.36). Interpreting the results as a percent change, a 10% increase in MnBP and the AA score would result in a 1.8% increase, and for MHBP- a 1.7% increase in the SRS total raw score. Further, maternal urine mono-carboxy-isononyl-phthalate (MCNP), mono-2-ethyl-5-oxohexyl phthalate (MEOHP), and mono-ethyl-phthalate (MEP) showed inverted U-shaped log-log relationships with child SRS score. Interactions with sex were suggested ($p<0.2$) for mono-3-carboxypropyl phthalate (MCPP), MEOHP, Mono-2-methyl-2hydroxypropyl phthalate (MHiBP), and the molar sum of DEHP metabolites. Meconium phthalate metabolites MnBP, MBzP, and the AA score had similar effect estimates as maternal urine in unadjusted models but were not statistically significant in covariate adjusted models. A statistically significant U-shaped association was observed for meconium MiBP.

Conclusions: Higher levels of a subset of phthalates measured in third trimester maternal urine were associated with higher degree of autism traits, some in a sex-specific manner, in this high-familial autism risk cohort. Phthalates were detected in meconium, but findings were not fully consistent with urine. Further exploration of prenatal phthalate exposure and autism-related phenotype is warranted.

421.008 *(Poster)* Autism Spectrum Disorder Prevalence in Children Aged 12-13 Years from the Longitudinal Study of Australian Children

T. May[1]*, A. Brignell*[2] *and K. Williams*[3]*, (1)Level 5, 246 Clayton Road,, Monash University, clayton, VIC, Australia, (2)Murdoch Children's Research Institute and University of Melbourne, Melbourne, Australia, (3)Department of Paediatrics, Monash University, Clayton, VIC, Australia*

Background: There has been an increase in autism spectrum disorder (ASD) prevalence worldwide including Australia.

Objectives: Provide an ASD prevalence update from parent and teacher report using the Longitudinal Study of Australian Children (LSAC).

Methods: The LSAC is a prospective cohort study of Australian children representative of the population with two cohorts: Kinder (birth year 1999/2000) and Birth cohort (birth year 2003/2004). Children in the Birth and Kinder cohort with parent- and teacher-reported ASD prevalence were compared to children without ASD. There were N=3,381 (66%) responding in the Birth cohort at age 12 and N=3089 (62%) for the Kinder cohort at age 16. Main outcome measures were the proportion of parent and teacher reported ASD in the cohorts from age 10-16 years; quality of life measured by the Paediatric Quality of Life Inventory, and emotional/behaviour problems as measured using the Strengths and Difficulties Questionnaire.

Results: Parent-reported ASD prevalence increased to 4.36% [95% CI 3.56 -5.19] at age 12-13 years in the Birth cohort and 2.60% [95% CI 2.07-3.31] in the Kinder cohort. Kinder cohort ASD-children had more parent- and teacher-reported social problems, and lower parent-reported social and psychosocial quality of life.

Conclusions: As expected, parent-reported ASD prevalence continued to rise. Higher prevalence in the Birth cohort may relate to milder cases of ASD being diagnosed.

421.009 *(Poster)* Autism Spectrum Disorder Prevalence in Immigrant Communities in Minnesota: Data from the MN-ADDM Study

A. N. Esler[1], *J. A. Hall-Lande*[2], *J. Poynter*[3], *E. Hallas-Muchow*[1] *and A. Hewitt*[4], *(1)University of Minnesota, Minneapolis, MN, (2)UCEDD, University of MN, Minneapolis, MN, (3)Pediatrics, University of Minnesota, Minneapolis, MN, (4)U of MN, Minneapolis, MN*

Background: Children of immigrants may have higher rates of autism spectrum disorder (ASD) (Crafa & Warfa, 2015), particularly those from countries with a low human resource index (Barnevik-Olsson et al., 2008; Keen et al., 2010; Magnusson et al., 2012). Through previous surveillance projects, we have been tracking prevalence of autism in Somali and Hmong children in Minnesota. Minnesota has the largest population of Somali immigrants, an estimated 57,000 people, and the second largest population of Hmong, close to 60,000 people (American Community Survey, 2017). In a previous study focused on Minneapolis, Somali children with ASD were far more likely to have co-occurring ID than children with ASD in other racial/ethnic groups (Hewitt et al., 2016; Esler, Hall-Lande, & Hewitt, 2017). However, in a subsequent study with an expanded geographic area, rates of ID did not differ for any racial/ethnic group.

Objectives: We will compare ASD prevalence in 8-year-olds across racial/ethnic groups from the Minnesota site of the CDC Autism and Developmental Disabilities Monitoring Network (MNADDM), surveillance years 2014 and 2016, with a focus on two large racial/ethnic groups in MN: Somali and Hmong. We will also compare the co-occurrence of ID in children with ASD across racial/ethnic groups.

Methods: We will combine data from 2014 and 2016 surveillance years to obtain adequate sample sizes to compare prevalence across our populations of interest. Prevalence calculations utilize standardized ADDM methods (Christensen et al., 2016) involving systematic review of health and special education records of 8-year-old children within our defined surveillance area. The area includes nine school districts in two large urban counties. Population denominators are obtained from the National Center for Health Statistics Vintage 2018 Bridged-Race Postcensal Population Estimates for 2016 and adjusted to include only children living in the surveillance area. A child is classified as Somali or Hmong based on reported home language in education and health records.

Results: Sample sizes from surveillance year 2014 lacked power to detect differences, but estimates revealed nonsignificant trends of higher ASD prevalence for Somali children (1 in 26) and lower ASD prevalence for Hmong children (1 in 54) compared to the overall MN prevalence of 1 in 42 children. To increase power, prevalence estimates from combined surveillance years 2014 and 2016 will be compared across racial/ethnic groups assuming a Poisson distribution. Chi squared and Fisher's exact tests will be used to identify differences between populations. We will also compare rates of ASD for children in MN with overall U.S. prevalence reported by the CDC. Finally, we will compare prevalence of co-occurring ID in children with ASD across racial/ethnic groups.

Conclusions: Because ASD early identification can improve outcomes, identifying subgroups of children with a higher prevalence or more severe forms of ASD can inform public health policy and improve outcomes for individuals with ASD and their families. Differences in prevalence by racial/ethnic group may suggest barriers to service utilization. Culturally sensitive methods for outreach and diagnosis may be warranted to decrease disparities in evaluation and diagnosis of ASD.

421.010 *(Poster)* Comorbidities of Children with Autism Spectrum Disorder at the Time of Evaluation Among a Sample of Puerto Rican Children

S. Cepeda[1], *I. Soto-Infante*[2], *I. Martinez*[3], *L. Deliz*[1,4], *N. Delgado-Torres*[4], *M. Pacheco*[3] *and L. Morales*[3], *(1)School of Behavioral & Brain Sciences, Ponce Health Sciences University, Ponce, PR, (2)School of Behavioral & Brain Sciences, Ponce Healh Sciences University, Ponce, PR, (3)Public Health, Ponce Health Sciences University, Ponce, PR, (4)Centro Ponceño de Autismo, Ponce, PR*

Background: The Autism Spectrum Disorder is a neurobiological condition where deficiencies are presented in various areas such as social communication, and stereotyped behavior patterns, and a conglomeration of various activities and limited interests, among others. This disorder begins from childhood and is prevalent throughout life. Notably, when the DSM-V was released, he introduced the novelty of accepting the possibility of a concurrent diagnosis (or comorbid) autism (ASD) and Attention Deficit Disorder (ADHD). Other studies consider that autism can occur in conjunction with conditions such as intellectual disabilities, speech and language disorders, anxiety, dyspraxia, bipolar disorder, depression and obsessive-compulsive disorder, among others. In the research field, Autism remains an innovative topic. This condition is considered a medical epidemic worldwide. Current statistics in the United States report that 1 in 59 children has autism diagnosis. In Puerto Rico, the prevalence of autism is 1 in every 62 children by 2012. It is noteworthy that Latin American statistics are not updated and research with this population are scarce.

Objectives: This research aims to establish which are concurrent conditions (comorbidities) of children diagnosed with Autism Spectrum Disorder in a Satellite Center at South Puerto Rico. This study will estimate the prevalence of comorbidities presented in children with ASD in a group of Puerto Rican children.

Methods: This study used a database created with interviews from mothers of children with neurodevelopmental conditions that visited the Satellite Center for evaluation purposes and information collected from evaluation reports. For this analyzes only confirmed cases of ASD using DSM-V criteria were included. After quality control, the analyzes were performed with 160 confirmed ASD cases [mean age 5.2 ±2.8]. Statistical analyzes such as univariate and bivariate analyzes were performed, due to sample size nonparametric test were used to assess differences by sex. Prevalence of comorbidities were estimated among the study population in general and by sex.

Results: 82.8% (n=130) of cases were male and 17.2% (n=30) were females. The most frequent reported comorbid disorders were significant Speech and Language delay with 72%(n=103) of cases. Followed by sensory deficits with 26.6% (n=38), and Attention Deficit Disorder and Hyperactivity 25.2% (n=36). When compared reported comorbidities by sex. Male children with ASD were two times more likely to report motor problems than female with ASD (OR=2.0,95%CI 0.9, 7.5). In terms of sensory problems female with ASD were 80% more likely to report sensory problems than male with ASD (OR= 0.2, 95%CI 0.8, 0.5).

Conclusions: This study confirms what's exposed in the literature, that Autism Spectrum Disorder is most often diagnosed in males than females. Also provides a list of signs and symptoms that could lead to a possible diagnosis, being speech delay the principal symptom reported. It is important to continue doing research with the goal to decrease the age of diagnosis and promote early interventions in Puerto Rican children.

421.011 *(Poster)* Comparison of Two Surveillance Case Definitions for Monitoring Prevalence of Autism Spectrum Disorder Among 8-Year-Old Children

M. J. Maenner[1], *S. J. Graves*[2,3], *M. A. Honein*[2], *G. Peacock Goebel*[2], *C. A. Boyle*[1] *and P. M. Dietz*[2], *(1)Centers for Disease Control and Prevention, Atlanta, GA, (2)CDC, Atlanta, GA, (3)Oak Ridge Institute for Science and Education, Oak Ridge, TN*

Background: Since 2000, the Autism and Developmental Disabilities Monitoring (ADDM) Network conducts population-based surveillance of autism spectrum disorder (ASD) in multiple US communities among 8-year-old children. To classify ASD, ADDM sites collected verbatim (text) descriptions of behaviors from medical and educational evaluations which were then reviewed and coded by ADDM clinicians. This process was labor-intensive and took at least four years to publish the data from a given surveillance year. The need to produce more timely public health data—combined with increased community recognition of ASD over the intervening time period—led to a re-evaluation of the ADDM methods. We identified a potential new surveillance case definition requiring less time and less data collection and undertook a comprehensive assessment comparing the new case definition to the previous one.

Objectives: To compare and evaluate a new ASD surveillance case definition to the previous ASD case definition in the ADDM Network.

Methods: The new case definition is based on community identification of ASD and includes children with a diagnostic statement of ASD in an evaluation, ASD classification in special education, or an ASD ICD-9 billing code in hospital or other health system records. Using the previous and new case definitions on data from eight ADDM sites for surveillance year 2014, we compared prevalence (overall and within subgroups), as well as other important surveillance indicators including median age at earliest developmental evaluation, median age at first ASD diagnosis, and proportion with co-occurring intellectual disability. Additionally, we examined the percent of children included as ASD cases in all ADDM sites from 2000-2012 that met the new case definition. We estimated the amount of data collection and time required by the new and previous case definitions.

Results: Overall, 4045 children met the previous ASD case definition for surveillance year 2014 compared to 4025 children who met the new case definition, producing ASD prevalence estimates of 1.73% and 1.72%, respectively. Using the previous case definition as the "gold standard", sensitivity of the new case definition was 87.3% and positive predictive value was 87.7%. ASD prevalence by race/ethnicity or sex did not differ between the two case definitions. Median age of earliest evaluation, median age of first ASD diagnosis, or proportion with intellectual disability did not significantly change under either case definition. From 2000-2014, the percent of children classified by ADDM as having ASD that met the new case definition increased from 64.0% to 87.1%, suggesting community diagnoses of ASD have increased over time. The new case definition does not require clinical review and is expected to require about half as much data collection as the previous case definition and yield more timely reporting.

Conclusions: The new ASD case definition is a more direct barometer of community identification of ASD and should considerably reduce resource and time requirements for conducting autism surveillance while retaining very similar measurement properties to the previous case definition. Timely data will be useful in monitoring changes in prevalence and planning for needed services in the community.

421.012 *(Poster)* Cumulative Parental Occupational Exposures and Severity of Autism Spectrum Disorder

E. C. McCanlies[1], *J. K. Gu*[2], *C. C. Ma*[3], *W. T. Sanderson*[4], *Y. Ludena*[5] *and I. Hertz-Picciotto*[6], *(1)CDC/NIOSH, Morgantown, WV, (2)HELD/BB, NIOSH, Morgantown, WV, (3)BB, NIOSH, Morgantown, WV, (4)College of Public Health, University of Kentucky, Lexington, KY, (5)UC DAVIS, Davis, CA, (6)University of California at Davis, Davis, CA*

Background: Previously, we found that parental solvent exposure was associated with autism spectrum disorder (ASD) but did not evaluate if parental occupational exposures were associated with the severity of ASD symptoms.

Objectives: To investigate if cumulative parental occupational exposures are associated with the severity of ASD symptoms.

Methods: Between 2003-2012, demographic, health, and parental occupational history information were collected as part of the CHildhood Autism Risks from Genetics and Environment (CHARGE), a population based case-control study that enrolls both children with autism and from the general population who are between the ages of 2 - 5 years old, born in California, living with at least one biologic parent, and residing in the catchment areas of a specified list of California Regional Centers that coordinate services for persons with developmental disabilities. All the children underwent cognitive, social, and medical evaluations at either the University of California, Davis, Medical Investigation of Neurodevelopmental Disorders Institute (UC Davis MIND) in Sacramento, CA or the University of California, Los Angeles (UCLA) Neuropsychiatric Institute and are defined as either ASD or typically developing (TD). After excluding TD children, their parents, and individuals who did not have complete data, 532 children with ASD and their parents were included in this study. Parental occupational exposures were assessed by two industrial hygienists, who reached consensus in categorical exposure scores. For each job that the parent held, the industrial hygienists estimated the frequency and intensity of 12 exposures. Cumulative exposure was then derived by multiplying the [frequency of exposure (0-3)] x [intensity of exposure (0-3)] x [work hours/week] for each job held three months prior to pregnancy until birth of the study child and summing across jobs to create a summary score. The summary score was then log transformed for analysis. The 10-point scale of the Calibrated Severity Score, based on Autism Diagnostic Observation Schedule-2, was used (1 = mild ASD symptoms, 10 = high ASD symptoms) as the outcome. Multiple regression was used to evaluate associations between each of the cumulative occupational exposure scores and ASD severity adjusting for maternal age, smoking, length of breastfeeding, birthplace, regional center, total years of education, and alcohol consumption.

Results: The mean ASD severity score was 7.41 ± 1.55. Maternal occupational exposure to phenol was positively associated with ASD severity (β=1.18, p =0.014) as were pharmaceuticals (β=0.45; p =0.038). There were no occupational exposures in fathers alone that were associated with ASD severity. However, when mothers and fathers were combined, higher ASD severity was associated with occupational exposures to phenols (β=0.91, p < 0.001), pharmaceuticals (β=0.33; p =0.036), and disinfectants/cleaners (β=0.23; p = 0.032).

Conclusions: Data from this observational autism study suggests a linear dose-response relationship of occupational exposures during the pregnancy to phenol, pharmaceuticals, and disinfectants with ASD severity. Higher cumulative exposure levels were associated with higher ASD severity.

421.013 *(Poster)* Distributional Properties and Criterion Validity of a Shortened Version of the Social Responsiveness Scale: Implications for Quantitative Trait Research

K. Lyall[1]*, C. Ladd-Acosta*[2]*, M. Hosseini*[3]*, A. J. Kaat*[4]*, L. A. Croen*[5]*, J. N. Constantino*[6]*, H. E. Volk*[2] *and C. J. Newschaffer*[7]*, (1)A.J. Drexel Autism Institute, Drexel University, Philadelphia, PA, (2)Wendy Klag Center for Autism and Developmental Disabilities, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, (3)Johns Hopkins University, Baltimore, MD, (4)Department of Medical Social Sciences, Northwestern University, Chicago, IL, (5)Division of Research, Kaiser Permanente, Oakland, CA, (6)Washington University School of Medicine, St. Louis, MO, (7)College of Health and Human Development, Pennsylvania State University, University Park, PA*

Background: The Social Responsiveness Scale (SRS) is a widely-used and well-established quantitative measure of social communication and autism-related traits with strong psychometric properties. Recently, a 16-item shortened version of the scale was developed, but its performance has not been tested as a stand-alone questionnaire, nor have its properties been examined in a general-population sample.

Objectives: We sought to 1) compare the distributional properties and performance of the 16-item "short version" of the SRS to the original 65-item "full version" and 2) conduct a validation study of these versions (goal n=400).

Methods: 1) Data was drawn from the Environmental Influences on Child Health Outcomes (ECHO) Program. 10 ECHO Cohorts contributed data to these analyses, comprising 2,354 individuals from both general population and ASD-focused studies (aged 3-18 (mean 6.7 years), n=136 with ASD). 16-item scores were derived from existing 65-item data (majority school-aged SRS-2). Distributional properties were compared by density plots of standardized short and full total raw scores. Criterion validity was examined using ROC curves, estimating associations with established ASD risk factors, and assessing correlation in parent-child scores. 2) Participants in our validation study, conducted at the Drexel Autism Clinic seeing patients referred for ASD diagnosis, and through a Kaiser Permanente general population-based sample, were given either the short or full SRS. Analyses comparing distributional properties and basic statistics were conducted based on these administrations.

Results: Within the ECHO data, standardized distributions of short and full SRS scores were highly overlapping; though short scores had a higher peak and slightly narrower distribution, means and overall distributions were comparable, particularly within the higher score range (indicative of greater ASD traits). Furthermore, discriminative ability of the two scores with ASD diagnosis was nearly identical, with area-under-the-curve values of 0.8548 and 0.864 for the full and short forms, respectively. Preliminary analyses of risk factors in ECHO data suggest similar associations between maternal age and both the full and short scores. Correlation in parent-child scores in these data was somewhat stronger based on full scores (r=0.25 for father-child and 0.11 for mother-child) than short (r=0.21 and 0.08), though the number with parental SRS scores (n=124) limited our ability to assess familiality. Within our field validation study, approximately 175 individuals have been enrolled to date, with data available from 80 from the Drexel Autism Clinic. Within this sample, standardized distributions of the two scores differed, with mean scores approximately 2 standardized points higher using the short form than the full scale.

Conclusions: Distributional properties and ASD discriminative ability of the shortened and full SRS appear similar based on existing data deriving short scores from full scale administrations. However, preliminary data from field validation work suggests potential differences in short scores when derived from 16-item stand-alone administrations. These results, together with the need to compare key SRS properties not adequately addressed here (e.g., familiality/heritability), suggest further consideration of the impacts of relying on shortened quantitative trait measures for etiologic research is warranted.

421.014 *(Poster)* Ethnicity, Providers, and Recognizing Autism in Arizona

J. Anbar*, B. Pope, C. Cutshaw and S. Pettygrove, Mel and Enid Zuckerman College of Public Health, University of Arizona, Tucson, AZ*

Background: ASD (Autism Spectrum Disorder) prevalence estimates vary by race/ethnicity. While the disparity in prevalence of ASD between Hispanics and non-Hispanic Whites (NHW) has narrowed since 2000, Hispanic ASD prevalence is most recently estimated as just 62% the prevalence of ASD among NHW. Differences by race/ethnicity in the types of providers who evaluate children may contribute to differences in treatment for ASD and subsequent detection of cases by surveillance systems.

Objectives: Evaluate the effects of ethnicity on patterns of practice and community recognition of ASD cases.

Methods: Cases from the Arizona Developmental Disabilities Surveillance Program (ADDSP) from surveillance years 2000 to 2010 were included; these cases were ascertained according to the CDC's Autism and Developmental Disabilities Monitoring Network protocol. Cases were defined as having community recognition of their condition if they had a clinical diagnosis and/or they received special educational services for autism. We used chi-square tests to evaluate differences by ethnicity in which types of providers had evaluated each case and differences in the likelihood of community recognition for cases who had been examined by each type of professional. Finally, we used logistic regression to look for differences by race/ethnicity in community recognition among all cases ever evaluated by each type of provider.

Results: ADDSP identified 2,303 children who met case criteria for ASD. Among these cases, 1,437 were NHW and 555 were Hispanic. Psychologists without doctoral level training evaluated the largest proportion of cases (72.5%), followed by speech and language specialists (54.7%). Compared to NHW, Hispanic cases were less likely to have been evaluated by a physician ($p<0.01$) and more likely to have been evaluated by a speech and language specialist ($p<0.05$). NHW were more likely to have community recognition; 67.9% of NHW had community recognition compared to 59.3% of Hispanics ($p<0.001$). Compared to NHW, the odds ratio for recognition Hispanics was 0.69 (0.56-0.84). Cases were more likely to have community recognition if they had been evaluated by physicians (OR=3.34; 2.75-4.05 CI). Other provider types had half the odds of recognizing ASD with significant odds ratios ranging from 0.42 – 0.54.

The odds of community recognition for Hispanics was lower than for NHW among all cases who had ever been seen by specific types of professionals: education specialist OR=0.56 (0.38-0.84), an occupational therapist OR=0.61 (0.44-0.85), a physical therapist OR=0.33 (0.17-0.62), a psychologist without doctoral training OR=0.70 (0.55-0.89), or a speech & language specialists OR=0.60 (0.46-0.78).

Conclusions: Differences in access to providers combined with differences in how evaluation by specific provider types translates into community recognition of ASD may contribute to disparities in service access and broader community recognition of ASD in Arizona.

421.015 *(Poster)* Examining the Variability and Resource Burden of Determining ASD Prevalence Estimates within Electronic Health Record Systems

*A. Vehorn and **Z. Warren**, Vanderbilt University Medical Center, Nashville, TN*

Background: The research and public health communities are currently debating the value of varying methodologies for ascertaining autism spectrum disorder (ASD) prevalence.

Survey, record review, screening/assessment, and hybrid methods yield varying estimates over time. Additionally, many of these methodologies are time and labor intensive resulting in reporting delays. For example, there is currently a 2-year time delay in CDC's Autism and Developmental Disabilities Monitoring (ADDM) network methodology. To this end, epidemiologists are exploring the potential value of administrative and computational methods of estimating prevalence of ASD with efficiency and accuracy (e.g. moving toward real-time estimates of ASD).

Objectives: In order to examine the initial variability of electronic health record (EHR) based prevalence estimates, we targeted cohorts of children within a contiguous geography for a series of consecutive birth years (2010-2014). This is the same geography utilized by the Tennessee ADDM Network. These birth years and geography will be represented in pending CDC ADDM 4 and 8-year old surveillance cycles affording for direct comparison of results. We hypothesize that this EHR based method will result in higher prevalence estimates, and that the costs/resources of these estimates will represent a fraction of other review methods.

Methods: Data request was made to the Mid-South Clinical Data Research Network (CDRN), the largest medical network in this area, to extract individuals with current addresses in the specified geography and ICD-9/10 ASD codes present in their EHR. This was completed for consecutive birth years from 2010 to 2014. In addition to diagnostic codes, data regarding basic demographics; race/ethnicity, sex, and geo-codable data were obtained.

Results: We were able to ascertain ICD-9/10 prevalence estimates for ASD across a large geography (entire TN ADDM geography within primary medical source reported in recent surveillance cycles) for 5 birth years within a single week and with estimated costs less than $1000. ASD prevalence ranged from 1:51 (birth year 2013) to 1:55 (birth year 2014 and 2010).

Conclusions: Administrative prevalence estimates obtained from coherent EHR systems may provide quick and resource efficient methods for enhancing understanding of ASD prevalence across large geographies. This method appears to be a currently viable strategy within some large networks. It has the potential to help move toward real-time population estimates across larger age ranges and to yield strategies for understanding prevalence of groups of individuals over time. Although promising, the limited nature of administrative data and errors in estimation will be further investigated and discussed.

421.016 *(Poster)* Frequency of Autism Spectrum Disorder in a Spanish Cohort of Children with Premature Birth

***M. Magan Maganto**[1], R. Canal-Bedia[1], Á. Bejarano[1], M. V. Martín Cilleros[1], A. Calvarro-Castañeda[1], A. Hernández Fabián[2] and M. Posada[3], (1)University of Salamanca, Salamanca, Spain, (2)Hospital Clínico Universitario de Salamanca, Salamanca, Spain, (3)Institute of Rare Diseases Research & CIBERER, Instituto de Salud Carlos III, Madrid, Spain*

Background: Autism Spectrum Disorder (ASD) is a neurodevelopmental disorder that has a higher risk of appearing in children with premature birth, with a recent meta-analysis reporting a general prevalence of 7% (one in every 14) (Agrawal, Rao, Bulsara & Patole, 2018), compared to 1.7% (one in 59) prevalence in the general population (CDC, 2018). With the improvements in neonatal care that have occurred in recent decades, the chances of survival of children born prematurely are greater (Anderson et al. 2011). Although there have been many advances to reduce the incidence of problems associated with premature birth, there is still a high risk of co-occurrence, such as physical and neurodevelopmental disorders for this population, which may even persist in adolescence as behavioral or academic problems or deficits in executive function (Twilhaar, de Kieviet, Aarnoudse-Moens, van Elburg & Oosterlaan, 2018). This makes the population of premature children with ASD a particularly vulnerable group throughout their childhood. Hence the importance to study the expression of ASD in a population with premature birth.

Objectives: The objective of this research is to study the frequency and neuropsychological characteristics of ASD in a cohort of children (7 to 9 years old) with premature birth (below 37 weeks) and/or low birth weight (under 1500 kg).

Methods: A cohort of participants with premature birth, who were between 7-9 years old at the time of the assessment, was selected. Families from the selected cohort were contacted from the hospital by post and/or telephone to explain the research objectives, asking for collaboration in the study and providing informed consent in case of acceptance. Once the signed informed consent forms were received by the research team, families were contacted, and they were offered an appointment to conduct a neuropsychological assessment. When children showed signs of ASD, a referral to the diagnostic unit was made for differential diagnosis.

Results: Of the 133 children who met the inclusion criteria, 120 letters were sent to their families, as 12 of the premature newborns did not survive and one did not have a postal address. 58 families responded by agreeing to collaborate with the study. So far, 46 evaluations have been made, of which four of the children evaluated have ASD (9%). These results are preliminary, and the study is still ongoing, so current results should be interpreted with caution and additional data on participants' neuropsychological characteristics are expected.

Conclusions: In our country there is no study of the frequency of ASD in children born prematurely. The results of this study would be of great importance on a national level, but they would also provide evidence at an international level to better understand the frequency of ASD and associated neuropsychological characteristics in children with premature birth. Results could improve detection procedures and support systems for this at-risk population. In this way, the services could offer a better intervention in the shortest possible time to improve their adaptive functioning and generate a future with a better quality of life for the child and their families.

421.017 *(Poster)* Gears: Gene-Environment Autism Research Study through Collaboration with SPARK Research Match

L. P. Grosvenor[1], *H. E. Volk*[1], *L. Song*[1], *J. I. Feinberg*[1], *J. Daniels*[1], *M. Landrum*[2], *B. Vernoia*[3], *C. W. Lehman*[3], *J. K. Law*[4,5], *C. Ladd-Acosta*[1], *K. S. Benke*[6] *and M. D. Fallin*[1], *(1)Wendy Klag Center for Autism and Developmental Disabilities, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, (2)Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, (3)Simons Foundation, New York, NY, (4)Maryland Center for Developmental Disabilities, Kennedy Krieger Institute, Baltimore, MD, (5)Johns Hopkins University School of Medicine, Baltimore, MD, (6)Mental Health, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD*

Background: Despite evidence for a role of pre- and peri-natal risk factors for autism spectrum disorder (ASD), few studies have examined interactions between genetic variation and perinatal environment in a well-powered setting. The Genes and Environment Autism Research Study (GEARS) leverages data from Simons Powering Autism Research for Knowledge (SPARK; SPARKforAutism.org), an online research platform for individuals with ASD and their families, to enable the study of gene-environment interactions on a large scale.

Objectives: GEARS contacted participating SPARK families with the goal of successfully administering a perinatal environmental questionnaire and obtaining permission to link their genetic and phenotypic data. In this abstract, we aim to demonstrate the feasibility of online recruitment via SPARK, to show the frequency of perinatal risk factors among a subset of SPARK mothers, and to explore crude associations with ASD-associated traits as an initial indication of the utility of this GEARS integrated data.

Methods: SPARK sent email invitations to mothers of children with ASD ages 2 to 12 years who had already provided saliva samples and completed SPARK phenotypic questionnaires. Mothers were first asked if they were interested in participating in GEARS and then asked to complete the GEARS questionnaire, which included questions about the presence of medical risks and other environmental exposures during pregnancy. Fathers were provided the option to decline use of their genetic data in later GEARS analyses. Means and frequencies of self-reported responses were estimated as well as crude associations to ASD severity and traits measured by three questionnaires: Social Communication Questionnaire (SCQ), Developmental Coordination Disorder Questionnaire (DCDQ), and Repetitive Behavior Scale-Revised (RBS-R).

Results: Of the 2,089 mothers invited, 1,346 (64.4%) indicated interest in participating and 1,255 (93.2%) completed the questionnaire. One father opted out. The total time for recruitment and data collection was 6 weeks. Over 90% of mothers rated their GEARS participation experience as "Good" (5 /5) and >80% reported that the research topic is of "High" importance to them (5/5). Forty-eight percent of mothers reported drinking alcohol during pregnancy, 16% smoked, 15.7% of births were premature, the mean BMI of mothers was 27.3 (SD= 8.1), and mean paternal age was 32.7 years (SD= 6.16). Increasing SCQ score was significantly associated with multiple perinatal factors including premature birth ($p<0.001$), paternal age ($p< 0.001$;), maternal BMI ($p<0.05$), alcohol use ($p<0.001$) and smoking ($p<0.05$) during pregnancy. Coordination and repetitive behavior ratings were also significantly associated with premature birth (DCDQ $p<0.001$; RBS-R $p<0.01$), smoking (DCDQ and RBS-R $p<0.05$) and alcohol consumption during pregnancy (DCDQ $p<0.001$).

Conclusions: This study demonstrates the feasibility of fast, online-based data collection to integrate perinatal environmental information into a well-characterized genetic research cohort for ASD and will enable well-powered gene-environment interaction studies. Our preliminary results indicate face validity of the self-reported perinatal based on previously reported means and frequencies and given detected associations with measures of ASD severity and traits. Currently in-progress integration of genetic data for these participants may provide insight to the combined role of environmental exposures and genome-wide genetic risk factors in for ASD.

421.018 *(Poster)* Genetic Liability to Autism and Educational Attainment: Investigating Causal Associations and the Possible Role of IQ through Two-Sample Mendelian Randomization.

C. Dardani[1], *B. Leppert*[2], *L. Riglin*[3], *D. Rai*[1], *L. D. Howe*[4], *G. Davey Smith*[2], *K. Tilling*[2], *A. Thapar*[3], *N. Davies*[2], *E. Anderson*[2] *and E. Stergiakouli*[2], *(1)Population Health Sciences, Bristol Medical School, Centre for Academic Mental Health, Bristol, United Kingdom, (2)Population Health Sciences, Bristol Medical School, MRC Integrative Epidemiology Unit, Bristol, United Kingdom, (3)MRC Centre for Neuropsychiatric Genetics and Genomics, Cardiff University, Cardiff, United Kingdom, (4)MRC Integrative Epidemiology Unit, Population Health Sciences, University of Bristol, Bristol, United Kingdom*

Background: The association patterns of Autism Spectrum Disorder (ASD) with educational attainment seem to be complex. Observational evidence suggests that ASD is associated with poor academic outcomes, while high parental educational attainment seems to be associated with risk of ASD in the offspring. Despite recent evidence on strong positive genetic correlations between ASD and educational attainment, little is known on the causal nature of the associations and the possible role of IQ.

Objectives: A. Assess the bidirectional causal associations between genetic liability to ASD and educational attainment within a Mendelian randomization (MR) framework.

B. Assess whether the identified causal effects were independent of IQ by using an extension of MR, Multivariable MR.

Methods: MR is a form of instrumental variables analysis, using common genetic variants as proxies for exposures of interest and allowing the assessment of their causal effects on health-related outcomes. The method under certain assumptions, has the potential to unpick the direction of the causal effect and investigate the presence of pleiotropy. However, in cases that multiple exposures are suspected to have causal effects on an outcome, and the exposures seem to be genetically and phenotypically related, it can be difficult to disentangle the direct causal effects of each exposure on the outcome through univariable MR. For this reason, we used Multivariable MR, in which multiple exposures are entered within the same model and their direct effects on the outcome can be estimated. The latest GWAS summary statistics for ASD, IQ and educational attainment were used. In order to increase the power of the study, instruments were extracted from the overlapping set of SNPs between ASD, IQ and educational attainment. This ensured that we retained in the analyses as many instruments as possible. Causal effect estimates were generated using Inverse variance weighted models. Sensitivity analyses were performed to assess the robustness of the estimates and the presence of pleiotropy.

Results: There was limited evidence to suggest a causal effect of genetic liability to ASD on educational attainment (MRIVWb= 0.02; 95%CI: -0.04 to 0.08; pval= 0.52). On the contrary, there was evidence consistent with a positive causal effect of genetic liability to higher educational attainment on risk of ASD (MRIVWOR: 1.51; 95%CI: 1.28 to 1.77; pval= 5.5x10-07), which was found to be largely attributed to the effects of IQ (EA: MVMRIVWOR: 1.26; 95%CI: 0.95 to 1.65; pval= 0.10; IQ: MVMRIVWOR: 1.29; 95%CI: 1.02 to 1.64; pval= 0.04).

Conclusions: The present finding of a positive causal effect of genetic liability to higher educational attainment on risk of ASD is likely to reflect parentally transmitted effects. IQ plays a central role in these effects, and this can have important implications for future research in the field of ASD aetiopathogenesis.

421.019 *(Poster)* Global Epidemiology of Autism Spectrum Disorders

J. Zeidan[1]*, M. Elsabbagh*[1]*, A. Ibrahim*[1] *and A. Yusuf*[2]*, (1)McGill University, Montreal, QC, Canada, (2)Psychiatry, McGill University, Montreal, QC, Canada*

Background: According to the WHO most recent estimates, 1 in 160 children worldwide has an ASD. However, this is an average estimate and the last survey on global prevalence of autism and pervasive developmental disorders dates back from 2012. Since then, diagnostic criteria have changed, and many more epidemiological surveys have been conducted. Therefore, it is necessary to have up-to-date estimates from various world regions to inform policy, services, and further research.

Objectives: We conducted an update to the 2012 systematic review of epidemiological surveys of autism worldwide (Elsabbagh et al. 2012).

Methods: We adopted a systematic review methodology in the identification of epidemiological reports of autism published from 2012 to present. We systematically searched online databases including Medline/PubMed for studies that reported prevalence or cumulative incidence of autism disorders. A complementary hand search was performed based on the references. Data was extracted on main characteristics including year and country/region of data collection, age of participants, the presence of intellectual disability, sample sizes, prevalence rates and confidence intervals, diagnostic criteria as well as study design. Analysis was performed by subregions of countries defined according to the WHO classification.

Results: From a total of 1105 records retrieved, 49 studies met the eligibility criteria, with the majority being conducted in Europe and the US. However, relative to the 2012 review, more prevalence estimates are now available from previously under-represented regions including Africa, Eastern Europe, and the Eastern Mediterranean.

The review included studies with various designs including epidemiological surveys, cohort studies, registry and administrative data, with a greater contribution from school-based surveys. Based on the evidence reviewed, the prevalence estimates of autism ranged from 11-390/10 000. The male-to-female ratio ranged between 1 and 5.2.

Consistent with the 2012 systematic review, there was substantial variability in estimates within and across geographic regions. Despite this variability, the evidence reviewed does not support differences in autism prevalence by geographic region. Similar to the last review, a consistent increase in the prevalence estimates over time was found but very few studies since then have addressed controversies related to this time trend.

Conclusions: The results are in line with reports indicating a global increase of ASD prevalence and highlight the recent availability for estimates from some previously under-represented regions. This represents a step towards filling an important knowledge gap. However, there is still a need for more robust data in order to address questions of high public relevance and value worldwide.

421.020 *(Poster)* Grandparental Alcohol and Tobacco Use and Risk of Autism Spectrum Disorder in Grandchildren

M. Pearl[1]*, K. Berger*[2]*, N. Y. Krigbaum*[3]*, P. M. Cirillo*[3]*, V. Poon*[2]*, B. Cohn*[3] *and G. C. Windham*[1]*, (1)Environmental Health Investigations Branch, California Department of Public Health, Richmond, CA, (2)Sequoia Foundation, La Jolla, CA, (3)Public Health Institute, Oakland, CA*

Background: Evidence of multigenerational effects of environmental and nutritional exposures is supported by a growing body of experimental and epidemiologic research. Behavioral changes have been induced in grand-offspring of nicotine-exposed male and female mice. In a recent cohort study in England, smoking during pregnancy by the maternal grandmother was associated with increased risk of diagnosed autism and two autistic traits (Social Communication and Repetitive Behavior) in grandchildren, independent of maternal smoking. No studies have considered the impact of grandpaternal smoking or grandparental alcohol intake on future risk of autism in grandchildren.

Objectives: We sought to evaluate grandmaternal and grandpaternal prenatal smoking and alcohol consumption in relation to risk of autism spectrum disorder (ASD) in their grandchildren.

Methods: The California Health and Development Study cohort includes over 15,000 women (F0) pregnant in Northern California between 1959 and 1967. Women were interviewed in early pregnancy about themselves and their partners. Their offspring (F1) were linked to the next generation's (F2) birth records in California to identify grandchildren, and those were linked to the Department of Developmental Services records to identify ASD cases. Smoking at the time of pregnancy and average weekly number of drinks of wine, beer and hard alcohol were reported by the grandmother. Log-binomial regression models estimated relative risk of ASD with any smoking, any drinking, and weekly number of alcoholic beverages (continuous) for grandmothers and grandfathers, with generalized estimating equations to account for clustering of grandchildren to the same grandparents. Confounders from the F0 generation included grandmaternal age, race, and parity, and grandpaternal education and household income; models of smoking and alcohol were mutually adjusted for each other. In a sensitivity analysis, F1 maternal age and parity were also included as confounders.

Results: The final F2 sample size was 18,149 grandchildren, with 110 ASD cases. Prevalence of smoking and alcohol use around the time of the grandmother's pregnancy was 34.6% and 52.7% among grandmothers, and 42.3% and 74% among grandfathers, respectively. Grandpaternal smoking was related to ASD (adjusted RR=2.03, 95% confidence interval [1.25, 3.3]), but grandmaternal smoking was not (aRR=0.9 [0.6, 1.5]). Increasing total alcohol consumption was suggestive of increased ASD risk (aRR=1.04 [0.96, 1.13] per grandmaternal drink consumed; aRR=1.04 [0.99, 1.10] per grandpaternal drink consumed), with stronger associations for hard alcohol (aRR=1.11 [1.00, 1.24] per grandpaternal drink consumed; aRR=1.15 [0.97, 1.36] per grandmaternal drink consumed). There was no association of ASD with increasing wine or beer consumption, or with any vs. no alcohol consumption, for either grandparent. Adjusting for F1 covariates did not alter results.

Conclusions: The results support a role of perinatal grandparental behavioral factors in risk of ASD in grandchildren, particularly grandpaternal smoking and grandparental alcohol consumption. Larger epidemiologic studies with information on smoking and alcohol in the F0 and F1 generations and animal studies are needed to confirm these findings and investigate biological mechanisms, including epigenetic alterations to the germ line.

421.021 *(Poster)* Health Disparities in Middle and High School Youth with Autism Spectrum Disorder: Participation in Extracurricular Activities, Community Involvement, and School Engagement

A. Curhan[1], *G. F. Azad*[1], *E. Pas*[1] *and H. E. Volk*[2], *(1)Department of Mental Health, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, (2)Wendy Klag Center for Autism and Developmental Disabilities, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD*

Background: Autism Spectrum Disorder (ASD) can put individuals at risk for social isolation, disconnection from work, and diminished community participation in young adulthood. Participation in extracurricular activities, community involvement, and school engagement during secondary school may help buffer against these outcomes by providing individuals with ASD the opportunity to learn prosocial skills, develop initiative, and establish peer relationships. Though prior research indicates that individuals with ASD have lower levels of participation (Ratcliff et al., 2018), sociodemographic differences have not yet been explored.

Objectives: This study examines sociodemographic disparities in participation and engagement among youth with ASD.

Methods: Using data from the 2011/12 and 2016/17 National Survey of Children's Health (NSCH), we examined the rate of parent-reported engagement in sports, clubs, community service, work for pay, homework completion, and school interest. Sociodemographic factors examined included child's race (white vs. not white), parent report of child's sex (male vs. female), parent earning wages below the federal poverty level (yes vs. no), and parental education (high school or less vs. more than high school). We used chi-square tests to identify significant differences in rates of engagement based on each sociodemographic factor.

Results: There were $N = 676$ youth with ASD (mean age = 14.43 +/- 1.71, 82% male, 80% White) in 2011/12 and $N = 586$ youth with ASD (mean age = 14.56 +/- 1.70, 81% male, 81% White) in 2016/17. There were no significant differences in the rate of homework completion or school interest based on any sociodemographic factor examined. In 2011/12 only, youth with ASD were less likely be involved in work if they were female (8% vs. 19%, $p = .003$) or if they had a parent with an education level of high school or less (13% vs. 21%, $p = .01$). Across both years, youth with ASD whose parent reported lower educational attainment were less likely to be involved in clubs (43% vs. 56%, $p < .001$, 21% vs. 43%, $p < .001$, respectively) and sports (26% vs. 40%, $p < .001$, 16% vs. 31%, $p = .01$). In 2011/12 only, youth with ASD had lower levels of engagement in clubs if they came from a family of low SES (35% vs. 50%, $p = .04$). In 2016/17 only, male youth with ASD were less likely to be engaged in clubs (37% vs. 48%, p=.03). Youth with ASD had lower rates of participation in community service if they were not white (51% vs. 66%, $p = .001$ in 2011/12) or if they had a parent with lower educational attainment (58% vs. 69%, $p = .003$ in 2011/2012 and 28% vs. 42%, $p = .01$ in 2016/17).

Conclusions: Across both years, data demonstrate clear demographic disparities among youth with ASD. This was more evident for parents with less education, students of color, and students whose families were low SES. Though some associations were no longer significant in 2016/17, these results suggest a continued need for targeted interventions to promote engagement among youth with ASD to further narrow this disparity gap.

421.022 *(Poster)* Interaction of Blood Manganese Concentrations with GSTT1 in Relation to Autism Spectrum Disorder in Jamaican Children

M. H. Rahbar[1,2,3], *M. E. Samms-Vaughan*[4], *M. Lee*[1,2], *J. Zhang*[1,5], *J. Bressler*[3,6], *M. Hessabi*[1], *M. L. Grove*[6], *S. Pellington*[4] *and K. A. Loveland*[7], *(1)Biostatistics/Epidemiology/Research Design (BERD) core, Center for Clinical and Translational Sciences (CCTS), The University of Texas Health Science Center at Houston, Houston, TX, (2)Division of Clinical and Translational Sciences, Department of Internal Medicine, McGovern Medical School, The University of Texas Health Science Center at Houston, Houston, TX, (3)Department of Epidemiology, Human Genetics, and Environmental Sciences, School of Public Health, The University of Texas Health Science Center at Houston, Houston, TX, (4)Department of Child & Adolescent Health, The University of the West Indies, Mona Campus, Kingston, Jamaica, (5)Department of Biostatistics and Data Science, School of Public Health, The University of Texas Health Science Center at Houston, Houston, TX, (6)Human Genetics Center, School of Public Health, The University of Texas Health Science Center at Houston, Houston, TX, (7)Department of Psychiatry and Behavioral Sciences, McGovern Medical School, The University of Texas Health Science Center at Houston, Houston, TX*

Background: Autism Spectrum Disorder (ASD) is a complex lifelong neurodevelopmental and behavioral disorder, characterized by impairments in social interaction and communication, and by repetitive, rigid behavior. Although the causes of ASD remain largely unknown, the evidence suggests that it is likely the result of interactions between various factors including genetic and environmental exposures occurring in utero or very early in infancy.

Since 2009, our research team has investigated the role of glutathione-S-transferase (GST) genes (*GSTM1*, *GSTP1* and *GSTT1*) that are activated under conditions of oxidative stress, and six heavy metals/metalloids (lead (Pb), mercury (Hg), arsenic (As), cadmium (Cd), manganese (Mn), aluminum (Al)) in relation to ASD in Jamaican children. These genes encode enzymes that play a major role in detoxification by mediating the transfer of reduced glutathione to electrophilic xenobiotic substrates. We have previously observed that blood Mn concentrations (BMC) and *GSTP1* have a significant interaction in relation to ASD.

Objectives: The objective in this study is to investigate the additive or interactive associations of *GSTT1* polymorphisms of GST genes, in relation to ASD in Jamaica.

Methods: We used data from 266 case-control pairs of children 2-8 years old from our autism project in Jamaica. For the *GSTT1* gene, since the assay does not distinguish between a normal homozygote (I/I) and a heterozygote (I/D), we considered only a recessive model using a binary variable to represent their genotype: I* and DD. We used conditional logistic regression (CLR) to compare demographic characteristics and socioeconomic status (SES) including parental education between case and control groups. We categorized BMC into four quartiles and then used CLRs to assess their associations with ASD status and various exposure variables including genotypes for *GSTT1*. Using univariable and multivariable CLR models, we assessed the possible association between the categorized BMC and ASD status and the interaction effects between BMC and *GSTT1* in relation to ASD.

Results: The mean age of ASD cases and typically developing (TD) controls was 63.5 and 64.0 months, respectively. About 81% of the ASD cases and TD controls were male. Nearly all of the ASD cases (95.5%) and TD controls (97%) were Afro-Caribbean. In models using CLR with ASD status as a dependent variable with the categorized BMC and *GSTT1* as independent variables, the interaction between *GSTT1* and BMC was significant ($P = 0.02$). Specifically, considering the lowest quartile blood concentrations of Mn as the referent category, we found that among children with DD genotype, the odds of being in the fourth quartile of BMC was higher for ASD cases than for TD controls (MOR=3.32, 95% CI:1.08 -10.17, $P = 0.04$). Association of BMCs with ASD status among children with different *GSTT1* genotypes based on interactive (metal *GST gene) recessive genetic models using CLR models, adjusted by potential confounders, overall was significant ($P = 0.04$).

Conclusions: Although we found a potential role of *GSTT1* as an effect modifier when assessing the role of BMC in ASD based on interactive models, we believe this finding requires replication in other populations.

421.023 *(Poster)* Investigating the Associations between Genetic Liability for Rheumatoid Arthritis and Autism and Autistic Traits

A. Ly[1,2]*, B. Leppert*[1]*, D. Rai*[2,3]*, H. J. Jones*[1,2] *and E. Stergiakouli*[1,4]*, (1)Population Health Sciences, Bristol Medical School, MRC Integrative Epidemiology Unit, Bristol, United Kingdom, (2)Population Health Sciences, Bristol Medical School, Centre for Academic Mental Health, Bristol, United Kingdom, (3)BASS Autism Services for Adults, Avon & Wiltshire Partnership NHS Trust, Bristol, United Kingdom, (4)School of Oral and Dental Sciences, University of Bristol, Bristol, United Kingdom*

Background: Autism spectrum disorders, hereafter autism, are neurodevelopmental disorders characterised by social interaction and social communication issues in addition to restricted or repetitive patterns of behaviour and interests. Abnormal inflammatory activity is thought to occur in autism.

Higher prevalence of autism in offspring born to mothers with autoimmune disorders such as rheumatoid arthritis has been reported. It is possible that in utero exposure to elevated levels of maternal autoantibodies and inflammation is an underlying mechanism in autism development. Thus far, the relationships between genetic liability for rheumatoid arthritis and autism and autistic traits have yet to be investigated.

Objectives:

1. To investigate the association between maternal and offspring's own genetic liability for rheumatoid arthritis and autism-related phenotypes in the offspring
2. To investigate the possible causal effect of maternal rheumatoid arthritis on development of autism in the offspring

Methods: To capture maternal and own genetic liability for rheumatoid arthritis, standardised polygenic risk scores (PRSs) were constructed using genetic data from participants of the Avon Longitudinal Study of Parents and Children (ALSPAC) and summary statistics from a rheumatoid arthritis genome-wide association study (GWAS) on individuals of European ancestry. Single nucleotide polymorphisms (SNPs) from autosomal chromosomes that passed a 0.05 GWAS p-value threshold were included.

To test genetic association, modified Poisson regression was performed with i) rheumatoid arthritis PRS for ALSPAC mothers and ii) rheumatoid arthritis PRS for their offspring as exposures, and validated cases of autism and severe presentation of four autistic traits in the offspring (social and communication difficulties [SCDC], coherence, repetitive behaviours and sociability) as outcomes. Ten genetic principal components were adjusted for.

To test for causality, bi-directional two-sample Mendelian randomisation (MR) was also performed to assess the possible causal effect of rheumatoid arthritis on autism (instrument selection p-value threshold: 1e-06) and visa versa (instrument selection p-value threshold: 1e-08). Techniques such as inverse-variance-weighting (IVW) and MR-Egger regression were used. Heterogeneity and horizontal pleiotropy were assessed.

Results: As illustrated in Table 1, we found little evidence of associations between i) rheumatoid arthritis PRS for mothers and ii) rheumatoid arthritis PRS for offspring and autism-related phenotypes.

As illustrated in Table 2, our MR results provide little evidence for a causal effect in either direction. There was also little evidence for heterogeneity and horizontal pleiotropy.

Conclusions: There was little evidence for associations between i) rheumatoid arthritis PRS for mothers and ii) rheumatoid arthritis PRS for offspring and autism and autistic traits in the offspring. Our results looking at lifetime risk for rheumatoid arthritis suggest no causal risk of maternal rheumatoid arthritis on autism-related phenotypes.

421.024 *(Poster)* Maternal Dietary Patterns during Pregnancy in Association with Child Autism-Related Traits

R. Vecchione[1]*, C. Zhong*[2]*, R. J. Schmidt*[3]*, L. A. Croen*[4]*, M. D. Fallin*[5]*, I. Hertz-Picciotto*[6]*, C. J. Newschaffer*[7] *and K. Lyall*[8]*, (1)Drexel University, Philadelphia, PA, (2)Department of Epidemiology and Biostatistics, Drexel University, Philadelphia, PA, (3)Public Health Sciences, University of California Davis, Davis, CA, (4)Division of Research, Kaiser Permanente, Oakland, CA, (5)Wendy Klag Center for Autism and Developmental Disabilities, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, (6)University of California at Davis, Davis, CA, (7)College of Health and Human Development, Pennsylvania State University, University Park, PA, (8)A.J. Drexel Autism Institute, Drexel University, Philadelphia, PA*

Background: Maternal diet during pregnancy is critical to fetal neurodevelopment. Emerging research has linked prenatal and periconceptional intake of certain nutrients with autism spectrum disorder (ASD) and ASD-related traits, but research considering combined effects through use of dietary patterns capturing usual intake of a range of nutrients is lacking. Further, while existing research has provided evidence for immune disruption in ASD, studies have not examined dietary patterns related to inflammation.

Objectives: To examine maternal prenatal diet based on the Empirical Dietary Inflammatory Pattern (EDIP), which captures inflammatory potential of the diet, and the Alternative Healthy Eating Index for Pregnancy (AHEI-P), which captures adherence to healthy eating guidelines (and is linked with lower inflammation), in association with child autistic traits and cognitive development.

Methods: Participants were drawn from the Early Autism Risk Longitudinal Investigation (EARLI), an autism-enriched risk cohort that followed mothers who already had a child with ASD through a subsequent pregnancy until that child was age 3. Dietary patterns were derived from intake of foods reported on a validated Food Frequency Questionnaire (FFQ), collected in the first half of pregnancy, according to published guidelines (modified for pregnancy, excluded alcohol, coffee and tea). 189 mother-child pairs with reported prenatal diet and child outcome measures at 36 months, including the Social Responsiveness Scale (SRS) and Mullen Scales of Early Learning (MSEL), were included here. Multivariable linear regression accounting for maternal demographic factors, body mass index, and child sex was used to examine the association between EDIP and AHEI-P scores (in quartiles with the first as reference(Q1)) and SRS (total raw) and MSEL scores (early learning composite). We also examined adjustment for folate.

Results: Crude analyses suggested positive associations between SRS scores and the EDIP (indicating more autistic traits with a more pro-inflammatory diet), and inverse and positive associations with SRS and MSEL scores, respectively, in association with the AHEI-P (indicating fewer autism-related traits and higher cognition related to a healthier diet). In adjusted analyses, AHEI-P associations with SRS scores were not observed (Q3 vQ1 ß =-4.66, 95% CI -17.83, 8.51; Q4vQ1 ß =-7.47, 95%CI -20.17, 5.23), while associations between SRS scores and EDIP were suggestive, though not significant, for the third quartile of the EDIP (ß=11.65, 95%CI-.44, 23.75; Q4 was no longer elevated). Associations were suggested with the third quartile of the AHEI-P (Q3vQ1, ß=11.51, 95%CI 2.53, 20.48; Q4 was no longer elevated) and higher EDIP scores (Q3vQ1, ß=-8.26 , 95% CI -17.38, .87; Q4vQ1 ß=-5.19, 95%CI -14.47, 4.07) in adjusted analyses of MSEL scores. Estimates additionally adjusted for folate were similar.

Conclusions: Results are consistent with the hypothesis that pro-inflammatory maternal dietary patterns may increase ASD-related traits in children, and that healthier/anti-inflammatory maternal dietary patterns may reduce such traits. However, further work is needed to investigate these and other dietary patterns. Because nutrients do not act in isolation in biological pathways relevant to ASD, and maternal dietary patterns capture combined effects of foods and nutrients, targeting dietary patterns may be a key strategy for identifying modifiable risks of ASD-related outcomes.

421.025 *(Poster)* Maternal Fish Intake during Pregnancy in Association with Child Autism-Related Traits

C. Vigna[1], *R. Vecchione*[1], *C. Whitman*[2], *J. Braun*[3], *A. Chen*[4], *G. B. Hamra*[5], *B. Lanphear*[6], *K. Yolton*[7], *L. A. Croen*[8], *M. D. Fallin*[9], *I. Hertz-Picciotto*[10], *E. M. Kauffman*[11], *Y. Xu*[7], *C. J. Newschaffer*[12] *and K. Lyall*[11], *(1)Drexel University, Philadelphia, PA, (2)A.J. Drexel Autism Institute, Philadelphia, PA, (3)Brown University, Providence, RI, (4)University of Cincinnati, Cincinnati, OH, (5)Epidemiology, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, (6)Health Sciences, Simon Fraser University, Burnaby, BC, Canada, (7)Cincinnati Children's Hospital Medical Center, Cincinnati, OH, (8)Division of Research, Kaiser Permanente, Oakland, CA, (9)Wendy Klag Center for Autism and Developmental Disabilities, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, (10)University of California at Davis, Davis, CA, (11)A.J. Drexel Autism Institute, Drexel University, Philadelphia, PA, (12)College of Health and Human Development, Pennsylvania State University, University Park, PA*

Background: Fish is the primary source of omega-3 polyunsaturated fatty acids (PUFAs) critical for neurodevelopment, but also of potential contaminants such as mercury. Guidelines for pregnant women recommend at least weekly intake of fish like salmon, rich in omega-3 PUFAs, and avoidance of larger fatty fish (e.g, swordfish, mackerel, tuna, etc.) that may bioaccumulate certain toxicants. While previous work has suggested positive associations between maternal fish intake during pregnancy and child neurodevelopment, prospective studies focused on ASD-related traits are lacking.

Objectives: To examine the association between prenatal fish intake and child autistic traits and cognitive development.

Methods: Participants were drawn from two US prospective pregnancy cohorts: the Early Autism Risk Longitudinal Investigation (EARLI), an autism-enriched risk cohort, and the Health Outcomes and Measures of the Environment (HOME) Study, a population-based cohort. A total of 426 subjects reported fish intake during pregnancy and child outcome measures collected at age 3 (EARLI) or 3-8years (HOME). Multivariable linear regression accounting for potential demographic confounders, prenatal vitamin and supplement use, and maternal body mass index, was used to examine the association between maternal fish intake and child raw total SRS scores in both cohorts, and cognitive scores in each cohort: Mullen Scales of Early Learning (MSEL) early learning composite scores in EARLI and Bayley Mental Development Index in HOME. Maternal fish intake was categorized by timing in pregnancy, type of fish, and frequency of intake: none, low (monthly), and high (≥once/week). We also examined total intake across pregnancy and consistency of intake across the first half and second half of pregnancy. Secondary analyses examined associations by child sex and cohort-stratified analyses of SRS scores.

Results: Most participants had no or low fish intake across pregnancy (69.7%). In adjusted analyses, relative to no intake, higher fish intake in the second half of pregnancy was associated with increased SRS scores (e.g, greater ASD-related traits; ß=5.60, 95% CI 1.76, 12.97). We also observed a stronger association for women who switched from lower to higher intake (ß=9.44, 95% CI 1.03,17.86). When examining fish type, particularly in the second half of pregnancy, intake of shellfish and fatty fish (including tuna, shark, mackerel, and swordfish) were both associated with increased SRS scores, while intake of salmon was associated with decreased SRS scores (ß=-4.66, 95% CI 10.3, 0.97). Higher fish intake was associated with increased cognitive scores (indicating improved performance) across pregnancy in EARLI (MSEL ß=6.55, 95% CI -1.94, 15.04) but not HOME (Bayley scores ß=-0.78, 95% CI -5.86, 4.31); no clear patterns with fish type emerged. In secondary analyses, cohort-stratified SRS results were similar, and associations with both SRS and MSEL scores for frequency of intake in late pregnancy were stronger in male than in female children.

Conclusions: Findings suggest late pregnancy may be a potential critical window for fish intake in association with ASD-related traits. Continued investigation of these associations with ASD-related traits is needed, particularly examining the relative contribution of beneficial fats vs. potential contaminants in different fish types.

421.026 *(Poster)* Meconium Androgens Are Correlated with ASD-Related Phenotypic Traits in Early Childhood.

D. Terloyeva[1], *A. J. Frey*[2], *E. M. Kauffman*[2], *B. Y. Park*[3], *L. Mathew*[2], *A. Bostwick*[2], *E. L. Varner*[2], *B. K. Lee*[1], *L. A. Croen*[4], *M. D. Fallin*[5], *I. Hertz-Picciotto*[6], *K. Lyall*[2], *C. J. Newschaffer*[7] *and N. Snyder*[2], *(1)Epidemiology and Biostatistics, Drexel University, Philadelphia, PA, (2)A.J. Drexel Autism Institute, Drexel University, Philadelphia, PA, (3)California State University, Fullerton, Fullerton, CA, (4)Division of Research, Kaiser Permanente, Oakland, CA, (5)Wendy Klag Center for Autism and Developmental Disabilities, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, (6)University of California at Davis, Davis, CA, (7)College of Health and Human Development, Pennsylvania State University, University Park, PA*

Background: It is known that steroid hormones are crucial for sex-differentiation of the human fetus and brain development. Several studies have suggested a potential link between steroid hormone levels and autism spectrum disorder (ASD). Previous studies utilizing umbilical cord blood or amniotic fluid have produced inconsistent results which may be due to specimen availability and timing of collection. Notably, access to amniotic fluid is prone to selection bias and androgen concentrations in cord blood represent levels later in pregnancy and do not capture cumulative exposure. To overcome these limitations this study used meconium – the first stool of a newborn – to estimate prenatal androgen exposure.

Objectives: This study investigated the association between levels of the major androgens: testosterone (T), dehydroepiandrosterone (DHEA) and androstenedione (A4), measured in meconium, and ASD-phenotype at 12 and 36 months of age. Analysis was performed on both unconjugated (U-) and conjugated (T-) forms of androgens.

Methods: The sample was drawn from the Early Autism Risk Longitudinal Investigation (EARLI), an enriched risk pregnancy cohort where enrolled families had a child with an ASD diagnosis and an infant sibling was followed prospectively. Meconium androgens were measured by liquid chromatography-mass spectrometry as either the unconjugated or total amount for each androgen. Autistic traits were measured at 12 months with the Autism Observation Scale for Infants (AOSI) and at 36 months with the Social Responsiveness Scale (SRS). Separate robust linear regressions were fit to assess the association between each of the log-transformed androgens and log-transformed total AOSI and SRS scores. A three-way interaction term between sex of the child, sex of the proband, and androgen concentration was introduced into every model. Stratified analyses were conducted for each of the groups defined by the proband's sex and child's sex.

Results: The study enrolled 244 children, of whom 137 (61 males, 76 females) provided data on both outcomes and had meconium androgen measurements. Evidence for the three-way interaction was observed in models predicting AOSI with T-A4 (P=0.047), SRS with U-T (P=0.053), and SRS with U-DHEA (P=0.05). In the adjusted model; T-T, U-A4, and U-DHEA were positively associated with AOSI among females with female probands, predicting 11%, 57%, and 28% increases in the expected AOSI with every 25% increase in the respective androgen concentration. In the same group, U-T and U-DHEA were positively associated with SRS, predicting a 6%, and 21% increase in the expected SRS with every 25% increase in the respective androgen levels. Additionally, higher concentrations (25% increase) of U-T and T-T predicted higher SRS (3% and 4% increase, respectively) in males with male probands.

Conclusions: We observed that the effect of fetal androgen levels on ASD phenotype is different by sex of both the younger sibling and the older affected proband. A positive link between some androgens and quantitative ASD phenotypes have been most frequently found among female children with female probands, which supports the theory postulating greater etiologic liability among relatives of ASD-affected females. However, the findings must be considered within the constraints of the enriched cohort design.

421.027 *(Poster)* Predicting Age of Diagnosis in Children with Autism Spectrum Disorder Using Deep Learning Approaches

C. Wentz[1], *K. Zhou*[2], *C. Bai*[3], *L. R. Ketcheson*[4], *D. H. Charbonneau*[5], *X. Zhang*[3] *and S. Lu*[3], *(1)Department of Kinesiology, Wayne State University, Detroit, MI, (2)Computer Science, Wayne State University, Detroit, MI, (3)Wayne State University, Detroit, MI, (4)Department of Kinesiology, Health and Sport Studies, Wayne State University, Detroit, MI, (5)School of Information Sciences, Wayne State University, Detroit, MI*

Background: Revised estimates of Autism Spectrum Disorder (ASD) suggest that 1 in 59 children are diagnosed with the disorder. While these new numbers represent a heighten awareness on the importance of early identification, the average age of diagnosis in the United States remains after 4 years of age. This is despite the fact that an ASD diagnosis can be made reliably as early as 2 years of age. Given ample research which supports early intervention results in the most optimal outcomes, more information is needed to determine factors contributing to the age of ASD diagnosis. This information may shed light on potential factors placing families at a greater risk to obtain a diagnosis considered late in childhood development.

Objectives: Given the importance of early identification of ASD, the main objective of this study was to analyze a large and representative sample of individuals with ASD to determine any factors that predicted the age of diagnosis. Two big data analysis were applied to predict year of diagnosis. The fully connected neural network (NN) is one of the fundamental architectures building blocks for deep learning, in where one hidden layer with 20 units is applied. The Random Forest (RF) is an ensemble learning method, which constructs a multitude of trees and drives the final classification result by a majority vote policy.Outcomes from this study have the potential to uncover new insight and factors that could facilitate an earlier ASD diagnosis.

Methods: The Simons Foundation Autism Research Initiative (SFARI) is a nationally representative clinical and genetic database that includes data on individuals with Autism as well as their families. Information about participants diagnosed with ASD were extracted from the data set, comprising a sample of 36,174 participants. To investigate participants, 125 different features were extracted and transferred to six categories based on age range such as developmental language level and sleep behavior.

Results: Based on preliminary results from the trained models, the testing accuracy for the RF prediction model is able to predict the age of ASD diagnosis at the accuracy of 85.1%. In the fully connected NN, the model is able to predict the age of ASD diagnosis at the accuracy of 84.3%.

Conclusions: Collectively, this information may lend support for factors that should be considered by clinicians and service providers in the early evaluation and identification of ASD. The current research represents a promising method to uncover factors that could help to facilitate an earlier diagnosis. Finally, given the growing volume of big data initiatives in ASD, future research should continue to explore disparities in age of diagnosis, health and family quality of life.

421.028 *(Poster)* Prenatal Perceived Stress As a Risk Factor for ASD

D. H. Hoang[1] *and R. J. Schmidt*[2]*, (1)University of California, Davis, Davis, CA, (2)Public Health Sciences, University of California Davis, Davis, CA*

Background: The prenatal period is a sensitive time when a mother's behaviors can affect her child's life indefinitely. Specifically, maternal activities during pregnancy and their relation to autism spectrum disorder (ASD) is an area of research that requires more inquiry. In addition to genetic factors, many environmental factors such as what she ingests, inhales, or experiences, has lasting effects on the neurodevelopment of her child[1-4]. Only two retrospective studies[5,6] have shown prenatal stress to be associated with a higher risk of ASD, but there has been no prospective data to show this association. Moreover, a mother's stress during pregnancy may be even more of a concern for high-risk younger siblings of children with ASD[7], which has not yet been studied.

Objectives: The objective of this study is to examine the effects of prenatal perceived stress on high-risk moms as a risk factor for ASD in their child.

Methods: This prospective cohort study includes 265 high-risk pregnant women that already have at least one child with ASD and are at an increased risk of having another child with ASD. The exposure of interest was maternal perceived stress during pregnancy and the outcome of interest was child diagnosis of ASD. Logistic regression models were used to determine the relationship between prenatal perceived stress and ASD, controlling for maternal race and ethnicity, exposure to natural or man-made disasters, diabetes (Type 1, Type 2, and Gestational), hypertension, and preeclampsia. Perceived stress was measured using Sheldon Pearson's Perceived Stress Scale, which is the most widely used psychological instrument to measure perceived stress[8]. Child neurodevelopment was assessed longitudinally from birth through three years of age by trained psychologists and an ASD diagnosis was given if the child met criteria based on an algorithm including Autism Diagnostic Observation Schedule, Second Edition (ADOS-2) comparison score and Mullen Scales of Early Learning (MSEL) score.

Results: In the second trimester, a one point increase in perceived stress score resulted in 8% higher odds of having a child diagnosed ASD (OR 1.08, 95% CI (1.02, 1.14)). In the third trimester, a one point increase in perceived stress score resulted in 11% higher odds of having a child diagnosed with ASD (OR 1.11, 95% CI (1.05, 1.17)). Findings in the first trimester were not significant.

Conclusions: This is the first study to find associations between perceived stress and ASD in high-risk mothers that already have at least one child with ASD. Significant findings in line with previous literature of prenatal stress as a risk factor for ASD. Increased risk of ASD due to increased perceived stress in the second and third trimesters of pregnancy are important findings that could lead to target intervention programs to alleviate or even mitigate stress for women, especially during this window of pregnancy. It is critical to improve our current understanding of stress during fetal development so we can better design and recommend interventions for pregnant women.

421.029 *(Poster)* Prenatal and Perinatal Risk Factors for Autism Spectrum Disorder

J. Kim[1]*, G. Bong*[2]*, M. Oh*[3] *and H. Yoo*[4]*, (1)Psychiatry, Seoul National University Bundang Hospital, Seongnam, Korea, Republic of (South), (2)Psychiatry, Seoul National University Bundang Hospital, Seungnam, Korea, Republic of (South), (3)Psychiatry, Kyung Hee University Hospital, Seoul, Korea, Republic of (South), (4)Psychiatry, Seoul National University Bundang Hospital, Seongnam, Korea, The Republic of*

Background: Identifying modifiable risk factors for autism spectrum disorder (ASD) has important clinical implications, especially in view of the rapid increase in reported prevalence of ASD. It is assumed that environmental factors play a causal role in the development of ASD. However, there was not sufficient evidence to implicate any prenatal or perinatal factor in ASD etiology. Previous studies regarding prenatal and perinatal factors in ASD revealed controversial results.

Objectives: The purpose of this study is to evaluate the prenatal and perinatal history of ASD, as compared to their unaffected siblings, and to identify a number of environmental risk factors that may be associated with the ASD in Korean population.

Methods: Subjects with ASD (ASD) and their unaffected siblings (SIB) were recruited. The clinical best estimate diagnosis of ASD was made for both groups by child psychiatrists according to the Diagnostic and Statistical Manual of Mental Disorders (DSM-5). All subjects with ASD and SIB were assessed using Korean versions of Social communication questionnaire, Autism Diagnostic Interview-Revised and Autism Diagnostic Observation Schedule. Prenatal and perinatal history was obtained from the interview and questionnaire with primary caregivers and each facet was compared in those with ASD and SIB. Differences in parental and child characteristics between children with and without ASDs involving continuous and categorical data were compared using independent t-tests and chi-square tests, respectively. The effect of each prenatal and perinatal factors were compared between probands with ASD and SIB using multiple logistic regression. A multivariable logistic regression was conducted for significant variables ($p < .05$) and borderline significant variables and adjusted ORs with their 95% CIs were generated.

Results: There were 662 probands with ASD (mean[SD] age=87.4[56.3] month; male, 86.7%; IQ=79.12[25.8]). A total of 380 SIB (mean[SD] age=91.0[55.8] month; male, 47.9%; IQ=104.9[19.7]) were included in the analysis. The ASD group showed significantly higher rates of oligohydramnios (OR 8.5, 95% CI [1.1, 66.1]) compared to SIB group. The ASD group also showed higher frequency of neonatal jaundice (OR 1.5, 95% CI [1.1, 2.2]). The frequency of admitting to the neonatal intensive care unit in any reasons (OR 2.4, 95% CI [1.1, 6.5]) and neonatal oxygen supply due to hypoxia (OR 1.7, 95% CI [1.2, 5.2]) were significantly higher in subjects with ASD compared to unaffected individuals.

Conclusions: Findings from our study suggests that prenatal and perinatal conditions, especially oligohydramnios, neonatal jaundice, admitting to the neonatal intensive care unit and neonatal hypoxia, are associated with increased risk of ASD. This might be consistent with the current hypothesis that exposure to ischemic-hypoxic conditions might be related to ASD.

421.030 *(Poster)* Prevalence of Autism Spectrum Disorders in Arizona American Indian/Alaska Native Children

A. Benavides[1]*, F. Gachupin*[2]*, J. Andrews*[1] *and S. Pettygrove*[3]*, (1)Pediatrics, University of Arizona, Tucson, AZ, (2)Department of Family and Community Medicine, University of Arizona, Tucson, AZ, (3)Mel and Enid Zuckerman College of Public Health, University of Arizona, Tucson, AZ*

Background: Autism spectrum disorders (ASD) are developmental disabilities (DD) tracked by the Autism and Developmental Disabilities Monitoring (ADDM) Network, a group of programs funded by The Centers for Disease Control (CDC) since 2000. In 2002, the ADDM network began reporting prevalence estimates by Race and Ethnicity for non-Hispanic White, non-Hispanic Black, non-Hispanic Asian/Pacific Islander and Hispanic of any race. American Indian/Alaska Native (AIAN) prevalence has not been previously reported by ADDM. There are no established prevalence estimates for individuals of AIAN descent.

Objectives: The goal of this project was to provide an initial prevalence estimate for ASD in AIAN children aged 8 years.

Methods: ADDM collects data on children who received clinical or educational services related to ASD or other DDs during the identified study year and were demonstrated to be living in the surveillance area. This project used data for children aged 8 years in 2000 – 2014. Population denominators for calculating ASD prevalence estimates were obtained from the national Center for Health Statistics Vintage Bridged-Race Postcensal Population estimates for children aged 8 years and older by county, race, ethnic origin and sex. The number of children living in the surveillance area was calculated by comparing school enrollment in the included districts to the total enrollment for Maricopa County for 3rd grade in each study year and using that proportion to adjust the postcensal population denominators. The standard coding for ADDM includes classifying all individuals reporting Hispanic ethnicity as Hispanic. Given the numerous tribes in Arizona who are also of Hispanic ethnicity we revised the coding structure to prioritize AIAN race above all data. Population denominators and ASD case counts previously report were used for the non-Hispanic white group and the original ethnicity grouping for Hispanic, any race. Statistics comparing groups included chi-square, prevalence estimates and confidence intervals, and t-tests.

Results: Prevalence estimates for each race and ethnicity grouping differed significantly, with Hispanic children at 6.3 per 1000, AIAN children at 12.6 per 1000 and non-Hispanic White children at 19.5 per 1000. In addition, a comparison of the new Hispanic category excluding individuals who are AIAN demonstrated a significantly lower prevalence than the estimate with Hispanic of any race previously calculated at 10.4 per 1000. Over time, the risk indices for the AIAN group were higher than Hispanics but the gap began closing in approximately 2010. The mean risk index for AIAN is 1.02% and for Hispanics excluding AIAN is 0.63%.

Conclusions: The national ADDM process identifies cases as Hispanic above any race and these individuals have been counted as Hispanic. Reclassifying these individuals as AIAN increases the counts available for estimating prevalence and changes the makeup of the Hispanic group for Arizona. There is a high proportion of individuals of AIAN descent in Arizona relative to other locations in the country. It is important to provide baseline prevalence estimates for ASD in this population to assist tribes in understanding the potential service needs of this growing population.

421.031 *(Poster)* Prevalence of Autism in South Texas Region Reveals Lower Rate in 8 Counties

M. Svoboda[1]*, A. Martinez*[1]*, C. L. Magrane*[2]*, B. de la Cruz*[3,4]*, C. Osonma*[5] *and S. Osborne*[6]*, (1)Baylor College of Medicine, San Antonio, TX, (2)Autism Lifeline Links, San Antonio, TX, (3)PACED Behavior, LLC, San Antonio, TX, (4)Graduate School of Education and Psychology, Pepperdine University, Malibu, CA, (5)Special Reach, San Antonio, TX, (6)Camp CAMP, San Antonio, TX*

Background: Prevalence of Autism Spectrum Disorder (ASD) is found to be much lower in the Hispanic population. Detailed prevalence and incidence data in the South Texas region, which has a large Hispanic population, are unknown.

Objectives: This study estimated the prevalence of ASD in the greater San Antonio, Texas region, and assessed the supply of medical providers in the same region to understand gaps in services needed in this community.

Methods: The study outlined 8 counties in South Texas that comprise the greater San Antonio area (Bexar, Bandera, Comal, Kendall, Atascosa, Guadalupe, Medina, and Wilson Counties), which made up our CBSA (core based statistical area). ASD prevalence was estimated by using data from multiple sources including commercial payors, Medicaid, Medicare, Tri-Care, as well as school district data from those with an educational (rather than medical) diagnosis of ASD. To evaluate the CBSA's supply of local providers, over 330 providers/community workers were contacted across the CBSA and underwent a strategic interview to capture information on important questions regarding autism services in the community.

Results: ASD prevalence in the San Antonio CBSA was found to be 1 in 79, which is slightly lower than the national average of 1 in 59. Prevalence varied slightly by the source: for those ages around 6-11 years, the Medicaid group is 1 in 139, commercial insurance group is 1 in 169, Tri-Care group is 1 in 42. The school districts list the prevalence of an educational diagnosis of ASD at 1 in 70. Gender differences were noted at 4:1 boys to girls - similar to national data. All groups showed a significantly lower prevalence rate among Hispanics (approximately 5:1). It remains uncertain if this is a disparity due to lack of access or socioeconomic status or if there is a genetic predisposition causing a decrease in the autism prevalence in Hispanics. Given the approximately 30,000 births in the CBSA per year, the incidence was estimated at 391 cases per year. In regard to the provider capacity for ASD medical diagnoses and medical treatment, the number of doctors was found to be significantly lacking. In the CBSA, only 3.5% of the market doctors in ASD related specialties actually work with ASD patients. The mix of providers varies significantly at the county level. Given the incidence, the CBSA would need 5.7 multidisciplinary diagnostic teams to meet the need in this area. There are not enough providers to meet the need.

Conclusions: The prevalence of ASD in the Greater San Antonio area is lower than the national average. Gender ratio of ASD was similar to the national average. Prevalence rate among Hispanics was markedly lower than in non-Hispanic whites. In addition, the number of medical providers who diagnose and treat ASD is markedly less than needed to serve the need in this area.

421.032 *(Poster)* Psychotropic Medication Prescriptions in Children with ASD

J. Rast[1]*, A. Roux*[1]*, K. Anderson*[2] *and P. Shattuck*[1]*, (1)A.J. Drexel Autism Institute, Drexel University, Philadelphia, PA, (2)Life Course Outcomes Research Program, Drexel University A.J. Drexel Autism Institute, Philadelphia, PA*

Background: Children with an autism spectrum disorder (ASD) may benefit from medication to treat symptoms of ASD and co-occurring conditions such as attention-deficit/hyperactivity disorder (ADHD), anxiety, and aggression. Prescribing guidelines based on impairment profile are lacking, and clinical practice often takes a trial-and-error approach to prescription use. Only two prescription are approved for use in ASD (risperidone and aripiprazole, both for the treatment of irritability). A national profile of medication use in children on the autism spectrum is lacking and this exploratory study will address that gap.

Objectives: This study will present recent, nationally representative findings of the prevalence of psychotropic medication use in children age 18 and younger with ASD.

Methods: This study used data from the Medical Expenditure Panel Survey (MEPS) to describe psychotropic medication use in children with ASD. The MEPS is a nationally representative panel survey of health, health service use, medical events, health insurance coverage, and pharmacy use in non-institutionalized children and adults in the US conducted by the Agency for Healthcare Research and Quality (AHRQ) in the US Department of Health and Human Services (HHS). We combined MEPS years 2010-2016, resulting in a sample size 561 children with ASD ages 18 and under.

To identify psychotropic drug use, we used the Cerner Multum therapeutic class code to identify psychotherapeutic agents (code 242) from the prescribed drugs file and estimated prevalence of use in children with ASD. We calculated the cost spent on all psychotropic medications in a year for each person and reported the average for out-of-pocket expenditures and total cost. We then examined the frequency of individual medications within this therapeutic class.

Results: Thirty two percent of children with ASD had at least one prescription for a psychotropic medication in the year they were surveyed, and one quarter had six or more. Among children 12-18 years, 51% had at least one prescription for a psychotropic medication, and 42% had six or more. Average yearly expense for medication was $77 out of pocket, with a mean total expense of $2069 per person. Costs were similar in children age 11-18. The most common medication was fluoxetine, with 7% of children having a prescription for that in a year (11% of children ages 12-18), followed by sertraline (5% of all children, 9% of children ages 12-18), risperidone (4% - 6%), aripiprazole (3%), trazadone (3% - 5%), and escitalopram (2% - 4%).

Conclusions: One third of all children with ASD, and half of children ages 12-18, were prescribed at least one psychotropic medication in a year. Most were prescribed more than one. Future research should consider the presence of other co-occurring conditions that are common indications for medication use in children with ASD, including ADHD. Understanding prescribing patterns and how these connect to successful outcomes is an important step to building clinical guidelines for medication use in this population.

421.033 *(Poster)* Quantitative Trait Score Anomalies in ASD-Enriched Risk Families: Discrepancies between Social Responsiveness Scale T-Score and ASD Case Status in Younger Siblings of ASD Probands

K. Lyall[1], *E. M. Kauffman*[1], *M. D. Fallin*[2], *C. Ladd-Acosta*[2], *H. E. Volk*[2], *L. A. Croen*[3], *S. R. Dager*[4], *H. C. Hazlett*[5], *R. Landa*[6], *D. S. Messinger*[7], *S. Ozonoff*[8], *J. Piven*[9] *and C. J. Newschaffer*[10], *(1)A.J. Drexel Autism Institute, Drexel University, Philadelphia, PA, (2)Wendy Klag Center for Autism and Developmental Disabilities, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, (3)Division of Research, Kaiser Permanente, Oakland, CA, (4)Radiology, University of Washington, Seattle, WA, (5)University of North Carolina, Chapel Hill, NC, (6)Center for Autism and Related Disorders, Kennedy Krieger Institute, Baltimore, MD, (7)University of Miami, Coral Gables, FL, (8)Psychiatry and Behavioral Sciences, University of California at Davis, MIND Institute, Sacramento, CA, (9)*Co-senior author, University of North Carolina, Chapel Hill, NC, (10)College of Health and Human Development, Pennsylvania State University, University Park, PA*

Background: The Social Responsiveness Scale (SRS) is a quantitative measure that enables examination of ASD-related traits across the population and has strong agreement with ASD diagnosis. Few studies have detailed SRS scores or thresholds with case status in high familial risk studies, which enroll younger siblings (or their pregnant mothers) of a child already diagnosed with ASD.

Objectives: To examine the distribution of SRS scores and correspondence with ASD diagnosis in younger siblings from ASD-enriched risk studies.

Methods: Participants included 275 children (ages 2.9-9.3, mean 3.4 years) drawn from 4 high familial risk cohorts: the Early Autism Risk Longitudinal Investigation (EARLI), Markers of Autism Risk in Babies-Learning Early Signs (MARBLES), the Infant Brain Imaging Study (IBIS), and four sites from the Baby Siblings Research Consortium (BSRC). We examined SRS score distributions and agreement between published SRS thresholds and ASD diagnosis. Cases with consistent SRS scores (T>=60, the established cut-off consistent with ASD) and cases with inconsistent SRS scores (T <60) were compared on basic characteristics and available neurodevelopmental testing.

Results: 71 of the younger siblings received an ASD diagnosis. Of these, 60% had “inconsistent” T scores (<60, n=43; T score mean=49.3, range=38-59; raw score mean=38.44); the remainder had “consistent” T scores (n=28; T score mean= 72.9, range=61-101; raw score mean=96.39). Parental SRS scores did not significantly differ between the groups, though father scores were slightly higher in the consistent than inconsistent group (T=51 vs 45, respectively; p= 0.21). Proband (the older sibling diagnosed with ASD) scores and ages did not significantly differ between these groups (T~80 in both), though probands were slightly younger in the consistent case group (proband mean age=5.7 years and 6.4 years in the consistent and inconsistent groups, respectively; p= 0.49). The majority of children in both case groups had been administered the preschool version of the SRS (86% and 79% in the inconsistent and consistent, respectively), and 70% of both groups were male. There were not significant differences in demographic characteristics between the groups. In the subset of cases with data available on other neurodevelopmental testing (n=39), Vineland Adaptive Behavior Scales scores were higher in the inconsistent than consistent case group (composite score 88.68 vs 77.76, respectively, p=0.01), but there was no difference in Autism Diagnostic Observation Scale severity score (p=0.51). In comparison to ASD cases, over 90% of children receiving no diagnosis of ASD had T scores in the consistent range (mean T score=45, range 34-84).

Conclusions: We observed lower than expected agreement between SRS T scores and ASD diagnosis in participants from these studies enriched for high familial risk of ASD. This discrepancy did not appear to be fully explained by version differences or potential biases in reporting of traits in the younger sibling (given similarities in proband scores). Further research in larger samples will be needed to address other potential explanations, such as potential diagnostic differences in studies with close follow-up of infant siblings, and/or the presence of greater phenotypic variation (a wider spectrum of symptomatology) of ASD in multiplex families.

421.034 *(Poster)* Reported and Substantiated Child Maltreatment Among Children Identified By the Missouri Autism and Developmental Disabilities Monitoring Network

A. E. Duncan[1], *R. Fitzgerald*[2], *M. Jonson-Reid*[1], *B. Drake*[1] *and J. N. Constantino*[2], *(1)Brown School, Washington University in St. Louis, Saint Louis, MO, (2)Washington University School of Medicine, St. Louis, MO*

Background: Studies have shown that although children with autism spectrum disorder (ASD) are more likely to be reported for child maltreatment than children without ASD from the general population, reports of maltreatment among children with ASD are less likely to be substantiated, and there are no significant differences between children with and without ASD in the prevalence of having a substantiated report. It is unknown, however, whether this pattern holds when children with ASD are compared with children who have substantial aggregations of ASD symptomatology but do not meet full diagnostic criteria for an ASD.

Objectives: The objectives of this study were to estimate the prevalence of past three year reported and substantiated child maltreatment in the past three years among children identified by the Missouri Autism and Developmental Disabilities Monitoring Network (MOADDM) as having clinical or near-clinical level symptomatology, and to investigate whether the nature and conclusions of these reports differ between the two groups.

Methods: State records of reports of child maltreatment from July 1, 2016 to June 30, 2019 were matched with records of children aged 9-17 years who had been identified through MOADDM in 2010, 2012, and 2014 as potential ASD cases (n=1920). Children confirmed as meeting criteria for ASD (n=1242) by ADDM methodology were compared to children whose cases were reviewed on the basis of symptom aggregation but were determined not to meet ASD criteria (n=678) on prevalence of report of child maltreatment, as well as type of maltreatment reported and report conclusion using chi-square and Fisher's exact test.

Results: A similar percentage of children with and without confirmed ASD had a child maltreatment report in the past three years (13.20% vs. 12.24%; p=.55). Among the 247 children with reports, there were no significant differences between groups for type or number of types of maltreatment reported: 57.09% had reports of neglect, 53.04% had reports of physical abuse, 20.24% had reports of emotional abuse, and 10.93% had reports sexual abuse. Two or more types of maltreatment had been reported for 30.7% of children with reports. A higher percentage of reported children with confirmed ASD had a substantiated report than reported children with non-confirmed ASD (7.93% vs. 3.61%); however, this difference fell short of statistical significance (p=.19).

Conclusions: These data critically build upon knowledge of the rates of child maltreatment from population-ascertained cohorts of children with ASD symptomatology and clarify the burden of child maltreatment suffered by this fragile population. Children identified through the MOADDM surveillance system who did not meet criteria for ASD after clinician review did not differ significantly from those who did meet ASD criteria in terms of likelihood of being reported for child maltreatment or having a report substantiated. These findings suggest that previously observed elevations in the prevalence of reports of child maltreatment for children with ASD may not be restricted to children whose burden of ASD symptoms fall above the threshold for clinical diagnosis.

421.035 *(Poster)* School Attainment and Employment of Individuals with Autism Spectrum Disorder: A Prevalence Study Using European Data from Denmark

*G. Toft[1], **C. Liu**[2], J. Menon[1], M. Johnson[3], G. Loss[2] and V. Ehrenstein[1], (1)Department of Clinical Epidemiology, Aarhus University, Aarhus, Denmark, (2)Personalized Health Care Data Science, Real World Data, F. Hoffmann-La Roche Ltd, Basel, Switzerland, (3)Personalized Health Care Data Science, Real World Data, F. Hoffmann-La Roche Ltd., Welwyn Garden City, United Kingdom*

Background: Information on education and employment prospects in adulthood among individuals with autism spectrum disorder (ASD) diagnosed in childhood is limited. The largest study to date among 680 individuals receiving special education services in the United States, reported that 35% of the participants attended college and 55% held paid employment during the first 6 years after high school; however, that study lacked a general-population comparison group.

Objectives: This population-based European study evaluated education and employment among individuals with and without ASD in Denmark.

Methods: A prevalence study was conducted using data from several registries in Denmark. We identified 810 individuals with a diagnosis of ASD recorded before the age of 12 years and 8,100
age-, sex-, and region-matched individuals without ASD. Individuals were born in Denmark between 1989 and 1991 and survived until age 25 years. Log-binomial regression, adjusted for demographics, socioeconomic factors, and comorbidities, was used to estimate prevalence ratios (PRs) with 95% confidence intervals (CIs) for completing primary, secondary, and post-secondary education, and obtained employment by age 25 years.

Results: Most individuals with ASD, and the matched population, were men (86.7%). Compared with the matched members of the general population, individuals with ASD had a higher prevalence of depression (28.6% vs. 12.4%), bipolar disorder (29.9% vs. 5.8%), and attention deficit hyperactivity disorder (26.7% vs. 4.8%). Prevalence of primary school completion was similar between those with and without ASD (96.9% vs. 98.5%; adjusted PR 0.99 [95% CI 0.98–1.00]). Compared with the matched population, those with ASD had a markedly lower prevalence of secondary school completion by age 25 (35.3% vs. 78.2%; adjusted PR 0.64 [95% CI 0.58−0.70]) and post-secondary education completion (8.6% vs. 27.0%; adjusted PR 0.56 [95% CI 0.45–0.70]). Around half (51.4%) of the individuals with ASD did not have a complete set of primary school test results, likely due to attending a special needs or private school without requirement for final test results. Among individuals with a final primary school test score, those with ASD had, on average, higher marks than those without ASD. At 25 years of age, 27.2% of individuals with ASD had employment lasting ≥6 months, compared with 77.7% of individuals in the general population (adjusted PR 0.51 [95% CI 0.45–0.58]). Furthermore, compared with those without ASD, a higher proportion of those with ASD were receiving public benefit (21.4% vs. 10.7%) or pension (35.6% vs. 2.8%).

Conclusions: In a population-based European cohort, individuals with ASD in Denmark had similar prevalence of primary school completion as members of the general population of the same age, sex, and region but had a lower prevalence of completing education beyond primary school and retaining employment. Among those with school test results, individuals with ASD achieved higher marks on average than the general population. Many individuals with ASD were financially dependent on public support. The study was limited to Danish children born 1989–1991 and information on disease severity and IQ was unavailable.

421.036 *(Poster)* School Function and Comorbid Psychiatric Conditions As Mediators to Predict Cyberbullying Involvement in Youth with Autistic Traits in a Nationally Representative Sample

H. T. Lin[1]*, Y. M. Tai*[2] *and S. S. F. Gau*[1]*, (1)Department of Psychiatry, National Taiwan University Hospital & College of Medicine, Taipei, Taiwan, (2)Department of Psychiatry, Beitou Branch, Tri-Service General Hospital, Taipei, Taiwan*

Background: Cyberbullying has become an international concern among youths with autistic traits in the digital age. It requires the attention of professionals in the fields of mental health and education due to its potentially severe consequences such as adjustment disorder, and suicidal behaviors among these victims. However, there is limited knowledge about the mediators for these associations.

Objectives: This study aimed to investigate whether school dysfunction, comorbid psychopathologies, such as anxiety/depression, inattention, hyperactivity/impulsivity, and oppositional behaviors, mediated the link between autistic traits and cyberbullying involvement.

Methods: The data is derived from a nationally representative sample of 9486 students (aged 9-14 years) from 69 schools in Taiwan. Autistic traits were measured by the Social Responsiveness Scale. Cyberbullying involvement was assessed by the Cyberbullying Experiences Questionnaire. Clinical questionnaires for school function and anxiety/depression were examined using the Chinese version of the Social Adjustment Inventory for Children and Adolescents and Child Behavior Checklist, respectively. ADHD-related symptoms including inattention, hyperactivity-impulsivity, and oppositional defiance were assessed by the SNAP-IV. The sample was divided into two groups, respectively, according to the status of cyberbullying victimization and perpetration. We compared demographic data and information from above questionnaires by independent T-test and Chi-squared test. Multiple mediation model was used to examine the mediating effects of comorbid psychopathologies on cyberbullying victimization and perpetration.

Results: The prevalence rates of cyberbullying victimization and perpetration were 14.3% and 8.8% respectively. Cyberbullying victimization and perpetration were positively associated with autistic traits, parent-reported school dysfunction, and comorbid psychiatric conditions. We also found specific mediating effects of hyperactivity/impulsivity and parent-reported school dysfunction on both cyberbullying victimization and perpetration, independent of age and sex.

Conclusions: Our results support a strong association between autistic traits and cyberbullying victimization and perpetration, as well as provide evidence showing some psychopathology such as hyperactivity/impulsivity and school dysfunction mediating such associations. Early identification and intervention of these difficulties may offset the risks of cyberbullying. Our findings need to be replicated in a longitudinal study.

421.037 *(Poster)* Sensory Features and Associated Eating and Sleeping Problems in a Population-Based Sample of Eight-Year-Old Children with ASD

A. V. Kirby[1]*, D. A. Bilder*[2]*, A. V. Bakian*[2]*, J. Davis*[3]*, C. Kingsbury*[4] *and W. M. McMahon*[2]*, (1)University of Utah College of Health, Salt Lake City, UT, (2)Psychiatry, University of Utah, Salt Lake City, UT, (3)Educational Psychology, University of Utah, Salt Lake City, UT, (4)Children with Special Health Care Needs, Utah Department of Health, Salt Lake City, UT*

Background: Sensory features are believed to be highly prevalent among children with autism spectrum disorder (ASD), and can include under- or over-responsivity and unusual sensory interests. Existing literature suggests sensory features may be present in 54-94% of ASD cases (Baranek et al., 2006; Tomchek & Dunn, 2007) and are related to health behaviors including sleeping and eating (Mazurek & Petroski, 2015; Mazurek et al., 2013), yet most studies use clinical or convenience samples, which introduce bias. There is a strong need for population-based studies to understand sensory features in a broader context of children with ASD.

Objectives: The objectives of the proposed analyses are to use a population-based sample of children with ASD to determine the prevalence of sensory-related features among 8-year olds, evaluate differences in sensory-related features by sex, and explore relationships between sensory-related features and abnormalities in eating and sleeping.

Methods: To accomplish the objectives, we used population-based data from the Utah Autism and Developmental Disabilities Monitoring Network (ADDM) project in study years 2010 and 2012 (N=873 eight-year-old children with ASD, 81% male). The sample is 75% White, non-Hispanic, consistent with state demographics. Sensory variables were abstracted from medical and educational records using the Centers for Disease Control and Prevention's ADDM methodology (see Table 1). We examined differences in the occurrence of sensory features by sex and presence of eating/drinking and sleeping problems using chi-square analysis. We used multivariable logistic regression, adjusted for sex, to determine if sensory features are associated with sleeping and eating problems.

Results: Sensory variable frequencies are displayed in Table 1. Collectively, 80.5% of the children had a positive indication for ≥ 1 sensory variable. Presence of sensory features did not differ by sex (X^2=0.15, p=0.70). Significantly more children with ASD who had abnormalities in eating or drinking also had the presence of sensory features (86% vs. 69%; X^2=35.15, p<0.001). Differences were also noted in sleeping difficulties, with 85% of children with sleeping problems also presenting with sensory features (vs. 76%; X^2=9.52, p<0.01). When entered into a multivariable logistic regression models, we identified that children with sensory features were significantly more likely to have eating/drinking problems (Odds ratio: 2.75 [95% confidence interval: 1.95-3.87]) and sleeping problems (Odds ratio: 1.70 [95% confidence interval: 1.21-2.39]).

Conclusions: Our results from a large, population-derived sample support existing literature suggesting high prevalence of sensory features in children with ASD, and relationships between sensory features and eating/drinking and sleeping problems. The frequency of 80.5% identified in this study is on the higher end of previously reported ranges derived from samples of convenience (reports range from 54-94%), which further justifies the inclusion of sensory features in the DSM-5 diagnostic criteria and reinforces their clinical relevance. Although the dataset we used did not allow for more nuanced understanding of the types of sensory features, as would be captured using a standardized sensory measure, our study adds new information about the prevalence of these features among children with ASD.

421.038 *(Poster)* Sex Differences in the Association of Neonatal Thyroid Stimulating Hormone and Autism Spectrum Disorder

J. Ames[1], *G. C. Windham*[2], *K. Lyall*[3], *M. Pearl*[2], *M. Kharrazi*[2], *C. K. Yoshida*[1], *J. Van de Water*[4], *P. Ashwood*[5] *and L. A. Croen*[1], *(1)Division of Research, Kaiser Permanente, Oakland, CA, (2)Environmental Health Investigations Branch, California Department of Public Health, Richmond, CA, (3)A.J. Drexel Autism Institute, Drexel University, Philadelphia, PA, (4)MIND Institute, University of California, Davis, Davis, CA, (5)MIND Institute, University of California, Davis, Sacramento, CA*

Background: Maternal and neonatal thyroid function is essential to neurodevelopment. Exposure to maternal hypothyroid conditions in utero has been linked to autism spectrum disorder (ASD), with one study noting a stronger impact on female offspring. To-date, evidence examining sex differences in the association of neonatal thyroid levels and ASD risk is limited. However, growing research indicates sexual dimorphism in the development and sensitivity of the fetal thyroid gland, with possible implications for long-term health.

Objectives: To determine if relationships between neonatal thyroid hormone levels and subsequent diagnosis of ASD or intellectual disability (ID) differ by sex.

Methods: The Early Markers for Autism (EMA) Study is a population-based, case-control study of children born during 2000-2003 in Southern California. We obtained neonatal thyroid stimulating hormone (TSH) levels measured during routine newborn screening among children later diagnosed with ASD (n=524), ID (n=124), and general population controls (n=402). Controls were randomly sampled from birth certificate files and frequency matched to ASD cases by sex, birth month, and birth year. Using odds ratios (ORs) obtained from multivariate unconditional logistic regression, we examined sex differences in TSH between ASD or ID status vs. controls in models stratified by sex and through inclusion of an interaction term. Sex-differences in TSH relationships were further analyzed with respect to ASD subgroups defined by co-occurring ID (composite scores on standardized cognitive tests less than or equal to 70) and onset type (early onset ASD vs. ASD with regression) ascertained by expert review of records from the California Department of Developmental Services. We examined neonatal TSH both as a continuous (ln-transformed) variable and as quartiles. We adjusted models for matching factors (birth month and year), birthweight, gestational age, maternal education, parity, maternal Hispanic ethnicity, and age at newborn bloodspot collection.

Results: Among controls, males had higher geometric mean TSH levels than females (4.7 vs. 4.0 µIU/ml, p=0.04) whereas TSH levels did not vary by sex among children with ASD (4.4 vs. 4.5 µIU/ml, p=0.78). We observed a positive association between continuous neonatal TSH levels and ASD among female children (adj-OR: 1.99, 95%CI: 1.03-3.75) and no association among male children (adj-OR: 0.91, 95%CI: 0.70-1.19) (p-interaction=0.16). These TSH relationships remained elevated in females for subphenotypes of ASD+ID (adj-OR: 2.39, 95%CI: 0.85-6.77; p-interaction=0.44) and early onset ASD (adj-OR: 3.36, 95%CI: 1.42-7.98; p-interaction=0.10). Sample sizes within female strata of other ASD subphenotypes were insufficient for analysis. Among males, TSH relationships were generally null for all ASD subphenotypes examined. Though the sex interaction was not significant, TSH was also associated with higher odds of ID among females (adj-OR: 3.83, 95%CI: 1.53-9.63) but not among males (adj-OR: 0.92, 95%CI: 0.58-1.46) (p-interaction=0.70). Patterns of association were similar in models using TSH quartiles.

Conclusions: Our findings suggest that neonatal TSH may impact neurodevelopment in a sex-specific manner, with female children demonstrating greater thyroid-related susceptibility to ASD and ID than male children. Given that high neonatal TSH, indicative of thyroid insufficiency, is modifiable, continued study of these sex-differences are needed and could inform future development of sex-specific thyroid therapies.

421.039 *(Poster)* Temporal Trends in Domain-Specific Adaptive Behavior (AB) Scores in Cohorts of 8-Year-Old Children with Autism Spectrum Disorder (ASD)

S. M. Furnier[1], *E. Rubenstein*[2], *M. J. Maenner*[3], *S. Ellis-Weismer*[1], *D. Christensen*[3] *and M. S. Durkin*[4], *(1)University of Wisconsin-Madison, Madison, WI, (2)Waisman Center at UW Madison, Madison, WI, (3)Centers for Disease Control and Prevention, Atlanta, GA, (4)Population Health Sciences, University of Wisconsin School of Medicine and Public Health, Madison, WI*

Background: With increased interest in characterizing level of functioning in individuals with ASD, AB test scores may measure variation in functioning otherwise unaccounted for by measures used to assess severity of ASD symptomatology or cognitive impairment, such as Autism Diagnostic Observation Schedule-2 calibrated severity scores and intelligence quotient (IQ). A previous population-based analysis found that the proportion of children with ASD and significant AB limitations decreased over time between 2000-2010, suggesting that as ASD prevalence has increased so has the proportion with no AB limitations. Whether this trend occurred across all AB domains or was limited to specific domains, however, is unknown.

Objectives: The aim of this study was to expand on this earlier finding regarding trends in AB limitations based on composite AB scores by assessing whether temporal increases in mean AB scores in successive cohorts of children with ASD occurred across specific AB domains: socialization, communication, daily living skills (DLS), motor skills.

Methods: Cross-sectional data from all contributing Autism and Developmental Disabilities Monitoring Network (ADDM) surveillance sites from 2002-2010 and 2014 were pooled. The ADDM Network is a multisite surveillance system incorporating health and school records and clinician reviews to estimate the number of 8-year-olds in the population meeting DSM criteria for ASD. Of the 26,885 ASD cases identified between 2000-2014, a subsample of 8,695 children had domain-specific Vineland Adaptive Behavior Scales (VABS) scores. The association of surveillance year with domain scores from the most recently administered VABS test was estimated through multiple linear regression, controlling for characteristics which differed between those with and without domain scores, including IQ, age at administration of the test, race, age at earliest known ASD diagnosis, and socioeconomic status (SES), as well as test edition, sex, and study site, overall and stratified by IQ, race, sex, and SES.

Results: Overall, the proportion of cases with domain scores indicating mild or more AB limitations (score≤70) decreased over the study period. The average AB domain score change associated with one surveillance year progression ranged from +0.63 (95% CI 0.24-1.01, p<0.01) for motor to +1.68 (95% CI 1.33-2.03, p<0.0001) for DLS. The temporal trend of increasing AB domain scores with successive cohorts generally held when analyses were stratified by IQ and sociodemographic characteristics with the largest increases in every stratum in DLS. In general, associations were stronger in those with IQ>70 relative to those with IQ≤70, girls relative to boys, white relative to non-white children, and high relative to lower SES. Analyses limited to sites contributing data from at least four surveillance years and with AB domain scores available for 20%+ of cases resulted in the same overall trends, with the strongest association in DLS, followed by communication, socialization, and finally motor.

Conclusions: This analysis suggests that with each successive cohort of 8-year-old children with ASD between 2002-2014, AB scores increased within each domain. Further research is needed to understand the reasons for this trend, including potential effects of early intervention or disparities in access to care.

421.040 *(Poster)* The Association between Atopic Diseases and Neurodevelopmental Disabilities in a Longitudinal Cohort

X. Qu[1], *L. C. Lee*[2], *X. Hong*[3] *and X. Wang*[3], *(1)Department of Epidemiology, Johns Hopkins University Bloomberg School of Public Health, Baltimore, MD, (2)Department of Epidemiology, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, (3)The Center on the Early Life Origins of Disease, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD*

Background: With increasing prevalence of atopic diseases and neurodevelopmental disabilities among children in the US, research has been exploring the connection between the two. For example, some reported the link between various atopic diseases with autism spectrum disorders (ASD) and attention deficit hyperactivity disorders (ADHD); however, results have been inconsistent.

Objectives: To investigate whether asthma, atopic dermatitis (AD) and allergic rhinitis (AR) are more prevalent in children with ASD, ADHD, and other neurodevelopmental disabilities (NDDs), compared to those without any NDDs.

Methods: 3153 children enrolled at birth and followed prospectively in the Boston Birth Cohort:160 with ASD, 422 with ADHD (without ASD diagnosis), 1133 with other NDDs, and 1438 without any NDDs. Children with ASD and ADHD were classified in the ASD group. Other NDDs included mental, behavioral and neurodevelopment disorder excluding ASD and ADHD. NDDs, asthma, AD and AR were defined based on ICD codes of physician diagnoses documented in the electronic medical records. Multivariable logistic regressions were carried out to estimate the association (odds ratio (OR) and 95% confidence interval (CI)) between asthma, AD and AR and NDDs (i.e. ASD, ADHD, and other NDDs), respectively. All multivariable regression models adjusted for the following confounders: child sex, birth year, child birth weight, child age at last visit, maternal highest education level, maternal race/ethnicity, maternal age at delivery, maternal pre-pregnancy Body Mass Index (BMI) and maternal smoking during pregnancy. Small proportion of missing values of maternal pre-pregnancy BMI, maternal smoking status during pregnancy, and maternal education level were imputed using the value with highest frequency.

Results: The prevalence of asthma among children with ASD, ADHD, other NDDs and without any NDDs were 31.9%, 40.5%, 30.1% and 21.4%; with the adjusted ORs 1.22 (0.84-1.77), 1.60 (1.24-2.06) and 1.29 (1.07-1.56), respectively. The prevalence of AD among children with ASD, ADHD, other NDDs and without any NDDs were 36.3%, 38.9%, 33.3% and 26.5% respectively; with the adjusted ORs 1.42 (0.99-2.03), 1.68 (1.31-2.15), 1.33 (1.12-1.59), respectively. The prevalence of AR among children with ASD, ADHD, other NDDs and without any NDDS were 24.4%, 33.7%, 25.2% and 15.7%; with the adjusted ORs 1.17 (0.78-1.76), 1.55 (1.19-2.04) and 1.44 (1.17-1.77), respectively.

Conclusions: Overall, there were positive associations between atopic diseases and neurodevelopmental disabilities; however, after child and maternal factors are taken into account, the associations diminished in ASD group. This could be, in part, due to ASD group has the smallest sample size among all NDDs groups. Our findings provide evidence of higher prevalence of atopic diseases among children with NDDs (as compared to those without NDDs) in this US urban population. It is possible that the atopic diseases included in the study share common etiology and that the NDDs are so as well to some extent. It raises the hypothesis that certain pathogenic pathway maybe shared by atopic diseases and NDDs. Findings from this study may inform health care providers and parents to pay more attention on detecting, preventing, and treating atopic diseases among children with NDDs.

421.041 *(Poster)* The Etiological Relationships between Maternal Health and Autism Spectrum Disorder

M. Janecka[1], *A. Kodesh*[2], *S. Levine*[3], *D. Schendel*[4], *J. Buxbaum*[5], *S. Sandin*[5] *and A. Reichenberg*[1], *(1)Seaver Autism Center, Department of Psychiatry, Icahn School of Medicine at Mount Sinai Hospital, New York, NY, (2)Department of Community Mental Health, University of Haifa, Haifa, Israel, (3)University of Haifa, Haifa, Israel, (4)Aarhus University, Aarhus, Denmark, (5)Department of Psychiatry, Icahn School of Medicine at Mount Sinai, New York, NY*

Background: We have shown that mothers of children with autism spectrum disorder (ASD) have considerably higher burden of disease around pregnancy than mothers of unaffected children. Nevertheless, the full spectrum of maternal medical diagnoses has never been comprehensively assessed for their association with offspring ASD.

Objectives: The goals of our study were (i) to identify all maternal medical diagnoses around pregnancy associated with ASD risk in offspring, and (ii) to distinguish the effects of maternal health before, during and after pregnancy on the risk of ASD.

Methods: We used medical information on Israeli children (N=89,483) born 1998-2007 and their parents, to identify diagnoses more common around the pregnancies (pregnancy + preceding 1 year) of mothers of children with ASD, than of mothers of control children. In all analyses, we used logistic regression analysis and controlled for child's year of birth, maternal age and family's socioeconomic status. In order to eliminate the associations arising due to a correlation between diagnoses, we tested the effects of all diagnoses significantly associated with ASD after false discovery rate adjustment for multiple testing ($q < 0.05$) in a joint, penalized regression model. In order to resolve whether these associations are underlain by shared genetic factors, or by disruption of fetal development, we compared the ASD risk associated with maternal number of diagnoses during pregnancy, with the risk associated with diagnoses that are unlikely to directly affect the fetus, i.e. those recorded before or after pregnancy.

Results: Twenty eight ICD-9 codes recorded in mothers 21 months prior to child's birth were associated with ASD in offspring in the initial, single-diagnosis models. Entering these items into a single penalized regression model eliminated all but 13 of these associations, suggesting the issue of phenotype correlation in epidemiological studies. Maternal diagnoses most strongly associated with ASD included psychiatric, metabolic and genitourinary diagnoses (e.g. depression: OR=1.25 (1.04-1.48); non-inflammatory disorders of cervix: OR=1.22 (1.06-1.41); disorders of adrenal glands: OR=1.71 (1.03-2.86)). Comparison of the effects of maternal disease burden before, during and after pregnancy revealed that only the number of diagnoses recorded during and after, but not before, were significantly associated with ASD risk in children (during: OR=1.11 (1.07-1.14), after OR=1.05 (1.01-1.08)).

Conclusions: Our analyses suggest pervasive effects of maternal health on the risk of ASD in offspring. We have identified both known and potentially novel early-life risk factors for ASD, highlight the utility of unbiased, data-driven approaches in epidemiology of ASD.

421.042 *(Poster)* Utilization of the Maternal and Child Health Handbook in Early Identification of Autism Spectrum Disorder and Other Neurodevelopmental Disorders

T. Hirota[1,2], *S. Bishop*[1], *M. Adachi*[3], *M. Takahashi*[3], *H. Mori*[3], *A. M. Shui*[1] *and K. Nakamura*[4], *(1)University of California San Francisco, San Francisco, CA, (2)Graduate School of Medicine, Hirosaki University, Hirosaki, Japan, (3)Research Center for Child Mental Development, Graduate School of Medicine, Hirosaki University, Hirosaki, Japan, (4)Department of Neuropsychiatry, Graduate School of Medicine, Hirosaki University, Hirosaki, Japan*

Background: Despite the importance of incorporating caregivers' concerns about their child's development into the early identification and detection of autism spectrum disorder (ASD) and other neurodevelopmental disorders (NDDs), findings from existing research studies may not reflect concerns that caregivers raise at home while observing their child's behavior and development continuously and prospectively.

Objectives: 1) To examine how prospectively recorded information about the child's early development corresponded with diagnoses of ASD at 5 years of age and 2) to investigate what milestone items can discriminate NDD from non-NDD as well as ASD from non-ASD NDD (intellectual disability, attention-deficit hyperactivity disorder, and developmental coordination disorder).

Methods: Samples are children who participated in developmental checkups, conducted in all 5- year-old children residing in Hirosaki city, Japan. Each NDD case was ascertained following the developmental screening and the subsequent in-person assessment. Developmental milestone data were extracted from the Maternal and Child Health Handbook (MCHH), which is a booklet distributed by municipalities to all pregnant women residing in Japan as universal health care. Binomial logistic regression analysis was conducted to examine the associations between each milestone item of the MCHH and NDD.

Results: Among 720 children who underwent the assessment, 455 children received one or more NDD diagnosis (ASD: n = 124, non-ASD NDD: n = 331). There were 18 milestone items/early signs discriminating NDD from non-NDD; parental concerns about motor milestones emerged first, followed by concerns about social play and speech development. Sixteen items were identified to be early predictors for children who were later diagnosed with ASD compared to non-ASD NDD. These concerns encompassed multiple areas of development, including play, speech, motor, and social interaction. More concerns became noticeable as the child's development progressed. While the motor milestone items became pronounced and started differentiating NDD and non-NDD by 12 months of age, very few milestone items discriminated ASD from non-ASD NDD prior to 24 months.

Conclusions: The present study demonstrated the utility of the MCHH as a tool to educates parents to understand what they need to look for in charting their child's developmental milestones. Additionally, findings from the present study provided us with further understandings of important milestone items that could be early predictors for ASD and other NDDs if not attained by certain developmental periods.

421.043 *(Poster)* Validation of Electronic Health Record Autism Diagnoses in a Pediatric Healthcare Network for Screening and Study Recruitment

S. F. Lynch[1], *E. Schriver*[2], *Y. Lo*[3], *D. Mowery*[3], *R. T. Schultz*[4] *and W. Guthrie*[4], *(1)Institute for Biomedical Informatics, University of Pennsylvania, Philadelphia, PA, (2)Penn Medicine, Philadelphia, PA, (3)University of Pennsylvania, Philadelphia, PA, (4)Center for Autism Research, Children's Hospital of Philadelphia, Philadelphia, PA*

Background: Learning health systems (LHS) merge healthcare delivery with research, data science, and quality improvement processes, in order to facilitate both research and clinical innovations. This work is made possible by the use of electronic health records (EHR) in clinical care, but relies upon methods to identify patients with a specific condition. Within autism spectrum disorder (ASD) research, algorithms that identify ASD patients from clinical notes have been proposed, but they are complex, difficult to implement, and sensitive to the data source, thus limiting generalizability across healthcare systems. Other studies propose simpler International Classification of Disease (ICD) code-based models, but these lack validation against an external data source, relying instead on manual chart review of the EHR itself.

Objectives: Measure the performance of ASD ICD code-based models in identifying patients with ASD as determined by a gold-standard research ASD diagnostic assessment.

Methods: We studied 566 children with parental concerns about or community diagnosis of ASD, who also had EHR data from at least one clinic visit at the Children's Hospital of Philadelphia. Independent gold-standard research diagnostic evaluations confirmed an ASD diagnosis in 79% of this cohort. Performance of the ASD ICD based models was measured by positive predictive value (PPV) and sensitivity. Sensitivity was measured relative to the full cohort, as well as a model specific subcohort with enough visits to make a model positive possible.

Results: Of the 411(73%) patients who had one or more (1+) ASD ICD code in their EHR, 362(88%) received an ASD diagnosis during the research evaluation, yielding a PPV of 88% and sensitivity of 81%. The more restrictive 2+ ASD ICD model yielded a PPV of 89% and sensitivity of 69%. The 1+ Expert ASD ICD model yielded a PPV and sensitivity of 88% and 56%. However, in the subcohort of patients seen by a psychologist, psychiatrist, or neurologist (vs other provider), sensitivity was 91%. The PPV of 1+ ASD ICD before age 5 was 93% with a sensitivity of 21%, increasing to 49% in the model specific cohort. With regards to identifying patients without ASD, the model of 0 ASD ICD yielded a PPV of 44% and sensitivity of 58%. When restricted to patients with 8+ clinical visits, PPV improved to 68% but sensitivity reduced to 32%.

Conclusions: The model of one or more ASD ICD code in a patient EHR performed well, but not perfectly for identifying ASD. Alternative algorithms can increase PPV at the expense of sensitivity. Requiring an ASD ICD code before age 5 improves PPV substantially. This may be helpful when recruiting research subjects from clinical settings, potentially obviating the need for time-consuming research evaluations to confirm diagnosis. In contrast, 2+ ASD ICD codes or expert ASD ICD codes did not significantly improve PPV. Results also indicated that lack of an ASD ICD code is informative, especially for patients who had 8+ visits. Overall, our results demonstrate that EHR diagnoses are remarkably consistent with independent, gold-standard research evaluations, which should facilitate future learning health system research.

421.044 *(Poster)* What Are People Googling about Autism? Trends in Internet Google Queries about Causes and Treatments of Autism over the Past 15 Years: An Exploratory Infodemiology Study

J. F. Huber[1,2,3] *and F. Saposnik*[4]*, (1)Pediatrics, Hospital for Sick Children, Toronto, ON, Canada, (2)Autism Services, ErinoakKids Centre for Treatment & Development, Oakville, ON, Canada, (3)Division of Developmental Pediatrics, Dept of Pediatrics, University of Toronto, Toronto, ON, Canada, (4)McMaster University, Hamilton, ON, Canada*

Background: Over 70% of people search for health information online (Fox, 2013). While the internet has widespread information about autism spectrum disorder (ASD), it has also led to misinformation and perpetuated misperceptions related to the causes and treatment of ASD (Cruchet et al., 2016). Infodemiology is an area of public health informatics research using big data analytics to understand online search behavior. *Google Trends* is the most common infodemiology tool used to analyze online search data (Mavragani et al., 2019).

Objectives: The objectives were to: 1) use infodemiological data to analyze trends in internet searches over time about causes and treatments of ASD; and 2) inform clinicians and ASD/health organizations about public online queries regarding ASD.

Methods: The infodemiology methodology framework for *Google Trends* analyses as outlined by Mavragani et al. (2019) was used. *Google Trends* applies algorithms to assess frequency of online searches comparing different terms. These analyses focused on Google searches in the United States from 2004 (earliest data available) until present (2019). The terms analyzed were comprised of key words from common questions in clinical practice about *causes* of ASD including: vaccines, genetics, environmental factors, and microbiome; and separate analyses for queries about *therapies* including: ABA (applied behavior analysis), gluten free diet, chelation therapy, marijuana, probiotics, and stem cell therapy.

Results: Google Trends results are normalized on a scale ranging from 0 to 100 to represent the frequency and relative interest of search topics. For online searches about *causes* of ASD (Figure 1), vaccines had the greatest search volumes compared to other terms, with an initial peak observed in 2008, reaching the highest frequency in 2015, with a current upward trend. In comparison, searches about the role of genetics, environmental factors and microbiome occurred less frequently.

For online searches about ASD therapies (Figure 2), ABA consistently had a high frequency of online interest since 2004 with a slight decrease between 2010-2013, followed by steadily rising interest. The analyses of chelation therapy and gluten free diet showed high trending interest in 2005 and 2007, respectively, followed by a steady decline since. Searches for ASD and marijuana had an initial rise in 2009 and continue to trend upward, coinciding with increased legalization of marijuana. Searches about probiotics and stem cell therapies have both been relatively low yet are gaining interest, with more overall queries about probiotics than stem cell therapy.

Conclusions: Infodemiology using *Google Trends* is an effective strategy to analyze large-scale data trends in web-searches about ASD. High interest continues surrounding vaccinations and ASD with less searches about the role of genetics. ABA exhibited a consistently high frequency of online interest, while other therapies trended and then lost interest over time (i.e., gluten free diets and chelation therapy). Marijuana, less so probiotics and stem cell therapy, appear to be gaining interest online. This information can be used to inform clinicians, guide clinical conversations and help ASD advocacy/health organizations develop targeted education and online communication strategies to provide up-to-date, accurate and evidence-based information in areas of public online interest.

Epigenetics

POSTER SESSION — **EPIGENETICS**
422 - Epigenetics Posters

422.001 *(Poster)* Altered DNA Methylation in a Severe Subtype of Idiopathic Autism: Sex Differences and Potential for Identifying Epigenetic Signatures for ASD

V. W. Hu[1]*, Y. Hong*[2]*, M. Xu*[3] *and H. T. Shu*[1]*, (1)Biochemistry and Molecular Medicine, The George Washington University, Washington, DC, (2)Planning Systems International, Inc., Arlington, VA, (3)Shanghai Eighth People's Hospital, Shanghai, China*

Background: Although differences in DNA methylation have been associated with both syndromic and idiopathic autism, differential methylation has not been previously examined with respect to sex differences and utility as an epigenetic screen for idiopathic autism spectrum disorder (ASD). Moreover, the clinical heterogeneity of individuals with idiopathic ASD has posed a challenge with regards to identifying significantly differentially methylated genes.

Objectives: The goals of this study were to: 1) investigate differences in the DNA methylation profiles of lymphoblastoid cell lines (LCL) derived from a subgroup of severely affected individuals with idiopathic autism and their respective sex-matched siblings; 2) describe ASD-relevant pathways and functions that may be impacted by the differentially methylated genes; 3) identify sex-dependent differences in methylation patterns; and 4) examine the potential for identifying epigenetic biomarkers in peripheral tissues.

Methods: Individuals with idiopathic autism associated with severe language impairment were identified by cluster analyses of ADI-R scores to reduce clinical heterogeneity among cases. Differentially methylated genes (DMGs) in the DNA of cases and controls, either combined or divided into discovery and validation sets, were investigated using Affymetrix Human Promoter GeneChips and identified using Partek Genomics Suite software. Multi-experiment Viewer microarray analysis software was used for additional statistical and classification analyses to explore the potential of identifying DMGs that can distinguish cases from controls. Pathway and functional analyses of the DMGs were performed using Ingenuity Pathway Analysis software.

Results: This study reveals statistically significant differences in DNA methylation in LCL derived from individuals sampled from a severely affected subgroup of individuals with idiopathic ASD and from their unaffected sex-matched siblings and shows, for the first time, genome-wide, sex-dependent differences in methylation profiles and pathways pertinent to autism. Synaptogenesis, semaphorin, and mTOR signaling pathways are consistently over-represented among DMGs identified from independent paired analyses of cases and controls divided either by sex or by separation into discovery and validation groups. Moreover, the DMGs are statistically enriched in genetically defined autism risk genes. In contrast to DMGs in males, DMGs in females are associated with metabolic pathways that implicate mitochondrial and metabolic dysfunction, especially in fatty acid and branched chain amino acid pathways. Classification analyses using machine learning approaches further demonstrate that a limited number of DMGs exhibit potential to serve as class predictors with moderately high sensitivity and specificity.

Conclusions: DMGs in LCL derived from a severe subtype of idiopathic autism consistently implicate common pathways known to be impacted in ASD. Class prediction analyses suggest the potential for developing an epigenetic screen for ASD.

422.002 *(Poster)* Multi-Omics Approach to Study the Effects of Air Pollution on Neural Cell Development.

K. C. Lewis[1], *S. M. Bilinovich*[1] *and D. B. Campbell*[2], *(1)Pediatrics and Human Development, College of Human Medicine, Michigan State University, Grand Rapids, MI, (2)Department of Pediatrics and Human Development, Michigan State University, Grand Rapids, MI*

Background: Epidemiologic studies have established that air pollution exposure contributes to an increased risk of autism spectrum disorder (ASD) diagnosis. We investigated the effect of a component of air pollution, diesel particulate matter, on neuron development. To understand the whole effect of this toxicant we integrated omics data at the DNA accessibility, RNA expression, and protein abundance levels.

Objectives: 1) Find differential gene expression between control and 4 increasing doses of air pollution. 2) Determine changes in gene promoter accessibility following exposure. 3) Impact of air pollution on protein abundance. 4) Integration of multi-omics approaches to understand exposure effect on biological pathways.

Methods: ReNcell CX cortical neural progenitor cells were exposed to 0, 10, 20, 50 and 100 ug/mL of air pollution for 24 hours. Cells were harvested for RNA-seq to determine gene expression (n=4), ATAC-seq (Assay for Transposase Accessible Chromatin) to determine DNA accessibility (n=2) and mass spectrometry to determine protein abundance (n=3).

Results: RNA-seq revealed a total of 10,098 genes were differentially expressed (q <0.05) following diesel particulate matter (DPM) exposure. At 10 ug/ml, there were 59 genes differentially expressed; at 20 ug/ml DPM, there were 500 genes differentially expressed; at 50 ug/ml DPM, there were 3,806 genes differentially expression; and at 100 ug/ml DPM, there were 5,733 genes differentially expressed. More than 200 of these differentially expressed genes are present on the SFARI database of ASD candidate genes, suggesting a convergence of genetic and environmental influences on ASD risk. Analyses of the downregulated DE genes indicated enrichment of genes involved in gene expression, nervous system process and chromosome organization. Analyses of upregulated genes indicated enrichment of genes involved in neuron apoptotic process, negative regulation of cell projection organization, and negative regulation of neuron differentiation and neurogenesis. ATAC-seq indicated decreased chromatin availability of genes involved in neuron differentiation, neuron projection development, nervous system development and axon development following DPM treatment. DNA promoters that were more accessible following DPM treatment were enriched for detection of chemical stimulus and metabolic processes. Integration of downregulated RNA differentially expressed genes and downregulated proteins resulted in pathway overrepresentation of neuron migration and axon guidance.

Conclusions: The multi-omics data analysis offers a more complete understanding of how neural progenitor cell development is affected following air pollution exposure. We observe an abundance of ASD associated genes significantly differentially expressed at all doses. Further, biological pathways impacted by genetic variants are also impacted by air pollution exposure, suggesting convergent molecular mechanisms.

422.003 *(Poster)* Placental Epigenome-Wide Association Reveals Co-Methylated Loci within 22q13.33 Integrating Genetics and Maternal Environment in the Marbles Prospective Autism Study

Y. Zhu[1,2,3,4], *B. I. Laufer*[5], *C. E. Mordaunt*[2,3,4], *D. H. Yasui*[6], *J. M. Jianu*[1], *R. Marathe*[1], *C. K. Walker*[7], *S. Ozonoff*[8], *I. Hertz-Picciotto*[5], *R. J. Schmidt*[9] *and J. LaSalle*[5], *(1)University of California, Davis, Davis, CA, (2)Genome Center, University of California, Davis, Davis, CA, (3)Medical Microbiology and Immunology, University of California, Davis, Davis, CA, (4)MIND Institute, University of California, Davis, Sacramento, CA, (5)University of California at Davis, Davis, CA, (6)University of California, Davis, United States, CA, (7)University of California, Sacramento, CA, (8)Psychiatry and Behavioral Sciences, University of California at Davis, MIND Institute, Sacramento, CA, (9)Public Health Sciences, University of California Davis, Davis, CA*

Background:

Most autism spectrum disorder (ASD) cases appear to be multifactorial, involving common genetic variation and environmental factors. DNA methylation shows dynamic changes during fetal development and contains the molecular memory of *in utero* experiences such as maternal nutrition and exposures. Placenta, normally discarded at birth, is a potentially rich source of epigenetic biomarkers that can provide mechanistic insight into heterogeneous etiologies of ASD. Unlike most other human tissues, placenta contains partially methylated domains that reflect methylation landscapes in oocytes and pre-implantation stages of development.

Objectives:

This study sought to identify specific regions of differential methylation reflecting ASD risk in placenta for early ASD prediction and biological insight. At each genetic region showing differential methylation, we also are investigating the influence of both common genetic variation and *in utero* maternal environment on DNA methylation levels.

Methods:

We performed whole genome bisulfite sequencing (WGBS) analyses on a total of 179 placenta samples from newborns later clinically classified as having ASD, non-typical development (Non-TD) or typical development (TD). Both male and female samples were included from the MARBLES (Markers of Autism Risk in Babies-Learning Early Signs) prospective high-risk cohort study. This study recruited pregnant women who had a prior child with ASD. In the discovery group (46 ASD and 46 TD), differentially methylated region (DMR) analysis was performed to assess DNA methylation differences between ASD and TD. Analysis of replication with another cohort and prediction with other 87 samples are ongoing. In order to incorporate genetics, whole genome sequencing (WGS) was also performed on a subset of matched cord blood DNA samples (41 ASD and 37 TD).

Results:

In the discovery group, a total of 139 DMRs discriminating ASD from TD placental samples were identified, averaging 2kb in length (methylation difference > 5%, permutation-based $p < 0.05$) (**Figure 1**). These ASD DMRs mapped to 170 genes significantly enriched for functions in development and neural differentiation (adjusted $p < 0.05$). Fourteen ASD hypomethylated DMRs, including two with genome-wide significance, mapped to a single 118 kb block at 22q13.33 (**Figure 1**). Those 14 DMRs had methylation levels highly associated with each other, forming a 22q13.33 methylation block (**Figure 2**). Five out of 14 DMRs in the 22q13.33 block were significantly associated with SNPs located inside the DMRs. Furthermore, methylation levels within five out of 14 DMRs in the 22q13.33 methylation block were significantly associated with measured placenta folate level and 5,10-methylenetetrahydrofolate concentrations (adjusted p-value < 0.05).

Conclusions:

Together, these results suggest that placental methylation levels within the 22q13.33 methylation block were sensitive to both genetic and environmental factors. Further replication analysis is ongoing. These results provide evidence that placental methylation levels reflect the intersection of genetic and environmental etiologic factors in combination with prior results on brain tissue from persons with autism.

Family Issues and Stakeholder Experiences

ORAL SESSION — FAMILY ISSUES AND STAKEHOLDER EXPERIENCES
314 - Family and Community Training, Awareness and Diversity

314.001 *(Oral)* Can Autism Trainings Reduce Implicit and Explicit Stigma? Comparing a Participatory Training to a Training Developed without Autistic Input

K. Gillespie-Lynch[1], *J. Bailey Bisson*[2], *N. Tricarico*[3], *B. Kofner*[4], *A. J. Harrison*[5], *R. Obeid*[6], *S. Saade*[7], *N. Daou*[8] *and P. Bongiovanni*[9], *(1)Department of Psychology, College of Staten Island; CUNY Graduate Center, Brooklyn, NY, (2)Clemson University, Clemson, SC, (3)College of Staten Island, City University of New York, Staten Island, NY, (4)CUNY, NY, NY, (5)Educational Psychology, University of Georgia, Athens, GA, (6)Department of Psychological Sciences, Case Western Reserve University, New York, NY, (7)Psychology, Université du Québec à Montréal, Montreal, QC, Canada, (8)McNeese State University, Lake Charles, LA, (9)CUNY, Staten Island, NY*

Background: As increasing numbers of autistic students enter college, they often exhibit academic strengths (Bakker et al., 2019). However, they also face stigma, which contributes to mental health problems (Botha et al., 2018). Autism stigma is associated with more acceptance of inequality (Gillespie-Lynch et al., 2019), suggesting that social dominance orientation (SDO) contributes to stigma, as it does to generalized prejudice (Bäckström & Björklund, 2007). Online trainings have been used to improve explicit autism stigma among college students in Japan, Lebanon and the US (Gillespie-Lynch et al., 2015; Obeid et al., 2015; Someki et al., 2018). Although implicit stigma has been highlighted as an important target for anti-stigma research (Stier & Hinshaw, 2007), prior research has not attempted to reduce implicit autism stigma. Nor has prior research included autistic students in the process of developing trainings to improve understanding.

Objectives: 1) Examine predictors of explicit autism stigma, including SDO and implicit stigma.

2) Evaluate if a participatory autism training (developed in collaboration with autistic students) or a non-participatory training (developed without autistic input) is more effective at reducing implicit and explicit stigma.

Methods: Four autistic college students and four high school students helped adapt an autism training by making concepts/assessments more accessible/engaging. After pilot assessments of the participatory training with high school (n = 53) and college students (n = 431) in NYC and an initial evaluation of the non-participatory training with college students in Quebec (n = 179) and Georgia (n = 84), we revised the trainings. College students in NYC were randomly assigned to either the participatory (n = 103) or the non-participatory training (n = 102). Pre- and post-tests consisted of an IAT (implicit stigma), social distance scale (explicit stigmal = .87), and a participatory autism knowledge measure (=.84).

Results: A regression revealed that heightened implicit stigma (B = -.18, p = .006), SDO (B = .30, p < .001) and reduced autism knowledge (B = -.21, p = .004) and quality of prior contact with autism (B = -.22, p = .001) predicted explicit stigma ($R2$= .35). Improvements with training in implicit stigma, $F(1, 161) = 36.28$, p < .001, $\eta^2 = .18$, explicit stigma, $F(1, 203) = 4.74$, p = .03, $\eta^2 = .02$, and knowledge were observed, $F(1, 203) = 20.90$, $p < .001$, $\eta^2 = .09$. A trend toward improved explicit stigma following the participatory relative to the non-participatory training was observed (p = .08).

Conclusions: Implicit stigma and SDO contribute to explicit stigma towards autism, suggesting that interventions that have been effective at reducing implicit biases (e.g., receiving feedback about implicit biases and education about strategies to reduce biases; Devine et al., 2012), may also reduce autism stigma. Carefully designed trainings can ameliorate implicit and explicit stigma. Although our participatory training was not significantly more effective than our non-participatory training, our participatory knowledge measure exhibited better internal consistency than published non-participatory measures. Autism trainings can provide insights about factors that shape attitudes toward autism while promoting understanding and acceptance.

314.002 *(Oral)* Feasibility and Impact of the Implementation of Caregiver-Oriented and Non-Specialist Facilitated TEM - Transforming Everyday Moments - Workshops in Argentina

A. Rattazzi[1], *K. Houghton*[2], *P. Landolfi*[1] *and S. H. Cukier*[1], *(1)PANAACEA, Buenos Aires, Argentina, (2)Lancaster University, Asheville, NC*

Background: In many low and middle-income countries such as Argentina, parent-implemented interventions are sometimes the only available treatment for children with ASD. One of such parent-implemented interventions existing in Argentina is called TEM - Transforming Everyday Moments - workshop, a caregiver-oriented workshop intended for caregivers of children diagnosed with ASD under the age of 6 and low verbal abilities. This workshop offers tools to caregivers to promote play, engagement, shared enjoyment and communication skills. Since 2013 more than 100 TEM workshops have been done, reaching more than 1300 caregivers. In 2018, 100 caregivers from the 24 provinces were trained as facilitators via a 2-month online TEM training course, so that they could implement TEM workshops in their cities. This study aims to show the results related to feasibility and impact of this online training course for 100 facilitators.

Objectives: 1) To assess the feasibility of training 100 caregivers as TEM workshop facilitators in the 24 provinces of Argentina via a 2-month online training course. 2) To assess the impact of the implementation of TEM workshops for caregivers participating in the workshops.

Methods: In 2018 100 caregivers of individuals with ASD were selected to participate in the TEM online training course. They were asked to complete multiple-choice assessments after each lesson and submit videos which were evaluated by a tutor. At the end of the online course, facilitators provided a TEM workshop to local caregivers. All participants in the local TEM workshops were invited to complete a feedback survey about the workshop.

Results: 1) Feasibility: 42% of facilitators reached criteria to be certified as facilitators. TEM workshops were implemented in 16 of 24 Argentine provinces. 2) Impact: to date, 794 caregivers have participated in TEM workshops implemented by the online-trained facilitators. In the anonymous feedback survey, caregivers referred the following: a) How useful was the TEM workshop overall? (possible scoring 1-10, 1 being not useful and 10 being extremely useful): 672 scored 10 (84,6%), 75 scored 9 (9,4%), 37 scored 8 (4,7%), 7 scored 7 (0,9%); b) How much do you believe your playing skills have changed after the workshop? (1 being no change and 10 being maximum change): 501 scored 10 (63,1%), 114 scored 9 (14,4%), 137 scored 8 (17,3%), 24 scored 7 (3%), 8 scored 6 (1%), 4 scored 5 (0,5%), 1 scored 2 (0,1%) and 5 scored 1 (0,6%); and c) Would you recommend this workshop to other caregivers?: 790 answered Yes (99,5%), 4 answered Maybe (0,5%), and none answered No.

Conclusions: In countries like Argentina there are many barriers for families to access services for their young children with ASD. In this context, parent mediated interventions can sometimes be the only source of tools and strategies to improve the socio-communicative and play abilities of children with ASD. Training non-specialists via an online course to become facilitators of a free parent-training workshop is a feasible alternative to expand access to services and has a positive impact in caregivers, empowering them and improving joint engagement with their children.

314.003 *(Oral)* Gender Variance in Neurodivergent Children and Youth: A Pond Network Pilot Report

M. C. Lai[1,2,3], *M. R. Palmert*[3], *D. P. VanderLaan*[4], *P. Szatmari*[1,2,3], *J. P. Lerch*[5] *and E. Anagnostou*[6], *(1)Centre for Addiction and Mental Health, Toronto, ON, Canada, (2)Department of Psychiatry, University of Toronto, Toronto, ON, Canada, (3)The Hospital for Sick Children, Toronto, ON, Canada, (4)Department of Psychology, University of Toronto at Mississauga, Mississauga, ON, Canada, (5)Wellcome Centre for Integrative Neuroimaging (WIN), University of Oxford, Oxford, ON, United Kingdom, (6)Holland Bloorview Kids Rehabilitation Hospital, Toronto, ON, Canada*

Background: Gender variance refers to an individual's variation in gender role behaviors and identity, deviating from culturally specific gender norms associated with assigned sex at birth. Previous studies reported increased wishes to become other gender in children diagnosed with ASD or ADHD, mostly measured by a parent-reported single item. Clinical and registry studies also showed increased gender identity variance in autistic compared to neurotypical adults. In our previous community-based study of school-age children that also included those with ASD (N=80) or ADHD (N=247), we used a well-validated parent-report instrument (Gender Identity Questionnaire for Children, GIQC) and found ASD (but not ADHD) children displayed heightened gender variance; moreover, in neurotypical children, gender variance was higher in assigned females than males, and was associated with autistic traits. These findings need to be replicated with better-powered sample. Furthermore, it remains unclear whether gender variance is associated with neurodevelopmental categorical diagnoses or dimensional traits and if this relationship varies with age across childhood and adolescence.

Objectives: In this pilot report from the Endocrine and Sex/Gender Platform of the Province of Ontario Neurodevelopmental Disorders (POND) Network, we investigated a sample of children and youth enriched with clinical diagnoses of ASD or ADHD, including birth-assigned males and females, regarding: (1) how gender variance varies by categorical diagnoses and assigned sex; (2) whether gender variance is associated with dimensional ASD and ADHD traits; and (3) how gender variance varies by age.

Methods: Sample included 371 participants aged 2-21 years enrolled in POND Network: N=165 ASD (mean age 9.4 years; 130 biological male, 35 biological female), N=111 ADHD (mean age 9.9 years; 78 male, 33 female), and N=95 typically developing (mean age 12.6 years; 53 male, 42 female). Gender variance was estimated by the GIQC total score, dimensional autistic traits by the Social Communication Questionnaire (SCQ) total score and the Repetitive Behaviors Scale–Revised (RBS-R) total score, and dimensional ADHD traits (attention- and activity/impulsivity-regulation) by the Strengths and Weaknesses of Attention-Deficit/Hyperactivity-symptoms and Normal-behaviors (SWAN). ANOVA was used to investigate categorial group differences on gender variance. A multiple regression model examined the most significant predictors of gender variance among age, assigned sex, dimensional traits, and categorical diagnoses.

Results: Two-way ANOVA showed significant main effects of diagnosis ($F_{(2, 365)}$=9.6, p<0.001, η_p^2=0.050) and sex ($F_{(1, 365)}$=16.7, p<0.001, η_p^2=0.044) on GIQC score, without significant diagnosis-by-sex interaction ($F_{(2, 365)}$=0.46, p=0.63). Overall, ASD group had higher gender variance than ADHD (p_{Tukey}<0.001) and typically developing groups (p_{Tukey}=0.001), whereas the latter two did not differ from each other (p_{Tukey}=0.94); assigned females, irrespective of diagnosis, had higher gender variance than assigned males. Multiple regression identified significant predictors of gender variance being: sex (standardized coefficient Beta=-0.23), age (Beta=0.14), SCQ score (Beta=0.28) and SWAN activity/impulsivity-regulation score (Beta=-0.33).

Conclusions: Autistic children and youth are more likely to display heightened gender variance than typically developing or ADHD children and youth. Gender variance is higher in assigned females and older children and youth, and those with higher autistic traits and lower activity-impulsivity regulation, even after accounting for categorical diagnostic status.

314.004 *(Oral)* Helping Double Rainbows Shine: How Teachers Support Gender Diverse Youth on the Autism Spectrum.

S. Barber[1]*, S. DiVall*[2] *and F. Orlich*[2]*, (1)University of Washington, Seattle, WA, (2)Seattle Children's Hospital, Seattle, WA*

Background: Autism Spectrum Disorder (ASD) is a neurodevelopmental disorder with social communication impairments that impact peer relationships and school experiences. Research has shown that youth with disabilities and youth who identify as LGBTQ+ face significant risk factors (Murray, 2003; Robinson & Espelage, 2012; Sadowski, 2008), but little qualitative research has been conducted with youth with ASD who identify as transgender or gender diverse (Strang et al., 2018). Kosciw et al. (2016) found that LGBTQ+ youth who could identify at least one supportive adult ally at their school reported having a more positive view of their school's climate. By interviewing adolescents with ASD who identify as transgender or gender diverse, greater understanding of their personal school experiences can be gained, aiding in the development of more supportive teacher practices that meet their needs.

Objectives: To 1) understand how teachers influence the perception of safety and support of gender diverse youth with ASD regarding their gender identity, 2) how teachers influence these students to feel unsupported in their gender identities, and 3) how these students perceive that their gender identities could be better supported in schools.

Methods: This basic qualitative study included 10 participants diagnosed with ASD and identified as transgender or gender diverse (M_{age} = 16.7 years, range = 14-19). Data was collected via one-to-one semi-structured interviews conducted in an outpatient hospital setting. Interviews were transcribed and a coding scheme was developed. Using the coding scheme, thematic analysis was utilized to detect commonalities and themes across interviews.

Results: Participants reported teachers as being a significant source of potential support or invalidation of their gender identities. Teachers who gave space for and respected students' personal agency regarding disclosing gender status, preferred pronouns and names were perceived as more supportive than those who did not honor student agency. Participants also reported that teachers who actively upheld and enforced formal and informal school policies around bullying and homophobic/transphobic rhetoric were more supportive than teachers who passively reacted or ignored such behaviors. Teachers who were open, genuine, and warm were considered more supportive than teachers who were not or appeared to be saying things for personal gain or district requirements. These themes were connected with positive perceptions of support and safety around gender identity for these participants.

Conclusions: Our results support and build on previous findings indicating that teachers influence school climate for LGBTQ+ youth. Youth with ASD who identify as transgender or gender diverse reported that teachers who were warm, genuine, and actively responded to homophobic/transphobic remarks helped build a more positive, supportive school climate regarding gender identity than teachers who reacted passively. Overall, findings provide direction for the development of teacher trainings on discussing LGBTQ+ topics with students, promoting personal student agency around gender identity, and how to actively respond to potential homophobic/transphobic comments and behaviors.

ORAL SESSION — FAMILY ISSUES AND STAKEHOLDER EXPERIENCES
315 - Family Dynamics and Demographic Effects

315.001 *(Oral)* Trajectory of Change in the Observed Couple Relationship Quality of Parents of Children with Autism

H. K. Schiltz[1]*, J. Greenlee*[2]*, D. Bolt*[2] *and S. Hartley*[2]*, (1)Psychology, Marquette University, Milwaukee, WI, (2)University of Wisconsin-Madison, Madison, WI*

Background: In cross-sectional studies, parents of children with autism spectrum disorder (ASD) have been found to differ, in both adaptive and maladaptive ways, in their romantic couple relationship experiences relative to other parents (Hartley et al., 2017; Sim et al., 2016). Little is known, however, about the trajectory of change in the quality of the couple relationship across time in parents of children with ASD. The *Vulnerability-Stress-Adaptation* model (Karney & Bradbury, 1995) posits that changes in couple relationship quality are shaped by the stressors that partners and the couple experience, existing vulnerabilities that each partner brings into the relationship, and ability to use adaptive couple processes to navigate stressors.

Objectives: This study's goal was to explore change in the observed quality of couple interactions across a three-year time span. Additionally, we explored the role of parenting stressors (child's ASD symptoms and co-occurring emotional and behavioral problems) and parent vulnerabilities (Broad Autism Phenotype [BAP] and depressive symptoms) on the initial level and trajectory of change in quality of observed couple interactions.

Methods: This longitudinal study included 378 parents (N=189 couples) of a child with ASD. Data was collected across four time-points, each approximately one year apart. Parents were predominantly White and non-Hispanic, and children had an average of 7.9 years old. ASD diagnosis was documented by an educational or medical professional using the ADOS. The Social Responsiveness Scale -2 (SRS-2; Constantino & Gruber 2012) and the Child Behavior Checklist (CBCL; Achenbach & Rescorla, 2001) were used to measure ASD symptoms and co-occurring emotional and behavioral problems. The Broader Autism Phenotype Questionnaire (BAPQ: Hurley et al., 2007) and Center for Epidemiologic Studies Depression Scale (CESD; Radloff, 1977) were used to measure parent BAP and depressive symptoms. A 7-minute videotaped couple problem-solving interaction in which couples discussed a topic of disagreement was coded using the Marital Interactions Coding Scales (Frosch et al. 1998).

Results: Structural equation modeling using the lavaan package (Rosseel, 2012) in R revealed that on average, global relationship quality demonstrated a significant linear decline across time (β=-0.70, p <0.001). There was a significant negative effect of mother's depressive symptoms on the intercept (level of relationship quality), and a significant negative effect of father's initial level of depressive on the slope of observed relationship quality (β=-0.32, p=0.04). Likewise, there was a significant negative effect of father's BAP on the slope of decline in relationships quality (β=-0.32, p=0.03). Greater levels of depressive symptoms or BAP in fathers were related to more negative decline in relationship quality across time. The effect of child SRS-2 and CBCL on intercept and slope were not significant.

Conclusions: Findings suggest that on average, there is a linear decline in observed global relationship quality of couples with a child with ASD across a span of three years. Rate of decline in couple relationship quality was predicted by father initial level of depressive symptoms and BAP. Child variables did not predict change in relationship quality across time. These findings have implications for programs aimed at enhancing romantic couple relationships.

315.002 *(Oral)* Responsive Parenting Interacts with Child Genetics to Predict Heterogeneous Patterns of Social Development in ASD

B. Caplan[1], *J. Blacher*[2], *A. Eisenhower*[3], *B. L. Baker*[4] *and S. S. Lee*[4], *(1)UC San Diego Department of Psychiatry, Child and Adolescent Services Research Center, San Diego, CA, (2)Graduate School of Education, University of California Riverside, Riverside, CA, (3)University of Massachusetts Boston, Boston, MA, (4)Psychology, UCLA, Los Angeles, CA*

Background: Autism spectrum disorder (ASD) is characterized by substantial heterogeneity in social phenotypes (Masi et al. 2017). Emerging research suggests that social environments such as parenting and individual genetic variants both play key roles in the social development of children with or without ASD. However, a more nuanced understanding of how these factors interact is needed to: (1) parse apart diverse sources of social heterogeneity in ASD, (2) resolve inconsistencies in the literature, and (3) develop and select optimal treatments based on individual differences.

Objectives: Given the need to characterize novel sources of heterogeneity in ASD, the present study sought to: (1) evaluate the interactive or additive effects of responsive parenting and biologically plausible candidate genes (5-HTTLPR, DRD4, OXTR) in predicting trajectories of social functioning over time, (2) test competing models of GxE (i.e., diathesis stress vs. differential susceptibility), and (3) assess child emotion regulation as a mechanism of GxE.

Methods: Participants were 104 children with ASD ages 4 to 7 years (M = 5.6 years) and their primary parent (89% mothers) sampled from a multi-site longitudinal study of developmental processes in ASD. Eligible participants met criteria for ASD using gold-standard methods (ADOS-2) and exhibited IQ ≥ 50 (on WPPSI-III). Children were assessed at three additional time points across 1.5 years. Parents and children participated in a free play parent-child interaction at Time 1, which was coded for responsive parenting using an established coding system (PDI-R; Caplan et al., 2019). Teachers provided assessments of child social functioning (SSiS) at all three time points, and parents reported child emotion regulation abilities (Emotion Regulation Checklist) at Times 2 and 3. Children and parents were invited to provide DNA saliva samples (Oragene; OG-500) as part of a follow-up procedure. Covariates (parent genotype, race/ethnicity) controlled for gene-environment correlation artifacts.

Results: Structural equation models revealed that the association between responsive parenting and social skills growth over time was significantly moderated by child genotype. Results for 5-HTTLPR suggest a *differential susceptibility* model of GxE (β = 0.20, p <.01; see Figure 1), such that children with the SS genotype demonstrated more positive growth in teacher-rated social skills with higher levels of responsive parenting, and less growth with low responsive parenting. DRD4 interacted with responsive parenting in a *diathesis stress* manner (β = 0.26, p =.03; see Figure 2), such that children with the 7-repeat allele (7+) fared worse in the context of low levels of responsive parenting only. OXTR did not moderate the relationship between responsive parenting and social skills growth, nor did parent-reported emotion regulation mediate the GxEs found.

Conclusions: Findings of the present study are preliminary and require replication in larger samples, yet highlight the importance of taking a biopsychosocial approach to understanding phenotypic heterogeneity in ASD. That 5-HTTLPR and DRD4 moderated parenting effects suggest a potential role for serotonin and dopamine systems in environmental sensitivity in ASD. Elucidation of GxEs in ASD will help to inform targeted treatment efforts based on individual differences.

315.003 *(Oral)* Exploring the Experiences of Families of Latino Children Newly Diagnosed with ASD

C. N. Coffield[1], *D. M. Spitalnik*[2], *J. F. Harris*[3] *and M. J. Jimenez*[4], *(1)Pediatrics, Rutgers RWJ Medical School, New Brunswick, NJ, (2)Pediatrics, Rutgers Robert Wood Johnson Medical School, New Brunswick, NJ, (3)Children's Specialized Hospital, Mountainside, NJ, (4)Departments of Pediatrics & Family Medicine and Community Health, Rutgers Robert Wood Johnson Medical School, New Brunswick, NJ*

Background: Latino children experience disparities in age of diagnosis of ASD and linkage to Early Intervention Services and subspecialty care, despite the evidence that early identification and intervention improves outcomes. To gain insight into the factors that impact these processes, this study investigated the experiences of Latino families with young children during the critical first year following ASD diagnosis.

Objectives: The goal of this study was to understand the impact of ASD diagnosis on Latino families and the pathway(s) from initial identification of concerns to receipt of diagnosis and linkage to services across the first year post-diagnosis.

Methods: We conducted semi-structured interviews with Latino parents whose children were diagnosed with ASD during the previous 3-6 months. Parents were invited to participate in two interviews: 1 at time of first follow up appointment, and another 6 months later. Interviews were recorded and transcribed verbatim in the language in which they were conducted. Spanish interviews were then translated to English by a professional translation service and reviewed by bilingual study team members for accuracy. Qualitative data was analyzed iteratively as it was collected using the constant comparative method. We met regularly to develop and revise the coding tree. Divergent views among team members were resolved by consensus. Themes were identified through a process of immersion/crystallization. An advisory committee composed primarily of Latino stakeholders contributed to the development of interview questions and provided cultural context throughout the research process, including review of findings, to establish trustworthiness.

Results: Twenty Latino parents of 21 children newly diagnosed with ASD were interviewed at time 1, 3-6 months post-diagnosis. Nineteen families of 20 children were also interviewed again at time 2, about 6 months later. At time 1 children averaged 39 months of age (range=22 - 61 months). Four major themes emerged from the interviews: (1) Families did not feel heard when sharing concerns about their child's development with professionals for the first time; (2) Parents were surprised that the diagnostic process relied on parental description of child development and behavior, as well as observation of the child and not on medical tests; (3) Characteristics of autism were more behavioral and less physical than parents expected; and (4) Having a child diagnosed with autism is a significant moment for families, and is impacted by the way the clinician shares the diagnosis.

Conclusions: Latino parents in our sample described barriers that affected the timeliness and experience of receiving a diagnosis of ASD for their child. These findings have important implications for clinicians, particularly around enhancing communication with families. Respecting and validating parental concerns, not assuming knowledge of ASD or the diagnostic process, and attending to all facets of both verbal and non-verbal communication with parents when sharing a diagnosis all emerged as important considerations for pediatric providers.

315.004 *(Oral)* The Effects of Family Sociodemographic Factors on the Autism Spectrum Disorder Diagnostic Process from a Clinic Intake Perspective

K. N. Dovgan[1]*, K. Nowell*[2]*, R. M. O'Donnell*[3] *and B. Sutton*[4]*, (1)Psychology, Marist College, Poughkeepsie, NY, (2)Thompson Center for Autism & Neurodevelopmental Disorders, Columbia, MO, (3)Health Psychology, Thompson Center for Autism & Neurodevelopmental Disorders, Columbia, MO, (4)University of Missouri, Columbia, MO*

Background: With growing awareness of Autism Spectrum Disorder (ASD), screening and referrals for diagnostic evaluations have increased. However, there are disparities in the diagnostic process across demographic backgrounds. Contributing factors include socioeconomic status (SES), lack of access to healthcare, and difficulty navigating the healthcare system.

Objectives: This project aimed to assess the impact of socio-demographic factors on the diagnostic process of children with suspected ASD. We hypothesized that the intake process would take longer for individuals from marginalized backgrounds.

Methods: This study used referral-tracking data collected between March 2011 and July 2018 at a reputable clinic specializing in ASD. The sample included 6,098 patients referred for diagnostic clarification. Variables included age of patient, gender of patient, distance to the clinic, and family's SES (a composite score of median income, free & reduced lunch rates, and high school graduation rates for the patient's zip code). We used multivariate regressions to investigate the relation between socio-demographic factors and whether a referral packet was returned, whether an evaluation was completed, and time lag between diagnostic processes.

Results: Patients were typically 6.45 years old (SD = 4.65) and male (76.6%). Families lived an average of 85.17 miles (SD = 66.15) from the center. The average SES was 5.20 (SD = 1.00), where 1 represented low SES and 15 represented high SES. 3,689 families (60.5%) returned their referral packet, but then only 57.9% eventually underwent a diagnostic evaluation. The average time between referral and return of packet was 98.10 days (SD = 163.20). The average time between referral and diagnostic evaluation was 334.23 days (SD = 214.56).

Controlling for covariates, only age and distance were significant predictors of returning a packet. After the clinic received a packet, younger children were more likely to undergo a diagnostic evaluation. Controlling for covariates, further distance predicted quicker packet return times and quicker time to evaluation. In addition, a child's age predicted longer delays to an evaluation.

Of the families that did return a packet, most of the patients were male (77%), not Hispanic (94.5%), had public (60%) or private (39%) insurance, and were not eventually diagnosed with ASD (61.8%). The households were typically Caucasian (89.65%), had incomes under $50,000, had High School (32.7%) or Some College (33.5%) education, and had 3.99 dependents (SD = 1.47).

Conclusions: These results describe some of the impact of the clinical intake process on current health disparities in ASD. Our study did not support previous research findings that SES is a significant obstacle to obtaining diagnostic services. However, our study did find significant differences for families who lived farther from the clinic and had older children. These results have practical significance for families navigating the diagnostic system for their child with developmental delays, for clinicians invested in improving the screening process for diverse families, and for researchers interested in describing and predicting evaluation outcomes.

POSTER SESSION — FAMILY ISSUES AND STAKEHOLDER EXPERIENCES
423 - Family Issues and Stakeholder Experiences Posters

423.001 *(Poster)* "Having All of Your Internal Resources Exhausted Beyond Measure and Being Left with No Clean-up Crew:" Defining Autistic Burnout

D. M. Raymaker[1]*, C. Nicolaidis*[1]*, S. K. Kapp*[2]*, M. E. Hunter*[3]*, A. R. Teo*[4]*, N. A. Steckler*[4]*, B. L. Lentz*[1]*, A. Delos Santos*[1]*, A. Joyce*[3] *and M. Scharer*[1]*, (1)School of Social Work, Portland State University, Portland, OR, (2)Department of Psychology, University of Portsmouth, Portsmouth, United Kingdom, (3)AASPIRE Community Council, Portland, OR, (4)Oregon Health & Science University, Portland, OR*

Background: Autistic burnout is an urgent issue within the adult autistic community, described as a state of incapacitation, exhaustion, and distress often resulting in loss of vocation, health, and quality of life, and, at times, leading to suicidal behavior. Yet little is known empirically about autistic burnout.

Objectives: We aimed to use a community-based participatory research (CBPR) approach to gain a deeper understanding of autistic burnout, to begin to characterize it, and to explore its potential links to suicidal behavior through qualitative analysis of public writings and existing and new interviews with autistic adults.

Methods: The Academic Autism Spectrum Partnership in Research and Education (AASPIRE) used a CBPR approach to conduct this study. AASPIRE is a long-running CBPR collaborative comprised of autistic people, academic researchers, family members, disability professionals, and clinicians, many of whom identify as belonging to multiple roles. Autistic community partners directed and participated in all aspects of this study including identifying the research topic, developing the grant proposal, creating study materials, analyzing and interpreting data, and creating dissemination materials. We compiled 19 interviews and 19 public internet sources on autistic burnout. Interview participants were a U.S. national sample of autistic adults who identified as having been professionally diagnosed with an autism spectrum condition. We conducted a thematic analysis, using a hybrid inductive and deductive approach, at semantic and latent levels, through a critical paradigm. We addressed trustworthiness through multiple coders, peer debriefing, and examination of contradictions.

Results: Autistic adults described the primary characteristics of autistic burnout as chronic exhaustion, loss of skills, and reduced tolerance to stimulus. They described burnout as happening because of life stressors that added to the cumulative load they experienced, and barriers to support which created an inability to obtain relief from the load. These pressures caused expectations to outweigh abilities resulting in autistic burnout. Autistic adults described negative impacts on their health, capacity for independent living, and quality of life, including resultant suicidal behavior. They also discussed a lack of empathy from neurotypical people and described acceptance and social support, time off / reduced expectations, and doing things in an autistic way / unmasking as associated with their experiences of recovery from autistic burnout.

Conclusions: Autistic burnout appears to be a phenomenon distinct from occupational burnout or clinical depression, as it had different defining characteristics. Better understanding autistic burnout could lead to ways to recognize, relieve, or prevent it, including highlighting the potential dangers of teaching autistic people to mask or camouflage their autistic traits, and including burnout education in suicide prevention programs. These findings highlight the need to reduce discrimination and stigma related to autism and disability. We are currently using the findings to develop and test a new measure of autistic burnout.

423.002 *(Poster)* "I Think It's the Way of the Future": Stakeholders' Perspectives on Participatory Research within the Autism CRC

J. den Houting *and E. Pellicano, Macquarie University, Sydney, Australia*

Background: Participatory approaches to research are gaining increased popularity as efficacious methods for conducting health research and research with minority populations. Such approaches engage community stakeholders not only as research participants, but as active and equal partners in the research process. A growing evidence base indicates that these approaches result in research that is more relevant, appropriate, and beneficial to the target community. In autism research, though, participatory research remains rare. In Australia, the Cooperative Research Centre for Living with Autism (Autism CRC) has been at the forefront of a movement to increase community engagement in autism research. Despite these organisational efforts, it is unclear whether individual stakeholders are similarly dedicated to participatory research.

Objectives: This study sought to understand Autism CRC stakeholders' experiences of, and attitudes towards, participatory research. We investigated participants' understandings of participatory research, and their own experiences of participatory research to date. We also examined participants' perceptions of the benefits and challenges of participatory research, and gathered their suggestions for ways to facilitate future community engagement. Finally, we gained their views on the potential systemic and contextual factors that impact upon community engagement in autism research.

Methods: Participants were a subsample from a larger participant group (n = 65) who completed an online survey investigating participatory research within the Autism CRC. Within the online survey, 25 (38%) participants indicated a willingness to engage in a follow-up interview. All participants were academic partners (research professionals and research students) or community partners (autistic people, family members, service providers etc.) involved in Autism CRC-funded research projects. Interviews were semi-structured, and conducted via web-conferencing or face-to-face.

Results: Data collection is ongoing, with 16 interviews completed to date. Participants include 11 academic partners and 5 community partners, including 4 autistic adults. Interviews range from 40 - 64 minutes, with an average of 52 minutes.

Based on preliminary analyses, participants demonstrated consistent but somewhat superficial understanding of participatory research. Most participants described participatory research in terms of community engagement "at every stage of the research process", but few mentioned key participatory concepts such as power-sharing. Participants also described experiences of community engagement largely at a consultative level, although many stated that they would prefer their research to be more participatory. Importantly, participants commented on a perceived shift in the broader autism research context, describing autism research as becoming more respectful towards and inclusive of autistic people.

Conclusions: Initial analysis indicates that autism stakeholders have a fundamental understanding of participatory research and are supportive of increased community engagement in autism research – consistent with the Autism CRC's focus on participatory research. Participatory practices, however, appear to lag behind stakeholder attitudes, suggesting that there is considerable room for improvement to ensure the genuine engagement of community partners in Autism CRC research.

423.003 *(Poster)* A Case Study Exploring How the Special Interests of a Group of Female/Gender Non-Binary Autistic Adults Promote or Hinder Their Ability to Thrive

H. M. Brown[1]*, E. Bochinski*[2]*, M. J. Searle*[3]*, K. Howard*[1]*, L. Trafford*[1]*, E. Gaudet*[4]*, R. E. Hudson Breen*[5] *and S. Thompson-Hodgetts*[6]*, (1)Educational Psychology, University of Alberta, Edmonton, AB, Canada, (2)Centre for Autism Services Alberta, Edmonton, AB, Canada, (3)Queen's University, Kingston, ON, Canada, (4)Educational Psychology, University of Alberta, Edmonton, AB, CANADA, (5)Department of Educational Psychology, University of Alberta, Edmonton, AB, Canada, (6)University of Alberta, Edmonton, AB, Canada*

Background: Adults with autism are among our most vulnerable and poorly-served citizens as many have few close friends, are dependent on families, and struggle with employment. In other words, many are “failing to thrive.” One theoretical framework for ‘thriving’ in neurotypicals suggests that it occurs over time through the complex interplay between (1) the person’s sparks and (2) the support from sources that nurture those sparks (Benson & Scales, 2011). Researchers define ‘sparks’ as “a passion for a self-identified interest, skill, or capacity that metaphorically lights a fire in [a person’s] life, providing energy, joy, purpose, and direction”(Scales et al., 2011, p264). Thus, the special interests (SIs) of autistics should theoretically hold great promise for fostering their ability to thrive given that as many as 95% of autistics hold SIs, and their time spent pursuing SIs can amount to that of a part-time job.

Objectives: To understand how autistic adults feel their SIs promote or hinder their ability to thrive.

Methods: An autism service provider and researchers created a series of support sessions for women/gender non-binary autistics around employment experiences. We used a participatory approach such that autistic researchers (students and professor) were part of the research team. Participants created a graffiti wall using the spark questions (Table 1b), forming a visual display of the cumulative thought process of the group (Figure 1). Data sources included the graffiti wall and transcripts of participant dialogue during and after its creation. Participants also completed the Workplace PERMA Profiler, a survey of “flourishing” (similar to thriving), which examines well-being across five domains. (Scores range from 1 to 10; Table 1a). Using a mixed methods approach to integrate the qualitatively generate data (analyzed using a purely inductive, grounded method) with the PERMA measure allowed us to examine the convergence between the two data sources.

Results: Graffiti wall: Participants reported a large number of sparks (n=28), and all reported more than one. They also reported that many people in their lives nourished or had knowledge of their sparks. And, there was a high level of agreement that having a safe space was critical for the expression of their sparks and that neurotypical expectations and societal norms interfered with their sparks. Survey: Mean Workplace PERMA Profiler scores tended to be similar to previously published scores (Butler & Kern, 2016) across all domains except for Engagement, which was higher in our sample (Table 1a). Engagement, which refers to “being absorbed, interested and involved in one’s work”, shares similarities with the concept of sparks. Thus, these autistic participants had high thriving scores on the domain most closely related to the expression of their sparks.

Conclusions: As predicted by theoretical models, the findings of this small, exploratory study suggest that our participants feel their well-being is enhanced by engaging in their sparks and SIs. Given that young people with sparks often have richer, more meaning-filled lives, it may be important to nurture the autistic tendency to develop intense SIs in order to promote their ability to thrive.

423.004 *(Poster)* A Collective Case Study of Inclusion in Mainstream Community Programs for Children with Autism

S. Hodgetts[1], *S. K. Phelan*[2], *J. Ryan*[3], *D. B. Nicholas*[4] *and A. McKillop*[5], *(1)Department of Occupational Therapy, University of Alberta, Edmonton, AB, Canada, (2)Occupational Therapy, University of Alberta, Edmonton, AB, Canada, (3)Rehabilitation Medicine, University of Alberta, Edmonton, AB, Canada, (4)University of Calgary, Edmonton, AB, Canada, (5)University of Alberta, Edmonton, AB, Canada*

Background: Inclusion is often understood as a mindset where children feel a sense of belonging regardless of ability or disability. Inclusive communities are linked with improved emotional, social and academic outcomes, development of friendships, skill development, and tolerance of diversity for all children, including those with autism. Inclusive communities are also linked with broad societal benefits, such as decreased stigma associated with disability and difference. Children with ASD participate in significantly fewer community-based programs than their peers, often attributed to child and/or family factors such as a lack of financial resources, perceived competence, and emotional and social functioning. The focus has largely been on such individual features, and the broader social-ecological factors influencing inclusion are often ignored.

Objectives: (1) To compare how parents of children with autism versus program staff define inclusion in community programs, and (2) to identify and understand social-ecological facilitators and barriers to inclusion in community programs for children with autism.

Methods: This study used a collective case study approach, with cases anchored around mainstream community programs identified as inclusive. Data collection for each case included: semi-structured interviews with parents whose child participated in the community program and corresponding community program leaders; a textual analysis of policies and practices extracted from program documents (program guides, websites, medical forms, registration forms, mission, vision and value statements, and inclusion policies accessed online or provided by program staff); and observation field notes.Cases were analyzed individually, followed by a cross-case analysis, through an iterative process of coding, categorizing, and constant comparative analysis, informed by grounded theory techniques.

Results: Four cases were anchored around programs (dance, swimming, cycling, day camps) that all identified as inclusive. A total of eight parents (seven mothers and onefather) with a child with autism (mean age = 7 years; range 3-10 years), and 10 program staff have been interviewed to date across cases. One program was perceived as an exemplary example of inclusion by parents and program staff, whereas three programs were perceived as exemplary by program staff, but not by parents. Addressing objective one, preliminary analysis suggests that parents primarily view inclusion as an overarching philosophy that supports social belonging, whereas staff primarily discussed practices related to accommodations and aide support, more in line with current conceptualizations of integration. Addressing objective two, preliminary analysis supports one overarching theme, “It’s a philosophy, not a practice or policy”, and three sub-themes, “Experience with autism decreases stigma”, “Open communication is key”, and “Resources can help, but also hinder inclusion”.

Conclusions: Our data suggest that programs that identify as inclusive are not always experienced as such by parents of children with autism, particularly when they are not perceived to demonstrate a philosophy that embraces diversity and ability. This research may increase reflection of one’s own and organizational assumptions of autism and of current inclusive practices and policies, to facilitate understanding and inclusion of children with autism in community programs.

423.005 *(Poster)* A Comparison of Parenting Daily Hassles in Parents of Children with Autism and Typically Developing Children

K. Stover[1,2] *and J. A. Brian*[3], *(1)OISE - APHD, University of Toronto, Toronto, ON, Canada, (2)Bloorview Research Institute, Holland Bloorview Kids Rehabilitation Hospital, Toronto, ON, Canada, (3)Holland Bloorview Kids Rehabilitation Hospital, Toronto, ON, Canada*

Background: Parenting a child with ASD is highly stressful and reported to be more difficult than parenting children with different types of disability, or with no disability; however, the daily hassles that contribute to the increased stress for this specific group have not been studied systematically. Hassles are “experiences and conditions of daily living that have been appraised as salient and harmful or threatening to the endorser’s well-being” (Lazarus, 1984).

Objectives: The goal of this research was to determine what areas of daily strain are most prevalent in the lives of parents with young children with autism.

Methods: Parents (n=16, 100% mothers) of children with ASD (14 males, 2 females) were recruited through a large rehabilitation hospital in Toronto, Canada. Data from the typically developing comparison group were obtained from a database at an affiliated university. A fixed variable matching procedure was used to select the comparison group (n=16, 100% mothers). Parenting daily hassles were assessed using an adapted version of the *Parenting Daily Hassles* scale (Crnic & Greenberg, 1990; Arimura, 2008). Demographic features were assessed using a questionnaire. We investigated which specific daily hassles uniquely characterize the lives of parents of children with ASD in comparison to parents of typically developing children. Independent- and paired-samples *t*-tests were used to explore differences between groups and within the ASD group on continuous variables. The majority of variables met the broad assumption of normality (skew < |2.5|; kurtosis < |3.5|). The Bonferroni correction was used when several statistical tests were performed simultaneously.

Results: Parents of children with ASD experienced overall higher levels (Cohen’s $d = .58$), higher frequency, and higher intensity of daily hassles than parents of typically developing children. Further, some daily hassles items relating to restricted, repetitive patterns of behaviour, interest or activities were associated with greater intensity ($p = .005$) and frequency ($p = .004$) of daily hassles in parents of children with ASD. Further, mean parent ratings on the items associated with characteristics of ASD (e.g., impairments in social communication) were significantly higher than parent ratings on the set of items categorized as unrelated to characteristics of ASD (Cohen’s $d = 1.16$). Demographic factors such as marital status also influenced parenting daily hassles, with parents of children with ASD experiencing greater levels of daily hassles when raising a child as a single parent ($p = .012$).

Conclusions: Overall, this study provided an initial exploration of the daily hassles associated with parenting a young child with ASD. While previous research has looked at global life stress in parents of children with ASD, this study is unique in its examination of specific daily tasks and experiences that contribute to parent stress. In addition, these findings serve as a starting point for future research exploring the experiences, frustrations, and needs of parents raising children with ASD. This line of research is important for policymakers to consider when developing programs and services for this population, as combating parental stress and fostering parental well-being are critical for positive family functioning and child development.

423.006 *(Poster)* A Comparison of Parenting Stress in Mothers of Children with Autism between Japan and the U.S.: A Qualitative Analysis of Interviews with Mothers

*N. Porter[1], **K. A. Loveland**[2], K. Morimoto[3], T. Yamane[4] and Y. S. Posey[5], (1)Department of Human Development, Washington State University, Pullman, WA, (2)Department of Psychiatry and Behavioral Sciences, McGovern Medical School, The University of Texas Health Science Center at Houston, Houston, TX, (3)Kyoto City Children's Welfare Center, Kyoto, Japan, (4)Graduate School of Human Development and Environment, Kobe University, Kobe, Japan, (5)University of Houston, Law Center andThe University of Texas Health Science Center at Houston, Houston, TX*

Background:

Factors influencing stress in mothers of children with ASD are complex and reflect the socio-cultural context of parenting. Findings reported here are part of our on-going cross-cultural research project on mothers of children with ASD.

Objectives:

To compare factors associated with parenting stress in mothers of preschool children with ASD between Japan and the U.S. to improve understanding of how cultural factors related to parenting stress may lead to improved methods for culturally adapted interventions.

Methods:

- Forty-seven mothers of preschool children diagnosed with ASD participated (24 from US, 23 from Japan). The mothers and their parents were native born in the US or Japan.
- Mothers were recruited from clinics, schools, treatment centers, and parent organizations.

1. Instruments/Measures

- Questionnaires completed by mothers
    - Parenting Stress Index (English and Japanese versions). We examined the percentages of the mothers with a clinically significant level of parenting stress (>85 %ile) for each country.
    - Developmental history and demographics (English and Japanese), including time of the first formal diagnosis, time between when differences first were noticed and formal diagnosis, and the number of treatment programs child was in.
- Interview with mothers
    - We asked mothers to describe their stress related to parenting children with autism. and to rate their physical and emotional health on a scale of 1 (low) to 10 (high).

1. Analysis

- Used deductive coding of parenting stress using the names of subscales in the original PSI as categories.
- Used Fisher’s t-test to compare frequencies of categories between the US and Japan.
- Used t-test to compare the differences in demographic characteristics, formal diagnosis and treatment programs.

Results:

1. Quantitative analyses

- About 60% of mothers in both countries reported a clinically significant level of parenting stress (PSI). The parenting stress was particularly high related to Child Characteristics in both countries.
- Maternal self-report of physical and emotional health was low (average between 5-6) in both countries.

- US children received formal diagnosis slightly earlier than Japanese children, but the difference was not statistically significant.
- US children received a significantly higher number of treatments than Japanese children.

2. Qualitative Analyses

- Mothers in both countries had high stress related to child problem behavior and to child's behavioral or developmental characteristics.
- U.S. mothers reported high stress related to parental role restrictions influenced by the cultural orientation of independence and human agency, whereas for Japanese mothers, stress was influenced by a group-oriented culture that values conformity, and the expectation that mothers must be selflessly devoted to their children and emotionally close.

Conclusions:

- Because mothers in both countries had high stress related to child problem behaviors, supports for mothers of children with autism will enhance well-being of both children and their parents.
- US mothers of children with autism will benefit from support such as respite care to reduce stress related to time-management.
- For Japanese mothers, support providers should understand that parents may feel discouraged by children's inappropriate behavior in school settings with group activities. Support providers should also understand that Japanese mothers may minimize their struggles because of cultural norms and expectations about motherhood.

423.007 *(Poster)* A Cross Sectional Study of Environmental Influences on Participation in Children on the Autism Spectrum

K. Simpson[1] *and D. Adams*[2]*, (1)Autism CRC, Brisbane, QLD, Australia, (2)Autism Centre of Excellence, Griffith University, Brisbane, Australia*

Background: Children on the autism spectrum are reported to participate less in home and community activities compared to their peers (Askari et al., 2014). They also show a decline in participation as they age (Simpson et al., 2019). This has implications on the child's long-term health and well-being. Research has focused on attendance and levels of participation; however, little is known about environmental factors which may impact on the participation of children who have autism and if these factors change over time.

Objectives: The aim of this study is to investigate environmental factors that parents identify as impacting on children's participation in home and community activities.

Methods: A cross sectional study was used to explore parent perceptions of environmental facilitators and barriers to participation in children on the autism spectrum across home and community settings. Parents of children age 5-6 years (n = 72) and children aged 9-10 years (n = 94) completed the Participation and Environment Measure for Children and Youth.

Results: Parent-identified barriers varied across the sample and differed between the age groups. The most commonly identified barrier for home participation was the cognitive demands of the task, with over 25% of parents endorsing this item in both age groups. Supportive factors in the home environment included the physical layout, sensory environment and attitudes of therapists and professionals with over 50% of parents identifying these as aiding or not an issue for their child's participation. In contrast, group differences were identified on the physical and social demands of the activity. Parents of the older children more frequently reported these items as a barrier to participation while parents of the younger children endorsed these items as usually helping participation. Further group differences were reported with the child's relationship with family members identified as a barrier by parents of older children, but not for younger children. In the community, approximately 50% of parents commonly endorsed two main barriers, social demands and sensory qualities of the setting, and over 40% of parents in both groups identified the availability and adequacy of programs as a barrier to their child's participation. Further analysis of differences based on gender and level of ability will be discussed.

Conclusions: The findings from this research highlight the importance of considering barriers based on the child profile (e.g. age) when developing supportive programs. The importance of further longitudinal studies to explore cohort differences in this study will be discussed. Parents identified more factors in the home environment that facilitate participation than in the community suggesting that parents are successfully adapting the home environment to support their child. Factors which may create more supportive and accessible community programs to facilitate participation will be discussed.

423.008 *(Poster)* A New Measure of Family Adjustments and Accommodations in Intellectual and Developmental Disorders

M. Udhnani[1]*, A. Wang*[2]*, L. Becker*[3]*, A. Thurm*[4]*, E. Berry-Kravis*[5] *and J. S. Miller*[1]*, (1)Center for Autism Research, Children's Hospital of Philadelphia, Philadelphia, PA, (2)Rush University Medical Center, Chicago, IL, (3)NIH, Bethesda, MD, (4)National Institute of Mental Health, Bethesda, MD, (5)Pediatrics, Neurological Sciences, & Biochemistry, Rush University Medical Center, Chicago, IL*

Background: Parents of children with intellectual and developmental disabilities (DD) often adjust their lives around their child's symptoms and need for extra care, as a way to maximize success and prevent or reduce stress. Adjustments might include reducing demands placed on a child, acquiescing to the child's requests, or avoiding exposure to situations that could lead to disruptive behavior (Storch et al., 2007), but can also include major alterations in career plans, living arrangements, family goals, etc. Unfortunately, current measures of family impact focus on parent stress (Abidin, 2012), which would not acknowledge the adjustments a family may have made to reduce or prevent stress. Additionally, a measure of stress would not capture the positive family changes some parents attribute to having a child with special needs.

Objectives: Develop a measure of family adjustments and accommodations to having a child (or adult member) with a DD in order to broadly capture the impact of having a family member with special needs.

Methods: 133 Items were developed based on previously collected qualitative parent interview data measuring developmental concerns, challenging behaviors, and parent priorities for a rare genetic disorder associated with intellectual disability (creatine transporter deficiency; CTD). We framed items around several themes that emerged from the previous data, including specific behavioral concerns (safety, attention difficulties, mood/irritability, property destruction, negative attention-seeking behaviors), the daily impact of having a child with a DD, and shifts in long-term plans. We also created items specifically for families of adults with DD. Feedback about item organization, inclusion, and phrasing was sought from three clinical experts, a parent, and a biostatistician, with consensus that the measure could be broadly applicable to other DDs. The questionnaire has been distributed to 26 (and counting) families of children with CTD, Fragile X Syndrome (FXS), autism spectrum disorder (ASD), Williams Syndrome, and Angelman Syndrome (AS) across three different sites. Families also completed a feedback form that evaluated their impressions of the scale.

Results: To date, 26 participants (18 FXS, 1 FXS+ASD, 6 CTD, and 1 AS; M_{age} = 16.4, *SD* = 8.4, range: 2-31) have completed this scale. Twenty-one parents also rated their overall impression of the scale and its usefulness in informing researchers about their child. Nineteen of 21 parents rated the questionnaire as "good" or "excellent," and 20 of 21 rated it as "moderately useful" or "very useful." Comments from parents include, "I think this questionnaire covered the vast majority of what it's like to parent a child with a developmental disability". Data collection is ongoing, and we anticipate having data from 50 participants that will be available for presentation.

Conclusions: This study serves as a preliminary step in understanding the experience of raising a child with special needs, from a more holistic perspective than just level of functioning or current stress. With ongoing data collection, future directions will include conducting item-level analyses to refine the measure, and then determining its utility to inform clinical decision-making and potential response to services and/or intervention.

423.009 *(Poster)* A Qualitative Examination of a Community-Based Advocacy Mentorship Program for Latinx Families

P. Luelmo[1]*, J. Padilla*[2] *and C. Kasari*[3]*, (1)Special Education, San Diego State University, San Diego, CA, (2)Autism Learning Partners, Downey, CA, (3)University of California, Los Angeles, Los Angeles, CA*

Background: Latinx children with autism are more likely to experience inequities in the healthcare and education systems in the United States. For example, in California Latinx children receive about only 50% of State-sponsored resources and services when compared to White children. Research suggest that Latinx parents are in need of advocacy training in order to address factors that might be behind the disparity in diagnosis and services. This study is a qualitative data analysis of an intervention study designed to rigorously test, using randomization, a parent-to-parent advocacy program for parents of children with ASD within a mostly Latinx population in Southern California. This study focuses on exploring the strengths and challenges that Latinx parents who participated in an advocacy intervention study encountered.

Objectives: RQ- What are the strengths and challenges of implementing a parent-to-parent advocacy mentorship program within an urban Mostly Latinx context?

Methods: Seven one-on-one interviews were conducted with the intervention participants of a community-based advocacy mentorship program in Spanish (n=3) and English (n=4). Guided by the study's research questions (i.e., feasibility of a parent-to-parent advocacy intervention), the researchers conducted *apriori* coding of the transcripts and identified a preliminary list of categories based on the interview questions (e.g., How helpful would you describe the mentorship program you participated in?). Then, the researchers used line-by-line coding to assign categories to phrases, sentences or paragraphs within the different responses; multiple categories could be assigned simultaneously to accurately capture the overall message of the passage. Information from the category applications and identification of the subcategories guided the development of the final themes.

Results: Three themes emerged from the data analysis. 1) Usefulness and Strengths of the Advocacy Mentorship: Overall, all participants responded very optimistically to the intervention. 2) The trustworthiness of having a parent mentor from the community as the interventionist: All participants expressed gratitude and a trustworthy relationship with the parent mentor. Specifically, participants expressed that parent mentors were passionate and the fact that they had themselves a child with a disability helped them connect with them. 3) Challenges and Recommendations for Future Mentorship Interventions: Most participants expressed that the program was effective. One suggestion that came across was to let more people know about programs for Latinx parents. Participants expressed that other members of their community do not have this information nor are aware of advocacy programs.

Conclusions: Some challenges were particularly salient in recruiting and working with a low-income mostly Latinx population. For example, while most of the participants showed great interest in engaging in the intervention, participants found scheduling for the sessions difficult. A second challenge, was addressing a general unfamiliarity from the participants about research studies. Finally, there were difficulties in recruiting participants for an advocacy intervention in a hostile socio-political environment towards the Latinx population, particularly those from immigrant backgrounds. Hence, while a majority of participants engaged in the study, and had overwhelmingly positive feedback about the intervention, others probably required other engagement strategies to get them to participate.

423.010 *(Poster)* An Exploration of Parents' Perceptions Participating in an Intervention for Their Toddlers with Autism Spectrum Disorder

J. Amsbary*, UNC Chapel Hill, Chapel Hill, NC*

Background: Implementation science plays a key role in understanding and interpreting the successful use of early interventions for toddlers with autism spectrum disorder (ASD; e.g, Odom, 2009). In order for providers *and* parents to successfully use and implement interventions, it is necessary to study, evaluate, and ensure high quality implementation processes as perceived by stakeholders, or families in early intervention. Specifically, applying the National Implementation Research Network's *Formula for Success*, there is a need to determine underlying (a) effective intervention components such as descriptions and understanding of target goals, strategies, and outcomes; (b) effective implementation processes, such as the coaching process and the extent to which parents and others are able to deliver the intervention strategies; and (c) enabling contexts, such as where and during which routines and activities the intervention is effective; that parents perceive as leading to successes and challenges for achieving improved outcomes (Blasé & Fixsen, 2013).

Objectives: Relative to an intervention for toddlers with ASD, the study aimed to identify what: (a) intervention components; (b) implementation (coaching) processes; (c) contextual factors of the intervention parents perceived as helpful or not helpful in leading to optimal outcomes?

Methods: After obtaining IRB approval, we used qualitative methodology to explore parents' perceptions of an early intervention for toddlers with ASD. Data were collected through 12 face-to-face interviews with parents from a variety of demographic backgrounds who participated in an early intervention for toddlers with ASD. Each interview was transcribed and systematically coded using Atlas.ti qualitative coding software. Transcripts were analyzed individually through iterative coding cycles. First, data were descriptively coded. Then, data were coded using a priori themes of helpful and unhelpful intervention components, implementation processes, and contexts. Two coders coded all transcripts and met regularly for consensus coding to establish credibility and reliability of the data.

Results: Major findings in the study indicate parents were satisfied with the intervention yet individual perspectives varied. Many parent participants perceived intervention components such as homework and specific strategies as helpful. Parents perceived coaching practices such as watching the interventionists' model strategies as useful and effective. Parents explained positive experiences were influenced by the interventionists' qualities and the trusting relationship that developed between themselves and the interventionists. They further perceived the context of service delivery including clinic and home sessions as enhancing their experiences.

Parents felt their children's goals were appropriate, yet did not consistently report involvement in the goal development. Parents desired additional information related to ASD, resources, and individualized directions following their completion of the intervention. They reported mixed levels of comfort practicing the intervention strategies in front of their interventionists and mixed levels of success integrating the strategies into their daily lives. Parents felt the intervention could have been longer and experienced some challenges fitting the fixed intervention session times into their schedules.

Conclusions: In sum, parents' overall perceptions indicate the need to individualize early intervention services for toddlers with ASD in order to match service style and practice with unique family characteristics, dynamics, structures, and preferences.

423.011 *(Poster)* Are Lay Theories about Developmental Disorders Related to Labeling Others As Having "Developmental Disorders"?

A. Taniguchi[1] *and T. Yamane*[2]*, (1)Graduate School of Human Development and Environment, Kobe University, Kobe, Japan, (2)Graduate School of Developmental and Environment, Kobe University, Kobe, Japan*

Background: Recently, "developmental disorders" have received much attention in Japan. In Japan, it is a comprehensive concept including autism, Asperger's syndrome, other pervasive developmental disorders, learning disorders, and attention deficit and hyperactivity disorder. The concept of "developmental disorder" is highly recognized and will be used at medical and educational settings. However, it is expected that some adverse effects will exist. Specifically, it is assumed that misunderstanding spreads and encourages labeling of others. Based on current study, it seems that "developmental disorders" for around people is regarded as a broader more comprehensive concept compare to professional about that. To clarify the concept of "Developmental Disorders" in society, we examined lay theories about developmental disorders. Lay theories refer to simple concepts held by people about various things in daily life (Furnham, 1988). Once people internalize the lay theory, they unconsciously apply it to each problem, and express and enact a specific emotion in a manner suited to the lay theory (Averill, 1980). It is assumed that people who have lay theories about developmental disorders will lead to developmental disorders to other people encountered in daily life.

Objectives: We examined whether the lay theories about developmental disorders are related to labeling others as having developmental disorders.

Methods: Questionnaire surveys were conducted with 346 Japanese university students. In the first part of the questionnaire, the participants wrote what they thought about developmental disorders following the phrase "People with developmental disorder" and within the time limit of 2 minutes. Next, to measure the labeling of developmental disorder, we asked two questions: (1) the frequency with which they believe that their family, friends, colleagues, and strangers have developmental disorders, and (2) the extent of their confidence in such beliefs. The higher the frequency and confidence, the easier is labeling. Additionally, to examine the validity of the developmental disorders' stigma scale, we asked social desirability, other scale of stigma.

Results: To confirm the lay theory, we identified the frequent words using text mining. The case of " people with developmental disorder" is "Have", and it occurred with "Ability "and "Talent." This suggested that there is a belief that people with developmental disorders have excellent ability. Correspondence analysis revealed that the first axis was named "Dimension of Difference" and the second axis was named "Concreteness of Impressions."

To examine the effect of lay theory about developmental disorder toward labeling, we conducted multiple regression analysis with frequency scores in each scene as the dependent variables. Results revealed that the model was significant for families, friends, and people on the scale, and the main effect of the Dimension of Difference score was significant. This means that people who described the differences in characteristics between themselves and people with developmental disorders had high labeling score.

Conclusions: Possibility, lay theories lead people to label others as having developmental disorders. In the future, it is necessary to clarify the concept of "developmental disorder" in society in greater detail.

423.012 *(Poster)* Aspirations and Needs for Successful Post-Secondary Transitions: Stakeholder Voices

H. Able[1]*, N. Bagatell*[2] *and J. McNeill*[3]*, (1)University of North Carolina at Chapel Hill, Chapel Hill, NC, (2)University of North Carolina at Chapel H, Chapel Hill, NC, (3)School of Education, University of North Carolina, Chapel Hill, NC*

Background: ASD is a lifelong disorder and many individuals require continual supports to ensure success. Despite the best efforts of special education, the outcomes for individuals with ASD after high school are less than optimal. Of particular concern is a sub-group of adolescents without intellectual disabilities (ID). Although these individuals have the potential to fully participate in mainstream community activities, outcomes for many adults without ID are surprisingly poor in the areas of secondary education, employment, independent living, and social participation (Taylor, Henninger, & Malick, 2015). These individuals are three times more likely to have no daytime activity compared to adults with ID (Taylor & Seltzer, 2011). The transition process is a time of great opportunity and risk for these adolescents and their families; however, relatively little research has addressed transition from the perspective of both adolescents and parents.

Objectives: To identify adolescents' and parents': (a) aspirations for adult life; (b) views of transition areas for which they feel most and least prepared; and (c) views of needed services to support the transition to adult life.

Methods: Parents and adolescents (ages 13-18) in general education at least 50% of the day participated in separate focus groups. Thirty-six parents and 26 adolescents (ages 13-17) from both rural and urban areas were asked about their goals after high school, and the services and supports they have used and need to facilitate a successful transition to adulthood. Using a card sort activity, participants provided information about which transition areas for which they felt most and least prepared. Focus groups were audio taped and transcribed verbatim. A constant comparative method and consensus coding process were used to validate the major themes highlighted by parents and adolescents.

Results: The parents were generally positive about their youth, highlighting strengths while acknowledging their individual challenges. Interestingly, parents and adolescents' views were often similar but differed in subtle ways. While the adolescents had aspirations for independence, they expressed concerns regarding future employment, education, ability to live independently, and develop relationships. Parents' goals focused on successful employment and independent living whereas adolescent goals related to employment focused on their specific interests such as computers or fantasy novels. Parent concerns related to social interaction (e.g., having friends to do things with), getting a job, and living independently. However, adolescents' major concerns related to being financially secure, and having a safe place to live and the social skills needed to maintain employment rather than for social community participation. Both parents and adolescents identified needs for continued supports, including social support for the adolescent and family, accessible and useable information about the adult service system, and continued professional supports according to adolescents' individualized needs.

Conclusions: The adolescent and family perspectives indicated a need for capacity building supports tailored to *what really matters* to stakeholders for achieving successful adult outcomes. Based on our study's results, those supports include social support for the adolescent and family, accessible and useable information about the adult service system, and continued professional supports according to adolescents' individualized needs.

423.013 *(Poster)* Assessing the Service Needs of Families with Children with ASD in the Inland Empire

M. R. Ledoux[1]*, A. Losh*[2]*, E. Veytsman*[2] *and J. Blacher*[2]*, (1)Graduate School of Education, University of California, Riverside, Riverside, CA, (2)Graduate School of Education, University of California Riverside, Riverside, CA*

Background: More children with autism spectrum disorder (ASD) are in need of specialized services to support their academic, behavioral, and social wellbeing (Baio et al., 2018; Fombonne, 2018; Matson & Kozlowski, 2011). Early intervention, reliant upon early diagnosis, has been shown to significantly benefit young children with ASD and their families (Koegel et al., 2014; Rogers, 1996). While schools and in-home services have made strides towards improving access to services, large regions exist in which necessary assessment and intervention services are severely lacking, leading to geographical pockets of underserved families. One such area is the Inland Empire (IE) region of Southern California, where families have described their struggles with accessing timely diagnostic and intervention services. This pilot study aimed to examine the service needs of families with children with ASD in the IE using online methodology with families. The goal is to expand the sample over the coming months in order to gather data that will ultimately promote service delivery options for underserved families in the region.

Objectives:

1. What are the current service needs of children with ASD and their families in the IE?
2. What gaps currently exist in services for children with ASD?

Methods: An online survey was developed and distributed to a preliminary group of parents of children with ASD in the IE region (N=17), recruited through a university autism screening clinic. Recruitment is ongoing and is intended to validate the online survey as an acceptable measure of service needs. In the preliminary sample, parents reported the average age of their child to be 12 years (range 5-17; SD=4), with an average age of diagnosis at 6 years (range 2-14; SD=4). The survey asked open- and close-ended questions about the diagnosis process, accessing services, perceptions of service needs, and satisfaction with different aspects of the service delivery system (see Table 1). Likert scale survey items were analyzed quantitatively and open-ended responses will be coded qualitatively to assess the specific needs of families of children with ASD in the IE region.

Results: Preliminary analyses indicated that only 29% (n=4) of participating parents agreed that the assessment needs of individuals with ASD are currently being met, only 14% of participants (n=2) agreed that the intervention needs of individuals with ASD are currently being met, and 71% (n=10) reported that they wished their child had been receiving additional services; they also feel that there are services currently missing. Together, results highlight unmet needs in both the assessment process and ongoing services for individuals with ASD and their families. Future qualitative analyses will further assess the experiences of families of children with ASD in the IE region.

Conclusions: Results captured the need for increased services in the IE region. Parents indicated the need for increased access to comprehensive assessment as well as the ability to obtain interventions for their children with ASD. The results of the larger sample may inform service providers, medical professionals, and policymakers in the IE to support the growing number of individuals with ASD and their families.

423.014 *(Poster)* Associations between Comorbid Psychopathology in Youth with Autism Spectrum Disorder and Caregiver Coping

M. Menezes*, M. F. Robinson and M. O. Mazurek, University of Virginia, Charlottesville, VA*

Background: Comorbid mental health conditions are common in autism spectrum disorder (ASD), and they are detrimental to child well-being. Psychopathology co-occurring with ASD may also negatively impact caregiver well-being. Studies of whether having a child with ASD and a comorbid psychiatric disorder is associated with greater caregiver burden have found mixed results. One study found that a comorbid mental health problem was not associated with greater caregiver burden once other youth characteristics were taken into consideration (Kring, Greenberg, & Seltzer, 2008). Another study found that comorbid attention-deficit/hyperactivity disorder (ADHD) contributed to greater caregiver stress (Theule, Wiener, Tannock, & Jenkins, 2010). No study has investigated the potential effects of caring for a child with ASD and a comorbid diagnosis of anxiety and/or depression on caregiver coping.

Objectives: The aim of this study was to examine whether having a child with a mental health condition (i.e., anxiety, depression, and/or ADHD) comorbid with ASD was associated with poorer caregiver coping in a large nationally representative sample of families.

Methods: Data from this study were obtained from the 2016 National Survey of Children's Health, a nationally representative caregiver survey of over 50,000 young people focused on child and adolescent health and well-being. Participants included in this analysis (n = 1008) were caregivers of children 6-17 years of age (M=12.11; 81.3% male) with a current ASD diagnosis. Comorbid mental health condition was based on whether the caregiver responded that their child had ever been diagnosed by a health care provider with anxiety, depression, and/or ADHD and that they "currently have the condition." Caregiver coping was operationalized as how well the caregiver was "handling the day-to-day demands of raising children." Responses were dichotomized to "very well" and "somewhat well/not very well/not very well at all." Three binary logistic regression models were run with anxiety, depression, and ADHD as the predictors and caregiver coping as the outcome. Age and gender of the child and family household income were included as covariates in all models.

Results: Results found that child anxiety was associated with 1.39 times greater odds that the caregiver is not coping "very well" (i.e., coping "somewhat well/not very well/not very well at all") with the daily demands of raising children (p = .011). Results also found that child depression was associated with 1.74 times greater odds that the caregiver is not coping "very well" (p = .003). In addition, results indicated that child ADHD was associated with 1.35 times greater odds that the caregiver is not coping "very well" (p = .02).

Conclusions: Results indicate that having a child with ASD and a comorbid psychiatric disorder (i.e., anxiety, depression, and/or ADHD) does influence caregivers' self-reported coping. Caregivers are not coping very well with the dual diagnosis of their children. This is likely because psychiatric comorbidities include symptoms that are different from the core symptoms of ASD and result in additional functional impairment. Treatment planning should account for the added stress associated with caring for a child with ASD and a comorbid mental health condition.

423.015 *(Poster)* Beyond the Exam Room: Partnering with Latino Families to Address Healthcare Disparities for Children with Autism

M. Dillon[1]*, H. Park*[1]*, M. Cuevas*[1]*, P. Chung*[1]*, B. Peralta*[1]*, J. G. Gehricke*[2]*, F. Burgoa*[1]*, J. Burgoa*[1]*, B. Felipe*[1]*, P. Felipe*[1]*, G. Velasco*[1] *and P. Velasco*[1]*, (1)Pediatrics, University of California - Irvine, Santa Ana, CA, (2)The Center for Autism & Neurodevelopmental Disorders, University of California, Irvine, Santa Ana, CA*

Background: Research has demonstrated disparities in healthcare access and outcomes for children with autism based on demographic factors like ethnicity and socioeconomic status. This case study illustrates ways clinics can implement community outreach programs to address underserved populations in an effective, empowering, and culturally sensitive way.

Objectives: To improve access, information, and care for Latino Families raising children with autism by engaging parents from a Latino Family Advisory Committee (FAC) in the planning, development and implementation of educational and research projects at an autism center.

Methods: As part of the Autism Speaks Autism Treatment Network (ATN), The Center for Autism & Neurodevelopmental Disorders (CAND) at the University of California, Irvine, began recruiting families to form two FAC's in 2015. Because CAND serves a large Latino population, and there has been limited autism research focused on this population, CAND aimed to create an FAC specifically for Latino parents. A bilingual developmental-behavioral pediatrician and bilingual social worker helped form the Latino FAC. To maximize involvement, in-person meetings are held on weeknight evenings 6-9 times throughout the year to accommodate parents' work schedules. Children are welcome to attend and stay with the group during the meeting. The Latino FAC has collaborated on research projects with the ATN and planned and executed educational events for families at the local level.

Results: The Latino FAC has been instrumental at CAND in implementing research projects with the ATN and by providing feedback on protocols and forms translated into Spanish to make research projects more inclusive of and accessible to Latino families. The Latino FAC's local outreach and educational efforts with CAND began with quarterly Latino Family Day potluck lectures attended by 20-25 families. CAND applied for community level and state grants to expand these efforts. For the past 2 years the Latino FAC activities have included involvement in the planning and implementation of a California Department of Developmental Services grant aimed at reducing disparities in access to care for underserved families. Latino FAC parents have led discussions and shared their experiences during events.

Over the past year, the Latino FAC has contributed to the development and implementation of the following programs offered in Spanish reaching over 200 Latino families:

- Transition at age 3
- Transition to adulthood
- Autism 101
- Understanding Special Education
- Navigating Behavioral Health
- Developmental Screening events
- Ask the Experts panel
- Parent Empowerment Series

Participant feedback has indicated the Latino FAC parents sharing their stories has helped other parents feel less alone and more supported.

Conclusions: The Latino FAC has provided consultation on the planning of research with the ATN and educational activities at CAND so these efforts will appeal to and better meet the needs of the Latino community. Improving access to information and care, as well as providing research opportunities for traditionally underserved communities, can be achieved by creating and consistently involving a family advisory committee that includes members of the specific population(s). Developing projects with direct input from FAC parents and soliciting frequent input is essential for successful engagement of the community.

423.016 *(Poster)* Bilingual Language Practices of Mexican Heritage Families with ASD

S. R. Cohen[1]*, J. Miguel*[2] *and A. Wishard Guerra*[3]*, (1)University of California - San Diego, La Jolla, CA, (2)UC San Diego, San Diego, CA, (3)UC San Diego, La Jolla, CA*

Background: Language and communication challenges associated with ASD are complex when we acknowledge the child's language exposure (e.g., the number of languages spoken), the quality of the interactions between the target child and caregiver, and the context in which these interactions occur. Historically, practitioners have not supported using multiple languages to interact with children with ASD (Kay-Raining Bird, Lamond, & Holden, 2012). To eliminate the challenges associated with language learning, practitioners encouraged children and families to interact in the societally dominant language (English) to eliminate "confusion." Current studies are now identifying strengths including a *bilingual advantage* in the language skills of multilingual children with ASD (Gonzalez-Barrero & Nadig, 2017). This study utilizes a language socialization lens to examine the bilingual interactions of children with ASD and their caregivers.

Objectives: The purpose of this study was to describe the bilingual interactions between children with ASD and their caregivers during routine daily activities at home.

Methods: Six Mexican immigrant families caring for a child with ASD were asked to video record themselves engaging with their children in their daily, routine activities over 10 days. We asked the following questions: (1) What is the dominant language spoken across these families' daily routines; 2) In what types of daily activities did Spanish language interactions occur? 3) In what types of activities did English language interactions occur? 4) Who dominated the language interactions (parent or child)?

Over 18 hours of video recordings were collected across 168 videos (R = 10 seconds to 39 minutes each). Mexican immigrant mothers' (M age = 36.5) all spoke Spanish at home, and reported an annual family income range from under $15,000 to $35,000. Child participants (M age = 5; all male) were receiving intervention (e.g. home behavior therapy or school based therapy) in English. Some families had a bilingual service provider who clarified instructions in Spanish.

Results: Less than half (48%) of all recordings (N = 80) featured Spanish language interactions as compared to English language interactions (39.5%). Very few video recordings (12.6%) contained no language. Spanish was spoken most frequently in Academic Caregiving (e.g., doing homework) (36.3%) and Non-Academic/Play Conversations (e.g., playing with play-doh) (31.2%). English was spoken in Non-Academic/Play Conversations (43.9%) and Adaptive Caregiving activities (36.4%). In most of these language interactions the target child dominated interactions (43.4%). Mothers dominated 40% of the conversations. Siblings, fathers, and extended families dominated the rest of the conversations.

Conclusions: To better understand immigrant families' language practices from a strength-based approach, we used a language socialization lens (Garret & Baquedano-López, 2002) to examine the context, content, and goals of the language interactions. Forthcoming analyses will examine the specific contributions of the parent and the child to the language interaction, the complexity of the language used by the parent and the child, the quality of adult scaffolding (e.g., how does the parent scaffold abstract thinking), the content of the language interaction, and whether the language used in the interaction is associated with the complexity of the adult and child language use.

423.017 *(Poster)* Building Acceptance and Support of Autism in the Community through Service Learning

J. McNeill[1]*, H. Able*[2] *and L. Fanning*[3]*, (1)School of Education, University of North Carolina, Chapel Hill, NC, (2)University of North Carolina at Chapel Hill, Chapel Hill, NC, (3)School of Education, University of North Carolina at Chapel Hill, Chapel Hill, NC*

Background: Given the upward trend in the prevalence of autism spectrum disorder (ASD), it is highly likely that a person will at some point meet, work with, or befriend an individual with ASD. Myths and misconceptions have been associated with ASD by the general public, often influenced by media and word-of-mouth (Mitchell & Locke, 2015). As institutions of higher education increasingly tackle social justice and equity, service-learning initiatives show promise for addressing such issues by engaging undergraduate students in diverse communities (Lieberman, 2014). The nature of direct interaction with diverse children and families through service learning has been shown to support a developing understanding of difference as opposed to deficit (Able et al., 2014). Further, service learning can directly support individuals with ASD through the provision of family respite and volunteer support for community providers.

Objectives: Our study analyzed the impact of an undergraduate service-learning course on students' knowledge and attitudes regarding individuals with ASD and the benefits to families and community partners.

Methods: Fifty-six undergraduate students each completed 30 hours of service learning with individuals with ASD in family or community contexts including camps, recreation centers, and intervention clinics. Students completed pre- and post-course surveys of knowledge and beliefs about ASD and wrote a final reflection of their service learning experience. Eight students participated in a post-course focus group and ten family and community partners were interviewed. Closed-ended survey responses were analyzed using t-tests. Qualitative data was systematically coded and constantly compared by two coders.

Results: Students significantly increased their knowledge of ASD-related interventions, school-aged services and supports, and resources addressing the lifespan as a result of the community and family experiences. Students indicated increased confidence in explaining the characteristics of ASD and interacting socially with peers with ASD. See Table 1 for complete survey results. Qualitative data echoed the survey findings. Students highlighted a new appreciation of ASD as a broad spectrum and challenged assumptions related to competence, socialization, and sensory-related behaviors. Students also increased their understanding and appreciation of community-based services for individuals with ASD. Parent and community partners noted the importance of the students seeing individuals with ASD across multiple environments, including home, school, and community. Service recipients felt that these experiences helped to "demystify and humanize" individuals with autism, emphasizing the benefit for the students and their "buddies" with ASD, but also for other individuals with ASD these students may interact with in the future. Stakeholders also reported the value of the service learning for providing family respite, valuable social experiences for the individuals with ASD, and for staffing community programs in need of volunteers.

Conclusions: Our results endorse the positive impact service-learning experiences can have in shifting student perspectives and support for individuals with ASD they encounter in their personal and professional lives. Service learning presents a unique opportunity for mutual benefit, allowing both students and individuals with ASD to learn from each other in natural contexts.

423.018 *(Poster)* Caregiver Strain in Children with ASD Predicts Parenting Style

A. Rovane[1]*, R. Hock*[2] *and A. Englert*[3]*, (1)Psychology, University of South Carolina, Columbia, SC, (2)University of South Carolina, Columbia, SC, (3)College of Social Work, University of South Carolina, Columbia, SC*

Background: Autism Spectrum Disorder (ASD) is a rising healthcare concern, with prevalence rates estimated at 1 in 59 individuals (CDC, 2019). A recent meta-analysis concluded that parents of children with ASD exhibited more negative parenting behaviors toward their children than parents without (Ku, Stinson, & McDonald, 2019). The increase in negative parenting behaviors (e.g., expressions of anger, etc.) is presumably due to increased parenting stress (Abidin, 1992) but may also be due to caregiving strain associated with caring for a child with ASD. Indeed, parents of children with ASD report higher stress and greater caregiver strain than parents of children with other developmental disorders or typically developing children (Hayes & Watson, 2013; Khanna et al., 2012). Like stress, caregiving strain may predicate negative parenting behavior, and it is not known whether this differs for mothers and fathers. It is relatively unknown what sources of caregiver strain may elicit certain parenting styles and parenting behavior.

Objectives: The current study examines how different types of caregiving strain may be implicated in parenting styles in ASD. The aims of this study are twofold: 1) To evaluate whether different types of caregiver strain contribute to negative parenting styles and 2) To determine whether this association differs between mothers and fathers.

Methods: Participants were mothers (n=35) and fathers (n=21) of children with ASD who were recruited for participation in a co-parenting intervention study. The survey included demographic questions, the PDD Behavior Inventory (Cohen, 2003), the Caregiving Strain Questionnaire (Brannan, Heflinger, & Bickman, 1997), and The Parenting Scale (Arnold, et al., 1993). Stepwise regression models were constructed to examine the relative influence of 3 types of caregiving strain (objective, subjective-internalizing, and subjective-externalizing) on 2 different parenting styles. Parenting styles included overreactive parenting, which is characterized by criticism and/or argumentativeness, as well as hostile parenting, indicating use of physical or verbal force. Separate models were constructed for mothers and fathers. Covariates included child behavior problems, race, education level, and number of children in the home. Assumptions for multiple regression models were met.

Results: In the final models for mothers, only subjective externalizing strain emerged as a significant predictor for overreactive parenting (R^2= .40, β= .64, p<.001), and the model was not significant for hostile parenting. For fathers, the final models revealed that only objective strain emerged as a significant predictor for over-reactive parenting (R^2= .61, β= .83, p<.001), and no strain predicted hostile parenting.

Conclusions: Findings suggest that caregiver strain contributes to overreactive, but not hostile, parenting style. The patterns of association were different for mothers and fathers. Objective strain contributed to fathers' overreactive parenting, while subjective-externalizing strain contributed to mothers'. This difference may be due to the fact that mothers are more responsive to emotional strain, whereas fathers are more affected by situational strain. The lack of association with hostile parenting may be due to the relatively low ratings across parents. These differences are important to consider in treatment planning and service considerations for caregivers of children with ASD.

423.019 *(Poster)* Caregivers' Experiences and Requests for Support during Follow-up: Caregiver-Mediated Jasper Intervention

S. L. Arbuckle[1]*, L. Baker Worthman*[2] *and S. Y. Shire*[3]*, (1)Special Education, University of Oregon, Eugene, OR, (2)Department of Health and Community Services, St. John's, Newfoundland and Labrador, Canada, (3)University of Oregon, Eugene, OR*

Background: Caregiver-mediated social communication intervention can lead to gains in children's engagement and communication as well as caregivers' use of intervention strategies (e.g., Shire et al., 2015). However, after intervention ends, less is known about if and when caregivers may desire support to maintain these gains as their children's needs change.

Objectives: This mixed methods study uses (a) quantitative data from a novel mobile health questionnaire (MHQ) given weekly during the three months following intervention to examine if, when, and how often caregivers endorsed a need for support and (b) qualitative data from focus groups to explore caregivers' experiences during the follow-up period.

Methods: Fifteen children ages 2.0-8.7 years (*M*=55.8 months) with outside diagnoses of autism were included. Children and their primary caregivers received 12 weeks of a caregiver-mediated developmental social communication intervention- Joint Attention, Symbolic Play, Engagement, and Regulation (JASPER: Kasari et al., 2006) from local community interventionists employed by a provincial public health system in Canada. The five interventionists were trained to fidelity in JASPER by the study team with fidelity checks all scoring at or above the required criterion of 80%.

Measures: The MHQ included 3 questions rated from 1 (typical/ no support needs) to 7 (getting worse/ high support needs), modeled after Clinical Global Impressions (Guy, 1976). Weekly, caregivers rated the child's social communication, engagement, and their perceived need for support. Three focus groups each with 3-4 families were led by the local health region leadership. Open-ended questions addressed families' experience in the 3-month follow-up period.

Results: Children's engagement and communication in follow up: MHQ scores ranged from 1 to 4 for question 1 and question 2 (*M*=2.16, *SD*=.875; *M*=2.10, *SD*=.854).

Need for support during follow up. Scores ranged from 1 to 5 for question 3 (*M*=2.29, *SD*=.74).

Caregivers reported a need for support (MHQ score of 3-7) on average 4 times over 12 weeks. Interventionists responded within 24 hours with an email to check-in and provided suggestions to resolve challenges.

Constant comparative analysis of coding of the focus group data led to five themes including feeling sufficiently supported by weekly check-ins during follow up which encouraged accountability and personal reflection on strengths and challenges. However, the families also reported challenges to maintain children's engagement and regulation, to replicate the intervention structure in their homes, and to integrate strategies into more 'naturalistic' daily routines.

Conclusions: On average, caregivers indicated a need for support 4 times during the follow up period. Caregivers were provided with email and phone calls from their interventionists which families reported were sufficient to resolve challenges such that no family requested a video conference or home visit. Focus group discussions indicated a desire for readily-accessible electronic resources (e.g., strategy videos, activity lists) to support continued learning. However, five families indicated no support needs. Understanding child and family predictors that may differentiate support needs may help plan to allocate limited resources.

423.020 *(Poster)* Challenges and Contributors to Self-Efficacy for Parents of Toddlers with Autism: Early Intervention Considerations

H. Schertz *and J. N. Lester, Indiana University, Bloomington, IN*

Background: Early social challenges in autism can test parents' confidence as they seek interaction with their toddlers. A central purpose of early intervention (EI; IDEA: Part C, 2004) is to build family capacity through participatory experiences to enable parent competence and confidence, defined as parent self-efficacy (PSE), to support child learning. Participatory EI practices have been associated with PSE, which in turn relates to positive indicators of child functioning. Parents' perceptions of their ability to effect child learning may thus respond differentially to professionally-directed versus professionally-supported EI practices. Understanding of particular EI features that support PSE is needed to advance family-inclusive practices with potential to improve outcomes for parents and their toddlers on the autism spectrum.

Objectives: The study's purpose was to qualitatively explore how parents of toddlers with autism viewed their competency in relation to their EI experience as it pertained to facilitating toddler learning. The overarching research question was: How do parents' experiences undermine or support their perceived ownership of the parent-child social learning process and confidence to support child learning?

Methods: In-depth interviews were conducted with 11 parents of toddlers with autism (aged 16-30 months) who experienced both professionally-directed and professionally-supported EI approaches. Participants were drawn from a larger three-site study of parent-mediated intervention. Participants had also received community-based professionally-implemented intervention. Parents responded to open-ended questions on topics related to interaction with professionals and their own ability to promote their toddlers' active social engagement. Drawing from a thematic methodological and analytical framework, we conducted independent qualitative coding of transcribed interviews using codes that accommodated lower and higher levels of inference. Data triangulation was supported across investigators, supplementary data sources (e.g., intervention records), and participants. Following discussions and multiple coding cycles, 76 primary codes resulted, forming the basis for systematic interpretation. Codes were organized into categorical sets, followed by development of themes.

Results: Four themes and associated subthemes resulted from the analysis. The first, "autism-related early challenges to PSE," found an early period of adjustment sometimes followed by parents struggling to connect with the child as social challenges emerged. The second theme, "parent-professional roles and PSE," uncovered three subthemes: Parent as follower and professional as expert, parent involved in an ancillary role, and parent in the driver's seat, with increasingly strong evidence of PSE with each subtheme. The third theme, "manifestations and personal contributors to PSE," revealed parents' specific and general examples of their own expertise. Fourth, in "child autonomy as an extension of PSE," participants showed a high level of acceptance of their toddlers' natures and preferences, validating their awareness of the transactional nature of the parent-child social learning process.

Conclusions: Bandura's theory of self-efficacy informed our interpretation of findings that PSE supported parents' motivation to master tasks. Parents' shared perceptions revealed that parent-professional role inequality appeared to negatively impact their PSE while a more participatory approach fostered competency through conceptually-based learning and active engagement in the learning process, preparing them to take the lead in promoting toddler learning. Results highlight the importance of participatory EI practices.

423.021 *(Poster)* Characterizing Discussions between Pediatric Healthcare Providers and Autistic Adolescent Patients and Their Families about the Transition to Adulthood

E. Sartin[1]*, R. K. Myers*[2]*, M. E. Carey*[2]*, C. G. Labows*[3]*, B. E. Yerys*[4]*, C. C. McDonald*[5]*, C. J. Mollen*[6] *and A. E. Curry*[2]*, (1)Children's Hospital of Philadelphia, Philadelphia, PA, (2)Center for Injury Research and Prevention, Children's Hospital of Philadelphia, Philadelphia, PA, (3)Center for Injury Research and prevention, Children's Hospital of Philadelphia, Philadelphia, PA, (4)Center for Autism Research, Children's Hospital of Philadelphia, Philadelphia, PA, (5)University of Pennsylvania, Philadelphia, PA, (6)Pediatrics, Children's Hospital of Philadelphia, Philadelphia, PA*

Background: The transition to adulthood is a significant challenge for autistic adolescents and young adults (AYA). The 2015 National Autism Indicators Report found that more autistic AYA reported feeling disconnected from work and education than peers with other disabilities such as speech-language impairment, learning disabilities, or emotional disturbances (Roux et al., 2015). The Interagency Autism Coordinating Committee, which is charged with advising the Department of Health and Human Services on concerns among the autistic community, highlighted the need for services to improve the functioning and quality of life of autistic AYA in the transition to adulthood. However, research has yet to characterize discussions between health care providers (HCPs), a resource for information regarding health and well-being, and patients and families as they prepare for this transition.

Objectives: To determine the extent to which HCPs (Physicians, Nurse Practitioners [NPs], Mental HCPs, and Social Workers) discuss transition to adulthood (TTA) topics with autistic and non-autistic AYA patients and their families. Specifically, we report the specific TTA topics different HCP groups discuss and their perceived level of comfort with these discussions.

Methods: We conducted a survey with HCPs who see both autistic and non-autistic patients from the Philadelphia metro-region to capture: 1) demographic information; 2) whether they discuss 16 TTA topics with their patients (yes/no); and 3) their perceived comfort with these discussions (not at all/a little/somewhat/very/extremely). As a first step, we explored the data to characterize trends across HCP professions and patient groups.

Results: 103 HCPs completed the survey. Compared to other HCPs, physicians and social workers had large difference in comfort discussing the TTA topics with autistic versus non-autistic patients. For example, approximately twice as many physicians reported feeling "very" or "extremely" comfortable discussing TTA topics with non-autistic (73%) patients compared to autistic patients (37%). Figure 1 depicts percentages of HCPs reporting TTA discussions by topic, profession, and patient diagnosis. With respect to specific topics, 45% of all HCPs reported discussing pregnancy and parenting with autistic patients compared to 64% discussing this topic with non-autistic patients. Conversely, 86% reported discussing community resources with their autistic patients compared to 62% discussing this topic with non-autistic patients. Across both patient populations, the majority of HCPs reported discussing transition to adult healthcare, mental health, and education planning; less discussed topics including housing, housekeeping, and legal skills.

Conclusions: HCPs reported discussing different TTA topics with autistic and non-autistic patients, which may be influenced by profession and clinical role. The majority of HCPs reported feeling uncomfortable with TTA discussions with autistic patients, but felt more comfortable having TTA discussions with non-autistic patients. This could potentially lead to HCPs failing to discuss important health topics, like pregnancy prevention, with autistic AYA patients. Future efforts to enhance HCPs comfort with discussing TTA topics with autistic patients may help to ensure that all AYA patients receive information needed to support healthy transition to adulthood.

423.022 *(Poster)* Communal Coping As a Moderator of the Relation between ASD Symptom Severity and Functioning in Typically-Developing Siblings.

B. Southern[1]*, S. W. Eldred*[1]*, T. S. Tomeny*[1]*, L. K. Baker*[2] *and J. R. Pederson*[3]*, (1)Psychology, The University of Alabama, Tuscaloosa, AL, (2)Hassenfeld Children's Hospital at NYU Langone, New York, NY, (3)Communication Studies, The University of Alabama, Tuscaloosa, AL*

Background: Previous research on typically-developing (TD) siblings of children with ASD is often mixed (e.g., Meadan et al., 2010), suggesting that negative outcomes likely occur only under certain conditions. One potential predictor of TD sibling functioning is the degree of challenging behaviors in the sibling with ASD, with more severe problems associated with worse TD sibling functioning (e.g., Hastings, 2003; Petalas et al., 2012). To this end, elevated ASD symptom presentations may prove stressful for TD siblings and the family as a whole. Yet, a longstanding line of research shows that coping abilities can mitigate the effects of stressors (Compas et al., 2001). Communal coping, the extent to which a group (i.e., a family) works together to solve collective problems (as opposed to approaching them individually; Lyons et al., 1998), may be a particularly important determinant of TD sibling functioning.

Objectives: This study tested TD sibling-reported communal coping within the family as a potential moderator of the relation between caregiver-reported ASD symptoms in the child with ASD and TD sibling-reported emotional and behavioral functioning.

Methods: The sample was 106 dyads that consisted of a caregiver (87.7% female) and a TD sibling (M_{age} = 13.76; SD_{age} = 1.91; 53% female) of a child with ASD (M_{age} = 11.47; SD_{age} = 4.01; 13% female). Caregivers completed the Children's Social Behavior Questionnaire (CSBQ) as a measure of ASD symptoms in the child with ASD. TD siblings completed the Strengths and Difficulties Questionnaire (SDQ), which measures their own emotional and behavioral functioning, and the Communal Coping During Family Challenges scale (CCFC), assessing their perspectives on collective coping within the family.

Results: The overall multiple regression analysis predicting TD sibling emotional and behavioral functioning was significant, $F(3,102) = 4.87$, $p = .003$, $R^2 = .13$. TD sibling-reported communal coping moderated the relation between ASD symptoms in the child with ASD (as reported by parents) and TD siblings' own perceptions of their emotional and behavioral functioning, $B = .005$, $SE = .002$, $p = .03$. When communal coping was reported as low or moderate, the relation between ASD symptoms and TD sibling emotional and behavioral functioning was nonsignificant, $B = -.03$, $SE = .05$, $p = .53$; $B = .04$, $SE = .03$, $p = .15$, respectively. However, ASD symptoms and TD sibling functioning related positively when communal coping was high, $B = .12$, $SE = .05$, $p = .01$. Specifically, TD siblings reported the least emotional and behavioral problems when ASD symptoms were mild and communal coping was high (Figure 1).

Conclusions: The results of this study suggest that communal coping may serve as a protective factor or buffer for TD sibling emotional and behavioral functioning. Again, previous research suggests that TD siblings likely only experience negative adjustment under certain conditions, such as when the child with ASD has severe symptoms and the TD sibling perceives little communal coping within their family. As such, communal coping could serve as one potential target for interventions aimed at improving functioning among families.

423.023 *(Poster)* Connected Versus Disconnected: Perspectives of Latino Parents of Children with Autism Spectrum Disorder Regarding Their Child's Teacher

L. Hauptman[1]*, **F. A. Castellon***[2] *and C. Kasari*[1]*, (1)University of California, Los Angeles, Los Angeles, CA, (2)University of California Santa Barbara, Santa Barbara, CA*

Background: For Latino parents of children with autism spectrum disorder (ASD), forming collaborative relationships with teachers can be especially challenging because of possible barriers, such as language or power dynamics, as well as stereotypes that Latino parents are not involved in their child's education (Gonzalez & Ayala-Alcantar, 2008; LeFevre & Shaw, 2012; Burke et al., 2018). Outcomes related to parent-teacher partnerships such as academic improvement and quality of life (Eskow et al., 2018; Hsiao et al., 2017) make pursuing partnerships beneficial for families. Despite these benefits, little is known about how Latino parents feel about relationships with their child's teacher.

Objectives: The purpose is to determine the nature of the relationships that Latino parents of elementary school-aged children with ASD have with their child's primary school teacher, and to describe the characteristics that make up these relationships.

Methods: Forty-one Latino parents of elementary school-aged children with ASD who were recruited for a larger study (N=94) responded to the prompt: “Is there anything you would like to say about your child’s teacher?” Qualitative responders had a mean age of 39.50, lived in the U.S. an average of 24.89 years, and there was representation from kindergarten-5th grade. Spanish responses were translated to English by native speakers. Forty percent of responses were double coded. Consensus coding was used for discrepancies. Inductive coding was used to review responses. Main themes of parent-teacher connection and parent-teacher disconnect emerged. Deductive coding was then implemented.

Results: Of the 41 participants, 16 (39%) described feeling connected with their child’s teacher: they felt they understood each other and agreed with what the teacher was doing. Twenty (49%) parents described feeling disconnected with the teacher: the parent did not agree with the teacher’s methods, and did not feel like they understood their child. Five (12%) parents made general teacher or school comments, not related to relationships.

Within the connection theme, sub-codes emerged: makes the effort, child inclusion, good communication, and general positive. In general, parents felt more connected with teachers when they felt they were getting to know their child and their family, and contributed extra effort to ensure the child was learning.

Within the disconnect theme, sub-codes emerged: minimizes needs, lack of communication, teacher unprepared, mistreatment, and general negative. Parents felt more disconnected with their child’s teacher if they did not feel the teacher was properly trained, did not understand their child’s needs, or did not communicate with parents.

Conclusions:

Identified codes assist in dispelling the myth that Latino parents do not want to be involved in their child’s education (Gonzalez & Ayala-Alcantar, 2008). Results indicated that Latino parents, like most parents, want teachers to communicate with them and understand their family’s needs, which are key components that lead parents to feel connected or disconnected with teachers. This study found similar results to past studies that did not focus on Latino families (e.g., Blue-Banning et al., 2004), showing that communication and feeling understood is important. Themes could be used as tools for teachers to mitigate productive relationships.

423.024 *(Poster)* Developing and Evaluating an Autism-Specific Research Passport

M. Ashworth[1]*, L. Crane*[2]*, R. Steward*[3]*, J. Davies*[4]*, L. Kenny*[5]*, M. Bovis*[6] *and E. Pellicano*[7]*, (1)Centre for Research in Autism and Education, UCL Institute of Education, University College London, London, United Kingdom, London, United Kingdom, (2)Centre for Research in Autism and Education, UCL Institute of Education, University College London, London, United Kingdom, (3)Centre for Research in Autism and Education, UCL Institute of Education, University College London, London, United Kingdom,, London, United Kingdom, (4)Centre for Research in Autism and Education, UCL Institute of Education, London, United Kingdom, (5)Centre for Research in Autism and Education (CRAE), London, United Kingdom of Great Britain and Northern Ireland, (6)Kings College London, London, United Kingdom, (7)Macquarie University, Sydney, Australia*

Background: There has been a dramatic increase in the amount of autism research taking place across the world. Despite the potential for autism research to benefit the lives of autistic people and their families, they often report negative perceptions of research: feeling excluded from research, reporting poor management of expectations, receiving little or no feedback (during and after the process) and viewing their participation as tokenistic.

In other areas that autistic people often report negative experiences, such as in healthcare and the criminal justice system, ‘passports’ have been developed to support and empower autistic people and their families, and to enable professionals to meet the needs of those with whom they are working. Yet, to date, there have been no published evaluations of their utility. In addition, no passports have been designed specifically for researchers working with autistic people and their families.

Objectives: This project aimed to develop and evaluate the utility of a ‘Research Passport’ for use by autistic people, their families and researchers, with the aim of improving participant satisfaction with autism research. It also sought to examine whether the Research Passport might enable researchers to improve their practice and approach to research.

Methods: This study involved three key phases of an iterative design process. In Phase 1, in-depth qualitative focus groups were conducted with autistic adults (n=10), parents of autistic children (n=4) and autism researchers (n=6) to gather their views on what kind of information the Research Passport should include. In Phase 2, a prototype Research Passport was co-created with community members. In Phase 3 (ongoing), the Research Passport prototype will be evaluated via a survey and interviews with autistic people, parents and researchers to gather their experiences of the research process with and without the assistance of a Research Passport.

Results: Thematic analysis of Phase 1 focus groups showed that autistic adults, parents and researchers thought a Research Passport would be a useful tool. The passport would be a means to start a dialogue between participants and autism researchers to ensure taking part in research was a supportive and respectful experience. Nevertheless, participants also highlighted that the Research Passport should not be considered a "cure all" for all problems in autism research, and it should not become a "burden" for participants or researchers by being too long and difficult to complete. User testing in Phase 2 helped to develop a refined version of the Research Passport by assessing how effectively participant and researcher contributions for the passport are gathered. Its perceived success will be evaluated through user testing in Phase 3 before and after using the Research Passport.

Conclusions: The Research Passport aims to be a novel, evidence-informed tool, freely available for autistic people and researchers' use for research projects. These findings from Phase 1 clearly demonstrate the perceived need and utility of this tool by community members. The co-creation of the Research Passport should ensure that it is tailored to the needs of community members *and* researchers.

423.025 *(Poster)* Development and Evaluation of the "Puente" Promotora Model to Reduce Ethnic Disparities in Developmental Disability Service Utilization

S. R. Rieth[1]*, G. May*[2]*, K. S. Dickson*[3]*, R. Zaragoza*[4]*, D. Storman*[5]*, R. Plotkin*[4]*, C. Corsello Orahovats*[6] *and L. Brookman-Frazee*[3,7,8]*, (1)San Diego State University, San Diego, CA, (2)Psychiatry, UC San Diego, San Diego, CA, (3)Child and Adolescent Services Research Center, San Diego, CA, (4)San Diego Regional Center, San Diego, CA, (5)Exceptional Family Resource Center, San Diego, San Diego State University Research Foundation, San Diego, CA, (6)Division TEACCH, University of North Carolina, Chapel Hill; Chapel Hill, NC, Raleigh, NC, (7)Psychiatry, University of California, San Diego, La Jolla, CA, (8)Autism Discovery Institute, Rady Children's Hospital-San Diego, San Diego, CA*

Background: Ethnic disparities in access to evidence-based community services for youth with developmental disabilities are a pressing concern. In 2016, the California Department of Developmental Services launched an initiative to address significant disparities in service expenditures for Latinx clients. In response, the San Diego Regional Center (SDRC) initiated a partnership with academic and community partners to identify disparity reduction targets for its clients and develop and implement a disparity reduction model.

Objectives: This presentation will describe the development and initial outcomes from an evaluation of the "PUENTE" Promotora model developed by the partners.

Methods: Service utilization data from 27,343 SDRC clients were examined to identify targeted diagnoses and ages for intervention. Through collaboration among SDRC, researchers, a family resource center, and the developer of a Promotora-delivered psychoeducational curriculum, the PUENTE model was developed. The goal of the intervention is to promote psychoeducation and empowerment for parents of Latinx youth ages 11 to 16 with developmental disabilities.

SDRC case managers referred Latinx families identified to underutilize services. Promotoras were assigned to the families and conduct home visits for 12 weeks to deliver an adapted version of the *Parents Taking Action* curriculum (Magaña, Lopez, & Machalicek, 2017). Promotoras for the program were caregivers of individuals with developmental disabilities who have extensive experience navigating the service system. At intake and exit, an independent program evaluator administered a range of caregiver self-report measures. Measures examine caregivers' knowledge of disabilities, strain, depression, and self-efficacy. Promotoras and caregivers were also asked to complete surveys upon completion of the program to assess feasibility, acceptability, and adaptations.

Results: A total of 34 youth clients were identified by SDRC service coordinators and referred to the PUENTE program. Across all families who initiated the service, youth were an average of 13.5 years old (SD=1.8) and 64% male. Youth diagnoses were: 33% ASD, 33% ID, and 33% multiple diagnoses (ASD/ID, ID, CP, ID/CP/EP). The majority of families served reported incomes below the poverty line and less than a high school level of parent education (61% and 58%, respectively).

Initial feasibility and outcome data for the program are promising. Promotoras rated caregivers as highly engaged in the intervention (M=4.69 on 1-5 scale, SD=0.34) and caregivers indicated high satisfaction with the PUENTE program overall (M=3.88 on 1-4 scale, SD = 0.13). When asked what they learned through the PUENTE program, 62% of families reported becoming more knowledgeable about the Individualized Education Plan process and requesting services at or related to school specifically, and 62% mentioned becoming stronger advocates for their child broadly. Analyses revealed parents reported significantly fewer depression symptoms ($p<.05$) and significantly higher perceptions of parental self-efficacy after participation ($p<.05$).

Conclusions: Preliminary data demonstrate the feasibility and appropriateness of the PUENTE program to reach Latinx families with youth with developmental disabilities. These outcomes are in contrast to previous reports of Latinx families reporting low satisfaction with services and being less likely to receive guideline-concordant care, particularly for autism. Additional impact of the intervention and mechanisms for sustainability will be discussed.

423.026 *(Poster)* Differences in Caregiver and Child Factors Considering the Birth Order of Children with ASD

S. C. Boland[1]*, R. A. Lindsey*[1] *and T. D. Barry*[2]*, (1)Washington State University, Pullman, WA, (2)Psychology, Washington State University, Pullman, WA*

Background: Parenting a child with a disability can negatively impact caregivers' distress (Raina et al., 2004). Though research has investigated the ways in which caregiver factors, such as self-efficacy and stress, are associated with one another (Kuhn & Carter, 2006), there is limited research on how these factors differ across varied family structures. Given the heightened distress among parents of children with ASD and the reliance of parent report in clinical evaluation, it is essential to understand how nuances in family structure (e.g., birth order) may impact caregivers' reports of their own wellbeing and their children's symptomatology.

Objectives: To investigate how the birth order of children with ASD may impact reporting of parental wellbeing/competency and child symptomatology.

Methods: Participants were 155 caregivers with one child with ASD categorized into three birth order groups: caregivers who have (1) a first-born child with ASD and then typically-developing (TD) child(ren) (First-Born condition); (2) TD child(ren) and then a non-first-born child with ASD (Non-First-Born condition), and (3) one child with ASD (Only-Child condition). Caregivers completed questionnaires related to parental factors such as family resources (FRS), caregiver distress (DASS), efficacy/satisfaction (PSOC), ASD knowledge (ASK-ASD), and perceived social support (MSPSS). Caregivers also reported on child factors including internalizing/externalizing behaviors of the child with autism (BASC-3) and ASD symptom severity (CSBQ).

Results: Zero-order correlations among the parent and child variables are presented by birth order condition in Table 1. A one-way ANOVA examining group differences (Table 2) indicated that the three birth order conditions did not differ significantly on caregiver distress, family resources, ASD symptom severity, and externalizing behaviors. The mean score for the not-first-born condition was significantly higher than the other two groups for satisfaction, whereas the mean score for the first-born condition was significantly lower than the other two groups for efficacy. The mean score for the only-child condition was significantly higher than the first-born condition for perceived social support, lower than the other two groups for ASD knowledge, and higher than the other two groups for child internalizing behaviors.

Conclusions: There is currently limited research on how child birth order may affect caregivers' reports of their own experiences when raising a child with autism. In the current study, despite comparable ratings on family resources and ASD severity, there was a significant effect of birth order on several parent factors and child internalizing behaviors. Given the findings on satisfaction and efficacy, having one or multiple TD children before having a child with autism may enhance feelings of readiness or competency as a parent. Interestingly, caregivers of the first-born group reported less efficacy and perceived social support than the only-child group, perhaps due to possible stress of having a second child while simultaneously navigating the autism diagnosis of the first child. The results suggest that having multiple children in the family may increase parents' actual knowledge of ASD. This finding, in combination with the only-child condition being the only group to have a significant negative correlation between efficacy and knowledge, prompts the need for further research.

423.027 *(Poster)* Do Serbian Parents of Children with Autism Spectrum Disorder Experience a Greater Degree of Stigma Than Parents of Children with Physical Disabilities

M. Čolić[1] *and I. Milačić-Vidojević*[2]*, (1)Faculty of Special Education and Rehabilitation, University of Belgrade, Belgrade, CA, Serbia, (2)Faculty of Special Education and Rehabilitation, University of Belgrade, Belgrade, Serbia*

Background: Although researchers have been exploring experienced stigma among parents of children with Autism Spectrum Disorder (ASD) in the past 10 years, no such studies were conducted in Serbia and in neighboring countries. The literature suggests that parents of children with ASD experience a greater degree of stigma compared to parents of children with different types of developmental disabilities.

Objectives: Aim of the present study was to compare stigmatized experiences of parents of children with ASD and physical disabilities (PD) in Serbia.

Methods: The convenient sample consisted of 82 Serbian parents (40 of children with ASD and 42 of children with PD) participated in the study. The parents were recruited via NGO and public schools across country. For the purpose of this study we developed the Experienced Stigma Scale. We applied EFA and CFA and out of 20 included items, 8-item solution clustered into 2 factors proven to be the best. It is 5-point Likert scale where higher score represents greater degree of an experienced stigma.

Results: The parents of children with ASD reported a greater level of experienced stigma in comparison to parents of children with PD (mean rank = 277.61 and 216.87 retrospectively; $U = -4.744$, $p = 0.000$). Additionally, parents of children with ASD reported that most negative experiences reported are: people on the street judged them when child misbehaves (AS = 3.58, SD = 1.107), the friends felt uncomfortable when child with ASD was present (AS = 3.18, SD = 1.238), and the friends visited them less often since they knew about the ASD child (AS = 3.08, SD = 1.559).

Conclusions: Results of the present study showed that parents of children with ASD experienced more stigma in comparison to the parents of children with PD. In addition, they experienced the most stigma in relation with their friends.

423.028 *(Poster)* Does Participatory Programming Promote Positive Outcomes for Autistic College Students? a Cross-Institutional Survey Study

A. Riccio[1]*, S. K. Kapp*[2]*, E. Cage*[3]*, J. Vincent*[4]*, D. DeNigris*[5]*, A. Jordan*[6]*, J. Delos Santos*[7]*, P. Dwyer*[8]*, B. Kofner*[9]*, J. Solomon*[10]*, D. S. Smith*[11]*, M. Hossain*[12] *and K. Gillespie-Lynch*[13]*, (1)Department of Psychology, The Graduate Center, City University of New York (CUNY), New York, NY, (2)Department of Psychology, University of Portsmouth, Portsmouth, United Kingdom, (3)University of Stirling, Stirling, United Kingdom, (4)York St. John University, York, United Kingdom, (5)Psychology & Counseling, Fairleigh Dickinson University, Madison, NJ, (6)CUNY, Staten Island, NY, (7)Hunter College, City University of New York, New York, NY, (8)Department of Psychology, University of California, Davis, Davis, CA, (9)CUNY, NY, NY, (10)Job Path NY, New York, NY, (11)College of Staten Island, CUNY, Staten Island, NY, (12)Psychology, Pace University, New York, NY, (13)Department of Psychology, College of Staten Island; CUNY Graduate Center, Brooklyn, NY*

Background: As more autistic people attend university, available social supports may significantly impact their identity development and well-being in college. Prior research has examined programs at a single university (e.g., Hillier et al., 2018) or inferred general patterns by recruiting students and parents from numerous institutions without examining how institution-specific factors impact their perspectives (e.g., White et al., 2016; Cai & Richdale, 2016). While this research is important for gaining information about the needs of autistic students and their families, prior research does not consider how factors in the college environment may shape development. We, members of a participatory mentorship program for autistic university students, wished to examine the degree to which participatory programming may promote positive outcomes.

Objectives: We examined if specific types of supports are associated with individual and community identity and well-being across institutions. We hypothesized that:

- Students involved in participatory (or autistic-led) programs would exhibit heightened autism identity and pride;
- Autism identity would be positively associated with QoL (Quality of Life), well-being, and a sense of belonging at university.

Methods: Autistic college students and academics and non-autistic researchers collaboratively developed hypotheses and an online survey. Participants (*n*=85, *Mage*=23.88, 50.6% male, 67.1% White, 72.9% undergraduates; representing 8 countries and 48 universities) completed an online survey assessing supports, autism traits, involvement with the neurodiversity movement, QoL, well-being, university belonging, a text-based autism identity (assessing identification with the autism community) and a picture-based scale (assessing affect, anxiety, pride, and energy in response to core autistic experiences; developed by our participatory research group).

Results: Correlations revealed that involvement with autistic-led programming was associated with heightened well-being, belonging, and QoL but not autistic identity (Table 1). The autistic identity measures were unrelated to each other. Only involvement with the neurodiversity movement was associated with autism community identification. Follow-up regressions controlling for gender, age, autistic traits, and student level revealed that autistic-led programming, but not neurodiversity involvement, was associated with belonging.

Heightened autistic traits were associated with reduced well-being and QoL. Unexpectedly, neurodiversity involvement was *negatively* associated with QoL and well-being. Follow-up regressions revealed this was attributable to associations between neurodiversity involvement and heightened autistic traits.

Well-being and QoL, but not belonging, were associated with heightened affect, pride, and energy and reduced anxiety about autistic experiences. When gender, age, traits, and student level were included in regressions including all four emotional reactions to autism, heightened autism traits and reduced anxiety about autistic characteristics predicted QoL and well-being.

Conclusions: When autistic students play a leadership role in developing university supports, their peers benefit. While directionality cannot be inferred, clear relationships between participatory programming, well-being, QoL, and a sense of belonging at university were observed. Universities should include autistic students in developing and delivering autism supports to promote leadership skills and belonging. Positive attitudes toward autistic experiences may promote well-being and QoL among autistic students. Educators should focus on fostering a sense of pride in autistic students and researchers should prioritize participatory research methods to better understand and serve diverse autistic people.

423.029 *(Poster)* Early Detection, Diagnosis and Intervention Services for Young Children with Autism Spectrum Disorder across Regions of Europe According to the Gross Domestic Product (GDP)

Á. Bejarano[1], *R. Canal-Bedia*[1], *M. Magan Maganto*[1], *C. Fernandez Alvarez*[1], *M. V. Martín Cilleros*[1], *M. C. Sánchez Gómez*[1], *P. García-Primo*[2], *M. R. Sweeney*[3], *A. M. Background: The perspectives of parents and professionals towards detection and diagnosis of Autism Spectrum Disorder (ASD) play a fundamental role in guiding the improvement of services, but both viewpoints have rarely been considered jointly in the European regions. With regard to the socio-demographic aspects, studies have shown that individuals with ASD belonging to families with a high parental socio-economic status (SES) are detected and diagnosed earlier, and that their families report greater satisfaction with services.

Objectives: The aim of this study is to know the relationships between the Gross Domestic Product (GDP) across European countries and the access and quality of services of detection, diagnosis, and early intervention for young children with ASD, and how this relation can explain the satisfaction of the autism community (families and professionals). Hence, it is important to identify the variables that predict service satisfaction in all GDP regions to obtain detailed information about the views held by various European stakeholders on such services, in order to inform the decisions of policy makers -at both a national and European level- affecting the financing of services.

Methods: Twenty focus groups were carried out in 10 European countries within the framework of the Autism Spectrum Disorders in the European Union (ASDEU) network, leading to the development of two independent surveys that were distributed online among families with a child with ASD and professionals who reported working or have worked with same study population in the same period of time or in recent years (N = 2,032). Questions aimed to collect specific data about detection, diagnosis and intervention of young children with ASD (level of satisfaction, age of access, etc). Multinomial regression analyses were conducted to compare the different regions of Europe according to the GDP (low GDP (under 20,000 euros); medium GDP (20,000 to 30,000 euros); high GDP (30,000 to 40,000 euros); very high GDP (over 40,000 euros)).

Results: Overall, 60.2% of respondents reported positive satisfaction with services. Respondents in regions with low or medium GDP were more likely to give low ratings to detection, diagnostic and intervention services (4.48) than those living in regions with higher GDP (4.96). European regions with lower incomes reported delays to service access more frequently. However, in these regions residents reported an earlier age of access to services compared to European regions with higher GDP. Furthermore, a positive predictor of satisfaction among families and professionals in all regions was shorter waiting times (< 6 months) to access to the health services.

Conclusions: Although, overall, families and professionals express satisfaction with detection, diagnosis and intervention services for children with ASD in their communities, there are differences between countries with different GDPs. Considering that most of the respondents in the medium and low GDP groups were from Poland and Spain, discrepancies could be explained by sampling bias. Furthermore, policy makers should reduce waiting times between services as it was a significant predictor of satisfaction in all GDP regions.

423.030 *(Poster)* Effects of an Mbsr Parent Intervention on Internalizing Problems in Children: ASD Status As a Moderator

H. A. McGregor*, C. M. Sanner and C. L. Neece, Psychology, Loma Linda University, Loma Linda, CA*

Background: Children with autism spectrum disorders (ASD) are at high risk for increased levels of behavior problems and developing internalizing problems. Previous literature has highlighted the impact of parental stress on the development of behavioral problems in children with ASD, particularly externalizing behavior problems; however, little research has examined the relation between parenting stress and internalizing problems in children with ASD.

Objectives: We investigated whether decreases in parenting stress through the use of MBSR would lead to reductions in internalizing behavior problems among children with ASD and children with developmental delays (DD), and whether this relation would be moderated by the child's ASD status. Additionally, we examined whether individual increases in the mindful facets of acting with awareness and non-judgment, from pre- to post- treatment, would be associated with reductions in internalizing problems among children with ASD and children with DD, and whether this relation was moderated by the child's ASD status.

Methods: The current study utilized data from the Mindful Awareness for Parenting Stress (MAPS) Project which included 80 families of preschool children between the ages of 3 and 5 (M = 3.5, SD = .96) with ASD (N = 49) and DD (N = 31) whose parents reported high levels of parenting stress. Families were randomized to either to immediately attend a Mindfulness-Based Stressed Reduction (MBSR) intervention or to a wait-list control group.

Results: We found that children whose parents were assigned to the MBSR treatment group, were reported to have greater reductions in internalizing problems compared to children whose parents were assigned to the waitlist-control group, b = -5.71, p < .05. Furthermore, we found that children of parents who reported greater increases in acting with awareness post-treatment had greater reductions in internalizing problems, b = -2.57, p < .05. Additionally, results indicated that children whose parents had greater increases in non-judgment post-treatment had greater reductions in internalizing problems, b = -1.85 , p < .05. However, ASD status was not a significant moderator in any of the analyses, ps > .05.

Conclusions: These findings suggest that parents' use of MBSR, specifically acting with awareness and acting non-judgmentally, may lead to reductions in internalizing problems for both children with ASD as well as children with DD. Given that internalizing problems are highly comorbid in children with ASD, these findings have important implications for future parenting interventions and understanding how parents utilization of MBSR may lead to reductions in internalizing problems of children with ASD or DD.

423.031 *(Poster)* Environmental Barriers and Facilitators to Primary Care for Adults with Autism: Multi-Informant Qualitative Results

L. I. Duker (Stein)[1]*, A. Pomponio*[2] *and B. Pfeiffer*[3]*, (1)Division of Occupational Science and Occupational Therapy, University of Southern California, Los Angeles, CA, (2)Temple University, Philadelphia, PA, (3)Rehabilitation Sciences, Temple University, Philadelphia, PA*

Background: Primary care is associated with positive societal outcomes, including improved access to healthcare services, health outcomes, and cost savings. Few studies have documented the primary care health experiences of adults with autism spectrum disorder (aASD). However, those existing studies report that aASD experience numerous challenges in the receipt of primary care, reporting decreased satisfaction and increased unmet physical and mental healthcare needs.

Objectives: As the number of aASD who require primary care is likely to increase over the next decade, there is a pressing need to improve the quality of primary healthcare for aASD with empirically validated, client-centered strategies and tools. Therefore, the purpose of this study was to describe the barriers and facilitators to positive primary care health encounters for aASD and provide strategies to address these challenges.

Methods: As part of a larger mixed methods convergent parallel design study, interviews were conducted with adults with ASD (n=34) and caregivers (n=31) in Los Angeles and Philadelphia; interviews lasted an average of 28 and 37 minutes (respectively) and were transcribed verbatim. Thematic analysis was employed to describe barriers and facilitators to primary care health encounters, as reported by each group.

Results: Three main overlapping themes emerged from the interviews. The first theme, *It's All About the Doctor,* focused on the importance of provider attributes, and those attributes' ability to either positively or negatively impact the care experience for adults with ASD. The second theme, *The Environment Is So Overwhelming* highlighted the significance of the waiting room and private clinic room environments. Lastly, the identification and utilization of tailored *Strategies and Accommodations* was reported as essential by all participants; however, the need for advocacy was also expressed, as many participants reported feelings of shortcoming when trying to utilize strategies during care and/or engage the provider in their use.

Conclusions: Findings provide insight into the barriers and facilitators to care as well as the techniques perceived by aASD and caregivers to facilitate positive primary care health encounters for aASD. Areas of overlap provide a blueprint for high-priority obstacles to address in intervention development in order to improve the quality of primary healthcare services for aASD.

423.032 *(Poster)* Examination of Predictors and Mediators of Life Satisfaction of Caregivers of Children with Autism Spectrum Disorder

L. K. Baker[1]*, T. S. Tomeny*[1]*, S. W. Eldred*[1]*, C. A. Paisley*[2] *and J. A. Rankin*[1]*, (1)Psychology, The University of Alabama, Tuscaloosa, AL, (2)The University of Alabama, Tuscaloosa, AL*

Background: Research on caregivers of children with ASD has found increased risk of negative outcomes associated with parenting a child with ASD (e.g., Dabrowska & Pisula, 2010). Additionally, the severity of their child's autism symptoms is often examined as a predictor of negative outcomes for caregivers (e.g., Garcia-Lopez et al., 2016). More recently, the field of ASD research has recently begun to focus on more positive outcomes, such as life satisfaction, for caregivers of children with ASD (e.g., Ekas & Whitman, 2010). As such, examination of the potential relation between autism symptom severity and caregiver life satisfaction, as well as potential mediators of this relation is important for caregivers of children with ASD.

Objectives: The current study sought to 1) examine autism symptoms severity in the child with ASD as a predictor of caregiver life satisfaction, and 2) examine caregiver distress and caregiver social support as mediators of the relation between autism symptom severity and caregiver life satisfaction.

Methods: Participants included 106 primary caregivers (*M* = 41.40, *SD* = 5.12) and 68 secondary caregivers (*M* = 42.87, *SD* = 6.91) with of children ASD ages 3 to 17 years (*M* = 11.47, *SD* = 4.00). Caregivers completed measures to assess ASD symptom severity in their children with ASD, a self-report measure of overall distress, and a self-report measure of overall life satisfaction. Two parallel mediation models were examined such that autism symptom severity in the child with ASD served as the predictor of primary caregivers' and secondary caregivers' life satisfaction. It was predicted that autism symptom severity (X) would be related to caregiver life satisfaction (Y) through caregiver distress (M_1) and caregiver social support (M_2).

Results: For primary caregivers, autism symptom severity of children with ASD did not demonstrate a direct pathway to life satisfaction, when controlling for distress and social support (*B* = 0.001, *SE* = 0.03, *p* = .971). However, bootstrapped confidence intervals indicated an indirect effect through distress (*B* = -0.04, Boot *SE* = 0.02, 95% CI = [-.07, -.01]). In contrast, no indirect effect through social support was found (*B* = 0.01, Boot *SE* = 0.02, 95% CI = [-.03, .04]). For secondary caregivers, autism symptom severity of children with ASD did not demonstrate a direct pathway to life satisfaction, when controlling for distress and social support (*B* = 0.02, *SE* = 0.03, *p* = .608). Additionally, no indirect effects through distress (*B* = -0.03, Boot *SE* = 0.02, 95% CI = [-.08, .003]) or social support were found (*B* = -0.01, Boot *SE* = 0.01, 95% CI = [-.04, .02]).

Conclusions: Despite the general lack of support for the hypothesized parallel mediation models, this study highlights the importance of researchers continuing to explore positive outcomes for family members of children with ASD. These results suggest that clinicians working with families of children with ASD may want to assess for caregiver distress, social support, and life satisfaction to identify those family members who may be functioning at an adequate level and those who may be struggling.

423.033 *(Poster)* Examining the Impact of Familial and Sociocultural Factors on Concurrent Anxiety Symptoms in Children with ASD

N. V. Rodas[1] *and J. Blacher*[2]*, (1)Psychology, University of California, Los Angeles, Los Angeles, CA, (2)Graduate School of Education, University of California Riverside, Riverside, CA*

Background: Anxiety disorders are prevalent in about 40% of youth with ASD (Jennett et al., 2013), in contrast to the prevalence rate of approximately 10% in children with neurotypical development (Costello et al., 2011). While research regarding the etiology of anxiety in ASD is continuing to develop, there is a need to examine how familial and sociocultural factors may also be implicated in the development of anxiety. Lower socioeconomic status has been widely implicated as a risk factor of psychopathology, including anxiety disorders in typically developing children (Lemstra et al., 2008). Researchers have also found that lower SES is related to higher rates of comorbid psychopathology in children and adolescents with ASD (Rosa et al., 2016). Therefore, there is a need to investigate the relationship between SES and anxiety symptoms in children with ASD.

Furthermore, in studies examining family culture in children with neurotypical development, Latino youth have been shown to present with higher levels of anxiety symptomatology when compared to their White peers (Varela et al., 2004). Given that children with ASD are more likely to present with anxiety symptoms, it is imperative to examine whether Latino children with ASD may be significantly more at risk in order to help target interventions.

Objectives: The first aim of this study was to examine the relationship between SES and anxiety symptoms, as well as to examine the extent to which anxiety symptomatology varies by child ethnicity. We examined the following research questions: 1) To what extent does SES relate to anxiety symptoms in a sample of children with ASD? 2) To what extent do anxiety symptom levels differ between Latino and White children? A secondary aim was to examine a moderation model linking maternal acculturation, maternal familism, and child anxiety symptoms in Latino families.

Methods: Participants were mothers and their children with ASD. The sample was comprised of White (non-Hispanic; n=42) participants or Latino participants (n=74). We conducted a regression analysis, controlling for child sex and ethnicity, in order to determine whether SES was associated with concurrent anxiety symptoms. Next, we ran analysis of covariance (ANCOVA) in order to elucidate the ethnic differences in anxiety symptoms. Lastly, we examined the extent to which acculturation, familism, and child anxiety were related in the subsample of Latino children with ASD.

Results*:* We found that SES was inversely associated with child anxiety symptoms (*B* = -6.48, *p* < .05). Further, Latino and White children with ASD did not differ in their anxiety symptom levels (*F* (1, 116) = 0.27, *p* = 0.59). Additionally, maternal familism was found to moderate the relationship between maternal enculturation and child anxiety.

Conclusions: Our findings highlight the importance of identifying and targeting interventions for high-risk children. Additionally, enculturation and familism may be salient targets of intervention within the context of child anxiety treatment for Latino families.

423.034 *(Poster)* Examining the Role of Socioeconomic Position in the Quality of Life of Mothers Raising a Child/Children with ASD: A Qualitative Investigation in Greece.

C. Dardani[1]*, S. Mavropoulou*[2] *and A. Zissi*[3]*, (1)Population Health Sciences, Bristol Medical School, Centre for Academic Mental Health, Bristol, United Kingdom, (2)School of Early Childhood & Inclusive Education, Queensland University of Technology, Brisbane, Australia, (3)Department of Sociology, University of the Aegean, Mytilene, Greece*

Background: There is amassing evidence suggesting that parents, especially mothers, of children with ASD are more likely to experience increased levels of stress and lower quality of life compared to parents of children without ASD. Researchers so far have focused on the possible role of ASD symptomatology and parental behavioural, cognitive and personality characteristics in the experience of parenting a child with ASD. Over the last years, research is growing on whether parental income, educational attainment, employment status and access to resources are possible factors contributing and differentiating the quality of life of parents raising a child/children with ASD.

Objectives: To explore the role of socioeconomic position, through the Erik Olin Wright's operational framework (1985), in the quality of life of mothers raising a child/ children with ASD.

Methods: The study was designed using a comparative qualitative methodology. By employing purposive sampling, 83 mothers raising either one or more children with ASD were recruited from an urban environment (Thessaloniki, Greece). Erik Olin Wright's conceptualization of social class position was adopted to classify mothers across four social class positions. Based on Wright's conceptualization of social class, mothers' position was classified by parental income, educational attainment, skills, credentials, control over productive assets and/or organisational assets. On this basis, 35 mothers were classified as low-income/working class, 25 as petty-bourgeoisie, 25 mothers as high-income with highly specialized credentials/upper class, and 8 mothers were classified as long-term unemployed. Semi-structured interviews were conducted using a guide covering a broad range of topics including: first signs of autism in their child and diagnostic process, explanations and perceptions on the causes of ASD, their lived experience of motherhood, their relationships with their spouse, relatives and wider social networks, perceived stigma and social support, pathways to healthcare, educational and therapeutic service use, personal development and coping strategies and expectations for the future. All the interview transcripts were, initially, analysed using template analysis in accordance with the principles of thematic analysis and computer software (NVivo, version 10.1.3).

Results: The analysis of the narrative material suggested that regardless of social class, parenting a child with ASD is a major life-changing event affecting several spheres of the emotional and social life of mothers, affecting ultimately their quality of life. However, low-income/working class mothers appeared to have limited access to specialized educational and intervention resources and negative experiences regarding healthcare system navigation. In addition, they seemed to have poor social networks and recalled experiencing stigmatization. Importantly, through these narratives, several factors of empowerment and resilience were identified- practical as well as psychological.

Conclusions: To our knowledge, this is the first and largest study investigating the role of the socioeconomic position in the quality of life of mothers raising children with ASD in Greece. The present empirical findings highlight the importance of the socioeconomic position in the lived experience of parenting a child with ASD as well as the urgency for designing and delivering of specialised services approachable and sensitive to mothers from disadvantaged socioeconomic positions.

423.035 *(Poster)* Exploring the Experience of Australian Parents and Caregivers in Noticing the First Signs of Autism Spectrum Disorder

H. Smith[1,2], M. H. Black[1,2], M. Falkmer[1,2,3], C. Thompson[1,2] and ***B. T. Milbourn***[1,2]*, (1)School of Occupational Therapy, Social Work and Speech Pathology, Curtin University, Perth, WA, Australia, (2)Curtin Autism Research Group, Curtin University, Perth, WA, Australia, (3)CHILD, Swedish Institute for Disability Research, School of Education and Communication, Jönköping University, Jönköping, Sweden*

Background: The early identification of Autism Spectrum Disorder (ASD) is critical to ensuring that children and families receive appropriate and efficient access to services, resources and supports. Parents and caregivers are often the main source of information regarding the early signs of ASD in their children. There is currently limited evidence on what specific early signs are first noticed by parents/caregivers, and the experiences of parents/caregivers in reporting these signs and seeking advice and diagnosis.

Objectives: This study explored the first signs of ASD that parents/caregivers were noticing in their children prior to them receiving an ASD diagnosis and their experience reporting these signs to health professionals.

Methods: An explanatory sequential mixed method approach in two phases was utilised. Phase one involved secondary analysis of survey responses from 521 parents/caregivers of children with ASD. This secondary analysis included qualitative exploration of the first signs of ASD reported by parents/caregivers as well as quantitative investigation of gender differences in the age that first signs were initially noticed, when help was sought and when a diagnosis was obtained. Phase two included focus groups with 24 parents/caregivers of children with ASD to gain a deeper understanding of what signs first raised parents' concern about their children's development, and how parents/caregivers experienced the process of seeking advice and obtaining a diagnosis.

Results: Qualitative analysis of the survey data revealed four themes related to the type of signs of ASD parents first observed. These included: 1) difficulties with social interaction and engagement, 2) delayed or regressed milestones, 3) restrictive or repetitive behaviours and 4) sensory issues. A lack or regression of speech was the most commonly reported first sign by parents (50.59%), followed by odd and repetitive behaviours or play (26.6%), and difficulty meeting milestones (25.78%). There were no differences between the gender of the child and when the parents first sought advice or when a diagnosis was received. Signs leading to parental concern were identified earlier in female children compared to males. In Phase two analysis of interview data also identified four themes which reflected the parent's experiences. These themes included: 1) first signs, 2) seeking advice, 3) seeking diagnosis, and 4) after diagnosis.

Conclusions: Across both phases of the study, parents/caregivers commonly reported that sensory issues, a lack or regression of speech, social difficulties, repetitive and restricted behaviours and 'meltdowns' were the first signs they recognised that caused them to have concerns regarding the child's development. Parents/caregivers reported many barriers to support, including their own apprehension about seeking help, health professionals being dismissive, lacking knowledge about early manifestations of ASD and deficient in empathy for parents' concerns. Parents/caregivers also reported significant difficulty in navigating the healthcare system. Parents/caregivers required health professionals to take them seriously and implement a more empathetic approach when presenting concerns. Parents/caregivers also need more informed and clearer pathway to obtaining an ASD diagnosis to ensure more efficient and timely diagnosis.

423.036 *(Poster)* Exploring the Relationship between Family Empowerment and Quality of Life for Mothers and Fathers of Children with Autism Spectrum Disorder

A. Englert[1]*, A. Rovane[2] and R. Hock[3], (1)College of Social Work, University of South Carolina, Columbia, SC, (2)Psychology, University of South Carolina, Columbia, SC, (3)University of South Carolina, Columbia, SC*

Background: Recent estimates show approximately 2.8 million people in the United States are diagnosed with Autism Spectrum Disorder (ASD). Parents of children with ASD consistently report reduced quality of life (QoL), due to the impact of caring for a child with ASD, which is a growing health concern in the U.S. While research has explored the role of challenging child behaviors and symptoms on QoL, more research is needed to understand intra-parental factors that contribute to QoL for both mothers and fathers. Family empowerment, or confidence to complete parent-related tasks, may play an important role in QoL for parents of children with ASD.

Objectives: The objective of this study is to examine the relationship between family empowerment and QoL for parents raising a child with ASD, and whether it differs between fathers and mothers.

Methods: Participants (Mothers n= 32, Fathers n=24) were recruited through a community organization as part of an intervention study. Parents were included if they were actively parenting a young child (age 4-8) with ASD and sharing parenting with a co-parent. Participants provided informed consent and responded to a baseline questionnaire. Family empowerment was measured using the family subscale of the Family Empowerment Scale. Quality of life (QoL) was measured with the Quality of Life Autism scale, which assesses domains such as satisfaction with life, emotional distress levels, achieved self-gratification, etc. Two multiple regression models were used to address the study aims, one for mothers and the other for fathers.

Results: All assumptions for regression analyses were met. Regression models accounted for possible covariates (i.e., level of education, employment, number of children in the home, and if the parent had a household partner); all emerged as nonsignificant predictors in both models. For mothers, the regression model explained 58% of the variance in QoL. Family empowerment was significantly associated with QoL (β=.63, *p<.000)*. For fathers, neither family empowerment nor the overall regression model was significant.

Conclusions: Study findings support the hypothesis that mothers' sense of family empowerment contributes to their QoL. However, this hypothesis was not supported for fathers. It is possible that this relationship is stronger for mothers because they generally devote more time and energy to parenting tasks. This finding can be further explored by comparing the effects of parent education and support programs on mothers' and fathers' empowerment and QoL over time. These differential effects have implications for future research, and practice.

423.037 *(Poster)* Family Accommodation in Children with Autism: Relation to Symptomatology and Child Characteristics

Y. Duchovni[1], C. Schallamach[1], E. R. Lebowitz[2], D. A. Zachor[3], E. Ben-Itzchak[4] and ***J. Koller***[5]*, (1)The Hebrew University of Jerusalem, Jerusalem, Israel, (2)Yale Child Study Center, Yale School of Medicine, New Haven, CT, (3)The Autism Center/ALUT, Pediatrics, Tel Aviv University /Shamir (Assaf Harofeh) Medical Center, Zerifin, Israel, (4)Bruckner Center for Research in Autism, Communication Disorder, Ariel University, Ariel, Israel, (5)Seymour Fox School of Education, Hebrew University of Jerusalem, Jerusalem, Israel*

Background: Family accommodation refers to ways in which parents modify their behavior to help a child alleviate distress associated with emotional disorders (Lebowitz & Bloch, 2012; Lebowitz, Scharfstein & Jones, 2014). Such accommodation is common among families of children with OCD and anxiety disorders and is associated with increased symptom severity, lower functioning, and poorer treatment outcomes (Caporino et al., 2011; Lebowitz, Scharfstein & Jones, 2014; Storch et al., 2007).

One study to date has examined family accommodation of repetitive and restrictive behaviors and stereotyped interests (RRBs) in autism. Feldman et al (2019) found such accommodation to be highly prevalent, positively correlated with symptom severity and negatively correlated with adaptive functioning.

Objectives: To confirm earlier findings in a larger sample and explore the relationship between family accommodation and clinical correlates.

Methods: Participants include 125 children (34 females; mean age = 6.37, SD = 3.09) diagnosed at a tertiary center in central Israel, and their parents. Participants underwent comprehensive diagnostic assessments including developmental/cognitive evaluations, the Autism Diagnostic Observation Schedule 2 (ADOS2; Lord, DiLavore & Gotham, 2012), and the Vineland Adaptive Behavior Scales 2 (VABS-2; Sparrow, Balla & Cicchetti, 2005). Additional measures include parent-report measures of family accommodation (FAS-RRB; Feldman et al, 209), RRBs (RBS-R; Bodfish, Symons, & Lewis, 1998), and child anxiety (SCARED; Birmaher, Brent, Chiappetta, Bridge, Monga & Baugher, 1999).

Results: Family accommodation was highly prevalent, with 81.51% of parents reporting accommodating at least once monthly and 56.3% reporting daily accommodation. Accommodation positively correlated with RRB severity (r=.799, p<.001) but not with autism severity as measured by the ADOS severity score (r=-.013, p=.901). Accommodation negatively correlated with adaptive behavior skills (r=-.496, p<.001) and positively correlated with anxiety (r=.544, p<.001). A multiple regression analysis found that accommodation was predicted by RRB severity, adaptive behavior and anxiety (F(2,62)=40.195, p<.001, R2=.660) with RRB severity predicting higher levels of family accommodation (B=.461, SE(B)=.067, t=6.901, p<.001) after accounting for adaptive behavior and anxiety. No other variable explained unique variance in FAS-RRB. A one-way ANOVA was conducted to evaluate the relationship between child gender and family accommodation, yielding an insignificant result (p=.35). These analyses were repeated separately for children above and below age six. Below age six, results indicated patterns similar to the total sample. Above age six, however, no correlation was found between VABS-2 and FAS-RRB. A multiple regression was conducted on the older group, examining the contribution of RRB severity, adaptive behavior and anxiety level to family accommodation (FAS-RRB). The overall model predicted the FAS-RRB score (F(2,30)=27.678, p<.001, R2=.728). RRB severity (B=.416, SE(B)=.074, t=5.639, p<.001) and the SCARED (B=.361, SE(B)=.12, t=3.014, p=.005) explained unique variance in the FAS-RRB total score.

Conclusions: This study provides additional evidence that parents of children with autism commonly accommodate their child's RRBs and reveals the relationship between family accommodation, clinical parameters and child characteristics. Results point to differences in the relationship between these variables and age and to no such differences between genders. Future work should focus on the developmental nature and impact of family accommodation.

423.038 *(Poster)* Family Relationships and Young Adults' Well-Being: The Moderating Role of the Broader Autism Phenotype

A. Jensen*, Brigham Young University, Provo, UT*

Background: Research highlights that the quality of relationships with parents (Agerup et al., 2015) and siblings (Jensen et al., 2018) is linked to young adults' well-being. The positive benefits of social relationships, however, may be lessened for those who are higher in Broader Autism Phenotype (BAP) characteristics (Jobe & White, 2007).

Objectives: The current study extends this literature and focuses on two types of family relationships, parents and siblings, and examines whether links between relationship quality and young adults' well-being vary by BAP characteristics.

Methods: Data come from 866 young adults living in the United States, surveyed via Amazon Mechanical Turk. Participants ranged between 18 and 29 years old (*M age* = 25.43, *SD* = 2.54). The sample was mostly female (58%) and Caucasian (73%). Participants reported on their own BAP characteristics using the Autism Spectrum Quotient questionnaire (Baron-Cohen et al., 2001), and on their closeness and conflict with their parents and closest aged sibling, their depressive symptoms, and self-esteem.

Results: Analysis was conducted in a hierarchical ordinary least squares regression. Models were tested separately for each dependent variable: depressive symptoms and self-esteem. In the first model, each model included demographics (of the parent and participating young adult), sibling structural factors (e.g., age spacing, birth order, coresidence with sibling), conflict with parents (a composite score of conflict with mother and father), closeness with parents (also a composite variable), conflict with closest aged sibling, closeness with closest aged sibling, and the participants' BAP characteristics. In the second model, four two-way interactions were included: conflict with parents X participant BAP, closeness with parents X participant BAP, conflict with sibling X participant BAP, and closeness with sibling X participant BAP.

Results for depressive symptoms revealed main effects: BAP characteristics and conflict with parents were positively associated, and closeness with parents and sibling were negatively associated with depressive symptoms. An interaction between BAP characteristics and conflict with parents revealed that conflict with parents was positively associated with depressive symptoms, but was stronger for those lower in BAP characteristics.

Results for self-esteem revealed main effects: BAP characteristics and conflict with parents were negatively associated, and closeness with parents and sibling were positively associated with self-esteem. An interaction between BAP characteristics and conflict with parents (Figure 1) revealed a negative association between conflict with parents and depressive symptoms for those high in BAP characteristics, but a stronger negative correlation for those low in BAP characteristics. An additional interaction between BAP characteristics and conflict with a closest aged sibling (Figure 2) revealed that the association between conflict with a sibling and depressive symptoms was only significant for those high in BAP characteristics.

Conclusions: Overall, these results suggest BAP characteristics play a nuanced role in the link between family relationships and well-being. Although those with higher BAP characteristics typically displayed poorer well-being, conflict with parents was not linked to additionally poor well-being as was seen with those low in BAP characteristics. On the contrary, higher BAP characteristics may exacerbate the link between conflict with siblings and self-esteem.

423.039 *(Poster)* Family Satisfaction of School Services for Elementary Learners with Autism

S. Szendrey[1], *B. Tomaszewski*[2,3,4], *A. Sam*[5] *and S. Odom*[2], *(1)Allied Health, University of North Carolina at Chapel Hill, Chapel Hill, NC, (2)Frank Porter Graham Child Development Institute, University of North Carolina at Chapel Hill, Chapel Hill, NC, (3)Psychiatry, University of North Carolina at Chapel Hill, Chapel Hill, NC, (4)TEACCH Autism Program, University of North Carolina at Chapel Hill, Chapel Hill, NC, (5)Frank Porter Graham Child Development Institute, Carrboro, NC*

Background: Several researchers have examined family satisfaction with health and educational services for families of children with ASD (Rattaz et al. 2014; Renty & Roeyers, 2006). Some have focused on the satisfaction of a particular service (e.g., assistive technology services) (Bitterman et al., 2008; McIntyre & Zemantic, 2017), but few have looked at satisfaction from a more detailed perspective. This study aimed to evaluate families' opinions on detailed components of school services, interactions with school team, and general student outcomes.

Objectives: The purpose of this study is to evaluate the results of a family satisfaction survey for parents of elementary students with ASD and investigate the influence of family and school characteristics on data collection and results.

Methods: Participants included 375 parents and their elementary school student with ASD who were part of a larger randomized controlled trial of a comprehensive treatment model for elementary school students with ASD (Mean age= 7.83 years, SD= 1.81 years, Range 5-12). Parents completed the Family Satisfaction Survey. Most of the respondents were mothers (74.6%).The children were mostly Male (79%), Caucasian (44.0%), and Non-Hispanic (80.6%). Chi-square tests, *t*-tests, and correlations were performed to examine associations among family satisfaction question, child and family demographics, child characteristics, and school characteristics.

Results: A majority of parents and caregivers were generally satisfied with aspects of programs and services, interactions with the school team, and child outcomes (Overall Family Satisfaction Mean = 3.95, SD = .74). Most parents and caregivers were extremely satisfied with the level of respect school/program staff shows to their family culture, families feeling like full team members on their child's educational team, and communication between the family and school personnel. Satisfaction ratings did not differ by child age, child IQ, maternal education, or household family income. Parents of students in noninclusive programs rated satisfaction in communication as higher than students in inclusive programs, X^2 (4) = 18.58, p =. 001. Satisfaction ratings did not differ by school location, Title 1 eligibility, or percent of students on free and reduced lunch at the school. However, there were 143 students who were missing data who participated in the larger study. Missing data was from more schools that met Title 1 eligibility, $X^2(1) = 10.24$, p = .001, parents whose children were more likely to be Hispanic or Latino, X^2 (1) = 6.85, p = .002 and NonWhite, X^2 (6) = 51.3, p =.001.

Conclusions: Overall, a majority of families were generally satisfied with their child's school services. By investigating specific components of both educational services and interactions between families and team members, though, results from this survey can provide targeted areas for school teams to further improve experiences for families of children with ASD (i.e., improving support for families implementing IEP goals at home). Additionally, results from this survey show missing information for critical groups (i.e., nonwhite families and Title I eligible schools) indicating there is a need for researchers to examine methods of collecting data from diverse populations.

423.040 *(Poster)* Family Wellbeing in Parents Following Their Child's Early Diagnosis of Autism Spectrum Disorder: A Retrospective Study

S. Rabba[1], *C. Dissanayake*[2] *and J. Barbaro*[1], *(1)Olga Tennison Autism Research Centre, La Trobe University, Melbourne, VIC, Australia, (2)Olga Tennison Autism Research Centre, La Trobe University, Melbourne, Australia*

Background: The post-diagnostic experience can have a substantial impact on parental coping, resolution, mental health and overall Quality of Life (QoL). To date, there is limited research on factors that may contribute to a family's resilience in the context of a child's early diagnosis of ASD. Despite literature highlighting the impact and pressures of parenting a child with autism, research about what helps parents during the post-diagnostic period is scarce.

Objectives: The aim in the current study was to identify protective and risk factors associated with positive outcomes in family's post-diagnosis in order to inform the need for targeted parenting interventions at this time.

Methods: Eighty-nine parents (female = 78) of children who previously received a diagnosis of ASD (< 6 years) were asked to (retrospectively) reflect on the time of diagnosis when completing an online battery of questionnaires designed to measure individual, parent, and family wellbeing.

Results: Three simultaneous multiple regressions assessed the relationship between protective factors (family support, parenting self-efficacy, adaptive coping) and risk factors (parenting stress, intolerance of uncertainty, maladaptive coping and depression) and family wellbeing. Findings indicated that family support (spousal and familial support) and parenting stress had the strongest association with family QoL (emotional wellbeing, family interaction and parenting).

Conclusions: Strong family support following a child's diagnosis may play a key role in enhancing family quality of life and promoting resilience. Implications of the findings emphasise a need to strengthen internal family resources, such as familial and spousal support. Understanding the function of parenting stress and developing greater family support for parents, may be the first step in helping families successfully adapt to their child's diagnosis.

423.041 *(Poster)* Gender-Based Stereotypical Roles in Parents Caring for Autistic Children in Nigeria and South Africa

O. A. Kehinde[1]*, B. Ntombela*[2]*, C. Hermann*[3] *and O. J. Lindly*[4,5]*, (1)English, University of Zululand, KwaDlangezwa, South Africa, (2)Department of English, University of Zululand, KwaDlangezwa, 3886, South Africa, (3)Psychology, University of Zululand, KwaDlangezwa, 3886, South Africa, (4)Department of Health Sciences, North Arizona University, North Arizona, AZ, (5)Health Sciences, Northern Arizona University, Flagstaff, AZ*

Background: Gender-based stereotypical behaviours are not unique to larger social settings as they have been noticed within the family system in terms of definitive roles played by men and women. This situation though is more prevalent in some cultures and societies than others; but in most African society, women are less *voice-able and visible* through certain cultural and ideological stereotypical practices. It is important to better understand gender roles in this context because of the potential health implications for parents of children with ASD (e.g. caregiver strain and distress may be greater in women than in men), as well as influence of such situation on the quality of care to be received by these children.

Objectives: This study aimed to investigate the real-life stereotypical roles of women and men (parents) in Nigerian and South African contexts with regard to intervention and management of autism spectrum disorder (ASD).

Methods: A nonrandom purposive sampling was adopted to purposively sample parents of children with ASD within age 3-15 years (n=15) from Nigeria and (n=10) South Africa. A 15-item questionnaire was employed. Descriptive statistical analysis and thematic analysis were performed on the data. The analysis also drew introspection from van Dijk's model of critical discourse analysis to contextualize overt or covert gender-based ideology and stereotype and to reduce the level of bias in collected data.

Results: The study revealed that in Nigerian context and South African context respectively, 79% women and 21% men and 93% women and 7% performed the same (non-cumbersome ones) roles on interventions and management of ASD, while 87% women, 13% men, and 98% women and 2% men perform cumbersome roles in taking care of their autistic children. Lastly, the study found that African cultural hegemony and ideological leaning empower men to select roles being play at any social situation. This affects fostering of mutual collaboration between parents, and makes women's role in the intervention and management of autism more burdensome in terms of time and stress and distress they are exposed to.

Conclusions: The study's findings suggest that family ties are not strengthened and roles not equally shared. Additionally, reasonable awareness on ASD has not received necessary attention in that regards. The study recommends mutual collaboration devoid of stereotypical roles among men and women in selecting intervention and caring for their children with autism through increased parent education about the benefits of sharing responsibility in intervention and management of a child's ASD; or through clinician-facilitated planning that can be easily done after day work, free time and vacations.

423.042 *(Poster)* Increasing Rural Early Intervention Providers Use of Parent Coaching and Evidence-Based Strategies to Support Toddlers on the Autism Spectrum

L. Fanning[1]*, K. Hume*[2] *and H. Coleman*[3]*, (1)School of Education, University of North Carolina at Chapel Hill, Chapel Hill, NC, (2)Frank Porter Graham Child Development Institute, University of North Carolina at Chapel Hill, Chapel Hill, NC, (3)Specialized Education Services, UNC - Greensboro, Greensboro, NC*

Background: Parent-implemented intervention is an established evidence-based practice supporting the development of very young children with Autism (Wong et. al., 2015). Few studies have examined implementation of a comprehensive family-implemented intervention program targeting rural families.

Objectives: The first aim was to determine whether a functional relationship exists between the FITT training and coaching model and provider use of parent coaching strategies. The second aim was to determine whether a functional relationship exists between the FITT training and coaching model and the EI provider fidelity in use of the FITT model.

Methods: The study utilized a single-subject ABAB design with three community EI providers examining the impact of FITT training and weekly coaching on the use of coaching strategies with parents and fidelity to the FITT manual.

Results: Following the implementation of the intervention, all three participants demonstrated immediacy of the effects, increases of 17.7%, 26,.7%, and 58.51%. PND calculations were 88.9% or higher across participants. Fidelity scores were also calculated following intervention implementation showing immediacy of effects, increases of 76.5%, 82.3%, and 32.3%. PND calculations of 100% across participants.

Conclusions: Results showed significant increases in use of FITT coaching strategies and fidelity of intervention implementation across participants. Study suggests FITT can implemented with fidelity in community settings, though more research is needed with larger, more representative sample size.

423.043 *(Poster)* Interaction of Children with ASD and Their Siblings, Mothers and Friends

Y. Rum[1]*, D. A. Zachor*[2] *and E. Dromi*[3]*, (1)Tel Aviv University, Tel Aviv, Israel, (2)The Autism Center/ALUT, Pediatrics, Tel Aviv University /Shamir (Assaf Harofeh) Medical Center, Zerifin, Israel, (3)Constantiner School of Education, Tel Aviv University, Tel Aviv, Israel*

Background: The study of sibling interactions in the context of autism spectrum disorder (ASD) has been a neglected corner (Knott et al., 2007; Bontinck et al., 2018). This is surprising, considering the essential role of siblings in social development (Brody, 2004; Hughes et al., 2006) and the fact that social difficulties are a core characteristic of autism. Recently, it was found that having a typically developing (TD) sibling is associated with better social functioning among children with ASD (Ben-Itzchak, Nachshon & Zachor, 2018). This emphasizes the importance of studying the unique elements characterizing the sibling interactions.

Objectives: To investigate the interaction of children with ASD and their siblings in comparison to their interactions with other close, familiar social partners: mothers and TD-friends.

Methods: Qualitative and quantitative data were collected in a Multiple Case Studies design. Six case studies were performed; at the center of each case was a child with ASD, each was observed interacting with an older TD-sibling, the mother, and with a TD-friend. Friends were recruited according to matching reports of the ASD-children and their mothers and based on predefined criteria. Each dyad was observed in 3 different contexts (a total of 54 videotaped observations). The analysis was done both on a global and a micro-analytic level. Each case study was analyzed as a stand-alone, and further analysis of cross-case comparisons was conducted.

Results: The overall analysis revealed an 'intermediate pattern' in the spatial setting with the siblings: the pattern was very dynamic with the friends; with siblings, the pattern was less dynamic, and with mothers, the least. Similarly, an 'intermediate pattern' was found in the level of scaffolding by the partner: mothers scaffolded the most, and friends the least.

An analysis of variance was performed in order to compare the frequency and type of behaviours of the ASD-children with the three partners. Since the design included repeated measures in a small sample – a bootstrapping re-sampling was used (see table 1). Consistent with the research hypothesis, mothers demonstrated a higher frequency of discourse and pro-social behaviours compared to siblings or friends. As hypothesized, the ASD-children demonstrated a higher frequency of discourse behaviours while interacting with the mothers, compared to their interactions with friends. Contrary to the hypothesis, no significant difference was found in the performance of discourse behaviours by the children with ASD while interacting with their mothers, compared to interacting with siblings.

Results emphasize the investment of the mothers in supporting an intensive and structured interaction, as compared to the unstructured, 'scattered,' un-scaffolded interactions with the friends. Interactions with the friends were more challenging but offered more opportunities for the ASD-children to lead in social play.

Conclusions: The uniqueness of the sibling interaction is in being a '*zone of proximal social-communicational development*' (ZPSCD), where the challenge of interacting with another child is more accessible for a child with ASD. It is suggested that such experience support communication with peers. The findings have theoretical and practical implications regarding the involvement of siblings in social intervention programs.

423.044 *(Poster)* Interventions Addressing Stress Levels in Caregivers of Children with Autism Spectrum Disorder: An Examination of Parental Demographics

D. J. Patel[1]*, M. Cobian*[2]*, S. P. Santhanam*[3] *and N. Reyes*[4]*, (1)Children's Hospital Colorado, aurora, CO, (2)Children's Hospital Colorado, Aurora, CO, (3)Speech, Language, Hearing Sciences, Metropolitan State University of Denver, Denver, CO, (4)JFK Partners, University of Colorado Anschutz Medical Campus, Aurora, CO*

Background: Extensive research studies have identified that parents of children with autism spectrum disorder (ASD) often experience higher levels of psychological stress and lower levels of well-being compared to parents of typically developing children (Abbeduto, et al., 2014; Woodman, 2014) and children with Down syndrome (Dabrowska & Pisula, 2010). Several researchers have investigated the efficacy of cognitive behavior therapy (CBT) in addressing stress levels in caregivers of children with ASD (e.g., see De Paz and Wallander, 2017). However, little is known about the demographic composition of parents who are included in those studies. Understanding demographics of participants included in these intervention studies is crucial in determining disparities for caregivers with diverse backgrounds.

Objectives: The objectives of this study were (1) to learn the ethnic, racial, and educational composition of caregivers included in CBT-based intervention research designed to address stress levels in caregivers of children with ASD; and (2) to compare demographic composition of these participants with those of the United States population.

Methods: Multiple databases were searched to review studies that met the following inclusion criteria: 1) an intervention was delivered to one or both parent caregivers of a child with a primary diagnosis of ASD under the age of 18 years; 2) the intervention was CBT-based, including CBT, Mindfulness, and Acceptance and Commitment Therapy; 3) the study participants were located in United States; 4) the study was published in English, in the United States, in a peer-reviewed journal, and between 2010-2018. Given improvements in research and intervention, focus was given to studies published in the last decade. Literature reviews were assessed for studies meeting inclusionary criteria, but the review article itself was an exclusionary criterion. A total of ten studies met inclusion criteria and were used for this literature review.

Results: Ethnic and racial data were collected on 10 studies with a total of 675 caregivers who participated in CBT-based intervention addressing stress levels in caregivers of children with ASD. A smaller sample of data on maternal education status was also collected (See Table 1 for demographic information of participants). Chi-square analyses demonstrated significant differences in the demographic composition of those included in this research than compared to that of the United States population. Specifically, results (see Table 2) indicated a significant underrepresentation of Caucasian, Native American, and multiracial caregivers. There was also significant underrepresentation of caregivers from lower education backgrounds.

Conclusions: Results indicated that parents from lower educational backgrounds are less likely to participate in interventions addressing stress. Also, an underrepresentation in participation was found of Caucasian, Native American, and multiracial caregivers. The reasons for this underrepresentation are likely to be complex, and factors such location of study (rural versus urban settings), limited knowledge/awareness about research studies in diverse communities, and decreased family resources (e.g., time, transportation) may contribute to decreased participation. Thus, reducing barriers to research participation, increasing education and awareness of available supports and treatments for caregivers, and providing access to such treatment in culturally and linguistically appropriate ways, might be crucial.

423.045 *(Poster)* Life of a Typically Developing Sibling of Individual with Autism: Impact of a Peer Support Group

D. Taneja[1] *and S. P. K. Jena*[2]*, (1)Action For Autism, New Delhi, India, (2)Delhi University, New Delhi, India*

Background: Having a person with autism can be challenging for all family members, including the typically developing siblings of the person with autism. In most communities, parents of children with similar conditions have the opportunities to interact while availing services for their child or by participating in parent support groups. However, it is very common for typically developing siblings to be left behind, as there are not enough support groups for typically developing siblings. They go through life feeling 'alone', often resenting their sibling with disability, and not fully understanding the implications of having a brother or a sister with autism. Further, this is of greater concern in low and middle income countries like India, whereby no state support is currently available, and the unspoken cultural expectation is that the typical sibling will care for the autistic sibling once the parents are no more. To understand the experiences of typically developing siblings of individuals with autism, we conducted an Awesome Sibling Meetups (ASM), a peer support programme based on the American based sibling support model called *Sibshops.*

Objectives: This study aimed at highlighting the feelings and emotions felt by the typically developing siblings of children with autism. It further aimed at exploring the impact of the peer support programme on the experience of the typically developing siblings towards their sibling with autism.

Methods: 9 typically developing siblings participated in a peer-support programme at Action for Autism, the National Centre for Autism in India. 12 sessions of 3-4 hours each were conducted over a period of 4 months. The sibling support model *Sibshops* was adapted to the Indian cultural context and was considered a safe place for siblings to share their feelings with other sibling participants. The typically developing siblings as well as their parents were interviewed at the beginning and end of the programme. In addition, activities of the peer-support programmes were designed to capture different emotions and feelings towards the typically developing siblings. These were audio recorded and transcribed. Qualitative analysis was conducted for the same.

Results: Findings from the sibling measures indicated an increase in the knowledge of autism, a decrease in anger/resentful feelings towards autistic siblings as well as the use of more positive coping styles. Further findings indicated a decrease in the emotional conduct, as well as peer problems between the typically developing siblings and those with autism. Parents also reported a decrease in negative behaviours towards the autistic siblings by the typically developing siblings.

Conclusions: This is one of the few studies in a low resource country like India that focuses on typically developing siblings of children with autism. Results support the need for group interventions and controlled evaluation of sibling support groups to improve the mental health functioning of typically developing siblings. The study pointed to further implications for running sibling support groups in low resource countries.

423.046 *(Poster)* Lived Experiences of Siblings of Individuals with an Autism Spectrum Disorder (ASD): Informing the Design of a Stress Management and Resiliency Group Intervention

D. A. Iannuzzi[1]*, L. A. Fell*[2]*, G. K. Perez*[3]*, B. Goshe*[4]*, C. M. Luberto*[5]*, E. Park*[6]*, K. Kuhlthau*[6] *and L. Traeger*[7]*, (1)125 Nashua Street, MassGeneral Hospital, Boston, MA, (2)Division of Academic Pediatrics, MGH, Boston, MA, (3)Health Policy Research Center at Mongon Institute, Mass General Hospital/Harvard Medical School, Boston, MA, (4)Psychiatry, Mass General Hospital, Boston, MA, (5)Health Policy Research Center at Mongon Institute, Mass General Hospital, Boston, MA, (6)Massachusetts General Hospital, Boston, MA, (7)Psychiatry, Massachusetts General Hospital, Boston, MA*

Background: Many teen siblings of individuals with autism experience unique stressors that can impact their lives and the lives of other family members. The existing literature on the psycho-social well-being of siblings of individuals with an ASD has presented contradictory findings in that these siblings have the potential to both thrive and/or experience emotional adjustment difficulties while experiencing significant stressors. Factors leading to these disparate outcomes have not yet been identified. There are few studies focused on addressing the psycho-social needs of this population and, to date, an evidence-based mind body resiliency intervention, targeted to their needs, has not been developed.

Objectives: This study was designed to explore the lived experiences of teen siblings of individuals with an ASD as reported by teens and parents. The purpose of the study was to identify common stressors and concerns unique to siblings of individuals with an ASD to modify and adapt a stress management and resiliency group intervention.

Methods: In-depth semi-structured interviews were conducted via videoconferencing, with 8 neurotypical teen siblings (ages 13-17) and 6 parents (do we have mean age or range) of families who had at least one affected child (ages 13-17) and one neurotypical child. Participants were recruited from across the United States and Canada. The interviews were audio-recorded and transcribed. Multidisciplinary research team members coded and analyzed the transcription data using a content analysis approach.

Results: Key stressors and concerns endorsed by neurotypical teen siblings included 1) Wanting to help their sibling with an ASD and not knowing how 2) Reluctance to talk about their sibling with peers 3) Concerns regarding embarrassment and fear of judgment by others if the affected sibling should display maladaptive behavior when out in public 4) Worries about caregiver responsibilities in the future. Core themes which emerged from the parent interviews included: 1) Expectations for typical sibling to watch sibling with ASD, 2) Missing out on events that neurotypical teen is involved in due to needs of family member with ASD 3) Concern about typical sibling not wanting to invite friends over to their home, and 4) Not being able to do group activities together as a family. Both parents and siblings reported significant stress due to the unpredictability of behavior of the individual with an ASD.

Conclusions: The results of this study contribute to the existing literature on the impact and nature of the specific stressors experienced by teen siblings. These data will inform the development of an intervention designed to support siblings of individuals with an ASD. Addressing these concerns in designing the intervention will enhance its relevance to teen siblings of individuals with an ASD. This program will be aimed at building that can help buffer the impact of these stressors, which can have significant implications on peer and familial relationships.

423.047 *(Poster)* Longitudinal Transactional Associations between Child Functioning and Parenting Experiences in Families of Children with Autism

A. E. Chavez[1]*, T. Soto*[2]*, A. Eisenhower*[3] *and A. S. Carter*[1]*, (1)Department of Psychology, University of Massachusetts Boston, Boston, MA, (2)William James College, Newton, MA, (3)University of Massachusetts Boston, Boston, MA*

Background: Raising a child with autism spectrum disorder (ASD) can present unique parenting challenges, as children with ASD have difficulty engaging in reciprocal social interactions and communicating their needs. Parenting and family adaptations may impact developmental outcomes for children with ASD. Further, parents and children can have reciprocal, or transactional influences on each other's behaviors and general functioning over time. Yet, limited work addresses these reciprocal associations in early childhood. Additionally, little attention has been paid to parents' experiences of positive impacts, or the perceptions and experiences that enrich parents' lives as a result of raising a child with a developmental disability.

Objectives: The current study examined longitudinal associations between child functioning (a latent construct comprised of ASD symptoms, communication skills, and social and emotional competencies) and parent-reported negative and positive impacts on family life across early childhood in families of children with ASD. Child functioning, negative impact, and positive impact were each conceptualized as multi-dimensional constructs. The role of social support was examined as a moderator in both sets of relations.

Methods: Data were drawn from a three-wave longitudinal study of 170 children recently diagnosed with ASD (ages 18-33 months at Time 1). Participants from the larger study were included in the current project if mothers responded to a measure of parent negative and positive impact at any study time point. Data were collected once a year over a three-year period. Per self-report, mothers predominantly identified as being non-Latinx White (84%), having a middle to upper class household income (88%), and having completed at least two years of college (79%). Longitudinal latent variable cross-lagged panel analyses were used to model associations between child functioning and parent negative and positive impact. An indicator of each latent construct was used in multiple regression analyses to explore the role of social support as a moderator in the association between child functioning and parent negative and positive impact.

Results: Results indicated that the associations between child functioning and parent negative impact were initially transactional and moved to being parent-driven as children entered preschool-age, with child functioning no longer exerting an effect on parent negative impact. No cross-lagged associations were identified between child functioning and positive impact. Social support did not moderate results.

Conclusions: Findings suggest that interventions aimed at reducing parent negative impacts may carry over to influence developmental outcomes for children with ASD, and that the capacity for reduced parent negative impacts to influence children's outcomes persists into the preschool years. Meanwhile, interventions to directly target social communication skills may have their greatest impact on parent well-being during the toddler years but less impact by the preschool years. The interrelatedness of child functioning and parenting experiences in early childhood lends evidence for strengthening parents' resources and capacities when their children are at an early age, as these pathways may be more malleable and may lead to greater benefits for children with ASD.

423.048 *(Poster)* Maternal Depression Surveillance: Optimizing Clinical Care and Support to Families Enrolled in a Longitudinal Assessment Study from Birth through 30 Months

C. Rhodes[1]*, C. Klaiman*[2] *and G. Ramsay*[3]*, (1)Marcus Autism Center, Atlanta, GA, (2)Marcus Autism Center, Children's Healthcare of Atlanta and Emory University School of Medicine, Atlanta, GA, (3)Emory University, Atlanta, GA*

Background: Research estimates that 13% of women experience postpartum depression. Additionally, mothers of children with autism often experience higher levels of stress and depressive symptoms than mothers of typically developing children (Abbeduto et al. 2004; Singer, 2006; Zablotsky, Anderson, & Law, 2013). Despite some research regarding correlations between maternal depression and symptoms of autism, few studies have explored how depressive symptoms may impact child bearing decisions after the oldest child receives a diagnosis of autism, quality of life, and potential depressive symptoms related to diagnosis of later born child. (Zablotsky, Anderson, & Law, 2013).

Objectives: 1**.**.Present results from a maternal screening component within a longitudinal research study recruiting pregnant mothers and infants; 2. Describe strategies to clinically address any significant signs of depression identified and refer mothers for appropriate care; and 3. Examine influence of positive screens on study enrollment, attrition and follow through.

Methods: 150 high risk for autism infants and 100 infants at low risk for autism will be recruited. High risk (HR) infants are siblings of children already diagnosed with ASD; low risk (LR) infants have no familial history of ASD. Infants are enrolled at birth and followed through 30 months, with assessments at 12, 21 and 30 months. Mothers enrolled in the study will be administered two screening tools, pre-and-post-partum, to assess general and postpartum depressive symptoms: Edinburgh Postnatal Depression Scale (EPDS; Murray & Cox, 1970) and Patient Health Questionnaire (PHQ-9; Kroenke, Spitzer, & Williams, 2001). Score of 10 or higher indicates possible depression. In addition to total score >10, response to EPDS item 10 and PHQ item 9 (suicidal thoughts) is flagged. Mothers who screen positive on EPDS or PHQ are contacted by a Clinical Care Coordinator and receive support and resources including information about post-partum depression, post-partum support groups, community mental health/therapy referrals or emergency services.

Results: 132 infants have been enrolled to date, 75 HR and 57 LR. The number of mothers who screened positive was higher than anticipated. .18 of study participants (24 mothers) screened positive (+) on EPDS first screen (.20 high risk mothers and .14 LR); 40% of HR mothers (N=6) and .12 of LR mothers (N=1) endorsed item 10 (suicidal thoughts). Two high risk mothers who screened positive on EPDS reported receiving medication for depression during pregnancy.

Conclusions: In this study population, prevalence of depressive symptoms for HR mothers has been found to be much higher than expected (20%) and higher than in the general population. Among LR mothers, the positive screen rate was slightly higher than expected (14%). Longitudinal studies of HR infants should account for these findings and proactively establish mechanisms to assure the well-being of participant families. Maternal depression surveillance may also be helpful in understanding study participation and treatment decisions: to what extent does the presence of depressive symptoms in both HR and LR mothers contribute to study withdrawal or treatment refusal.

423.049 *(Poster)* Measuring the Impact on Parents of an Autism Diagnosis in Their Young Child

S. Rabba[1], *C. Dissanayake*[2] *and J. Barbaro*[1], *(1)Olga Tennison Autism Research Centre, La Trobe University, Melbourne, VIC, Australia, (2)Olga Tennison Autism Research Centre, La Trobe University, Melbourne, Australia*

Background: The impact of a child's diagnosis of Autism Spectrum Disorder (ASD) on parents has important implications for a family's wellbeing and adaptation. Understanding the impact of diagnosis may lead to improved outcomes for the child and family.

Objectives: The aim in this study was to develop a measure that will quantify the impact of an ASD diagnosis on parents/caregivers and examine demographic variables that may contribute to this impact.

Methods: The "Impact of Diagnosis Questionnaire" (IDQ) was developed to assess the perceptions of mothers and fathers who had a child diagnosed with ASD (< 6 years old). It was completed by 89 participants (mothers $n = 76$). Exploratory Factor Analysis (EFA) was conducted to determine the underlying factor structure of the IDQ. A series of one-way ANOVAs and independent samples t-tests were also conducted to identify the relationship between demographic variables (e.g., child gender, parent employment status, gestational age, number of autism diagnoses in family) and parents' perceived impact of diagnosis, as measured using the IDQ.

Results: The EFA identified a three-factor structure of the IDQ. The dimensions of impact were defined as 1) Emotional response/distress, 2) Attribution/cause, and 3) Acceptance. The IDQ demonstrated good internal consistency with Cronbach's alpha approaching .80 on each sub-scale: 1) Distress ($\alpha = .77$), 2) Attribution ($\alpha = .79$), and 3) Acceptance ($\alpha = .78$). Parents of male children reported more distress than parents of female children. The presence of other children diagnosed with ASD in the family was related to the impact of diagnosis, such that parents in multiplex families reported greater acceptance whereas parents in simplex families reported greater distress post-diagnosis. Parents of children born preterm reported more distress as a result of the diagnosis compared to parents of children born full-term.

Conclusions: A number of child characteristics were found to be related to parental responses of an early childhood diagnosis of ASD. With this knowledge, we may be able to provide more targeted support and intervention to parents who require it most. Further investigation of the impact of diagnosis on parents may also provide us with a greater understanding about potential protective factors for parental wellbeing post-diagnosis. Future studies should examine the validity of this novel measure.

423.050 *(Poster)* Mother and Father Effects on Child Problem Behaviors in Families with a Child with ASD: A Dyadic Structural Equation Model

K. A. Pedersen[1,2], *W. L. Cook*[3], *B. J. Taylor*[4], *M. Siegel*[5], *E. Touchette*[1], *C. Peura*[6] *and S. L. Santangelo*[7], *(1)Center for Psychiatric Research, Maine Medical Center, Portland, ME, (2)Department of Medicine, Tufts University School of Medicine, Boston, MA, (3)Dyadic Data Consulting, Portland, ME, (4)Psychiatry, Maine Medical Center Research Institute, Portland, ME, (5)Maine Medical Center - Tufts School of Medicine, Westbrook, ME, (6)Spring Harbor Hospital, Westbrook, ME, (7)Psychiatry, Maine Medical Center and Tufts University School of Medicine, Portland, ME*

Background: Several studies have examined mother reports of problem behaviors in their children with autism spectrum disorder (ASD). However, few studies have examined the relative contributions of mother and father characteristics on child outcomes, largely due to limited father participation in research. Research testing dyadic models simultaneously examining mother and father effects is also lacking.

Objectives: Describe a sample of mothers and fathers and their children with ASD who were hospitalized in a specialized inpatient psychiatric unit due to problem behaviors. Test a dyadic model examining parenting efficacy as a mediator between parental stress and child problem behaviors for both mothers and fathers.

Methods: Fifty mother and father couples with a child hospitalized in a specialized inpatient psychiatry unit were prospectively enrolled in this study. ASD diagnosis of the child was confirmed by the ADOS-2, administered by a research-reliable examiner, and clinical evaluation with DSM-5 criteria. Both parents completed the Aberrant Behavior Checklist Irritability subscale, Parent Stress Index Short Form 4, and Difficult Behavior Self-efficacy Scale at hospital admission. Due to the high correlation ($л=.76$, $p<001$) between mother and father reports of child problem behaviors, a combined score was created with the average of the two. A variant of the actor-partner interdependence model (APIM) evaluated the effects of parent characteristics on child problem behaviors. Descriptive statistics were conducted using SPSS v.25, and the APIM was tested using AMOS v.25.

Results: Mothers were on average 42 years old (SD=7.3) and fathers were 44 years old (SD=8.2). The majority of parents were married (86%) biological mothers (82%) and biological fathers (76%). The average child age was 13 years (SD=3.7, range 5-19), 82% were male, 98% were Caucasian, and 94% were non-Hispanic/non-Latino. Average nonverbal IQ score was 71 (SD=28.8, range 30-145), and the mean Vineland Adaptive Behavior Scale II composite score and Vineland expressive communication subscale scores were 55 (SD=14.6) and 7 (SD=4.2) respectively. A slight majority completed ADOS-2 modules 1 or 2 (53%) indicating minimally verbal communication status. APIM results indicated mothers' parental stress was a significant predictor of mothers' parenting self-efficacy ($\beta=-.58$, $p\leq0.001$). Fathers' parental stress predicted both their parenting self-efficacy ($\beta=-.64$, $p\leq0.001$) and child problem behaviors ($\beta=.43$, $p\leq.01$). Fathers' parenting self-efficacy partially mediated the relationship between their parental stress and child problem behaviors ($\beta=.32$, $p\leq.04$) (see Figure 1).

Conclusions: Self-efficacy is the belief that one can produce a desired behavior change. For both mothers and fathers, parental stress reduced their parenting self-efficacy, which can reduce their persistence and effectiveness in managing their child's behavior. Interventions that reduce stress in mothers and fathers (such as mindfulness training) may enhance their parenting self-efficacy and subsequently improve child behavior. Surprisingly, fathers' parenting self-efficacy positively predicted child problem behaviors. The fact that only father characteristics predicted child problem behaviors suggests that greater effort should be devoted to collecting data from both parents and evaluating these data using the appropriate dyadic models.

423.051 *(Poster)* Occupational Well-Being and Organizational Outcomes in Registered Behavior Technicians

***A. Holbrook**, C. K. Toolan and C. Kasari, University of California, Los Angeles, Los Angeles, CA*

Background: One of the largest certified occupational groups providing intervention services to individuals with ASD are Registered Behavior Technicians (RBTs). RBTs are human service professionals, or workers who respond to the needs of people (e.g., doctors, nurses, social workers; Freudenberger, 1974). As human service professionals, RBTs face significant occupational stressors that can be emotionally challenging and reduce occupational well-being (Maslach & Jackson, 1981). Studies repeatedly find that ASD service providers report elevated levels of burnout (e.g., emotional exhaustion; Griffith et al., 2014). Furthermore, the intention to leave one's occupation is particularly high among RBTs. Specifically, 41.6% of RBTs reported they were highly or somewhat likely to leave the occupation (Kazemi et al., 2015). This is significant as the national yearly average for employee turnover across industries is only 17.9% (Boushey & Glynn, 2012). RBT burnout and turnover impacts multiple levels of stakeholders, including individuals with ASD, RBTs, and organizations providing intervention services – yet to date no studies have examined the relation between job burnout and turnover in RBTs.

Objectives: 1) Explore the associations between job resources, job demands, and organizational outcomes (i.e., turnover intention, organizational commitment, and job performance). 2) Examine the relationship between occupational well-being (i.e., burnout and work engagement) and organizational outcomes.

Methods: The sample includes 311 RBTs (M_{age}= 27.71 years, *SD*=7.29) with diverse ethnic/racial backgrounds. Participants were primarily female and held a college degree or higher. Job resources included social resources (i.e., supervision, role clarity), and training satisfaction. Job demands examined included challenging behaviors and low client skill level. Burnout (i.e., negative emotional response to work-related stress) was measured using the Maslach Burnout Inventory. Work engagement (i.e., positive, fulfilling work-related state of mind) was measured by the short version of the Utrecht Work Engagement Scale. Organizational outcomes included turnover intention, organizational commitment, and job performance, which were all measured by self-report questionnaires. Multiple linear regressions were conducted to explore the relationship between occupational well-being and organizational outcomes.

Results: Correlations between job resources, job demands, and organizational outcomes are found in Table 1. Burnout, specifically emotional exhaustion, and work engagement were both significant concurrent predictors of RBT job turnover intention (Table 2). High emotional exhaustion and low work engagement were associated with poor organizational commitment. Low burnout (i.e., high personal accomplishment) was associated with better job performance.

Conclusions: Findings highlight that many job resources, including training and supervision, are associated with key organizational outcomes. Furthermore, burnout and work engagement are related with organizational outcomes, such that poor occupational well-being is related to poor organizational outcomes. Therefore, companies should aim to reduce negative organizational outcomes, such as turnover, by providing support or job resources to RBTs to help alleviate burnout and increase work engagement. By improving occupational well-being and organizational outcomes, there may be positive cascading effects for individuals with ASD receiving intervention services from RBTs.

423.052 *(Poster)* Parent Education and Community Experience (PEaCE): Results from 5 Cycles of Self-Report Questionnaires

***J. Hai**, Education, UC Santa Barbara, Santa Barbara, CA*

Parent Education and Community Experience (PEaCE): Results from 5 cycles of Self-Report Questionnaires

Background: Parents of children with Autism Spectrum Disorder (ASD) report greater parenting stress, marital distress, and mental health symptomology than parents of typically developing children, as well as parents of children with other types of disabilities (Hayes & Watson, 2013; Karst & Van Hecke, 2012; Dabrowska & Pisula, 2010). Research suggests that social support, parenting self-efficacy, and coping styles moderate the association between autism and parenting stress (Dunn et al., 2001; Kuhn & Carter 2006). Parent support groups in general have been shown to raise awareness, decrease stress, and increase empowerment among participants (Soloman, M., Pistrang, N., Barker, C., 2001). Although many support groups of varying structures exist for parents of children with ASD, little research exists on the mental health outcomes of these groups.

Objectives: The objective of the present study is to determine the impact of a 7-week Parent Education and Support group on the mental health and quality of life of parents of children with ASD.

Methods: Participants were 44 parents, families (i.e. parent dyads) were placed into 5 different cycles. Demographic questionnaires represented a diverse group of individuals with varying backgrounds consisting of Asian/Pacific Islander, Hispanic/Latinx, Middle Eastern, and Caucasian descent. Before the intervention, all parents completed standardized self-report assessment measures of parenting stress, anxiety, depression, marital adjustment, and satisfaction with life. All parents completed these measures again seven weeks later post intervention. The intervention consisted of a seven-week curriculum that incorporated educational components within a discussion-based support group. The curriculum included psycho-education about ASD, exploring strengths and challenges, discussion of resources for families with ASD (e.g. autism friendly hair dressers, dentists, community activities, etc.), navigating public education (e.g. advocacy in schools, Individualized Education Plans, Special Education, etc.), self-care, and coping skills. Parents met weekly with two graduate student clinicians, supervised by a licensed psychologist. Free childcare was provided for all participating parents to allow participation of parents who might otherwise not be able to attend.

Results: Paired samples T-Tests revealed a significant increase in the Service System subscale of the Family Empowerment Scale, and trends for increases on the Family and Community/ Political subscales. Analyses also revealed significant decreases in Pessimism as measured by the Questionnaire on Resources and Stress, as well as a trend for increased Satisfaction with Life after participation in the Parent Education and Support Group.

Conclusions: Trends in the parenting stress, family empowerment, and life satisfaction measures were promising and support the utility of this parenting education and support program.Additionally, parents who have participated in these groups frequently request ongoing support group meetings. The goal for these facilitated parent education and support groups is that parents will build social connections, increase their understanding of their child and how to support him/her, increase their awareness of resources available to them, and build effective coping strategies. It may also be of interest to collect qualitative data from future participants to better understand the impact of participation in this group.

423.053 *(Poster)* Parent Trajectories during Diagnostic Ascertainment in Families of Children with and without Autism Spectrum Disorder

E. Hickey[1]*, M. L. Stransky*[2]*, S. broder-Fingert*[1]*, J. L. Kuhn*[3]*, J. Levinson*[4] *and E. Feinberg*[4]*, (1)Boston Medical Center, Boston, MA, (2)Boston University, Boston, MA, (3)Pediatrics, Boston Medical Center, Boston, MA, (4)Boston University School of Public Health, Boston, MA*

Background: Parents of children with autism spectrum disorder (ASD) report heightened levels of parenting stress,[1] poorer coping,[2] and lower levels of social support[3] relative to other parents; they also report that their children have a greater negative impact on the family.[4] Limited research has investigated these outcomes over time, among very young children (18-24 months) who have been screened for, and newly diagnosed with, autism, and are members of historically underrepresented and underserved populations (e.g. racial/ethnic minority groups, families with low socioeconomic status).[5-8]

Objectives: The current study explored trajectories of parenting stress, coping, social support, and negative impact on the family over four times points, from initial positive screening for ASD risk. Our research questions were: (1) Among low income, racially/ethnically diverse children with identified risk for autism, are there baseline differences in parenting stress, parent coping, parent social support, and negative family impact between parents of children with ASD compared to parents of children without ASD; and (2) In this same sample, are there differences in stress, coping, social support, and negative family impact trajectories (change over time) between these two groups?

Methods: The current study was a secondary data analyses of data collected as part of an NIMH funded randomized controlled trial of Family Navigationrom 340 parents/guardians of children, aged 15-29 months (*M*=21.54, *SD*=3.48), identified as "at-risk" on the Modified Checklist for Autism in Toddlers Revised with Follow-Up (MCHAT-R/F)[9] during routine screening for ASD across 11 urban pediatric clinics from 2015-2019. Parents reported on their own level of overall parenting stress (Parenting Stress Index – Short Form),[10] ASD-specific parenting stress (Autism Parenting Stress Index),[11] problem-focused coping (Brief COPE),[12] parental social support (Medical Outcome Study-Social Support Survey),[13] and their perception of the child's relative negative impact on the family (The Family Impact Questionnaire).[14] Baseline group mean comparisons were investigated using independent samples t-tests. Generalized estimating equation models were constructed to compare trajectories of parents of children with ASD to parents of children without ASD, while controlling for site, parent ethnicity, and treatment (i.e., the presence of a Family Navigator).

Results: Parents of children with ASD reported a lower level of negative impact on the family compared to parents of children without ASD (*M*=35.45 and 37.11, respectively, F=7.85, *p*=.005); no other statistically significant differences were apparent at baseline. Parents of children with ASD showed a steeper increase in their level of reported APSI (=2.04, *p*=.037) and their use of problem-focused coping strategies (=0.89, *p*=.043) over time compared to parents of children without ASD, when controlling for site, treatment, and ethnicity.

Conclusions: Results indicate that parents of children with ASD begin to experience higher increases in ASD-specific parenting stress, yet also increase their use of problem-focused coping early during the diagnostic process. Thus, it is important to consider how this type of coping may moderate stress in families of children with ASD at the unique time period in which they are going through the process of determining an ASD diagnosis.

423.054 *(Poster)* Parental Health Literacy and Services Use for Young Children with ASD

O. Lindly[1]*, J. Cabral*[2]*, R. Mohammed*[3]*, K. Mistry*[4] *and K. Kuhlthau*[5]*, (1)Health Sciences, Northern Arizona University, FLAGSTAFF, AZ, (2)Memorial Sloan Kettering, New York, NY, (3)Massachusetts College of Pharmacy and Health Sciences, Boston, MA, (4)Agency for Healthcare Research and Quality, Rockville, MD, (5)Massachusetts General Hospital, Boston, MA*

Background: Health literacy (HL) is a modifiable capacity that includes parents' abilities to access, process, and use health information and services to make appropriate health decisions for young children. Because autism spectrum disorder (ASD) is complex, parents often face numerous decisions about treatment and services (hereinafter services) for their child's ASD. Their decision-making is further complicated by the many potential services available for ASD with varying evidence levels. It is, therefore, critical to better understand the relationship between HL and services use among parents whose young children have ASD.

Objectives: This study aimed to (1) describe key aspects of parental HL, (2) examine how HL influences ASD services use, and (3) identify HL improvement strategies related to ASD services use from the perspectives of parents whose young children have ASD.

Methods: This study used mixed methods including a telephone-administered survey followed by a video-based focus group. We recruited parents of a young child with ASD enrolled in the Simons Powering Autism Research for Knowledge study from November 2018 to June 2019. We targeted recruitment to 10 states with the lowest high school graduation rates. In total, 82 parents completed the structured survey and 44 of them also completed a focus group (Table 1). Survey items included family sociodemographic characteristics, ASD services use, and parental HL assessed by the Newest Vital Sign. Survey data were analyzed using appropriate statistical tests. The focus group guide contained questions about parents' perspectives on HL, how their HL influenced ASD services use, and strategies to improve HL. Directed content analysis was used to analyze focus group data.

Results: For Aim 1, the following HL aspects were identified: 1) ASD services information is often accessed from multiple sources and varies in quality and utility; 2) approaches to understanding information commonly involves "doing your own research", determining information credibility, and observing the child's response to a given service; and 3) ASD services information may empower parents to pursue services intended to optimize their child's health. Most focus group participants had adequate health literacy (88.6%). For Aim 2, the following themes emerged on HL and ASD services use: HL facilitated educational and behavioral services use, HL was one factor influencing decisions to use psychotropic medication, family support services were most influenced by perceived need and services availability, and parent resources and beliefs were other salient factors influencing ASD services use. Among focus group participants, HL level did not have statistically significant associations with ASD services use (Table 2). For Aim 3, the following themes were identified relating to improvement strategies: increased parent and clinician education on services and tools to facilitate holistic ASD care are needed, services information should be provided to parents throughout the diagnostic odyssey, and greater accessibility may increase parental uptake of scientific ASD services information.

Conclusions: Parental HL plays a role in services use for young children with ASD. Varying parental HL levels should be recognized and better integrated into ASD care, along with recognition that other factors (e.g., parent resources) may influence decision-making.

423.055 *(Poster)* Parentification and Family Relationships, Adjustment, and Caregiving Intentions Among Young Adult Siblings

A. K. Nuttall[1] *and J. H. Beffel*[2]*, (1)Michigan State University, East Lansing, MI, (2)Human Development and Family Studies, Michigan State University, East Lansing, MI*

Background: Autism Spectrum Disorder (ASD) impacts the entire family system, including typically developing siblings (TDS; Karst & Van Hecke, 2012). Young adulthood (age 18-25) is a critical period for understanding the experiences of TDS because TDS may maintain caregiving roles with siblings rather than the expected decreases in contact during this developmental period (Lindell & Campione-Barr, 2016; Heller & Arnold, 2010). However, TDS may report poor sibling relationships (Orsmond & Seltzer, 2007). Given the potential for TDS to serve in caregiving roles across the lifespan and the risk to sibling relationships during young adulthood, it is critical to understand these processes.

TDS' childhood caregiving roles may influence sibling relationships in young adulthood. During childhood high levels of caregiving for siblings and parents are referred to as sibling-focused and parent-focused parentification respectively (Nuttall et al., 2018). Among young adults, experiences of parent-focused parentification are associated with less intention to provide future caregiving to siblings (Nuttall et al., 2018) and increased depressive symptoms (Tomeny et al., 2017). In contrast, experiences of sibling-focused parentification are associated with positive sibling relationships (Tomeny et al., 2017) and positive sibling relationships likely predict TDS' future involvement with siblings (Bigby, 1998). Furthermore, sibling-focused parentification may also result in positive parent-child relational and adjustment outcomes by freeing up parents to reciprocate TDS' caregiving (Walker & Lee, 1998).

Objectives: We examined TDS' relationships with siblings and parents as potential mediators between parentification experiences and caregiving intentions and adjustment outcomes, hypothesizing that sibling-focused parentification would be associated with more caregiving intention and better adjustment through positive relationships with siblings and parents.

Methods: Study participants were college students age 18 to 25 who self-identified as TDS. Parentification experiences were assessed with the Parentification Inventory (Hooper et al., 2011). Relationships with siblings and with parents were assessed with the Network of Relationships Inventory (Furman & Buhrmester, 1985). Adjustment measures included self-esteem (Rosenberg, 1989) and depressive symptoms (Radloff, 1977). Future intention was assessed with a single ordinal item as in previous studies (Nuttall et al., 2018).

Results: Indirect effects were tested using a Bayesian approach given the ordinal intentions outcome (Muthén et al., 2016). Sibling-focused parentification was associated with increased positive relationships with siblings and increased negative and decreased positive relationships with parents. Positive relationships with siblings with ASD were associated with greater intention to provide future caregiving whereas negative relationships with parents were associated with lesser intention to provide future caregiving. Positive relationships with siblings with ASD mediated the association between sibling-focused parentification and intentions to provide future caregiving to siblings with ASD [95% CI: 0.005, 0.069]. Sibling-focused parentification and sibling and parent relationship quality were not associated with adjustment.

Conclusions: The present study underscores the importance of caregiving experiences and current sibling relationships in understanding young adult typically developing siblings' intentions for continued caregiving involvement with their siblings in adulthood. Findings suggest relational interventions to improve sibling caregiving experiences.

423.056 *(Poster)* Parenting Stress and Related Factors of Preschooler with Autism Spectrum Disorder in Northern Taiwan: A Preliminary Result

Y. L. Chiu[1] *and Y. T. Wu*[2]*, (1)Department of Social Work, National Taiwan University, Taipei, Taiwan, (2)School and Graduate Institute of Physical Therapy, National Taiwan University College of Medicine, Taipei, Taiwan*

Background: Research shows that parents of children with Autism spectrum disorder (ASD) experience greater stress and other negative health outcomes than parents of typically developing children or children with other disabilities. Parents who have children with ASD, living in the urban area such as Taipei city, are more likely to have high socioeconomic status. Parents often take their children to multiple lessons either in hospitals or clinics because of unique features of National Health Insurance. Therefore, an understanding of parenting stress in children with ASD is needed for family-centered services of early intervention. Hou et al. have reported that Taiwanese mothers of children with ASD showed higher levels of parenting stress and depressive symptoms than parents of children with developmental delay. However, few studies have investigated potential factors that might result in high degree of parenting stress.

Objectives: This study aimed to (1) examine parenting stress in Taiwanese parents of children with ASD; (2) examine parents' demographic, child developmental and behavioral factors potentially relating to parenting stress.

Methods: Preschoolers, living in Northern Taiwan, aged 2.5-5 years with a clinical diagnosis of ASD were recruited in this study. At enrollment, a trained research staff administered the Mullen Scale of Early Learning (MSEL) to assess the children's developmental skills. Primary caregivers were asked to fill out the Child Behavior Checklist for Ages 1.5-5 (CBCL/1.5–5), Parenting Stress Index (PSI), and Social Responsiveness Scale Second-Edition (SRS-2). Father and mother were individually asked to fill out the Parenting Sense of Competence Scale (PSOC). Descriptive statistics were used to analyze demographic data (i.e., parental age and education, weekly time for early intervention and socioeconomic status index). A linear regression analysis with the stepwise method was used for exploring potential factors relating to parental stress.

Results: The present study recruited 19 children with ASD (17 boys and 2 girls, mean age: 47.74 ± 9.93 months). About 61% of caregivers reported high level of PSI total scores. Univariable regression analyses revealed that MSEL expressive language (ß = 1.90), CBCL/1.5-5 total (ß =1.01), SRS-2 total (ß =1.48) and PSOC mother's efficacy scores (ß = -7.46) were each related to PSI total scores (all p's < 0.05) (Table 1). Demographic variables, however, had no significant effects on PSI scores. The preceding significant variables were subsequently introduced into multivariable model using the stepwise regression (Table 2). The higher SRS-2 scores (ß = 1.11, p =0.002) and higher PSOC maternal efficacy scores (ß = -4.68, p = 0.01) were associated with higher parental stress.

Conclusions: Primary caregiver's in Northern Taiwan exhibited higher parental stress. The result showed that child's developmental and behavioral problems, the severity of ASD and parental sense of competence were found to associate with parental stress level, whereas family's socioeconomic status and the total time spent on receiving early intervention services did not. It is necessary to incorporate parents into early intervention programs and to empower parents to develop optimal parenting skills for children with ASD.

423.057 *(Poster)* Parents' Education Levels and Parent-Mediated Intervention Outcomes for Children with Autism

X. Liu[1] *and H. Schertz*[2]*, (1)Indiana University - Bloomington, Bloomington, IN, (2)Indiana University, Bloomington, IN*

Background: Sociodemographic factors, including parents' educational background, may influence the style of parent-child interactions or the dynamics of involvement with professionals. Intervention studies have found that involving parents has resulted in improved ability to support child learning, including learning for toddlers with autism. Less clear is whether educational background influences parents' success in promoting learning for toddlers with autism. Early interventionists may face challenges in providing effective guidance for parents to integrate their conceptual learning into daily activities. The Joint Attention Mediated Learning (JAML) intervention is a family-centered, parent-mediated intervention for toddlers with autism for which positive child and parent outcomes were found in previous studies. An important question for parent-mediated intervention is whether providing broad-based conceptual support with parent latitude in activity decisions is effective for parents of different educational backgrounds. The current study explored this question.

Objectives: To examine differences in parent and child outcomes when groups of JAML participants with and without college degrees are compared.

Methods: A total of 30 parent-child dyads from a larger three-site randomized control trial (RCT) of the JAML intervention were included in this study. Toddlers aged 30 months or younger who met ASD criteria were randomly assigned in pairs within sites to experimental or control groups. Intervention Coordinators (ICs) conducted weekly 1-hour home-based sessions with parents for 32 weeks. The ICs facilitated parents' learning of five mediated learning principles: focusing on social interaction (FO), organizing/planning for engagement (OP), encouraging self-reliance (EN), giving meaning and promoting motivation for engagement (GM), and expanding engagement across environments. Each week parents received conceptual guidance on integrating the mediated learning principles to promote developmentally ordered preverbal social communication outcomes. Further, ICs guided parent reflection on their use of the principles by reviewing videos of parent-child interaction.

The Preverbal Joint Attention Measure (PJAM; Schertz) was used to measure children's outcomes and parents' application of mediated learning principles was assessed with the Mediation of Social and Transactional Engagement Measure (MOSTE; Schertz & Horn, 2018). Ten-minute parent-child interaction videos were recorded pre- and post-intervention and three independent observers coded the occurrences of targeted child and parent outcomes for each. Inter-rater reliability was established and maintained between coders (kappa = .85). Parents' education background was categorized into two groups by the presence or absence of a 4-year college degree. A one-way MANOVA was used to analyze group differences for child and parent outcomes.

Results: Neither pre-intervention nor post-intervention differences were found to differ significantly in parents' application of JAML between the two groups, $F(5, 24) = 1.93$, $p = 0.13$, $F(5.24) = 1.73$, $p = 0.17$. Similarly, no significant group differences were found in children's outcomes, $F(3, 26) = 0.66$, $p = 0.58$.

Conclusions: Neither parent nor child outcomes from the JAML intervention were influenced by parents' educational backgrounds. The results suggested that the JAML intervention was effective for parents and toddlers regardless of parent educational backgrounds. Future studies should expand the number of participants and explore whether other sociodemographic factors impact intervention outcomes as well as possible effects over time.

423.058 *(Poster)* Perceptions, Experiences and Needs of Parents of Culturally and Linguistically Diverse Children with Autism: A Scoping Review

H. Meadan[1]*, K. Guldberg*[2]*, D. Papoudi*[3] *and C. Joergensen*[4]*, (1)University of Illinois, Champaign, IL 61820, IL, (2)University of Birmingham, Birmingham, United Kingdom of Great Britain and Northern Ireland, (3)Autism Centre for Education and Research (ACER), Birmingham, United Kingdom of Great Britain and Northern Ireland, (4)School of Education, University of Birmingham, Birmingham, United Kingdom*

Background: Recent findings show that the estimated percentage of children identified with autism spectrum disorder (ASD) is higher than in previous years. In the USA it is estimated that 1.7% of children are identified with ASD and in the UK approximately 1% of children are identified with ASD. Although ASD occurs in all racial, ethnic, and socioeconomic status groups, children with ASD from diverse backgrounds are consistently underrepresented and underserved.Researchers have reported that African-American and Hispanic populations are less likely to be diagnosed with ASD, often receive the initial diagnosis at later ages, and experience dispatities in access to services in comparison to other racial and ethnic groups. Furthermore, studies have also documented lower participation rates of minorities in research studies of ASD. To date, limited information is available in the literature about the lived experiences and specific needs of culturally and linguistically diverse (CLD) families with children with ASD.

Objectives: The purpose of this study was to explore the perceptions, experiences, and needs of CLD families with children with autism in the USA and the UK. A scoping review was conducted.

Methods: The Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) framework was used to identify studies for the scoping review. A keyword search was performed in four databases and included all possible combinations of keywords from three groups related to autism, culturally and linguistically diversity, and family. Following screening and careful review for all inclusion criteria 32 studies were identified for the review. Data from all studies were extracted, reliability across researchers were assessed, and thematic analysis was conducted to identify themes related to the experiences and needs of CLD families with children with ASD.

Results: The majority of the identified studies were published after 2016 (n=19) and were conducted in the USA (n=25). In addition, most of the identified studies employed qualitative methodology (n=27) and included the mother as the participant. Four key themes were identified in the analysis of the 32 studies: (a) knowledge of and beliefs about autism, (b) autism and the impact on the family, (c) family experiences of accessing services and support, and (d) perceptions and impact of multilanguage.

Conclusions: Overall, the results indicate that the perceptions of autism by CLD families are influenced by lack of knowledge about autism and cultural, linguistic and religious contexts. The experiences of CLD families included coping with the autism diagnosis and the social stigma associated with autism, and difficulties in accessing services and support. In addition, many CLD families experienced challenges related to the language preference in bilingual environments. Future research needs to investigate the experiences of a wider range of cultural and linguistic communities. There is a need to identify ways for supporting individuals with autism which are sensitive to culture, religion and language and incorporate the CLD group's values and practices. The findings from this scoping review inform implications for policy, research, and practice.

423.059 *(Poster)* Positive Familial Effects of Autism Spectrum Disorders: A Phenomenology of Parents' and Siblings' Shared Experiences

***G. K. Weaver**, Department of Education, Liberty University, Lynchburg, VA*

Background: There is overwhelming evidence of the burden and stress put on families of children identified with an autism spectrum disorder (ASD), yet there is a significant deficit in the literature regarding the positive impacts of ASD. Researchers investigating the effects of ASD report positive impacts in passing, but tend to focus on the prevalence and difficulties associated with the disorder. Effects like increased stress, marital discontentment, and stigmatization are commonly expressed by families, but the growth and joy anecdotally expressed by parents is not often reflected in the literature.

Objectives: Through the lens of Seligman and Darling's (2007) systems approach to childhood disability and in an effort to investigate the positive impacts of having a family member with ASD, I conducted a qualitative transcendental phenomenological study. The purpose of this study was to explore the shared experiences of immediate family members of individuals with ASD by identifying what traits and experiences parents and siblings associate with a positive outcome related to the individual with ASD.

Methods: After receiving IRB and district approval, recruited twelve individuals from seven ethnically diverse families from a North Texas school district's autism program email list. The final sample included six mothers, three fathers, two sisters, and one brother. Upon receiving informed consent, I administered a questionnaire followed by semi-structured interviews, including a picture presentation measure. Questionnaire results were analyzed using Google Form charts and graphs, while interview and picture presentation measures were transcribed, open-coded, analyzed, and triangulated with questionnaire findings to corroborate and give fuller understandings and description to the themes identified.

Results: The process of thematic analysis revealed the themes of (a) identity-centered positives, (b) growth-centered positives, and (c) environmental-centered positives, as the positive effects of having a family member with ASD. It was also clear that many of the positive effects parents attribute to their child's ASD are intellectual in nature as phrases like "increased understanding" and "more awareness" were used throughout interviews. Language level of the affected child was also a significant indictor of certain positive themes; families with a verbal child with ASD shared positive effects of humor and personality more readily than families with a minimally verbal child with ASD, whom were more likely to describe positive impacts of familial closeness and "finding joy in simplicity."

Conclusions: The clearest implication of this research on the field of ASD research is that it fills a significant gap in research investigating the positive effects of individuals with ASD on their family systems. These findings could lead to improved practice within various systems. For professionals and researchers, results are important for interventions and the initial diagnostic process. Families and self-advocates can be encouraged by these findings as they search for their own stories in the anecdotes of the participants. Research that illuminates the qualities individuals with ASD boast can encourage neurodiverse populations to confidently share their talents with the world.

423.060 *(Poster)* Predicting Positive and Negative Aspects of Psychological Wellbeing in Parents of Autistic Children: The Roles of Intolerance of Uncertainty and Coping

***R. Y. Cai**[1], M. Uljarevic[2] and S. R. Leekam[3], (1)Aspect Research Centre for Autism Practice, Autism Spectrum Australia, Melbourne, VIC, Australia, (2)Department of Psychiatry and Behavioral Sciences, School of Medicine, Stanford University, Stanford, CA, (3)School of Psychology, Cardiff University, Cardiff, NSW, United Kingdom*

Background: Research has consistently shown that parents of children with autism spectrum disorder (ASD) are more likely to report chronic stress and symptoms of anxiety and depression when compared to parents of typically developing children and children with other psychological or physical conditions. However, a significant proportion of parents does not show elevated affective symptoms, even reporting positive effects of raising a child with ASD. Certain individual characteristics might either put parents at risk or allow them to cope more effectively under the strenuous conditions of raising children with disabilities. Previous research has suggested that higher levels of intolerance of uncertainty (IU) and certain coping styles are associated with higher parental levels of anxiety and depression. However, no research has examined the inter-relationships between coping and IU in predicting anxiety and depression in parents of children with ASD. Further, the influence of these factors on positive aspects of psychological wellbeing remains unexplored.

Objectives: To characterize IU and coping (avoidant and problem solving coping styles) in relation to positive and negative aspects of wellbeing in mothers of children with ASD.

Methods: Fifty mothers of children with ASD (M_{age} = 44.28 years, SD_{age} = 6.58) completed questionnaires assessing anxiety and depression (Hospital Anxiety and Depression Scale [HADS]), positive psychological wellbeing (Oxford Happiness Questionnaire), IU (IU-12 Scale) and avoidant and problem solving coping (Ways of Coping Questionnaire).

Results: Higher use of avoidant coping and higher levels of IU were associated with higher levels of anxiety ($r = .46$, $p = .001$, and $r = .50$, $p < .001$, respectively) and depression ($r = .54$, $p < .001$ and $r = .41$, $p = .003$, respectively) but not positive wellbeing. While higher use of problem solving coping was associated with better positive wellbeing ($r = .42$, $p = .008$), the opposite pattern emerged for depression ($r = -30$, $p = .044$) and no significant association was found for anxiety. A series of regression models showed that 1) IU and avoidant coping were both unique independent predictors of anxiety ($t = 3.21$, $p = .002$, $\beta = .41$ and $t = 2.67$, $p = .01$, $\beta = .34$, respectively), with the full model accounting for 36.1% of variance ($F = 12.45$, $p < .001$); 2) IU, avoidant and problem solving coping were each unique independent predictors of depression ($t = 3.31$, $p = .002$, $\beta = .39$, $t = 3.23$, $p = .002$, $\beta = .38$ and $t = -2.94$, $p = .005$, $\beta = -.33$, respectively), with the full model accounting for 48.2% of variance ($F = 13.32$, $p < .001$); and 3) problem solving coping significantly predicted positive wellbeing ($F = 7.77$, $p = .008$) accounting for 17.4% of variance.

Conclusions: Our study identified unique contribution of different aspects of coping and IU to positive and negative aspects of wellbeing in parents of children with ASD. Identifying such factors is a crucial first step in developing intervention programs to help improve the psychological wellbeing of parents.

423.061 *(Poster)* Promoting Caregiver Integration into Clinical Care and Research across a Large Autism Treatment and Research Network

A. Hess[1], *A. Fedele*[2], *J. S. Anixt*[3], *D. S. Murray*[4] *and D. L. Coury*[5], *(1)Psychology, Nationwide Children's Hosptial, Columbus, OH, (2)Autism Speaks, Mullica Hill, NJ, (3)Division of Developmental & Behavioral Pediatrics, Cincinnati Children's Hospital Medical Center, Cincinnati, OH, (4)Autism Speaks, Boston, MA, (5)Nationwide Children's Hospital, Columbus, OH*

Background: The combined Autism Speaks Autism Treatment Network (ATN)/Autism Intervention and Research Network on Physical Health (AIR-P) focuses on the improvement of health and well-being of children with ASD by conducting intervention research, determining and disseminating best practice, and developing resources for families and providers. While parent / family input has been solicited since the start of the network, we have now further extended this involvement to include partnering on all network activities.

Objectives: To increase patient / parent involvement in health care and conduct of research into autism interventions.

Methods: The ATN /AIR-P has a family advisory committee (FAC), with two or more members representing each of the 12 Network clinical sites. Each site has a local FAC that is typically led by the network FAC reps in conjunction with clinical site staff members. In 2017, a self-advocate was also added to the FAC in order to increase the patient voice across Network activities. Over the past three years we have increased the FAC involvement through several initiatives to ensure that there is FAC representation on all Network activities (i.e. committees, workgroups, and research team members). The network FAC has grown from a single voice in 2009 to now comprising over 35 members who are the parents of young children to young adults from multicultural, diverse backgrounds, representing a cross section of parents of individuals diagnosed with ASD, offering a comprehensive view of the issues and treatment needs across the lifespan. After an in-person meeting in 2019 and a training on research, the number of FAC involved in the Scientific Review Committee (SRC) increased from 4 to 15. FAC members participate in identifying external research grants, co-author manuscripts, review research proposals, participate in the development of research protocols, and are key members of the SRC. A panel of FAC members participated in network long-term planning, identifying the primary treatment areas of emphasis for the current five-year plan. Methods used to facilitate and promote FAC participation include a charter and contract to clearly define membership roles, expectations, and payment of stipends for participation in Network activities. Scheduling meetings / conference calls at times convenient to the FAC, hosting one-on-one calls with the FAC reps, and recording meetings are some ways the Network has found to be helpful for engagement. Increased FAC involvement has occurred thanks to active FAC leadership and strong support by Network leadership.

Results: As FAC members have become more integrated in network activities they have provided increasingly focused and pertinent topic areas for advancing care, many of which had not been considered by network clinicians and researchers.

Conclusions: Integration of caregivers and patients into clinical research and health care delivery processes can be successfully achieved with a goal to improve family and patient satisfaction with care. Families are best able to identify those issues of greatest importance to them and addressing these issues can lead to best outcomes.

423.062 *(Poster)* Promoting Translational Research: Assessing Successful Autism Genetic Discoveries from a Patient Perspective

Z. Talebizadeh[1,2], *A. Shah*[1] *and E. Brower*[3], *(1)Children's Mercy Hospital, Kansas City, MO, (2)University of Missouri-Kansas City School of Medicine, Kansas City, MO, (3)Psychology, University of Nebraska Medical Center, Omaha, NE*

Background: Patient advocates have long voiced concerns over the need to improve translational aspects of genetics research studies and to engage community members in the research process. Researchers have also noted a paucity of translational research in the genetics field. While the majority of reports recognize the need to place the patient and family at the center of genomic medicine implementation, they only provide recommendations, but not actionable plans for building implementation science frameworks. There is a great need to increase public involvement in genetics research, and develop standardized methods of reporting their engagement; the impact of such involvement may be evaluated by assessing both qualitative and quantitative data. As one path toward addressing these challenges, we have developed AutGO (Autism Genetics Outcomes), an initiative to support broad stakeholder partnerships and advance a new integrated concept called GO (i.e., research approaches that draw on both genetics and clinical outcomes perspectives).

Objectives: One effective way to illustrate the potential product of a GO conceptual framework is through prototype representation; i.e., by identifying research example(s) that illustrate aspects of the GO concept. To do so, we conducted literature review and assessed three successful autism genetic discoveries from the GO perspective.

Methods: Traditionally, outcomes research focuses on identifying and prioritizing patient needs, however, addressing those needs may be beyond the scope of genetics research. This incompatibility has been one of the key obstacles that prevented formation of partnerships between these two disciplines. One solution is to build partnerships based on flexible and mixed methods, such as actionable GO projects. To date, we have accomplished the following: identified inclusion criteria for GO hypotheses, developed a semi-structured literature review protocol to collect stakeholders' perspectives for developing such hypotheses, and identified three autism related prototypes exemplifying a GO concept. Figure 1 summarizes the methodological concept behind our literature review process.

Results: By applying lessons learned from AutGO, we assessed autism genetic findings from a patient perspective. To do so, we evaluated three successful/replicated discoveries (related to *PTEN*, *MET*, and Fragile X genes) from the standpoint of both scientific impact and patient-centeredness. The following elements were distilled: (1) if/how patient and/or parent concerns contributed to the study inception/development process, and (2) if/how they contributed to developing treatments and improving patient health outcomes, and (3) highlight elements included in hypothesis generation, research design, and data evaluation that were key factors in making these discoveries successful. Figure 2 summarizes one prototype.

Conclusions: Such a unique retrospective assessment of the genetic findings will facilitate developing a practical set of recommendations (conceptual framework) for the policy makers, funding agencies, and the research community to further promote designing research protocols that have a higher likelihood of contributing to translational research. Gathering and sharing such dual perspectives could facilitate igniting interest on the topic of making a bridge between outcomes and genetics research in autism, and promote building synergistic frameworks among relevant, but currently disconnected, initiatives that are aiming to increase patient-centeredness.

423.063 *(Poster)* Quality of Life in Mothers and Fathers of Individuals with ASC: Different Patterns of Relationships in a Hungarian Sample

M. Molnar-Varga[1,2]*, K. Stefanik*[2,3] *and M. Gyori*[1,2]*, (1)Institute for the Psychology of Special Needs, ELTE University, Budapest, Hungary, (2)HAS-ELTE 'Autism in Education' Research Group, Budapest, Hungary, (3)Institute of Special Needs Education for People with Atypical Behavior and Cognition, ELTE University, Budapest, Hungary*

Background: Parents of individuals with ASC were shown to have a lower overall level of quality of life (QoL) than parents of typically developing individuals and of individuals with other forms of atypical development (Eapen & Guan, 2016). Previous studies did not find significant differences in the levels of the QoL of mothers and fathers (Dardas, 2014), but the potential predictors did not totally overlap in the two groups (Shu, 2009; Dardas, 2015).

Objectives: The main objectives of the present study were to explore: (1) differences between mothers and fathers of individuals with ASC in their QoL and psychological well-being; and (2) the presence of the internationally known relationships between parental QoL and well-being in our sample from Hungary.

Methods: Data were analyzed from groups of parents (mothers and fathers) of 29 individuals with ASC (n = 58, 29 mothers and 29 fathers; mean age 44 years, SD 8.5, range 29-70 years), providing data on 54 male and 4 female individuals with ASC (median age 9.5 years, SD 7.4, range 3 – 38 years). There were no significant differences between parental groups in age and in type of residential settlement. Data were collected via an on-line questionnaire battery, which included the WHO-QoL BREF; the Quality of Life in Autism Questionnaire (QoLA); the Sense of Coherence Questionnaire (SOC); the Parenting Sense of Competence Scale (PSOC); the Depression, Anxiety and Stress Scales (DASS); the Support Dimension Scale (Kopp & Kovacs, 2006) and Social Communication Questionnaire (SCQ) on the offsprings' ASC-relevant behaviors.

Results: We found significantly lower values in case of mothers in autism-related QoL (F=0,646 p=0.008) and tendency-level differences in physical QoL domain (F=9.140 p=0.058) and PSOC total score (F=5.721 p=0.086) of mothers and fathers. The perception of offsprings' social-communication symptoms showed significant differences between parents (F=2.751 p=0.016); fathers rated higher the level of SCQ while mothers perceived more severe difficulties of their child. QoLA-A results of mothers and fathers had significant positive correlation with all domains of BREF and with SOC, PSOC total; and showed negative correlation with DASS domains. In case of mothers, autism-related QoL was strongly positively correlated with Physical QoL (BREF DOM1: R=-0.378 p=0.047) and with parameters of own psychological well-being (SOC, DASS, PSOC) and tendentiously with social supports; while in fathers autism-related QoL was in positive relation with SCQ total of their children (R=0.433 p=0.024), BREF physical and psychological domains, DASS Stress output (R=0.464 p=0.013) and PSOC total (R=-0.375 p=0.049).

Conclusions: Results, coming from the first ASC parental study on the issue in Hungary, are overall in line with previous findings from other countries: mothers seem to have an overall lower QoL than fathers, in relation to the autism of their children; and their various QoL indicators are more related than those of fathers. As a novel aspect, the different patterns of relationships between various QoL indicators in parents raises the possibility that factors influencing the parental perception of their QoL could be different in mothers and fathers - an issue which requires further analysis.

423.064 *(Poster)* Research Participants' Perspectives on a Peer-Coaching Intervention for Parents of Children with Autism

H. S. Lee[1]*, L. Hauptman*[1]*, S. F. Vejnoska*[2]*, S. Iadarola*[3]*, D. S. Mandell*[4]*, A. Gulsrud*[5]*, A. C. Stahmer*[6] *and C. Kasari*[1]*, (1)University of California, Los Angeles, Los Angeles, CA, (2)University of California, Davis, Sacramento, CA, (3)University of Rochester Medical Center, Rochester, NY, (4)Center for Mental Health, University of Pennsylvania, Philadelphia, PA, (5)UCLA Semel Institute for Neuroscience & Human Behavior, Los Angeles, CA, (6)Psychiatry and Behavioral Sciences, University of California at Davis MIND Institute, Sacramento, CA*

Background:

Community-partnered approaches are increasingly used in research to increase interventions' feasibility and relevance to the community. Past research has shown success in engaging traditionally underrepresented families of children with autism by partnering with community members who serve as peer coaches that deliver interventions directly to families (Magaña, Lopez, & Machalicek, 2015).

Although studies report including peer coaches' feedback during intervention development and implementation, their perspectives in using the intervention *after* having participated in a study are not well documented. To improve community-implemented interventions, it is important to gain input from both types of research participants – intervention recipients and peer coaches, and to learn from their experience after having used the intervention.

Objectives:

This study examined feedback from peer coaches and intervention recipients to improve a peer-coaching intervention for under-resourced, minority parents of children with autism.

Methods:

Data for this project come from a 12-week pilot of Mind the Gap (MTG), a peer-coaching intervention for under-resourced parents of children with a recent diagnosis of autism who are new to navigating the service system.

To assess the feasibility of MTG, semi-structured interviews were conducted at the end of the pilot with thirteen participants at the four Autism Intervention Research Network on Behavioral Health (AIR-B) sites. Seven were experienced parents of children with autism who received training from the research team and served as peer coaches; six were coaching recipients and predominantly female, Hispanic and fell below the federal poverty level standards.

Open coding of interviews resulted in preliminary codes. Then, two independent coders applied codes to all interviews and reconciled differences through consensus, establishing a final list of themes.

Results:

Both peer coaches and coaching recipients were highly satisfied with the intervention content, coach-parent matching, and flexibility of the intervention that allowed both in-person and phone meetings. Parents especially liked coaches' guidance on who to contact for services, reminders to make calls, and encouragement. While most parents liked the pacing of the intervention, some suggested longer intervention sessions, spaced further out.

Peer coaches noted the importance of in-person meetings in developing personal connections with parents though meetings were sometimes difficult due to distance, traffic, and time. Another challenge was completing datasheets that were too complicated, redundant and hard to fill out while being present with parents. Coaches requested more space to write notes, to better capture families' complex situations. Feedback on technology was mixed.

Conclusions:

Overall, research participants were satisfied with the content, peer-coaching format, and flexibility of MTG. It was clear from interviews that peer coaches highly valued interpersonal relationships with parents they were working with, and sometimes data collection interfered with active listening. Also, as coaches were parents themselves, their limited availability served as a barrier. Future research should prioritize creating easier data collection methods and findings ways to reduce burden for community partners while maintaining research rigor.

423.065 *(Poster)* Rethinking Stakeholder Roles in ASC Early Interventions: Moving from Participants to Engaged Collaborators

A. Wainer[1]*, K. M. Walton*[2]*, A. R. Borowy*[2] *and R. A. Gordon*[3]*, (1)Department of Psychiatry, Rush University Medical Center, Chicago, IL, (2)Nisonger Center, The Ohio State University, Columbus, OH, (3)Psychiatry, Rush University Medical Center, Chicago, IL*

Background: Children with Autism Spectrum Conditions (ASC) experience a variety of challenges, including problems with social communication, cognition, and adaptive skills. Multiple types of early interventions (EI) are available; yet, data about how to select, prioritize, and individualize different intervention approaches for a particular child is absent. Further, there is a clear mismatch between the range of outcomes studied in research, and the outcomes/values described by stakeholders like adults with ASC, caregivers and clinicians. This may reflect the fact that stakeholders have rarely been engaged in discussions about which outcomes and measurement approaches should be used in EI research.

Objectives: The goal of this effort, called Project STEER (**St**akeholders **E**ngaging in **E**arly Intervention **R**esearch) is to develop a sustainable model that puts stakeholders at the center of ASC EI research.

Methods: In its initial year, Project STEER has used a Participatory Action Research approach to develop a research agenda that reflects strategies, measurement, and outcomes relevant to ASC EI stakeholder goals and priorities. Our participatory action approach uses collaborative reflection and systematic data collection to mobilize specific actions; this approach has been particularly well suited for the current project aims given that a lack of collaboration, focus and clearly defined next steps have hampered prior attempts to create a meaningful research agenda in this area. Project STEER stakeholders include adults with ASC, parents of children with ASC, and community-based clinicians/policy makers in Columbus, Ohio and Chicago, Illinois. Across Columbus and Chicago, Project STEER has successfully engaged a total of 34 stakeholders (10 autistic adults, 10 parents of children with ASD, 10 clinicians/policy makers, 4 researchers) in facilitated group meetings to collectively define problems with current approaches to identifying and measuring EI outcomes and jointly identify recommendations that put stakeholder-driven perspectives at the center of the EI research agenda

Results: Project STEER facilitated discussions elucidated several areas that are considered high-priority research topics by stakeholder groups. Themes identified by the groups focus on better support for families, more coordinated and cohesive service delivery systems, increased emphasis on quality of life for the child and family, and consideration of intervention approaches and treatment targets that account for the heterogeneity of ASC. In addition, stakeholders identified a need for more effective and accessible dissemination of research findings, particularly those outlining best practices and evidence-based interventions for young children with and at-risk for ASCs.

Conclusions: Project STEER represents a critical step forward in realigning the research questions and approaches considered and used by researchers with the goals and priorities of stakeholders. The first phase of the project has allowed for identification of topics that stakeholders believe should be at the center of scientific endeavors. Using this information, we will next use Delphi methodology to further refine this collaborative research agenda with a group of stakeholders across the United States. The finalized Project STEER agenda will be disseminated broadly across lay, scientific and policy-focused outlets.

423.066 *(Poster)* Satisfaction with Informal Supports Predicts Resilience in Families of Children with Autism Spectrum Disorder

V. C. Fong[1]*, E. C. Gardiner*[2] *and G. Iarocci*[3]*, (1)Psychology, Simon Fraser University, Vancouver, BC, Canada, (2)Pediatrics, University of British Columbia, West Vancouver, BC, CANADA, (3)Psychology, Simon Fraser University, Burnaby, BC, Canada*

Background: Recently, research on families with autism spectrum disorder (ASD) has shifted from a deficits-based model to a more complex and nuanced understanding of adaptation and healthy functioning. For many families, resilience and strength is observed (Gardiner & Iarocci, 2012). While the majority of research on resilience has focused on identifying characteristics of the child with ASD and their caregivers, less research has been dedicated to examining factors and resources that may promote resilience in families. Informal supports may impact resilience by alleviating stress related to caregiving, preventing social isolation, and enhancing overall well-being (Gonza, Ruiz-robledillo, & Andre, 2014). Informal supports for families of children with ASD can take many forms and includes supports from family, friends, as well as other caregivers of children with ASD. By identifying protective factors that are impactful on resilience, professionals working with families of children with ASD can help to build upon these strengths and encourage strategies that promote optimal functioning.

Objectives: To examine the role of informal supports using the Beach Centre Family Quality of Life Scale (FQOL; Hoffman, Marquis, Poston, Summers, & Turnbull, 2006) in predicting resilience in families using the Family Resilience Assessment Scale-ASD (FRAS-ASD; Gardiner, Mâsse, & Iarocci, 2019) controlling for demographic variables (e.g., age, gender, and family income) and child behavioural problems.

Methods: The study is based on data from 174 caregivers of children with ASD between the ages of 2 to 35 (M=11.93, SD=5.85). Caregivers most frequently rated their children's intellectual functioning as 'high average' and their social functioning as 'low average'. Caregivers completed the satisfaction with informal supports domain of the FQOL Scale (e.g., my family members have friends or others who provide support) and the FRAS-ASD. Hierarchical multiple regression analyses were conducted with the FRAS-ASD total score entered as the dependent variable, demographic and child behavioural problems were controlled for in the first step, and satisfaction with informal supports entered as the main predictor variable.

Results: Findings revealed that satisfaction with informal supports significantly predicted family resilience after controlling for age, gender, family income, and child behavioural problems.

Conclusions: Greater satisfaction with informal supports (e.g., feeling that the family has the support from friends and outside help to relieve stress) predicted greater resilience in families of children with ASD. Findings highlight the importance of targeting these informal support networks in services and interventions in order to support families in achieving their optimal well-being.

423.067 *(Poster)* Seeking Help and Support: The Trajectories of Parents with Young Children on the Spectrum

I. Courcy[1] *and C. Des Rivières-Pigeon*[2]*, (1)Sociology, University of Quebec in Montreal, Montreal, QC, Canada, (2)Sociology, University of Quebec at Montreal, Montreal, QC, Canada*

Background: Parents are usually the main actors in seeking help when concerns are raised about their child's development. In the context of autism, seeking for information and specialized intervention is often described as an emotionally difficult obstacle course entailing a series of tasks that does not always lead to obtaining the desired support (Singh 2016, Nicholas et al. 2016). However, the relations mobilized (or neglected) by parents in this trajectory have never been explored.

Objectives: To analyse parental trajectories in seeking for help and support taking into account the different relationships parents mobilize to obtain information and specialized services for their young child on the autism spectrum. The theoretical framework combines the cultural approach of social networks (Eve 2002) and the concept of trajectory as a social process (Allen et al. 2004, Singh 2016, Strauss 1985).

Methods: Qualitative interviews with a name generator questionnaire were conducted with 18 Quebecer parents with children between 4 and 10 years old (Canada). A qualitative analysis of content by emerging themes was conducted in order to identify the different actions undertaken over time and the different actors mobilized in the parent's support networks.

Results: The results show 4 component phases of the parental trajectories: 1) the entry into the trajectory initiated by the first concerns about to the child's development, 2) the deployment of the trajectory of seeking for help and support mainly oriented towards the diagnosis, 3) the pursuit of the trajectory aimed at obtaining specialized intervention and 4) the stabilization of the trajectory characterized by an anticipation of the child's future needs and the possible extension of the parental trajectory beyond the child's majority.

Different persons have helped or hindered in these phases: 40 types of significant relations were identified in parental trajectories originating from informal (e.g. family, friends, co-workers) and formal (e.g. physician, teacher) support networks.

During the first three phases, the presence of a large number of professionals was often the result of seeking and consulting for information and specialized intervention without obtaining the desired support. A decrease in the relations with family members and friends during the second phase was noted. The perceived quality of the information or support received was not associated with the kind of relationship, except for the other parents of children in the spectrum. In fact, these parents met on self-help groups and social media, were identified in all families as having provided information and helped in obtaining formal services.

Conclusions: In order to better understand the parental trajectories in seeking help for the child, we must take into account all the relationships that are likely to provide them with informal and formal support. The contribution of the community sector in parental trajectories shows the importance of mutual support between parents. This result must be put in the current Quebec context where the public service offer does not yet meet the needs of all children on the spectrum.

423.068 *(Poster)* Sources of Stress for Parents of Children with ASD Studying in Hong Kong Mainstream Schools

H. Tse *and K. Wong, Psychology, The University of Hong Kong, Hong Kong, Hong Kong*

Background: Studies have shown parenting stress for parents of children with autism spectrum disorder ("ASD") are higher than typically developing children or children with other disabilities (Hayes & Watson, 2013). However, previous studies usually employed measurements of parenting stress directly linked to behavior characteristics of the children, e.g. the Parenting Stress Index (Abidin, 1990), less focus has been put on stress induced from the school life of their children, such as homework supervision or relationship with teachers. Previous studies showed parenting stress in typically developing students increased when homework load increased in US (e.g. Pressman et al., 2015). In places like Hong Kong with a competitive education system, helping children to strive better at school could be a top stressor for parents.

Objectives: Understand how school life plays a part in parenting stress for parents of children with ASD in mainstream schools among other stressors, and how the severity of social impairment of their children relates to the stressors.

Methods: This study is part of a territory-wide school support project, "JC A-Connect Jockey Club Autism Support Network", for students with ASD in Hong Kong mainstream primary and secondary school. We asked parents about difficulties they encountered in parenting, then compiled a list of 20 stressors into a Source of Stress checklist ("SOS", See Table 1 for the items). Parents rated the stressors using a 6-point Likert scale to indicate to what extent they agree each was a source of their stress.

Exploratory factor analysis was performed on SOS and the items were classified into six subscales, namely general parenting, child's schoolwork, parent-child relationship, child's school-life related, child's peer relationship, and child's difficult behaviors (See Table 1).

Parents also filled in the Social Responsiveness Scale – Second edition (SRS-2), a rating scale measures social impairments associated with ASD symptoms (Constantino & Gruber, 2012). Correlations on total score of SRS-2 with subscale scores of SOS were examined.

Results: Table 1 shows the mean SOS rating obtained from parents of children with ASD. Items with mean over 3.5 suggest parents in general agreed them to be stressors. Both primary (N=4581) and secondary school (N=1246) parents reported "the future prospect of their child to fit in the society" as the top stressor. "Helping child with homework" and "prepare for exams" is similarly stressful for primary school parents, while for secondary school parents, it is the second top stressor. Child's difficult behaviors and child's peer relationship are also mild stressors. On the other hand, child's school-life and parent-child relationship were less likely to be parents' sources of stress.

Upon inspecting correlations between total score of SRS-2 and item/subscale scores of SOS, the SRS-2 correlated strongly with the top stressor "child's future prospect". However, it correlated mildly with the factors "child's schoolwork" and "school-life" (see table 2)

Conclusions: The top stressors, "child's future prospect" and "child's schoolwork", correlate at different level of strength with the child's ASD symptoms. Results suggest that studying parenting stress focusing on child's behavior characteristics alone may not represent its full picture.

423.069 *(Poster)* Stick to It: Parental Stress, Resilience, and Satisfaction in Caregivers of Children with Autism

***C. S. Borgen**, St. Joseph's Children's Hospital, Paterson, NJ*

Background: A link between parental stress and children with behavioral problems for families of children with autism spectrum disorder (ASD) and other developmental disabilities has been demonstrated (Hayes & Watson, 2013); the same findings have been replicated in ethnically diverse/minority populations, as well (Valicenti-McDermott et al., 2015). Parents' satisfaction with their parental role has been found to influence their reported feelings of stress (Samadi et al., 2014); yet, the need to better understand parental satisfaction in parents of children with ASD continues to require more scrutiny. There has been a call to better understand the protective factors that help explain resiliency of families of individuals with developmental disabilities (Leone, Dorstyn, & Ward, 2016).

Objectives: This study seeks to answer the call for research which highlights the importance of considering the family system in research on youth with ASD (Schiltz et al., 2018). The current study seeks to understand how parental satisfaction predicts parent stress and the degree to which resiliency and gender impact the relationship.

Methods: Survey and self-report questioners were provided and completed by 101 parents of a child or multiple children diagnosed with autism spectrum disorder in a regional children's hospital in the American Northeast region. The survey was composed of a demographic questionnaire and three self-report scales, including a Resiliency Scale (Sui et al., 2009), Caregiving Stress Appraisal Scale (Abe, 2001), and Parental satisfaction with caring for a child with Developmental Disability Index (Samadi & McConkey, 2014).

Results: To assess how parental stress is a function of multiple risk factors, specifically whether resiliency moderates the relationship between parental satisfaction and parental stress, a hierarchical multiple regression analysis was conducted; gender was entered as a covariate. Gender was not a statistically significant predictor significant, $b = .09$, $t(96) = .49$, $p = .63$. The overall model was statistically significant, $R^2 = .28$, $F(4, 96) = 9.12$, $p < .001$. The interaction between resiliency and parental satisfaction was a significant change to the model $F(1, 96) = 5.17$, $p < .05$, ΔR^2 change = .04. Examination of the interaction plot showed a statistically significant effect for high scorers of resiliency, satisfaction positively predicts parental stress; as satisfaction increases, stress increases, $b = .39$, $t(96) = 1.93$, $p = .05$.

Conclusions: Findings demonstrate the importance of resiliency and parental satisfaction for parents of children with ASD. Parents with higher scores had lower overall levels of parental distress than those with lower of average resiliency levels. Parents of children with ASD may benefit from evidence based interventions focused on increasing resiliency. Behavioral parent training, cognitive behavior therapy third wave cognitive behavioral therapies have been found to have empirical support to increase resiliency in parents (McConnell & Savage, 2015; Öst, 2008). The pattern of higher levels of parental satisfaction predicting higher levels of parenting stress seems counterintuitive but may be suggestive of stress being a derivative of parents placing high importance on their caregiver role and a drive to maintain a standard of care and investment.

423.070 *(Poster)* Stigma Among Latin-American Caregivers: The Impact of Parental Education Level, Severity of ASD Symptoms, and Child Age.

***A. Torres**[1], C. Montiel-Nava[1], M. C. Montenegro[2], D. Lecusay[3], L. Pesina Avalos[2], C. Guzman[2], S. H. Cukier[4], R. A. Garcia[5], G. Garrido[6], C. S. Paula[7], A. Rattazzi[4], A. Rosoli[8] and D. Valdez[9], (1)Psychological Science, University of Texas Rio Grande Valley, Edinburg, TX, (2)University of Texas Rio Grande Valley, Edinburg, TX, (3)Psychology Department, University of Texas Rio Grande Valley, Edinburg, TX, (4)PANAACEA, Buenos Aires, Argentina, (5)Clínica Las Condes, Santiago, Chile., Santiago, CHILE, (6)Universidad de la República, Montevideo, Uruguay, (7)Developmental Disorder Program, Universidade Presbiteriana Mackenzie, São Paulo, Brazil, (8)Projects, Organizacion Estados Iberoamericanos, Santo Domingo, Dominican Republic, (9)Universidad de Buenos Aires- FLACSO, Buenos Aires, Argentina*

Background: Caregivers of children with Autism Spectrum Disorder (ASD) report high levels of stigma. Caregivers stigma plays a pivotal role in timely access to service and the quality of services received by children with ASD. Results suggest that stigma negatively correlates with services received and the educational level of mothers. Additional, due to the stigma associated with ASD, caregivers delay seeking services for diagnosis and treatment. Furthermore, higher levels of stigma among caregivers also correlates to more severe symptoms and behavioral problems in children. The majority of data about perceptions of stigma in caregivers of individuals with ASD comes from the body of the research conducted on in English speaking developed countries, with few reports on Latino populations.

Objectives: This study aims to examine the role of parental education level, the severity of ASD symptoms, and child age in the experience of stigma among caregivers from Latin-America countries.

Methods: This study includes data from an online survey of 2817 caregivers from six Latin-America Countries. The survey requested information about family demographics, affected individual characteristics, and parent/caregiver perceptions, including stigma and parent education.

Results: An ANOVA demonstrated significant differences in stigma among the different age groups [F (2, 2436) = 8.698 p<.01]. A post-hoc test revealed that the caregivers of children of ages 0-6 years of age had significant higher mean levels of stigma (M= ,1.86 SD= .61) compared to the 7-17 (M= , 1.76 SD= .60) and the >18 (M= 1.83, SD= .60) groups. A multiple regression analysis demonstrated that the education levels of the primary caregiver only explains 0.4 % of the variance [Adjusted R^2 = F (1, 2432) = 9.63, P<.01A second multiple regression analysis found that intellectual, language, and symptom severity levels combined accounted for only 1.5 % of the variance [R^2 = F (2, 1463) = 9.58, P<.01]. Language level (β =.036, p<.01) and symptom severity level (β = .062, p <0.05), but not level of intellectual functioning (β = -.012, p >.05). were significant predictors of stigma.

Conclusions: Education and severity explain minimal variance of the stigma experienced by Latin-American caregivers. A limiting factor to our study was ceiling effect caused by a highly educated sample (81%% with a high school diploma or higher); which might be a potential confounding variable. Caregivers of preschool age and adult individuals reported higher levels of stigma compared to elementary school children and adults. For the younger children, the impact on receiving a new diagnosis could explain the results. Results could be also related to the unmet needs regarding health and educational services for their children. Understanding how Latino parents perceive stigma across the lifecycle of their children will help in tailoring services, which will result in better outcomes

423.071 *(Poster)* Teaching Transferable Workplace Skills in a Business Setting - a Pilot Program

M. Madfis[1]*, L. Cattan*[2] *and P. Rowan*[2]*, (1)Yes She Can Inc., White Plains, NY, (2)Yes She Can Inc, White Plains, NY*

Background:

When young adults exit high school or college they don't have the critical skills for success at work which are: motivation and ability to persevere, good social communication skills, problem solving skills, cognitive and emotional adaptability, flexibility, collaboration skills, ability to understand another's perspective, and good emotional regulation. These skills are not natural to people with ASD. Special education does not teach these skills. Furthermore, they are not the focus of conventional "pre-vocational" Medicaid funded programs for people with developmental disabilities.

In order to address this gap, a business-focused model was developed in 2013 by Yes She Can to teach these critical skills in an authentic business environment – a resale store for American Girl dolls. These skills are directly taught using techniques that are effective for ASD. Clinical social workers and psychologists and business managers coach and assess trainees regularly on their achievement of these targeted skills. While the business itself may change based on the demographic and interest of autistic adolescents and adults, the training model may be replicated to increase the number of individuals served and increase the employment rate.

Objectives:

The pilot program has demonstrated that this approach is effective in teaching critical workplace skills, based on rigorous assessments of participants. The objective is to determine if the model can be replicated by other organizations, with published and licensed manuals documenting the curriculum and teaching processes.

Replication of a proven model will speed time to market with minimal risk for new or existing organizations with the outcome of increasing the number of young adults with essential skills for success in the workplace.

Methods:

Yes She Can created their original job skills curriculum applying basic business processes and behaviors that are typical in most work environments, and coaching methods based on proven clinical techniques.

Yes She Can clinical staff created a comprehensive assessment process to measure progress towards trainee acquisition of 32 key skills and the impact of the program on achieving them. Data is collected daily in 4 categories: general business skills, technical skills, communication and emotional regulation skills, and self-advocacy and personal care skills.

Results:

Yes She Can has served 40 trainees in the past 5 years. In 2019, 16 trainees attend 2-3 times/week, have received 3500+ hours of coaching, with 3 staff coaches, 4 volunteer coaches, 3 peer mentors, 2 MSW candidates. Of the 20 participants enrolled since 2017, 7 became employed in jobs in their interest areas, 2 have internships, 6 are enrolled in college, 3 are in the job search.

All participants have been able to apply their new skills to their personal lives, enabling them to increase independence and self-esteem, reducing isolation and depression.

Conclusions:

Starting and implementing a non-traditional job skills program takes creativity, business acumen, and autism expertise. Yes She Can's pilot program is a proven success and should be replicated in other communities. By presenting the program at INSAR 2020, established agencies and potential startups will learn about Yes She Can's success and be inspired to partner for replication.

423.072 *(Poster)* The Cultural Validation of the PEERS Social Skills Program for Ethnically and Linguistically Diverse Families

A. M. Martin[1]*, J. Blacher*[1]*, E. Baker*[2]*, E. Veytsman*[1] *and K. K. Stavropoulos*[1]*, (1)Graduate School of Education, University of California Riverside, Riverside, CA, (2)University of California Riverside, Riverside, CA*

Background: Treatment efficacy of the PEERS social skills (SS) program has been demonstrated through significant improvements in social skills, frequency of social engagement, and reduced autism-related deficits in social responsiveness (Laugeson et al., 2015). However, individuals who are Latinx are often not included in such studies (Schohl et al., 2014). In order to have more representative participant samples in SS interventions, researchers must determine ways to adapt SS interventions to be more inclusive and culturally sensitive.

Objectives: This study addressed the following research questions: 1. Are culturally and linguistically diverse parents satisfied with the PEERS program? 2. Do parents find the program valid and useful? 3. What cultural adaptations are necessary for program success?

Methods: Two groups were recruited (1) an active treatment (AT) group and (2) a waitlist control (WLC) group. The AT group contained 7 adolescents (*M* age=13.3, *SD*=2.0) and their parents. Ethnicity included 2 White, 4 Latinx, and 1 biracial participant. Six families primarily spoke English and 1 participant was Spanish-speaking only. Of the 4 English-speaking Latinx, all indicated some level of Spanish language comprehension on the Bidimensional Acculturation Scale (BAS; Marin & Gamba, 1996), suggesting that the group was predominately bilingual. A WLC group contains 8 adolescents (*M* age=13.5 *SD*=2.2) and their parents, 3 White and 5 Latinx families. Parents received post- intervention satisfaction questionnaires; they also participated in semi-structured interviews conducted at two time points post intervention. Data collection from the first group has been completed; the WLC group will be completed in February 2020.

Questionnaires included a general satisfaction survey and a modified Intervention Rating Profile (IRP15; Martiens et al., 1985). Social validity was measured through an interview adapted from the Gresham and Lopez (1996) framework for determining validity from post-intervention interviews.

Results: With regard to research question #1, 100% of parents reported high levels of satisfaction regarding their overall experience and with skills taught during PEERS. In terms of validity, (question #2) all families agreed that the intervention was appropriate for their child's behavior problems and would recommend the intervention to teachers and parents. During open-ended interviews, parents noted that the group felt inclusive, despite language and cultural differences. However, interviews also indicated that cultural adaptations may be necessary (question #3). Latinx parents reported feeling overwhelmed with weekly homework assignments (major component of PEERS) that required them to deviate from what they considered cultural parenting norms (e.g. the program requires adolescents to have get-togethers with same-aged peers, rather than with family). One mother described the experience as "making her feel like she was changing her culture," and having to "overcome the fear of having to parent differently" to avoid limiting her child's growth.

Conclusions: Forthcoming qualitative analyses should reveal additional insight into the dynamics that cultural parenting norms play in an intervention that has been validated primarily with White participants. Future suggestions include adapting portions of the program to allow Latinx families to practice homework assignments with extended family members instead of non-related adolescent peers.

423.073 *(Poster)* The Effect of Resilience and Social Support upon Stress, Anxiety and Depression Among Danish Parents of a Child with Autism

M. E. Andersen[1]*, V. Bitsika*[2] *and C. F. Sharpley*[3]*, (1)Department of Psychology, University of Southern Denmark, Odense M, Denmark, (2)University of New England, Armidale, NSW, Australia, (3)Brain-Behaviour Research Group, University of New England, Armidale, NSW, Australia*

Background: Parenting a child with autism is associated with specific and general challenges increasing the experience of psychological distress including a higher prevalence of anxiety and depression. High levels of stress, anxiety and depression may further impact family functioning. It is thus important to understand the factors that may help protect against the development of mental health difficulties and which can be targeted in interventions. In a previous study Bitsika and colleagues showed a buffering effect of resilience upon stress, anxiety and depression in parents of a child with autism.

Objectives: The objectives were to investigate the effect of resilience and social support upon stress, anxiety and depression in Danish parents of a child with autism.

Methods: Data was collected as part of a larger longitudinal survey among Danish parents of a child with autism. Zungs self-rating anxiety scale (SAS) and depression scale (SDS) were used to assess anxiety and depression. A SAS total score above 36 or SDS total score above 40 have previously been used as an indicator of a clinically significant level of anxiety or depression respectively. Connor-Davidson Resilience Scale (CD-RISC) was used to assess resilience and the Multidimensional scale of perceived social support (MSPSS) was used to assess the experience of social support. Demographic information was collected on child and family characteristics including parents experience of daily personal stress levels on a scale from one to ten, with 10 indicating a very high level of daily stress.

Results: 849 parents participated in the survey (86% females) with a mean age of 44.88 (SD=6.94) years. Mean total SAS score was 38.89 (SD=10.02) and 56% of the parents met the criteria for a clinically significant level of anxiety. Mean total SDS score was 46.79 (SD=7.54) and 78% of the parents met the criteria for a clinically significant level of depression. The mean of average daily stress was 6.70 (SD=2.38).

The level of daily stress correlated significantly with both SAS (r=.526; p<.000) and SDS (r=.562; p<.000). When controlling for resilience the correlation remained significant for both SAS (r=430; p<.000) and SDS (r=.471; p<.000). However, the correlation was significantly reduced for both SAS (z=2.55; p=.011) and SDS (z=2.54; p=.011). When controlling for the experience of social support the correlation remained significant for both SAS (r=.466; p<.000) and SDS (r=.502; p<.000) and there was no significant change in the correlation for either SAS (z=1.63; p=.103) or SDS (z=1.72; p=.085).

Conclusions: In line with previous studies high levels of anxiety and depression symptoms were found among parents of a child with autism. Replicating the study of Australian parents, resilience was found to buffer the effect upon stress, anxiety and depression. A buffering effect was not found for social support. The results indicate that while the stress associated with parenting a child with autism poses a risk for mental health difficulties, this risk may be reduced by supporting the development of parental resilience. However, it is important to further investigate how these factors may interact over time.

423.074 *(Poster)* The Experiences of Autistic Mothers during Pregnancy and the Postnatal Period

S. Hampton*, R. Holt, C. Allison and S. Baron-Cohen, Autism Research Centre, Department of Psychiatry, University of Cambridge, Cambridge, United Kingdom*

Background: Research into how autistic women experience the challenges involved in pregnancy, childbirth and parenting is scarce. For autistic women, it is possible that the sensory challenges of pregnancy and childbirth, as well as the social demands of interacting with medical professionals may make the perinatal period additionally challenging. It is therefore important to explore whether autistic women feel that they are receiving the support they need and what adjustments or additional support may be required.

Objectives: The study aimed to explore autistic women's experiences of pregnancy and the postnatal period, in order to identify how autistic women can be best supported during this time.

Methods: An anonymous online survey was completed by 660 non-autistic mothers (mean age 40.61 years (SD = 9.95)) and 529 autistic mothers (mean age 42.43 years (SD = 9.53)). Groups were matched on ethnicity, educational level and number of children. Respondents from both groups were predominantly UK based. Mothers completed questions concerning their experiences of pregnancy, birth and the postnatal period, including their relationships with healthcare professionals, their level of satisfaction with the health care they received and whether they chose to disclose to their autism diagnosis to professionals.

Results: Autistic mothers tended not to disclose their diagnosis to professionals, with 81% not disclosing to their midwife during pregnancy and 93% not disclosing to their health visitor postnatally. Only 23% of autistic mothers felt that their midwives had a good understanding of autism and only 6% of autistic mothers felt that medical professionals understood how autism affected them while giving birth. Autistic mothers were significantly less likely than non-autistic mothers to be satisfied with the health care they received during pregnancy and childbirth, as well as being significantly less likely to feel that medical professionals had an accurate understanding of what they were perceiving physically during childbirth. They were also significantly more likely to feel judged by medical professionals during the postnatal period and significantly more likely to worry that their baby would be taken away from them. Results remained significant after controlling for age, country of residence, income, marital status and the presence of medical and psychiatric conditions.

Conclusions: These findings highlight that autistic mothers are not receiving the support they need during pregnancy, birth and the postnatal period. The findings point towards the need for greater autism understanding among medical and healthcare professionals who work with autistic women during the perinatal period. This is one of the first studies of autistic mothers who are a vulnerable group and whose support needs require further research.

423.075 *(Poster)* The Interaction of Caregiver-Reported Family Functioning and ASD Symptom Severity in Predicting Caregiver Depressive Symptoms

A. M. Birnschein[1], *C. A. Paisley*[2], *T. S. Tomeny*[1], *L. K. Baker*[3] *and J. R. Pederson*[4], *(1)Psychology, The University of Alabama, Tuscaloosa, AL, (2)The University of Alabama, Tuscaloosa, AL, (3)Hassenfeld Children's Hospital at NYU Langone, New York, NY, (4)Communication Studies, The University of Alabama, Tuscaloosa, AL*

Background: Previous research has demonstrated that caregivers of children with autism spectrum disorder (ASD) report more stress than caregivers of typically developing children (Keenan, Newman, Gray, & Rinehart, 2016). Further, caregivers of children with elevated autism severity experience increased rates of stress and depressive symptoms (Ingersoll & Hambrick, 2011). Beyond the child's functioning, however, mothers' level of stress predicts maternal depressive symptoms, warranting the investigation of factors contributing to caregiver functioning (Weitlauf, Vehorn, Taylor, & Warren, 2012). Discrepancies between parental perceptions of family functioning, for example, are related to caregiver mental health outcomes, with caregiver disagreement predicting poorer caregiver mental health (Johnson, Frenn, Feetham, & Simpson, 2011).

Objectives: The present study investigated whether caregiver reported depressive symptoms are predicted by child autism symptom severity and whether this relation is moderated by caregiver perceptions of the general functioning of the family.

Methods: One hundred and six caregivers (M_{age} = 41.40, SD_{age} = 5.12, 88% female) of a child with ASD completed a series of questionnaires as part of a larger study. Caregivers reported on their child's ASD symptoms via the Children's Social Behavior Questionnaire (CSBQ; Luteijn et al., 2000), their own depressive symptoms via the Depression, Anxiety, and Stress Scale (DASS; Lovibond & Lovibond, 1995), and family functioning via the short form of the McMaster Family Assessment Device (FAD; Epstein et al., 1983).

Results: The multiple regression analysis explained significant variance when predicting caregiver depressive symptoms, $F(3,102) = 19.39$, $p < .001$, $R^2 = .36$, with family functioning moderating the relation between ASD symptom severity and caregiver depressive symptoms, $B = .18$, $SE = .09$, $p = .04$. When family functioning was reported as moderate to good, no relation between ASD symptom severity and caregiver depressive symptoms emerged, $B = .06$, $SE = .05$, $p = .17$: $B = -.05$, $SE = .07$, $p = .49$, respectively. The relation between ASD symptom severity and caregiver depressive symptoms was significant, however, when family functioning was relatively poor, $B = .18$, $SE = .07$, $p = .02$. Specifically, caregiver depressive symptoms were highest when ASD symptoms were high and family functioning was poor (see Figure 1).

Conclusions: The results of this study demonstrate that poor family functioning may be a specific risk factor for caregiver depressive symptoms, particularly when the child exhibits severe ASD symptoms. These findings suggest that improving functioning within the family unit may serve as a beneficial target for intervention, particularly when aiming to improve caregivers' moods.

423.076 *(Poster)* Timing of Placement and Transition Practices in Primary and Secondary School Transitions of Children with ASD

S. Hochheimer[1], *F. A. Castellon*[2], *J. Chiappe*[3], *A. M. Dimachkie*[4], *E. McGhee Hassrick*[5], *L. Hauptman*[6], *R. E. King*[7], *H. S. Lee*[6], *L. Levato*[7], *D. E. Linares*[8], *H. J. Nuske*[9], *N. Sparapani*[10], *S. F. Vejnoska*[11], *S. Kataoka*[12], *D. S. Mandell*[9], *A. C. Stahmer*[13], *C. Kasari*[6] *and J. Li*[14], *(1)University of Rochester, Rochester, NY, (2)University of California Santa Barbara, Santa Barbara, CA, (3)University of California Los Angeles, Los Angeles, CA, (4)Human Development and Psychology, UCLA, Los Angeles, CA, (5)A..J. Drexel Autism Institute, Drexel University, Philadelphia, PA, (6)University of California, Los Angeles, Los Angeles, CA, (7)University of Rochester Medical Center, Rochester, NY, (8)Maternal and Child Health Bureau, Office of Epidemiology and Research, Health Resources and Services Administration, Rockville, MD, (9)Center for Mental Health, University of Pennsylvania, Philadelphia, PA, (10)School of Education, University of California, Davis, Davis, CA, (11)University of California, Davis, Sacramento, CA, (12)Psychiatry, University of California, Los Angeles, Los Angeles, CA, (13)Psychiatry and Behavioral Sciences, University of California at Davis MIND Institute, Sacramento, CA, (14)UC Davis, Davis, CA*

Background: Transitioning to new schools is challenging for students with autism spectrum disorder (ASD), due to difficulties managing change, insistence on routines/sameness, and anxiety in unfamiliar settings. Existing transition programs may not address the needs of these students by utilizing effective transition strategies (Nuske, et al. 2018). In particular, concerns about latency of placement within the school year have been raised by community stakeholders, which may affect a team's ability to plan for transition, prepare the child, and coordinate services. "Building Better Bridges" (BBB) seeks to improve the transitions between school systems for students with ASD through parent, student, and teacher-level supports that encourage communication and engagement with school teams, particularly for those in under-resourced communities (e.g., low income; racial/ethnic identities that are under-represented in research).

Objectives: Describe baseline characteristics of participants in the BBB program, gather educator report on current practices, and potentially inform future exploration of associations between these characteristics and latency of placement.

Methods: Participants were recruited into this RCT across four sites of the Autism Intervention Research Network on Behavioral Health: Los Angeles, CA; Sacramento, CA; Philadelphia, PA; and Rochester, NY. We recruited primary caregivers (n = 165) and pre-transition educators (n = 128) of students with ASD transitioning to primary (Kindergarten 55%) or secondary (Middle school 27%; High school 18%) placements. At baseline (during pre-transition school placement), caregivers provided demographics. Educators completed the Information on Transition Practices Questionnaire (ITP), developed to describe current transition practices occurring in educational settings (e.g., meetings, information offered to families, communication between pre- and post-schools). ITP items were obtained through reviews of school transition literature (Nuske et al., 2018). Throughout participation, caregivers reported on when they received information on their child's new school placement.

Results: Caregivers were mostly female (88%), English-speaking (79%), with average household incomes of less than $50,000 a year (76%), and ethnic/racial diversity (41% Hispanic/Latinx; 16% African American/Black). Pre-transition, only 51% of caregivers reported knowing the new school name, and only 4% of caregivers reported knowing the new teacher's name. Families averaged 3 months (*SD* = 2.36 months) between finding out the new school placement and the first day of school (range 0 - 9 months). On the ITP, pre-transition educators reported a mean 28.6% of items as typical transition practices, with the most common practices being to "attend or hold a transition planning meeting," and "maintain communication with the family before a child starts at a new school." Educators completed 25.4% of the items only some of the time, and did not regularly complete 46% of items. The most commonly neglected items were "having a process for assessing the effectiveness of school transitions," and "hav[ing] the receiving teacher visit the current school or classroom before a child transitions."

Conclusions: These data represent a mismatch between effective transition strategies and teacher utilization. School placement information is not always timely, and is often provided when teachers are unavailable to offer transition supports. Variability in placement latency suggests that future research should explore associations among latency and transition outcomes.

423.077 *(Poster)* Training Immigrant Parents of Children with ASD Who Have Limited English Proficiency

N. Lim[1]*, M. O'Reilly*[2]*, F. Vargas Londono*[3] *and A. Russell-George*[1]*, (1)The University of Texas at Austin, Austin, TX, (2)UT Austin, Austin, TX, (3)Special Education, The University of Texas at Austin, Austin, TX*

Background: As noted by the National Research Council (2001), parent training is an essential component of successful interventions for children with autism spectrum disorder (ASD). Conventional training procedures often involve verbal instructions and verbal feedback. However, a parent whose first language is a not English might not necessarily speak or understand the language used by the trainer. The probability of this occurring is high, given the increase in people in the US with limited English proficiency. Research suggests that the number of people who reported themselves as being of limited English proficiency increased from 13 to 25.1 million between the years 1990 and 2013 (Zong & Batalova, 2016).

Objectives: The primary aim of the present study was to address the question of how to provide effective parent training in the presence of a language barrier between the trainer and the parent. Specifically, the effectiveness of a video prompting intervention on the fidelity of implementation of immigrant mothers of children with ASD was investigated.

Methods: A multiple baseline design across three mother-child dyads was used. Spanish-speaking, immigrant mothers with limited English proficiency were trained to teach their children with ASD to dress themselves. During baseline, the trainer provided each mother with the visual schedule and terminated the session if the mother performed a step incorrectly. Intervention involved video prompting and role-playing with the trainer. Post-intervention sessions were identical to baseline in that sessions were terminated if the mother performed a step incorrectly. Termination of sessions did not occur during maintenance and follow-up. No verbal feedback was given by the trainer during all sessions across phases.

Results: All mothers reached mastery criterion (i.e., fidelity of implementation was at 100% across two consecutive sessions) during role-plays with their trainers. Average number of trials to criterion was 12.67. Generalization to sessions with their children was observed for two out of three mothers. The third participant could not complete post-intervention sessions due to scheduling conflicts. Treatment gains for mothers who completed post-intervention sessions were maintained during 1- and 4-month follow-ups. Child independence in getting dressed also increased for both children. Social validity was assessed and all mothers rated the intervention to be highly acceptable. Blinded inter-observer agreement was collected for at least 33% of sessions across phases and was at 90% or above across participants. Treatment fidelity was collected for 33% of intervention sessions and was at 98% or above across all participants.

Conclusions: This pilot study suggests that video prompting could potentially mitigate language barriers and successfully teach immigrant mothers with limited English proficiency to use visual schedules and the least-to-most prompt hierarchy to facilitate child independence in dressing. An area for future research is whether a video-based intervention can be delivered via technology without the presence of the English-speaking trainer to increase cost-effectiveness. Another area for future research is to explore how video-based interventions can be used to teach parents with limited English proficiency when a model who speaks their primary language is unable to be found for the creation of the videos.

423.078 *(Poster)* Trends in U.S. Autism Research Funding: Interagency Autism Coordinating Committee Autism Research Portfolio Analysis Report

J. Rava[1]*, S. Daniels*[2]*, O. Celestin*[3] *and K. Ferrara*[4]*, (1)National Institute of Mental Health, Office of Autism Research Coordination (OARC), Rockville, MD, (2)National Institute of Mental Health (NIMH), Rockville, MD, (3)OARC, NIH/NIMH, Bethesda, MD, (4)National Institute of Mental Health (NIMH), ROCKVILLE, MD*

Background: In this poster, the Office of Autism Research Coordination (OARC) of the U.S. National Institutes of Health (NIH) will present findings from the upcoming *2017 Interagency Autism Coordinating Committee (IACC) Autism Research Portfolio Analysis Report* that describes autism research investments spanning government and private funders.

OARC/NIH coordinates and manages the IACC, a federal advisory committee composed of federal officials and public stakeholders. The Committee was established by Congress to coordinate federal agency activities and to provide advice to the Secretary of Health and Human Services related to autism spectrum disorder (ASD). The IACC's *Strategic Plan*, created with input from public stakeholders, provides a framework to guide the efforts of U.S. federal agencies and partner organizations to support ASD research. OARC conducts an annual portfolio analysis of U.S. research projects to help guide the IACC's strategic planning efforts and inform the IACC of progress toward implementation of the *Strategic Plan*. The portfolio analysis can also be used by government agencies and non-government organizations to better understand trends in ASD research funding in the U.S.

Objectives: OARC will present findings from its *2017 IACC ASD Research Portfolio Analysis Report*, which reflects the most recent information available on autism research investments made by federal and private funders of ASD research in the U.S.

Methods: Research project data including project description, institution, and funding amount were collected from multiple U.S government and non-government funders of autism research. All projects included in the *Portfolio Analysis* were coded according to the seven research questions and 23 objectives outlined in the *2016-2017 IACC Strategic Plan*. Each of the questions in the *Strategic Plan* address general topic areas that are represented as community-focused questions (e.g., How can I recognize the signs of ASD, and why is early detection so important?). Each question includes three to four broad objectives; there is also one cross-cutting objective on the topic of ASD in females. The data were analyzed in several ways to provide information on the types of research being funded and the research topic areas supported by each funder.

Results: OARC collected U.S. ASD research project data for 2017 and aligned research projects with the 23 objectives in the *Strategic Plan*. The analysis provides an overview of the distribution of research projects and funding across the seven *Strategic Plan* Question areas, analysis of projects across multiple scientific subcategories, a breakdown of federal and non-federal funders' contributions to ASD research investments, geographical distribution of research projects, and trends in research funding over time. The data provide information on the degree to which the objectives and budget recommendations described in the *IACC Strategic Plan* are being met.

Conclusions: These analyses of ASD research funding provide a broad overview of the autism research landscape in the U.S. and the roles of government and non-government funders in supporting ASD research.

423.079 *(Poster)* Understanding Barriers to Minority and Underrepresented Populations' Participation in Autism Research

S. Palmer[1]*, V. Ranganathan*[2]*, M. Tafolla Magana*[3]*, K. Murillo*[3]*, A. Gulsrud*[4]*, K. Diehl*[5]*, N. Nagpal*[5]*, A. Daniels*[5]*, R. T. Schultz*[6]*, J. Pandey*[6] *and S. Consortium*[7]*, (1)CHOP Center for Autism Research, Philadelphia, PA, (2)CHOP, Philadelphia, PA, (3)UCLA, Los Angeles, CA, (4)UCLA Semel Institute for Neuroscience & Human Behavior, Los Angeles, CA, (5)Simons Foundation, New York, NY, (6)Center for Autism Research, Children's Hospital of Philadelphia, Philadelphia, PA, (7)SPARKForAutism.org, New York, NY*

Background: Racial, ethnic and socioeconomic disparities are well documented and continue to persist in almost every facet of health (Barrett et al 2017). SPARK (Simons Foundation Autism Research for Knowledge) is an autism research initiative, sponsored by an additional research grant dedicated to reducing persistent racial and ethnic disparities among participants in the study. Surveys were administered to community members and healthcare providers in two children's hospital networks.

Objectives: To better understand the prevalent disparities in autism research participation amongst community stakeholders and healthcare providers of various ethnic and racial backgrounds. More importantly, the study seeks to implement the suggestions obtained from the surveys to improve recruitment efforts and increase participation amongst underrepresented communities.

Methods: IRB approval was obtained to administer surveys to community members and healthcare providers across the SPARK Disparities Sub-Study network. Presently, two SPARK sites (CHOP and UCLA) administered 5 provider surveys and 20 community surveys. Provider survey respondents were of similar race, age, and gender identity (80% were white females aged 35-59) but provided a vast array of services, ranging from social workers to medical doctors, to the autism population in their community.

Community member survey participants varied in nearly every demographic measure captured. Respondents self-identified as 35% Black, 40% Asian, 20% White and 5% Other; 90% female and 10% male. Participants' education and income levels varied from some college to MD/PhD/JD with income ranging from $20,000-34,999 to $200,000. Printed survey forms were distributed and collected for analysis following focus group participation.

Results: Survey results highlighted multiple barriers to autism research participation including knowledge and awareness of the study, logistical barriers, fear of research and mistrust of clinical/research staff. Participants reported their desire of increased incentivization including compensation with Amazon and Prepaid Debit cards. Moreover, community members expressed the need for email communication of research updates and novel findings from SPARK.

All providers also noted the potential benefits of additional incentives such as links to other studies and social/clinical resources at SPARK clinical sites. To better equip providers for participant recruitment, all survey participants suggested clinical sites offer parent workshops in the community, regular provision of promotional materials and periodic SPARK email updates.

Amongst community members, 40% of participants reported feeling "very comfortable" participating in SPARK and 85.7% believe a study like SPARK is beneficial. However, 50% of survey participants do not seek care at the associated SPARK clinical site.

Conclusions: Providers and community members alike shared SPARK participation is beneficial to communities of interest but also perceive the barriers, including mistrust of staff and the need for additional family resources. Providers emphasized the importance of their role in recruitment and their need for more accessible printed materials to be better equipped for study promotion. Addressing these barriers and implementing these suggestions will be critical to increasing participation of underrepresented populations in autism research, specifically in SPARK. Ongoing data collection from all four sites will allow us to make regional comparisons about participation trends in survey responses with a more generalizable sample.

423.080 *(Poster)* Understanding Patients' and Caregivers' Experiences in Autism Spectrum Disorder through Social Media Listening Analysis

S. Kyaga[1]*, L. Duchatel*[2] *and M. Abarqi*[1]*, (1)Servier, Suresnes, France, (2)69, Groupe361, Lyon, France*

Background: Understanding the unique experiences of children and adolescents with autism spectrum disorder (ASD) and their caregivers is vital to improve their medical care and to support caregivers. Conventional methods to assess patient experience using surveys are limited by biases and may therefore not adequately reflect the challenges of patients and their caregivers. Social media platforms and other internet resources are used by patients and their caregivers to obtain disease-related information, identify healthcare resources, network with fellow patients, and communicate daily-life challenges and experiences online. These resources could provide a more reliable view of the challenges related to ASD.

Objectives: The objective of the present study was therefore to use social media listening (SML) to better understand patients' and caregivers' expectations, challenges and life goals.

Methods: Publically available verbatim in 5 languages (English, French, Italian, Spanish, German) posted by patients, caregivers, healthcare professionals and patients associations between May 2018 and May 2019 on the Web, social networks and other digital media were searched using children or adolescent ASD-related terms.

By using the software Opinion Tracker© and Talkwalker© based on natural language processing (NLP), posts were retrieved by patient- and disease-related keywords to derive a large set of verbatim. The software assessed relevance and excluded duplications. Online content was anonymized, and all relevant global and local laws affecting and relating to the use of social media were aligned with the conduct of this study.

Results: Nearly 2 million posts containing any word, sentence or expression related to children and adolescent ASD were retrieved. Following the automatic sort, a total of 4 000 posts were selected for further analysis by manually reading these verbatim. Most posts were by parents (51.8%) and other caregivers (18.8%), while 8.0% were by individuals with ASD, 8.8% by patients associations and 9.4% by health care professionals (HCPs). Out of the 4 000 verbatim, a total of 504 (US: n=204; Spain: n=75; France: n=75, Germany: n=75; Italy: n=75) were selected for further qualitative assessment and categorizing below:

With regards to ASD, 89% viewed it as a functional variation and 11% as a disability. The main themes of comments were centered on parenthood/education (28%), social acceptance (18%), therapies for autism (15%), schooling (13%), how to relate to persons with ASD (13%), and diagnosis (6%). Most comments (73%) related to parenthood/education were centered around parenthood difficulties, while most comments (47%) on social acceptance were centered on issues of discrimination.

Conclusions: To our knowledge, this is the first time that SML has been used as a method to assess the experiences of children and adolescents with ASD and their caregivers on an international scale. Most comments were centered on parenthood and social acceptance, reflecting the difficulty that parents face and the perceived discrimination and lack of social acceptance that children and adolescents with ASD experience. These results highlight the need to further support caregivers and to increase the understanding and acceptance of the unique capabilities that children and adolescents with ASD hold.

423.081 *(Poster)* Understanding the Emergency Department and in-Patient Hospital Experiences of Autistic Adults

A. Urbanowicz[1,2,3], *K. Brooker*[4,5], *S. K. Kapp*[3,6], *M. E. Hunter*[7], *D. M. Raymaker*[2,3] *and C. Nicolaidis*[2,3,8], *(1)Social and Global Studies Centre, RMIT University, Melbourne, VIC, Australia, (2)School of Social Work, Portland State University, Portland, OR, (3)Academic Autism Spectrum Partnership in Research and Education (AASPIRE), Portland, OR, (4)Queensland Centre for Intellectual and Developmental Disability, MRI-UQ, The University of Queensland, Brisbane, Australia, (5)Cooperative Research Centre for Living with Autism (Autism CRC), Brisbane, QLD, Australia, (6)Department of Psychology, University of Portsmouth, Portsmouth, United Kingdom, (7)AASPIRE Community Council, Portland, OR, (8)Department of Medicine, Oregon Health & Science University, Portland, OR*

Background: Autistic people are high users of emergency department (ED) and in-patient hospital services, often seeking care in times of physical or mental health crisis. Research into the experiences of autistic children found communication and sensory challenges are common in hospital settings (Muskat et al., 2015) and that creating "sensory friendly" environments (Wood et al., 2019) and training staff about autism (McGonigle et al., 2014) may be beneficial. However, we know little about the experiences of autistic adults accessing ED and in-patient hospital services and what resources may improve their experiences.

Objectives: We aimed to 1) identify the needs of autistic adults and their supporters when accessing the ED and in-patient hospital services; 2) identify the support needs of hospital staff caring for autistic adults; and 3) understand what resources could improve the hospital experiences of autistic adults.

Methods: We used a community-based participatory research (CBPR) approach, whereby academics and community members serve as equal partners throughout the research process. Team members worked collaboratively to develop study materials, analyze and interpret data, and disseminate project findings. We conducted interviews with 42 participants (see Table 1) in their preferred format (telephone n=14, email n=14, in person n=8, video call n=4, online text-based chat n=2). Verbal interviews were transcribed verbatim. We conducted a thematic analysis using an inductive approach, on a semantic level, and a constructivist paradigm. The academic team members reviewed 10 transcripts and devised an initial coding schema that was discussed with community partners and refined following their input. All interviews were then coded by two members of the academic team to ensure trustworthiness.

Results: Many, but not all, autistic adults reported traumatic hospital experiences and felt that hospital staff were not knowledgeable about autism. Whether or not the autistic adult felt the staff were knowledgeable influenced their decision to disclose their autism diagnosis, with some adults choosing not to disclose due to fear of discrimination. Difficulties with hospital staff not communicating in an accessible manner were common, with staff often deferring communication to a supporter if they were present. Experiences of overload, meltdown and/or shutdown due to sensory sensitivities, and the busy and unfamiliar hospital environment, were also common. Use of accommodations such as earplugs or headphones reportedly improved experiences. Hospital staff stated establishing effective communication with their autistic adult patients was key to providing effective care. Participants provided suggestions for implementing accommodations in hospitals including having a paper-based report outlining the accommodations a particular autistic patient requires that can be handed to hospital staff upon arrival and having information about the patient's accommodation requirements in their electronic health record.

Conclusions: ED and in-patient hospital visits are often challenging for all people, but they may be more so for autistic adults. However, providing individualized accommodations to autistic adult patients during their ED or in-patient hospitals visit could reduce trauma and improve their healthcare experiences. Our next steps are to develop resources based on our findings, and to implement and trail them in multiple ED and in-patient hospital settings.

423.082 *(Poster)* Unveiling the Service Delivery Landscape for Individuals with Autism Spectrum Disorders: Parents' Experiences of Service Navigation within Urban and Rural Areas in Alberta.

D. B. Nicholas[1]*, W. Mitchell*[2] *and R. Zulla*[3]*, (1)University of Calgary, Edmonton, AB, Canada, (2)Social Work, University of Calgary, Calgary, AB, Canada, (3)School of Public Health, University of Alberta, Edmonton, AB, Canada*

Background: Across their lifespan, children with autism spectrum disorder (ASD) and their families will have multiple needs and thus require finding services from a variety of different sectors. There is limited understanding about how 'navigation' is experienced by families with ASD and how they manage the intersection across ministries and services.

Objectives: As part of a larger study, the aim is to learn how families navigate services and resources and to understand the lived experiences relative to navigation and its impact.

Methods: Using a mixed methods approach surveys and individual and group interviews were conducted in urban and rural areas. NVivo data management and analysis software was used. Content of the navigation experience was identified, including contextual elements that shaped the navigational processes. Analysis was comprised of 1) line-by-line coding, 2) review of codes for textual linkages both within and across transcripts and 3) examination of the emerging categorization of codes in yielding themes. Interrater review of data by leaders in the ASD field verified themes.

Results: Survey as well as individual and group interview data were collected from 44 parents of a child or children with ASD. Findings demonstrate that the search for services across health, education, disability and the social care sectors is fraught with multiple gaps. Parents describe the service delivery landscape as a 'maze' comprised of 'multiple hoops' that involve lengthy paperwork, engaging with multiple people, enduring long waiting times for services, and tirelessly advocating for services that the child with ASD is qualified for and needs. This landscape is further complicated with frequent changes in program and funding eligibility, and parental gaps in awareness of services, and a lack of knowledgeable service providers regarding service access pathways. This has resulted in parents feeling "burnt out" and distrustful of services, and parental worry about whether or not services will be available for their child in the future. To buffer these stressful experiences, parents have relied extensively on their personal skills/resourcefulness (e.g., being proactive) and their social networks accrued throughout their journey of navigating services. Implications of these findings suggest that facilitating the experience of searching for services for parents must move beyond individual capacity-building initiatives.

Conclusions: Systemic processes need to be developed, with continual updating to ensure ongoing and equitable access to services.

423.083 *(Poster)* Use and Benefit of Dyadic Coping for Marital Satisfaction in Parents of Children with Autism

J. M. Putney[1] *and S. Hartley*[2]*, (1)Human Development and Family Studies, University of Wisconsin-Madison School of Human Ecology, Madison, WI, (2)University of Wisconsin-Madison, Madison, WI*

Background: Parents of children with autism spectrum disorder (ASD) have been found to be at increased risk of experiencing dissatisfying marital relationships (Sim et al., 2016). It is critical to identify the specific couple-level processes that contribute to this risk that could be modified in interventions.

Objectives: The goal of the study was to understand the use and benefit of dyadic coping (defined as the processes used by partners in the face of stress) in parents of children with ASD. The study aims were: 1) compare the self-reported use of *positive* and *negative dyadic coping* in parents of children with ASD versus a comparison group of parents of children without neurodevelopmental disabilities; 2) determine whether *positive* and *negative dyadic coping* mediates the association between level of parenting stress and marital relationship satisfaction.

Methods: In total, 184 couples who had a child with ASD (aged 5 to 12 yrs) and a matched comparison group of 183 couples who have a child without neurodevelopmental disabilities participated in the study (N = 734 parents). Children with ASD had a documented diagnosis of ASD via medical or educational records that included the Autism Diagnostic Observation Schedule. Parents were interviewed about family socio-demographics and separately completed self-report measures on their dyadic coping behaviors, perception of parental stress, and level of marital relationship satisfaction. Dyadic coping was measured using the Dyadic Coping Inventory (Bodenmann, 2008). Marital relationship satisfaction was measured with the Couple's Satisfaction Index (Funke & Rogge, 2007). Parental stress was measured using the Burden Interview (Zarit, Reever, & Bach-Peterson, 1980).

Results: A multivariate analysis of covariance (MANCOVA) indicated a significant difference in dyadic coping between parents of children with ASD and the comparison group parents (F (33, 2124.903) = 10.3788, $p < 0.001$, *Wilks'* $\lambda = .635$, $\eta p2 = .141$). Univariate tests indicated significant group differences in *Positive Dyadic Coping* (F (358) = 10.45, $p < 0.001$) and *Negative Dyadic Coping* (F (358) = 11.12, $p > 0.001$). Multilevel models conducted in Hierarchical Linear Modeling software indicated that both *Positive Dyadic Coping* and *Negative Dyadic Coping* mediated the association between-level of parenting stress and level of marital relationship satisfaction across couples.

Conclusions: Mothers and fathers of children with ASD report using less positive dyadic coping and more negative dyadic coping than parents of children without ASD. Mothers of children with ASD, in particular, reported providing and receiving lower levels of support from their partner as well as taking on more stress responsibility in the relationship than their peers who have children without ASD. D*yadic coping* may be an important couple process that drives the pathway between level of parenting stress and marital relationship dissatisfaction, and thereby a key target for interventions.

423.084 *(Poster)* Use of Stakeholder Focus Groups to Develop Content and Structure of a New Measure of Social Communication for Young Children with Autism Spectrum Disorder

K. M. Walton[1]*, A. R. Borowy*[1] *and C. Taylor*[2]*, (1)Nisonger Center, The Ohio State University, Columbus, OH, (2)The Ohio State University, Columbus, OH*

Background: Children with autism spectrum disorder (ASD) show pervasive, often severe deficits in social communication that are a major target of early intervention programs. Sensitively and efficiently tracking both long- and short-term change in early social communication skills is essential in both research and community settings. However, current measures of social communication in ASD suffer from limited sensitivity to change, incomplete content coverage, and high burden of administration (Anagnostou et al., 2015).

Objectives: As part of a larger effort to develop a new parent- and teacher-report measure of social communication in young children with ASD, this study aimed to identify key social communication domains, skills, and behaviors considered most important to parents, teachers, and experts.

Methods: Twenty-one parents, nine teachers, and fourteen expert clinicians participated in a total of seven focus groups regarding their perceptions of social communication challenges and needs in young children (ages 2-6) with ASD. Thematic analysis was used to analyze focus group transcripts and extract themes and subthemes from the groups.

Results: Participants identified challenges with expressive language, receptive language, and social skills. In addition, they noted important differences in social behaviors across contexts and partners, and described ways in which communication challenges and emotion regulation problems compounded and interacted with one another. Respondents also identified strategies for supporting and building social communication skills. Sub-themes included content regarding differences in interactions with adults vs. peers, key deficits in use of expressive communication in flexible and functional ways, and difficulties with understanding and responding to others' emotions.

Conclusions: Parents, teachers, and experts identified a number of key concerns with social communication in young children with ASD. Some identified areas of concern (e.g., interaction between communication and emotion regulation deficits; differences in communication capacities and strategies across settings) are not well represented on existing measures of social communication intended for use in this population. As development and validation of this new measure of social communication continues, focus group content will be integrated during the item development process, including addition of items in areas tapping key areas of divergence between focus group themes and current measure content. This strategy is consistent with best practices in development of patient-reported outcome measures (Food and Drug Administration, 2009) and will likely result in a measure with increased relevance and sensitivity to changes in key areas of social communication related concerns for parents and teachers.

423.085 *(Poster)* Using Parent Reported Outcomes to Prioritize Quality Improvement Initiatives in the Autism Learning Health Network

D. S. Murray[1]*, A. Fedele*[2]*, J. S. Anixt*[3]*, K. Kuhlthau*[4]*, C. Lannon*[5] *and D. Coury*[6]*, (1)Autism Speaks, Boston, MA, (2)Autism Speaks, Mullica Hill, NJ, (3)Division of Developmental & Behavioral Pediatrics, Cincinnati Children's Hospital Medical Center, Cincinnati, OH, (4)Massachusetts General Hospital, Boston, MA, (5)Anderson Center for Health systems Excellence/Department of Pediatrics UC Medical School, Cincinnati Children's Hospital/University of Cincinnati, Cincinnati, OH, (6)Nationwide Children's Hospital, Columbus, OH*

Background: The combined Autism Speaks Autism Treatment Network (ATN)/Autism Intervention and Research Network on Physical Health (AIR-P) is developing an Autism Learning Health Network (ALHN) focused on improving the health and well-being of children with ASD. A Learning Network (LN) integrates research, quality improvement (QI), and clinical care and leads to more rapid integration of successful practices into care. A LN uses rigorous QI methodology to identify aims, drivers of change, and intervention strategies and to measure outcomes. Input from patients, family members, clinicians, and researchers is crucial to this work. ALHN was developed to achieve this goal of transforming and disseminating best practices more rapidly.

Objectives: To determine priority areas to improve the health and quality of life (QoL) of children with Autism Spectrum Disorder (ASD) based on parent-reported concerns.

Methods: Families of children with ASD, clinicians, and researchers participated in a formal QI design process to identify the purpose and goals of ALHN. In the design process, families identified challenging behaviors as the priority target for improvement and a driver of overall health and QoL. Data collection tools were developed to address the aim. Parent-reported outcome (PRO) measures in the form of ALHN-specific questionnaires and standardized assessment tools for behavior (Aberrant Behavior Checklist-ABC) and Quality of Life (QoL; PROMIS measures) are collected to assess and track over time. Families of children, ages 18 months to 17.5 years, enrolled in ALHN through 12 participating clinical sites are provided access to a mobile application (app) and are asked to complete PRO measures at enrollment and over time. Descriptive data regarding the type, frequency, and severity of behavior challenges reported at enrollment for the first 750 children enrolled in ALHN are presented as proportions or means as appropriate. Student's T-test was used to compare differences between genders.

Results: The mean (SD) age of the ~750 children enrolled in ALHN is 8.4 (2.7) years, with 80% male. Challenging behaviors occurred in the past month in 94% of children with 86% of these behaviors described as moderate, severe or extremely severe and with 62% occurring on a daily basis or multiple times / day. Behavioral symptom domains most frequently reported as problematic include Attention Deficit / Hyperactivity Disorder (ADHD) (63%), Irritability (54%), and Anxiety (47%). On the ABC, the mean (SD) scores for the hyperactivity and irritability scales are 18.2(10.5) and 13.9(9.3), respectively, with no statistically significant differences by gender. The mean (SD) score on the PROMIS is 23.5 (3.7), significantly lower than reported general pediatric population means, and similar between genders.

Conclusions: Preliminary findings from ALHN PRO data indicate high rates of challenging behavior and lower than population-average QoL for children enrolled in ALHN, with no significant differences by gender. Parent reported data support prioritization of QI initiatives focusing on the most common drivers of challenging behaviors (ADHD, irritability, anxiety) as an approach to improving behavioral impact and QoL in children with ASD.

423.086 *(Poster)* Using Visual Methodology to Learn about Eating Preferences and Oral Care in Latino Children with and without Autism

L. I. Florindez[1]*, D. C. Florindez*[2]*, D. H. Como*[1]*, J. Polido*[3] *and S. A. Cermak*[4]*, (1)Division of Occupational Science and Occupational Therapy, University of Southern California, Los Angeles, CA, (2)University of Southern California, Los Angeles, CA, (3)Children's Hospital, Los Angeles, Los Angeles, CA, (4)USC Mrs. T.H. Chan Division of Occupational Science and Occupational Therapy, University of Southern California, Los Angeles, CA*

Background: Few children and adolescents meet the current recommendations concerning optimal nutrition guidelines. When race/ethnicity is considered, Latino children eat less healthy than their non-Latino White counterparts. Studies focusing on diet and its relation to oral care in Latino children have been minimally researched. However, this is a key area to focus inquiry, as Latinos disproportionately experience oral health problems when compared to other ethnic groups.

Objectives: Using a photo-based food journal as an inclusive participatory visual research, the primary aim of this study was to explore what Latino parents/caregivers of children with and without Autism Spectrum Disorders (ASD) learn about their child's diet and food habits in relation to their oral health following a visual food journaling activity. As a secondary aim, the study sought to explore whether differences in diet emerged between children with and without Autism.

Methods: Participants were Latino parents/caregivers from 18 families (10 with children with Autism and eight with neurotypical children) who completed a visual food journal and photo elicitation interview. Each family was interviewed twice by the research team. The data for this study was drawn from interview data and a visual food journal completed by the participants between the two interviews. To complete the journals, participants were instructed to take pictures of their child's meals for 3 days of the week, to cover both weekdays and weekends, including the contents of the meal. Each family was empowered to choose the layout of each photo so long as they included photos pertinent to diet and food choices

Results: The process of taking photos and discussing them with the researcher helped to attune the parents to the eating and food habits of their children. The themes that arose were: "Maybe I don't do as well as I thought I did" (Visual methodology (VM) as opportunity to identify areas where the parent wants to improve eating patterns); "He is actually pickier than what I thought" (VM as opportunity to learn more about children's eating patterns); "Food became fun" (VM as means of creating change and encouraging children to try new foods); "At home, we eat better" (VM as opportunity to highlight strengths of family's eating patterns); and "Sugar is the devil" (VM as highlighting the negative impact of consuming too much sugar). Though there did not appear to be major differences between diets of children with ASD and neurotypical children, parents with children with ASD noted how the process of documenting food intake affected their children who were food selective to be slightly more open to trying new foods.

Conclusions: Visual research methodologies, such as photo journaling, are an important strategy to consider to empower participants to be part of the research process and part of the outcomes. The process of taking photos helped Latino parents better situate the barriers, beliefs, and behaviors influencing diet and food consumption in their children within the larger context of relating to their overall oral health.

423.087 *(Poster)* Validation of a Novel Community Disability Stigma Scale Among Parents from WIC Clinics

O. J. Lindly[1]*, M. M. Abdul-Chani*[2]*, C. Moreno*[3]*, J. Reeder*[4] *and K. Zuckerman*[5]*, (1)Health Sciences, Northern Arizona University, Flagstaff, AZ, (2)Psychology, The University of Alabama at Birmingham, Birmingham, AL, (3)Northern Arizona University, Flagstaff, AZ, (4)Oregon WIC Program, Portland, OR, (5)Division of General Pediatrics, Oregon Health & Science University, Portland, OR*

Background: Stigma and its presentation differs across socio-demographic groups, and may impact access to care for children with disability. Knowledge about developmental disabilities may differ by socio-demographic category, which may impact community stigma. While there is growing literature with regard to stigma in diverse cultural groups, no validated measures of community disability stigma designed for families living in diverse, low-income communities, who may be at high risk for disability disparities exist.

Objectives: (1) To develop and validate a brief English and Spanish measure of stigma perceived by community members towards children with disabilities and (2) assess variation in community disability stigma by parent demographics and awareness of developmental disabilities, in a sample of low-income families.

Methods: A cross-sectional survey was self-administered to 539 parents at the Supplemental Nutrition Program for Women, Infants, and Children (WIC) in six Oregon counties from July-October 2015. Eligible families had a child aged 2-5 years enrolled in WIC. Surveys were conducted in English or Spanish with bilingual oral administration if needed. Seven questionnaire items assessed perceived disability stigma by people in the participant's community. Items were adapted from the Community Autism Stigma Scale. The questionnaire also included self-reported measures of knowledge about developmental disabilities (e.g., autism) and contact with individuals with developmental disabilities. Child and family sociodemographic characteristics were also assessed. Internal consistency reliability was examined, and structural validity was examined using factor analysis. Nested multivariable linear regression was performed to determine (1) associations of child and family sociodemographic characteristics and (2) additional associations of parent knowledge and contacts related to developmental disabilities with community disability stigma.

Results: 522 parents provided data on the seven disability stigma items and comprised the analytic sample. Most participants were Latinx (58.2%), had lived outside the U.S. (54.6%), had a high school education or less (60.5%), received WIC services in a metropolitan area (89.3%), and knew someone with a developmental disability (55.8%). Based on initial results, two disability stigma items were dropped from subsequent analyses. The remaining five items had reasonable internal consistency (SD=0.76) and performed well in the confirmatory factor analysis (Figure 1). The average score on the 5-item community disability stigma scale was 1.99 (SD=0.7). "People do not know very much about children with disabilities" and "People are uncomfortable around children with disabilities" were the most strongly endorsed items. Multivariable analysis results revealed Latinx (English proficient and Limited English Proficient) parents reported significantly less community disability stigma than white, English proficient parents. Parents who knew one or more individuals with a developmental disability versus those who did not reported higher community disability stigma (Table 1). When adjusting for knowing someone with a disability, Latinx English proficient families, continued to report less community disability stigma than white, English proficient families.

Conclusions: The disability stigma scale demonstrated sound psychometric properties in this diverse, community-based sample suggesting it may be more broadly used and adapted. Latinx families perceived less community disability stigma than other groups, indicating that cultural differences exist in how most low-income families perceive stigma in their communities.

423.088 *(Poster)* Validation of the Parent Empowerment and Efficacy Measure, Taiwan Version in Taiwanese Preschoolers with Autism Spectrum Disorder: Preliminary Results

J. L. Lai[1], *L. J. Kang*[2,3] *and Y. T. Wu*[4], *(1)Department of Social Work, National Taiwan University College of Social Sciences, Taipei, Taiwan, (2)Graduate Institute of Early Intervention, College of Medicine, Chang Gung University, Taoyuan, Taiwan, (3)Department of Physical Medicine and Rehabilitation, Chang Gung Memorial Hospital, Linkou, Taoyuan, Taiwan, (4)School and Graduate Institute of Physical Therapy, National Taiwan University College of Medicine, Taipei, Taiwan*

Background: The Parent Empowerment and Efficacy Measure (PEEM) is widely used to measure parents' sense of control of capacity to engage confidently with the challenges of being a parent. However, the psychometric properties of the PEEM in Asian populations such as Taiwanese people has not been established. In addition, research shows that primary caregivers of children with Autism Spectrum Disorder (ASD) face emotional and psychological strains, changes in lifestyle, and economic hardship associated with caring for their child. Such distress has been documented to place children at risk for adverse developmental outcomes. Parent's empowerment and efficacy in children with ASD is necessary to be evaluated and addressed.

Objectives: The study aimed to describe the translation of the PEEM to Mandarin Chinese as a Taiwan version, and to examine the psychometric properties of reliability and validity of the PEEM-T among the caregivers of Taiwanese preschoolers with ASD.

Methods: Translated Procedures

We adapted Beaton's (2000) procedures for translating the PEEM into the Taiwan version. These guidelines serve as a template for the translation and cultural adaptation process. The process involves five stages: translation, synthesis, back translation, expert committee review and pretesting.

Data collection and Analysis

The translated version of PEEM was administered to a study sample that comprised 30 Taiwanese parents of preschoolers with ASD and 30 parents of typically developing (TD) preschoolers. Each parent is required to fill up the PEEM-T for two times within a week of interval. The PEEM-T was either sent to the parents through postal service or parents came to our laboratory to complete the questionnaire.

The internal consistency of the PEEM Taiwan version was analyzed by calculating Cronbach's α coefficient. Besides that, the caregivers who completed the second assessment after one week were assessed for the test-retest reliability by calculating the Pearson correlations coefficients.

Results: The PEEM was translated by our team members that fluent both in Chinese and English. The resulting translated versions then was back-translated and compared to the original PEEM. Furthermore, we discussed some of the specific terms with the primary author through e-mail communication to make sure that the items reflected the meanings of original items accurately. The content validity of this measure was then confirmed by an expert meeting. The final version of PEEM-T approved by the author was used to examine reliabilities.

Our preliminary results with a study sample of 19 parents of preschoolers with ASD showed that the PEEM-T exhibited excellent internal consistency that the value of Cronbach's α coefficient was 0.954 ($p < 0.05$). Besides that, the items in two PEEM-T subscales also revealed excellent internal consistency that the value of Cronbach's α coefficient was 0.917 ($p < 0.05$) and 0.922 ($p < 0.05$), respectively. Furthermore, PEEM-T revealed moderate to high degree of test-retest reliability for all items (see Table 1, r=0.475-0.901, all p's < 0.05).

Conclusions: Our preliminary findings revealed PEEM-T is a reliable questionnaire. We will continuously to expand the sample size and test the reliabilities and validities for the translation version.

423.089 *(Poster)* What Researchers Should Know to Maximize Subject Recruitment and Retention

A. Halladay[1,2], *D. S. Mandell*[3], *M. Xie*[4] *and A. T. Singer*[1], *(1)Autism Science Foundation, New York, NY, (2)Rutgers University, Piscataway, NJ, (3)Center for Mental Health, University of Pennsylvania, Philadelphia, PA, (4)University of Pennsylvania, Philadelphia, PA*

Background: Many autism studies experience poor or slow recruitment, leading to early termination of the study, and low statistical power to test the questions of interest. Unfortunately there has been little systematic data collection directly from potential study participants on their personal experiences with research and what prevents them from participating in studies. The present study directly assessed autistic individuals and their caregivers to determine which factors affect participation. The sample included those who had participated and those who had never participated. This study, the Autism EXPECT study (Experience of People Enrolled in Clinical Trials), included 31-questions about logistical and personal factors that may affect enrollment in and completion of studies that require in-person visits. The results will be used to create a blueprint for researchers on how to motivate potential participants and engage in effective recruitment and retention strategies.

Objectives:

1. To estimate the frequency of various barriers to research participation among autistic individuals and their families
2. To examine factors associated with endorsing particular barriers and categories of barriers.

Methods: Survey development occurred in multiple stages, including conducting cognitive interviews and focus groups with autistic individuals, caregivers, advocates and researchers. The finalized survey was fielded using the SurveyMonkey Platform and was approved through the University of Pennsylvania IRB. Results were summarized using descriptive statistics and differences between groups estimated using Chi-Square and t-tests.

Results: Data collection is ongoing. To date, 398 autistic individuals or their caregivers provided complete survey information. Three quarters had participated in research before. Of those who had participated in research, commonly-endorsed factors that would increase the likelihood that they would participate in research included: the study will help me or my family (96%); there will be follow up (88%); a coordinator will guide us through visits (85%); and there will be help navigating local service providers (84%).

Of those who had not participated in research, 48% responded that they had not heard of opportunities that would be relevant to them. In general, this group endorsed fewer and often different factors that may motivate them to participate in research than did the other group. Most commonly endorsed motivating factors to participate in research were: the study would help families like mine (96%) and I cared about the research question (89%). Factors like being given access to treatment (30%); being asked by their doctor or teacher (15%); or given a report that could be used for IEP planning (33%) were not endorsed by most.

Conclusions: There were distinct but sometimes overlapping factors that influenced study participation in those that had participated vs. those that had not. The biggest influence to future participation in both groups was personal satisfaction or reward, such as helping their own family or others. Surprisingly, logistical barriers related to factors like hours when studies occurred or availability of parking or childcare were not frequently endorsed These results provide actionable information that researchers and IRB committees can use when designing protocols and determining incentives for families and individuals across the spectrum.

423.090 *(Poster)* When Should Parents Talk with Their Autistic Child about Autism? Insights from Autistic Young Adults

A. Riccio[1]*, B. Kofner*[2]*, T. Oredipe*[3]*, S. K. Kapp*[4] *and K. Gillespie-Lynch*[5]*, (1)Department of Psychology, The Graduate Center, City University of New York (CUNY), New York, NY, (2)CUNY, NY, NY, (3)College of Staten Island, CUNY, Staten Island, NY, (4)Department of Psychology, University of Portsmouth, Portsmouth, United Kingdom, (5)Department of Psychology, College of Staten Island; CUNY Graduate Center, Brooklyn, NY*

Background: A large body of literature examines parental interpretations of their child's autism diagnosis. Positive interpretations of autism by parents have been found to lead to desirable parent and child outcomes (Pakenham et al., 2004; Wachtel & Carter, 2008). However, research linking parents' descriptions of autism with their children's understanding of autism and autistic identity development had not been conducted. Autistic adults who learn they are autistic late in life often share a sense of relief associated with knowing their diagnosis; some indicate that they wish they had known earlier.

Objectives: 1. Analyze if parental decisions to disclose/withhold their child's autism diagnosis influence adolescents' perceptions of autism and 2. Evaluate when autistic college students recommend that parents disclose their child's autism diagnosis to the child.

Methods: Adolescent participants (n=15, $Mage$= 16.2) and their mothers were recruited from an informal educational program in NYC. Adolescent participants completed in-person interviews; mothers completed online questionnaires. Autistic college students (n=85, $Mage$=23.88, 50.6% male, 67.1% White, 72.9% undergraduates representing 8 countries and 48 institutions) completed an online survey including the question: "If you had a child with autism, when would you tell them about autism?"

Results: Only participants whose parents disclosed their diagnosis voluntarily (n=6) described strengths (n=3) or neutral differences (n=3) when asked to define autism. All participants who were told about their diagnosis by a parent involuntarily (n=6) or not yet been informed of their diagnosis (n=3) focused solely on challenges associated with autism, compared with a third (n=2) of those whose parents voluntarily disclosed (Table 1).

Autistic college students highlighted the importance of developmental level, particularly self-understanding, as the guiding factor to consider when deciding when to disclose their child's diagnosis. When students specified an age (28.75% of sample), they recommended disclosing during early/middle childhood. An autistic author selected this quote as an example of the open communication that parents should have with their autistic children: "I would never attempt to hide the information, and would treat it in a fully natural way in order to avoid giving the impression that there was any stigma surrounding autism. As they grew older and depending upon fluency of communication, I would casually drop information as it became relevant and answer any questions they might have on the subject."

Conclusions: Data from autistic adolescents suggest that parents deciding to voluntarily disclose their child's autism diagnosis to their child positively impacts their children's perceptions of autism. Data from autistic college students indicates that autistic people feel that the timing of disclosure should be tailored to the child's developmental level, particularly their understanding of themselves and autism. When they did specify a preferred age of disclosure, autistic people tended to recommend disclosure in early childhood. The key recommendation from this research is that parents should explain their child's diagnosis to them in a way that they can understand soon after diagnosis. Future longitudinal research should examine how parental disclosure decisions contribute to autistic identity development over time.

423.091 *(Poster)* 'When You'Re Going to Talk to a Family about Concerns, Your Language Matters': Parent Experience Related to Participating in Prospective Infant Sibling Research

S. Jilderda[1]*, D. B. Nicholas*[2]*, L. Zwaigenbaum*[3]*, I. M. Smith*[4]*, J. A. Brian*[5]*, L. A. Sacrey*[6] *and C. Kilmer*[2]*, (1)Autism Research Centre, Glenrose Rehabilitation Hospital, Edmonton, AB, Canada, (2)University of Calgary, Edmonton, AB, Canada, (3)University of Alberta, Edmonton, AB, Canada, (4)Dalhousie University / IWK Health Centre, Halifax, NS, CANADA, (5)Holland Bloorview Kids Rehabilitation Hospital, Toronto, ON, Canada, (6)Autism Research Centre, Glenrose Rehabilitation Hospital, Edmonton, AB, CANADA*

Background: Little is known about parents' experiences of discussing early signs of ASD in their children with clinicians. It is generally assumed that parents want to be informed about concerns as early as possible, but uncertainty about future implications of concerns may influence parental receptivity. Understanding parental experiences is vital, given growing evidence for the role of parents' feelings of efficacy, and hope in supporting their coping as well as in promoting positive child outcomes. 'Infant sibling' research (i.e., prospective studies of infants with an older sibling with ASD) offers a unique opportunity to explore changes in parental perspectives over time.

Objectives: We used a qualitative approach to better understand factors that influence parental receptiveness to information about early concerns with respect to their infants. Specifically, we asked parents about their experiences of receiving information about their children, what was perceived as helpful vs. unhelpful approaches to information sharing, and recommendations for improvement.

Methods: Eight parents who had completed the Canadian infant sibling study participated in a semi-structured interview. Development of the interview was informed by a focus group with five parents who had participated in infant sibling research (non-overlapping with participants in the current study). The interview was conducted over the phone by an interviewer naïve to the families, and took approximately 60 minutes to complete. Transcriptions of interviews were coded in NVivo 12, using an interpretive description approach, which garners experiential and theoretical understanding of informants' perspectives.

Results: All parents reported that they had been informed about the possibility of receiving unexpected information as a result of participating in infant sibling research. Analyses of parents' study-related experiences informed a conceptual model (Figure) that included three key components: (1) Motivations for participating in the study (e.g., have 'another set of eyes' on child, 'get foot in the door' for supports, helping future families through research), (2) Mitigating factors influencing positive and/or negative experiences (e.g., parent readiness, experience of diagnostic journey with older child) which led to varied outcomes, and (3) Parent responses to these experiences. Parents described that perceived positive experiences (e.g., respectful communication, clear 'presentation of facts', consistency of study, 'unbiased set of eyes') resulted in increased engagement, and parents reported improved outcomes (e.g., earlier detection, diagnosis, access to services). Experiences perceived as more negative (e.g., disagreement about concerns, perceived bias of study staff, study staff unfamiliar with child, ambiguous feedback, unsympathetic feedback) led some parents to disengage from the study, completing only selected assessments or interviews, and losing trust in study staff.

Conclusions: These preliminary findings indicate that language used when sharing concerns is important, but there is no one right way to communicate concerns to families. These findings inform approaches related to sharing early ASD-related developmental concerns in both research and clinical contexts. This work is ultimately aimed at building personalized approaches to sharing concerns with families that meet them 'where they are at' in order to promote positive parental experiences and child outcomes during a potentially overwhelming time.

423.092 *(Poster)* "Mama, Vamos a Informarnos [Mom, We Are Going to Educate Ourselves]": The Many Roles of Typically-Developing Siblings in Low-Income Latino Familie

T. De Los Santos[1]*, I. Arriaga*[1]*, A. Gulsrud*[1] *and D. Hayes-Bautista*[2]*, (1)UCLA Semel Institute for Neuroscience & Human Behavior, Los Angeles, CA, (2)David Geffen School of Medicine at UCLA, Los Angeles, CA*

Background: Sibling relationships tend to be our longest lasting and most influential (Cicirelli, 1995); however, little is known about these relationships in ethnic and racial minority groups of individuals with a sibling with autism (Lobato et al., 2005). In typically developing siblings, Kao et al (2011) found that Latino siblings were more likely to report having "caregiving" responsibilities in comparison to their European American sibling counterparts, yet little is known about the roles and responsibilities of neurotypical siblings of children with autism.

Objectives: This study aims to understand the roles and responsibilities of neurotypical siblings of children with autism, particularly within underserved/low-income Latino families, who live within Los Angeles County.

Methods: 25 self-identified Latino parents of children with ASD and 3 key informants (community leaders) were interviewed. Participants were recruited using snowball sampling and targeted Facebook advertisements. Criteria for study participation included residence in Los Angeles County, being of Latin American descent, and a parent of a child between the ages of 2 and 10 years with a professional diagnosis of ASD. Enrollment was limited to participants with low socio-economic status (SES) as defined by the U.S. Federal Poverty Guidelines used to determine financial eligibility for federal programs. In addition, key informants were eligible if they worked with low-income, Latino parents of children with autism. Focus groups and interviews were audio-recorded, transcribed verbatim, and independently coded for major conceptual models. Exploratory, qualitative analysis was conducted using a modified grounded theory approach. Six raters coded each transcript to ensure reliability. Data triangulation and methodology triangulation were employed to ensure validity and reliability of data interpretation.

Results: Most parents reported that their neurotypical children actively sought to help and supervise their child with autism. For instance, some mothers would use phrases, such as "little mom" or "*cuidador* (protector)" in reference to their neurotypical child. Monolingual Spanish-speaking mothers often reported relying on their neurotypical children for emotional and informational support as well, especially as it related to seeking out autism-related resources and information. As one mother recalled, "my daughter, the eldest, was always on the computer and [she would say,] 'We are going to educate ourselves. We are going to do this, this, and that.' And there she was, everywhere with me." Many of the monolingual Spanish-speaking mothers also reported turning to their neurotypical children when they needed support with technology, such as in finding ways to translate webpages and how to navigate their mobile technology to find autism related information.

Conclusions: Among low-income Latino families with a child with autism, neurotypical siblings adopt roles as caretakers and advocates for their siblings. They also help their parents navigate autism related services and information, especially information available digitally. Once a child receives an autism diagnosis, parents have access to many support systems and parent-specific resources; however, within Los Angeles County, there remains few services available to support and educate neurotypical siblings. These findings call attention and may promote development and dissemination of sibling-centered services, such as support groups.

423.093 *(Poster)* "Setting Them up for Success": Extension Educator Experiences with Inclusion of Youth with Autism in 4-H

C. E. McCormick[1]*, R. A. Mason*[2]*, B. A. Beaulieu*[1]*, K. J. Muller*[3]*, A. Morgan*[4]*, V. Peskova*[1] *and K. Parker*[5]*, (1)Human Development and Family Studies, Purdue University, West Lafayette, IN, (2)Educational Studies, Purdue University, West Lafayette, IN, (3)410 South Adeway, Purdue University Cooperative Extension, Fowler, IN, (4)Purdue University Cooperative Extension, Crawfordsville, IN, (5)Purdue University Cooperative Extension, West Lafayette, IN*

Background: People with Autism Spectrum Disorder (autism) living in rural communities often have difficulty accessing services compared to those living in higher resource areas. People with autism also face the challenge of un- or underemployment in adulthood and a lack of services to specifically support the transition to independent adulthood. Educational experiences in community settings that provide opportunities for school aged children and adolescents to learn job-related skills may be one way to increase employment for people with autism when they transition to adulthood. Participation in extracurricular activities also provides opportunities to learn social skills, develop relationships, and engage with the community. 4-H, an inclusive community based program that provides real-life educational activities, is well positioned to address the needs of youth with autism in rural communities; however, minimal empirical evidence exists about the implementation and effectiveness of inclusive practices in 4-H programs.

Objectives: To identify barriers to accessing 4-H programs and gaps in support for students participating in 4-H programs

Methods: Two, one-hour focus groups (total N =20) were conducted with Extension Educators from throughout the state of Indiana. Topics of discussion covered: 1) perceived barriers to enrollment for youth with autism; 2) Extension Educator background and training; 3) challenges for Educators and youth related to inclusion; 4) effective inclusion strategies; and 5) areas of additional need and support. Focus group sessions were transcribed and analyzed to extract themes, with a specific focus on existing supports, current challenges, and potential new resources.

Results: All Extension Educators reported working with youth on the spectrum within their programs, including livestock, crafts, public speaking, Junior Leaders, and summer camps. Several of the Extension Educators were also parents of children with autism or other disabilities. Although inclusion of youth with autism was common and encouraged, minimal formal training or resources were provided to Educators. Their training typically occurred on their own or through Educator-to-Educator sharing of resources. Educators reported challenges with working with club leaders and judges who are sometimes resistant to accommodations and with lack of clear communication with parents about their child's needs. Educators also described 4-H as having it's own unique culture that could be difficult for families new to the program to navigate. Suggestions for additional supports included training that Educators could receive and then share with their volunteer/club leaders and materials that focus on how to meet individual needs vs autism specific so participating in 4-H could still be the "one time they are not singled out."

Conclusions: Initial analyses indicate a strong desire from Education Educators to fully include youth on the spectrum within their programs; however, Extension offers minimal formal supports and training to implement inclusive practices. Fully inclusive programming will require buy-in from multiple levels of the 4-H organization, particularly club leaders and judges who work directly with the youth and have demonstrated some resistance to accommodations. Future directions include conducting interviews with club leaders, parents, and youth with autism with the long term goal of developing new training materials that incorporate multiple stakeholder perspectives.

Gastrointestinal (GI)

POSTER SESSION — GASTROINTESTINAL (GI)
424 - Gastrointestinal (GI) Posters

424.001 *(Poster)* A Qualitative Study of Family Experiences with Having a Child with Autism Spectrum Disorder and Co-Occurring Gastrointestinal Symptoms

C. B. Holingue[1,2]*, O. Poku*[2]*, S. Murray*[2] *and M. D. Fallin*[1,2]*, (1)Wendy Klag Center for Autism and Developmental Disabilities, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, (2)Mental Health, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD*

Background: Despite the high prevalence of GI symptoms in individuals with ASD, there has been little research aimed at understanding the experiences of individuals with co-occurring ASD and GI symptoms. Qualitative research is a valuable tool for identifying the scope of an issue, capturing the complexities and nuances of human experience, and identifying targets for intervention.

Objectives: We conducted semi-structured interviews to explore parents' perceptions of their and their children's experiences of gastrointestinal symptoms while living with ASD. We sought to 1) understand how parents identify when their child is having GI symptoms or distress, and 2) gain a deeper understanding of the challenges families and individuals with ASD face regarding GI symptoms.

Methods: One-on-one semi-structured interviews were conducted with 12 parents of children with ASD. Parents were also given the option to have their child join the interview. Participants were eligible if they were a parent or primary caregiver of a child with an ASD diagnosis who experienced GI symptoms anytime from the age of 3 to 17. Directed content analysis was conducted using core interview questions to partially inform the identification of themes across interviews following a general inductive approach.

Results: Three themes emerged from qualitative interviews. First, most parents reported that their child did not verbally communicate that they were experiencing GI symptoms or had difficulty expressing the nature of their symptoms. Parents relied on non-GI-specific behaviors (e.g. irritability, sleep issues, aggression) and more obvious signs/symptom (e.g. bloating, gas). Next, GI symptoms were associated with poorer functioning and lower wellbeing of the child and family. The child's GI symptoms affected their ability to attend, stay, and focus in school, as well engage in social or extracurricular activities. Parents reported that the child's GI symptoms affected the temperament of the whole household and in some cases was traumatic. Parents also reported financial stress associated with the child's GI symptoms. Lastly, while some parents reported satisfaction with a particular provider or health care setting, they tended to have negative experiences when seeking medical help for their child's GI symptoms. Common frustrations were the shortage of providers, long wait times, financial and insurance obstacles, and office environments not being accommodating to children with ASD. Parents felt they were not taken seriously due to their child having ASD, or that providers were not adequately trained to treat children with ASD. Some families were turned away from care because of their child's behavior. Parents expressed wanting to find someone who is curious enough to dig deeper and help them find solutions for their child.

Conclusions: These findings stress the importance of better understanding the landscape of GI-related issues in individuals with ASD, including the importance of accurate measurement of symptoms, the association with wellbeing, mental and physical health issues, and access to quality health services. GI symptoms in children with ASD place an incredible toll on the wellness of both the child and also the surrounding family.

424.002 *(Poster)* Gastrointestinal Issues Affect Psychometric Measurements in a Sex-Specific Manner

J. Sotelo Orozco[1] *and I. Hertz-Picciotto*[2]*, (1)Public Health Sciences, University of California at Davis, Davis, CA, (2)University of California at Davis, Davis, CA*

Background: Autism Spectrum Disorder (ASD) is currently estimated to affect 1 in 59 children. Although ASD primarily impacts the brain, links with other systems have become increasingly clear—in particular gastrointestinal (GI) issues seem to occur more often in individuals with ASD. Several studies have found strong links between GI symptoms and autism severity in children. Considering the brain and gut functions are closely integrated by a bidirectional communication called the gut-brain axis, the pain and discomfort caused by GI symptoms can understandably worsen behavior and contribute to the severity of the disorder. Furthermore, boys are disproportionately affected by ASD (with an estimated 4:1 male to female ratio). However, little is known about how sex differences in association with GI issues affect cognitive/behavioral outcomes.

Objectives: The objective of this study was to investigate the correlation of GI issues among boys and girls with ASD compared to typically developed (TD) controls in association with psychometric measurements.

Methods: Children (ASD n=245 (male=183, female=64); TD n=210 (male=154, female=56)) in this preliminary investigation are a subset of the Childhood Autism Risk from Genetics and Environment (CHARGE) Study. Cognitive skills were measured using the Mullen Scale of Early Learning (MSEL). The child's adaptive function was evaluated using the Vineland Adaptive Behaviors Scales (VABS). Additionally, the Aberrant Behavior Checklist (ABC) was used to rate inappropriate and maladaptive behaviors. GI issues were assessed using a parental reported questionnaire to determine if abdominal pain, gaseous/bloating, diarrhea, constipation, pain on stooling, blood in stool, and/or blood in vomit were present in the last 3 months. Three-way ANOVA, followed by the Tukey test, was used to determine how psychometric measurements were affected by child's diagnosis, the presence of GI issues and sex.

Results: Children with ASD scored significantly poorer on all MSEL and VABS subscales assessments and had greater inappropriate/maladaptive behaviors on the ABC subscales as compared to TD controls. Additionally, the presence of +GI issues correlated with significant impairments in MSEL and VABS subscales and correlated with increased maladaptive behavior on the ABC compared to individuals without -GI issues. Interestingly, girls with ASD and +GI issues had significant deficits in daily living skills, and overall poorer composite scores on the VABS, as well as trends for decreased socialization, decreased visual reception, and increased social withdrawal compared to ASD girls without -GI issues. Furthermore, ASD girls with +GI issues also had significantly increased inappropriate speech compared to ASD boys without –GI issues. The results for the final presentation will include all eligible children in the CHARGE study.

Conclusions: The results from this subset of CHARGE participants shows that GI issues negatively affect behavioral and neurodevelopmental measurements. In particular, females with +GI issues were more negatively impacted. These results suggest sex-differences may differentially affect the gut-brain axis among individuals with ASD.

424.003 *(Poster)* Integrative miRNA-mRNA Co-Expression Analysis of Right-Sided Colonic Hypomotility in Children with Autism

S. J. Walker[1]*, E. Koukos*[1]*, T. Simon*[1] *and A. Krigsman*[2]*, (1)Wake Forest Institute for Regenerative Medicine, Winston-Salem, NC, (2)Pediatric Gastroenterology Resources of New York and Texas, Austin, TX*

Background: Gastrointestinal (GI) symptoms are more common in children with autism spectrum disorder (ASD) compared to typically developing (TD) children. Of the GI symptoms most commonly observed in children with ASD, chronic constipation is reported by parents to be especially problematic. In children with ASD who have sought medical assistance for chronic constipation on a background of colonic inflammation, two clinical trends (phenotypes) were observed based on the children's response to anti-inflammatory therapy: (1) patients who experience remission from constipation while undergoing anti-inflammatory therapy (*fast responders*), and (2) patients who experience recurrent right-side fecal loading while undergoing anti-inflammatory therapy (*slow responders*). In an earlier study we showed that total gene expression derived from right colon biopsies of 35 patients (*15 fast responders, 20 slow responders*), distinguished the fast responders from slow responders.

Objectives: The objective of this study is to further characterize the two ASD subgroups through microRNA (miRNA) and total gene (mRNA) co-expression analysis to identify potential molecular regulators of the atypical constipation phenotype.

Methods: In the original pilot study, heirarchical clustering of the right colon gene expression profiles from 35 patients resulted in two distinct clusters; the separation was based largely on clincal phenotype (*fast* vs *slow* responder; **Figure 1** - left panel). In this follow-up study, miRNA expression profiles were assessed for 12 of the 35 original right colon biopsies (*6 fast responders, 6 slow responders*) and analyzed together with mRNA profiles. Total RNA was quantified using NanoDrop and miRNA expression was assessed based on ~800 known miRNAs using NanoString nCounter SPRINT protocol. Differential expression of miRNA in fast vs. slow responders was determined using nSolver software and miRNA-mRNA co-expression was evaluated using Ingenuity Pathway Analysis (IPA).

Results: We identified 12 significantly differentially expressed miRNAs (p=0.05; **Figure 1** - right panel) between fast and slow responders and 8 of those had been experimentally observed to target 400 unique mRNAs (IPA). IPA co-expression analysis showed that of the 400 mRNA targets (p=0.05), there were 24 mRNAs that overlap with the 1500 total differentially expressed transcripts (DETs) (p=0.01) between slow vs fast responders. Results demonstrate an upregulation of transcripts involved in oxidative phosphorylation, reactive oxygen species and oxidative stress, and a downregulation of oxidative-stress response elements in slow responders that may suggest an overall decreased mitochondrial function in cells.

Conclusions: The central finding of the co-expression analysis was an increased expression of genes involved in mitochondrial dysregulation pathways in slow responders compared to fast responders, resulting from a decreased expression of their respective inhibitory miRNAs. As mitochondrial function contributes to intestinal epithelial cell homeostasis, this dysregulation in the right colon suggests an underlying mechanism to explain atypical motility that is observed in slow responders even after treatment for inflammation.

424.004 *(Poster)* The Gut Microbiome in Youth with Autism Spectrum Disorder Whom the Presented Lower Diversity in Bifidobacterium Spp. and Veillonellaceae Family with Worse Communication and Language Ability

S. S. F. Gau[1] *and S. S. F. G. Chen*[2]*, (1)Department of Psychiatry, National Taiwan University Hospital & College of Medicine, Taipei, Taiwan, (2)Graduate Institute of Clinical Medicine, College of Medicine, National Taiwan University, Taipei, Taiwan*

Background: Gastrointestinal (GI) symptoms are a common comorbidity in patients with autism spectrum disorder (ASD), but the underlying mechanisms are unknown. Many studies have shown alterations in the composition of the fecal flora and metabolic products of the gut microbiome in patients with ASD. Convergent evidence supports that gut microbiota can influence brain development and behavioral phenotypes through the neuroendocrine, neuroma, and autonomic nervous systems. Literature documents an abnormal gut microbiota is associated with ASD. Here, we hypothesized that bidirectional interactions between the central nervous system (CNS) and the gastrointestinal tract (brain-gut axis) and the role of the gut microbiota in the CNS and ASD.

Objectives: This work aimed to discover microbiome- mediated ASD symptoms and identify the potential biomarker for developing a safe and effective treatment for ASD in the future.

Methods: The sample consisted of 56 youths with clinical diagnosis of ASD (aged 4-18 years old) according to the DSM-5 diagnostic criteria. The diagnosis of ASD was further confirmed by the Autism Diagnostic Interview-Revised and Autism Diagnostic Observation interviews. They and their parents also received the psychiatric interview (K-SADS-E) about other diagnoses. Their parents reported their autistic symptoms (SRS, CAST, SCQ), psychopathology (CBCL, SNAP-IV), and social functions/quality of life (SAICA). The participants received neuropsychological functions (CPT, CANTAB) if applicable. The stool samples of all the subjects were collected and prepared for the 16s rRNA amplicon and V3V4 sequencing of microbiome analyses. The statistical analyses were performed by the principal coordinates analysis and random effect model applied to connect the microbiota and behavioral assessments.

Results: We have collected the multi-dimensional data from 56 children with ASD. Based on the microbiome analysis of stool samples collected from 56 children with ASD, we found that children with ASD had a lower abundance of Bifidobacterium spp. and Veillonellaceae family, but a high presence of Bacteroides spp (25.27%) followed by Faecalibacterium prausnitzii (9.6%) as compared to "MicrobiomeDB-HMP I." We found that the Bacteroides and Klebsiella were against each other in ASD children, and worse language/communication ability was associated with a higher percentage of Bacteroides and lower percentage of Klebsiella. We also found the gender effects on alpha diversity that ASD males presented the lower alpha diversity than ASD females. In fecal metabolites, principal coordinates analysis (PCoA) revealed that social behavior deficits might relate to beta diversity.

Conclusions: Our results provide evidence to support the altered gut microbiome in youths with ASD, specifically, lower amount of Bifidobacterium spp. and Veillonellaceae family, but a high presence of Bacteroides spp and Faecalibacterium prausnitzii; and these altered gut microbiomes were associated with some clinical features. Further studies with increased sample size and advanced analysis combining neuropsychological and neuroimage measures are warranted.

Gastrointestinal (GI) / Immunology

ORAL SESSION — **GASTROINTESTINAL (GI) / IMMUNOLOGY**
316 - Understanding Gastrointestinal and Immune Symptoms, and their Interactions

316.001 *(Oral)* Identifying Factors That Alter the Gut Microbiome and Affect Associated Gastrointestinal Symptoms in Autism Spectrum Disorder

R. A. Luna*, Baylor College of Medicine, Houston, TX*

Background: The microbiome-gut-brain axis has become a compelling area of investigation in autism spectrum disorder (ASD), specifically in the pediatric population where the microbiome is dynamically developing. Chronic gastrointestinal (GI) symptoms remain a significant co-morbidity in ASD, with implications for behavioral challenges and quality of life in children and adults. Microbially-mediated therapies have shown promise for the treatment of GI symptoms in both pre-clinical models of ASD and in open-label trials, and the baseline functional gut microbiome may prove to be an objective indicator of which individuals would benefit from these types of interventions. However, a multitude of confounders have been identified that have contributed to the discordance of findings from multiple studies of the gut microbiome in ASD.

Objectives: This presentation will focus on the identification of clinical factors that are important considerations when evaluating microbiome and metabolome data. Using the extensive data obtained from a large, well-controlled pediatric cohort (including children with and without ASD, with and without GI issues, and unaffected siblings), the effects of dietary preferences, medication regimens, behavioral characteristics, and therapeutic options will be discussed.

Methods: Previously collected data, including detailed clinical history, several behavioral surveys, and diaries (stooling pattern, diet, and GI symptoms) from a total of 300 children (autistic and typically developing (TD)) recruited across the United States has been integrated with stool-based laboratory data that includes microbiome (bacterial and fungal), metabolome, metaproteome, and metagenomic (whole genome sequencing) characterization. Beyond the evaluation of the larger cohort, serial samples were evaluated following antibiotic and probiotic administration (separately) in two pilot studies. Dietary differences were also explored with regard to the level of processed food consumption, dietary variety, and in comparison with participants from a residential facility that employs nutritional intervention.

Results: The presence of GI symptoms was significantly ($p<0.05$) associated with specific behavioral patterns, with the strongest associations to higher scores on the Sensory Profile-2 and Repetitive Behavior Scale-Revised. As expected, a variety of microbes and metabolites correlated with behavioral variables associated with GI symptoms. Increased GI and behavioral scores were observed in the ASD+GI group compared to the TD+GI group even when on the same ultra-processed food diet. Participants from the residential facility had a mainly unprocessed food diet compared to their peers and also showed improved GI and behavior scores as well as microbiome and metabolome differences compared to an age-matched subset.

Conclusions: Based on our large comprehensive study, there is no single microbe or group of microbes associated with a diagnosis of ASD. This is likely due to the inherent heterogeneity within the single diagnostic code of autism spectrum disorder, and moving forward, it is vital that the clinical characteristics that comprise complex phenotypes in ASD be considered when stratifying cohorts. Diet, age, behavioral and GI profiles, and medications all play crucial roles in shaping the functional microbiome. Significant efforts are still needed in the investigation of the microbiome-gut-brain axis in ASD, especially in adults as almost all research in this area has been focused on the pediatric population.

316.002 *(Oral)* CD8+ T Lymphocyte Numbers Are Greater in Colonic Tissue from GI-Symptomatic Children with Autism Compared to Controls

S. J. Walker[1]*, H. Ali*[1]*, T. Simon*[1] *and A. Krigsman*[2]*, (1)Wake Forest Institute for Regenerative Medicine, Winston-Salem, NC, (2)Pediatric Gastroenterology Resources of New York and Texas, Austin, TX*

Background: Gastrointestinal (GI) problems are more common in children with autism spectrum disorder (ASD) than in typically developing (TD) children. Moreover, many children with ASD present with GI symptoms suggestive of an inflammatory bowel disease-like (IBD-like) condition. However, following investigative ileocolonoscopy with biopsy, conventional histology with hematoxylin and eosin (H&E) staining often does not reveal significant inflammatory infiltrate. Using immunohistochemistry, an earlier study reported an increase in cytotoxic T lymphocyte (CD8+) cell density and intraepithelial lymphocyte numbers in children with ASD and GI symptoms that was disproportionate to the inflammation seen on routine histologic evaluation, indicative of a distinct lymphocytic colitis.

Objectives: The goal of this study was to investigate this finding further by comparing levels of CD8, a cytotoxic T cell and gut inflammation marker, in colonic biopsy samples from GI-symptomatic children with ASD, with and without a histological finding of inflammation, compared to TD children either without colonic inflammation ('control') or with Crohn's disease.

Methods: Biopsies from the right colon were obtained via colonoscopy from children with ASD and from TD children representing 4 groups: (1) ASD with inflammation in the right colon on routine H&E stain, (2) ASD without colonic inflammation on routine H&E stain, (3) TD without colonic inflammation on routine H&E stain and, (4) TD with Crohn's disease (CD) on routine H&E stain. Immunohistochemistry staining was performed on thin sections using mouse anti-human CD8 antibody (1:750) followed by biotinylated anti-mouse antibody (1:300). Next, a peroxidase kit reagent (Vector, #PK 7100) was added, followed by the addition of ImmPACT DAB peroxidase (HRP) substrate. Samples were observed under the light microscope until the brown CD8 color stain became apparent (usually ~1 minute) and the reaction was immediately stopped by submerging the tissue slide in water. Tissues stained with secondary antibody *only* served as the negative control. For CD8+ T cell quantitation, slides were scanned using a Hamamatsu scanner and the scanned images were analyzed with Visiopharm software using specific custom apps developed in-house.

Results: Preliminary immunohistochemical analysis using a CD8-specific antibody revealed a range of CD8+ cells from 118 (± 48) to 184 ((± 70) between the four groups (**Figure 1**). While group means differed, the lone statistically significant difference was between group 1 (ASD with colonic inflammation) and group 3 (TD 'control') ($P=0.0088$).

Conclusions: Preliminary data suggests three under-recognized histologic inflammatory observations in ASD-associated colitis. First, CD8+ cells are present in concentrations significantly higher in the GI symptomatic ASD colon compared to normal colonic mucosal tissue. This confirms a pathologic presence of mucosal CD8+ as described earlier (Furlano 2001). Second, this CD8 colonic mucosal inflammatory presence was greater than that seen in CD. Third, even mucosal tissue without cellular infiltrate on routine H&E had elevated CD8 presence as compared to controls, approaching statistical significance. All three of these cellular inflammatory observations are in accord with numerous publications describing the pro-inflammatory cytokine presence in both GI mucosa and peripheral blood in ASD, and our own clinical observation of improved GI symptoms following treatment with anti-inflammatory agents.

316.003 *(Oral)* The Relationship between Gastrointestinal Symptoms and Gastrointestinal Polygenic Risk Scores Among Children with and without Autism Spectrum Disorder

C. Ladd-Acosta[1]*, V. Morrill*[2]*, K. S. Benke*[3]*, J. Brinton*[4]*, G. N. Soke*[5]*, L. Schieve*[5]*, V. Fields*[5]*, C. B. Holingue*[6]*, M. D. Fallin*[1] *and A. M. Reynolds*[4]*, (1)Wendy Klag Center for Autism and Developmental Disabilities, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, (2)Johns Hopkins University, Baltimore, MD, (3)Mental Health, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, (4)University of Colorado Denver School of Medicine, Aurora, CO, (5)Centers for Disease Control and Prevention, Atlanta, GA, (6)Center for Autism and Related Disorders, Kennedy Krieger Institute, Baltimore, MD*

Background: Children with autism spectrum disorder (ASD) are reported to have a greater prevalence of gastrointestinal (GI) illnesses and symptoms than children without ASD. Identification of specific risk factors related to increased GI symptoms in children with ASD may inform prevention and treatment strategies.

Objectives: We sought to test whether polygenic risk scores (PRS) using common genetic risk variants for 3 gastrointestinal (GI) conditions: Crohn's disease (CD), ulcerative colitis (UC) and inflammatory bowel disease (IBD) were related to any of 9 co-occurring GI symptoms, such as diarrhea or constipation, in children with and without ASD, and whether the GI condition PRS liability differs between children with and without ASD.

Methods: We used data from phase 1 of the Study to Explore Early Development (SEED), a multi-site, case-control study of children 2-5 years of age born between 2003 and 2006 (589 with ASD, 725 controls without ASD). Using publicly available genome-wide association study (GWAS) consortia results for the above 3 GI conditions, we computed a PRS for each condition for each SEED participant to capture genetic liability for GI condition risk. Logistic regression models, adjusted for genetic ancestry, were used to estimate the association between standardized GI condition PRS values and (dichotomous) GI symptoms in typically developing children to assess performance of the GI condition PRS in the SEED sample. The same logistic regression was then run among children with ASD to compare whether GI condition PRS performance is similar in ASD. Finally, we estimated associations between odds of ASD and standardized GI condition PRS via logistic regression, adjusted for 10 genetic ancestry principal components.

Results: Among control children, we observed increased odds of diarrhea, gas, loose stools, and loose stools with alternating constipation for each 1 SD increase in UC-PRS adjusted odds ratio (aOR) diarrhea: 4.55 (95% (confidence interval) CI: 1.55-18.20); aOR gas: 1.81 (95% CI: 1.03-3.33); aOR loose stool: 1.87 (95% CI: 1.02–3.62); aOR loose stools with constipation: 2.62 (95% CI: 1.31-5.82)). Similar results for diarrhea were observed for CD-PRS and IBD-PRS among controls although not statistically significant (e.g., aOR diarrhea for CD-PRS: 2.00 (95% CI: 0.61-7.54); for IBD-PRS: 2.42 (95% CI: 0.86-8.03)). However, among children with ASD we did not observe significant associations between any GI symptoms and GI condition PRS. Further, none of the GI condition PRS differed significantly between ASD cases and controls (CD-PRS: aOR ASD: 0.97 (95% CI: 0.85-1.08); UC-PRS aOR ASD: 1.05 (95% CI: 0.93-1.20); IBD-PRS aOR ASD: 1.06 (95% CI: 0.92-1.22).

Conclusions: We found expected associations between GI symptoms and PRS for 3 GI conditions in typically developing children enrolled in SEED but did not observe this relationship in children enrolled in SEED with ASD. Further, we did not observe associations between GI condition PRS and ASD outcome. Our results suggest that risk factors for GI symptoms may be different among children with ASD than in typically developing children; this warrants further investigation into the relationships between GI symptoms and ASD.

316.004 *(Oral)* Large-Scale Transcriptome Analysis in Autism Spectrum Disorder Identifies Diminished Monocyte-Specific Metabolic and Inflammatory Pathways

*X. Fan[1], D. Tylee[2], A. Kolevzon[3], S. Glatt[4], J. Buxbaum[5] and **M. S. Breen**[6], (1)John Hopkins University, Baltimore, MD, (2)Yale School of Medicine, New Haven, CT, (3)Seaver Autism Center, Department of Psychiatry, Icahn School of Medicine at Mount Sinai Hospital, New York, NY, (4)SUNY Upstate Medical University, Syracuse, NY, (5)Department of Psychiatry, Icahn School of Medicine at Mount Sinai, New York, NY, (6)Psychiatry, Genetics and Genomic Sciences, Icahn School of Medicine at Mount Sinai, New York, NY*

Background: Autism spectrum disorder (ASD) is a common neurodevelopmental disorder with high phenotypic and genetic heterogeneity. Much effort has been made to identify whether the apparently distinct genetic and environmental risk factors that give rise to ASD tend to converge into one or more unifying pathophysiological mechanisms that are shared across a broad collection of individuals with ASD. Given the emerging link between ASD and immune function, it is plausible that immune dysregulation is a likely converging point, where a diversity of factors could contribute to ASD symptoms.

Objectives: The overall objective of this study is to uncover robust and reproducible changes in peripheral blood transcriptome profiles with ASD. Moreover, we seek to explore whether common and rare genetic risk loci for ASD display changes in blood transcriptome data and whether these genes share common immune cell-type properties.

Methods: We performed a large-scale RNA-sequencing study of peripheral blood leukocytes derived from infants diagnosed with ASD (n=499) and other neurodevelopmental disorders (NDD; n=365). These data were integrated with several single-cell RNA-sequencing data sets to inform immune cell type-specific changes in genes and molecular pathways that are discretely associated with ASD in the blood circulation.

Results: In ASD, we observed consistent down-regulation of cell-cycle, neurotrophic-, mTOR-, PI3K-AkT-, MAPK-, cytokine- and IGF1-signaling. Several transcription factors were identified that drive these differential molecular responses, including STAT5B, STAT3 and STAT6. Importantly, these down-regulated gene signatures in ADS were enriched for both rare and common ASD genetic risk loci. Integration with scRNA-sequencing data revealed that these genes collectively converged on monocyte-specific gene expression signatures. Notably, these results cross-validate in a non-overlapping sample of ASD (n=626) and typically developing children (n=447) mined from the public domain.

Conclusions: Collectively, these findings provide new insights into how the heterogeneous genetic basis of ASD converge on diminished monocyte-specific molecular pathways in peripheral blood. Deeper study into these findings may accelerate the identification of actionable biomarkers and drug targets leading to next-generation screening and treatment approaches.

317.001 *(Oral)* Autism-Linked Mutations Disrupt the Protein Network States That Mediate Synaptic Plasticity

***S. E. Smith**, University of Washington, Seattle, WA*

Background: Protein products of autism risk genes do not act in isolation, but as a complex networks of interacting proteins that control neuronal development, synaptic homeostasis and socially motivated behavior. These protein networks translate information about external cues into biochemical logic circuits, allowing the cell to perform molecular calculations and execute an appropriate response to a given stimulus. Autism-linked mutations to individual members of a protein network have the potential to cause network-wide disruptions, altering these molecular calculations and leading to inappropriate cellular responses.

Objectives: To characterize the molecular calculations performed by a synaptic protein interaction network composed of the protein products of autism-linked genes, and to understand how autism-linked mutations alter those calculations.

Methods: We developed a multiplex co-immunoprecipitation system capable of measuring 400+ binary interactions among a 21-member protein interaction network. We performed NMDA and DHPG stimulation on acute cortical slices from juvenile and adult wild-type mice and mice carrying autism-linked mutations ($FMR1^{-/y}$, $Shank3B^{-/-}$, $Ube3a^{OE}$, $Homer1^{-/-}$), and compared the acute changes in protein network structure following stimulation. We also examined homeostatic plasticity by shaving the whiskers unilaterally in juvenile and adult mice, and comparing the protein network states in the deprived vs control whisker barrel cortex.

Results: We identified unique protein interaction network patterns associated with each type of stimulation. We also identified specific changes in the way the protein network responded to each type of stimulation in the mutant animals. For example, Fragile X animals showed a normal response to NMDA but no response to DHPG, and appeared DHPG-stimulated at baseline, consistent with the mGluR hypothesis. $Shank3B^{-/-}$ mice, in contrast, also showed a normal response to NMDA, appeared normal at baseline, but showed a non-typical response to mGluR stimulation. $Homer1^{-/-}$ mice showed very few changes in response to any type of stimulaiton, indicating a generalized reduction in the capacity for synaptic plasticity.

Conclusions: Our approach enables us to quantify, on the level of protein interactions, how autism-linked mutations affect molecular information-processing pathways at the synapse. We find that different ASD-linked mutations disrupt a consistent set of molecular calculations, but each mutation affects network states in distinct ways. We will discuss how an understanding of protein network signaling bridges the gap between our knowledge of specific gene disruptions, and how those disruption affect cellular-level processes during development and synaptic plasticity events.

317.002 *(Oral)* Return of Individual Genetic Results in the Largest Recontactable Cohort of People with Autism

J. R. Wright[1], *S. Ganesan*[1], *J. Hall*[1], *B. Han*[2], *C. Diggins*[1], *T. Greene*[1], *S. Consortium*[3], *P. Feliciano*[1] *and W. K. Chung*[4], *(1)SFARI, Simons Foundation, New York, NY, (2)Simons Foundation, New York, NY, (3)SPARKForAutism.org, New York, NY, (4)Department of Pediatrics, Columbia University, New York, NY*

Background: SPARK — the largest recontactable cohort of people with autism spectrum disorder (ASD) — seeks to engage at least 50,000 individuals with autism and their family members in research. A tenet of the study is to form a partnership with participants and return research results to them — including any genetic variants believed to be a major contributing risk factor to their ASD. A pilot study of nearly 500 families affected by ASD found such genetic variants in 10 percent of affected individuals.

Objectives: More than 20,000 families are currently enrolled in SPARK, making it the largest autism study to return genetic results to families. SPARK is rapidly increasing the number of families receiving genetic results and has identified several challenges in returning individual research results at this scale.

Methods: SPARK returns genetic findings associated with ASD that meet American College of Medical Genetics (ACMG) criteria for likely pathogenic (LP) and pathogenic (P) variants. Currently, SPARK is returning LP/P variants within a predefined list of 176 high-confidence ASD genes or CNVs. All variants are confirmed in a Clinical Laboratory Improvement Amendments (CLIA) laboratory. At the time of enrollment, each participant can set preferences to accept or decline to receive genetic results related to autism; a parent consents for children and dependent adults. Participants may receive their result from a genetic counselor (at no cost to them) or from their own provider. SPARK provides gene-specific guidebooks to providers, genetic counselors and participants that explain the features associated with the individual's genetic result.

Results: SPARK has identified nearly 400 returnable genetic results to date from 5,242 simplex and 1,119 multiplex families that include at least one child with autism. Participants with a returnable result include 261 males and 105 females (a ratio of 2.5:1, compared with an overall ratio of 4:1). As expected, SPARK identified returnable genetic results in individuals with intellectual disability (ID) and/or seizures. 58.5 percent of people with a result had intellectual disability ID or developmental delay (DD) and 11.4 percent endorsed seizures, compared to 41.7 percent with ID/DD and 5.2 percent with seizures in all sequenced participants. SPARK has notified 191 participants of their ASD-related genetic results, and 118 have received their results. Of these 118 families, 97 received the result from a SPARK-provided genetic counselor or investigator and 21 chose their own medical provider. 94% of confirmed returnable results occurred *de novo* in the individual with autism, and 6% were inherited from a parent, some of whom do not have an ASD diagnosis. Genetic results inherited from parents take more time to return than *de novo* variants.

Conclusions: Large-scale return of genetic results is feasible but requires constant adjustment as no one protocol can account for all situations. A commitment to the return of genetic results is an important goal for all genetic research projects. SPARK's experiences can inform the process for other genomic research studies.

317.003 *(Oral)* Hematopoietic Stem Cell Rescue of Angelman Syndrome Phenotypes Using Preclinical Models

A. Adhikari[1], *N. A. Copping*[1], *J. Beegle*[2], *H. Nelson*[2], *H. O'Geen*[3], *K. Fink*[4], *D. J. Segal*[3], *J. S. Anderson*[5] *and* ***J. L. Silverman***[1], *(1)Department of Psychiatry and Behavioral Sciences, MIND Institute University of California Davis School of Medicine, Sacramento, CA, (2)Institue for Regenerative Cures (IRC) UC Davis School of Medicine, Sacramento, CA, (3)Department of Biochemisty and Pharmacology, UC Davis Genome Center & UC Davis MIND Institute, Davis, CA, (4)Department of Neurology, Institue for Regenerative Cures (IRC) UC Davis School of Medicine, Sacramento, CA, (5)Internal Medicine, Institue for Regenerative Cures (IRC) UC Davis School of Medicine, Sacramento, CA*

Background: AS is a rare neurodevelopmental disorder characterized by developmental delay, impaired communication skills, ataxia, motor and balance deficits, intellectual disabilities, microcephaly, and seizures. The genetic cause of AS is loss of expression in the brain of UBE3A (ubiquitin-protein ligase E6-AP), due typically to a 4-Mb de novo deletion of the maternal 15q11-q13 region. Due to brain-specific imprinting, the paternal allele is silenced, thus loss of the maternal allele causes UBE3A deficiency throughout the brain. Novel strategies to treat Angelman Syndrome are critical as there is no cure or corrective therapy available to patients. A novel approach being developed by our laboratories is the use of hematopoietic stem cells (HSC), which offer a promising approach for life-long delivery of functioning UBE3A to affected cells, i.e., neurons.

Objectives: To assess in vivo efficacy of HSC therapy in a single gene disorder, AS, a platform for single gene ASDs.

Methods: We created and modified a lentiviral vector expressing secretable UBE3A, engrafted of the modified/transplanted HSC to have the ability to systemically secrete the enzyme thus providing functional UBE3A through a process called “cross-correction”. The studies tested N=10-15 of each of two genotypes (AS and WT) and three treatment (treated with transduced cells, treated with non transduced cells, non transplanted AS and WT mice) yielding 5 groups. Data suggested that immune deficient AS mice, capable of human cell engraftment, have numerous behavioral AS phenotypes attributed solely to the *Ube3a* deletion and not an artifact of immune alteration.

Results: Immunodeficient AS mice transplanted with human CD34+ HSC transduced with the Ube3a lentiviral vector displayed a significant improvement in motor and cognitive behavioral assays including open field, rotarod, beam walking, and novel object recognition as compared to nontransplanted AS mice and those transplanted with unmodified human CD34+ HSC. Gait analyses also demonstrated improvement in mice transplanted with the Ube3a lentiviral vector transduced cells and were similar to the wild type control cohort. High delta power in EEG was normalized with HSC treatment. A normal hematopoietic profile was observed in the blood, spleen, thymus, and bone marrow upon detection of human T cells, B cells, macrophages, and CD34+ cells. A lack of tumorigenicity was also observed with the Ube3a vector transduced cells as demonstrated in an in vitro immortalization assay.

Conclusions: This data demonstrates strong evidence for the use of this therapy to treat Angelman Syndrome. We are currently assembling a pre-IND package to submit to the FDA for a future clinical trial for Angelman Syndrome.

317.004 *(Oral)* Prospective Phenotyping in DDX3X Syndrome, a Significant Contributor to Autism in Females

D. Grice[1]*, J. Buxbaum*[2]*, Y. Frank*[1]*, I. Giserman-Kiss*[3]*, D. Halpern*[4]*, A. Kolevzon*[4]*, P. M. Siper*[4]*, L. Tang*[4] *and J. Zweifach*[4]*, (1)Icahn School of Medicine at Mount Sinai, New York, NY, (2)Department of Psychiatry, Icahn School of Medicine at Mount Sinai, New York, NY, (3)University of Massachusetts Boston, Brookline, MA, (4)Seaver Autism Center, Department of Psychiatry, Icahn School of Medicine at Mount Sinai Hospital, New York, NY*

Background: Five recent studies in autism spectrum disorder (ASD) have shown that mutations in the X-linked DDX3X gene are significantly associated with ASD, particularly in females. Moreover, review of phenotypes of individuals ascertained for DDX3X mutations demonstrate high rates of ASD and ASD traits in DDX3X mutation carriers. In broader studies, mutations in the DDX3X gene are emerging as one of the most common molecular findings in ASD, developmental delay (DD) and intellectual disability (ID) in females, accounting for 1-3% of unexplained DD/ID in females. Participants with DDX3X mutations present with a variable constellation of phenotypes, including ASD, mild to profound ID, nonverbal to verbal language abilities, and the presence or absence of brain structural defects; however, prospective assessments of the syndrome are lacking. In addition, evidence indicates that there are 3 distinct subclasses of DDX3X syndrome-associated mutations: DDX3X syndrome associated with either (i) loss of function (LoF; i.e., amorphic) alleles, (ii) hypomorphic missense alleles, or (iii) dominant-negative (DN; i.e., antimorphic) missense alleles. To date, only a single study has examined genotype-phenotype correlations in the syndrome.

Objectives: To carry out extensive, prospective assessment of individuals with DDX3X syndrome, and to carry out genotype-phenotype correlations to understand how DDX3X mutations exert their effects on behavioral phenotypes.

Methods: Ten participants (ages 3-16) have undergone comprehensive phenotyping at the Seaver Autism Center at Mount Sinai, using arefined assessment protocol developed based on prior approaches and preliminary data in DDX3X syndrome. A multidisciplinary team of expert clinicians (psychiatry, psychology, neurology, clinical genetics) are involved in aspects of the evaluation. All available medical records are obtained and reviewed with a particular focus on behavioral and neuroimaging results. Genetic reports are reviewed by a certified genetic counselor. Assessments include neuropsychiatric and medical examinations, standardized diagnostic, cognitive, language, and motor assessments, and caregiver report questionnaires.

Results: We have carried out detailed phenotyping in 10 DDX3X participants. Our results show that ASD (60%), ID (70%), language delay (100%), and structural brain defects (33%) are prominent. Seizures were reported in 2 girls (20%). We observed a broad range of cognitive function with 2 individuals showing FSIQ in the low average or borderline range, 2 individuals with moderate ID and 6 individuals with severe or profound ID. Receptive and expressive language varies broadly in these individuals. Six (6) participants were minimally verbal or nonverbal, 2 used phrase speech or simple sentences, and 2 were verbally fluent.

Conclusions: We confirm high rates of ASD in DDX3X syndrome. In addition, we observe a broad range of functioning. All DDX3X mutations we studied to date are in females, as are almost all prior reports. This is because the DDX3X gene is located in a short region in Xp11.4 that escapes X-inactivation, and females are thus functionally heterozygous for the mutation. We will continue to define the phenotype of DDX3X syndrome, and we are beginning to use in vitro methods to classify mutations as LoF, hypomorphic or DN, for future genotype-phenotype correlations. DDX3X syndrome provides a unique window into ASD in females.

Immunology

POSTER SESSION — **IMMUNOLOGY**
425 - Immunology Posters

425.001 *(Poster)* Activation of Microglia Mediates ASD like Phenotype in Mice Following in Utero Exposure to Anti-Caspr2 Antibodies.

L. Brimberg[1], *D. Comoletti*[2], *C. Bagnall-Moreau*[3], *P. T. Huerta*[4], *B. Volpe*[5] *and B. Diamond*[6], *(1)Center for Autoimmune and Musculoskeletal Diseases, The Feinstein Institute for medical Research, Manhasset, NY, (2)CHINJ - Neuroscience and Cell Biology, Rutgers - Robert Wood Johnson Medical School, New Brunswick, NJ, (3)The Feinstein Institute for Medical Research, Manhasset, NY, (4)Laboratory of Immune & Neural Networks, Feinstein Institute for Medical Research, Manhasset, NY, (5)Laboratory of Biomedical Science, The Feinstein Institute for Medical Research, Manhasset, NY, (6)The Feinstein Institute for Medical Research, Manahasset, NY*

Background: The concept that the in utero environment, and specifically maternal antibodies, can contribute to the development of Autism spectrum disorders (ASD) has been entertained for over a decade. We have identified antibodies targeting the protein Caspr2 to be present in high frequency in mothers with an ASD child. A single exposure in utero to a monoclonal anti-Caspr2 antibody, derived from a mother of an ASD child, can lead to an ASD like phenotype in mice offspring. We have generated a new model in which anti-Caspr2 antibodies are present during gestation in mice immunized with the extracellular portion of Caspr2 to better mimic the human condition, and to allow us to ascertain the role of microglia and its inhibition as a potential therapeutic,

Objectives: To examine microglial activation in ASD and to assess microglia as targets for potential therapeutic strategies.

Methods: C57BL/6 female mice from Jackson Laboratories are immunized with the extracellular region of human Caspr2 purified from supernatant of transfected, glycosylation-deficient HEK293T GnTI− cells . Control female mice are immunized with adjuvant only. Titers to Caspr2 are determined by a cell based assay against both human and mouse Caspr2 . Since Caspr2 is considered to be expressed almost exclusively in the CNS and is sequestered by the BBB, anti-Caspr2 antibody are not pathogenic in the immunized mice which have no compromise to the BBB.

Results: We have generated a new model in which anti-Caspr2 antibodies are present during gestation in mice immunized with the extracellular portion of Caspr2. Male and not female mice of dams harboring polyclonal anti-Caspr2 antibodies showed abnormal cortical development, decreased dendritic complexity of excitatory neurons and reduced numbers of inhibitory neurons in the hippocampus, as well as repetitive behaviors and impairments in novelty interest in the social preference test. Since microglial-dependent pruning is one mechanism that may account for the diminished dendritic arborization, we assessed microglia in these mice. They have a higher activation score and reduced ramifications based on colocalization of CD68 with Iba1a, cell shape and Scholl analysis compared with control mice. Importantly, in a pilot study, a diet containing colony stimulating factor 1 receptor (CSF1R) inhibitor, PLX 3397, begun when the mice were 12 weeks of age, led to a 90% loss of microglia, normalized repetitive behavior, and increased dendritic arborization in these mice.

Conclusions: The data suggest the potential pathogenicity of anti-Caspr2 antibodies, and is consistent with the concept that anti-brain antibodies present in women during gestation can alter fetal brain development and may result in ASD in a subset of offspring. Our new model can be utilized to assess microglia as targets for potential therapeutic strategies.

425.002 *(Poster)* Acute Peripheral Immune Activation Alters Cytokine Expression and Glial Activation in the Early Postnatal Rat Brain

J. Van de Water[1], *M. R. Bruce*[2], *K. Streifel*[3] *and P. Lein*[4], *(1)MIND Institute, University of California, Davis, Davis, CA, (2)University of California - Davis, Davis, CA, (3)Uc-Davis, Davis, CA, (4)University of California-Davis, Davis, CA*

Background: An acute peripheral immune response can be widely systemic, affecting a variety of tissues and organ systems, although the tissue-specific response may vary greatly. For example, peripheral immune stimulation has been shown to influence neuroinflammatory responses in the central nervous system (CNS). Specific effects seen in the brain following peripheral immune challenge include global changes in expression of interferon response genes as well as alterations in cell-specific transcriptional programming, particularly in microglia. These transcriptional alterations of neuroimmune signaling in early life are hypothesized to result in developmental priming, potentially leading to enduring consequences in response to later life exposures.

Objectives: The influence of an acute peripheral immune challenge on neuroinflammatory responses in the early postnatal brain in the context of genetic background and sex is not well characterized. To address this gap in knowledge, we evaluated the peripheral and central nervous system (CNS) immune responses to a mixed immune challenge in early postnatal rats of varying strains and sex.

Methods: On postnatal day 10 (P10), male and female Lewis and Brown Norway rats were injected intramuscularly with either a mix of bacterial and viral components in adjuvant, adjuvant only, or saline. Immune responses were evaluated at 2, and 5 days post-challenge. Cytokine and chemokine levels were evaluated in serum and in multiple brain regions using a Luminex multiplex assay. Multi-factor ANOVAs were used to compare analyte levels across treatment groups within strain, sex, and day of sample collection. Numbers and activation status of astrocytes and microglia were also analyzed in the cortex and hippocampus by quantifying immunoreactivity for GFAP, IBA-1, and CD68 in fixed brain slices. Immunohistochemical data were analyzed using a mixed-model regression analysis.

Results: Acute peripheral immune challenge differentially altered cytokine and chemokine levels in the serum versus the brain. Within the brain, the cytokine and chemokine response varied between strains, sexes, and days post-challenge. Main findings included differences in T-helper (Th) type cytokine responses in various brain regions, particularly the cortex, with respect to IL-4, IL-10, and IL-17 levels. Additionally, peripheral immune challenge altered GFAP and IBA-1 immunoreactivity in the brain in a strain- and sex-dependent manner.

Conclusions: These findings indicate that genetic background and sex influence the CNS response to an acute peripheral immune challenge during early postnatal development. Additionally, these data reinforce that the developmental time point during which the challenge occurs has a distinct effect on activation of CNS-resident cells.

425.003 *(Poster)* Cytokine Alterations on Clinical Characteristics in Chinese Children with Autism Spectrum Disorder

C. Hu[1], *Y. Sun*[2], *Y. Wang*[1], *C. Liu*[1], *B. Zhou*[1], *H. Li*[1], *Q. Xu*[1] *and X. Xu*[1], *(1)Children's Hospital of Fudan University, Shanghai, China, (2)Institute of Neuroscience, Chinese Academy of Sciences, Shanghai, China*

Background: Autism spectrum disorder (ASD) is a neurodevelopmental disorder in which genetics, together with environmental risk factor play a key aetiological role. Multiple evidence indicates a link between immune dysfunction and ASD. However, few data showed the relationships between cytokine level and clinical characteristics of Chinese ASD patients.

Objectives: To investigate cytokines alterations in Chinese ASD children with regression and allergy.

Methods: We reanalyzed our previously published data for case-control study. ASD children who were diagnosed and qualified for the inclusion criteria were recruited in the research as experimental group, typically developing children from a Kindergarten and early childhood education center as control group. Research method: 11 cytokines plasma levels were measured according to Miliplex BMS protocol. The clinical characteristics of ASD group: We recorded the medical history including regression and allergy, medical assessments including Autism Diagnostic Observation Schedule, second edition (ADOS-2) and Griffiths Mental Development Scales (GMDS).

Results: The cohort included 65(55 male) ASD children and 42(28 male) TD children, aged 19 to 79 months.

1) The results of plasma cytokine levels showed: Plasma TNFa and Eotaxin levels were significantly higher in ASD group (TNFa: median 16.26, range 6.89–28.45pg/mL, P =0.045; Eotaxin: 72.18, 23.87–490.69pg/mL, P=0.016) than in TD group(TNFa: 14.19, range 7.40–25.21pg/mL; Eotaxin:55.72, 19.24-170.94pg/mL). There was a trend for Plasma TGF-β1(ASD: 5337.0, 931.67–34107.0pg/mL; TD: 2680.0, 574.08–18194.0pg/mL, P = 0.066). TGF-β1 was significantly increased in ASD male group than TD group (ASD: 5411.0, 931.67–34107.0pg/mL; TD: 2681.0, 838.28–16695.0pg/mL, P = 0.033).

2) The average ADOS total score is 21.17±9.88（SA:16.97±2.40; RRB:2.36±1.54） of 65 ASD children. The average GMDS DQ is 55.03±14.65 (Locomotor: 67.42±12.89; Personal-social：52.07±14.95；Hearing and Speech: 52.07±20.93; Eye and Hand: 55.34±17.01；Performance: 60.10±21.79)。

3) 17 of 65 ASD children had regression. Compared with ASD children with no regression(ASDnr) and TD children, ASD children who had regression(ASDr) had higher trend for plasma TGF-β1 (ASDr:7359.0, 1164.0–24649.0pg/mL; ASDnr:3413.0, 931.67–34107.0pg/mL; TD:2680.0, 574.08– 18194.0pg/mL, P=0.070) and Eotaxin (ASDr:72.42, 23.87–490.69pg/mL; ASDnr:71.0, 23.87–192.31pg/mL; TD: 55.72, 19.24-170.94pg/mL, P=0.056). For male, the increase of TGF-β1 was most significant in ASDr, almost three-fold higher than TD (ASDr:7359.0, 1164.0–24649.0pg/mL; ASDnr:4452.0, 931.67–34107.0pg/mL; TD: 2681.0, 838.28– 16695.0pg/mL, P=0.039).

4) Since we did not have data of TD children for allergic history, we compared cytokines of ASD children with allergy (ASDa: 29/65) and non-allergy (ASDna: 36/65). Compared to ASDna, ASDa showed higher TNFa level (ASDa: 17.14, 6.89–26.60pg/mL; ASDna: 15.6, 7.93–28.45pg/mL, P =0.038).

Conclusions: The pilot findings showed that TGF-β1, TNFa and Eotaxin may have associations with neurodevelopment progression of children, especially in boys. TGF-β1 and TNFa may have potential role in the mechanism of regression and allergy in ASD in Chinese population.

425.004 *(Poster)* Dysregulated Immune Gene Expression in Monocytes in Children with Autism Spectrum Disorders.

H. K. Hughes[1,2], *S. Dada*[3], *A. Vogel Ciernia*[3] *and P. Ashwood*[1,2], *(1)MIND Institute, University of California, Davis, Sacramento, CA, (2)Department of Medical Microbiology and Immunology, University of California, Davis, Davis, CA, (3)University of British Columbia, Vancouver, BC, Canada*

Background: Immune dysfunction is a common co-morbidity seen in autism spectrum disorders (ASD), with innate immune dysfunction seen both in the brain and periphery. Evidence of this dysfunction includes altered numbers and activity of circulating monocytes as well as their counterparts in the brain, the microglia. Previous work has identified significant differences in the cytokine responses of peripheral blood monocyte cytokine after *ex vivo* Toll-like receptor (TLR) stimulation. However, an unbiased transcriptomic analysis of the response of ASD monocytes to different TLR agonists has not been examined. As early innate immune activation is largely driven by signaling through TLRs, we hypothesized that activation of different TLRs would impact gene expression in ASD monocytes compared to monocytes from typically developing (TD) controls.

Objectives: We aimed to identify gene expression profiles in TLR stimulated monocytes from ASD children compared to TD controls.

Methods: We isolated peripheral blood monocytes from 27 children with ASD and 23 TD children and treated them with either lipoteichoic acid (LTA) or lipopolysaccharide (LPS) to activate TLR-2 or 4 respectively. Following 24 hours of stimulation, we processed cells for RNA sequencing to profile mRNA expression between non-treated (NT), LTA and LPS treated samples for each diagnosis (TD or ASD).

Results: We identified differentially expressed genes in non-treated compared to stimulated cells for both TD and ASD samples. Both LPS and LTA induced expression of immune genes, with a subset that were differentially regulated in ASD compared to TD samples. In response to LPS treatment, monocyte cultures from ASD children showed a unique increase in genes within the KEGG pathway for Pathogenic *E. Coli* infection, a pathway that was not enriched in the controls. This pathway included elevated expression of key immune regulator genes such as FAS cell surface death receptor (FAS), nuclear factor kappa B (NFKB1), Interleukin Receptor Type1 (IL1R1), and TGF beta Kinase 3 (TAB3) in ASD. Notably, TD monocytes showed a consistent decrease in expression of genes associated with translation and rRNA metabolism in response to both LTA and LPS. A comparable decrease was not observed in the ASD monocytes, suggesting a failure to properly regulate a prolonged immune response.

Conclusions: We demonstrated that activation of TLR-2/4 in ASD monocytes led to differential gene expression compared to monocytes from TD controls, with enrichment for genes involved in inflammatory responses. Additionally, ASD monocytes did not significantly down-regulate genes involved in translation compared to controls, suggesting deficits in translational regulation. As monocytes are involved in early orchestration of the immune response, our findings will help elucidate the mechanisms regulating immune dysfunction in ASD and provide novel targets for future therapeutic development.

425.005 *(Poster)* Investigating the Causal Relationship between Inflammation Biomarkers and Autism Spectrum Disorder: A Two-Sample Mendelian Randomization Study

B. Du[1], *W. Zhang*[2], *P. Wu*[3], *Z. Hu*[1] *and X. Kun*[1], *(1)Center for Medical Genetics, School of Life Sciences, Central South University, Changsha, China, (2)Biology Department, College of Arts & Sciences,, Boston University, boston, MA, (3)School of Life Sciences, Central South University, changsha, China*

Background: Previous studies have presented surging evidence which supports a close, potentially causal link between inflammation biomarkers and autism spectrum disorder (ASD). Investigating whether there exists genetic causality might shed light on underlying pathophysiology and provide further insights into therapeutic effects of attenuating inflammation.

Objectives: To identify whether increased inflammation levels of C-reactive protein (CRP) and interleukin-6 (IL-6) contributed genetically to higher risk of ASD.

Methods: We conducted a two-sample Mendelian randomization study using genome-wide significant SNPs correlated with CRP in 204,402 European individuals and IL-6 in 8,189 European participants from CHARGE Inflammation Working Group and I Young Finns Study, respectively. Summary statistics of ASD were retrieved from a recent published study involving 18,381 cases and 27,969 controls by iPSYCH and PGC. The inverse-variance weighted method, weighted median method, and MR-Egger were incorporated in our analysis using R version 3.4.2 and TwoSample MR R package.

Results: Totally, 46 and 5 SNPs were validated as instrumental variables for CRP and IL-6 to estimate the causative effect of inflammation exposureles on ASD. We failed to find a statistically significant causality between CRP and ASD (effect size = 0.016, se = 0.053, P = 0.763, per), neither between IL-6 and ASD (effect size = -0.023, se = 0.067, P = 0.736). The MR-Egger intercept was compatible with no unbalanced pleiotropy (P = 0.48 and P = 0.24, respectively).

Conclusions: Mendelian randomization analyses using current GWAS summary results did not suggest a causal link between CRP or IL-6 and ASD.

425.006 *(Poster)* Maternal Asthma and Infection during Pregnancy May be a Risk Factor for Neuropsychiatric Problems in Offspring throughout Childhood and Adolescence.

S. Patel[1], *M. N. Cooper*[2], *H. Jones*[3,4], *A. O. Whitehouse*[2], *R. C. Dale*[4] *and A. J. Guastella*[1], *(1)Brain and Mind Centre, Children's Hospital Westmead Clinical School, Faculty of Medicine and Health, University of Sydney, Sydney, NSW, Australia, (2)Telethon Kids Institute, University of Western Australia, Perth, WA, Australia, (3)University of Sydney, Sydney, NSW, Australia, (4)Kids Neuroscience Centre, The Children's Hospital at Westmead, Faculty of Medicine and Health, University of Sydney, Sydney, NSW, Australia*

Background: Emerging research suggests that maternal immune activation during pregnancy, caused by acute infection or chronic immune conditions, may increase risk of neurodevelopmental and neuropsychiatric disorders in offspring. MIA has been linked to increased risk of Autism Spectrum Disorder, schizophrenia, anxiety and depression in offspring. No studies have investigated whether MIA confers a risk for broad neuropsychiatric symptoms in children across childhood and adolescence.

Objectives: Using data from the Western Australia Pregnancy Cohort (Raine) Study, we investigated whether maternal immune conditions during pregnancy was associated with increased behavioral and emotional problems in offspring longitudinally across development. We also examined whether exposure to more than one maternal immune condition conferred greater risk to offspring outcomes than single exposures.

Methods: Mothers (Generation 1; N=1905) were classified into the following immune categories: AAAE (Asthma/Allergy/Atopy/Eczema; N=1267); infection (during pregnancy; N=1082); no AAAE or infection (N=301). The Child Behavior Checklist (CBCL) was administered for offspring (Generation 2; 921 females, 984 males) at ages 5, 8, 10, 14 and 17 years. The CBCL produces three T scores: Total behavior, Externalizing behavior, Internalizing behavior. We also analysed CBCL 'morbidity' (T scores above 60), which is an established threshold of clinically significant level of concern. Generalized estimating equations were used to investigate the effect of maternal immune status on CBCL scores.

Results: All AAAE conditions (one or more) were associated with significant increases in CBCL scores (β ranging 1.54 to 2.49) and morbidity (OR ranging 1.34 to 1.58) on the Total, Externalizing, and Internalizing scales. A single AAAE condition was associated with significant increases in scores (β ranging 1.20 to 2.04) and morbidity (OR ranging 1.33 to 1.54) on all three scales. Two or more AAAE conditions were associated with larger increases in scores (β ranging 1.84 to 2.93) and morbidity (OR ranging 1.35 to 1.68) on all three scales. All infection conditions (one or more) were associated with significant increases in CBCL scores (β ranging 0.76 to 1.27) on all three scales and morbidity on the Total and Externalizing scales (OR 1.19 and 1.16, respectively). A single infection condition was associated with increases in Total and Externalizing scores (β 0.71 and 0.67, respectively), but no significant increases in morbidity. Two or more infection conditions were associated with larger increases in scores (β ranging 2.22 to 2.83) and morbidity (OR ranging 1.53 to 1.73) on all three scales. For those whose mothers reported both AAAE and infection (at least one of each condition), larger increases in CBCL scores (β ranging 1.97 to 2.59) and morbidity (OR ranging 1.44 to 1.53) were observed across all three scales.

Conclusions: MIA was associated with a small increase in behavioral and emotional problems in offspring throughout childhood and adolescence. MIA may confer risk to neurodevelopment in a cumulative manner; exposure to more than one AAAE and/or infection condition was associated with greater elevation in CBCL scores than single exposures. These results highlight the need to understand MIA, fetal development, and long-term outcomes, with potential to advance early identification and intervention strategies.

International and Cross-Cultural Perspectives

PANEL SESSION — **INTERNATIONAL AND CROSS-CULTURAL PERSPECTIVES**

213 - From Clinic to Community: The Role of Sports, Dance, and Education in Improving Developmental Outcomes for Children with Autism Spectrum Disorder Globally

Panel Chair: David Austin, *School of Psychology, Deakin University, Burwood, VIC, Australia*

Discussant: James Charles, *Deakin University, Burwood, VIC, Australia*

Community-based interventions for children with Autism Spectrum Disorders (ASD) complement and enhance best practice clinical care, improving social connectedness, mental health and motor functioning, increasing physical activity and reducing risk for poor physical health outcomes later in life. Community-based interventions are 'strengths-based' and provide real opportunities for children and families to thrive. This panel is centred around a global perspective describing how we can develop the necessary 'evidence-based bridge' from clinic to community to enable sports, dance and educational sectors to work together to improve developmental outcomes of children with ASD. This will include a special focus on best-practice approaches to community-based interventions in indigenous communities, where in Australia, for example, there are limited clinical services available. Latest evidence on the benefits of participation in organised physical activity for children with ASD and parent reported barriers and facilitators will be presented. The panel will overview critical gaps in advocacy and measurement of community-based interventions and introduce the AllPlay™ program as one type of evidence-based platform to fill these gaps.

213.001 *(Panel)* Get Moving: The Importance of Accessibility of and Advocating for Physical Activity Programs for Individuals with Autism Spectrum Disorder (ASD)

R. B. Wilson[1], *S. Jeste*[2], *C. Lord*[2], *C. Giza*[1], *J. Goldman*[1], *M. Choe*[1], *S. Freeman*[3], *T. Paparella*[4], *D. W. Austin*[5], *J. McGillivray*[6] *and N. Rinehart*[6], *(1)UCLA Medical Center, Los Angeles, CA, (2)University of California, Los Angeles, Los Angeles, CA, (3)Child Psychiatry, UCLA Medical Center, Los Angeles, CA, (4)University of California Los Angeles, Los Angeles, CA, (5)School of Psychology, Deakin University, Burwood, VIC, Australia, (6)Deakin University, Burwood, VIC, Australia*

Background: Motor impairments are prominent in individuals with autism spectrum disorder (ASD), and these impairments often impact the individual's ability to engage in organized physical activity programs [OPA] (McCoy et al, 2016). Given the benefits of physical activity on health outcomes, social development, and improvement of motor impairments, there is a need for evidence-based OPA for individuals with ASD (Howells et al, 2019; Wilson, RB et al 2018). However, there remains a paucity in the literature regarding the outcomes associated with OPA for individuals with ASD.

Objectives: Identify opportunities to improve accessibility of and advocacy for OPA for individuals with ASD.

Methods: First, a systematic review of the field and literature was conducted and revealed that physical activity for children has important developmental benefits, but few studies are focused on outcome measurement of OPA in ASD. Second, three gaps were identified that should be addressed to improve accessibility of and advocate for OPA for individuals with ASD: (1) measuring and demonstrating positive outcomes of participation in OPA, (2) scalability of OPA for large populations of individuals with diverse ASD symptomatology, and (3) building partnerships with academic institutions to aid in gaps 1 and 2. Thought leaders in the field of neurology, neurodevelopmental disorders, sports medicine, psychology, child development, and large OPA serving individuals with ASD convened to discuss how to address these gaps.

Results: In review of the gaps, it was concluded that the following items should be addressed to improve access to and advocacy for evidence-based OPA for individuals with ASD: (1) Outcome measurement should focus on health and wellness, motor skills, social and behavioral, quality of life (QOL), and academic achievement. QOL measures should also be included for caregivers. (2) To build scalable programs there is a need to show the economic benefits of OPA. Specifically, improved physical health and decreased poor health outcomes. Outcome measures that are easily used by families and participants such as smartphone applications should be considered for large scale data collection. Lastly, accreditation and reliability of program delivery is needed in order to ensure individuals with diverse ASD symptomatology are being adequately served. (3). Partnerships with academic programs can improve outcome measurement by guiding OPA toward validated measures of brain and behavior. Partnerships with academic programs can also lead to creation and validation of measures that can be utilized broadly across OPA. Funding of community research partners can be established with academic institutions to guide physical activity organizations in accurate data collection.

Conclusions: Evidence-based OPA for individuals with ASD have the potential to improve health and wellness, social and behavioral outcomes, motor skills, and overall QOL. To improve access to and advocacy for these programs it is imperative that validated outcome measures of brain and behavior be systematically utilized to build the evidence base for OPA. These measures can guide the development of successful large scale OPA. Partnerships with academic institutions can support these goals by providing community-based OPA the guidance needed to measure outcomes and serve diverse populations of individuals with ASD.

213.002 *(Panel)* Introducing the Allplay Program: Building an Evidence-Based Approach to the Inclusion of Australian and Aboriginal and Torres Strait Islander in Organised Physical Activity

N. Rinehart*, J. Charles, C. Sivaratnam, K. Howells, J. McGillivray, A. Mantilla and N. Papadopoulos, Deakin University, Burwood, VIC, Australia*

Background: Many children with Autism Spectrum Disorders (ASD) are excluded from participating in organised physical activity, such as sport and dance; and when they do participate it can be a negative experience. In Australia, Aboriginal and Torres Strait Islander children with disabilities encounter further access barriers due to their Aboriginality (Dew et al., 2018). A unified novel platform called AllPlay™ has been developed by Deakin University researchers to promote the inclusion of all children in sport, dance and education using evidence-based strategies and programs.

Objectives: The objective of this paper is to provide an overview of the methodology used for building the AllPlay program, highlighting key preliminary findings from systematic reviews, surveys, and feasibility and pilot studies for our AllPlay sports program.

Methods: AllPlay has four programs with strengths- and evidence-based strategies and resources that help ensure children with disabilities are given the same opportunities to engage in sports, dance and education as their typically developing peers. These are: AllPlay™ Footy, AllPlay™ Aboriginal and Torres Strait Islander, AllPlay™ Learn and AllPlay™ Dance. AllPlay™ uses a co-design participatory design method in which all critical stakeholders were engaged in a collaborative process to i) understand and clearly identify needs and foci for each program, ii) design and develop the programs and iii) test the programs throughout different stages of development. The data informing the development of the four programs was generated using mixed methods which generally included conducting scoping and systematic reviews, surveys, focus groups, pilot program studies, community consultations, and leading industry groups and rapid response teams.

Results: Our systematic reviews demonstrated the positive effects on physical, mental and social functioning for children with ASD when engaging in OPA programs (May et al, 2019, Howells et al, 2019, May et al, in press). Data from these reviews informed the development of culturally sensitive pilot programs in community settings that reduce children's anxiety levels and promote inclusion in OPA. Our pilot AllPlay Footy programs show that children with ASD (5-12 years of age) who participated in OPA have a significant decrease in total scores on DSM oriented anxiety and social problems, with no change in those who did not (Intervention n =19, Comparison n=20). A 'dose effect' on the number of OPA sessions a child attended and reduction in social problems was found. Australian data on the barriers and facilitators to inclusion in OPA from 1,529 parents of children with and without disabilities will also be presented.

Aboriginal and Torres Strait Islander community consultations showed transportation, costs and location are the most frequently reported barriers across all communities, followed by lack of knowledge about sports programs available. The most important goals for Aboriginal and Torres Strait Islander children in non-remote locations participating in footy included increasing their involvement in OPA, as well as learning social skills (e.g. teamwork and respect) and footy skills.

Conclusions: There is emerging literature to show the physical, mental and social benefits of participation in OPA for children with autism and neurodevelopmental disorders more broadly.

213.003 *(Panel)* Allplay Dance: Participating in the Social, Physical and Creative Activities of Dance for Children with ASD

***O. Millard**, N. Rinehart, E. Lindor, N. Papadopoulos and J. McGillivray, Deakin University, Burwood, VIC, Australia*

Background: AllPlay Dance is founded on a collaborative approach to research between the disciplines of Psychology and the Creative Arts. This genuine cross-disciplinary partnership brings a rigorous scientific methodology to an investigation of the benefits of dance for children with ASD, supported by responsive work in the development of dance programs. As well as directly measuring the benefits of the program for the participating population, the study acts a step in the continuing development of inclusive dance programs for children with a range of disabilities.

Objectives: This paper will discuss the benefits for children with ASD of participating in a dance program using quantitative and qualitative measures such as social functioning, cognitive skills, emotional and behavioural wellbeing, and movement abilities.

Methods: The AllPlay Dance program for children with ASD is a waitlist-controlled pilot which gives children agency in their own inclusion in a series of dance classes, culminating in an informal performance. The dance program was developed to include a variety of dance activities such as learning movement material, dance improvisation and supported group movement generation (choreography). Rudolph Laban's Movement Principles within the framework of *Body, Space, Energy and Time* were employed as a structure for dance teaching and choreography, in order to develop a transferable and scale able program. Through the principle of intersubjectivity, described by cognitive science philosopher, Hanne De Jaegher, as "participation in the investigation of how experience transforms when examining it together" (2016, 393), dance is considered to be a social practice as well as a situation in which one participates physically and creatively. Crucial to the development and the success of the program was the participation of "buddies" who were older and had an existing level of dance experience. Buddies partnered with children with ASD through the classes and in performance.

Results: We will present the preliminary findings of the project, including the social, cognitive, and motor outcomes of the waitlist control trial. We will also include a discussion about the successes and emerging understandings of a project that is scientifically underpinned while equally valuing the embodied and experiential understandings gained through a creative arts approach. The discussion will be based on the following topics: working across disciplines to research dance for children with ASD; the buddy system – older more experienced, dancing partners; dance as a social practice; questioning conventional dance values - from spectacle to experience.

Conclusions: While undertaking the work of a pilot in which the benefit of participating in dance activities for children with ASD was measured, the program was also undertaken with the long-term aims of developing inclusive approaches to dance classes that challenge ablist notions of dance- as -spectacle and enable children with ASD to benefit from participating in dance in their communities.

213.004 *(Panel)* Allplay Learn: Co-Designing with Early Childhood Educators and School Teachers to Help Create Inclusive Education Environments for Children with Disabilities and Developmental Challenges

***A. Mantilla**[1], N. Rinehart[1], J. McGillivray[1], R. B. Wilson[2] and B. Devenish[1], (1)Deakin University, Burwood, VIC, Australia, (2)UCLA Medical Center, Los Angeles, CA*

Background: The AllPlay™ Learn website and online professional learning courses for early childhood educators and school teachers was launched in August 2019 in Victoria, Australia. AllPlay Learn was developed in partnership with the Victorian Department of Education and Training. It was co-designed with early childhood educators, school teachers, families, education and health experts, government and peak-body organisations.

Objectives: AllPlay Learn aims to support the inclusion of children in early childhood education and care settings, mainstream and special education primary and secondary schools. The program developed provides strengths- and evidence-based strategies and resources for teaching the 1 in 5 Australian children with disabilities and/or developmental challenges at early childhood education and care settings and schools. This paper shows how co-design was used as a participatory design method in which all critical stakeholders engaged in a collaborative process to understand and identify the objectives of the program, as well as to design, re-design and test the program throughout its development.

Methods: Scoping and systematic reviews were conducted to identify children's strengths and a comprehensive range of evidence-based strategies for ASD and ADHD, and also other disabilities and developmental challenges including ODD, cerebral palsy and communication disorders. A specific systematic review on the shared strengths, capabilities and competencies of children with ASD was also conducted. A total of six focus groups (n= 46 participants) at two different time points (i.e. development and trial phase) and one survey (n= 338 respondents) were completed during a total period of 9 months with a mix of early childhood education and care educators and professionals, teachers, wellbeing officers, education support staff, assistant principals and principals from government schools and teachers from three ASD special schools. An additional focus group with parents or caregivers of primary school aged children with ASD was also conducted.

Results: Our analysis of the focus groups transcripts highlighted several challenges faced by educators, teachers and education staff including lack of knowledge and preparation, lack of funding and support in their classrooms, difficulties with heightened emotions and behaviour, and additional pressure and stress. A variety of strategies used by teachers, education staff and schools and critical moments for additional support (e.g. transitions) were also identified. Findings suggested the teachers' need for evidence-based strategies; a consolidated website with high-quality content knowledge and resources; the importance of collegial, family and school level support; and, a strong interest for professional learning on ASD (and other specific disabilities) to strengthen their competence, confidence and inclusive teaching practices.

Conclusions: AllPlay Learn has received strong and positive support from the education sector and wider community. Co-design will continue playing a key role in improving the program and assessing the efficacy of AllPlay Learn in increasing educators' competence and confidence teaching children with ASD, and the resulting impact these practices may have on children's learning, emotional regulation, conduct, attention, peer relations and pro-social skills.

ORAL SESSION — INTERNATIONAL AND CROSS-CULTURAL PERSPECTIVES
318 - Interventions and Outcomes across Cultures

318.001 *(Oral)* Better Sooner Than Later. Child, Family and System Predictors of Later ASD Diagnosis

C. Montiel-Nava[1], *D. Valdez*[2], *A. Rosoli*[3], *G. Garrido*[4], *S. H. Cukier*[5], *C. S. Paula*[6], *R. A. Garcia*[7] *and A. Rattazzi*[5], *(1)Psychological Science, University of Texas Rio Grande Valley, Edinburg, TX, (2)Universidad de Buenos Aires- FLACSO, Buenos Aires, Argentina, (3)Projects, Organizacion Estados Iberoamericanos, Santo Domingo, Dominican Republic, (4)Universidad de la República, Montevideo, Uruguay, (5)PANAACEA, Buenos Aires, Argentina, (6)Developmental Disorder Program, Universidade Presbiteriana Mackenzie, São Paulo, Brazil, (7)Clínica Las Condes, Santiago, Chile., Santiago, CHILE*

Background: Early diagnosis of ASD facilitates early access to intervention and promotes better developmental outcomes in young children. In general, results suggest that Latino children are diagnosed with autism spectrum disorder (ASD) later in life; usually with more severe symptoms, lower IQs, and more health conditions, compared with non-Latino children. Lack of knowledge about best practices for both early identification and intervention in Latin American Countries and Caribbean countries as in many other low resource settings has been influenced by parental health belief, maternal education, low literacy skills, symptoms severity and the scarcity of trained professionals working with those diagnosed with ASD. It is highly important to identify which variables have an impact on the age of diagnosis, and lead to earlier diagnosis.

Objectives: This study aimed to examine the association between child, family, and system factors and the age of the first diagnosis. Furthermore, the study addressed the contribution of each category of variables that might predict the age of ASD diagnosis

Methods: This study includes data of 2817 caregivers from Argentina, Brazil, Chile, Dominican Republic, Uruguay, and Venezuela. The survey was completed through an online platform in the participant countries. It requested information about family demographics, affected individual characteristics, service encounters, and parent/caregiver perceptions. Age of parental recognition and description of first signs were ascertained through the direct questions of the survey.

Results: Age range from 2 to 63 years of age (x=4.80;SD= 12.3. The mean age of first concern was 24.91 months (SD 20.60), and the mean age of diagnosis was 61.16 months (SD 53.51). Optimal linear combination of child factors (diagnosis, gender, comorbid medical disorders, language level, symptoms severity, intellectual functioning, and challenging behaviors) accounted for 8.9% of the variance in age of diagnosis [adjusted R^2=0.089 F=19.707, p<.001]. Diagnosis (Asperger's), Medical comorbidities (Epilepsy & Down Syndrome), Gender (Females), and Language Level (Complex Sentences) all independently predicted a later age of diagnosis. On the contrary, family factors (caregiver's educational level, stigma variables, and another member with ASD) only accounted for 1.5% of the variance [adjusted R^2=0.015 F=4.040, p<.001]. Later age of diagnosis was predicted by lower primary caregiver's educational level and higher stigma. Although, system factors (country of residence, insurance coverage and diagnostician person) do not contribute to the variance of the age of diagnosis [adjusted R^2=0.004 F=4.790, p<.001]; country of residence (Chile & Brazil) independently predicted later age of diagnosis

Conclusions: Caregivers were concerned about their child development by 25 months. However, the diagnosis came 36 months later, which corresponds to the start of formal schooling; similar to other studies conducted in Latin American Countries and Caribbean. Child factors (Asperger's diagnosis, medical comorbidities, being female and good language level) and a primary caregiver with an education level below high school diploma, and higher perception of stigma predicted a later diagnosis. A better understanding of cultural influences in the diagnosis would likely translate to the timelier identification and diagnosis independent of ethnicity.

318.002 *(Oral)* Stress and Resilience in Parents of Children with Autism: A Cross-Cultural Evaluation of Double ABCX Model Using Structural Equation Modelling

F. M. Kodakkadan[1]*, E. M. Lee*[2] *and S. D. Stagg*[3]*, (1)Anglia Ruskin University, Cambridge, United Kingdom of Great Britain and Northern Ireland, (2)School of Psychology and Sport Science, Anglia Ruskin University, Cambridge, United Kingdom, (3)Anglia Ruskin University, Cambridge, United Kingdom*

Background: The causes of stress for parents of children with autism and improving resilience are key research areas concerned with the well-being and quality of life.There is a global acceptance of diagnostic criteria for ASD; however, cultural differences in values to what is considered normal development may influence the diagnosis despite the biological cause. Raising a child with Autism Spectrum Disorder (ASD) involves unique challenges, and specific cultural challenges are often not considered in research (Freeth et al., 2014).Cultural factors may influence how autism is experienced, recognised and explained in diverse communities. For example, information that might be helpful for one parent may be too complicated or even unclear for another parent due to cultural beliefs and values, socioeconomic status, religion and stigma.

Objectives: The present study is a cross-cultural comparison of the factors associated with stress and resilience among the parents of children with autism, between UK and India, based on the double ABCX model.

Methods: An online survey was conducted with 120 parents from the UK (Age M=38; SD= 5.9) and 120 parents from India (Age M= 40; SD=6.7) who have children with ASD aged between 3-16 years. The mental health of the parents and child adaptive behaviour (factor aA); Perceived social support and perceived emotional support (factor bB); Parental attitude (factor cC) and Parenting stress and resilience were considered as factor xX. A new factor, affiliate-stigma, has been included as a cultural factor that enhances stress. The measures used were parenting stress index (PSI-SF), brief resilience scale (BRS), mental health continuum (MHC-SF), Vineland adaptive behaviour scale (VABS), multidimensional scale of perceived social support (MSPSS), perceived emotional support scale (PES), family impact questionnaire (FIQ), and affiliate stigma scale (ASS).

Results: Parents in India reported higher levels of stress and lower levels of resilience than their UK counterparts. Path analysis showed that both in the UK and India, perceived social support, perceived emotional support, child adaptive behaviour inversely, and affiliate stigma directly contributes to parental stress. Apart from these, in the UK, Mental health inversely, and in India, the parental attitude directly adds parental stress. Mental health is a strong positive, and affiliate stigma a weak negative predictor of resilience in both groups. Perceived emotional support and child adaptive behaviour are negative predictors of resilience among the UK participants, whereas parental attitude is a negative predictor in India.

Conclusions: The findings indicate that the factors that contribute to elevated stress among Indian and UK parents included their lower level of child's adaptive level, perceived social and emotional support and higher affiliate stigma. The data collected will be used to develop a culturally specific model of stress and resilience. This research will help to develop new, culturally specific strategies to provide interventions that will help parents overcome stress and enhance resilience. This research may also help to increase clinician's awareness and cultural responsiveness in order to support UK and Indian parents.

318.003 *(Oral)* The World Health Organisation Caregiver Skills Training Intervention for Families of Children with Autism Spectrum Disorder: A Focus on Implementation Strategies in Resource-Limited South African Settings

L. Schlebusch[1]*, N. Chambers*[2] *and P. J. de Vries*[3]*, (1)Centre for Autism Research in Africa, Division of Child and Adolescent Psychiatry, University of Cape Town, Cape Town, South Africa, (2)Centre for Autism Research in Africa, Division for Child and Adolescent Psychiatry, University of Cape Town, Cape Town, South Africa, (3)Centre for Autism Research in Africa, Division of Child & Adolescent Psychiatry, University of Cape Town, Cape Town, South Africa*

Background: Implementing and scaling-up evidence-based early interventions into real-world settings is complex and challenging, and even more so in resource-limited contexts in low- and middle-income countries. Various barriers and facilitators across multiple contextual levels influence the success of getting interventions into practice.*Implementation strategies* are the techniques used to overcome the barriers and enhance the facilitators to increase the uptake of evidence-based interventions within service delivery systems. It is essential to track and report these strategies with sufficient detail in order to build a stronger evidence base for implementation strategies.

Objectives: The purpose of this naturalistic, observational study was to identify and describe the implementation strategies used to put the World Health Organisation Caregiver Skills Training (WHO CST) intervention into practice in real-life, resource-limited settings in South Africa.

Methods: We used the strategy tracking approach developed by Bunger and colleagues to generate detailed information about the types of strategies used during the different phases of implementation. This approach allowed us to gather retrospective and prospective data from a variety of project personnel. This presentation focuses on the retrospective data collected during the earlier planning and exploration phases of the project. This process entailed the recall and review of project calendars, project progress reports, meeting minutes and project files during the planning and preparation months. Data regarding the implementation strategies were extracted and included in an activity log that recorded all the implementation activities (actions, methods, events, or efforts to promote adoption and facilitation of the intervention, including the purpose, estimated length of time, and individuals involved). Data were then coded to identify distinct strategies. Using a consensus approach, two coders categorised each activity according to the ERIC taxonomy of implementation strategies.

Results: Our systematic documentation and classification of implementation strategies was useful for capturing and specifying a broad range of formal and 'behind the scenes' strategies that can be replicated in research and practice. The key actions identified during the planning and preparation phases included: (1) the development of stakeholder interrelationships, (2) the training and education of stakeholders, and (3) adapting and tailoring to the local context. As an applied example, we report on the type of strategy used, the action, actor, target, temporality, dosage (participants and hours of effort), outcome, and justification for each of the three main categories identified in this study.

Conclusions: The use and tracking of implementation strategies are particularly important in resource-limited settings, where a lack of resources with which to implement public health programmes necessitates that the project leadership and implementation teams utilise existing resources thoughtfully. Studying and documenting strategies used during the planning and preparation phases of implementing the WHO CST intervention in South African settings allowed us to capture strategies that may be extremely important, yet less observable and unique to resource-limited environments. Furthermore, it provides a more nuanced understanding of what it takes to implement interventions in resource-limited settings.

318.004 *(Oral)* Does Gender Matter for Intervention and Personalized Support? the Perspective of Francophone Autistic Women in Quebec

***I. Courcy**, Sociology, University of Quebec in Montreal, Montreal, QC, Canada*

Background: There has been a growing interest in the reality autistic women in recent years. The intersectional approach is proposed in social research in order to reveal the specific barriers faced by autistic women according to the intersection of their multiple social identities (Saxe 2017). Many suggest that interventions and formal support should be tailored to the specific experiences of these women. But what do *they* think about that?

Objectives: This exploratory research aims to present the perspective of Francophone autistic women on the interventions and supports offered to them in Quebec.

Methods: Participants (n=16) were recruited through a call for research posted on university bulletin boards and on social media. The participants are between 19 and 51 years old and live in Quebec (Canada). They have been diagnosed with ASD or Asperger's syndrome. Two interviews (in person or online) were conducted in French with each of the participants. The phenomenological analysis of the data (van Manen 1990) provided their perspective on the support services offered to them as they experience it as an autistic woman.

Results: Participants talked about gender as a social performance and convention and several gender inequalities were raised. The majority of them critiqued the predominantly "masculine" social representations of autism. Many regretted that girls and women are poorly represented in research and cultural productions.

They shared a vision of themselves that went against what they identified as attributes related to the traditional diagnostic categories based on the "male profile". For example, some said they were very empathetic, had an interest in helping relationships, and had “no interest in trains or mathematics”. Some participants felt that being a girl had contributed to their late diagnosis, obtained as a result of hospitalization for a mental health problem. Based on their personal experiences, some felt that autistic women are more at risk of abuse, exploitation or violence in relationships and jobs.

Many disagreed with behavioural interventions because they aim to “normalize” and “conform” them. Other forms of specialized support were perceived as "enclosing" them in the diagnostic category. Another criticism was the massive investment in genetic research at the expense of finding concrete solutions for people's everyday lives. Finally, participants said they wanted to seek professional training to help others. They explained the added value of their experience to better understand, intervene and support autistic people.

Conclusions: The results show an overall perceived mismatch between the needs of autistic women and the measures of support generally offered. The professionalization of some to intervene in the field of autism appears as a self-determining initiative in the autistic community. The results illustrate the interaction between the social identities of being women and being autistic. Other research is necessary to continue this exploration by integrating other social identities (e.g. ethnicity, social class, sexual orientation). Taking into account people's point of view from their own interpretation scheme is an ethical and relevant way to advance knowledge about the social experience of autism.

POSTER SESSION — INTERNATIONAL AND CROSS-CULTURAL PERSPECTIVES
426 - International and Cross-Cultural Perspectives Posters

426.001 *(Poster)* A Country Profile: Bulgarian Children with ASD

***M. Barokova** and H. Tager-Flusberg, Department of Psychological and Brain Sciences, Boston University, Boston, MA*

Background: Bulgaria has a population of 7 million, out of which 670,000 are children between 0 and 9 years. Currently, there are no official statistics on the number of ASD diagnoses. However, the increasing number of conferences for clinicians, and workshops for parents, combined with the establishment of treatment/intervention centers around the country suggests that there is a growing awareness and demand for ASD services. Yet, little is known about the unique country/culture/language-specific characteristics of Bulgarian children with ASD, and these need to be considered in the choice and design of treatment/intervention services.

Objectives: I. To characterize an urban Bulgarian sample of children with ASD in terms of demographics, symptom severity, non-verbal IQ, and expressive vocabulary. **II.**To examine change in those characteristics one year later as a measure of effectiveness of already utilized treatments.

Methods: Thirty-eight children (9females) between the ages of 2;7 and 8;10 (*M*age=5;9) were recruited from local resource centers. All children had a community diagnosis of ASD or PDD based on ICD-10 criteria. In this study, diagnoses were confirmed with the ADOS. Participants were administered the MSEL Fine Motor (FM) and Visual Reception (VR) subscales to obtain a measure of non-verbal IQ. Participants’ parents filled out a demographic questionnaire, and the Bulgarian adaptation of the MCDI: Words and Sentences to obtain a total raw score of number of words the child uses. There were two data collection waves: N=20 in summer 2018, and N=18 in 2019. Twelve children from 2018 were re-tested in 2019 following the same procedure.

Results: I.Profile: There was a wide range of symptom severity, non-verbal IQ, and language ability in our sample (Table.1). The majority of parents had a college degree and average income (Table.1). Children’s MCDI raw scores were negatively correlated with their ADOS total scores ($r(35)=-.576$, $p<.01$), and positively correlated with their MSEL FM ($r(28)=.779$, $p<.01$) and VR raw scores ($r(25)=.748$, $p<.01$).

II.Assessment of Change: For the 12 (2 F) re-tested participants, there was a significant increase in MCDI scores (Z=-2.134, p<.05), MSEL FM (t(9) =-2.58, p<.05) and VR scores (t(8)=-2.32, p<.05), but no change in ADOS scores. Children's MCDI scores at T2 were correlated with their MCDI scores (rs(10)=.874, p<.01), MSEL FM (rs(8)=.879, p<.01), VR scores (rs(8)=.827, p<.01) at T1.

Conclusions: Our urban Bulgarian sample was marked by heterogeneity in all examined characteristics consistent with the literature on children with ASD from other countries. Even though all participants' native language was Bulgarian, more than half were exposed to English. Parents revealed that exposure came from educational videos, and that their children used many English words. This warrants further investigation of the nature of the exposure, and how it relates to children's language. Nevertheless, children's vocabulary in Bulgarian was associated with their symptom severity, and non-verbal IQ as reported in the literature, and similar associations were found across time. It remains to be determined whether the reported changes in ability across time are the result of development or of the increasing number and quality of services becoming available in Bulgaria, like ABA, ESDM, and OT.

426.002 *(Poster)* A Qualitative Look at the Autism Diagnostic Interview-Revised Spanish

M. E. Jaramillo[1] *and S. Magaña*[2]*, (1)University of North Carolina, Chapel HIll, Chapel Hill, NC, (2)University of Texas, Austin, Austin, TX*

Background: Autism diagnostic instruments, such as the Spain-based rendition of the Autism Diagnostic Interview-Revised (ADI-R; Lord, 1994) may not match the cultural and linguistic needs of Latin American families, both in the U.S. and in Latin America. Both the wording of the translations and the cultural context of the respondents may impact the culture-based construct validity of the instrument.

Objectives: The purpose of this study was to qualitatively assess the culture-based construct validity of select ADI-R items for use among Spanish-speaking populations, including Latina mothers of children with Autism in Guatemala and the U.S.

Methods: There are two unique phases of this study. First, we conducted a qualitative analysis of how U.S.-based Latina mothers responded to select ADI-R items. We drew from a sample of 50 Spanish speaking mothers from a sample of 50 previously recorded and de-identified administrations of the ADI-R Spanish (Magana, 2017). Phase one participants were recruited from clinics and parent support groups in two Midwestern U.S. cities (Magana, 2017). In this phase, we used inductive analysis to explore theories of cultural mismatch of the items and deductive analysis to generate themes that characterize how mothers are reporting symptoms. In the second phase, we conducted cognitive interviews with 7 mothers of children with Autism living in Guatemala. Mothers were probed on ten specific ADI-R items (selected by analyzing the results from the U.S.-based sample) to discuss how they perceived the questions. Inductive and deductive analysis was conducted by a primary and secondary coder to develop a thematic codebook.

Results: We identified various themes, including terminology and concept mismatch, respondent-introduced vocabulary, child-caretaker language mismatch concerns. Terminology was a common issue. For example, "*pronunciación* (pronunciation)" versus "*articulación* (articulation)" caused some confusion. There were also some conceptual mismatches, such as with the phrases "*frases raras* (weird phrases)" as well as, "small talk" and "hobby". Respondent-introduced vocabulary for child behaviors, particularly related to speech, social communication, and socially inappropriate behaviors. For example, mothers used the terms "*mochos*" and "*chipilón*" to describe their child's speech production. Lastly, analysis of the responses revealed that some U.S.-based Latina mothers may feel they cannot adequately judge their child's communication abilities due to language differences in the parent-child dyad.

In the Guatemalan sample, impressions and reactions to the ADI-R Spanish were overall positive as mothers valued the utility of the instrument in helping researchers, clinicians and families better understand Autism and their child's development. Mothers found the ADI-R Spanish tends to be wordy and would prefer questions be asked using more direct language. There was one item which some mothers pointed out as offensive and inappropriate due to the terminology used to describe a child with autism.

Conclusions: Latina mothers recognize the importance of measures like the ADI-R Spanish; yet cultural challenges are apparent. Themes were consistent across two samples and two qualitative methods. Results obtained will inform our future exploration of the cultural appropriateness of the ADI-R items and their use in research and clinical work with families of children with autism from Latinx backgrounds.

426.003 *(Poster)* Autism Services in Taiwan: Examining How Parents of Children with Autism Spectrum Disorder Perceive and Select Intervention Options

H. S. Ho[1]*, H. T. Wang*[2] *and A. Perry*[3]*, (1)York University, Markham, ON, Canada, (2)National Taiwan Normal University, Taipei, Taiwan (Province of China), (3)Psychology, York University, Toronto, ON, Canada*

Background: Although there currently does not exist a cure for ASD, an overwhelming number of interventions exist, with only a small subset of these interventions grounded in research. For parents, the selection of interventions for their child is one of the first decisions they must make following their child's diagnosis and, despite their best efforts, studies have shown that some parents engage in interventions that are ineffective, lack evidence, or are even harmful (Green, Pituch, Itchon, Choi, O'Reilly, & Sigafoos, 2006). Much of the literature related to decision-making is based within a Western cultural context, and less is known about how parents from other cultural backgrounds (e.g., Chinese) make these complex decisions.

Objectives: This study will expand on the limited knowledge on what types of interventions parents in Taiwan have used, are currently using, and would like to use. Specifically, this study will examine parents' knowledge of and attitudes towards ASD and various ASD interventions, and will identify factors that contribute to parents selecting or rejecting certain interventions for their child.

Methods: Framed within the Health Belief Model, a questionnaire was developed to examine parent knowledge, attitudes, and practices related to ASD and ASD interventions. Parents were asked 10 true/false questions about their knowledge of ASD and 11 questions, on a Likert-type scale, on their attitudes about ASD. Parents were also asked about what types of ASD services they are using, would like to use, or have previously used. In total, 170 parents who have a child (2 to 18 years old) with ASD in Taiwan completed the survey.

Results: Preliminary analyses show that, overall, parents had a good knowledge of ASD. Although the majority (86.9%) of parents had positive attitudes about their child's life, most parents (83.4%) also reported feeling stress due to their child's diagnosis. When deciding on an ASD intervention, parents rated distance, cost, and recommendations from medical professionals as the most important factors they consider. In terms of which services parents felt were most beneficial to their child's outcome, parents rated occupational therapy (40.6%), followed by applied behaviour analysis (13.7%), and parent training (12.6%) as the top services.

Conclusions: Preliminary results suggest that, although parents have a good understanding about ASD, there are still many barriers that exist for service utilization. In further analyses, we will examine what factors influence parental decision-making in selecting ASD interventions. A better understanding of how parents in Taiwan perceive ASD and ASD treatments may help inform future public health policy to address barriers that exist for parents.

426.004 *(Poster)* Barriers to Access Health Care Among Brazilian Children and Adolescents with Autism Spectrum Disorders

C. S. Paula[1], *B. Araripe*[2], *D. Bordini*[3], *G. R. Cunha*[4], *A. Rattazzi*[5], *A. Rosoli*[6], *C. Montiel-Nava*[7], *D. Valdez*[8], *G. Garrido*[9], *R. A. Garcia*[10], *S. H. Cukier*[5], *J. J. Mari*[2] *and S. C. Caetano*[2], *(1)Developmental Disorder Program, Universidade Presbiteriana Mackenzie, São Paulo, Brazil, (2)Psychiatry, Universidade Federal de São Paulo, SÃO PAULO, Brazil, (3)Departament of Psychiatry, Federal University of São Paulo, Sao Paulo, Brazil, (4)Departament of Psychiatry, Federal University of São Paulo - UNIFESP, São Paulo, Brazil, (5)PANAACEA, Buenos Aires, Argentina, (6)Projects, Organizacion Estados Iberoamericanos, Santo Domingo, Dominican Republic, (7)Psychological Science, University of Texas Rio Grande Valley, Edinburg, TX, (8)Universidad de Buenos Aires- FLACSO, Buenos Aires, Argentina, (9)Universidad de la República, Montevideo, Uruguay, (10)Clínica Las Condes, Santiago, Chile., Santiago, CHILE*

Background: Most people with autism spectrum disorder (ASD) from low-middle income countries face major barriers to receive satisfactory treatments from the health care systems. Lack of infrastructure is usually one of the main obstacles to access care, but sociodemographic factors can play a role in the process. Identifying such factors could help promote better assistance for the ASD population.

Objectives: to identify sociodemographic characteristics related to the received health treatments and barriers of access among Brazilian children/adolescents with ASD.

Methods: Study Design: Cross-sectional study. Sample: 927 families from all of five Brazilian regions who had children with ASD aged 3-17 years. Instrument: Brazilian version of the Caregivers Needs Survey questionnaire developed by Amy Daniels & Autism Speaks and completed online. Four multiple logistic regression analyses were used to identified predictors of the main health services received and the main barriers to access to treatment.

Results: The most commonly received treatments were behavioural intervention (32.4%) and drug treatments (28.1%). The main access barriers were structural: waiting lists (59.6%) and costs (38.7%). Health care received and barriers faced by individuals with ASD varied according to familial/individual sociodemographic characteristics: (1) families who exclusively used the public health service ($p < 0.01$) and whose parents/caregivers had lower education ($p < 0.01$) had a reduced chance of accessing **behavioural intervention**; (2) younger children (3-6 years old) received less **medication** than older children/adolescents ($p < 0.01$); (3) younger children (3-6 years old; $p < 0.01$); public health users ($p < 0.01$; 95%); children of less-educated parents/caregivers ($p = 0.04$); and those living in a state capital ($p = 0.04$) reported more problems with **waiting lists**; and (4) health insurance/private users ($p = 0.08$) faced more difficulties to access care than public health users, due to **cost of treatment**.

Conclusions: Brazilian families of children/adolescents with ASD face significant barriers to access to care that are influenced by children/adolescent's age, the region of residence, type of health care system used and the parents/ caregivers' education.

426.005 *(Poster)* Characteristics of AI/an Children and Families Referred for ASD Evaluation in Rural and Urban New Mexico

E. Geib[1], *B. Rennie*[2], *C. Vining*[3] *and C. Burnette*[4], *(1)Pediatrics, Center for Development and Disability, University of New Mexico, Albuquerque, NM, (2)University of New Mexico, Center for Development and Disability, Albuquerque, NM, (3)Pediatrics, University of New Mexico, Albuquerque, NM, (4)Integrated Center for Autism Spectrum Disorders, University of Nebraska Medical Center Munroe-Meyer Instittute, Omaha, NE*

Background: A limited amount of research is available about Autism Spectrum Disorder (ASD) in American Indian or Alaska Native (AI/AN) children in the United States. The most recent ADDM Network review gathered information about diagnosis and treatment in a population sample with less than 1% AI/AN children (Baio, Wiggins, Christensen, et al., 2018) and reported no statistics on age of diagnosis or disparities. Mandell et al. (2002, 2009) reported that AI/AN students among other minorities were less likely to be identified with ASD. Tincani, Travers, and Boutot (2009) hypothesized lack of access to adequate health care as a major barrier to AI/AN children obtaining an adequate diagnosis of ASD. New Mexico is a frontier state due to its low population and barriers to accessing resources. About 10% of its population is AI/AN with nineteen Pueblos, two Apache tribes, and the Navajo Nation. In light of the minimal amount of research, it is imperative to understand the characteristics of AI/AN children referred for a diagnostic evaluation for ASD in order to reduce barriers and provide adequate care.

Objectives: We compared referral sources, urban vs. rural area, age of diagnosis, and characteristics of ASD and neurodevelopment (i.e., language and cognitive abilities) between AI/AN and white children referred for clinical evaluation of ASD in New Mexico.

Methods: Analysis consisted of 68 AI/AN and 381 white children evaluated at UNM's Autism Spectrum Evaluation Clinic (ASEC) compiled data using information from clinical evaluations. Rural definition was based on the Office of Management and Budget (OMB) counties in New Mexico.

Results: Sixty-five percent of AI/AN children evaluated received a diagnosis of ASD in contrast with 57% of White children, which was not a significant group difference ($t = 1.15$, $p = 0.25$). Twenty-four percent of the AI/AN families were considered rural, the majority of referrals (43%) come from PCPs, and the average age of evaluation was 6 years old for AI/AN children, no group differences were found. Forty-six percent had received early intervention in contrast to White children (51%), and 19% had already received an educational eligibility of autism in contrast to 25% of White children. These differences did not reach statistical significance. Fifty percent of AI/AN who received a diagnosis of ASD also received a Language Disorder diagnosis, a significant difference to the 30% of White children, $t = 2.48$, $p = 0.014$. No significant group difference was found for children with ASD and a diagnosis of Intellectual Disability or Global Developmental Delay.

Conclusions: Our analysis provides a first step in understanding characteristics AI/NA referred for ASD evaluation. No significant group difference based on race (AI/AN vs. White) was found for referral sources, urban vs. rural area, age of diagnosis. A significant difference was found for children who receive diagnoses of ASD and Language Disorder. Future directions include clarifying the difference in language profiles of AI/AN children diagnosed with ASD and assess barriers and access to diagnostic evaluations.

426.006 *(Poster)* Combining Parents Taking Action and Pivotal Response Training to Support Latinx Mothers of Children with ASD

K. Lopez[1] *and M. Carrasco*[2]*, (1)Arizona State University, Phoenix, AZ, (2)School of Social Work, Arizona State University, Phoenix, AZ*

Background: In 2018, approximately 59.9 million Latinx people resided in the United States, of which 18 million were children (Pew Research Center, 2018; 2019). Although the Latino population comprises the largest ethnic minority group in the US, there have been identified disparities in ASD diagnosis and treatment access. Few diagnostic tools and intervention programs have been designed and explored for use with Latino children with ASD and their families. Parents Taking Action (PTA), is a culturally informed intervention program for Latinx families. PTA has been effective to enhance parent outcomes and improve use of services for Latinx children with ASD (Lopez et al., 2019). However, PTA has traditionally been a didactic program. Previous participants have requested behavioral coaching with their children in order to enhance the impact of the didactic format of PTA. In this study, we supplemented PTA with pivotal response training (PRT) sessions with Latina mothers of children with ASD. PRT was selected as the behavioral coaching model, given the emphasis on using naturalistic opportunities to enhance children's functional skills and communication. By including PRT with PTA, this study provides insight into culturally informed intervention along with the utility of PRT with a culturally diverse sample.

Objectives: Explore the impact of a culturally informed program and pivotal response training support on Latina mothers' use of intervention strategies.

Methods: Ten Latina mothers of children diagnosed with ASD were recruited for participation. Due to the attrition of three mothers, this study includes data from the seven mothers who completed all study components. Children were aged 2 to 7 years (See Table 1). Mothers received 14 2-hour sessions of the PTA program in their homes, from two *promotoras* (community healthcare workers). PTA content covers general information about ASD, treatment services, advocacy, self-care, and strategies to enhance children's social communication. Mothers also received 4 one-hour sessions of pivotal response training (PRT) from bilingual/bicultural coaches. Mothers completed questionnaires regarding child, parent, and family outcomes pre-intervention, post-intervention, and follow-up. Ten minutes of parent-child interaction were audio-visual recorded at these time points, if mothers agreed to the taping. We conducted paired sample t-tests to assess for changes in mothers' efficacy in using the strategies and frequency of using the strategies. Ongoing coding of parent-child interactions is currently underway.

Results: Paired samples t-tests indicated that mothers' report of efficacy in using the strategies and frequency of using the strategies was significantly greater after completing the intervention program (see Table 2).

Conclusions: The results of our study indicate that Parents Taking Action and PRT coaching have a positive impact on Latina mothers efficacy in using intervention strategies with their children. The study offers a unique and culturally informed model of intervention that fills the gap in need Latinx families experience as they raise children with ASD. Given the growing number of Latinx children diagnosed with ASD, this culturally informed intervention program offers a solution to the lack of ASD interventions designed for Latinx families of children with ASD. Limitations and implications of this study will be discussed.

426.007 *(Poster)* Cross-Cultural Differences in Vaccine Hesitancy and Attributions for Autism in Parents of Children with Autism

J. Chang[1] *and R. P. Goin-Kochel*[2]*, (1)Pediatrics, Texas Children's Hospital/Baylor College of Medicine, Houston, TX, (2)Baylor College of Medicine, Houston, TX*

Background: Vaccine hesitancy refers to a continuum of concerns about vaccines, including acceptance of vaccines in light of questions about their safety, as well as delays/refusals of some or all vaccines. In a recent study of 225 parents of children with autism spectrum disorder (ASD), 29% of parents were vaccine hesitant; significantly higher proportions of parents of color (collectively, Asian, Black, Hispanic, Other, or Bi-/Multi-Racial; 49%) were vaccine hesitant compared to White parents (22%; $p<.001$), which suggests important differences in beliefs about a link between ASD and vaccines across cultures.

Objectives: To (a) calculate the prevalence of vaccine hesitant parents (VHPs) within the SPARK (Simons Foundation Powering Autism Research for Knowledge) cohort, specifically across racial/ethnic groups; (b) compare beliefs about causes of ASD between hesitant and non-hesitant parents and across racial/ethnic groups; and (c) examine beliefs in causes of ASD and sociodemographic factors (e.g., parents' race/ethnicity, education level, household income) as predictors of vaccine hesitancy.

Methods: 8,854 SPARK parents completed the *Parents Attitudes about Childhood Vaccines* questionnaire (PACV; measure of vaccine hesitance) and the *Revised Illness Perception Questionnaire-ASD* (IPQ-R-ASD; measure of attributions for child's ASD). Descriptive statistics were calculated to determine prevalence of VHPs across racial/ethnic groups and other sociodemographic factors. Chi-square analyses compared sociodemographic characteristics between hesitant and non-hesitant groups, as well as personal beliefs about causes of children's ASD (IPQ-R-ASD Cause scale) across racial/ethnic groups.

Results: 22% of parents (n=1,962) were vaccine hesitant (PACV score≥50). VHP were less likely to be White (p<.0001) and were more likely to be American Indian (p=.0016), Black (p<.0001), Other (p<.0001), or Hispanic (p<.0001). Regarding causes, VHPs were more likely to attribute accident/injury (32% vs. 21%; p<.0001), alcohol consumption (31% vs. 22%; p=.0033), deterioration of child's immunity (57% vs. 17%; p<.0001), diet (40% vs 18%; p<.0001), environmental pollution (34% vs. 16%; p<.0001), worries about ASD (35% vs. 21%; p<.0001), general stress (27% vs. 20%; p<.0001), germ/virus (44% vs. 19%; p<.0001), in utero stress/accident (24% vs. 21%, p=.0003), negative attitudes (33% vs 22%; p<.0001), own decisions (30% vs. 21%; p<.0001), own emotional state (25% vs. 22%; p=.0035), poor medical care (50% vs. 20%; p<.0001), stress at birth (30% vs. 19%; p<.0001), and toxins in vaccines (78% vs. 10%; p<.0001) as causes of their child's ASD. In contrast, VHP were less likely to endorse chance (16% vs. 24%; p<.0001), parental age (19% vs. 23%; p=.0006), child's brain structure (17% vs. 31%; p<.0001), and genetics (18% vs. 35%; p<.0001) as causes. Further analyses examining racial/ethnic differences in endorsement of causes and predictors of vaccine hesitancy are forthcoming.

Conclusions: VHPs were less likely to endorse known causes of ASD (e.g., age, brain structure, and genetics) as causes of their child's ASD. Given similarities in this cohort compared to earlier work, it is expected that there will be different patterns of agreement with causes of ASD as a function of race by hesitancy status. This information may inform the design of targeted, preemptive educational information about vaccine safety that may need to be tailored to different cultural groups.

426.008 *(Poster)* Cross-Linguistic Evaluations of Language and Communication Among Bilingual (English/Spanish), Latino Children with Autism Spectrum Disorders

***S. Vanegas**, School of Social Work, Texas State University, San Marcos, TX*

Background: Latino children are affected by significant disparities in the diagnosis and treatment due to a number of cultural and linguistic factors (Zuckerman et al., 2014). A primary concern among Latino parents in the U.S. is whether bilingual exposure will result in further delays in their child's language and communication development. Emerging research on bilingual children with ASD finds little to no differences on early language milestones/development (e.g., vocabulary knowledge; Hambly & Fombonne, 2012; Petersen, Marinova-Todd, & Mirenda, 2012). However, most studies are based on retrospective review of clinical and educational records and parent's recall of child's early development. It is also unclear whether language profiles of bilingual children can be adequately measured by a single instrument and whether clinical and cognitive factors contribute to the development of both languages among bilingual children with ASD.

Objectives: The objective of this research is to compare English and Spanish profiles of bilingual, Latino children with ASD across multiple language measures and to examine underlying clinical and cognitive factors.

Methods: Latino children were eligible to participate if they had a prior ASD diagnosis, were between 6 and 14 years of age, and used verbal language to communicate in English and Spanish. Parents completed a battery of demographic and research questions, including the Language Background and Experience Questionnaire, the Social Communication Questionnaire, and the Behavior Rating Inventory of Executive Function (BRIEF). Children completed the Raven's Standard Progressive Matrices, core language and word association subtests from the Clinical Evaluation of Language Fundamentals-4th version, and two narratives based on the Frog, where are you? series by Mercer Mayer. Children completed all language measures in both English and Spanish, with each language assessed in separate sessions. To date, 13 children with ASD have participated in the research study, recruitment is ongoing.

Results: For the majority of the children (92%), Spanish was the first language learned, with most children learning their second language at 4.5 years of age. No significant differences were found across CELF-4 English and CELF-4 Spanish subtests (all p's > .05). Additional analyses found that BRIEF Global Executive Composite scores were negatively associated with CELF-4 English Core Language scores, $r(9) = - 0.827$, $p = .006$, CELF-4 English Expressive Language scores, $r(9) = -.718$, $p = .029$, and the CELF-4 English Word Association scores, $r(11) = -.615$, $p = .044$. Additionally, SCQ total score was positively associated with CELF-4 Spanish Word Association scores, $r(11) = -.653$, $p = .029$. Further analyses will explore these associations in a larger sample and will examine children's linguistic profiles in a narrative task administered in English and Spanish.

Conclusions: The preliminary analyses suggest that clinical and cognitive symptoms may function in a distinct manner in bilingual, Latino children with ASD. Executive functioning was found to be related to English language skills; whereas ASD symptoms were related to more efficient retrieval of semantic information in Spanish. The results of this can be used to inform culturally-sensitive interventions and therapies that can support the development of bilingual children with ASD.

426.009 *(Poster)* Determining Future Directions for Parent Education & Training Programmes in Autism Spectrum Disorder

***J. J. S. Dawson-Squibb**[1] and P. J. de Vries[2], (1)Division of Child & Adolescent Psychiatry, University of Cape Town, Cape Town, South Africa, (2)Centre for Autism Research in Africa, Division of Child & Adolescent Psychiatry, University of Cape Town, Cape Town, South Africa*

Background: The World Health Organization has recognised Autism Spectrum Disorder (ASD) as a public health concern and have recommended access to appropriate assessment and interventions. Psychoeducation and parent support soon after diagnosis are considered global best practice. Parent Education & Training (PET) programmes provide education, skills and support to parents. Despite the high need for PET there has been limited research in this field and few programmes are available, particularly in low- and middle-income countries (LMIC).

Objectives: To determine future directions for Parent Education & Training programmes in low-resource environments by 1) evaluating the broader evidence-base of PET; 2) conducting a comparative feasibility study of two PET programme in South Africa.

Methods: A scoping review of all peer-reviewed publications outside the USA was conducted. Two reviewers independently searched seven key databases for titles and abstracts. Four reviewers extracted data with a focus on descriptive characteristics of PET programmes, research methodologies and implementation factors. A mixed-methods quality appraisal of publications was performed. A comparative feasibility study of two PET programmes in a low resource setting was also conducted. EarlyBird/EarlyBird Plus (EB/EBP), a UK developed 12-week programme was compared to Autism Cares (AC), a locally developed 5-day programme. A mixed method, quasi-experimental design was used to collect pre, post, and 3-month follow-up data. Measures included standardised and custom-designed quantitative outcome measures and qualitative semi-structured interview data. A multi-stakeholder group used an ASD PET evaluation framework to compare the programmes.

Results: A total of 37 publications were found in the scoping review. These described a highly diverse range of PET programmes across 20 countries. Programmes varied significantly in their goals, modalities and length. A broad range of outcomes measures were used. Quality appraisal rated only 27% of studies to have met all the methodological quality criteria. Factors relevant to implementation such as manualisation, fidelity and cost were commented on infrequently.

In the comparative feasibility study eighteen parents participated in the EB/EBP programmes and eleven in Autism Cares. Strong parental acceptability for both programmes was found along with the need for some adaptations to the local context. Limited efficacy testing showed positive changes for parental stress, knowledge of ASD and changes in child, more so for EB/EBP. The multi-stakeholder group judged EB/EBP as most suitable for next-step research citing factors relating to implementation including scalability and sustainability.

Conclusions: Our findings contributed to the limited evidence-base for ASD PET in low-resource environments and highlighted the need for global collaboration in this area. We propose the following five recommendations for future directions of PET programmes: 1) expansion of local PET research in different settings; 2) creation of standardised outcomes for PET through involvement of global stakeholders; 3) dissemination of PET findings and lobbying of potential funders; 4) setting up of a global PET network; 5) caution around implementation of PET programme without a robust evidence-base that includes intervention outcomes as well as implementation outcome data.

426.010 *(Poster)* Diagnostic Patterns and School Placement Outcomes in Children with Autism Spectrum Disorder in Singapore

***M. Wong**, N. Mohd Zambri, T. Teo and H. C. Koh, Department of Child Development, KK Women's and Children's Hospital, Singapore, Singapore*

Background: Early identification of children with Autism Spectrum Disorder (ASD) leads to early access to intervention and better outcomes. The estimated prevalence in Singapore is 1%, although there are no national prevalence data. KK Women's and Children's Hospital (KKH) is the larger of two national Child Development Programme (CDP) assessment centres focusing on preschool diagnosis and intervention. KKH sees approximately 70% of national CDP referrals and utilises an ASD-specific interview and the Autism Diagnostic Observation Schedule (ADOS),with reference to the DSM criteria for diagnostic confirmation. Children who meet DSM criteria but whose parents declined the ADOS would be given a clinical diagnosis of ASD.

Objectives: This study aimed to examine diagnostic patterns (e.g. age of presentation with ASD, diagnostic trends) and school placement outcomes in children with ASD at a tertiary level child development centre in Singapore.

Methods: A retrospective review of clinical records was conducted from 2017 to 2019, for children who were born in years 2008, 2009, 2010 or 2011, and who received a diagnosis of ASD or who were referred to the ASD Clinic.

Results: Data were collected from 2577 children (82.7% males, 66% Chinese). 1859 (72.1%) underwent an ADOS and 1805 (97.1%) were confirmed to have ASD. On longitudinal follow-up, 2205 continued to have an ADOS or clinical diagnosis of ASD.

Of these 2205, although 1643 (74.5%) had an initial clinical diagnosis of ASD, a further 241 (10.9%) were initially diagnosed with Developmental Language Disorder and 240 (10.9%) with Global Developmental Delay.

There was a significant effect of birth-cohort on the age of presentation (Welch's $F(3,1182)=13.2$, $p<0.001$). Children with ASD born in 2011 presented at higher numbers and an earlier age ($n=607$, *M(SD)*=3.07(0.90) years), than those born in 2010 ($n=582$, *M(SD)*=3.27(1.04) years), 2009 ($n=567$, *M(SD)*=3.25(1.04) years) and 2008 ($n=449$, *M(SD)*=3.45(1.05) years).

There was also a significant effect of race on the age of presentation ($t=5.8$, $p<0.001$). Chinese children with ASD presented at an earlier age ($n=1447$, *M(SD)*=3.16(1.00) years), than those of other races (Malay, Indian, Eurasian and Others) ($n=757$, *M(SD)*=3.42(1.03) years).

There was no significant effect of gender on the age of presentation.

School placement outcomes were available for 1428 of the 2205 with a final diagnosis of ASD. 685 (48.0%) went to mainstream primary schools, 321 (22.5%) went to a specialised ASD school offering mainstream curriculum, 297 (20.8%) went to specialised ASD programmes offering functional curriculums, and 125 (8.8%) went to specialised schools for intellectual disability. Of the 685 children in mainstream, 240 (35.0%) were originally recommended specialised school placement following formal psychological school readiness assessments.

Conclusions: The age at which children with ASD first present to child development services has shown a decrease across the years. The effect of race warrants more investigation as to whether this is due to social inequalities, or differing cultural awareness of ASD. Having data on school placement outcomes will also guide resource allocation to tailoring appropriate mainstream or specialised school support where it is most needed.

426.011 *(Poster)* Disparities in Access to Autism Services Funding By Aboriginal Status Among Children in British Columbia, Canada

***M. Ressel**[1] and G. Iarocci[2], (1)Simon Fraser University, Burnaby, BC, Canada, (2)Psychology, Simon Fraser University, Burnaby, BC, Canada*

Background: Although rates of disability among Aboriginal children are twice that of all Canadian children (Di Pietro & Illes, 2016), the exact prevalence of Autism Spectrum Disorder (ASD) among Aboriginal children in Canada remains unknown. Government data suggest that the rates among Aboriginal children and non-Aboriginal children are similar, but that Aboriginal children may receive experience delays in ASD diagnosis.

Objectives: Given early access to ASD services has been shown to improve outcomes for children with ASD and their families (Bhopti, Brown, & Lentin, 2016), and the importance of equitable representation of children of all backgrounds in research (Di Pietro & Illes, 2014); the goals of this project were to: 1) assess differences in average age of ASD diagnosis between Aboriginal and non-Aboriginal children in British Columbia (BC) and, 2) depict the dispersion of registered autism service professionals, as a potential means of understanding disparities in access to autism services.

Methods: The ministry that oversees ASD service funding in BC shared data (December 2014 – August 2017) with the second author on the average age ASD funding case opened, and number of children receiving ASD funding, by aboriginal status, funding age category (under age 6, 6 - 18 years), and service delivery area (SDA). Descriptive analyses were conducted to compare the average age of ASD diagnosis, and proportion of Aboriginal and non-Aboriginal children receiving ASD funding in each age category and SDA, as well as in BC overall, and to identify the number of registered autism service providers in each SDA. Age disparities and dispersion of registered autism professionals will be depicted visually via a map of BC.

Results: Preliminary results suggest Aboriginal children comprise 9.98% of the population of all children in BC under age six, but receive only 7.18% of the ASD funding. For children six to 18 years, Aboriginal children represent 9.93% of the population and receive 6.71% of ASD funding. With regard to age disparities, Aboriginal children in BC receive ASD funding 4.08 months later than non-Aboriginal children in the under age 6 program, and, 6.40 months later, in the 6 –18 program. In two of the 13 SDAs, there are fewer than 10 registered autism providers, however, these do not coincide with SDAs with the greatest age disparities.

Conclusions: Aboriginal children in Canada face significant health disparities and underrepresentation in research. However, little remains known regarding ASD among Aboriginal children in Canada and internationally. Research on specific health disparities represents a critical step in addressing this inequity. Preliminary analyses suggest Aboriginal children may be less likely to access and/or experience delays in accessing early intervention services compared to non-Aboriginal children, and these disparities do not appear to be due to limited access to registered autism professionals in rural and remote locations. The project findings have the potential to increase awareness of disparities in research and service provision among Aboriginal children, and serve as a catalyst for developing public policies and services that address the specific needs of Aboriginal children with ASD in Canada.

426.012 *(Poster)* Disparities in Reported T-Scores of the 65-Item SRS and 16-Item SRS By Social Demographic Characteristics

P. C. Tsai[1], *R. A. Harrington*[1], *F. W. Lung*[2] *and L. C. Lee*[1], *(1)Department of Epidemiology, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, (2)Calo Psychiatric Center, Pingtung, Taiwan*

Background: The Social Responsiveness Scale (SRS) is an instrument that characterizes quantitative impairments in social reciprocity that define Autism Spectrum Disorder (ASD). This tool is able to assess autistic traits in large population-based studies because it quantifies dimensional impairments of ASD, and can be used in different settings against different norms and subgroups such as gender, age, or racial/ethnical background. Nevertheless, the 65-item SRS includes many items that are sensitive to (and can be influenced by) multiple factors, such as expressive language, global developmental level, behavior problems, age, and gender, according to previous studies. Therefore, a 16-item short form has been developed to only include items that are not significantly affected by those factors in the measurement of ASD symptoms.

Objectives: To compare internal consistency of the 65-item SRS (i.e. full form) and 16-item SRS (i.e. short form), and to examine disparities in reported T-scores of the full form and short form by child sex and social demographic characteristics in a community population of children aged 6-8 years.

Methods: The SRS data were collected by an epidemiologic autism study conducted in Pingtung, Taiwan. A total of 2917 caregivers completed the SRS for 1401 male and 1516 female children. Cronbach's alpha was calculated to evaluate the internal consistency. T-scores of both forms are standardized by the whole population.

Results: The short form demonstrates good internal consistencies with Cronbach's alpha values of 0.8 or above for both sexes and combined group. The T-scores of the full and short forms are almost identical with similar distribution patterns across all the social demographic characteristics such as child's birth order, mother's education, father's education, and respondent's education. Male children have higher SRS T-scores than female children. As for the respondents, other relatives reported the highest scores and teachers reported the lowest scores. In addition, biological fathers reported higher scores than did biological mothers. Furthermore, children whose parents have a higher education level were more likely to be rated with lower SRS T-scores. When categorized by respondent's education level, the pattern of SRS T-scores was consistent with the parents' education level. The above-mentioned results are true for both full and short form T-scores.

Conclusions: As expected, Cronbach's alpha is lower for the short form than the full form; however, the short form still has good internal consistency. T-score distributions of both forms are almost identical. Reported T-scores in both forms have the same patterns by social demographic characteristics. That is, the disparity of reported SRS scores remains the same even in the short form, which was designed to remove potential biases due to multiple child factors. Since the reported patterns and T-score distributions are almost identical in the full and short forms, our findings support considering the use of the 16-item SRS short form as a substitute for the 65-item SRS to save time from administering the longer tool. This consideration is particularly important for a large-scale population-based study to make implementation more feasible.

426.013 *(Poster)* Early Identification for Developmental Delays and Autism in Vietnam: Roles of Care-Givers and Health Providers

H. Hoang[1], *H. S. Vu*[1], *P. Hoang*[2], *C. Q. Tran*[2], *N. Tran*[2] *and N. Tran*[3], *(1)Center for Creative Initiatives in Health and Population, Hanoi, Viet Nam, (2)Center for Creative Initiatives in Health and Population, hanoi, Viet Nam, (3)Administration for Medical Service, Ministry of Health, Hanoi, Viet Nam*

Background: Early detection and early intervention of autism and other developmental disorders plays a crucial role in maximizing the development of children with these conditions. In Vietnam, child's development monitoring is not included within routine health check-ups and is not well aware by parents. Thus, many children at risk of developmental disorders are not detected early enough leading to missed opportunities for interventions at the most effective time. This paper describes a pilot for two screening models for developmental disorders, using an on-line platform, A365.vn, available in Vietnam. These models are; 1) integrating screening into primary health-care for children, 2) enabling caregivers to undertake screening for their children. The screening tools: CDC Milestones Tracker, Age and Stage Questionnaire (ASQ)-3, Modified Checklist for Autism in Toddlers revised (M-CHAT-R; for caregivers) and M-CHAT-R with follow up (M-CHAT-R/F (for health workers)) were used in the pilot.

Objectives: To describe the implementation process and results of piloting these screening models.

Methods: In Model 1, healthcare workers are trained to use and integrate the CDC, ASQ-3 and M-CHAT-R/F tools into routine child-health care activities, in particular immunization. This model was piloted in one district in Vietnam from 2015 – 2016, and is currently being piloted in two other districts. In Model 2 awareness of developmental disorders and the need for screening was raised nationwide, mainly through social media. Caregivers were encouraged to conduct screening tests at home using the guidance and tools available on a365.vn

Quantitative data for both models, including registered users' demographics and the screening test results, were collected from the back-end of a365.vn between October 2015 to October 2019. Unfinished test result data due to system errors was excluded. Data was analyzed using Excel and SPSS software.

Results: A total of 31,135 screening tests were completed between October 2015 and October 2019. The children screened were between the ages of 1 - 66 months. The average age of children screened and identified at risk of developmental disorders was 27 months. This is consistent with another study conducted in Vietnam in 2018. This showed the average age when parents first take their child for a developmental delay diagnosis is 27.47 months.

The number of tests completed by caregivers was 6.5 times higher than those completed by health workers. The number of children identified at risk of developmental disorders by caregivers was also higher than those identified by health professionals. Tests done by health professionals were mostly undertaken with financial support from the project.

Conclusions: For Model 1, if developmental screening for young children is to become a routine part of regular health check-ups then greater involvement of the health-sector is required. There must be training and financial support for grass-roots health workers to enable them to provide this activity as part of routine primary health care. For Model 2, communication is vital in raising awareness about the importance of early screening for developmental risks, amongst parents and other caregivers, and to provide them with information and tools to undertake screening for their children.

426.014 *(Poster)* Early Recognition of Autism, Comprehensive Management, Novel Research Initiatives, Empowering Health Professionals and Health Care Providers in a Tertiary Care Center: Experience over Last Two Decades

S. Gulati[1]*, V. Sondhi*[2]*, P. K. Panda*[3]*, R. Dubey*[2]*, A. Gupta*[3]*, J. S. Kaushik*[2]*, L. Saini*[2] *and S. Sharma*[2]*, (1)Center of excellence and advanced research for childhood neurodevelopmental disorders, Child Neurology Division, Department of Pediatrics, All India Institute of Medical Sciences, New Delhi, India, (2)Child Neurology Division, Department of Pediatrics, All India Institute of Medical Sciences, New Delhi, New Delhi, India, (3)Child Neurology Division, Department of Pediatrics, All India Institute of Medical Sciences, New Delhi, India*

Background: Our division has been actively involved in innovative research, training of physicians, empowering parents and holistic management of children with Autism Spectrum Disorder

Objectives: To provide an overview of results of 26 clinical studies in children with autism in last eighteen years in Child Neurology Division, Department of Pediatrics, AIIMS, New Delhi.

Methods: Around 4,000 autistic children have been managed in last 2 decades. Over 1000 children have been enrolled in 26 studies involving diagnosis(early signs of autism screening tool, AIIMS modified INDT ASD Diagnostic tool(mobile app), oxidative biomarkers, eye tracking), pathogenesis(clinical/whole exome sequencing , chromosomal microarray, vitamin D, other micronutrients, blood heavy metals, quantitative EEG, functional MRI brain, gut microbiota dysbiosis, advanced paternal age affecting sperm epigenome), co-morbidities(epilepsy, sleep disturbance, executive function, quality of life-QoL, parenting stress, coping strategy, depression in mothers) and management of autism(predictors of response to Applied Behavior Analysis-ABA, Gluten Free Casein Free Diet, probiotics, music therapy, communication based parental intervention, weighed compression vest-WCV), Alternative and Augmentative communication. Ongoing studies are exploring virtual reality and artificial intelligence for intervention. Association of molecular, genetics and environmental markers in ASD are being studied. Training of about 350 physicians in four national workshops, disability certification of 300 children and have been accomplished in last 4 years. Tele-consultation services have been initiated

Results: AIIMS modified INDT Diagnostic tool (age 1-14 yrs) and early signs of autism screening tool (1-18 months) tool have good psychometric properties. About 11% children with autism were found to have some genetic etiology. Autistic children were found to have higher blood lead levels ($p=0.01$), abnormalities in quantitative EEG and executive function ($p<0.0001$). 78% autistic children had sleep disturbances, 21% had epilepsy. 76% mothers had depression. Caregivers of autistic children with hyperactivity and epilepsy had more impaired QoL. WCV was found to reduce hyperactivity, inattention and withdrawn behavior ($p=0.02$, 0.03, 0.04 respectively).Younger age, higher education of parents, absence of epilepsy or hyperactivity and longer duration of ABA is associated with favorable response.

Conclusions: Innovative research exploring biomarkers, targeting novel diagnostics and therapeutics are imperative for improving care of children with Autistic Spectrum Disorder

426.015 *(Poster)* Examining Sociodemographic Disparities in Amount and Type of Intervention Use

H. S. Durham[1] *and A. J. Harrison*[2]*, (1)Education, University of Georgia, Athens, GA, (2)Educational Psychology, University of Georgia, Athens, GA*

Background: Research suggests that intervention for children with Autism Spectrum Disorder (ASD) in the preschool years plays a particularly vital role in beneficial outcomes (Zwaigenbaum et al., 2015). Unfortunately, many children do not receive intervention as early as they should for a myriad of reasons. Children from sociodemographic minority groups in the United States are at a particular disadvantage for receiving early interventions (Nguyen, Krakowiak, Hansen, Hertz-Picciotto, & Angkustsiri, 2016). Although there is emerging evidence documenting disparities for some sociodemographic groups in ASD treatment use, previous research has focused on a limited dichotomous variable of treatment receipt and typically examines a narrow definition of treatment types.

Objectives: To better understand the nature of treatment use disparities, the current study conducted a closer examination of how the specific number of weekly hours of multiple different intervention types differed between sociodemographic groups.

Methods: This study examined data collected from 2856 participants enrolled in the Simons Simplex Collection (SSC), a genetic and phenotypic database of individuals diagnosed with ASD (Fischbach & Lord, 2010). We examined the specific number of weekly hours of therapy in five different domains: Speech Therapy, Occupational Therapy, Intensive Therapy, Biomedical Therapy, and Classroom Intervention. Importantly this study looked at service utilization for the classically studied under five-year-old group as well as for children ages five and older. We looked to see if either age group differed on amount of weekly therapy based on sociodemographic variables including, mother and father education, annual household income, and family structure.

Results: Amount of occupational therapy (OT) for children under 5 years old was significantly related to mother, $F(7,167) = 3.89$, $p = .001$ and father, $F(8,167) = 3.45$, $p = .001$, education. Post hoc analyses revealed children whose father had an associate degree had significantly more weekly hours of OT ($M = 3.49$ hours) than those with a father that did not complete high school ($M = 0.27$ hours), $p = .005$. Similarly, follow-up analyses showed children with mothers who completed only some high school received significantly less OT hours than mothers with additional education: GED ($p = .000$), some college ($p = .000$), associates ($p = .000$), or bachelor's ($p = .000$). Amount of OT was not significantly related to any of the other examined sociodemographic variables. We did not find significant sociodemographic differences in any of the other four types of therapy examined for either age group.

Conclusions: In alignment with disparity reduction models that call for a better understanding of the inequities (Kilbourne, 2006), this research helps to demonstrate the extent of the problem by quantifying what types of treatment demonstrate the greatest disparities and by how much, through an examination of group differences in total numbers of weekly treatment. We found that parent education specifically impacted number of weekly hours of OT. Additional analyses will examine therapy use patterns among children 13 to 17-years-old and will also examine several additional sociodemographic factors such as child race and ethnicity.

426.016 *(Poster)* Examining the Association between Early-Life Language Exposure and Social Visual Engagement in Toddlers with and without Autism

***A. I. Mendez**, S. Shultz, A. Klin and W. Jones, Marcus Autism Center, Children's Healthcare of Atlanta and Emory University School of Medicine, Atlanta, GA*

Background: Infants preferentially attend to areas of the face that support their developmental goals. Attention to the eyes of others supports social development, while attention to the mouths of talking faces varies depending upon the mouth's adaptive value for early language learning (Lewkowicz & Hansen-Tift, 2012). For example, when first learning to make speech sounds, attention to mouths increases; while once these skills become more advanced, it decreases. Relatedly, trajectories of preferential looking to eyes and mouths vary by early-life language exposure: as compared to monolingual infants, bilingual infants preferentially attend to talking mouths for a protracted developmental period (Pons, Bosch & Lewkowicz, 2015). These processes, however, have not been extensively studied in children exposed to multiple languages who also have either autism spectrum disorder (ASD) or other non-autistic developmental disabilities. Here we investigate how early-life language exposure affects attention to faces in a clinical sample of toddlers with ASD or with other non-ASD developmental disabilities.

Objectives: To examine the degree to which early-life language exposure is related to social visual engagement in toddlers with ASD or with other non-ASD developmental disabilities.

Methods: Parent-reported language exposure in the home and eye-tracking data were collected from N=74 toddlers (*Mage(SD)*=25.09(6.54) mos.); all had some degree of English and non-English language exposure. For language-exposure level, those reporting <40% non-English were labeled "partially bilingual" (n=48), while those reporting between 40-70% non-English were labeled "fully bilingual" (n=26). Each group was individually-matched to a comparison monolingual sample on chronological age, non-verbal cognitive function (age equivalence on the *Mullen* visual reception domain), sex, and diagnosis (ASD or non-ASD). All children received a comprehensive developmental assessment using standardized instruments (*ADOS*, *Mullen*). Eye-tracking data were collected while watching video scenes of children in daycare settings and were quantified by measuring percentage of visual fixation to eyes, mouths, bodies, and objects. Between-group differences in visual fixation were tested by ANOVA.

Results: Analyses revealed no main effect of language-exposure on fixation time (all $p>0.05$). Analyses also revealed no interaction between diagnosis and language-exposure (all $p>0.05$). Analyses did show a significant main effect of diagnosis on fixation to ROIs: toddlers with ASD fixated on eyes and mouths significantly less than toddlers without ASD and significantly more on bodies and objects (all $p<0.05$).

Conclusions: In a clinical sample of toddlers with and without ASD, early-life language exposure did not significantly affect visual fixation to eyes and mouths. Instead, although toddlers in this sample without ASD had other intellectual, developmental, and language disabilities, their levels of fixations to eyes and mouth were greater than children with ASD, regardless of language-exposure. These results show promise for the use of eye-tracking-based measures to identify children with ASD, regardless of language exposure. Future work will examine how accurately performance-based, eye-tracking measures of social visual engagement can match diagnostic outcomes established by expert clinicians in children with varying levels of non-English early-life language exposure.

426.017 *(Poster)* Experiences of African Parents of Children with ASD: Implication for Research and Practice

***J. Paul**, Excella Developmental Services, Sacramento, CA*

Background: Autism is a neurodevelopmental disability that is characterized by difficulties in social communication, restrictive and repetitive behaviors and interests. Signs of ASD appears early in the child's early development.

Objectives: While autism is said to occur uniformly across cultures, little is known regarding the experiences of caregivers in the African region who generally lack proper assessment, diagnosis and intervention. This study sought to explore experiences of caregivers of ASD parents and their help-seeking behaviors.

Methods: An online survey was launched and distributed to African parents who were part of Pan African Congress on Autism. The survey was shared on 3 FB pages that are made up of parents of children with ASD. Participants came from 18 different African countries. The survey contained 21 questions and 155 parents/caregivers from 18 African countries. The purpose of the study was to understand the experiences of African caregivers of children with autism from the point they notice the first signs to diagnosis, intervention and education. The study also sought to understand help-seeking behaviors and struggles faced by caregivers.

Results: The participants included 125 boys and 31 girls. Age range of ASD individuals ranged from 18 months to 30 years of age. Out of 155 caregivers, 96% of caregivers noticed the early signs when their children were between ages 18 months-23 months; 24% noticed first signs between 24 months-35 months, 28% noticed between 0 and 35 months.

Of the 46% of the sample, caregivers noticed red flags before 24 months and 25% by age 3. When asked about early symptoms, 61% reported lack of communication as the first sign, 16%, repetitive and restricted interests, 9% sensory issues, and 14% other delayed milestones such as walking. Also, 47% of the children in the sample were nonverbal. When asked who they went to upon realizing that their child had a problem, 45% talked to a pediatrician, 31% talked to family members, 9% faith healers, 5.8% internet, 6% psychologist, 1.9% religious Leaders, and 1.2% psychiatrists.

Conclusions: In this pilot study, it is evident that African parents are recognizing the early signs early and are getting diagnosis early. The question however, remains, why does the prognosis remain poor? Although caregivers recognized early signs and received diagnosis, there were no available early intervention services. Worse still, although public education is free for primary age children in Africa, it is not free for children with Autism and families have to make arrangements for private school, provide an aide to accompany the child to public school or homeschool their child. While this is changing is some African countries, we are far from celebrating. As a results, parent and professional education in basic evidence based strategies would be beneficial for families. This will give them tools and strategies they need to help their children. Also, since over half of the parents went to pediatricians, providing pediatricians with information about autism, red flags and activities that parents can work on with their children at each developmental milestone would be helpful.

426.018 *(Poster)* Film and Television Representations of ASD: It's Not Just about Hollywood

M. Dean[1] *and A. Nordahl-Hansen*[2]*, (1)Education, California State University, Channel Islands, Camarillo, CA, (2)University of Oslo, Oslo, Norway*

Background: Recent years have seen a surge of new films and TV shows about ASD (Rohr, 2015; Veltman, 2009). These portrayals of ASD can be useful, because despite of the increased prevalence, many people still have not had direct substantive contact or personal experience with individuals with ASD. Many people form personal perceptions of ASD based on the characters they observe on the screen (Nordahl-Hansen, Øien, & Fletcher-Watson, 2018). Yet, misrepresentations may inadvertently shape misperceptions about individuals with ASD(Berger, 2017). Many characters with ASD, for example, are white young-adult males with savant skills (Singer, 2017); and this narrow scope may be less relatable to cross cultural audiences. Research is needed to examine existing empirical studies about media portrayals of ASD and to call attention to diverse film and television portrayals of ASD.

Objectives: This is a systematic review of research focusing on ASD-representations in film and television. Here we examine (1) the current state of research on ASD in film and television; (2) the extent two which media portrayals of ASD are culturally diverse, and (3) the academic and cultural diversity of the researchers studying ASD representations.

Methods: Data bases covering publications from various disciplines were used to ensure a comprehensive search. These include; PubMed, PsycINFO, ERIC, JSTOR, MLA, Project Muse, and Communication and Mass Media Complete. Articles were screened using the following criteria: (a) studies must have been published in scientific journals, (b) articles focused on film or television portrayals of ASD, and (c) the focus character with ASD was played by an actor. The initial search included 45 articles. Both authors screened these articles separately (Inter-rater reliability ICC= .85) ending with a total of 24 articles, which were read and coded by both authors and included in this study.

Results: Seventy-seven movies and television shows were discussed across the 24 articles. One hundred and thirty seven characters with autism across the life span and spectrum were represented. Television and film production primarily originated in the United States (62%), followed by UK (9%), Canada (5%), India (3%), Australia (3%), Sweden (2%); and Argentina, China, Finland, France, Indonesia, New Zeland, and Venezuala each produced one film or television show with a character with ASD. Researchers studying ASD representations were also from diverse backgrounds. Countries of origin included Australia, Canada, Germany, India, Norway, Spain, The Netherlands, Turkey, UK, and USA. Academic areas included; American Studies, Asian Diaspora, Education, Emergency Medicine, English, Mass Communication, Journalism, Psychology, Psychiatry, Sociology, and Spanish.

Conclusions: Compared to peer reviewed research studies, movies and television shows are able to extend ASD awareness by reaching an audience that far exceeds academic journals. While a majority of film and television representations of ASD originated in the USA, a notable number of characters with ASD have been developed in other countries. Likewise, researchers studying this topic are also academically and culturally diverse.The study of media portrayals of ASD is cross cultural and extends beyond traditional ASD-research areas of scholarship.

426.019 *(Poster)* Interventions for Individuals with Autism Spectrum Disorders in Low-and-Middle-Income Countries: A Systematic Review

L. Sun *and H. Schertz, Indiana University, Bloomington, IN*

Background: A proliferation of autism interventions targeting young children and adolescents with autism was documented in high-income countries (HICs). Despite some interventions being disseminated to low-and-middle-income countries (LMICs), it cannot be assumed that interventions validated as effective in HICs are equally effective in LMICs. A meta-analysis of community-based early interventions conducted in industrialized economies showed mixed region-specific effect sizes across child outcome measures. It is thus imperative to examine current autism interventions in LMICs.

Objectives: The study's purpose was to systematically review interventions for individuals with autism in LMICs and to answer the questions: (a) What autism interventions have been reported in LMICs? (b) How are those interventions replicated or adapted to local contexts?

Methods: Following the PRISMA guidelines, studies of interventions for individuals with autism in LMICs were searched across major databases and online first publications of autism-related journals. Studies meeting predetermined inclusion criteria were retained. Eighteen intervention studies were included for review.

Results: Twelve of 18 interventions were originally reported from HICs. Nine are parent/caregiver-implemented and the other half was delivered by professionals. Nine interventions were delivered at home and eight were in schools or clinics. The interventions focused on social communication/interaction, behavioral management, AAC, alternative therapies, and auditory integration. Of parent/caregiver-implemented interventions that reported the gender of implementers, 93.4% were delivered by mothers or female family members. Varying intervention duration was conventionally reported ranging between 10 days and an average of 19.5 months.

Interventions were delivered in countries in Africa, Asia, and Eastern Europe. Adaptions to HIC interventions were reported in the areas of (a) content (materials translated to local languages and adapted to local beliefs; intervention components added to ongoing routine care; increased intensity and duration); (b) context (age range of participants broadened due to late diagnosis; simplification of intervention language; interventions delivered in caregivers' preferred languages; task-sharing among local lay health workers); and (c) assessment (outcome assessments conducted in local language and cultural validation of standardized instruments [e.g. ADOS-2, ADI-R, CARS, etc.]).

Conclusions: Autism interventions in LMICs have burgeoned in recent years. Current intervention options presented recognizable patterns similar to those in HICs concerning the dominance of mothers' involvement in parent-implemented interventions, a preponderance of social communication and behavioral interventions, and the use of prevalent standardized measures from HICs. However, that twelve interventions were imported from HICs may speak to LMICs' limited access to locally initiated autism interventions among LMICs included in this review. Of note, intervention intensity reported across studies appeared to be low relative to NRC's recommendations, which could be explained by the unaffordability of intensive interventions. The unaffordability may be attributable to limited access to autism resources, local poorly coordinated service delivery and shortage of trained professionals.

Future efforts in capacity building of autism intervention practices in LMICs may include (a) considering including components amenable to adaptions; (b) to circumvent a shortage of trained professionals, empowering parents to support child learning in natural settings to breed more contextually relevant interventions from within.

426.020 *(Poster)* Outcomes of the Special Interest Group on the Topic of "Autism and Related Disorders in the Context of Humanitarian Emergencies"

A. Ibrahim[1]*, M. L. Beauchamp*[2]*, J. Zeidan*[1]*, A. Shih*[3]*, P. Dixon*[4]*, S. Dababnah*[5]*, M. Elsabbagh*[1] *and R. Nasir*[6]*, (1)McGill University, Montreal, QC, Canada, (2)Research Institute- McGill University Health Centre Montreal, Montreal, QC, Canada, (3)Autism Speaks, New York, NY, (4)Autism Speaks, Washington D.C., DC, (5)University of Maryland, Baltimore, Baltimore, MD, (6)Royal Free London NHS Foundation Trust, London, United Kingdom*

Background: UN figures estimate 48 million children are impacted by humanitarian emergencies, including armed conflict and natural disasters. Within this population, children with autism and related disorders are at further risk for poor outcomes related to health, mental health, physical injury and maltreatment. Little is known about these children and best practices to identify and support them.

Objectives: With the aim to launch a platform for communication and collaboration between researchers and key stakeholders in the humanitarian setting, an INSAR Special Interest Group (SIG) was formed in 2019 titled 'Autism and Related Disorders in the Context of Humanitarian Emergencies.' The objective of the SIG is to promote research and answer essential questions regarding the care and support of children with autism in the humanitarian context.

Methods: Forty participants from various backgrounds including post-graduate students, trainees, researchers, clinicians, medical doctors, interventionists, community organization officers, members of the autism community and advocates participated in the SIG. Following background presentations by professionals with expertise in the humanitarian setting, participants engaged in roundtable discussions addressing the following domains: clinical care, research, capacity building and advocacy. Participants were asked to consider challenges, gaps and potential action plans. Discussions were recorded by a note taker in each group and analyzed using a thematic analysis to identify domain specific and cross-over themes.

Results: Challenges and gaps identified were domain-specific and included: (1) the lack of epidemiological data (e.g., prevalence, comorbidity and impact of trauma); (2) limited understanding of cultural and contextual factors that impact presentation, identification and access to services; (3) limited evidence-base for interventions in the humanitarian setting; (4) limited resources (e.g., funding, trained professionals, infrastructure) for research and clinical care; (5) the low priority and limited voice of those with autism and related disorders in this setting.

Potential solutions by domains included: (1) empowering and engaging local professionals and possibly at-risk individuals/caregivers in capturing new and existing data; (2) involving local partners in capacity building (increasing knowledge and skills), including advanced crisis planning; (3) expanding research initiatives to low-resource humanitarian settings (e.g., WHO Caregiver Skills Training Programme); and (4) effective use of technology to improve training communication, coaching and supervision of local partners. In addition, there was some solutions that was mentioned across the various groups which resulted in the following cross-over themes: (5) multidisciplinary collaboration among stakeholders to improve implementation approaches; and (6) sustained, targeted advocacy and coalition building within the autism community, professional societies, and governmental, nongovernmental, intergovernmental and humanitarian organizations.

Conclusions: At the conclusion of the first meeting of this new INSAR SIG, participants outlined key gaps, challenges and potential solutions to address the needs of individuals with autism and related disorders facing humanitarian emergencies. Overall, there was a call for a cohesive and multidisciplinary approach in developing and/or adapting interventions that enhance the wellbeing of children and caregivers across all developmental disorders. Future directions will build on the themes identified in the SIG to support further systematic data collection on needs, barriers, and solutions in humanitarian contexts.

426.021 *(Poster)* Participation in Genetic Research Amongst Underrepresented Communities of Color

K. Murillo[1]*, M. Tafolla Magana*[1]*, S. Palmer*[2]*, V. Ranganathan*[3]*, J. Pandey*[4]*, A. Daniels*[5]*, R. T. Schultz*[4] *and A. Gulsrud*[6]*, (1)UCLA, Los Angeles, CA, (2)CHOP Center for Autism Research, Philadelphia, PA, (3)CHOP, Philadelphia, PA, (4)Center for Autism Research, Children's Hospital of Philadelphia, Philadelphia, PA, (5)Simons Foundation, New York, NY, (6)UCLA Semel Institute for Neuroscience & Human Behavior, Los Angeles, CA*

Background: It is well documented that communities of color are underrepresented in health research (Heiat et al., 2002, Kelly et al., 2005). Disparities are also prevalent in Autism Spectrum Disorder (ASD) research participation (Hilton et al., 2019). The Simons Foundation Powering Autism Research for Knowledge (SPARK) study, a nationwide autism genetic study, recognizes participation gaps amongst communities of color and have reported that 79% of SPARK participants are white. In an effort to understand participation barriers in genetic studies, focus groups were conducted with parents of individuals with ASD and other community stakeholders. The overarching goal is to improve the impact of targeted recruitment strategies to increase participation of traditionally underrepresented families in genetic research.

Objectives: To understand the disparities in genetic research participation, specifically in the SPARK genetic study, amongst ethnically and racially diverse individuals who have children with ASD and ASD community members. Moreover, the study aims to assess sensitive and culturally appropriate recruitment efforts to increase participation amongst underrepresented communities.

Methods: IRB approval was obtained to run three focus groups: two at UCLA (one for self-identified Asian parents of children with ASD and another for self-identified African American parents) and one at CHOP comprised of parents, self-advocates, and community members. Asian participants had an average income range of $99,285-$125,999 and African-American participants had an average income range of $64,000-$94,999. Group discussions were audio recorded, transcribed and coded for major conceptual models. Qualitative analysis was conducted using a modified grounded theory approach.

Results: Findings from all focus groups presented similar conclusions. All groups expressed the importance of explicit communication regarding the use of their genetic information. Asian immigrant parents discussed the importance of having the study available in different languages and felt that learning about genetics research directly from health professionals, specifically physicians, was important to their decision to participate. CHOP participants emphasized the influence of timing and understanding where a family is in their “autism journey” as important participation factors. They also stressed the need for varied recruitment materials (i.e. pictorial brochures and “Did you know?” ASD and SPARK fact bracelets) to broaden accessibility for families with different levels of educational attainment.

African-American parents expressed their distrust of genetic research due to the history of unethical research studies on African-Americans. Additionally, they described the impact of daily and long-term stressors as being in “survival mode.” Thus, participating in research does not take precedence over caring for their children. However, African-American parents revealed they are more willing to participate in research that addresses the systemic disparities on the availability of autism resources and treatment.

All participants discussed a desire to be directly connected to age appropriate resources, information for their child with autism and having a continuous relationship with the research institution.

Conclusions: The key to increasing participation is clearly communicating how genetic information will be used and making resources readily available and accessible. Understanding participants’ concerns may facilitate the development and implementation of a national strategy for reducing disparities in genetic autism research.

426.022 *(Poster)* Pilot Study of Citas: Communication Interaction Training on Autism for Spanish-Speaking Caregivers

L. Morgan[1]*, K. Guerra*[2]*, C. Chamorro*[3]*, S. Gillespie*[4] *and J. L. Stapel-Wax*[5]*, (1)Marcus Autism Center, Children's Healthcare of Atlanta and Emory University School of Medicine, Atlanta, GA, (2)Clinical/Research, Marcus Autism Center, Atlanta, GA, (3)Marcus Autism Center, Atlanta, GA, (4)Emory University, Atlanta, GA, (5)Emory University School of Medicine, Atl, GA*

Background: Descriptive research has documented that Latino children have less access, lower levels of utilization, and worse quality of health care when compared with white children (Liptak et al. 2008; Partish el al. 2012; Siller, Reyes, Hotez, Hutman, & Sigman, 2014)). Magaña, Lopez, & Machalicek, (2017) identified a lack of information in the community as important factor in the lack of service use for Latino families of children with ASD. Increasing ASD-related knowledge and provider trust are two strategies for decreasing disparities in the diagnosis and treatment of ASD among Latinos in the US (Zuckerman et al., 2017).

Objectives: The purpose of this study was to test the feasibility and acceptability of Communication Interaction Training on Autism for Spanish-Speaking Caregivers (CITAS), a 6-month parent intervention designed for Latino families and delivered within the context of a monthly parent support group.

Methods: Eleven Latino mothers of children diagnosed with ASD were recruited to participate in this research. Participants ranged in age from 27 to 30 years (M = 29.1, SD = 1.2) and their children had a median age of 54.5 months (IQR = 43-74). Caregivers reporting being of Mexican (n=10) and Guatemalan (n=1) descent. Annual household income ranged from <$25K (30%) to $26K-50K (70%). All caregivers participated in one of two CITAS cohorts. CITAS is a manualized 6-month, low-intensity group-delivered intervention aimed at caregiver increasing knowledge of autism and child development, sense of competence, quality of life, and decreasing parent stress. Two waves of data collection (pre and post CITAS participation) included a battery of caregiver report measures focusing on caregiver knowledge and caregiver self-efficacy. During the intervention, participation and attendance was tracked. Additionally, caregiver satisfaction surveys were collected at study exit.

Results: A mixed models analysis revealed no significant effects however medium and large effect sizes indicate that a lack of significance may be due to small sample sizes. Results revealed that caregivers participating in CITAS showed medium effect sizes for one subtest of the Parenting Stress Index (d=.37) and the Parenting Sense of Competence (d=.49). Large effect sizes were obtained for the Concepts of Development Questionnaire (d=.60) and for the Social Relationships subtest of the WHOQOL-BREF (d=.74). Participant survey results indicated high levels of satisfaction with CITAS participation with ‘agree’ and ‘strongly agree’ responses reported at a rate of 90%.

Conclusions: The results of this study indicate the promise of a brief, low-intensity treatment to significantly improve caregivers’ knowledge of child development, sense of parenting competence, and aspects of quality of life for Latino caregivers of children with ASD. These findings will be presented in terms of clinical implications and future research directions.

426.023 *(Poster)* Professionals’ Experiences of Gender Differences in Autism: A Qualitative Study Utilizing a Cross-Cultural and Cross-Professional Sample

K. Lundin[1]*, S. Mahdi*[2]*, J. Isaksson*[1] *and S. Bolte*[3]*, (1)Karolinska Institutet, Stockholm, Sweden, (2)Karolinska Institutet Center of Neurodevelopmental Disorders (KIND), Karolinska Institute Center of Neurodevelopmental Disorders, Stockholm, Sweden, (3)Center of Neurodevelopmental Disorders (KIND), Centre for Psychiatry Research; Department of Women’s and Children’s Health, Karolinska Institutet, & Stockholm Health Care Services, Region Stockholm, Stockholm, Sweden*

Background: Autism is associated with reductions in functioning and research indicates gender differences in functional outcomes for autistic people. Gender-related aspects of the environment, including gender expectations and socialization, likely interact with individual factors in causing different challenges for autistic females and males. Accordingly, gender expectations and potential biases among professionals working with autistic individuals might influence if an individual is identified and will receive relevant support. Gender differences in autism have largely been studied in relation to symptoms and in high-income countries, while there is a paucity of studies providing a cross-cultural and functional perspective.

Objectives: We aimed to gain insights in gender differences in functioning in autism by exploring the experiences of an international group of professionals working with people with autism.

Methods: Professionals’ experiences of gender differences in functioning among autistic individuals were explored using an open survey question. An invitation to participate was sent to an international group of autism experts and to be included professionals were required to have a minimum of five years of experience working with autistic people. The professions of the experts (n=102, 77% females) included occupational therapist, physician, psychologist, speech language pathologist and special education teacher. The experts represented 31 countries, and all six World Health Organization (WHO)-regions. The written responses were analyzed using inductive content analysis, aiming to explore recurring patterns across the data set.

Results: The content analysis yielded three main categories: i) *Matching the clinical conceptualization of autism* encompassing professionals experiencing autistic presentation among females as matching diagnostic manuals and the conception of autism less than male presentations. ii) *Co-existing problems* includes references where professionals expressed that autistic males display more conspicuous problems, including externalizing behavior and deficits in language production, while females display more internalizing problems such as anxiety. iii) *Navigating the social environment* encompasses professionals’ experiences of differences in how autistic males and females interact with their social surroundings. Professionals experienced that autistic females, compared to autistic males, displayed higher social motivation with more interest in social relationships, received more support from their female peers, and more often masked or camouflaged their difficulties, e.g. by imitating peers or following set patterns in conversation. Social motivation among autistic females was also described as posing a risk for more frequent social failures. While both autistic females and males were described as struggling to meet gender expectations, for females this regarded social expectations, and for males concerning physical performance in activities. Categories and sub-categories are presented in Figure 1.

Conclusions: Responses underline areas pertaining to functioning among autistic females and males respectively, with females being experienced as more difficult to identify due to behavior presentation that did not correspond to the conceptualization in diagnostic manuals. Females were also experienced as displaying less conspicuous co-existing problems and to camouflage their difficulties more, compared to autistic males. The higher social motivation among autistic females may contribute to detrimental outcomes for autistic females given a risk for more frequent social failures.

426.024 *(Poster)* Sensory Processing Difficulties and Food Selectivity in Children with Autism Spectrum Disorders: Evidence from a Developing Country

P. Malhi[1], *S. Saini*[2], *B. Bharti*[3], *S. Attri*[3] *and N. Sankhyan*[3], *(1)Department of Pediatrics, Post Graduate Institute of Medical Education and Research, Chandigarth,, India, (2)Pediatrics, Dr YS Parmar Medical College, Nahan, India, (3)Pediatrics, Post Graduate Institute of Medical Education and Research, Chandigarh, India*

Background:

There are number of comorbidities and aberrant behaviors associated with autism spectrum disorders (ASD) in children and one of the significant challenging behaviors is atypical feeding. Not much research has been done in the developing countries to understand the correlates of feeding problems in children with ASD.

Objectives: To examine food selectivity, mealtime behaviors, and sensory processing problems of children with ASD and to compare the profile with two control groups: healthy age matched typically developing children and siblings of children with ASD.

Methods: Fifty children (4-10 years) with a diagnosis of ASD (DSM 5) were recruited from the pediatric psychology and neurodevelopment clinics of a tertiary care center in India. The Brief Assessment of Mealtime Behavior in Children (BAMBIC) was used to assess the mealtime behavior of children. The BAMBIC consists of 10 items and these items assess 3 domains of mealtime behaviors including food refusal, limited variety of food intake, and disruptive mealtime behaviors. The Short Sensory Profile (SSP) was used to measure sensory processing problems in 7 domains. In addition, parents were interviewed about their child's dietary intake using a 3 day dietary recall including two non-consecutive weekdays and one weekend day. Two control groups were also recruited for comparison: healthy age matched controls and siblings of children with ASD. The study was cleared by the ethical review board of the institute and written informed consent was obtained from the parents.

Results:

As compared to the control groups, children with ASD had significantly higher problems on sub scales of food refusal (F=12.05, P=.0001) and displayed more disruptive behaviors during mealtimes (F=17.62, P=.0001) and total score on the BAMBIC scale (F=11.98, P=.0001). Children with ASD had significantly lower scores as compared to other two control groups in all the sub scales of SSP, except one, including tactile sensitivity (F=34.17, P=.0001), taste sensitivity (F=14.75, P=.0001), movement sensitivity (F=16.80, P=.0001), under-responsive (F=31.87, P=.0001), auditory filtering (F=29.15, P=.0001), and visual/auditory sensitivity (F=13.41, P=.0001). No significant differences were found between the groups on daily intake of calories and proteins. However, vitamin D (F=3.04, P=.05), folate (F=75.91, P=.0001), sodium (M=7.08mg, SD=1.15) and zinc (M=257mg, SD=100) were less likely to be consumed by the ASD children as compared to the controls. In addition, low levels of vitamin A, calcium and sodium were found in ASD children with food selectivity. Significant negative correlation was found between total BAMBIC scores and Vitamin A (r=-.35, P=.05), Calcium (r=-.28, P=.05), and sodium levels (r=-.29, p=.05) suggesting that low levels of Vitamin A, calcium and sodium are found more in children with ASD who are picky eaters and refuse more foods.

Conclusions:

Children with ASD have several feeding problems and these are associated with sensory processing sensitivities and nutritional deficiencies which may not lead to stunting or wasting in the short run. The study underscores the need for detailed evaluation of feeding problems and sensory processing problems in children with ASD in order to provide parents clear management guidelines to counter some of these problems.

426.025 *(Poster)* Severity of Autism in Relation to Socio-Demographic and Clinical Characteristics and Psychiatric Co-Morbidity of Autistic Children.

M. A. Zoromba*, Mansoura University, Port Said, Egypt*

Background: Autism is a neurodevelopmental disorder with unclear identified psychopathology. Studies from Egypt and the Middle East regarding autism are rare.

Objectives: Current Study aims to study the severity of autism in relation to socio-demographic characteristics and developmental condition of children, Clinical condition of mothers during pregnancy and labor, and Psychiatric co-morbidity among autistic children.

Methods: A descriptive study was utilized with a random sample of (84) children diagnosed with ASD by a consultant psychiatrist at child psychiatric department, Port-Said mental health hospital. Data collected using three tools; first for assessing socio-demographic and developmental characteristics of children, and clinical condition of mothers during pregnancy, the second for assessing the severity of autistic symptoms using Gilliam Autism Rating Scale (GARS), and the third for assessing co-morbid psychiatric disorders using Mini International Neuropsychiatric Interview for children (MINI-Kid).

Results: presented that 71.4% with moderate autism severity. Sibling gender, age of mother during pregnancy, mother co-morbid physical disease during pregnancy, child age of walking and child exposure to media related significantly to autism severity. More than two thirds (67.9%) of autistic children comorbid with psychiatric disorders. Anxiety is the most common (35.7%) followed by ADHD (32.1%). Numbers of co-morbid disorders related significantly to autism severity.

Conclusions: Severity of autism related significantly to Socio-demographic Characteristics and Psychiatric Co-morbidity.

426.026 *(Poster)* The Role of Indian Cultural Perceptions in Autism Spectrum Disorder: A Qualitative Study

A. Sasidharen*, Emory University, Atlanta, GA*

Background: Autism Spectrum Disorder (ASD) is a neurological disorder that impedes the social and communication development of a child. According to the Centers for Disease Control and Prevention, 1/59 children were diagnosed with ASD based on 2014 data of 8-year-old children. Although numerous studies indicate the benefits of early interventions for children at risk for ASD, many families access these services after the child has surpassed key developmental milestones. ASD impacts all racial/ethnic groups equally; however, few studies assess on the implication of culture regarding the familial experience of ASD. Due to stigma in some cultural communities, some families are less likely to share their concerns with others to avoid shame and humiliation. Limited studies assess the influence of culture on Asian families of ASD in the United States (U.S.), but numerous findings indicate the prevalence of stigma on mental illness in many Asian communities. Furthermore, a paucity of literature exists regarding the implications of culture in the process of acceptance and day-to-day life of Asian Indian families in the U.S. affected by ASD.

Objectives: This study aims to explore the impacts of cultural perceptions on Asian Indian mothers' acceptance of child's diagnosis, lifestyle choices, and relationship with cultural community.

Methods: Semi-structured Qualitative interviews were conducted with Asian Indian mothers who have ASD-diagnosed children (N= 20). Interview domains focused on mothers' experience of receiving an ASD diagnosis, process of acceptance, day-to-day life experiences, family/community members perception of ASD, experience with Indian culture, and resiliency/healing process. All audio-recorded interviews were transcribed verbatim to implement a thematic analysis via MaxQDA software.

Results: Several themes emerged from the data. During the initial stages of receiving a diagnosis, participants discussed their experiences of interacting with healthcare providers. Overall, participants' self-efficacy partially determined their lifestyle choices with their child of ASD. Regarding culture, participants discussed the lack of awareness about ASD in the Asian Indian community. Although many participants noted differences in their interactions with the Indian community living in the U.S. versus in India, some participants stated that stigma of ASD exists in both communities. However, family members and close social support systems served as protective factors in these respondents' ASD journey. Additionally, many participants defined ASD as their culture.

Conclusions: These findings support the need to further expand current outreach models to incorporate cultural context to spread awareness of ASD in various cultural communities. Future research can assess the indication of cultural perceptions and stigma in the choices of families from multicultural communities in the U.S. who are affected by ASD.

426.027 *(Poster)* Transcultural Adaptation of Autism Classification System of Functioning: Social Communication (ACSF:SC) for Use in Brazil

A. A. Cardoso Rodrigues[1]*, I. Lambertucci Cardoso*[1]*, D. Eloi*[1]*, K. Mareco*[1]*, D. Cardoso de Aquino*[2]*, D. Silva*[1] *and P. Nunes Gomes*[1]*, (1)Universidade Federal de Minas Gerais, Belo Horizonte, Brazil, (2)Rua Everest, Universidade Federal de Minas Gerais, Belo Horizonte, Brazil*

Background: The Autism Classification System of Functioning: Social Communication (ACSF: SC) was created by Canadian researchers to provide a common language for classifying social communication among preschool-age ASD children, focusing on their specific strengths and support needs. Unlike other existing instruments that focus on the deficits and symptoms of children with ASD, ACSF: SC emphasizes the child's capabilities.

Objectives: Accomplish the cross-cultural adaptation of the Autism Classification System of Functioning instrument: Social Communication (ACSF: SC) for use in Brazil.

Methods: Methodological study of cross-cultural adaptation of the ACSF: SC instrument. Are fulfilled the recommendations for cross-cultural adaptation of health protocols, which included secure permission, translation, back translation, proofreading and expert panel. In the second phase, the verification of the measurement properties of the instrument through a study of 30 fathers and mothers of children with ASD, ages between 3 and 5 years and 11 months. The sample was recruited from the Sensory Integration Laboratory (LAIS), Federal University of Minas Gerais (UFMG) and other university services, as well as private clinics. Initially, the inter rater reliability was assessed using the intraclass correlation index (ICC). Children were also evaluated with the Childhood Autism Rating Scale (CARS). To verify the correlation between the CARS and ACSF: SC, we used the Pearson correlation with level of significance of 0,05. All participants signed an informed consent form.

Results: The experts' evaluation showed that the translated version of the ACSF: SC instrument was well understood conceptually and culturally appropriate, with 48 sentences with higher agreement 90% for conceptual and cultural equivalence. Phrases that did not exhibit adequate levels of agreement was revised as suggested by the experts. The ICC result among examiners was 0.85. The average age was 52.54 ± 9.05 months, and 23.1% female and 76.8% male. The result of CARS pointed out that 80.8% had autism mild-moderate and 19.2% severe autism. The result of ACSF: SC pointed out that 11.5% of children had capacity and 3.8% typical performance level I, 15.4% capacity and the typical performance level II, 46.2% and 30.8% capacity performance in typical Level III, 23.1% capacity and 38.5% typical performance at level IV and 3.8% capacity and 11.5% typical performance at level V. Pearson correlation analysis between the CARS and ACSF: SC Typical Performance pointed $r = 0.419$ ($P < 0.05$) and ACSF: SC capacity was $r = 0.580$ ($p < 0.01$). Between ACSF: SC - Typical Performance and ACSF: SC–Capacity was $r = 0.876$ ($p < 0.01$).

Conclusions: The process of cross-cultural adaptation was rigorously performed. The equivalence between the original versions and translation of the ACSF: SC instrument is guaranteed, obtaining above agreement 90%. The instrument is easy to apply and may be useful in Brazil. However, this study has a limitations on sample size and profile and therefore future studies should include samples larger and several states.

426.028 *(Poster)* Voices from a Low-Resource Setting: Perceptions of Stakeholders of ASD in Mongolia

J. D. Lee[1] *and H. Meadan*[2]*, (1)Special Education, University of Illinois, Champaign, IL, (2)University of Illinois, Champaign, IL 61820, IL*

Background: Hardships of families of children with autism are exacerbated in low-resource settings (LRS) where little resources are available. While many nations attempt to ensure the rights of these families within the constraints of available resources, their success is heavily dependent on factors such as the governments' level of commitment, available infrastructure, and cultural views and stigmatization on disabilities. The gap in research of these LRS is concerning, and it may further marginalize these parts of the world in both research and practice. Among many LRS in the world, Mongolia may be a viable representative of an LRS as a post-communist, middle income country that is landlocked in Central and East Asia. In addition to its cultural and geographical advantages, Mongolia may also serve as an exemplar to other LRS due to its unique support system of nongovernmental organizations (NGO) that are consisted of parents of children with autism, various international development agencies, and the Mongolian government. However, there is no prior research conducted to examine the perceptions of Mongolian families of children with autism.

Objectives: This exploratory study examined the experiences and needs of parents of children with autism in Mongolia.

Methods: The qualitative inquiry included five focus group interviews with 30 Mongolian parents of children with autism and 15 individual interviews with various professionals who work with children with autism. The data were collected in Mongolia in summer of 2019, with logistical assistance from a local NGO of parents of children with autism. Data were analyzed using constant comparative method that involved open coding, generating codes and categories, and theme identification.

Results: Results from this study indicate that parents are facing both individual and systemic barriers for raising a child with autism in Mongolia. Parents reported severely limited availability of resources for diagnosis of and treatment for autism. These barriers included the scarcity of qualified providers, high-quality resources, support from their own government, and educational options for their children. Furthermore, parents reported difficulties in enrolling their children in public schools, often having to send their children to private schools or therapies that are costly. Parents also reported high level of stigmatization of disabilities, which results in isolation and embarrassment even from their own families. Interviews with the professionals also indicated difficulties of educating children with autism due to lack of resources both in pre-service training and professional development.

Conclusions: Based on the stakeholders' reported experiences and barriers, there is a clear need to develop a system of support for families of children with autism in Mongolia. The findings from this study have implications for both practice and policy. Firstly, due to high cost and very limited availability of professional services, researchers need to examine the potential of nonspecialist delivery of intervention (e.g., parent-mediated interventions). Secondly, as there are many other LRS that share similar characteristics with Mongolia, an intervention model could be developed in Mongolia, and its generalizability needs to be examined for application in other LRS.

426.029 *(Poster)* What Knowledge Regarding Autism Is Needed? - Stakeholder Priorities from the Netherlands

K. Greaves-Lord[1,2,3], *K. E. Van Den Bosch*[4], *L. van Bodegom*[5], *C. de Haan*[6], *R. de Lusenet*[5], *D. Weve*[7], *S. Piening*[3], *S. Louwerse*[8], *J. A. Landsman*[9], *A. Teunisse*[20] *and H. M. Geurts*[21], *(1)Child- and Adolescent Psychiatry/Psychology, Erasmus MC, Rotterdam, Netherlands, (2)Yulius, Dordrecht, Netherlands, (3)Autism Team Northern Netherlands, Jonx (Lentis), Groningen, Netherlands, (4)Karins Consultancy, Nijmegen, Netherlands, (5)Yulius, Dodrecht, Netherlands, (6)Gemeente Rotterdam, Rotterdam, Netherlands, (7)PAS Nederland, The Hague, Netherlands, (8)Erasmus MC - Sophia, Rotterdam, Netherlands, (9)University Medical Centre Groningen - Applied Health Research, Groningen, Netherlands, (10)PAS, The Hague, Netherlands, (11)Dept. of Psychology, Education, & Child Studies, EUR, Rotterdam, Netherlands, (12)Yulius Academy, Barendrecht, Netherlands, (13)NVA, de Bilt, Netherlands, (14)VAB, Netherlands, Netherlands, (15)AWA, Netherlands, Netherlands, (16)VU University Amsterdam, Amsterdam, Netherlands, (17)Psychology, University of Tilburg, TIlburt, Netherlands, (18)EUR, Rotterdam, Netherlands, (19)Department of Child and Adolescent Psychiatry, Curium-LUMC, Leiden University Medical Center, Oegstgeest, Netherlands, (20)Dr Leo Kannerhuis, Oosterbeek, Netherlands, (21)University of Amsterdam, Amsterdam, Netherlands*

Background: To ensure that resources reach where they are most needed and can make the most impact, all stakeholders from the autism community need to be involved in priority setting for autism innovation, research and implementation projects. Therefore, in the Netherlands, all autism stakeholders joint efforts to formulate an integrated Autism Knowledge Agenda.

Objectives: To formulate an integrated Autism Knowledge Agenda, based on the perspectives from a wide range of autism stakeholders from the Netherlands.

Methods: Based on previous inventarisations, 20 overarching themes were formulated. By broadly distributing an online questionnaire, these themes were considered by stakeholders from various perspectives, i.e. autistic people themselves, their relatives/loved ones, (mental) health care professionals, educational professionals, researchers, and policy makers. Participants were asked to 1) provide a grade (0-10) to each theme, including the opportunity to add new themes, and 2) prioritise themes, by indicating their top-3 priorities. Within their top-3 priorities, participants were able to provide grades regarding sub-themes, and to give suggestions on how to approach projects on these themes. Subsequently, focus-groups and a panel-discussion were conducted to create an integrated ranking of prioritized themes.

Results: In total, 1162 people participated, of which 56% autistic persons, 54% relatives/loved ones, 42% (mental) health care professionals, 8% educational professionals, 5% researchers, and 4% policy makers. These percentages add up to more than 100%, because 413 (36%) of the participants indicated to represent more than one perspective. For this reason, grades per theme were calculated for the total sample. The highest grades (≥ 8) were provided on the themes 'Dealing with (ones own) autism', 'Image-forming and inclusion', 'Care, treatment and medication', 'Well-being & meaning of life', 'Knowledge & information', 'Sensory processing', and 'Communication & Contact'. Subsequently, participants were assigned to one primary category (perspective), to provide all participants with equal votes, when setting the priorities for separate stakeholders. The number one priority for each stakeholder-group was: 'Dealing with (ones own) autism'(for autistic persons), 'Education' (for relatives/loved ones & educational professionals), 'Care, treatment, medication' (for care professionals), and 'Image-forming and inclusion' (for researchers & policy-makers). The Top-5 ranking that resulted from the integrated panel-discussion was: 'Dealing with (ones own) autism', 'Image-forming and inclusion', 'Care, treatment and medication', 'Well-being & meaning of life', and 'Education'.

Conclusions: Although differences between stakeholders exist regarding the prioritized themes that need further knowledge development, similarities were mostly found, and synthesized into a shared Autism Knowlegde Agenda. Currently, projectgroups of mixed stakeholders are formulating projects plans to together improve knowledge (utilization) on the prioritized themes.

426.030 *(Poster)* "Avoiding Climate Breakdown Will Require Cathedral Thinking": Are Environmental Justice and Neurodiversity Advocates Facing a Common Foe?

K. Gillespie-Lynch[1], *S. Saade*[2], *N. Daou*[3], *B. Kofner*[4], *R. Obeid*[5], *G. Y. H. Lam*[6], *B. Bockstal Fieulaine*[7], *E. Cappe*[8], *F. Picard*[9] *and J. MacCormack*[10], *(1)Department of Psychology, College of Staten Island; CUNY Graduate Center, Brooklyn, NY, (2)Psychology, Université du Québec à Montréal, Montreal, QC, Canada, (3)McNeese State University, Lake Charles, LA, (4)CUNY, NY, NY, (5)Department of Psychological Sciences, Case Western Reserve University, New York, NY, (6)Department of Educational and Psychological Studies, University of South Florida, Tampa, FL, (7)Département de Psychologie, Université Reims Champagne Ardenne, Reims, France, (8)LPPS, Université de Paris, Boulogne-Billancourt, France, (9)Univ Reims, Paris, France, (10)University of Lethbridge, Lethbridge, AB, Canada*

Background: Stigma reduces well-being among autistic people and their family members around the world (Grinker and Cho, 2013; Robertson, 2010). Goffman (1963) defined stigma as arising when attributes of an individual mark that individual as less than social norms, disqualifying that individual from full societal acceptance. Given that stigma arises when an individual "falls short" of culturally defined norms, it is not surprising that the degree to which autism is stigmatized varies across cultures (Obeid et al., 2015). A study examining predictors of differences in autism stigma among people in Lebanon and the US revealed that heightened acceptance of inequality, rather than collectivism, predicted stigma (Gillespie-Lynch et al., 2019). Subsequent research revealed that heightened autism stigma is associated with more generalized prejudice and social dominance orientation (SDO). These findings raise the possibility that stigma reflects a general desire to dominate others and that autism stigma (a lack of appreciation for neurodiversity) may be intertwined with a desire to dominate nature (a lack of appreciation for biodiversity). Indeed, the term neurodiversity was inspired by the desire to expand appreciation of biodiversity to include appreciation of neurological diversity (Blume, 1998; Singer 2017).

Objectives: The current study aimed to identify factors that contribute to differences in autism stigma in two multicultural countries: the US, a vast country with high levels of autism resources, and Lebanon, a small country with very limited autism resources. We hypothesized that reduced respect for biodiversity, empathy, and support for inclusion and heightened SDO and avoidance of uncertainty would predict stigma.

Methods: College students from Lebanon (n = 178; 31.5% male) and the US (n = 133; 33.1% male) participated in an online survey utilizing measures developed by autistic and non-autistic scholars. The survey assessed: demographics, explicit stigma (social distance scale; α=.87), autism knowledge (PAK-M; α =.80), respect for biodiversity (α=.73), SDO (α=.82), avoidance of uncertainty (α=.88), support for inclusive education (α=.73), and empathic concern (α=.34).

Results: A regression revealed that reduced respect for biodiversity (B = -.17, p = .003), autism knowledge (B = -.20, p < .001), and support for inclusive education (B = -.17, p = .001), heightened SDO (B = .24, p < .001) and uncertainty avoidance (B = .14, p = .006), and being male (B = .13, p = .008) and from Lebanon (B = -.18, p < .001) predicted heightened explicit stigma towards autism (R^2= .32). Empathic concern was unrelated to stigma (and exhibited low internal consistency).

Conclusions: These findings suggest that autism stigma and disrespect of biodiversity arise from a broader belief that those who are in power (e.g., "neurotypical humans" when compared to "neurodivergent" humans or humans in general when compared to other animals) deserve their privileges. By recognizing common causes shared by different social justice movements, we can work together to ameliorate stigma and combat environmental degradation by teaching the value of interdependence and respect for diverse ways of being. As Greta Thunberg noted, systems change requires "cathedral thinking" or a focus on the foundations of oppressive practices and attitudes.

Interventions - Non-pharmacologic - Infant, Toddler, and Preschool

POSTER SESSION — INTERVENTIONS - NON-PHARMACOLOGIC - INFANT, TODDLER, AND PRESCHOOL
427 - Interventions - Non-pharmacologic - Infant, Toddler, and Preschool Posters

427.001 *(Poster)* A Comparison of Parent Sensitivity and Responsivity across Parent Delivery of Different Intervention Approaches

S. F. Vejnoska[1], *A. C. Stahmer*[2], *P. Yoder*[3], *A. Estes*[4] *and S. J. Rogers*[5], *(1)University of California, Davis, Sacramento, CA, (2)Psychiatry and Behavioral Sciences, University of California at Davis MIND Institute, Sacramento, CA, (3)Department of Special Education, Vanderbilt University, Nashville, TN, (4)Speech and Hearing Sciences, University of Washington, Seattle, WA, (5)Department of Psychiatry and Behavioral Sciences, The Medical Investigation of Neurodevelopmental Disorders (MIND) Institute, UC Davis School of Medicine, University of California Davis, Sacramento, CA*

Background: Multiple intervention approaches that include parent participation have emerged as evidence-based practices in autism spectrum disorder (ASD; Schreibman et al., 2015). Structured behavioral interventions, such as Discrete Trial Training (DTT; Lovaas, 1987), are based on applied behavioral analysis (ABA). DTT emphasizes the provision of learning opportunities by utilizing antecedent and consequence strategies to enhance child learning with limited attention to the caregiver/child relationship. More recently, interventions such as the Early Start Denver Model (ESDM; Rogers & Dawson, 2010) blend the learning principles of ABA with relational strategies based on developmental science (e.g., developing sensitive and responsive interactions; Ingersoll et al., 2010). Developmental studies examining the effect of helping parents increase sensitive and responsive parenting behaviors that fit their child's learning needs have linked increases in these parenting behaviors to more positive outcomes for children with ASD (Gulsrud et al., 216; Rogers et al., 2014; Siller et al., 2013), but little attention has been paid to how these behaviors might vary as a function of intervention approach.

Objectives: Examine the role of parent coaching intervention in facilitating sensitive/responsive interactions

Methods: Data was collected as part of a larger randomized treatment study comparing DTT and ESDM intervention approaches. Participants in the parent study included toddlers with ASD and their primary caregivers. Over the year-long intervention, parents received coaching in parent ESDM (P-ESDM) or behavior management in the DTT condition. 83 children completed the study (42 DTT, 43 ESDM). Children were, on average, white (53%) males (75%), and 25 months old at entry (range 12-30). Video recordings of parent-child interaction during home toy play were collected monthly for 12 months. This study compares the quality of the parent-child interaction from months 1, 4, 8, and 12 using the Parenting Interactions with Children: Checklist of Observations Linked to Outcomes (PICCOLO; Roggman et al., 2013), a checklist of 29 observable developmentally supportive parenting behaviors in four domains—Affection, Responsiveness, Encouragement, and Teaching. Repeated measures, random effects models will be used to model change over time in parent sensitivity/responsivity. Secondary analyses will assess the four sub-domain scores as outcomes to probe specific areas that might explain any overall difference. With 83 parents, assuming a two-sided test and alpha = 0.05, we will have 80% power to detect a difference in slope as small as 0.25 standard deviations, assuming the correlation between the repeat assessments is at least 0.2.

Results: PICCOLO coding is underway (12% completed at submission) and will be completed by January 2020. Ten P-ESDM dyads and 11 DTT dyads have been coded. Preliminary analysis indicates no differences in overall performance on the PICCOLO between the P-ESDM dyads (M = 37.89, SD = 6.6) and the DTT dyads (M = 38.18, SD = 8.5) at study entry; $t(19)$= -0.08, p = 0.93.

Conclusions: Greater understanding of the effects of coaching in specific intervention strategies on parent-child interactions will lead to a greater understanding of how best to support parents of children with ASD. This information can be used to streamline parent coaching strategies.

427.002 *(Poster)* A Group-Based Approach to Parent-Mediated Intervention for Toddlers with ASD: Fostering Child Social Communication and Parental Self-Efficacy

I. Roth[1]*, K. Bernardi*[2]*, A. Solish*[3]*, E. M. Dowds*[4] *and J. A. Brian*[3]*, (1)Autism Research Centre, Holland Bloorview Kids Rehab, Toronto, ON, Canada, (2)Holland Bloorview Kids Rehab, Toronto, ON, Canada, (3)Holland Bloorview Kids Rehabilitation Hospital, Toronto, ON, Canada, (4)Autism Research Centre, Holland Bloorview Kids Rehabilitation Hospital-Autism Research Centre, Burlington, ON, Canada*

Background: Recent evidence from parent-mediated early intervention models for toddlers with ASD has demonstrated child- and parent-level gains following 3-12 months of intervention. Among this evidence is a cross-site RCT of Social ABCs™, a 12-week, in-home, parent-mediated intervention. In response to increasing demand for early intervention, we developed an abbreviated, group-based version of Social ABCs™, which takes place in clinic. This group model is being piloted to determine if similar gains occur when parents are taught the Social ABCs^{TM} strategies in a parent group format. Preliminary data (n=21), presented at INSAR 2019, demonstrated improvements in parents' use of the strategies, children's responsiveness, parent-reported number of words understood/spoken, and in parent stress levels.

Objectives: With additional participants and increased statistical power, this study aims to determine if any relationships have emerged between the parents' evaluation of self-efficacy, their stress levels, their use of the strategies, and their children's communication skills. The motivation for this work was to increase access to intervention at the earliest signs of concern.

Methods: Group Social ABCs^{TM} entails six weekly, group-based, didactic sessions for parents and nine one-on-one parent coaching sessions. Referrals were received from clinicians at a large pediatric rehabilitation hospital in Toronto, Canada. Data from 35 toddler-parent dyads (9 groups) were coded from video, and questionnaires were analyzed (see figures for demographics). Data from 51 dyads will be included for presentation at INSAR in May 2020.

Results: Feedback from parents led to program modifications following Groups 1 and 6, which have been maintained subsequently. Parents achieved implementation fidelity at a mean rate of 68.67% (SD=17.99) by the end of the program, increasing significantly from baseline, t = 11.89, p < .001. Toddler responsivity (% vocal responses to parent language opportunities) increased by 38.72% from baseline to week 6 (t=11.10, p < .001), at a pace commensurate with that reported in the RCT and a recent community implementation. Findings that are unique to the group model include decreased parent-reported ASD symptoms (Autism Parent Screen for Infants; p < .001) and increased words understood and spoken (MacArthur CDI; both p's < .001). Parents also reported increased self-efficacy over time (p = .011) and reduced parenting stress on all three domains of the Parenting Stress Index; p's < .05. The best predictor of toddler week-6 responsivity was parent week-6 implementation fidelity (R^2=.23, p = .003). Also, notably, parent self-efficacy significantly and strongly predicted (decreased) parental distress (R^2=.37, p < .001). The following demographic factors did not predict responsivity: Parent education level or ethnicity, parent baseline strategy use, child age or sex, child baseline language level. Parents and clinical staff have reported high levels of satisfaction with the program.

Conclusions: Group-based Social ABCs^{TM} is an efficacious way to enhance parent skills and toddler social-communication, with collateral effects of increasing parents' self-efficacy and reducing parenting stress. This is the first Social ABCs^{TM} study to show reduced parenting stress, which may be directly related to the group-based format, and to demonstrate an inverse relation between parent self-efficacy and stress.

427.003 *(Poster)* A Pivotal Response Treatment Package for Children with Autism Spectrum Disorder: An RCT Study

C. Wang*, Department of Social Psychology, Nankai University, Tianjin, China*

Background: Pivotal Response Treatment (PRT) is a comprehensive service delivery model that uses both a developmental approach and ABA procedures that aim to provide opportunities for learning within the context of the child's natural environments (Koegel, Koegel, Harrower & Carter, 1999; Koegel, Koegel, Shoshan & McNerney, 1999). Many recent RCT studies have reported its efficacy in improving children's social communications (Gengoux, et al., 2019).

Objectives: Our aim was to conduct a randomized controlled trial to evaluate a pivotal response treatment package (PRT-P) on the communication skills of children with autism spectrum disorder.

Methods: Twenty children with autism spectrum disorder and significant language delay between 2 and 5 years old were randomly assigned to PRT-P (n = 20) or the delayed treatment group (n = 20) for 12 weeks. Autism Diagnosis Observation Scale (ADOS), Social Communication Questionnaire (SCQ) and Childhood Autism Rating Scale (CARS) were used evaluate social communication skills before and after 12 weeks of treatment.

Results: Analysis of child utterances during the structured laboratory observation revealed that, compared with the delayed treatment group, children in PRT-P demonstrated greater improvement in frequency of functional utterances. The PRT-P group had significant reductions in the total score and the scores on social communication in ADOS after 12 weeks of treatment ($P<0.05$) as well as a significant reduction in the total score of the SCQ and CARS ($P<0.05$). The PRT-P group had a significantly greater reduction in the score on social interaction subscale than the delayed group ($P<0.05$).

Conclusions: This is a 12-week randomized controlled trial in which community treatment is delivered. PRT-P was effective for improving child social communication skills. Additional research will be needed to understand the best combination of treatment settings, intensity, and duration.

427.004 *(Poster)* A Robot-Based Play-Drama Intervention May Improve the Joint Attention and Functional Play Behaviors of Chinese-Speaking Preschoolers with Autism Spectrum Disorder: A Pilot Study

S. Chee[1]*, C. H. E. Cheng*[2]*, Y. Huang*[1]*, T. Wong*[3] *and W. W. Law*[3]*, (1)Educational Psychology, The Chinese University of Hong Kong, Hong Kong, Hong Kong, (2)The Chinese University of Hong Kong, Hong Kong, Hong Kong, (3)Chinese University of Hong Kong, Hong Kong, Hong Kong*

Background: Young children with Autism Spectrum Disorder (ASD) experience deficits in joint attention and play skills, which are typically developed within the first two years of life. Previous intervention studies have shown that explicitly and directly teaching children with ASD initiations of and responses to joint attention and play behaviors yields promising results (e.g., D'Ateno, 2003; Kasari et al., 2014). In contrast, Other studies have found that combining a play context with behavioral techniques, including prompting and reinforcement, may promote joint attention but not play behaviors (Baker, 2000; Kim et al., 2008). The present pilot study introduced a novel approach – a play-drama intervention protocol – to promote joint attention skills and play behaviors. Instead of using human beings as the actors in the dramas, we deployed social robots. Individuals with ASD show deficits in orienting themselves toward social stimuli, engaging with humans, and maintaining social relations (Social Motivation Theory of Autism; Chevallier et al., 2012). Besides, individuals with ASD have excessive reactivity and rapidly form memories of experiences possibly resulting in sensory and emotional overstimulation and distractions (Intense World Theory; Markham & Markham, 2010). Unlike human beings, robots operate within predictable and lawful systems, thus providing children with ASD with a highly structured learning environment and helping them to focus on the relevant stimuli.

Objectives: We examined whether a robot-based play-drama intervention would promote joint attention skills and play behaviors using randomized controlled trial design. If so, children in the intervention condition would have better joint attention and play skills than those in the wait-list control condition.

Methods: Chinese-speaking preschool children were randomly assigned to an intervention group (N = 12) and a waitlist control group (N = 11). Children in the intervention group watched three robot dramas and engaged in role-plays with both robots and human experimenters over the course of nine weeks. Both groups of children then took the Early Social-Communication Scales (ESCS; Mundy, Hogan, & Doelring, 1996) and the Structured Play Assessment (SPA; Ungerer & Sigman, 1981) in the pre- and post-tests. Parents completed the Social Responsiveness Scale (Gau et al., 2013).

Results: Our findings have shown that the robot-based play drama intervention promoted joint attention initiations and functional play behaviors, which were not directly and explicitly taught during training (See Figure 1 and Figure 2). The parents of the children in the intervention condition also rated their children as having less severe social impairments after the training. Both groups of parents gave high ratings on the social validity questionnaire.

Conclusions: A robot-based play-drama intervention can enhance the joint attention and play behaviors of children with ASD. In this protocol, children acted different characters and engaged in drama role-plays. Thus, they can discover the implications of their play behaviors and the impact of their responses on others. It may therefore motivate them to initiate joint attention with others and to understand how to respond to others' joint attention behaviors. Additionally, a play-drama intervention offers a structured approach to developing children's symbolic understanding and use of pretense.

427.005 *(Poster)* Adaptive Training for Community Intervention Deployment: Comparing Training Strategies for New Behavioural Interventionists

S. Y. Shire[1]*, W. I. Shih*[2]*, L. Baker Worthman*[3] *and C. Kasari*[2]*, (1)University of Oregon, Eugene, OR, (2)University of California, Los Angeles, Los Angeles, CA, (3)Department of Health and Community Services, St. John's, Newfoundland and Labrador, Canada*

Background: In order to bring known efficacious early intervention programs for children with autism and other complex communication needs into routine daily care, community clinicians require access to high quality professional development supports to grow the local capacity necessary to deliver complex behavioral interventions. This randomized controlled trial examines training tools to support the development of clinicians learning to deliver a social communication intervention within a provincial public health system in Canada.

Objectives: To examine strategies to support community interventionists' ability to deliver the Joint Attention, Symbolic Play, Engagement, and Regulation (JASPER: Kasari et al., 2006) intervention with high implementation fidelity. Specifically, to compare the effect of (a) Peer Coaching: weekly feedback from a local interventionist who has achieved over 90% fidelity with (b) Intensive Refresher: a 12-hour training conducted by a local Senior Trainer (ST) on trainee interventionists' JASPER fidelity and children's social communication and play skills.

Methods: Thirty community interventionists (e.g., speech language pathologists, psychologists) training to deliver JASPER, served 43 boys and 5 girls with ASD (diagnosed through the local health system) age 2.0-6.9 years (M=4.66 years). Interventionists were supervised by 5 local JASPER STs.

Intervention and training occurred in two phrases. Phase 1 began with a 5-day introductory training. Interventionists then practiced weekly with one child for 12 weeks with feedback from their ST. After 12 weeks, implementation fidelity was assessed. Eight interventionists demonstrated 90%+ fidelity while 22 were below 90%. For Phase 2, those below 90% were randomized to receive Peer Coaching or Intensive Refresher. All interventionists were assigned new child cases for another 12 weeks.

Interventionists' JASPER implementation fidelity was measured by scoring ten-minute interventionist-child interactions at treatment exit. Each video was coded for 32 items rated on a Likert scale from 0 (low quality, accuracy) to 5 (high) strategy implementation.

Children received two play-based assessments at baseline and exit including: (a) Structured Play Assessment (SPA: Sigman & Ungerer, 1981) and (b) Early Social Communication Scales (ESCS: Mundy et al., 2003) All assessments were video recorded and delivered by community staff who were independent of the local treatment team and reliable (administration fidelity *M*=81.87% ESCS, *M*=93.05% SPA). Independent, reliable coders blinded to timepoint and condition coded (a) the number of spontaneous unique play acts across 16 play levels from the SPA and (b) the number and type of spontaneous initiations of joint attention and requesting from the ESCS.

Results: Interventionists receiving Peer Coaching made significantly greater gains in JASPER fidelity than those receiving the Intensive Refresher ($F(1,126)=4.23$, $p=0.042$), reaching means of 85.44% and 87.32% respectively by exit. Overall, children paired with interventionists in both groups made significant gains in initiations of joint attention and requesting ($F(1,25)=4.94$, $p=0.036$) and total play types ($F(1,23)=4.78$, $p=0.039$). However, there was no significant difference in children's gains between groups.

Conclusions: Altogether, community interventionists can demonstrate high quality implementation. Weekly peer discussions which do not require the specialists nor the condensed intensity of the intensive refresher offer a less costly and more efficient option to provide effective training supports.

427.006 *(Poster)* An Intervention to Teach Social Referencing to Children with Autism

M. Sivaraman[1]*, J. Virues-Ortega*[2] *and H. Roeyers*[3]*, (1)Ghent University, Ghent, Belgium, (2)University of Manitoba, Winnipeg, MB, Canada, (3)Department of Experimental-Clinical and Health Psychology, Ghent University, Ghent, Belgium*

Background: Social referencing is characterized as a chain of behaviors which starts when an infant is confronted with an ambiguous object or event. In this ambiguous context, the infant may look toward another person, typically a parent or caregiver, who would then provide affective cues that serve as informational messages for either an approach or avoidance response. Although demonstrated by typically developing infants as young as 10 months of age, social referencing is absent or impaired in children with autism.

Objectives: The purpose of the present study is to evaluate the efficacy of an intervention to establish a social referencing repertoire in young children with autism using multiple exemplar training, prompting and contingent reinforcement.

Methods: The intervention was comprised of teaching trials involving multiple exemplars of standard and ambiguous task materials drawn from experimenter-defined categories of stimuli (e.g., food, art material, toys). Social referencing was taught as a two-step chain involving (a) a looking response, and (b) a discriminated response based on the facial expression of the caregiver. Each session comprised of 10 trials with ambiguous stimuli and data are reported as a percentage score for referencing responses. Measures of joint attention were collected pre- and post-training using the Early Social Communication Scale (ESCS; Mundy et al., 2003).

Results: Preliminary results were evaluated using a multiple baseline across participants design and show a systematic increase in referencing responses with the introduction of treatment for all three participants. On average, the participants exhibited 0% referencing responses in baseline, and this increased to 70% during the training. Measures of joint attention will be discussed in the context of the social referencing data obtained herein, and the interaction between these early social repertoires will be highlighted.

Conclusions: The intervention designed to teach social referencing to children with autism using operant learning procedures was effective. The empirical evidence in support of strategies for teaching early social repertoires will be discussed.

We will also present findings of an ongoing randomized control trial with 30 participants evaluating the intervention protocol.

427.007 *(Poster)* An Israeli Adaptation of the PEERS for Preschoolers Parent Mediated Social Skills Program - Preliminary Results of a Clinical Trial

G. Segall[1]*, T. Gev*[2]*, S. Israel Yaacov*[2]*, I. Mor Snir*[1]*, E. A. Laugeson*[3] *and O. Golan*[1,2]*, (1)Association for Children at Risk, Givat Shmuel, Israel, (2)Department of Psychology, Bar-Ilan University, Ramat-Gan, Israel, (3)UCLA Semel Institute for Neuroscience and Human Behavior, Los Angeles, CA*

Background: The significant role of parental involvement in intervention programs for children with ASD was documented in early intervention programs, and in adolescent social-skills training. However, social-skills training programs for young children with ASD were mostly school-based, with minimal parental involvement.

PEERS for Preschoolers (P4P; Laugeson, Park, & Sanderson, 2008) is a 16-week manualized social skills intervention for high-functioning children with ASD aged 4-7, as an adaptation of the Program for the Education and Enrichment of Relational Skills (Laugeson & Frankel, 2010). Children are taught age-appropriate social-skills while parents are taught how to support the practicing of learned skills during everyday life. Preliminary findings from this intervention (Sanderson et al., 2009, 2010) reveal significant improvements in parent and teacher reported social skills. However, P4P has not been cross-culturally evaluated and its effects on parents have not been tested.

Objectives: (1) To culturally adapt P4P in Israel. (2) To evaluate the effect the adapted P4P has on the social skills of Israeli preschoolers with ASD and on stress and reflective functioning of parents in a preliminary clinical trial.

Methods: The original P4P protocol was translated and adapted by a team of psychologists, using culturally-appropriate social activities (songs and games). A short free-play break was added for each session, to give children some time for regulation. The P4P protocol was then administered to 51 Israeli children with ASD (eight girls) aged 4-7 and their parents in groups of 7-10 children each. Parents reported pre- and post-intervention on the Social Skills Improvement System (SSIS), the Social Responsiveness Scale (SRS-2), the Quality of Play Questionnaire (QPQ), the Parental Stress Index (PSI) and the Parental Reflective Functioning Questionnaire (PRFQ). Teachers reported on the SSIS and the SRS-2.

Results: Analyses indicated significant improvements in children's social skills, as reflected through parent reported SSIS Social Skills index ($p<.01$), and SSIS communication ($p<.05$), cooperation ($p<.05$), assertion ($p<.01$), responsibility ($p<.01$), engagement ($p<.05$), and self control ($p<.01$) subscales. Parents also reported on reduced scores (indicating better social functioning) on the SRS-2 total score, as well as its social-awareness and social-communication subscales ($p<.05$ for all). Parents' report on the QPQ indicated significant improvements on the number of playdates children had at their- ($p<.01$) and their peers'- ($p<.05$) homes. Finally, parents self-reported on improved certainty about their children's mental states ($p<.05$) on the PRFQ, and on fewer difficulties taking care of their child ($p<.01$) on the PSI.

Teachers' reports indicated significant improvement on the SSIS Social Skills index ($p<.01$) and the SRS-2 Social Communication Index ($p<.05$). Intervention-related improvement on the PRFQ-Parental certainty of child's mental states was correlated with parent reported reduced ASD symptoms on the SRS-2 ($r=-.34$, $p<.05$).

Conclusions: The Israeli adaptation of P4P could serve as an effective parent-mediated social-skills intervention, which enhances children's social skills and some elements of parental reflective functioning. The effectiveness of the P4P and the mediating and moderating roles of parental factors should be examined in a future RCT.

427.008 *(Poster)* Are Play-Based Interventions for Children with Autisms Spectrum Disorder Effective?

L. Dijkstra-de Neijs[1]*, C. Tisseur*[2]*, H. Swaab*[3]*, I. A. van Berckelaer-Onnes*[4] *and W. A. Ester*[5]*, (1)SARR Expert Center for Autism, Lucertis Child- and Adolescent Psychiatry, Parnassia Group, Rotterdam, Netherlands, (2)YOUZ Child- and Adolescent Psychiatry, Parnassia Group, Dynamostraat 18, 3083 AK Rotterdam, Rotterdam, Netherlands, (3)Leiden University, Leiden, Netherlands, (4)Sarr Expert Centre for Autism, Lucertis Child and Adolescence Psychiatry, Rotterdam, Netherlands, (5)Department of Child and Adolescent Psychiatry, Curium-LUMC, Leiden University Medical Center, Oegstgeest, Netherlands*

Background: Play is crucial in becoming a mentally healthy adult. If children experience problems, play therapy is effective because it fits within their natural behaviour to develop novel skills. But some children, like children with ASD often show an aberrant play development. Whether play-based interventions are effective in children with ASD and their parents has not systematically been evaluated with a risk of bias (ROB)-assessment.

Objectives: Discovering if play-based interventions are effective in children with ASD and their parents, evaluated with a risk of bias (ROB)-assessment.

Methods: A systematic literature search according to the PRISMA guidelines on play-based interventions for children with ASD with and a Cochrane ROB-assessment.

Results: 76 records consisting of 22 RCT's evaluating 7* play-based interventions and 3 non-RCT's on 2** additional play-based interventions were identified. ROB-assessment classified 95% RCT's and all non-RCT's with high risk of bias. When heterogeneity, treatment duration/intensity and sample size were excluded from ROB-assessment, 76% of the studies classified as 'high risk of bias'. Social interaction, communication and parental behaviour are the most studied outcomes, presenting considerable effect sizes.

Conclusions: Whether play-based interventions for children with ASD are effective is unclear. This review shows that the majority of the evaluated studies have a high risk of bias. Future research should focus on improved study designs with less risk of bias to more clearly investigate the effect of play-based interventions on children with ASD.

427.009 *(Poster)* Beyond Intervention into Daily Life: A Systematic Review of Generalisation Following Social Communication Interventions for Young Children with Autism

S. Carruthers[1]*, A. Pickles*[2]*, V. Slonims*[3]*, P. Howlin*[4] *and T. Charman*[5]*, (1)King's College London, London, United Kingdom of Great Britain and Northern Ireland, (2)King's College London, Institute of Psychiatry, Psychology and Neuroscience, London, United Kingdom, (3)Guy's & St Thomas' NHS Foundation Trust (Evelina Children's Hospital), London, United Kingdom, (4)King's College London, London, United Kingdom, (5)Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, United Kingdom*

Background: Generalisation is the ability to apply learned behaviours in contexts other than the one in which it was initially acquired and may occur across people, settings, behaviours and/or time. Successful generalisation is necessary for an intervention to have the intended benefit on everyday life beyond the original learning environment. Researchers have generally considered autistic individuals to have difficulties generalising learned skills across novel contexts. However, there is no consensus on the extent or profile of generalisation following interventions for autistic individuals.

Objectives: Given the importance of generalisation, and the complexity of issues surrounding its assessment, this review aimed to explore generalisation in randomised controlled trials of early interventions for autistic children that target social communication skills. We aimed systematically to explore (i) the extent to which generalisation has been measured alongside a measure of initial target learning (see Figure 1), and (ii) the evidence for generalisation following intervention.

Methods: We conducted a systematic review of PsycInfo and PubMed. We screened 1117 abstracts and reviewed 82 full text articles. Inclusion criteria included that the study was a randomised controlled trial; all participants were aged below six years at baseline (i.e. age 0 to 5 years 11 months); intervention included a focus on the acquisition of social communication skills and included measures of child outcomes; and intervention and control groups each had a minimum of 10 children. It was also necessary that the RCT included a measure of initial target learning and generalisation.

Results: We identified nine RCTs (Table 1) that provided evidence of initial target learning and measured generalisation, of which eight demonstrated at least some successful generalisation across person, setting and/or activity. The findings did not support the widely reported generalisation 'difficulties' associated with autism. However, generalisation was not consistent across all skills within studies, and one study found no generalisation despite evidence for initial target learning within the intervention context. In general, there are few methodologically sound studies exploring generalisation in autism and no consensus on how it should be measured within trials. In particular, failure to demonstrate initial learning of target skills within the intervention setting and an absence of formal mediation analyses of the hypothesised mechanisms limit current research.

Conclusions: Despite frequent reference in the literature to problems of generalisation in autism, early intervention trials for autistic children provide evidence that generalisation can occur post-intervention. However, generalisation is neither consistent across skills, nor is it found in all studies. We outline proposals for future research, including a framework for measurement of generalisation that we hope will be useful for future studies. A more systematic and comprehensive approach to the measurement of generalisation, and how it can be enhanced, is now needed across the autism intervention literature.

427.010 *(Poster)* Can We Reach More Families Faster? a Community-Implemented, Parent-Mediated, Group Intervention for Autism and Disruptive Behavior

*T. Birenboim Avtalion[1], E. Y. Cohen[2] and **J. Koller**[3], (1)Seymour Fox School of Education, The Hebrew University of Jerusalem, Jerusalem, Israel, (2)The Hebrew University of Jerusalem, Jerusalem, Israel, (3)Seymour Fox School of Education, Hebrew University of Jerusalem, Jerusalem, Israel*

Background: As many as 50-70% of children with autism exhibit disruptive behaviors (DBs) including tantrums, aggression, noncompliance, property destruction, and self-injurious behavior (Hartley, Sikora & McCoy, 2008; Kaat & Lecavalier, 2013). Beyond obvious challenges, DBs often contribute to additional difficulties, including interfering with adaptive functioning and increasing social isolation (Scahill et al., 2012). DBs also pose challenges to caregivers, including reducing family quality of life (Allik et al., 2006, Simonoff et al., 2008). Evidence points to a bidirectional relationship, with child behavior problems and parenting stress exacerbating one another over time (Hayes & Watson, 2013; Lecavalier et al., 2006; Zaidman-Zait et al., 2013). DBs unaddressed in childhood can have significant long-term negative consequences for children with autism and their families.

Parent-mediated interventions (PMI) engage parents as agents of change (Bearss et al., 2015). The use of PMIs for children with autism has a solid and growing evidence base (e.g. Pickles et al., 2016). The Research Units in Behavioral Intervention (RUBI) protocol is a manualized PMI for DBs, developed for children with autism (Bearss et al., 2015). Several studies in the US have shown that the RUBI protocol reduces DB in children with autism when conducted in a one-on-one, lab-based setting (e.g. Bearss et al., 2015b). The current study examine the efficacy of the RUBI protocol in a community-implemented, group format with Jewish and Arab parents in Israel.

Objectives: To examine the efficacy of the RUBI protocol delivered to groups of Arab and Jewish parents in the community. The study also seeks to examine changes in participating and non-participating parents' stress levels following the intervention.

Methods: Participants included 34 parents (17 Jewish, 17 Arab) of children between four and eight years old with a diagnosis of autism and at least one DB, ascertained by the Aberrant Behavior Checklist (ABC). The intervention included 11 sessions and one home visit. Ten groups of three to four participants were conducted according to the RUBI protocol. Outcome measures were administered at baseline, weeks 4, 8, and 12, including the parent and teacher-report ABC (Aman, Singh, Stewart, & Field, 1985a,b), the Home Situations Questionnaire (HSQ; Barkley and Murphy 1998), and the Parenting Stress Index-Short Version (PSI-SR; Abidin, 1990), administered to participating and non-participating parents.

Results: Results indicated significant reduction of DBs over the course of the protocol. This includes parent-report ABC-Irritability subscale ($p=0.011$) and ABC-TOTAL score ($p=0.001$), and teacher-report ABC-Irritability subscale ($p=0.003$) and ABC-TOTAL score ($p=0.003$). Improvement was also indicated by the HSQ-Total score ($p=0.001$). Participating parents reported decreased stress on the PSI ($p=0.002$), while non-participating parents indicated no reduction in stress.

Conclusions: This study provides initial evidence for a community-based delivery of the RUBI protocol in a group format. Findings indicate significant reduction in DB and support the use of RUBI with Jewish and Arab families in Israel. Reduction in participating parents' stress, together with no such change in non-participating parents demands further consideration. These findings are preliminary and further study is necessary in the form of a randomized controlled study and long-term follow-up.

427.011 *(Poster)* Caregiver Role in Assisting Child Social Skill Development: Examining Caregiver-Child Relationships in the PEERS® for Preschoolers Program

R. S. Factor[1,2] *and A. Scarpa*[1,2]*, (1)Virginia Polytechnic Institute & State University, Blacksburg, VA, (2)Virginia Tech Autism Clinic & Center for Autism Research, Blacksburg, VA*

Background: Social impairments characteristic of Autism Spectrum Disorder (ASD) are evident in early childhood and tend to worsen with development (Rao, Beidel, & Murray, 2008). Despite the emphasis on early intervention and caregiver training, few evidence-based interventions explicitly address social skills in preschool-aged children (DeRosier et al., 2011; Reichow & Volkmar, 2010) and none actively integrate caregivers (Reichow, Steiner, & Volkmar, 2012). Research indicates that generalization beyond a social skills group setting might occur by including caregivers (DeRosier et al., 2011). The PEERS® program is an evidence-based caregiver-assisted social skills program for adolescents and young adults (Laugeson & Frankel, 2010), recently extended for preschoolers with ASD. An initial randomized controlled trial indicated benefits from PEERS® for Preschoolers (P4P), but did not examine caregiver outcomes.

Objectives: This project tests the hypothesis that P4P will improve social skills in children with ASD, caregiver confidence, and parenting skills. Thus, this study will explore caregiver-child mechanisms of P4P and whether parent confidence and style improve with intervention, even if not directly targeted.

Methods: Fifteen caregiver/child dyads (11 boys; 66.7% Caucasian) ranging from 4 to 7-years-old ($M = 4.87$; $SD = 1.25$) participated in four P4P groups, consisting of 16 1.5 hour sessions twice per week. One hour included separate child/caregiver didactics while the last 30 minutes were for caregiver-coached play. Children were required to have an ASD diagnosis, meet ASD criteria on the ADOS-2, be fluent in English, have an IQ greater than 70, be toilet trained, and able to tolerate a group setting. Measures used included the Parenting Scale (PS; measuring parenting style), Quality of Play Questionnaire (QPQ; measuring peer conflict during play dates), and the Parental Self-Efficacy in the Management of Asperger Syndrome (PSEMAS; assessing parental self-efficacy), administered at entry, midpoint, exit, and 6-8 week follow-up.

Results: Paired samples t-test revealed a significant decrease in PS overreactivity (e.g., harsh, authoritarian, irritability, anger displays) from entry to exit, $t(8) = -4.007$, $p = .005$, but was not maintained at follow-up, $t(9) = -1.66$, $p = .132$. There were no significant changes in the other PS domains (e.g., total score, verbosity, laxness). There were significant decreases in total PS scores from entry to follow-up $t(10) = 2.663$, $p = .025$, suggesting improvements in overall parenting styles (*M*entry = 3.189 *SD* = .024; *M*follow-up = 2.88, *SD* = .53). Finally, QPQ, revealed a significant decrease in conflict from entry to follow-up $t(13) = 2.31$, $p = .02$. QPQ conflict score was also correlated with parent-efficacy (confidence in coaching child) at follow-up ($p = .046$).

Conclusions: Results suggest P4P may aid in some parenting skills, specifically in learning how to react appropriately to their child, confidence in coaching their child, and overall more beneficial parenting skills. Improvements in these domains may indicate that some changes in caregiver behaviors that were not specifically targeted warrant further research to examine if caregiver changes are mechanisms that explain child social skill gains. Further research could also look at overall family dynamics and examine behavioral interactions between caregiver and child.

427.012 *(Poster)* Caregiver Skills Training for Families of Children with ASD in Vietnam

H. S. Vu[1]*, H. Hoang*[1]*, P. Hoang*[2]*, T. Quach*[1] *and T. Ho*[1]*, (1)Center for Creative Initiatives in Health and Population, Hanoi, Viet Nam, (2)Center for Creative Initiatives in Health and Population, hanoi, Viet Nam*

Background: In the context of low resource settings, where qualified early childhood interventionists and allied health therapists are lacking, a model developing the skills of caregivers to deliver interventions can be effective. Research evidence indicates that caregivers can work effectively with professionals to set intervention goals and can learn the necessary skills to deliver rehabilitation therapies for their children with Autism Spectrum Disorder (ASD). However, there are a number of challenges might prevent service providers and caregivers from actively engaging in caregivers training, and caregivers from applying their skills in daily care for their children. Since 2019, Center for Creative Initiatives in Health and Population (CCIHP) adapt and pilot the WHO Caregiver Skills Training (CST) Programme for families of children with ASD and other developmental disorders within health system in Vietnam.

Objectives:

- To present the process of adaptation and pilot the CST in health system in Vietnam
- To discuss challenges and lesson learnt for care-giver skills training

Methods: This pilot study employed mixed qualitative method with interviews, observation checklists and pre and post tests.

Results: Health providers were willing to learn and teach care-givers. However, clinical practice experiences of health providers might prevent them from obtain fidelity. In addition, workload at health facility is also a challenge for health providers to actively delivery care-giver training sessions and home visits.

Pre and posts showed improvement in knowledge of caregivers. Continuously encouragement and feedbacks motivated caregivers to employ knowledge into practice. In addition, online coaching (via Facebook groups) and online resources (video on a365.vn) were also recognized as good options. Home visits were highly appreciated, but sometimes it was challenging when people live in rural areas. However, further follow up and assessment will be needed.

Conclusions: The care-giver skills training is one potentially feasible solution for families with children with ASD in low resource settings. It is very important for researchers and clinical teams shared experiences and good lessons learnt in order to enhance its feasibility and acceptability in different social and cultural contexts.

427.013 *(Poster)* Classifying the Trajectory of Cognitive Development in Response to Early Intervention

S. Meredith Weiss*, A. Xinos and O. Allison, Temple University, Philadelphia, PA*

Background:

Early Intensive Behavioral Intervention (EIBI) can facilitate cognitive development for children with Autism Spectrum Disorder (Smith et al., 2000). Most children display behavioral improvements in response to EIBI, though there is wide variation in outcomes of treatment and in cognitive assessment scores. Prior investigations of individual differences in treatment response identified “rapid learners” (Eldevik et al., 2011) as children who demonstrated significant improvements in cognitive assessments, though others were identified as “moderate learners” (Sallows & Graupner, 2005) who acquire adaptive skills yet showed little change in cognitive scores.

Objectives:

A regression tree model classified the developmental trajectory of cognitive abilities in children with ASD undergoing community-implemented EIBI. Lasso regression is applied to identify ASD intake assessments which significantly contribute to cognitive trajectory classification.

Methods:

The trajectory of cognitive ability was operationalized by a child’s Mullen Composite Score (MCS) at baseline, year 1, and year. MCS trajectories were partitioned using an iterative, multivariate regression tree in R using the MVPART package. These classifications are confirmed using ANOVA and k-means clusters.

Results:

Participants included 62 children with ASD enrolled at age 24 months (M = 3.26, SD = 0.65),

who were classified by the model into four distinct groups of cognitive trajectories: Modest

Learners, Gradual Learners, Robust Learners and those with High-Functioning Autism. The MCS classifications were confirmed using ANOVAs. Modest Learners showed significant change in MCS from baseline to Year 1, $F(1,25) = 27.77$, $p=.00$, but not from Year 1 to Year 2, $F(1,25) = 0.382$, $p=.54$. Gradual Learners only made significant cognitive gains in the second year of treatment, $F(1,27) = 5.62$, $p=.03$. Robust Learners had significant increases in MCS both from baseline to Year 1, $F(1,47) = 70.92$, $p=.00$, and from Year 1 to Year 2, $F(1,47) = 11.29$, $p=.00$. Lastly, children classified as High-Functioning Autism exhibited only marginal changes in MCS were evident in baseline to Year 1, $F(1,47) = 4.37$, $p=.06$, and non-significant change during the second year.

A K-means cluster analysis confirmed the tree classifications, yielding four clusters of similar composition to the regression tree – the largest cluster contained 26 children, identical in composition to the Robust Learners decision tree classification plus one child formerly classified as a Gradual Learner. The remaining clusters were largely accurate as well, with the K-means cluster identifying 93.75% of Gradual Learners in the second cluster, 85.71% of Modest Learners in the third cluster, and the fourth cluster included 87.50% of children classified as High-Functioning Autism.

Variability in three ASD intake assessments predicted 79% of the variance captured by the cognitive trajectory classifiers: Response to Joint Attention (R2 =.46), Motor Imitation (R2 =.11), and Active but Odd behavior (R2 =.22), controlling for age, treatment site and treatment hours.

Conclusions: If applied to a larger sample, multivariate regression trees could provide a data-driven clinical tool to identify individual differences in cognitive trajectory following behavioral intervention in children with ASD.

427.014 *(Poster)* Communication and Behavior: How We Teach Parents to Support Each Domain in Their Young Children with Autism.

L. H. Hampton[1]*, Y. S. Stern*[2]*, K. Bearss*[3] *and M. Roberts*[2]*, (1)The University of Texas at Austin, Austin, TX, (2)Communication Sciences and Disorders, Northwestern University, Evanston, IL, (3)Psychiatry and Behavioral Sciences, University of Washington, Seattle, WA*

Background: Children with autism frequently exhibit challenges not only in social communication, but also with disruptive behaviors. Parents play an important role in social communication development and in the prevention and intervention of disruptive behaviors. When parents respond to child interests with rich linguistic modeling (Leezenbaum, Campbell, Butler, & Iverson, 2014; McDuffie & Yoder, 2010), children have larger vocabularies and stronger receptive language skills (Perryman et al., 2013). Similarly, when parents learn behavior management strategies their children have fewer disruptive behaviors (Bearss, Johnson, Handen, Smith, & Scahill, 2013; Ginn, Clionsky, Eyberg, Warner-Metzger, & Abner, 2017; Postorino et al., 2017). Recent meta-analyses have highlighted the importance of parent interventions for disruptive behavior (Postorino et al., 2017) and social communication (Roberts, Curtis, Sone, & Hampton, 2019). Yet no study had examined the impact of sequencing interventions and the effect on parent implementation across domains and on child skills. It is critical to understand how we sequence, combine, and teach parents different sets of strategies in early intervention (social communication, disruptive behavior) to best reduce family burden and to increase efficiency and efficacy of each intervention.

Objectives: To initially evaluate the effect of positive behavior support parent instruction on parent use of behavior strategies following a parent-mediated social-communication intervention, and the simultaneous maintenance of social communication support strategies.

Methods: A Multiple-baseline across behaviors, single-case design, was employed to examine the effects of parent instruction on 4 categories of behavior support strategies. Participants included 3 mother-child dyads. Parents had recently completed a parent-mediated social communication intervention (Kaiser & Hampton, 2016), and subsequently received instruction in positive behavior supports to address challenging behaviors (Bearss et al., 2018). Parent use of positive behavior support strategies was the primary outcome, and maintenance of social communication strategies and child rate of disruptive behavior were secondary outcomes. Reliability was measured for 20% of all outcomes, with point-by-point agreement greater than 80%. Fidelity of parent instruction was measured for 20% of sessions and was greater than 90% implementation.

Results: All parents demonstrated improved behavior support strategy use as demonstrated by increase in level and trend following each of the four strategy introductions. However, some variability was observed. In particular, all parents required a booster with additional feedback following the third phase of intervention, indicating that the curriculum may require additional supports during this phase. All parents also demonstrated a decrease in social communication support strategies throughout the positive behavior support training, indicating that it may be difficult for parents to integrate multiple methods of engaging with their child without specific coaching to do so.

Conclusions: Parents can learn positive behavior support strategies with minimal instruction over 12 weeks, however additional support may be required to help parents integrate and maintain all strategies. These results are especially important in the landscape of early autism interventions which often include multiple disciplines coaching parents to implement strategies at home (e.g. speech pathologists, and behavior analysts). Implications for clinical practice of coaching and instructing parents and for future research will be discussed.

427.015 *(Poster)* Correlates of Play Skills in a Diverse Population of Young Children with Autism

Y. C. Chang[1]*, S. Y. Shire*[2]*, W. I. Shih*[3] *and C. Kasari*[3]*, (1)Special Education and Counseling, California State University, Los Angeles, Los Angeles, CA, (2)University of Oregon, Eugene, OR, (3)University of California, Los Angeles, Los Angeles, CA*

Background: Children with autism often display more rote, repetitive, and less diverse play compared to their typically developing peers (Jarrold et al., 1996). Play skills are important for children's development and have been associated with gains in other developmental domains (Mundy et al., 1987; Pierucci et al., 2015).

Objectives: This study will 1) examine whether changes in play skills are associated with changes in other developmental skills after participation in JASPER and 2) identify potential moderators of the effect of treatment on changes in play skills in a diverse sample of young children with autism.

Methods: Participants included 174 young children diagnosed with ASD (*M*= 46.72 months; *SD* =7.5 months) from four different studies. Eighty-six percent of the sample was male and 75% reported ethnic minority backgrounds.

Ninety-three children participated in a play-based social communication intervention, Joint Attention, Symbolic, Engagement, and Regulation (JASPER; Kasari et al., 2006) that took place in community settings in the greater Los Angeles area. Eighty-one children received treatment as usual.

The *Mullen Scales of Early Learning* (Mullen, 1989) was used to measure visual reception, fine motor, receptive language, and expressive language. Children's mental age scores were calculated by averaging the age equivalent scores of the four domains. The average mental age of the sample was 26.34 months (*SD* = 10.99 months) and ranged from 8 to 57 months.

Structured Play Assessment (Ungerer & Sigman, 1981) was used to measure children's spontaneous play acts. The frequency and the number of different play acts by level (simple, combination, pre-symbolic, and symbolic) were coded by blinded raters.

Early Social-Communication Scales (Mundy et al., 2003) was used to measure children's spontaneous initiations of joint attention (IJA) and behavior regulation (IBR).

Results: Regression analyses were conducted to examine the association of changes in play with mental age and IJA. Children's gains from baseline to exit in combination play (p=0.0127), pre-symbolic play (p=0.025), symbolic play (p=0.028) were associated with increases in mental age from baseline to exit. Children's gains in combination play (p=0.049) and symbolic play (p=0.007) were also associated with increases in expressive language from baseline to exit.

Moderation: Baseline IJA moderated the effect of treatment on changes in combination play (p=0.001) and symbolic play (p=0.002). Children with greater IJA had greater improvement in combination and symbolic play if they received JASPER. There was no significant moderation by IJA at baseline with treatment on pre-symbolic play.

Conclusions: The results demonstrated that within a diverse sample of children with autism, change in play skills is associated with cognitive and communication gains. Additionally, children with more IJA made more gains in play during intervention. Future research should examine those children who are not as responsive to treatment and explore adaptive treatment approaches.

427.016 *(Poster)* Effectiveness of Community-Based Behavioral Interventions for Young Children with Autism: A Meta-Analysis

A. M. Penney[1]*, S. Coggeshall*[2]*, V. Zhou*[3]*, J. Munson*[4] *and A. Estes*[5]*, (1)Center on Human Development and Disability, University of Washington Autism Center, Seattle, WA, (2)VA - Puget Sound Health Services, Seattle, WA, (3)Seattle Pacific University, Seattle, WA, (4)Psychiatry & Behavioral Sciences, University of Washington, Seattle, WA, (5)Speech and Hearing Sciences, University of Washington, Seattle, WA*

Background: Early intensive behavioral intervention (EIBI) is recommended for young children with autism as soon as autism is suspected. While EIBI is widely accepted due to empirical demonstrations of effectiveness in research settings, less is known about the effectiveness in community-based settings. Currently, disparities in access to services disproportionately impact young children of color and those on Medicaid. Improving our understanding of community-based services is needed to address these disparities.

Objectives: Conduct a systematic review and meta-analysis to examine the effectiveness of community-based behavioral interventions for children under age 6 years.

Methods: A literature search generated 725 possible papers, of which 16 met inclusion criteria (children diagnosed with autism, under six years of age, group design, behavioral intervention, delivered by a person in a community setting, and reported in English). Each study was evaluated for 1) methodological characteristics (use of a control group, randomization, fidelity measurement, sample size), 2) participant characteristics (age, sex, race/ethnicity, inclusion/exclusion criteria, study attrition) and 3) intervention characteristics (targeted versus comprehensive intervention, parental involvement, intervention length, intervention setting). Four outcome domains were common across three or more studies and were the focus of the meta-analysis; adaptive behavior, cognitive functioning, autism symptom severity, and joint attention. Effect sizes were calculated using Hedge's *g*.

Results: Evaluation of each of the 16 studies revealed 13 of 16 studies used a control group and only 5 of 16 utilized randomization. Sample sizes varied greatly, with a range of 16-306 participants (average of 92). Results from 9 studies indicated a moderate association between intervention and adaptive behavior with an effect size of 0.42, 95%CI [0.21, 0.63]. Results from 8 studies indicated a moderate association between intervention and cognitive development with an effect size of 0.46, 95% CI [0.08, 0.85]. Results from 3 studies indicated a large association between intervention and joint attention with an effect size of 0.95, 95% CI [0.26, 1.63]. With regard to autism symptom severity, negative effect size indicates an improvement. Results did not reach statistical significance, but a moderate association was found, with an effect size of -0.29, 95% CI [-0.67, 0.09].

Conclusions: Community-based studies provided evidence for the effectiveness of EIBI in community-based settings; findings consistent with those of highly controlled efficacy trials. However, results also revealed the need for more high-quality community-based trials of EIBI. Future community-based implementation trials should consider challenges of research to practice, challenges associated with randomization in community settings, and access to robust sample size. Community-research partnerships may help address such challenges and achieve interventions that are more aligned with cultural values. As more studies focused on effectiveness are conducted, meta-analytic techniques can be used to address issues related to small sample sizes and to increase confidence in the emerging evidence that community-based interventions can lead to improvements in functioning for young children with autism.

427.017 *(Poster)* Effectiveness of Structured Supports in Increasing Object Imitation in Toddlers with Autism Spectrum Disorder

M. Frisch[1]*, N. Leezenbaum*[2]*, B. Tomaszewski*[3,4,5] *and K. Hume*[3]*, (1)UNC TEACCH Autism Program, University of North Carolina at Chapel Hill, Chapel Hill, NC, (2)University of Pittsburgh Medical Center, Pittsburgh, PA, (3)Frank Porter Graham Child Development Institute, University of North Carolina at Chapel Hill, Chapel Hill, NC, (4)Psychiatry, University of North Carolina at Chapel Hill, Chapel Hill, NC, (5)TEACCH Autism Program, University of North Carolina at Chapel Hill, Chapel Hill, NC*

Background: Imitation skills are significantly impaired in children with autism spectrum disorders (ASD) and are linked to future deficits in other areas of development (e.g., social communication; Toth, Munson, Meltziff, & Dawson, 2006). Engaging in imitation during interactions with caregivers creates experiences that support development and learning in early childhood (Ingersoll & Schreibman, 2006). Thus, imitation is a critical intervention target. Naturalistic developmental behavioral interventions (NDBIs) elicit imitation in children with ASD but research is unclear whether structured supports, which are shown to facilitate on-task engagement in individuals with ASD, pair well with these interventions (Hume & Odom, 2007; Ingersoll & Schreibman, 2006).

Objectives: The present study assessed whether a NDBI, with the addition of structured supports, facilitates imitation in toddlers with ASD.

Methods: Three toddlers (ages 27-31 months) with a confirmed diagnosis of ASD and poor imitation skills (<25% on the Motor Imitation Scale; Stone, Ousley, & Littleford, 1997) participated in a multiple-baseline design across participants design study (Hersen, Barlow, & Kazdin, 1984). Toddlers participated in two 20-minute sessions twice weekly. Baseline sessions followed Ingersoll & Schreibman's (2006) reciprocal imitation training (RTI) protocol. Treatment utilized the same protocol in a structured environment, using physical structure (child sits at table facing adult), utilization of a left-to-right activity system, and material structure (finished component, limited materials, segmenting steps). Each participant completed two generalization sessions, (1) novel setting and (2) novel setting and materials. Imitation was scored as a percentage passed of all actions modeled. Interobserver agreement and treatment fidelity data were collected for 20% of sessions across participants and condition, and social validity data were collected from parents related to intervention feasibility and perceived outcomes. Visual analysis of level, trend, variability, and rapidity of change was conducted to examine the functional relationship between structured supports and object imitation. Mean changes across phase and the percentage of non-overlapping data points (PND; Scruggs & Mastropieri,1998) were calculated.

Results: Rapid level changes were evident for all participants, trending from decreasing/highly variable in baseline to increasing/stable in the intervention phase (Figure 1). All three participants demonstrated stable data in follow-up probes and generalized object imitation to novel settings and materials in generalization probes. Means increased across participants from an average of 28% of all actions modeled in the baseline phase to 84% in the intervention phase and maintained at 98% at the follow-up data collection point. Object imitation generalized across setting (93%) and materials (87%). PND were calculated at 91.8% across participants indicating a highly effective intervention per Scruggs & Mastropieri (1998). Treatment fidelity and social validity data indicated that the treatment was implemented with integrity (90% fidelity) and was deemed feasible and effective by caregivers.

Conclusions: Our results suggest that NDBIs paired with structured supports were effective in rapidly increasing object imitation learning in toddlers with ASD. Findings indicate that structured supports may allow for increased attention to bids for imitation. Future studies should compare rates of learning in NDBIs with and without structured supports.

427.019 *(Poster)* Evaluation of the Autism Distance Education Parent Training (ADEPT) Program in Boise, Idaho: An Update

E. Harlan Drewel[1]*, T. Haase*[2]*, C. Blaisdell*[2] *and P. Schetter*[3]*, (1)St. Luke's Children's Hospital, Boise, ID, (2)St. Luke's Health System, Meridian, ID, (3)UC Davis, Sacramento, CA*

Background: Autism Spectrum Disorder (ASD) symptoms are mitigated when treatment starts early (Zweigenbaum, et al., 2015). An effective intervention for young children with ASD is Applied Behavioral Analysis (ABA) (Rogers and Vismara, 2008).

In Idaho, access to ABA treatment is improving but remains suboptimal. A semblance of ABA is provided by developmental disability agencies, but those providing treatment obtain less training and supervision in ABA compared to behavior therapists in other states. The quality and type of behavioral intervention offered by school districts is variable.

To address access issues, professionals at UC Davis MIND Institute designed the Autism Distance Education Parent Training (ADEPT) program for parents of young children with ASD. Parents review on-line modules demonstrating how to use ABA principles to improve functional skills and reduce problematic behaviors in their children. Parents then attend two, twelve hour, group parent training workshops led by treatment professionals to hone their ABA knowledge. Parents then have a home visit with two of the treatment professionals after each workshop. An unpublished pilot study at MIND showed an increase from pre to post training in parent-reported confidence in the ability to implement ABA principles and parent knowledge of ABA principles.

Providers at a children's hospital in Boise, Idaho implemented the ADEPT program with eight parents who had a child with ASD. Parent-reported confidence in the ability to implement ABA principles increased from pre to post training. Parent knowledge of ABA principles either remained the same or increased from pre to post training. These results were presented at a previous INSAR meeting.

Objectives: Providers in Idaho implemented the ADEPT program with more parents who had a child with ASD to continue to evaluate its benefit. Would a larger sample size show an increase in parent-reported confidence in the ability to implement ABA principles and parent knowledge of ABA principles from pre to post training? Would parenting sense of competence increase and autism-related parenting stress decrease from pre to post training? Positive outcomes would support continued implementation of the ADEPT program throughout Idaho.

Methods: Seven community-based providers (mental health providers, ABA therapists, occupational therapist) implemented the ADEPT program three separate times. Nineteen parents who had a child recently diagnosed with ASD (ages 2 to 8) participated.

Before and after training, parents completed the Autism Parenting Stress Index (Silva and Schalock, 2012), Parenting Sense of Competence Scale (Johnson and Mash, 1989), and surveys on parent-reported confidence in the ability to implement ABA principles and parent knowledge of ABA principles (unpublished).

Results: Consistent with previous results, parent-reported confidence in the ability to implement ABA principles increased from pre to post training. Parent knowledge of ABA principles remained the same or increased pre to post training. Autism-related parenting stress remained the same from pre to post training. Parenting sense of competence increased from pre to post training, which was a new finding.

Conclusions: Results support continued implementation of the ADEPT program. Investigating ways to increase parents' knowledge of ABA principles from pre to post training is warranted.

427.020 *(Poster)* Examining Parental Self-Efficacy in a Parent-Mediated Intervention for Children with Autism Spectrum Disorder

K. M. Russell[1] *and B. R. Ingersoll*[2]*, (1)Michigan State University, East Lansing, MI, (2)Psychology, Michigan State University, East Lansing, MI*

Background: Parental self-efficacy is defined as an individual's beliefs in their ability to effectively manage the different tasks and situations of parenting (Gross & Rocissano, 1988). Parental self-efficacy has been shown to directly affect the quality of parental care provided to children (Sanders and Woolley, 2005; Teti & Gelfand 1991; Tucker et al. 1998). Although research suggests that parent-mediated intervention (PMI) for children with autism spectrum disorder (ASD) can improve parent self-efficacy (Ingersoll et al., 2016), little research has focused on the child, parent, or environmental factors that influence parents' self-efficacy in their implementation of PMIs for children with ASD.

Objectives: This mixed-methods study identified factors that relate to parent-reported self-efficacy when implementing a telehealth-based PMI. Exploratory research will also be conducted to identify certain parent, child, and environmental factors that relate to parent self-efficacy.

Methods: Fifty-one parents of children with ASD received access to a self-directed web-based tutorial as part of one of two research studies evaluating the efficacy of a telehealth-based PMI (Ingersoll et al., 2016). Seventeen participants went through the online program on their own (self-directed) and 24 participants went through the program with therapist assistance and coaching. Parents used a 5-item, 5-point likert-type scale adapted from the Parent Adherence to Treatment and Competence measure (a-PATC; Kasari et al., 2010) to rate their feelings of self-efficacy within intervention implementation per lesson. Parents also completed two to three short answer responses per lesson regarding their child's response to intervention implementation and which techniques the parent felt were most successful and difficult to implement from the lesson. Correlations were used to examine the relationship between group assignment, parent demographics, general parent self-efficacy using the Parenting Sense of Competence Scale (PSOC; Gibaud-Wallston & Wandersman, 1978) at intake, child IQ at intake, and average parent self-efficacy in the intervention (a-PATC). Inductive thematic analysis is being used to identify common themes in parent short answer responses.

Results: Cronbach's alphas for the a-PATC for each lesson were ≥ .67 suggesting adequate internal consistency. Bivariate Pearson's correlations found that general parent-reported self-efficacy at intake on the PSOC significantly and positively related to parent-reported self-efficacy within the intervention program on the a-PATC ($r = .308$, $p < .05$; Table 1). Group assignment, child age, parent education level, and child IQ were not related to a-PATC scores. A median split of the overall average a-PATC scores identified parents as having either higher self-efficacy (average ratings of 3.91 and above) or lower self-efficacy (average ratings below 3.91). The final analysis will utilize theme counts to identify common themes in parents with higher and lower self-efficacy in the intervention.

Conclusions: Parents' feelings of self-efficacy about general parenting were related to parents' feelings of self-efficacy within intervention implementation. Findings suggest that clinicians and researchers should consider general feelings of parent self-efficacy before treatment when gauging parent self-efficacy within the intervention. As a result of this study, we also hope to identify themes influencing parent self-efficacy in intervention implementation to inform additional supports and increase parent self-efficacy within intervention implementation.

427.021 *(Poster)* Factors Predicting Likelihood of ASD Diagnosis within a Multi-Stage Screening Protocol

S. M. Brunt[1]*, A. S. Carter*[2]*, A. Eisenhower*[3]*, M. Troxel*[4] *and R. C. Sheldrick*[5]*, (1)Psychology Department, University of Massachusetts Boston, Boston, MA, (2)Department of Psychology, University of Massachusetts Boston, Boston, MA, (3)University of Massachusetts Boston, Boston, MA, (4)Clinical Psychology, University of Massachusetts Boston, Boston, MA, (5)Boston University School of Public Health, Boston, MA*

Background: Children from marginalized backgrounds are more likely to be neglected or missed during universal ASD screening in primary care (Guthrie et al., 2019), with Spanish-speaking families experiencing further boundaries to timely diagnosis and treatment (Zuckerman et al., 2017). Screening in Early Intervention (EI) may allow for quicker and more accurate identification of children at risk for ASD, especially for underdiagnosed groups.

Objectives: The aim of the present study is to determine how diagnostic rates for different demographic groups vary between a) EI sites participating in a targeted screening protocol and comparison EI sites and b) participating sites pre-implementation and post-implementation.

Methods: This study occurs within the context of a community-based, multi-stage screening and assessment protocol implemented in local Part C EI agencies. Children who screened positive on both stages of the screening process were referred for a diagnostic evaluation.

We utilize data obtained from the Department of Public Health to determine demographic, diagnostic, and service receipt information on children in local EI agencies. Participants were: a) enrolled in either a participating or comparison EI agency for at least 8 weeks during either the baseline period (January 2012-December 2013) or intervention period (July 2016-June 2018), b) between the ages of 14 and 34 months. Intervention sites were three agencies in Boston with high populations of Spanish-speaking (32.4%), racial/ethnic minority (75.6%), and low-income (70.0%) families. Three comparison sites, at which the screening protocol was not implemented, were examined during the same two-year time periods and were selected based on demographic similarity (23.7% Spanish-speaking, 64.9% minority and 71.5% low-income families).

Results: Logistic regressions predicting receipt of an ASD diagnosis based on site, demographic factors, and time suggested that across all sites, children of color were more likely to receive a diagnosis during the implementation period compared to baseline (p=.002). During the implementation period, Spanish-speaking children were more likely to receive a diagnosis at intervention sites than at comparison sites (p=.001). In fact, for intervention sites, diagnoses for Spanish-speaking children increased 71.6% from pre- to post-implementation, while rates for English-speaking children decreased by a non-significant 9.7%.

A two-way an interaction between site and language suggests that Spanish-speaking children were diagnosed later than English-speaking children only at comparison sites; diagnostic age did not differ by language status at intervention sites, $F(1, 947)=77.4$, p=.049.

Conclusions: Results suggest that implementing a community-based, EI-embedded, multi-stage screening and evaluation protocol, available in English and Spanish, a) increased the diagnostic rate for Spanish speaking families and b) decreased the disparity in age of diagnosis for Spanish-speaking families during the intervention period. The fact that financial status and race/ethnicity were not associated with intervention effects suggests that a lack of English language proficiency may be more of a barrier to timely diagnostic evaluations in the usual care context than other social determinants of health, at least among families already accessing EI. Future research should address whether Spanish-speaking families receiving a timely diagnosis are also able to connect to autism-specific services in a timely manner.

427.022 *(Poster)* Helping Optimize Language Acquisition (HOLA): Feasibility and Acceptability of Online Training Modules for Parents of Toddlers at Risk for ASD

R. L. Dodds*, Special Education & Counseling, California State University Los Angeles, Los Angeles, CA*

Background: Early access to evidence-based intervention (EBI) leads to best-case long-term outcomes for children with Autism Spectrum Disorder (ASD). Delay in the receipt of ASD-focused intervention has been associated with later autism severity, placement in segregated learning environments and lower scores on tests of student achievement. Parents from underserved communities often have less knowledge about ASD and are less likely to recognize ASD symptoms therefore, their children are less likely to receive early interventions for ASD. Additionally, underserved families may find interventions that require a significant time commitment or cause their child to react emotionally untenable due to cultural mismatch. The dissemination of brief, culturally competent parent-mediated intervention models can reduce the service-need discrepancy for underserved families.

Objectives: To this end, I developed and assessed a PRT training curriculum which includes 6 online training modules titled, Helping Optimize Language Acquisition (HOLA), based on the information, lessons and examples included in, "Using Pivotal Response Treatment to Teach First Words to Children with Autism" by Lynn Koegel. The 40 to 60-minute training modules provide parents of minimally verbal children with knowledge of child development, ASD symptomology, and teach them basic PRT strategies to improve their child's communication and social interaction in daily routines.

The research questions addressed in this study include; 1. Is HOLA feasible for diverse families with young children at risk for ASD? 2. Is HOLA acceptable to diverse families with young children at risk for ASD?

Methods: This project progressed in 4 stages: Development, refinement, recruitment and assessment of the HOLA online modules. Modules were developed using Canvas Studio and Camtasia software and refined according to feedback from a stakeholder advisory committee. 10 parents or caregivers of toddlers (16 to 48 months) who were minimally verbal and scored 6 or above on the MCHAT were recruited from an Early Intervention provider on the East Side of Los Angeles. Participants received a weekly link by email to complete the 6 online modules. Parent satisfaction was measured by a researcher developed likert scale, and feasibility was determined by recruitment rate and percentage of completion of modules and follow-up assessments. Additionally, the Maternal Autism Knowledge Questionnaire was given at both baseline and follow-up to assess the Impact of training on parent knowledge.

Results: This project will complete recruitment in March 2020.

Conclusions: HOLA has the potential provide parents who may have limited knowledge about ASD with information about their child's development as well as teach strategies to help their child communicate. This program has the potential to reduce disparities in underserved populations.

427.023 *(Poster)* Implementation of Video-Based Feedback Intervention within a Community Based Ndbi Program: Feasibility and Preliminary Results

C. B. Klein[1]*, J. Winter*[1]*, B. Vibert*[2]*, D. Swain*[1]*, A. Lemelman*[1]*, J. Giordano*[1]*, H. R. Thomas*[1]*, C. Lord*[3] *and S. H. Kim*[1]*, (1)Psychiatry, Center for Autism and the Developing Brain, White Plains, NY, (2)Autism Center, Child Mind Institute, New York, NY, (3)University of California, Los Angeles, Los Angeles, CA*

Background: The use of video-based feedback (VF) has been found to be effective in increasing parental sensitivity (Poslawksy et al., 2014) and responsiveness (Green et al., 2010) over the course of parent mediated interventions for young children with ASD. However, because VF interventions have not been implemented widely in community-based interventions yet, there is still a need to examine the feasibility of community implementation and treatment effects.

Objectives: We 1) demonstrate initial feasibility of a VF intervention implemented within an early intervention program; 2) examine preliminary treatment effects; and 3) identify predictors of treatment response.

Methods: Participants (15 toddlers with ASD and their caregivers) were drawn from a 6-month, community-based, stated-funded NDBI early intervention program consisting of group-based clinician-mediated intervention (6 hours/week) and individual parent-coaching sessions (3 hours/week). Children were randomized into the control group (n=7) which received "treatment as usual" and the treatment group (n=8) whose parents were instructed to record 30 minutes of interaction with their child at home to be reviewed by their therapists during individual coaching sessions. The Brief Observation of Social Communication Change (BOSCC, Grzadzinski et al., 2016) was used to measure child changes in social communication and the Measure of NBDI Strategy Implementation–Caregiver Change (MONSI-CC; Vibert et al., under review) was used to measure parents' interactive strategy use. Given the small sample size, both paired sample t-tests and Cohen's d as well as Reliable Change Index (RCI, Jacobson & Truax, 1991) scores were used to examine person-level changes. Pearson's r correlations between parent and child changes were examined.

Results: Out of 15, 10 families participated in the study for approximately 6 months, with 3 participants currently receiving treatment. Both groups demonstrated acceptable attrition rates ($M_{Treatment}$=25% (n=2); $M_{Control}$=0%). Parents recorded an average of 27.30 minutes/week (SD=5.79) of interaction at home for 6 months. Parent surveys for the treatment group (1-10, 10 indicating more positive feelings) indicated that parents felt that VF made the therapists' feedback easier to understand ($M_{Treatment}$=8.0, SD=1.40) and helped them learn new strategies ($M_{Treatment}$=8.36, SD=1.37). Parent feelings (1-10, 10 indicating increased negative feelings) of nervousness and stress of VF treatment were low ($M_{Treatment}$=2.2, SD=0.79; $M_{Treatment}$=4.2, SD=2.45). Children and parents in both groups showed reduction in symptoms and gains in interactive strategies with moderate to large effect size, with children in the treatment group showing a significant level of symptom reduction (BOSCC ASD Total Change; $M_{Treatment}$=7.4, SD=4.76, t(4)=3.50, p=0.03; Figure 1). In the treatment group, 60% of participants showed reliable reduction in autism symptoms (BOSCC), compared to 17% in the control group. Significant correlations were observed between child reduction in social communication symptoms (BOSCC) and improvements in parent strategy use (MONSI-CC; r=-0.70, p=.03).

Conclusions: Results demonstrate the initial feasibility of VF in community-based interventions; parents successfully incorporated the VF intervention into their routines and showed positive feelings towards the intervention. Preliminary findings also showed treatment effects for both children (core ASD symptom reduction) and parents (improvement in interactive strategies). Barriers to intervention implementation and sources of attrition will be explored further.

427.024 *(Poster)* Improvements in Family Empowerment Associated with Perceived Change in Social Ability: A Study of Preschoolers in Early Behavioral Intervention

*A. B. Lupas[1], F. Shic[2] and **M. B. Minjarez**[3], (1)Seattle Children's Autism Center, Seattle, WA, (2)Center for Child Health, Behavior and Development, Seattle Children's Research Institute, Seattle, WA, (3)Seattle Children's Hospital, Seattle, WA*

Background: A diagnosis of autism spectrum disorder (ASD) is typically followed by recommendations for intensive intervention, including early intensive behavioral intervention (EIBI). EIBI is well supported in the literature, with improved outcomes that span cognitive skills, social development, and adaptive functioning among others. Navigating service systems can be difficult for families unfamiliar with ASD, healthcare, or early behavioral intervention; thus, variables such as empowerment are of particular interest in parents of children with ASD.

Objectives: To conduct an exploratory study investigating whether and how changes in family empowerment and child skills correlate with one another in the context of EIBI services.

Methods: Data was collected from families of 31 children diagnosed with ASD who participated in EIBI (Age M=42.4 months, SD=11.2, Range = [19.3, 63.2]), provided at the outpatient clinic of a large children's hospital. All children were on Medicaid insurance and the majority were non-Caucasian in race/ethnicity. Naturalistic developmental behavioral intervention (NDBI) was delivered to the children 12 hours per week, for 12 weeks in a classroom setting; caregivers were also trained to deliver therapeutic techniques throughout the child's participation. Case management support was provided to assist families in accessing services following discharge from the program. Intervention services were delivered by board certified behavior analysts and behavior technicians and supervised by a licensed psychologist with extensive training and experience in the delivery of NDBI. Change in children's skills was measured by comparing baseline and post-treatment scores on the Adaptive Behavior Assessment System, Third Edition (ABAS-3). The changes in the ABAS-3 Global Adaptive Composite, Social, Conceptual, and Practical domains, and Communication subdomain, were all compared to change in family empowerment, measured by comparing baseline and post-treatment scores on the Family Empowerment Scale. All assessments were completed by children's primary caregivers.

Results: Correlational analyses were run to compare changes in assessment scores; an adjusted alpha was calculated using a Bonferroni correction. Both family empowerment (p=.026) and social skills (p=.022) were significantly improved from baseline to post-treatment. Correlation to change in family empowerment scores was not found to be significant for any ABAS-3 domain excepting the Social domain, r=0.513, p=0.016.

Conclusions: These results suggest a relationship between increased caregiver empowerment and improvement in children's adaptive social skills. While increases in other areas of the ABAS-3 were noted by caregivers, the Social domain was the only one to achieve significance when compared to changes in scores of family empowerment. Given the centrality of social deficits to the diagnosis, seeing an improvement in this core feature of ASD may lead families to feel more empowered. Additionally, feelings of disempowerment may be high at treatment onset, as early intervention tends to follow a new diagnosis of ASD, and families may encounter difficulties when attempting to access such a service. Following a successful treatment experience with a parent-training component, feelings of empowerment may then increase. Future research is needed to better understand the elements of early intervention programs that may correlate with increased reports of family empowerment.

427.025 *(Poster)* Increasing Early Social-Communication Skills of Preterm Children with Autism Spectrum Disorder through Focused Intervention Practices: Effects on Imitation, Joint Attention and Play.

***Á. Bejarano**[1], R. Canal-Bedia[1], M. Magan Maganto[1], A. Hernández Fabián[2], A. Calvarro-Castañeda[1], S. Manso de Dios[1], P. Malmierca[1] and M. Posada[3], (1)University of Salamanca, Salamanca, Spain, (2)Hospital Clínico Universitario de Salamanca, Salamanca, Spain, (3)Institute of Rare Diseases Research & CIBERER, Instituto de Salud Carlos III, Madrid, Spain*

Background: The prevalence of autism spectrum disorders (ASD) reported in children born premature or/and with low weight is higher than in the general population. This fact has led to the increase of early detection studies to investigate the early signs of ASD in preterm children. The aim of early detection is to identify early signs of risk of ASD in the child's development, in order to initiate earlier treatment, even before the child receives a formal diagnosis. Thus, early detection only makes sense if there are early treatments available that have proven their efficacy. Focused intervention practices (FIPs) are widely used to improve social communication skills, as they are specifically aimed at enhancing skills identified as core deficits in children with ASD such as imitation, joint attention and play.

Objectives: The general aim of this study was to pilot social-communication FIPs on facilitating imitation, joint attention and play skills for children born premature who showed early signs of ASD (later diagnosed with ASD). Hence, it is important to identify practices that might reduce impairment in social communication skills from the very beginning, as it has been recognised as one of the key problems in children with ASD. The specific aim of the study is to evaluate if these children benefit from early intervention practices focused on socio-communicative skills.

Methods: Families from Salamanca and Zamora areas (northwest of Spain) participating in the national health developmental surveillance program for preterm children were asked to participate within the research study. Neurodevelopmental assessments at ages of 12, 18, 24 and 36 months were performed. Children that show red flags at 18 months were asked to collaborate with the early intervention study. Children in the treatment group received FIPs targeting object and gesture imitation, joint attention, and play. Intervention was administered one hour per day, two days per week during 15 weeks. Treatment was conducted in a small room with identical play materials. FIPs uses several naturalistic techniques to teach social and communication skills.

Results: 25 children have collaborated with the surveillance program, but only 3 children showed early sings of ASD and agreed to participate with the early intervention study. Participants increased their imitation, joint attention and play skills In addition, participants exhibited increases in other skills, including language, adaptative behaviour and cognitive developmental measures. Also, ASD symptomatology scores(measured with ADOS-2, module T) were lessened after intervention. Families reported less stress at the end of the program and positive perspectives about their children's abilities.

Conclusions: These preliminary results suggest that apply FIPs for teaching imitation, joint attention and play to preterm children with early signs of ASD showed improvements in the targeted skills of intervention. This fact support a new and potentially important practice option for children who exhibit early signs of impairment in social-communicative behaviours, before receiving a formal diagnosis of ASD. Nevertheless, this is a pilot study and further research and implementation of FIPs interventions targeting social-communication skills for preterm children with ASD is needed.

427.026 *(Poster)* Individual Differences in Developmental Gains across One Year of Early Intervention for Pre-Schoolers with Autism

C. A. Bent[1]*, M. Yaari*[2]*, J. A. Smith*[3]*, C. C. Green*[4]*, C. Dissanayake*[5] *and K. Hudry*[6]*, (1)Victorian Autism Specific Early Learning and Care Centre, La Trobe University, Melbourne, Australia, (2)Department of Psychology, The Hebrew University of Jerusalem, Jerusalem, Israel, (3)School of Psychology and Public Health, Olga Tennison Autism Research Centre (OTARC), Melbourne, Australia, (4)Olga Tennison Autism Research Centre, La Trobe University, Bundoora, VIC, Australia, (5)Olga Tennison Autism Research Centre, La Trobe University, Melbourne, Australia, (6)Victorian Autism Specific Early Learning and Care Center, Olga Tennison Autism Research Centre, Melbourne, Australia*

Background: Many children with autism benefit from intensive early intervention. However, individual responses vary, and little is known about the profile of skills associated with more favourable outcomes. Age at intake and amount of intervention received are commonly identified as contributing to positive outcomes, as are symptom severity and developmental level. However, these factors have rarely been examined together, and total scores are often used to measure child characteristics, which may mask information about specific behavioural predictors.

Objectives: We aimed to identify discrete behaviours associated with developmental gains across one year of intervention, and to further examine the role of intervention dose and child age at intake, in a large sample of preschool children with autism.

Methods: Participants comprised 122 children aged between 1 and 4.8 years at intake, who received approximately 1-year of Group-Early Start Denver Model (Vivanti et al., 2017) between 2015 and 2018. Individual differences in outcomes were examined by computing a Reliable Change Index (RCI), a standard score to quantify statistically robust change at the individual level. The Autism Diagnostic Observation Schedule (ADOS-2) was conducted at intake, and single items representing discrete behaviours were examined as potential predictors of outcome (e.g., Pointing, Response to Joint Attention, etc.). The primary outcome of interest was Verbal and Non-Verbal RCI scores calculated from Mullen Scales of Early Learning (MSEL) Age Equivalent Scores (V/NVAE) scores.

Results: Large variability was evident in developmental gains, with RCI scores suggesting approximately one third of the sample demonstrated no reliable change in V/NVAE, with the remaining two thirds demonstrating possible or significant improvement (*Figure 1*). Stepwise regressions were conducted to examine the unique role of potential predictors. Pointing, less Overactivity, Response to Name, and Pretend Play were significant unique predictors of Verbal RCI scores, while Pointing and Less Overactivity were significant unique predictors of Non-Verbal RCI. Intervention dose and younger child age at intake were not significant predictors of statistically reliable change in V/NVAE in this cohort.

Conclusions: Discrete behaviours identified as important in predicting developmental outcomes included (1) tuning in behaviours (e.g., Response to Name, Overactivity), and (2) behaviours to engage others (e.g., Pointing and Play). Identifying discrete behaviours associated with more favourable developmental outcomes may inform future individualised treatment decisions and provide more clinically useful information than baseline total scores. Identifying behaviours associated with developmental outcomes may inform proximal intervention targets or the identification of individuals who may benefit from more targeted supported; this is particularly important given that approximately one third of the sample made no reliable change in verbal and nonverbal cognition.

427.027 *(Poster)* Intensive Intervention for Children with ASD: How to Change the Developmental Profiles?

A. Bentenuto[1]*, S. Perzolli*[2]*, G. Bertamini*[3]*, A. Peripoli*[2]*, L. Carrieri*[2]*, S. Cainelli*[2]*, N. Mazzoni*[1] *and P. Venuti*[1]*, (1)Psychology and Cognitive Science, University of Trento, Rovereto, Italy, (2)University of Trento, Rovereto, Italy, (3)Department of Psychology and Cognitive Science, University of Trento, Rovereto, Italy*

Background: Research focused on the efficacy of intervention proved improvements in both cognitive and social abilities reporting promising results (Ospina et al., 2008; Smith &Iadarola, 2015, Tiede et al., 2019). Developmental interventions are planned to aim the core deficits of children with ASD. Furthermore, the involvement of parents in the intervention setting has been recently and widely highlighted (Green et al. 2010; Fava et al. 2011; Strauss et al. 2012; Kasari et al. 2014).Consequently, The recent literature emphasizes the importance of the presence of both parents and school educators during the intervention

Objectives: Our main aim was to explore how the cognitive profile and the social communication skills of children with ASD would change after receiving an early and intensive intervention, in line with the characteristics of the intervention according to the “Italian model of intervention” (Venuti, Scattoni et al. 2016) that included three contexts: the rehabilitation, the educational school and the family.

Methods: Participants were 26 children with ASD (chronological age 2-5 years; Mean=39,6 months, SD= 12,7; Mean mental age= 29,5 months, SD =12,5). The sample consists of 14 children with high functioning (Mean CA =40, 1months, SD= 15,6; Mean MA=32,4 months, SD =14) and 12 children with low functioning(Mean CA =38, 7 months, SD= 6; Mean MA=26,3 months, SD =10,2). Data concerning the cognitive profile were collected using the Griffith Mental Development Scales (GMDS-ER, Luiz et al., 2006) and the information regarding the social communication abilities were obtained from Autism Diagnostic Observation Schedule-2 (ADOS- 2, Lord et al., 2014). These tools were administered pre e post intervention (average period of intervention 13 months, SD=3,5).

Results: A significant improvement in the mean of General Quotient of the children were found between T1 and T2 (p=0.05), in particular regarding the Communication and Performance Scale. Moreover, the Social Affect domain showed a significant decrease between T1 and T2 (p=0.05). The results showed that children with high functioning obtain the higher progression compared to children with low functioning. In particular,regarding the language skills the results showed a significant difference (p=0.05) in the increase between children with high functioning (Mean Communication Quotient T1= 68,1; SD =22, T2 =94; SD=22) and children with low functioning (Mean Communication Quotient T1= 48,1; SD =27,1;, T2=52; SD=30,6).

Conclusions: These preliminary results underline how the characteristics of initial cognitive profile of children can differentiate the development trajectory after a period of intervention. Furthermore,all children following this intervention present greater skills in the use of social signals aimed at maintaining interaction with each other and general improvements in the development profile. Considering the differences between the improvements of high- and low-functioning children, it seems that cognitive functioning might characterize an intensive intervention in high-functioning children while for low-functioning children a continuous intervention might provide better outcomes

427.028 *(Poster)* Knowledge, Self-Efficacy, and Practices Among Part C Early Intervention Providers Who Work with Children at Risk for ASD

A. B. Barber[1]*, S. E. O'Kelley*[2]*, K. R. Tomeny*[3]*, M. Busick*[4] *and M. Costo*[3]*, (1)Communicative Disorders, University of Alabama, Tuscaloosa, AL, (2)University of Alabama at Birmingham, Birmingham, AL, (3)University of Alabama, Tuscaloosa, AL, (4)Learning Tree, Birmingham, AL*

Background: Children under age 3 with suspected or confirmed ASD should receive a mix of naturalistic and developmental interventions that actively involve their families and address core and associated symptoms as early as possible (Zwaigenbaum et al., 2015). Many children and families receive these early intervention services through the federally funded Part C program which mandates that early intervention is provided to children under 3 who have developmental delays. However, community agencies often do not have the accessibility to ASD-specific interventions and thus families are not recipients of these best practices (Hume et al., 2007, Stahmer et al., 2005, & Siller et al., 2013). Rather, providers often select intervention approaches that are available to them (Paynter et al., 2017).

Objectives:

To measure Early Intervention Providers' ASD knowledge and beliefs; 2. To assess Providers' self-efficacy related to working with children who have ASD; and 3. To assess Providers' current intervention practices for working with young children with ASD.

Methods: Ninety-three Early Intervention Providers were recruited through an ASD workshop series. Providers completed a professional and demographic survey and the ASD Knowledge and Self Efficacy Questionnaire (ASD-KS; Atun-Einy & Ben-Sasson, 2017). The professional survey asked about demographic and education and asked them to name three intervention strategies they use when ASD is suspected. Three scales from the ASD-KS were used: Knowledge and Beliefs, Early ASD Markers, and Clinical Self Efficacy. Respondents were asked to indicate the degree to which they agreed with statements across each scale using a four to six point Likert scale.

Results: Preliminary analyses were conducted. Bivariate correlations between demographic and outcome variables indicated that higher levels of education were significantly correlated with knowledge of early markers (r = .302; p = .005) and clinical self-efficacy (r = . 355; p = .001). Years of experience and number of children with ASD on their caseloads were not correlated with any measure of knowledge or efficacy. Using an inductive approach to content analysis, themes were identified to capture intervention strategies implemented when ASD was suspected. Of the 19 broad themes that emerged from the first data pass, 4 are considered established interventions according to the National Autism Center (2015). Those were behavioral interventions, language training, natural teaching strategies, and self-management. Sensory interventions and visual supports were endorsed more than any other themes. Accuracy of Early ASD Markers and ratings of Clinical Self-Efficacy were also examined by discipline. Speech-Language Pathologists had the highest accuracy of red flags and Social Workers had the lowest accuracy. SLPs, Occupational Therapists, and Physical Therapists reported the highest level of self-efficacy. Providers with a degree in Special Education reported the lowest levels of self-efficacy. Across all roles, the average ratings of perceived self-efficacy indicated that respondents had low to average confidence in their skills for working with children with ASD.

Conclusions:

This study is one of the first to examine ASD specific knowledge, self efficacy, and practices among Part C Providers. The results offer implications for targeted preservice and in-service training.

427.029 *(Poster)* Learning to Eat at Home: Delivery of Telehealth-Home Based Interventions to Address Food Selectivity in Autism Spectrum Disorder: A Feasibility Study.

T. Kwok*, C. Raffaele, R. Perlin and S. Smile, Holland Bloorview Kids Rehabilitation Hospital, Toronto, ON, Canada*

Background: The prevalence of food selectivity in autism spectrum disorder (ASD) is up to 89%. Gastrointestinal dysfunction, abnormal oral motor functioning, behavioural and sensory processing differences are contributing factors that drive food selectivity. Nutritional deficiencies, obesity, and stressful parent child relationships are negative health outcomes experienced in this population. A multidisciplinary team assessment is recommended to manage feeding challenges in ASD. Sensory or behavioural interventions are commonly used to address food selectivity, not taking into account other contributing factors driving food selectivity. Limited access to feeding clinics and intervention programs, geographic barriers and cost are some factors that impact the successful management of food selectivity in ASD.

Objectives: To determine whether a multidisciplinary team approach evaluating contributions from medical, oral motor, behavioral, sensory, and environment domains, coined the MOBS^{E}© framework, when paired with videoconferencing for delivery of therapy (telefeeding), can assess and guide the treatment of food selectivity in ASD.

Methods: 20 families with ASD and food selectivity are being recruited. A systematic multidisciplinary team assessment using the MOBS^{E}© framework is used to identify contributing factors of food selectivity. Families receive up to 12 one hour feeding intervention sessions to address a priori feeding intervention goals agreed upon. Outcome measures include; the Canadian Occupational Performance Measure (COPM), 24 hour food diary, and parent and therapist satisfaction questionnaires.

Results: Thus far 7 families have completed the intervention (we anticipate n=20 by INSAR 2020). Six of seven (86%) participants and five of seven (71%) participants showed a clinically significant change with respect to their performance and satisfaction respectively, of a priori goal determined by parent and clinician (Table 1). All participants explored new foods, though the total number of foods did not change over the study period. All participants were satisfied with the telefeeding intervention. All therapists involved with intervention delivery were satisfied with the telefeeding intervention. Parent child interactions around feeding were consistently identified as a challenge that contributed to feeding difficulties in all participants.

Conclusions: Our preliminary data suggests that the use of telefeeding is feasible and satisfactory to providers and parents for delivery of therapeutic feeding interventions. The multidisciplinary MOBS^{E}© framework approach facilitated identification of specific factors that contribute to the feeding challenges in ASD. Addressing parent child interactions around feeding were found to be integral in the management of food selectivity in ASD. This feasibility study is a novel multidisciplinary approach to deliver individualized care with telefeeding intervention to address food selectivity in children with ASD. This novel approach will address barriers to accessing specialized feeding intervention in this vulnerable population.

427.030 *(Poster)* Looking Back and Moving Forward: Scoping Review of Interventions Delivered By Speech-Language Pathologists to Preschool Children with Autism

A. Binns[1]*, J. Oram Cardy*[2]*, R. Smyth*[3] *and A. Andres*[3]*, (1)Western University of Ontario, London, ON, Canada, (2)Western University, London, ON, Canada, (3)University of Western Ontario, London, ON, Canada*

Background: One of the most important predictors of successful long-term outcomes in children with autism is language and social communication skills, and parents consistently identify these skills as treatment priorities for their children with autism. Because speech-language pathologists (SLPs) are trained to support a range of different skill areas (e.g. speech production, augmentative communication, language, social communication, play development, feeding and swallowing), they are well-positioned to tailor their selection of intervention strategies to the unique communication needs of each individual child with autism. This is critical given the heterogeneity of Autism Spectrum Disorder (ASD). However, to date, there has yet to be a comprehensive scientific review of the extent, range, nature, and outcomes of specific interventions delivered by SLPs to preschoolers with suspected or diagnosed ASD.

Objectives: In order to fill the gap in the existing literature and inform clinical practice development, we aimed to understand the extent, range, nature, and reported effectiveness of interventions used by SLPs with preschoolers diagnosed with or suspected to have ASD.

Methods: Adhering to the Preferred Reporting Items for Systematic Reviews and Meta-Analyses for Protocols 2015 (PRISMA), we 1) identified relevant literature through librarian-assisted searches of 7 databases and by reviewing full text bibliographies; 2) conducted initial title and abstract screening, and planned aspects of data extraction; 3) iteratively developed the extraction form, and 4) collated and summarized results according to emergent understanding of the literature.

Results: The search yielded 19,796 records after removing duplicates; initial title and abstract screening yielded 1019 articles for full text review and 103 articles have met eligibility criteria. Final eligibility screening of full text is proceeding in parallel with iterative data extraction, which has yielded the preliminary findings reported here. At least three quarters of the articles published on SLP interventions for preschool children with autism have been published since 2000, with over half of those articles published within the last decade. Interventions provided by SLPs have covered a wide range of skill development areas including: social communication, augmentative and alternative communication, play development, imitation, speech production, pre-reading, receptive and expressive language, behaviour, feeding, and emotion regulation. Research on social communication and receptive and expressive language interventions are predominant and, notably, outcome measures used vary greatly across studies.

Conclusions: Findings from this scoping review will map information from empirical research about the types of interventions delivered by SLPs (e.g. oral motor speech intervention, social skills interventions, pre-literacy interventions). Findings will provide information about: intervention characteristics, dosage (i.e. intensity, frequency, duration), delivery methods, outcome measures used, and intervention results. This information will provide a basis to inform clinical practice development.

427.031 *(Poster)* Monitoring Parent Positive Support, Child Social Behavior and Expressive Language within a Randomized Controlled Trial of a Parent Mediated Intervention for Toddlers with Autism: Implications for Part C Early Intervention

K. M. Baggett[1]*, B. Barger*[2]*, C. Beacham*[3]*, H. Schertz*[4] *and S. Odom*[5]*, (1)Mark Chaffin Center for Healthy Development, School of Public Health, Georgia State University, Atlanta, GA, (2)Georgia State University, Atlanta, GA, (3)Marcus Autism Center, Children's Healthcare of Atlanta, and Emory University School of Medicine, Atlanta, GA, (4)Indiana University, Bloomington, IN, (5)Frank Porter Graham Child Development Institute, University of North Carolina at Chapel Hill, Chapel Hill, NC*

Background: This presentation reports results of an exploratory examination in which brief practitioner-friendly progress monitoring measures were used to assess the relationship between parent and toddler change within a parent mediated intervention implemented within a randomized controlled trial (RCT). The Joint Attention Mediated learning (JAML) program is a parent mediated, relationship-based and developmentally oriented intervention aimed at improving social communication outcomes of toddlers with autism. To date, practitioner measures of parent positive support and key child social and expressive language indicators have not been included in published studies of parent mediated interventions aimed at improving social communication outcomes of toddlers with autism. Practitioners, such as those providing Part C Early Intervention services, require brief, repeatable measures of parent-child interaction to make databased decisions about parent mediated intervention for toddlers with autism.

Objectives: The objective of this research is to examine whether pre-post intervention change in key parent positive supports, including following child lead and maintaining child interest, are positively and significantly correlated with child change in social behavior and expressive language as measured by progress monitoring measures designed for brief, repeated practitioner administration.

Methods: Thirty pre-post parent-toddler interaction videos were randomly selected from dyads participating in an RCT examining the effectiveness of the JAML program (Schertz et al., 2018). Videos were coded using two practitioner progress monitoring measures, the Early Communication Indicator (ECI; Greenwood et al., 2010) and the Indicator of Parent-Child interaction (IPCI, Baggett et al., 2010), with demonstrated reliability and validity for assessing the general outcomes of expressive communication and parent-child interactions that facilitate social competencies of infants and toddlers. Coders were naïve to treatment condition and timepoint. Twenty percent of videos were independently coded by two coders for the purpose of calculating interobserver agreement as defined by total number of agreements divided by total number of agreements and disagreements. Correlations were examined between pre-post change scores on the key parent indicant of following child's lead and maintaining child's interest and key child indicants of positive social behavior and use of words.

Results: Pre-post change in key parent positive supports, which included combined scores of following child lead and maintaining child interest, were moderately positively correlated with pre-post increases in child social behavior, including combined positive social behavior and follow through (r=.56, p=.03). Pre-post change in parent positive supports were also moderately and positively correlated with child use of words, with a trend toward significance (r=.47, p =.08)

Conclusions: These exploratory results provide preliminary evidence that the ECI and IPCI are sensitive to intervention change. Importantly, these metrics are brief, repeatable, and assess general outcomes pertaining social communication and expressive language, core concerns of autism. Specifically, pre-post change in key parent positive support was significantly and positively correlated with child positive social behavior change in the JAML intervention. Further, pre-post change in key parent positive support was moderately correlated with child expressive language, with a trend toward significance. These findings are encouraging and warrant examination within sufficiently powered studies.

427.032 *(Poster)* Outcomes of a Short-Term Low-Intensity Early Start Denver Model Implemented in the Taiwanese Public Health System: A Case Control Study

C. H. Chiang[1]*, T. L. Lin*[1]*, H. C. Wu*[2]*, S. Y. Ho*[3] *and C. C. Wong*[3]*, (1)Department of Psychology, National Chengchi University, Taipei City, Taiwan, (2)Department of Rehabilitation, Taipei Tzu Chi Hospital, Buddhist Tzu Chi Medical Foundation, New Taipei City, Taiwan, (3)Child Developmental Assessment & Intervention Center, Zhongxing Branch of Taipei City Hospital, Taipei City, Taiwan*

Background: Early Start Denver Model (ESDM) is one kinds of Naturalistic Developmental Behavioral Intervention**.** In the past nearly 10 years, most of the ESDM studies were reported in the west, how to ESDM in the Chinese culture such as Taiwan and merged into Taiwanese public health system is an open issue.

Objectives: The purposes of this study was to evaluate the outcomes of implementing the ESDM based on Taiwanese public health policy for young children with Autism Spectrum Disorder (ASD) in the Greater Taipei area in Taiwan.

Methods: A case control study was conducted. A total of 42 children with ASD aged between 25 and 46 months were recruited. A multidiscipline team included child psychiatrists and clinical psychologists based on DSM5 diagnosis of ASD. The ESDM intervention group (N = 21, mean age = 33.23 months) matched to the control group who got community-intervention (N = 21, mean age = 35.14 months) on chronological age, overall development quotient (DQ) and sex. Children in ESDM intervention group received 9 hours per week of oneonone ESDM intervention in clinical settings for 24 weeks. Children's outcome measures were administered pre and postintervention, comprising the cognitive ability, language, adaptive behaviors and symptom severity assessed by the Mullen Scales of Early Learning, Mandarin-Chinese Communicative Development Inventory (MCDI), Adaptive Behavior Assessment System (2nd Edition, ABAS-II), and Autism Diagnostic Observation Scales (ADOS), respectively.

Results: Firstly, using the ESDM fidelity instrument, the mean scores of intervention team's fidelity over the course of the intervention was 81.05 (SD = 2.22; range: 78.03–84.98). Secondly, from the pre- to post-intervention, the results indicated that ESDM intervention group showed significantly greater improvements in nonverbal cognitive ability (Cohen's *d* 1.288) and overall cognitive ability (Cohen's *d*.939) than the control group. Thirdly, there were not significant difference in vocabulary production, adaptive behaviors and symptom severity between ESDM group and control group.

Conclusions: The study provides the first data to supports on the efficacy of ESDM in Taiwan. The results suggest that a shortterm and low-intensity ESDM intervention directly delivered in clinical settings may be a promising early intervention for young children with ASD.

427.033 *(Poster)* Parent Delivered Strategies to Improve Eating, Drinking and Swallowing Difficulties of Young Children with Autism and / or Other Neurodevelopmental Disorders: Current Practice and Future Research

J. R. Parr[1]*, L. Pennington*[1,2]*, H. Taylor*[1]*, D. Craig*[1]*, C. Morris*[3]*, H. McConachie*[1]*, J. E. Cadwgan*[1,4,5]*, D. Sellers*[6]*, M. Andrew*[2]*, J. Smith*[1]*, D. Garland*[7]*, E. McColl*[1]*, C. Buswell*[2]*, J. Thomas*[1] *and A. Colver*[1]*, (1)Population Health Sciences Institute, Newcastle University, Newcastle upon Tyne, United Kingdom, (2)Great North Children's Hospital, Newcastle upon Tyne Hospitals NHS Foundation Trust, Newcastle upon Tyne, United Kingdom, (3)College of Medicine and Health, University of Exeter, Exeter, United Kingdom, (4)Paediatric Neurosciences, Evelina London Children's Hospital, Guy's and St Thomas' NHS Foundation Trust, Kings Health Partners, London, United Kingdom, (5)School of Life Course Sciences, Kings College London, London, United Kingdom, (6)Speech and Language Therapy, Sussex Community NHS Foundation Trust, Chailey Clinical Services, East Sussex, United Kingdom, (7)Cumbria, Northumberland, Tyne and Wear NHS Foundation Trust, Newcastle upon Tyne, United Kingdom*

Background: Eating, drinking and swallowing difficulties (EDSD) are common in young children with autism and/or other neurodevelopmental disorders. EDSD can be caused by physical and non-physical difficulties leading to inadequate calorie intake, affecting a child and parents everyday life. Autistic children commonly show non-physical EDSD such as restricted or selective eating and rituals associated with food or mealtimes. Autism is also often associated with physical neurodevelopmental conditions such as Down Syndrome and cerebral palsy leading to both physical and non-physical EDSD. Guidance on how to address these difficulties is lacking.

Objectives: We undertook a study to answer the question: What interventions, which could be delivered at home by parents, are available to improve eating in young children with neurodevelopmental conditions and are suitable for investigation in pragmatic trials? Our study focused on both physical and non-physical EDSD.

Methods: We undertook: 1. Updates of systematic reviews, and a mapping review of the research evidence for interventions and outcome measures. 2. Two national parent and professional surveys: one about current professional practice and what is received by parents, and a Delphi survey to identify the most important interventions and outcomes. 3. Focus groups with parents, professionals and young people to discuss current practice and consultation workshops to identify future directions and research.

Results: 951 parents and professionals participated across the study: 400 parents; 479 health professionals; 62 education professionals. 10 young people were interviewed. The limitations of the research evidence regarding interventions and tools to measure outcomes was identified. The survey showed a wide range of interventions are used in NHS practice – parents and professionals reported variability in provision. Professionals and parents of autistic children reported a lack of service provision for children with EDSD. Nonetheless, parents and professionals considered many interventions were important, and led to change in EDSD. They identified 19 interventions as important to deliver when needed, and 10 outcomes that were most important to measure (including nutrition, growth, and health/safety); young people agreed these were important outcomes. Parents and professionals were positive about a proposed 'toolkit' of interventions. They thought the toolkit contained interventions that were relevant for children with physical and non-physical EDSD, and the order these would be delivered could be prioritised through shared decision-making.

Conclusions: The challenges for future clinical trials of a toolkit of interventions were evident (for example, the range of interventions that children in a comparator group might receive). Parents and professionals thought that implementation of the toolkit as part of usual practice would be a positive step. However, this would require the toolkit to be operationalised through further development including an evaluation of the feasibility and acceptability of using the toolkit in clinical practice and in the home environment by parents. Subsequent evaluation of its effectiveness could then be undertaken. The findings of this study can be used to support service development for parents and children with autism and/or other neurodevelopmental disorders, and also by funders to consider whether to commission further research including trials of interventions.

427.034 *(Poster)* Parent Strategies for Improving Language in Minimally Verbal Preschoolers

C. K. Toolan[1]*, A. Holbrook*[1]*, L. Hughart*[1]*, A. M. Dimachkie*[1]*, R. Landa*[2] *and C. Kasari*[1]*, (1)University of California, Los Angeles, Los Angeles, CA, (2)Center for Autism and Related Disorders, Kennedy Krieger Institute, Baltimore, MD*

Background: Children's early language skills are learned through social interactions with caregivers. Core impairments in social communication skills can lead to missed opportunities for children with ASD to learn from these social interactions. Early interventions for ASD that target social communication and language vary in approach -- from adult-led and structured (e.g., Discrete Trial Training) to child-led and naturalistic (e.g., JASPER; Kasari et al., 2008, 2010).

Training parents in intervention strategies is effective for improving a wide range of children's outcomes (Schultz et al., 2011). Less is known, however, about which parent strategies are most effective in improving children's language.

Objectives: 1) Examine change in parent strategy use by treatment (DTT, JASPER) and across 6-month intervention period. 2) Explore relation between parent strategies, time, treatment, and child language outcomes.

Methods: This study uses secondary data from a social communication intervention RCT. Of the original 164 participants, 143 were included in the current study (had data at both timepoints, completed assessment with same parent at both timepoints, transcripts in English). Preschoolers with ASD (Mage=44.99 months, SD=5.46) using <30 spontaneous words at baseline received 6 months of either DTT or JASPER. Parents received training in intervention strategies (based on child's treatment) during the last two months of treatment.

At entry and exit, parent-child dyads completed a videotaped 10-minute free play assessment (PCX). PCXs were coded (ICCs=.75-.88) for parents' use of strategies common across ABA-based interventions, namely: responsiveness, prompting, pacing, and environmental arrangement. Items were rated on a 5-point Likert scale; higher ratings indicated more fluent and appropriate use of strategies.

PCXs were also transcribed, coded, and analyzed for the number of children's spontaneous communicative utterances (SCU) and number of different words (NDW).

Linear mixed models were used to examine change in parent strategy use by time and treatment. Negative binomial mixed models were used to examine change in children's language across time, treatment, and parent strategies. Analyses controlled for children's age, nonverbal IQ, ADOS severity, and parents' education levels.

Results: There was a time x treatment interaction for parents' responsiveness (p=.043) and prompting (p=.040). JASPER parents increased in their appropriate use of these strategies between entry and exit; DTT parents remained stable. DTT parents used environmental arrangement more appropriately than JASPER parents (p=.040) across timepoints. There were no differences in pacing by time or treatment.

Children's SCU increased over time (p<.001). Parents' responsiveness (p=.003) and prompting (p=.020) predicted SCU. Parents' responsiveness (p=.004) and prompting (p=.033) also predicted NDW, which increased over time (p<.001).

Conclusions: Parents improved in their use of ABA-based intervention strategies over a brief training period. Parent training in JASPER was particularly effective in teaching parents to contingently respond to children's communication and prompt appropriately (prompt hierarchy, developmental appropriateness). This is especially significant since these strategies also predicted children's language outcomes. Findings add to a growing base of literature on the effectiveness of parent training on child outcomes, highlighting parent strategies that ultimately support language development in minimally verbal preschoolers.

427.035 *(Poster)* Parent-Led Training for Motivating Eye Contact in Children with Autism Spectrum Disorder: Boscc Outcome Study

E. Lehtonen[1]*, M. Muuvila*[2]*, T. M. Helminen*[3]*, J. Lauttia*[4]*, S. Ahonen*[1]*, K. Eriksson*[5] *and A. Kylliainen*[1]*, (1)Faculty of Social Sciences/Psychology, Tampere University, Tampere, Finland, (2)Tampere University Hospital, Tampere, Finland, (3)Faculty of Social Sciences/Psychology, Tampere University, Tampere, Finland, (4)Faculty of Social Sciences/Psychology, Tampere Univeristy, Tampere, Finland, (5)Tampere University and Tampere University Hospital, Tampere, Finland*

Background: Difficulty in use of eye contact is one of the earliest signs that evokes concerns in parents of young children with ASD. It could be beneficial to aid a child with ASD to initiate spontaneous eye contact by encouraging it in everyday interactions as part of natural social engagement in situations considered the most rewarding for the child. We piloted a parent-led eye contact-specific training as an additional part of treatment as usual in young children with prominent features of ASD and developmental delay. Our earlier findings revealed that eye contact use increased in free-play with the parent in the training group. The increase in joint engagement was evident after the 2-year follow-up. It is not known, however, whether the eye contact use is generalized to interaction with other persons than parents or to other aspects of social behaviour.

Objectives: The aim of the study was to investigate whether a parent-led training method targeted to improve eye contact in young children with ASD would show improvements in social interaction with other adults than parents. The Brief Observation of Social Communication Change (BOSCC) was used as an outcome measure. BOSCC comprises of 16 observational items which include 9 items of social communication and 4 items of restricted, repetitive behaviours as 13 core items and 3 additional items of other behaviours.

Methods: Twenty young (age range: 2.5-5.5 years of age) children with prominent features of ASD and developmental delay were randomly divided into a training group (N=10) and a control group (N=10). The parents of the training group were taught to do three kinds of daily exercises with their child for 4 months. The BOSCC analyses were done from ADOS-2 -assessments at baseline, 4-6-month (short-term) and 2-year (long-term) outcome. The BOSCC was coded from two 6-minute segments of the 12-minute videos that included the same pre-agreed, recommended activities of ADOS-2. The coders were blind to the status of the video and in adequate agreement with each other. The outcome effect was counted as change score delta between the three measurements.

Results: The findings showed that there were no between group differences in delta scores in any of the summary scores at any measuring points. At the item level, however, there was a significant difference in the change of eye contact in short-term outcome in a way that the training group had improved more than the control group (U=19.5 p=.018). There was greater improvement in use of gestures (U=15.5. p=.013) and the in integration of vocal to non-vocal modes of communication (U=14.0 p=.010) between the short-term and long-term outcome in training group than in the control group.

Conclusions: Our preliminary findings indicate that the parent-led eye contact training has positive effect to the use of eye contact, and it might have benefits to other aspects of the non-vocal communication in the long run. It was interesting that the findings revealed generalization of the eye contact use in a semi-structured play session with a stranger adult.

427.036 *(Poster)* Parent-Mediated Interventions for Elevated Autism Risk: Considerations for Parenting Stress and Maternal Depression

A. M. Kellerman[1]*, S. Hollis*[2]*, C. Masters*[1] *and A. J. Schwichtenberg*[1]*, (1)Purdue University, West Lafayette, IN, (2)St. Mary's College, Notre Dame, IN*

Background: Providing empirically derived and affordable services to affected families is a primary goal of early detection researchers. Given the current prevalence of ASD, delaying services for infants at-risk for social communication difficulties is a missed opportunity to improve developmental trajectories. To better serve families, and as a measure of clinical best practice, researchers/practitioners are shifting their focus from a "wait-and-see" approach to *prospectively* providing services to children developing with elevated autism risks/concerns (ERCs). A handful of elevated-risk parent-mediated interventions (PMIs) have emerged and demonstrate subtle, yet significant shifts in social communication progress following treatment. These PMI designs have simple guidelines (e.g., increase responsiveness during play); however, less attention has considered maternal well-being within PMIs to monitor risks of maternal distress or depression that may impact treatment compliance and ultimately efficacy.

Objectives: To inform elevated-risk PMIs, this preliminary investigation addressed three aims: (1) descriptively characterized types of infant/toddler ERCs at enrollment, (2) assessed associations between total ERCs and mother reported indices of parenting stress and depression, pre- to post-intervention, and (3) assessed whether reported rates of maternal parenting stress and depression differ, pre- to post-intervention.

Methods: Twenty-one children with ERCs participated in an ongoing family routines-based PMI. At enrollment, mothers completed a series of standardized measures, including the Parenting Stress Index (PSI) Short Form and the Center for Epidemiologic Studies Depression Scale (CESD). An ERC Total Score of up to 5 was derived from reports of (1) prenatal/newborn concerns, (2) parents' developmental concerns, (3) pediatrician/clinician concerns, (4) sibling diagnostic history, and (5) flagged scores on developmental screeners. Qualifying ERCs per domain are summarized in Table 1.

Results: Overall, mothers endorsed an average of 2.95 ERCs for their infants/toddlers at enrollment. A series of partial correlations and general linear models, with terms for infant sex, income, and treatment condition, were conducted for Aims 2 and 3, respectively. Specific to Aim 2, infants/toddlers with more ERCs had, (1) mothers who endorsed significantly more stress related to their infant/toddlers being difficult before intervention, and (2) following intervention, mothers endorsed significantly more dysfunctional interactions (see Table 2). Unexpectedly, significant negative associations pre- and post-intervention for Total ERCs and depression concerns were observed such that more ERCs were associated with lower rates of maternal depression symptoms. Further inspection revealed this association to be primarily driven by the parent concerns ERC domain, r(16) =-.49, *p*=.02. In addition, other ERC domains such as sibling diagnostic history were more indicative of increased depression symptoms, r(16)=.44, *p*=.03. Specific to Aim 3, no significant mean level differences pre- to post-intervention for parenting stress or depression were observed.

Conclusions: To inform elevated-risk PMIs, this study provides preliminary support for considering and monitoring indices of maternal stress and depression when training mothers as interventionists. Future studies may build upon our preliminary investigation by further examining types of ERCs that may be more indicative of elevated stress and/or depressive symptoms, as well as how maternal reports of stress and/or depression relate to observed social behaviors during treatment.

427.037 *(Poster)* Parent-Nominated Target Problems to Assess Outcome in a Randomized Trial of Parent Training in Children with ASD and Disruptive Behavior

E. S. Sheridan[1]*, K. Bearss*[2]*, S. Gillespie*[3] *and L. Scahill*[4]*, (1)Center for Autism and the Developing Brain, Weill Cornell Medical College, White Plains, NY, (2)Psychiatry and Behavioral Sciences, University of Washington, Seattle, WA, (3)Emory University, Atlanta, GA, (4)Marcus Autism Center, Atlanta, GA*

Background: Disruptive behaviors that impair adaptive functioning are common complaints from caregivers of children with Autism Spectrum Disorder (ASD). These disruptive behaviors include aggression, tantrums, noncompliance, hyperactivity, impulsiveness, and self-injury.

Objectives: To describe the reliability and validity of parent-nominated target behavior problems to measure outcome in a multi-site, randomized trial of RUBI parent training versus psycho-education in young children with ASD and disruptive behavior.

Methods: Following a comprehensive assessment, participants (age 3 to 7 years) with ASD accompanied by moderate or greater behavioral problems were randomly assigned in a 1:1 ratio to manual-driven parent training (PT) or a structured parent education program (PEP) for 24 weeks. Moderate or greater behavioral problems was defined by a score of ≥15 on the Aberrant Behavior Checklist-Irritability subscale (ABC-I). To identify the parent target problems (PTPs), a clinician blind to treatment assignment interviewed parents to identify 1 or 2 chief complaints about the child's disruptive behavior. The description, which included frequency, duration, intensity, and impact of the behavior on family life, was documented in a brief narrative at baseline. The narratives were reviewed and revised at monthly follow-up visits to document behavior change over time. A panel of five raters was convened to rate change from baseline on a 9-point scale (1=normal; 2=markedly improved; 3=definitely improved; 4=equivocally improved; 5=no change; 6=possibly worse; 7=definitely worse; 8=markedly worse; 9=disastrously worse) at Weeks 8, 12, 16, and 24. Raters participated in a teleconference to calibrate the scoring of the PTPs on the 9-point scale. Following this calibration conference, raters independently scored PTPs for all cases blind to treatment condition.

Intraclass correlation (ICC) across the panel of five raters exceeded 0.7 at each time point (overall mean=.76, range=.74-.79) supporting solid inter-rater reliability. Thus, PTP scores for the two target problems were averaged across the five raters yielding a mean score for each child at each time point. The mean scores for PT was compared to PEP using an intent-to-treat mixed effects linear model.

Results: 169 children (mean age 4.7 ± 1.2 years, 87.5% male, 12.8% IQ < 70) of the original 180 study participants had complete PTP data. At Week 8, the difference in mean PTP scores between PEP and PT was moderate (effect size=.56, p=.001). By week 24, the difference between PEP and PT was large (ES=.75, p<.001). PT participants showed a more significant reduction in target problems than PEP participants.

Conclusions: The behavior narratives captured on PTPs offer a systematic method of tracking individual child-specific outcomes over time in a clinical trial. The FDA and other federal agencies have highlighted the importance of patient-reported outcomes. Parent/caregiver narratives provide important information about the patients with ASD that can also be used to track child-specific outcomes in clinical practice.

427.038 *(Poster)* Parent-Reported Generalization of Functional Communication Training in Young Children

N. M. Hendrix[1]*, M. J. O'Brien*[2]*, K. Pelzel*[3] *and K. Miller*[3]*, (1)Marcus Autism Center, Emory University School of Medicine, Atlanta, GA, (2)Pediatrics, University of Iowa Stead Family Children's Hospital, Iowa City, IA, (3)University of Iowa Children's Hospital, Iowa City, IA*

Background: Problem behavior is observed at substantially higher rates in children with autism spectrum disorder (ASD) than in their typically-developing peers (e.g., Soke et al., 2018). Functional communication training (FCT) is a behavior analytic approach that involves teaching an appropriate communicative response that serves the same function as a specific problem behavior (Reichle & Wacker, 2017). Despite their narrow aim, focused interventions like FCT may also reduce non-targeted behaviors; accordingly, there is hope that the effects of the treatment within the training context (e.g., during home-based therapy sessions) will generalize to other contexts (e.g., during car rides) and other behaviors. FCT is widely used for children with ASD (Tiger et al., 2008) and has strong evidence of its effectiveness, including findings from a recent randomized controlled trial (Lindgren et al., under review). Yet little is known about the generalized effects of FCT without programming for them.

Objectives: We evaluated treatment effects outside of the training context of parent-mediated FCT for young children with ASD conducted using a telehealth delivery model. We employed parent-rating scales used in previous behavioral treatment work (e.g., Bearss et al., 2015; Bearss et al., 2018; Scahill et al., 2016) for participants whose targeted problem behavior was effectively treated with FCT. We examined: 1) generalization of treatment effects to settings and contexts beyond the training setting, 2) generalization of treatment gains to various problem behaviors, and 3) parent perception of stress related to the child prior to and at study completion.

Methods: A sample of thirty young children (ages 21 to 84 months; 24 male, 6 female) with ASD who exhibited problem behavior was drawn from federally-funded, multi-site research on the assessment and treatment of problem behavior in children with ASD. Each participant received FCT treatment through weekly, 1-hour telehealth sessions for 2 to 6 months or until discontinuation criteria were met (i.e., problem behavior decreased by 80% or greater from baseline rates). Parents completed pre- and post-treatment rating scales (*Home Situations Questionnaire-Pervasive Developmental Disorders* [*HSQ-PDD*]; *Aberrant Behavior Checklist*, Irritability subscale [*ABC-I*]; *Behavior Problems Inventory* [*BPI*]; *Parenting Stress Index*, Child Domain [*PSI*]).

Results: A linear mixed model approach was used to compare scores on *ABC-I*, *BPI*, *HSQ*, and *PSI* measures. Statistically significant differences between pre- and post-treatment were found for the *ABC-I* ($F(1, 28) = 24.24$, $p < .001$), *BPI* ($F(1, 28) = 23.37$, $p < .001$), and *HSQ* ($F(1, 28) = 35.15$, $p < .001$) in the hypothesized direction. Analyses for the *PSI* demonstrated similar results ($F(1, 26) = 6.71$, $p = .016$) for all participants who completed pre- and post-treatment measures.

Conclusions: The current study extends the research on FCT for young children with ASD by indicating generalized effects of FCT across targeted and non-targeted problem behaviors across settings. Implications for generalization effects of parent-mediated treatments for young children with ASD will be discussed. Intentional integration of self-report measures—the standard for most behavioral and pharmacological treatments studies in ASD (Matson & Burns, 2019)—into behavior analytic treatment approaches will be discussed as well.

427.039 *(Poster)* Parental Stress As a Predictor for Treatment Outcome in Preschool Children with ASD and Other Social Challenges

I. Tripathi[1]*, Y. S. Lograsso*[2]*, E. Denluck*[1] *and E. A. Laugeson*[2]*, (1)UCLA Department of Psychiatry, PEERS lab: UCLA PEERS Clinic, Los Angeles, CA, (2)UCLA Semel Institute for Neuroscience and Human Behavior, Los Angeles, CA*

Background: Research suggests that parents of children with autism spectrum disorder (ASD) may experience higher levels of stress compared to parents of typically-developing children (Karst et al., 2014). These stress levels may be more pronounced during early childhood as parents begin navigating their child's diagnoses and seeking resources (Estes & Macduffie, 2019). Since caregivers with high stress levels may be less engaged in early intervention programs, they may in turn be less likely to implement good parenting practices that result in positive outcomes for their children (Estes & Macduffie, 2019). Consequently, parental stress has been associated with delays in social relatedness in children with ASD (Davis & Carter, 2008). Although preliminary research has also demonstrated that high parental stress may reduce the effectiveness of early teaching interventions for children with ASD (Osborne et al., 2007), there remains a dearth of literature investigating the effect of parental stress on treatment outcome specifically in early social skills interventions.

Objectives: The present study seeks to examine whether baseline parental stress predicts social skills treatment outcome for preschool children with ASD and other social challenges. We hypothesized that higher parental stress levels at baseline would predict lower improvements following social skills training.

Methods: Participants included 58 preschool children (75.9% male; mean age=4.57; *SD*=0.78) presenting for treatment through the UCLA Program for the Education and Enrichment of Relational Skills (PEERS®), an evidence-based, caregiver-assisted social skills intervention for youth with ASD and other social challenges (Laugeson et al., 2011). Baseline parent stress was measured using total pre-treatment scores on the Parenting Stress Index, Short Form (PSI-SF; Abidin 1995), with higher scores indicating greater parental stress. Treatment outcome was measured using change in total scores from pre- to post-test on the Social Responsiveness Scale-Second Edition (SRS-2; Constantino & Gruber, 2012), with decreases in SRS-2 scores representing greater improvement in social responsiveness.

Results: A paired sample t-test reveals significant improvement on the SRS-2 pre- to post-treatment (mean=6.586, *SD*=7.952, $p<.001$). A linear regression was calculated to predict treatment outcome on the SRS-2 in relation to baseline parental stress levels on the PSI-SF. Analyses reveal a significant regression ($F=8.632$, $p=.005$), with an R^2 of .134, indicating that higher baseline caregiver stress levels are related to greater improvements in social responsiveness at completion of the program, contrary to expectation.

Conclusions: Results of the present study differ from prior research documenting decreased effectiveness of early teaching interventions in stressed parents, with current data revealing that parents reporting higher baseline stress experience greater gains in their children's social responsiveness following treatment. These findings suggest that the PEERS® intervention, which includes elements of parent training, may offer highly stressed parents of children with ASD and other social challenges the skills required to communicate effectively with their child, possibly leading to reduced behavioral difficulties and improved social functioning. Overall, this study highlights the importance of providing targeted resources to parents with greater needs, as this may translate into enhanced treatment outcomes for children with challenging social behaviors.

427.040 *(Poster)* Pivotal Response Treatment Parent Training Delivered Via Telehealth: A Pilot Study

R. K. Schuck[1], *G. W. Gengoux*[1], *C. Ardel*[1], *K. Berquist*[1], *E. Orrick*[1], *E. Karp*[1] *and A. Y. Hardan*[2], *(1)Psychiatry and Behavioral Sciences, Stanford University School of Medicine, Stanford, CA, (2)Psychiatry & Behavioral Sciences, Stanford University, Stanford, CA*

Background: The high prevalence of autism spectrum disorder (ASD) requires the need for widespread dissemination of evidence-based treatments. Previous research has demonstrated that Pivotal Response Treatment (PRT) is an effective treatment for improving language and communication skills of young children with ASD. Parents can learn to implement PRT with fidelity, leading to gains in child language. However, access to such training programs is limited. Telehealth-delivered PRT parent training may be a promising approach to disseminate such treatment widely and quickly.

Objectives: The objective of this pilot study was to determine whether PRT parent training delivered via video conferencing was effective for improving child communication abilities.

Methods: To date, eleven participants (2 female; mean age=43 months) and their parents were recruited from a university ASD clinic/research program. Parents received 12 weeks of PRT training (1hr/week) that was delivered via video-conferencing. The majority of sessions included parent and child, with the clinician giving live feedback. Language and communication skills were assessed pre- and post-treatment using the MacArthur Bates Communication Development Inventories (CDI), Vineland Adaptive Behavior Scales (VABS), and a 10-minute language probe recorded at home, during which parents were instructed to try to get their child to communicate as much as possible. Social abilities were measured using the Social Responsiveness Scale-2 (SRS-2). All comparisons were conducted using paired-samples t-tests. Participant recruitment is ongoing.

Results: Number of words produced on the CDI significantly improved after treatment (baseline M=103.09, SD=101.93; week12 M=190.82, SD-146.03; t(10)=-3.115, p=.011), as did number of words understood (baseline M=173.00, SD=117.28; week12 M=200.27, SD=115.47; t(10)=-2.582, p=.027). Participants' overall communication standard score on the VABS also improved (baseline M=69.56, SD=10.03; week12 M=76.44, SD=10.32; t(8)=-3.077, p=.015). Following treatment, children showed improvement in independent use of intelligible speech as evidenced by significant increase in response to parents' non-verbal prompts (baseline M=0.18, SD=0.41; week12 M=4.09, SD=3.99; t(10)=-3.36, p=.007) and in spontaneous utterances (baseline M=2.27, SD=2.41; week12 M=5.18, SD=6.06; t(10)=-2.42, p=.036), when coded from the home video language probe. No significant changes in SRS-2 scores were found.

Conclusions: Preliminary results from this ongoing pilot study indicate that children improved their language abilities across a variety of measures after they and their parents took part in a 12-week telehealth PRT parent training program. Though the training focused on expressive language, receptive vocabulary also improved, indicating that the benefits may not be limited to the explicit aims of the training. The findings from the home videos indicate that children moved toward an increased spontaneity of speech. Increased responsiveness to non-verbal prompting also most likely reflects an improvement in parents' ability to prompt effectively using non-verbal means. These preliminary findings demonstrate that PRT parent training can be implemented via video conferencing and that it can lead to gains in child language. Additional findings from this ongoing study will be examined and if consistent with current observation will warrant future randomized controlled trials to replicate the findings and compare parental fidelity of implementation between PRT delivered via telehealth versus in-vivo.

427.041 *(Poster)* Pre-Pilot Evaluation of CST Program: A Qualitative Analysis

R. A. Garcia[1,2], *M. Irarrazaval Dominguez*[3,4,5], *M. P. Araya*[6], *G. Reginatto*[7], *T. Arratia*[7] *and* ***M. S. Burrone***[7], *(1)Autism Spectrum Disorders Program, Hospital Clínico, Clínica Psiquiátrica, School of Medicine, University of Chile., Santiago, Santiago, Chile, (2)Clínica Las Condes, Santiago, Chile., Santiago, CHILE, (3)Autism Spectrum Disorders Program, Hospital Clínico, Clínica Psiquiátrica, School of Medicine, University of Chile., Santiago, Chile, (4)Department of Mental Health and Substance Use, Ministry of Health, Santiago, Chile., Santiago, Chile, (5)• Millenium Institute for Research in Depression and Personality, Santiago, Chile, Santiago, Chile, (6)• Department of Mental Health and Substance Use, Ministry of Health, Santiago, Chile, (7)Institute of Health Sciences, Universidad de O´Higgins, Rancagua, Chile*

Background: Developmental Disorders are defined, according to ICD-10, as a set of conditions that are characterized by hyperkinetic activity and / or persistent and repetitive instances of alteration of social, aggressive or challenging behavior (WHO, 1994). These disorders usually begin in childhood with an alteration or delay of functions related to the maturation of the central nervous system (WHO, 2010). The consequences of these disorders in children and / or adolescents have direct and indirect consequences, which has been associated with reducing their health and wellbeing and their families (Peasgood et al, 2016). Training interventions on psychosocial skills and for caregivers are focused on transmitting to children and their caregivers methods and strategies to reduce problematic behavior and improve social behavior (WHO, 2018). The World Health Organization developed the Caregiver Skills Training Program (CST) to improve skills and quality of life in caregivers of children with autism.

Objectives: Conduct a qualitative assessment of the feasibility and acceptability of CST in the central commune of Santiago, Chile.

Methods: We conducted a pre-pilot study of CST in caregivers of children with autism in the central commune of Santiago, Chile, in 2017-2018. CST was implemented by two facilitators and included 9 group training sessions and 3 in-home visits. Feasibility and acceptability of CST was qualitatively assessed by an external team and included: 1- Focus groups with caregivers and 2- In-depth interviews with caregivers and facilitators.

Results: In focus groups with caregivers, 5 dimensions were identified: 1- Usefulness of the program, components and strategies; 2- Acceptability, implementation and impact; 3- Adverse effects; 4- Attendance barriers and abandonment; 5- Suggestions. Caregivers reported that liked the in-home visits, the content of the group training sessions and the interaction with other caregivers. They found that it improves the coping of challenging behaviors and mentions empowerment in facing demands of educational and family establishments. They did not report negative experiences, however, women mentioned that it was difficult for them to transmit the skills that they learned to their male partners. Among the suggestions of caregivers are: post-intervention follow-up, incorporation of aspects related to future challenges in adolescence, and training in educational establishments. In the in-depth interviews with facilitators, 7 dimensions were identified: 1- Acceptability; 2- Material evaluation; 3- Impact; 4- Barriers to implementation; 5- Training and supervision; 6- Home visit evaluation; 7- Suggestions. Facilitators reported that CST has good acceptability and that the quality of the content was good. Facilitators did not report negative experiences, however, they indicated that the content to provide in each session was long.

Conclusions: In the qualitative records analyzed CST appears to be a feasible and acceptable intervention for caregivers of children with autism in Chile. CST should be implemented from a mixed, large-scale approach, ideally including a randomized clinical trial, to prove benefits for children with autism and their caregivers.

427.042 *(Poster)* Predictors of Parent-Reported Use of Special Education or Early Intervention Services Among Preschool-Age Children with Autism in the SPARK Cohort

S. Xiao[1]*, A. Daniels*[1]*, L. Green Snyder*[1]*, J. K. Law*[2,3] *and W. K. Chung*[4]*, (1)Simons Foundation, New York, NY, (2)Maryland Center for Developmental Disabilities, Kennedy Krieger Institute, Baltimore, MD, (3)Johns Hopkins University School of Medicine, Baltimore, MD, (4)Department of Pediatrics, Columbia University, New York, NY*

Background: Accessing early intervention (EI) services is helpful to improving behavioral health outcomes for children with autism spectrum disorder (ASD). Prior research has shown that white, high-income families and those living in metropolitan areas are more likely to access EI services (Payakachat, Tilford & Kuhlthau, 2017; Monz, Houghton, Law, & Loss, 2019).

Objectives: To identify predictors of accessing special education or early intervention services among preschool age children with autism participating in the SPARK Study.

Methods: Data for this study come from SPARK, an online research study that includes individuals with a professional diagnosis of autism and their family members. SPARK collects participant information online. Parents were asked to complete the Social Communication Questionnaire (SCQ) and Background History Questionnaire (BHQ) about their children with ASD. A multivariate logistic analysis was used to identify predictors of accessing public EI services. The primary dependent variable, ever “accessing special education supports or early intervention services through the school” (Y/N), in addition to the independent variables for race, ethnicity, household income, sex at birth, zip code, and language level were used for analysis. A total of 2,388 children with ASD, between the ages of two and five were included in the study. Categorization of metropolitan vs. non-metropolitan were derived using zip codes based on US Census criteria.

Results: The majority of the sample were white (84%) and male (78%), with a mean age of 3.9 years (SD = 0.73). Close to half (45%) was non-verbal. The sample was approximately equally distributed across three household income brackets (<= $35K, between $36K and $80K, >= $81K), and close to two-thirds (63%) live in a metropolitan area. A majority (82.4%) reported having accessed services through the school. In the unadjusted analyses, male sex at birth, living in an urban area, and higher income were all positively associated with accessing EI services ($p<.05$). After adjusting for these factors and race, ethnicity, SCQ score, language level, and metro/non-metro area, families that reported a household income of >=$81K were 2.4 times more likely to access EI services compared with those in the lowest income bracket (<=$35K; 95% CI:1.81, 3.23). Additionally, families living in a metropolitan area were 1.3 times more likely to access EI services than those living in a non-metropolitan area (95% CI: 1.07, 1.69).

Conclusions: Findings from this study support prior research that has found that living in a metropolitan area and having a higher income are associated with a greater likelihood of accessing early intervention services. These findings also further underscore the need to increase access to early intervention among under resourced families.

427.043 *(Poster)* Preliminary Study on the Effectiveness of Kindergarten-Based Integrated Intervention in Children with Autism

I. Sergiyenko[1]*, N. Sinha*[2] *and I. Sergiyenko*[3]*, (1)INGO "Children With Autism Support Foundation "Child With Future", Kiev, Ukraine, (2)-, Ontario, ON, Canada, (3)Child with future, Kiev, UKRAINE*

Background: Autism spectrum disorder (ASD) occurs worldwide, however adequate therapy programs to support children with ASD are not readily available in many parts of the globe. Integrated models of therapy use a combination of existing therapies simultaneously to reinforce common goals, these often consist of both autism specific practices and general rehabilitation therapies. Due to the versatility of integrated therapy models they may be more accessible for countries in which autism awareness and support is not as prevalent.

Objectives: The current study assesses the effectiveness of an integrated model, which utilizes a combination of occupational therapy, speech-language pathology, and psychiatry within a classroom setting.

Methods: 36 children (aged 2-6) received integrated intervention as a full day kindergarten program (40 hours a week) over 12 months. Knowledge & cognition, communication, adaptability, and autonomy were assessed 3 times over the span of the intervention. Measures in developmental ability of these four domains were compared to the child's actual age and the expected developmental milestones of a typically progressing child to produce a measurement of developmental age. Variation in developmental age across assessment periods was then used to calculate effect size.

Results: The therapy shows a strong upward trend in improving autonomy (g=1.35) and adaptive score (g=1.12) after 6 months. Language (g=0.69) and knowledge (g=0.73) also show an upward trend after 6 months, however this result is inconclusive due to large standard deviation. However the effect was not linear as the consecutive 6 months of therapy yielded only a small positive effect for knowledge & cognition (g = 0.17), communication (g = 0.26), adaptability (g= 0.18) and autonomy (g = 0.23). The net effect over the full 12 months of therapy was highly effective across all 4 domains.

Conclusions: Integrated therapies come under particular interest internationally as they are more affordable and accessible to replicate than ASD specific therapies such as Applied Behaviour Analysis or TEACCH, however they are studied far less. This study shows integrated therapy to have some positive effect when applied as a full day program to preschool children, however it is highly likely that confounding variables are leading this effect. Future research should look towards identifying these confounding factors and the impact they have on developmental support.

427.044 *(Poster)* Reported and Actual Practices: Part C Early Interventionists Working with Families of Toddlers with or at Risk for ASD

***K. R. Tomeny**, M. Costo and R. A. McWilliam, University of Alabama, Tuscaloosa, AL*

Background: Early intervention is commonly provided to young children with or at risk for ASD through home- and community-based Part C services (IDEA, 2004). When working with children under 3, early interventionists should use a family-centered, routines-based, caregiver-implemented intervention approach in natural environments to build caregiver capacity and support child outcomes (e.g., McWilliam, 2010; Woods et al., 2011). A gap remains between recommended and actual practice in community-based intervention (e.g., Dingfelder & Mandell, 2011; Sawyer & Campbell, 2017), and studies have found discrepancies between interventionists' reported and actual practices (Campbell & Sawyer, 2009; Fleming et al., 2011). This phenomenon is possibly explained by the Dunning-Kruger effect (Dunning, 2011; Kruger & Dunning, 1999), emphasizing an inability to recognize one's own inabilities, resulting in inaccurate self-assessment of skills. To improve community-based early intervention for families of young children with or at risk for ASD, further examination of reported and actual practices is necessary.

Objectives: The primary objective was to examine differences between interventionists' reported and actual practices to support caregiver-implemented intervention during home visits with families of toddlers with or at risk for ASD. A second objective was to compare interventionists' and caregivers' reported practices.

Methods: Participants consisted of 11 Part C early interventionists and caregiver/child dyads. Children had a diagnosis of ASD or were at risk due to social communication delays. Interventionists video-recorded home visits with caregiver/child dyads and researchers rated interventionists' actual practices using the Caregiver-Implemented Intervention Scale (Authors, 2018). Interventionists and caregivers independently rated the interventionists' typical practices using the Family-Professional Interaction Questionnaire (Authors, 2018). All measures used four-point rating scales to evaluate interventionists' practices.

Results: Preliminary data analysis demonstrated interventionists' actual practices were lower (M = 2.65, SD = 0.83) than their self-reported practices (M = 3.14, SD = 0.49). Results from a Wilcoxon signed-rank test revealed the difference in this small sample was not statistically significant (Z = -1.68, p = .09), but the effect size using Cohen's d was .74, showing 3.4 of a standard deviation difference. Interventionists' reported practices (M = 3.14, SD = 0.49) and caregivers' reported practices (M = 3.04, SD = 0.24) were both relatively high, with no statistically significant or noteworthy difference (Z = -1.16, p = 0.25). Visual analysis revealed a trend of larger discrepancies between reported and actual practices for interventionists with lower actual practice scores, and smaller discrepancies for interventionists with higher actual practice scores, with the exception of one participant (see Figure 1). Findings on the entire sample will be presented.

Conclusions: Preliminary results demonstrate interventionists' actual practices were lower compared to their self-reported practices, but interventionists' and caregivers' reported practices were relatively similar. The Dunning-Kruger effect is one possible explanation for the observed trend of larger discrepancies for interventionists with lower actual practice scores and smaller discrepancies for interventionists with higher actual practice scores. This study adds to the literature on community-based intervention for families of young children with or at risk for ASD, providing further understanding of the research-practice gap and implications for professional development.

427.045 *(Poster)* Responsivity in Pre-Verbal Toddlers from a Large-Scale Community Demonstration Project of the Social ABCs Parent-Mediated Intervention

***E. M. Dowds**[1], I. Drmic[2], C. Roncadin[2], A. Solish[3], L. Zwaigenbaum[4], S. E. Bryson[5] and J. A. Brian[3], (1)Autism Research Centre, Holland Bloorview Kids Rehabilitation Hospital-Autism Research Centre, Burlington, ON, Canada, (2)Autism Spectrum Disorder Service, McMaster Children's Hospital - Hamilton Health Sciences, Hamilton, ON, Canada, (3)Holland Bloorview Kids Rehabilitation Hospital, Toronto, ON, Canada, (4)University of Alberta, Edmonton, AB, Canada, (5)Dalhousie University, Halifax, NS, Canada*

Background: Research in early parent-mediated intervention for toddlers with confirmed or emerging ASD has tended to exclude toddlers with baseline language development below a 12-month level. Information about response to early parent-mediated intervention in this group is thus limited and warrants further investigation in order to inform treatment development.

Objectives: To evaluate the role of baseline language level on response to intervention in toddlers who participated in the Social ABCs™ intervention for toddlers with identified ASD risk within a large scale community implementation.

Methods: The Social ABCs™ was delivered as part of clinical service in Hamilton Ontario (pop. 500,000). Participants included 136 families who completed the 12-week 1:1 coaching program; 98 boys (72%) and 38 girls (28%); mean age = 25.36 months (SD = 4.25; range = 14-34 months). Data were analyzed for those who completed coaching up to week 12. The primary measures of interest were video-coded child responsivity to parent language opportunities (at baseline and week 12), and a standardized measure of language using the Mullen Scales of Early Learning (MSEL) at baseline and six months after beginning the program.

Results: Toddlers' language development at baseline (MSEL Receptive and Expressive language age equivalent scores) significantly predicted week-12 toddler responsivity (R^2 = .147 and .153, respectively, both *p*'s < .001). Notably, however, baseline language level did NOT predict amount of child gain in responsivity (i.e., change from week 1 to 12); both *p*'s > .50. When the sample was divided based on baseline Receptive or Expressive Language level (< or ≥ 12 month age equivalent), all groups made approximately the same amount of gain in toddler responsivity (i.e., 38.23%, 39.0%, 39% and 38.12% for those with baseline RL or EL under 12 versus 12 or over, respectively). For all groups, regardless of baseline language level, gains in responsivity of almost 40% were achieved, with the steepest rate of gains between week 1 and 4 for all groups (see Fig. 1). Although baseline Receptive and Expressive language ability predicted some aspects of toddler responsivity, they did not predict rate of change over time.

Conclusions: Findings demonstrate that toddlers made comparable rates of improvement in responsivity to parent language opportunities regardless of whether they started the program with language levels above or below a 12-month level. This supports the inclusion of toddlers with very low baseline language levels in parent-mediated community early interventions. Findings support the effectiveness of brief parent-mediated intervention regardless of baseline language functioning.

427.046 *(Poster)* Restricted and Repetitive Patterns of Behavior and Interests in Children with Autism Spectrum Disorder: A Systematic Review of Behavioral Interventions

Q. Wei[1]*, W. A. Machalicek*[2] *and B. Crowe*[3]*, (1)Special Education and Clinical Sciences, University of Oregon, Eugene, OR, (2)University of Oregon, Springfield, OR, (3)University of Oregon, Eugene, OR*

Background: Restricted and repetitive patterns of behavior and interests (RRBIs) are among the core symptoms of autism spectrum disorder (ASD) are likely to have an onset during early childhood in individuals with ASD. However, interventions to address RRBIs lag far behind early interventions in the sociocommunication domain. To date, no review has concentrated on behavioral treatment of RRBIs specifically for children under eight years of age. Furthermore, previous reviews on RRBI interventions did not evaluate the methodological rigor of included studies and did not pay attention to types of intervention agents. Little is known about RRBI treatment in behavioral intervention literature for young children.

Objectives: The present review aims to address the following questions: What types of RRBIs and which operant functions have been included in behavioral intervention research? What are the effective behavioral interventions to decrease lower-order RRBIs (L-RRBI) and higher-order RRBIs (H-RRBI) of young children with ASD? How frequently were natural change agents involved in interventions addressing RRBIs? Are caregiver-implemented interventions effective in reducing RRBIs of young children with ASD? 4. Do single-case and group design research studies have adequate methodological rigor to provide empirical support for a specific intervention?

Methods: A comprehensive electronic database search was conducted using the following databases: ERIC, Academic Search Premier and MEDLINE. Key terms used in the search included auti*, pervasive developmental disorders, Asperger* in combination with each of the following terms: repetitive, stereotyp*, ritual*, restricted, rigid*, perseverative interest, circumscribed interest, sameness, self-stimulatory. Peer-reviewed journal articles in English published between January 2008 and July 2019 were included in the search process. Thirty-two studies that conducted an experimental design and included at least one participant under age eight were included for the final review. The following variables and outcomes were extracted to summarize the information from included articles: study design, demographic characteristic of participants, topography of RRBI, function of RRBI, intervention procedure, methodological rigor and intervention efficacy.

Results: Between 2008 and 2019, 32 articles involving 124 participants under eight years of age used behavioral interventions for different types of RRBIs. Findings suggested that L-RRBIs dominated the literature and were predominately treated with single-component interventions. Noncontingent reinforcement with competing stimuli is an evidence-based practice (EBP) for reducing L-RRBIs (55% percentage reduction of behavior). Consequence-based interventions (i.e., response interruption and redirection and inhibitory stimulus control) were more effective in reducing L-RRBIs (75% percentage reduction of behavior), but replications are required for them to be established as EBPs. Seven studies investigated H-RRBI interventions, and the most commonly used interventions were treatment packages. A progression to more rigorous designs is necessary to expand the evidence base of H-RRBI intervention practices. Only three studies examined interventions implemented by natural change agents had sufficient methodological rigor and generated positive results. However, the limited number of interventions carried out by caregivers precluded the investigation of intervention effectiveness and the comparison with clinician-delivered treatment.

Conclusions: Future research on both L-RRBI and H-RRBI needs to examine the efficacy of interventions implemented by natural change agents and the social validity of these interventions.

427.047 *(Poster)* Results from Infant/Toddler Pre-Emptive Intervention on Reduction of Dangerous Behavior and Increased Communication

L. Neely[1]*, A. Carnett*[1]*, J. Graber*[2]*, K. Cantrell*[2]*, E. Santos*[3]*, M. Svoboda*[4]*, A. Martinez*[4] *and W. J. Bosl*[5,6]*, (1)Educational Psychology, University of Texas at San Antonio, San Antonio, TX, (2)Autism Treatment Center, San Antonio, TX, (3)University of Texas at San Antonio, San Antonio, TX, (4)Baylor College of Medicine, San Antonio, TX, (5)Boston Children's Hospital Informatics Program, Harvard Medical School, Boston, MA, (6)Health Informatics and Clinical Psychology, University of San Francisco, San Francisco, CA*

Background: Social-communication delays are a core characteristic of autism spectrum disorder. For infants and toddlers at-risk for autism, a delayed communicative repertoire might result in the children utilizing dangerous behavior (e.g., head banging) to communicate needs/emotions. For up to 30% of the population, speech as a communication modality never develops. Pre-emptive interventions during the critical developmental phase where speech should develop (9 mos to 2 yrs) may mitigate dangerous behavior and promote-social communication. Researchers have validated functional communication teaching (FCT) in older populations as an effective intervention to teach functionally relevant communication that is safe and generalizable. FCT might be particularly effective as a pre-emptive intervention during the formidable developmental period of 9-mos to 2-yrs-old. However, to date, there is little research evaluating this technique as a pre-emptive intervention.

Objectives: The researchers conducted the current project within the scope of a larger project (Project PLAAY) investigating pre-emptive interventions to mitigate the symptomology of autism for at-risk infants and toddlers. The presented project aimed to teach communication to infants and toddlers who were engaging in emerging dangerous behavior (e.g., head banging) or who presented as profoundly delayed in the production of speech.

Methods: A total of 37 at-risk infants and toddlers (aged 9-36 months) have participated in the project to date. Researchers conducted single-case experiments for four of the participants to evaluate the effects of the intervention on the participants' communication and dangerous behavior. For the children who engaged in dangerous behavior, researchers conducted a functional analysis to identify the communicative function of the dangerous behavior. Researchers also conducted communication modality assessments for all participants presenting with severe speech delays. Following identification of the function of the dangerous behavior and preferred method of communication, researchers implemented FCT with the participant and their caregiver.

Results: Researchers evaluated the results using visual and statistical analysis. Visual analysis of graphical displays is the gold-standard technique using in single-case evaluations. The researchers complimented their visual analysis of the graphical displays with effect size analysis using the Tau-U effect size. Visual analysis of the intervention results indicated immediate and large improvements from baseline to intervention phase for functional communication. The graphs also indicated a large and immediate decrease in dangerous behaviors. Resulting Tau-U effect sizes ranged from 0.85 to 1.0 suggesting large effects across all dependent variables.

Conclusions: Preliminary results support the use of the PLAAY intervention to treat the emerging dangerous behavior and teach functional communication. While the researchers did not directly target happiness, the researchers did note increases in indices of happiness correlating with intervention, suggesting the participants enjoyed the intervention.

427.048 *(Poster)* Scope Profile (Social, Communication, Play and Education) - an Online Intervention Based Developmental Assessment & Evaluative Tool for Children with Developmental Delays

K. Rajaraman[1]*, N. Mundkur*[2]*, A. Nagaraj*[3]*, P. Sunil*[3]*, B. Koganty*[2] *and A. Nagvenker*[2]*, (1)Centre for Child Development and Disabilities, Bangalore, India, (2)centre for child development & disabilities, Bangalore, India, (3)Centre for child development & disabilities, Bangalore, India*

Background: An important challenge in early intervention of developmental disabilities in developing countries is the lack of indigenous tools for early identification that helps in planning & evaluating early intervention. With this in mind, SCoPE profile(Social, Communication, Play and Education) an online based tool was created. SCoPE profile assessment is semi structured way of assessment which helps in assessing the child's functioning age in 8 domains/15 sub domains with 222 language, learning, play, social & self help milestones which are presented in 3 developmental levels- Level 1(6-18months), Level 2 (18.1-36 months) &Level 3(36.1-54 months) linking to typical development of children between 6 months-54 months. SCoPE Profile assessment has a structured kit for assessing children & a description manual for scoring children's skills . Milestones in the checklist can be directly tested on the child by the therapist or can be an observed behavior during the assessment. Parent's feedback on child's skills are also considered in scoring.Each milestone is scored YES if mastered, Emerging if skills are emerging & NO if milestone is not achieved. Functioning age of the child in different domains is automatically calculated by the software & Primary health care provider is provided with Functioning age report & visual representation report. (figure 1) Time taken for doing SCoPE profile assessment is between 10-45 minutes based on the developmental age or level of the child. SCoPE profile is connected to an online early intervention program, assisted with coach support, which can be accessed in any far flung area and the impact of early intervention can be subsequently monitored with this tool.

Objectives: Functional age of children in Language and cognitive domains is important to plan intervention for children with developmental delays. Study was conducted to examine inter rater reliability & diagnostic accuracy of SCoPE profile in identifying children with developmental delay and also examine the concurrent validity of SCoPE profile's functional age in language & cognitive domains with Mullen scales of early learning (MSEL) in a sample of children with developmental delays.

Methods: Children aged 6- 54 months (n= 98 children) who came for regular developmental screening during their vaccination visit (n= 48 children) & those who came with concerns of developmental delay (n= 50 children) underwent comprehensive developmental assessment along with MSEL and SCoPE Profile. Functional age in language & cognitive domains was compared between both the scales in children with developmental delay.

Results: SCoPE Profile has good diagnostic accuracy & inter rater reliability with sensitivity of 98%, specificity of 85%, NPV of 97.5% and PPV of 87.9%. Pearson correlation analysis revealed a very strong correlation between SCoPE Profile functional age & MSEL age equivalence in receptive language ($r = 0.93$ $p < 0.001$) , expressive language ($r = 0.95$, $p < 0.001$), cognition ($r = 0.95$, $p < 0.001$) and fine motor skills ($r = 0.94$, $p < 0.001$).

Conclusions: SCoPE Profile can be used by general pediatricians in developing countries for early identification of children with developmental delays and also in planning & evaluating their early intervention.

427.049 *(Poster)* Sociability: Comparison across ESCS and ADOS and Prediction to Joint Engagement Gains for Preschoolers with ASD

M. Pizzano[1]*, A. J. Schlink*[2] *and C. Kasari*[2]*, (1)Education, University of California, Los Angeles, Los Angeles, CA, (2)University of California, Los Angeles, Los Angeles, CA*

Background: Joint attention (JA) is core to the social deficit of autism spectrum disorder (ASD) (Mundy, et al., 1986; Mundy, et al., 1994). Initiations of Joint Attention (IJA) and Responses to Joint Attention (RJA) have been related to language gains (Tomasello and Farrar, 1986). Positive social affect has been linked to social communication deficits in ASD (Kasari, et al., 1990; Mundy, et al., 1994), but it has not been operationalized by a measure or investigated as a predictor of outcome.

Objectives: The current study aims to identify a sociability variable and determine whether it is a unique predictor of child improvements in joint engagement within a randomized controlled intervention trial for preschoolers with ASD.

Methods: 94 families received caregiver-mediated intervention or caregiver education (Kasari, et al, 2014). ADOS items were labeled IJA, IBR, Sociability, or RJA based on Early Social Communication Scales (ESCS) coding conventions. ESCS Sociability is the percentage of child initiations to share a toy out of total opportunities. ADOS Sociability is the combination of responsive smile, facial expressions, and shared enjoyment. Sociability, IJA, IBR, and RJA on the ESCS and ADOS were correlated at entry via a multitrait-multimethod matrix. Spearman correlations were used for the nonnormal data and the ordinal matrix variables.

Ordinal logit regression models were used to assess the predictive value of, RJA, IBR, and Sociability as measured by the ESCS or ADOS in joint engagement change. Joint engagement was coded for total duration in mutually exclusive states as described in Adamson, et al., (2004) from a 10-minute taped caregiver-child interaction. Change scores across time from entry to exit were categorized into negative change, zero/minimal change, and positive change categories.

Results: Monotrait-monomethod validity diagonals confirmed convergent validity. IJA and RJA had significant associations between the ADOS and the ESCS (r=-0.329, n=94, p= <0.001; r= -0.459, n=94, p= <0.001). ADOS Sociability was moderately related to IJA on the ESCS (r= -0.325, n=94, p= <0.001; r= -0.330, n=94). ESCS sociability, however, was not significantly associated with any domain other than Fine Motor on the MSEL (r=0.215, n=94, p= <0.05).

Two models were used to determine whether entry IJA, RJA, and sociability were related to joint engagement gains: one for the domains as measured by the ESCS and one for the domains as measured by the ADOS. Results for the ESCS model showed no significant predictors of total joint engagement change with nonsignificant condition, total MSEL score, and chronological age covariates. The same model with ADOS domains showed that total Mullen score (B= -0.051, p= 0.000) and RJA scores (B= -0.485, p=0.005) were significant predictors of joint engagement change.

Conclusions: ESCS domains were not unique predictors, but cognitive scores and ADOS RJA were significantly predictive of total joint engagement change. For Module 1 RCT participants, cognition played a greater role versus IJA or Sociability in engagement gains. Further work determining predictors of improvement for preschoolers with ASD and limited language is needed.

427.050 *(Poster)* Social Communication Predictors of Successful Inclusion Experiences for Students with Autism in an Early Childhood Lab School

M. Siller[1]*, L. Morgan*[1] *and S. Fuhrmeister*[2]*, (1)Marcus Autism Center, Children's Healthcare of Atlanta and Emory University School of Medicine, Atlanta, GA, (2)Marcus Autism Center, Children's Healthcare of Atlanta, Atlanta, GA*

Background: Access to inclusive learning environments has been required by law for over 40 years. Yet, improvement in the rates of children experiencing inclusion has been insubstantial. While placement decisions should be based on student need, they are typically the result of multiple forces, including characteristics of larger systems and practices (Kurth, Morningstar, & Kozleski, 2014), family preferences and resources, and the availability of supplementary aids and services (IDEA, 2004). Research suggests that inclusive early childhood education can benefit the cognitive, communicative, social, and emotional development of young children with Autism Spectrum Disorder (ASD). However, research samples of children enrolled in such programs (e.g., Walden Early Childhood Program/Early Emory, Children's Toddler School, Project DATA) tend to be self-selected, and the factors that predict enrollment and attendance are poorly understood.

Objectives: This study examined predictors of preschool enrollment and attendance in an inclusive, university-based lab preschool (Preschool Education Lab, PEL) serving children with and without ASD.

Methods: PEL operates as a full-day, state-licensed preschool, and consists of three classrooms serving 2-, 3-, and 4-year-olds (class sizes of 12, 16, and 18 children, respectively). Each classroom is co-taught by three teachers, and includes 6 children with ASD. Classrooms for 2- and 3-year-olds are tuition funded; the classroom for 4-year-olds is publicly funded. Between July 2018 and October 2019, parents of 84 children with a prior ASD diagnosis or parental concerns about ASD contacted PEL to seek enrollment. Demographic information can be found in Table 1. Parents completed a battery of eligibility surveys, including a demographic survey, the MacArthur-Bates Communication Development Inventories (CDI), Modified Checklist for Autism in Toddlers (M-CHAT R; <31 months), and the Social Responsiveness Scale (SRS-2; >30 months). The enrollment decision-making process consisted of four steps – Step 1: Review of Eligibility Surveys; Step 2: In-Person Eligibility Observations (EO); Step 3: Invitation to Enroll; and Step 4: Sustained Preschool Enrollment. A flow diagram depicting families' progress across the steps is presented in Figure 1.

Results: We used logistic regression analyses (SAS, PROC LOGISTIC) to identify child or demographic characteristics that predict decisions at each step. Results showed that parent-reported gestures (CDI, total gesture score) were the strongest predictor of our decision to invite children for EOs (Step 1), *Wald's Chi-Square*=12.8, *p*<.001. In contrast, higher parent-reported language skills (CDI, words produced) [*Wald's Chi-Square*=0.0, *p*<.01], and a younger chronological age [*Wald's Chi-Square*=12.0, *p*<.001] were the strongest predictors of our decision to invite families to enroll in the preschool following an EO (Step 2). Whether eligible families chose to enroll (Step 3), and whether enrolled families chose to remain in our program (Step 4) was best explained using a range of practical considerations such as tuition expenses, daily commute, and alternative programming options.

Conclusions: This research paints a complex picture of forces that influence placement decisions for children with ASD who seek enrollment in an inclusive early childhood education program. A better understanding of these forces is necessary to evaluate outcomes and scale the availability of inclusive preschool options for children with ASD.

427.051 *(Poster)* Stress and Empowerment in Parents of Minimally Verbal Children with ASD Following an Enhanced Pivotal Response Treatment Group

A. V. Dahiya-Singh[1], *A. Scarpa*[2], *J. R. Bertollo*[3], *L. Antezana*[1], *T. McFayden*[1], *H. A. Kissel*[1] *and D. Swain*[1], *(1)Virginia Polytechnic Institute and State University, Blacksburg, VA, (2)Virginia Tech Autism Clinic & Center for Autism Research, Blacksburg, VA, (3)Center for Autism Research, Children's Hospital of Philadelphia, Philadelphia, PA*

Background: In addition to core social communication impairment in Autism Spectrum Disorder (ASD), many children with ASD demonstrate deficits in the use of functional language. Parents of children with ASD display increased levels of parenting stress compared to those of typical development (Hayes & Watson, 2013). This stress can negatively impact both child and parent treatment outcomes, including caregiver empowerment (Taylor et al., 2017). The current study assessed minimally verbal children with ASD in a Pivotal Response Treatment (PRT) group that targets child communication deficits, with a supplemental parenting stress treatment.

Objectives: 1) Identify baseline relationships among parenting stress, family empowerment, and child behaviors and 2) examine change in parenting stress and family empowerment from pre- to post- treatment.

Methods: Nineteen caregivers (M_{age}= 35.6) and their minimally verbal children (N_{male}= 18; M_{age}= 3.12) with diagnosed or suspected ASD were enrolled in group-based enhanced PRT parent-training. Prior to treatment, parents completed the following measures: Parenting Stress Index (PSI-4; Abidin, 2012) assesses parenting stress characteristics of child and parent; Family Empowerment Scale (FES; Koren, et al., 1992) measures empowerment in families as related to the caregivers, providers, and community; Child Behavior Checklist for Ages 1.5-5 (CBCL/1.5-5; Achenbach & Rescorla, 2001) assesses child emotional and behavioral problems. Bivariate correlations at baseline explored aim 1. Wilcoxon tests assessed pre-post change across treatment conditions based on a subset of families (n=9) with complete data.

Results: Bivariate correlations demonstrated significant positive relationships between PSI-Life Stress and CBCL-Anxious/Depressed (ρ= .728, p= .041), showing that higher parental life stress is related to higher child anxiety at baseline. Also, CBCL-Withdrawn/Depressed positively correlated with PSI-Parent (ρ= .824, p= .012), and PSI-Total Stress (ρ= .873, p= .005), showing that higher parent stress is related to higher child withdrawal. Correlations also demonstrated significant negative relationships of family empowerment (FES) with PSI-Parent (ρ= -.496, p= .043) and PSI-Total Stress (ρ= -.485, p= .048), showing that lower caregiver empowerment is related to higher stress.

Wilcoxon tests demonstrated significant changes on several parent and child stress characteristics from pre- to post- treatment in the following subscales: PSI-Reinforces Parent (Z= -2.55, p= .011), PSI-Competence (Z= -2.10, p= .035), PSI-Role Restriction (Z= -2.52, p= .012), and PSI-Depression (Z= -2.43, p= .015). The PSI-Child (Z= -2.02, p= .043), PSI-Parent (Z= -2.08, p= .038), and PSI-Total Stress (Z= -2.32, p= .021) significantly decreased from pre- to post-treatment. There was also a significant change in family empowerment following treatment, on the FES-Family subscale (Z= -2.37, p= .018). No significant differences were noted in internalizing or externalizing behaviors as a result of the current treatment.

Conclusions: The current study noted significant relationships between family empowerment, parenting stress levels, and child behaviors. Family empowerment is highly related to several stress characteristics in both parents and children. Post-treatment, parent-reported stress symptoms and family empowerment showed improvements. The findings further support the importance of addressing parenting stress and family empowerment in parent interventions for minimally verbal children with ASD, especially due to the comorbid child behavior symptoms that may impact parenting stress.

427.052 *(Poster)* The Effect of Joint Attention and Imitation on Language Growth during a Parent Mediated Intervention Trial for Autism Spectrum Disorder

A. Pomales-Ramos[1], *K. M. Frost*[2] *and B. R. Ingersoll*[2], *(1)Michigan State University, East Lansing, MI, (2)Psychology, Michigan State University, East Lansing, MI*

Background: Imitation and joint attention are important tools for social-communicative development during early childhood. During early development, children use imitation as their main form of communication (Nadel, 2002). Additionally, children learn to orient to novel environments though responding to joint attention (RJA). Children with autism spectrum disorder (ASD) often present with delays in imitation skills and deficits in joint attention. Previous literature has shown that targeting imitation and joint attention skills may lead to improvement in socio-communicative development (Ingersoll, 2012; Kasari, Paparella, Freeman, & Jahromi, 2008). However, little is known on how baseline levels of these skills predict treatment response in parent mediated interventions.

Objectives: The present study examined the effects of baseline imitation and RJA skills on language growth during a parent mediated intervention trial for ASD.

Methods: To date, 66 children with ASD (ages 19-93 months) were enrolled in an RCT of project ImPACT, an empirically validated parent-mediated intervention. Language was assessed at baseline, 3-4 months later, and 8-9 months later using the Vineland Adaptive Behavior Scales (VABS) and the MacArthur-Bates Communicative Development Inventories (MCDI). Spontaneous object imitation skills were examined in a social-interactive context using the Unstructured Imitation Assessment at baseline. RJA was measured at baseline using the Early Social Communication Scales, a structured observation measure.

Results: Multilevel linear growth models were used to examine whether RJA and object imitation skills predict language growth over a short-term period. Analyses included baseline chronological age, developmental quotient, and time as fixed effects; the main parameters of interest were the RJA*Time and Imitation*Time interactions. Intercept variance and residual variance were included as random effects. There were significant main effects of time for both sets of predictors, such that children had increased word production and increased communication age equivalents over time.

When controlling for the effects of age and developmental level, children with higher levels of baseline RJA had higher communication age equivalents and word production, as indicated by a significant effect of baseline RJA. A significant RJA*Time interaction for both outcomes indicated that children with higher baseline RJA had accelerated communication growth compared to those with lower baseline RJA (Table 1).

When controlling for the effects of age and developmental level, higher levels of baseline object imitation did not significantly predict communication age equivalents or word production. However, there was a significant Imitation*Time interaction, such that children with higher levels of baseline object imitation had accelerated communication growth for both outcomes compared to those with lower baseline object imitation skills (Table 2).

Conclusions: Imitation skills and joint attention at baseline predicted short term acceleration in language growth during a parent mediated intervention trial. Children with higher levels of RJA and imitation at baseline show more communication and expressive language growth over time. These findings have potential implications for understanding response to intervention, individualized goal setting, and identifying potential treatment targets to optimize outcomes.

427.053 *(Poster)* The Effect of Treatment Intensity and Style on Parent Sense of Efficacy in a Multisite Randomized Trial of ASD Intervention for Young Children

A. Estes[1]*, P. Yoder*[2]*, J. McEachin*[3]*, G. Hellemann*[4]*, J. Munson*[5]*, E. L. Gardner*[6]*, J. Greenson*[7]*, M. L. Rocha*[8]*, Z. Warren*[9] *and S. J. Rogers*[10]*, (1)Speech and Hearing Sciences, University of Washington, Seattle, WA, (2)Department of Special Education, Vanderbilt University, Nashville, TN, (3)Autism Partnership, Seal beach, CA, (4)UCLA, Los Angeles, CA, (5)Psychiatry & Behavioral Sciences, University of Washington, Seattle, WA, (6)Vanderbilt University, Nashville, TN, (7)University of Washington, Seattle, WA, (8)Psychiatry and Behavioral Sciences, UC Davis MIND Institute, Sacramento, CA, (9)Vanderbilt University Medical Center, Nashville, TN, (10)Department of Psychiatry and Behavioral Sciences, The Medical Investigation of Neurodevelopmental Disorders (MIND) Institute, UC Davis School of Medicine, University of California Davis, Sacramento, CA*

Background: Comprehensive, intensive intervention for young children with ASD delivered in the home by therapists requires a high level of parental engagement, time, and resources. To our knowledge, no randomized controlled trials have previously evaluated the secondary effects of these types of interventions on parents; thus, the impact on parent sense of efficacy is currently unknown. Home-based intervention has the potential to provide increased parent support but support may vary based on the number of intervention hours per week (intensity) and the type of parent involvement required (style). Pre-intervention parent characteristics such as parent stress may influence whether daily staff visits are experienced as supportive or as intrusive, for example. These differing experiences may influence a parent's sense of efficacy.

Objectives: To examine whether the effect of treatment style (discrete trial teaching/DTT vs naturalistic developmental behavioral intervention/ESDM) and intensity (15 vs 25 hours per week) on change in parent sense of efficacy varies by baseline level of parent stress.

Methods: We randomized 87 children with ASD, age 13 to 30 months, into one of four conditions: 15 versus 25 intervention hours crossed with DTT versus ESDM (see Consort Diagram; Figure 1). Intervention took place in-home for 12 months with highly trained, supervised intervention teams at three sites across the United States. Baseline parent stress (Questionnaire on Resources and Stress) was collected prior to beginning treatment. Parent efficacy (Parenting Sense of Competence questionnaire) was collected at baseline and 12 months later, at the end of treatment. The putative moderator was baseline parent stress. The dependent variable (DV) was parent efficacy. Analysis involved mixed effects modelling using full maximum likelihood estimation. For the DV, a random intercept and a fixed slope model was selected. We tested main effects and interactions involving time, treatment intensity and style, and baseline parent stress in the same model to test moderation effects.

Results: Changes in parent efficacy across 12 months of intervention were related to treatment intensity but not treatment style. Follow-up analysis evaluated whether baseline parent stress moderated the significant effect of treatment intensity (see Table 1). We observed a significant three-way interaction between time, intensity, and baseline parent stress. These effects remained significant when site was entered in the model.

Conclusions: In the context of a randomized, intent–to-treat intervention trial, the greatest gains in efficacy for high stress parents were found in the low intensity group. The greatest gains for low stress parents were found in the high intensity group. Style of intervention (DTT vs ESDM) did not have a main effect on parent efficacy. This is the first randomized study of which we are aware to address the question of what intensity and style of intervention will facilitate the greatest sense of efficacy for parents. Our findings suggests that a "one size fits all" approach to recommendations for treatment intensity may not be justified. Parent stress and intervention intensity may be important considerations to support improved parental efficacy.

427.054 *(Poster)* The Effect of the Transporters Emotional Understanding Intervention Program on the Promotion of Peer Cooperative Play in Young Children with ASD

T. Gev[1]*, E. Lavine*[1]*, I. Gordon*[1,2] *and O. Golan*[1]*, (1)Department of Psychology, Bar-Ilan University, Ramat-Gan, Israel, (2)Gonda Brain Research Center, Bar-Ilan University, Ramat Gan, Israel*

Background: Children with ASD often experience difficulties in emotion recognition (ER). Whereas ER deficits are believed to underly the social interaction difficulties children with ASD experience, the association between ER and social functioning in children with ASD was hardly examined. Moreover, examinations of the effect that interventions which aim to teach ER have on social functioning improvements were limited to parents' or teachers' reports.

Objectives: (1) to examine the differences between young children with ASD and their typically developing (TD) peers on ER, on the ability for peer cooperative play, and on the relationship between these two abilities; (2) to examine the effect that using *The Transporters* (TT), an animated series found to improve ER and social empathy, has

on the ability for peer cooperative play in young children with ASD.

Methods: for aim (1), two groups of 4-7 years-old children, 38 (9 girls) with ASD and 28 (5 girls) TD children, matched on age, gender and cognitive abilities, were recruited. Participants were tested on a 3-level ER task (Golan et al., 2010) and in addition participated in "Don't drop the ball! game" - a cooperative game with a peer, aimed to balance a ball on a board while trying to keep if from falling.

For aim (2), a group of twenty-three 4-7 year olds (2 girls) with ASD who watched TT daily for 8 weeks was compared to a matched group of 22 participants (6 girls) with ASD, who watched a control series. Participants took different versions of the ER task and the peer cooperative game twice – before and after watching the series. Peer interactions were video-recorded and micro-analytically coded for children's affect, affect energy, vocalization, instruction following, context adaptive social behavior, gaze direction, stereotypic behavior and play-promoting behavior.

Results: Children with ASD exhibited poorer ER on all generalization levels and showed difficulties to promote shared play, compared to their TD peers. During peer play, children with ASD showed less game-promoting behavior, and expressed positive affect longer, but less intensely than their TD peers. Participants' ER scores were positively correlated with their expression of positive affect and with game-promoting behavior in the ASD, but not in the TD group.

The examination of intervention effects revealed improved ER on all generalization levels when watching TT- but not the control series. Moreover, children from the TT group demonstrated improved play-promoting behavior following the intervention, compared to children from the control group (Fig. 1). A positive correlation was found between participants' improvement on ER tasks and their improvement on play-promoting behavior in the TT group, but not in the control series group.

Conclusions: Our findings indicate that ER deficits are associated with cooperative play difficulties in children with ASD, and that TT intervention-related gains in ER abilities are associated with peer cooperative play improvements. These findings provide additional support for the generalizability of TT training effects.

427.055 *(Poster)* The Impact of a Group-Based Early Start Denver Model Parent Education Program on Stress and Self-Efficacy in Parents of Young Children with Autism Spectrum Disorder in Taiwan

T. L. Lin[1,2]*, C. H. Chiang*[1]*, S. Y. Ho*[3]*, H. C. Wu*[4] *and C. C. Wong*[3]*, (1)Department of Psychology, National Chengchi University, Taipei City, Taiwan, (2)Research Center for Education and Mind Sciences, National Tsing Hua University, Hsinchu City, Taiwan, (3)Child Developmental Assessment & Intervention Center, Zhongxing Branch of Taipei City Hospital, Taipei City, Taiwan, (4)Department of Rehabilitation, Taipei Tzu Chi Hospital, Buddhist Tzu Chi Medical Foundation, New Taipei City, Taiwan*

Background: Increasing evidence shows that intensive early intervention can lead to improved outcomes for children with Autism Spectrum Disorder (ASD). However, in low-resourced regions, children with ASD can only receive limited early intervention, far below the recommendation of the National Research Council (U.S.) in 2001. Researches indicate that brief parent training can positively impact children's progress as well as parental level of stress or sense of competence. Hence, viewing parents of children with ASD as the primary intervention receivers is ideal in low-resourced regions.

Objectives: The current study was part of an effectiveness study for implementing the Early Start Denver Model (ESDM) in Taiwan. This study aimed to examine the effects of a parent education group based on ESDM principles within the Taiwanese health system for parents of young children with ASD in northern Taiwan.

Methods: A case control study was conducted with 42 children with a DSM-5 diagnosis of ASD aged 25–46 months. Children receiving one-on-one ESDM intervention in the ESDM group (N = 21, mean age = 33.23 months) and children receiving community intervention in the control group (N = 21, mean age = 35.14 months) did not differ at baseline in individual and family/parents demographic variables, overall development quotient and symptom severity, and were with no difference of mean intervention hours per week during the study. Parents in the ESDM group, who were in groups of three, participated in a biweekly one-hour parent education for 12 sessions. In these sessions, an ESDM-certified therapist taught parents ESDM strategies through lectures based on the ESDM parents' manual (Rogers, Dawson, & Vismara, 2012) and discussions on five-minute home videos of parent-child interactions. The parental outcome measures were obtained pre and post- education, comprising Parenting Stress Index (Third Edition) and Parental Self-Efficacy Scale, which was developed by Taiwanese researchers with excellent psychometric properties in reliability and validity.

Results: There were no differences between two groups in parental outcome measures at baseline. After 12 group-based parent education sessions, parents in the ESDM group reported some improvements in parental self-efficacy, and a significant decrease in parent-related parenting stress, especially in "Attachment" and "Role Restriction" subscales. Such parental progress in the ESDM group was not correlated with the children's progress. Parents in the control group showed no positive post-education changes in parental self-efficacy or parenting stress. The improvements of parents in the ESDM group in overall parental self-efficacy, parent-related parenting stress, and stress related to attachment were significantly greater than those of the control group parents.

Conclusions: This study suggests that an ESDM-inspired group-based parent education program can positively impact parenting stress and parental self-efficacy for parents of young children with ASD, especially helping parents to become closer to their children and more sensitively and effectively responding to children's need. Further studies in Taiwan need to investigate the relationship between the outcomes of child interventions and parent training through examining parent-child interactions and incorporating other groups (e.g., group with only parents who receive parent education/training, group with only children who receive interventions).

427.056 *(Poster)* The Relationship of Early Social Skills to Language, Social Behavior, and Overall Responsiveness to Early Intervention in Children with Autism

C. E. Karlen*, Washington University Saint Louis, Saint Louis, MO*

Background: Joint attention, the ability to coordinate one's attention with that of another person (Dawson et al., 2004), and imitation, the ability to copy another person's behavior (Sevlever & Gillis, 2010), are two of the initial methods by which children learn from and interact with the world around them (Trevarthan, 1979). These two skills are related to the development of language, social skills, and play. Further, they seem to come naturally in typically developing children. For children with autism spectrum disorder (ASD), however, these skills are often delayed or entirely absent, thereby potentially leading to significant impediments in the acquisition of crucial functional skills (Dawson et al., 2004). Social orienting theory posits that children with ASD exhibit such deficits in joint attention and imitation because of their lack of attention to social stimuli and, as a result, the decreased attempts by others in their environment to engage them (Dawson et al., 2004). One early intervention model that is based on social orienting theory is the Early Start Denver Model (ESDM), which considers dyadic interactions between the therapist and the child as a prime avenue for learning not only basic social skills such as joint attention and imitation but also more complex social skills, language, and play (Rogers & Dawson, 2010).

Objectives: The primary objective was to determine whether joint attention and imitation development were significantly correlated with each other as well as with social skills, language, and play development. A secondary objective was to demonstrate meaningful skill development in the first six months of ESDM intervention. A final objective was to examine whether joint attention and imitation at baseline would predict overall responsiveness to intervention.

Methods: Data, both archival and current, from 23 children from an ESDM program were examined to investigate these objectives. The primary outcome measure was the ESDM checklist, which was used both as an initial assessment measure as well as a progress monitoring tool.

Results: Results indicated that all children in the study made significant progress in all areas in the first six months of intervention. The hypothesized positive relationship between joint attention and imitation was supported; however, results did not indicate a trajectory wherein joint attention was acquired prior to imitation. Results supported the relationship between both joint attention and imitation skills and subsequent language, social, and play skills. Contrary to hypothesis, baseline skill levels did not significantly predict overall performance.

Conclusions: The results from the current study provide replication and extension of previous studies documenting the effectiveness of ESDM. Additionally, they give insight into the relationship between two skills often marked as deficits for children with ASD early on – joint attention and imitation – and other important domains, including language, social skills, and play. Specifically, joint attention and imitation development are significantly positively related. These two domains are further significantly positively related to language, social skills, and play.

427.057 *(Poster)* Understanding the Relationship between Problem Behaviors and Parental Stress in Children with ASD Following the UCLA PEERS® Intervention

S. V. Desar[1]*, Y. S. Lograsso*[2]*, Y. de Nocker*[3]*, E. Denluck*[1]*, H. R. Goodman*[4] *and E. A. Laugeson*[2]*, (1)UCLA Department of Psychiatry, PEERS lab: UCLA PEERS Clinic, Los Angeles, CA, (2)UCLA Semel Institute for Neuroscience and Human Behavior, Los Angeles, CA, (3)UCLA Semel Institute for Neuroscience & Human Behavior, Los Angeles, CA, (4)UCLA PEERS Clinic, Los Angeles, CA*

Background: Children with autism spectrum disorder (ASD) are known to possess a variety of behavioral difficulties, which may contribute to high levels of stress in their parents (Miranda, Mira, Berenguer, Rosello, & Baixauli, 2019). Parental stress may in turn further impact disruptive behaviors in children (Shawler and Sullivan, 2017), resulting in a bidirectional relationship between parental stress and problem behaviors. The UCLA PEERS® for Preschoolers program is a 16-week caregiver-assisted intervention designed to target children's social deficits and improve their relationship skills. PEERS® for Preschoolers has been shown to decrease children's problematic behavior (Park, Moulton, & Laugeson, under review); however, research has yet to examine changes in parental stress throughout the program. Furthermore, the relationship between children's problematic behaviors and parental stress throughout the program has not yet been evaluated.

Objectives: The present study aims to explore change in parental stress following the UCLA PEERS® for Preschoolers intervention. Further, the study seeks to examine a potential correlation between a reduction in children's problematic behavior and a reduction in parental stress following the intervention.

Methods: Participants included 44 children between 4-6 years of age (M=4.59; SD=0.757). All children in the sample had a parent-reported baseline T-score of ≥ 60 on the Social Responsiveness Scale, Second Edition (SRS-2; Constantino, 2005), indicating mild to severe deficits in social interaction. Preschoolers' problem behaviors were evaluated using the Social Skills Improvement System (SSIS; Gresham and Elliott, 2008) before and after the intervention. The Parent Stress Index (PSI-4; Abidin, 2012) was also conducted at pre- and post-intervention to assess any change in parents' stress levels.

Results: A paired samples t-test was conducted to examine the change in children's problem behavior and parental stress levels. As expected, the results indicate a significant decrease in problem behaviors, (t(43)=3.850, p<.005), and in parental stress levels, (t(43)=3.439, p<.01). In order to understand the relationship between the intervention's effects on children's problem behaviors and parental stress, a Pearson correlation coefficient (r) was calculated to compare the change on the SSIS and PSI-4 from pre- to post-intervention. Results indicate that the change in problem behavior scores of children with social interaction deficits following the PEERS® intervention is significantly correlated with a change in their parents' stress levels (r=.321, p<.05).

Conclusions: These findings support prior research indicating that the PEERS® for Preschoolers intervention is successful in significantly reducing children's problem behaviors, and also suggest that the intervention may successfully decrease parental stress levels. Further, these results indicate a correlation between child behavior and parental stress, supporting the bidirectional relationship suggested by previous studies. This study is important because a significant correlation between child behavior and parental stress will better inform caregiver-assisted interventions, leading to improvements in both parent and child outcomes. Future research might explore the sustainability of this relationship and its strength across populations with other developmental disabilities in order to promote more targeted caregiver-assisted interventions.

427.058 *(Poster)* Unintended Treatment Effects? Exploring Parent Factors in Enhanced Group Pivotal Response Treatment

J. R. Bertollo[1]*, A. Scarpa*[2]*, H. A. Kissel*[1]*, A. V. Dahiya-Singh*[1]*, T. McFayden*[1]*, L. Antezana*[1] *and D. Swain*[1]*, (1)Virginia Polytechnic Institute and State University, Blacksburg, VA, (2)Virginia Tech Autism Clinic & Center for Autism Research, Blacksburg, VA*

Background: Parenting stress is typically elevated for parents of children with autism spectrum disorder (ASD) relative to parents of typically-developing children or children with other neurodevelopmental disorders, and is further magnified when the child also has intellectual or language impairments (Davis & Carter, 2008; Hayes & Watson, 2013). This stress can result in lower parental self-efficacy and higher rates of parental depression and anxiety symptoms, making it even more difficult to handle challenging behaviors in children with ASD (Miranda et al., 2019). Thus, it is important to understand relationships among parent factors, such as stress, psychopathology, and perceived support, as well as treatments that can support parent outcomes.

Objectives: This study (1) assesses baseline relationships among several parent characteristics, including perceived mood, support, and self-efficacy, as well as ratings of affect and stress during a brief interaction with their child; and (2) explores pre-treatment to post-treatment change in these parenting factors, which, with the exception of parent stress, were not explicit treatment targets.

Methods: This study includes 28 parents of minimally verbal children (mean age=2.99 years) with diagnosed or suspected ASD. Parents participated in group-based Pivotal Response Treatment (PRT) supplemented with parent stress management training. Parents completed the following self-report measures from the Patient-Reported Outcomes Measurement Information System (PROMIS®) battery: Depression, Anxiety, Self-Efficacy, Social Isolation, and Emotional Support. They also completed measures about their feelings during a brief interaction with their child: Positive and Negative Affect Schedule (PANAS; Crawford & Henry, 2004) and Subjective Units of Parenting Stress Scale (SUPSS; adapted from Singh et al., 2007). Pre-treatment Spearman bivariate correlations were conducted between all aforementioned parent variables. For a subset of parents whose post-treatment data are currently available, paired Wilcoxon Signed-Rank Tests were conducted to assess change in PROMIS measures (n=6) and parent-child interaction variables (n=10).

Results: At pre-treatment, higher levels of stress during parent-child interaction were related to higher negative affect (ρ=.51, p=.006), higher emotional support was associated with less social isolation (ρ=-.44, p=.039), and increased depression was related to higher anxiety (ρ=.63, p=.002). Additionally, self-efficacy was significantly positively correlated with emotional support (ρ=.45, p=.034) and negatively with social isolation (ρ=-.54, p=.009), depression (ρ=-.57, p=.006), and anxiety (ρ=-.62, p=.002). There were significant pre-post decreases in SUPSS (Z=-2.55, p=.011), PANAS Negative Affect (Z=-2.26, p=0.024), PROMIS Social Isolation (Z=-2.02, p=.043), and Depression (Z=-2.02, p=.043), and significant pre-post improvement in Self-Efficacy (Z=-2.20, p=.028).

Conclusions: These results highlight (1) important relationships between parent factors, including the relationship of pre-treatment self-efficacy with parental emotional support, social isolation, and anxiety; and (2) improvements in parental self-efficacy, social isolation, stress, negative affect, and depression after a PRT parent training group supplemented with stress management intervention. While sample size is limited, these findings suggest the possible role of enhanced PRT to alter untargeted areas, such as parental depression, self-efficacy, and perceived social isolation, as well as additional stress management tools to decrease stress during parent-child interactions. Future research should explore these relationships with a larger sample, and ASD treatment should consider directly targeting parental factors.

427.059 *(Poster)* Utilization of Developmental and Behavioral Intervention Techniques in Usual Care: Initial Validation of a Self-Report Rating Scale in a Sample of Applied Behavior Analysis Providers.

K. M. Frost *and B. R. Ingersoll, Psychology, Michigan State University, East Lansing, MI*

Background: Naturalistic developmental behavioral interventions (NDBIs) are a class of early interventions for autism spectrum disorder with growing empirical support (Schreibman et al., 2015). NDBIs emerged through an integration of techniques from applied behavior analysis (ABA) and developmental psychology, and share several core features (Schreibman, Jobin, & Dawson, 2019). Measures of NDBI instructional strategies are in the early stages of development (e.g. the *NDBI-Fi*; Frost, 2018), and to date there are no self-report tools for assessing provider use instructional strategies from this class of interventions.

Objectives: The objectives of this study were to provide an initial validation of a self-report measure of the utilization of individual NDBI instructional strategies which was adapted from an observational measure, the *NDBI-Fi*.

Methods:

This study was conducted using an online survey of ABA providers across the United States recruited via the Behavior Analyst Certification Board mass email service (N=368). Qualifying providers reported that they currently engage in direct service provision for at least one child age 6 or younger. Respondents rated the percent of a recent session with a specific child that they used each of 20 instructional strategies. Descriptions of these instructional strategies were developed in a previous study via expert consensus. The survey also included questions about training background, service setting, and demographic variables.

Results: An exploratory factor analysis with principal axis factoring and Promax rotation indicated a 2-factor solution, according to examination of the eigenvalues and scree plot. Factor loadings in the pattern matrix suggested the presence of a behavioral strategies factor and a developmental strategies factor (Table 1). Four items were excluded due to cross-loading or low factor loadings (.4-.3-.2 rule; Howard, 2016). A behavioral scale (Cronbach's α=0.85) and developmental scale (Cronbach's α=0.83) were calculated by averaging across the items loading onto each factor. Linear regression showed that use of developmental strategies was significantly predicted by NDBI competency (β=6.56, p<0.001) when accounting for years of ABA experience (β=-0.303, p=0.057), providing evidence for convergent validity. Pearson correlations showed evidence of discriminant validity as well; as predicted, use of developmental strategies was not significantly correlated with competency in the TEACCH model (r=0.01), Discrete Trial Training (DTT; r=0.02), or Verbal Behavior (r=0.02), all of which are non-NDBI intervention models.

Conclusions: This study found that self-reported utilization of NDBI instructional strategies followed a two-factor structure, which aligns with the dual theoretical origins of this class of interventions. We also found evidence of convergent and discriminant validity for the developmental strategies; greater use of developmental strategies was positively correlated with self-reported competency in NDBIs, and uncorrelated with competency in non-NDBI intervention models (i.e. TEACCH, DTT, Verbal Behavior). Together, these results provide initial evidence for the validity of this self-report measurement tool of NDBI instructional strategies. Such work will support future research exploring the similarities and differences between NDBIs and usual care.

427.060 *(Poster)* What Is the Lasting Effect? Results of a 10-Year Follow-up of Early Intensive Behavioral Intervention

L. A. Oakes[1]*, S. Iadarola*[2]*, J. M. Keith*[3] *and R. E. King*[2]*, (1)The Ernest J. Del Monte Institute for Neuroscience, University of Rochester Medical Center, Rochester, NY, (2)University of Rochester Medical Center, Rochester, NY, (3)Clinical and Social Sciences in Psychology, University of Rochester, Rochester, NY*

Background: Although there is general consensus that moderate-to-high intensity early intervention is beneficial for children with developmental delays, little is known about the long-term effects of these interventions on outcomes of interest. In 2008, a novel, prospective study tested predictors of developmental outcomes (IQ, Adaptive behavior, ASD severity) after early intensive behavioral intervention (EIBI) for young children with autism spectrum disorder (ASD; aged 20-59 months) and compared those outcomes to a community-based sample of same-aged peers with ASD (Smith, Klorman, & Mruzek, 2015). Predictors included social engagement and sensory-motor rituals. At exit, across both groups, higher IQ predicted better outcomes and (after controlling for age/IQ), social engagement but not sensory-motor rituals predicted IQ and adaptive functioning. This 10-year follow-up study evaluates and compares the outcomes of children who originally received EIBI compared to treatment as usual (TAU) to examine the long-lasting impact of early intervention.

Objectives: Ten years after the original study:

1. We compared outcome of the EIBI group and TAU group on ASD symptom severity, IQ, adaptive skills, and overall clinical severity. Groups were also compared across academic skills development, language level, and rates of co-occurring mental health issues.
2. We assessed the original predictors on long-term outcome in the EIBI group. We hypothesized that high social engagement in the original study will predict superior outcome and high sensorimotor behaviors will predict lower outcome scores.

Methods: From the initial pool of 136 participants (71 EIBI, 65 TAU), 110 met eligibility criteria for the follow-up study. Of that subgroup, 38 EIBI and 22 TAU participants completed follow up. Participants completed assessments of IQ (Stanford-Binet-V), academic skills (Woodcock-Johnson), language (Clinical Evaluation of Language Fundamentals-V), and diagnostic classification (ADOS and Social Responsiveness Scale). Their parents completed interviews and questionnaires on ASD symptoms, co-occurring mental health issues (KSADS), adaptive skills (Vineland), social skills (Social Skills Improvement System), and communication (Children's Communication Checklist). Trained raters who were masked to initial treatment group assignment integrated all assessment results into a DD-CGAS score.

Results: The original sample demonstrated significant IQ group differences; i.e., EIBI participants (m = 60.5) scored significantly lower than the TAU group (m = 75). This significant difference maintained at follow-up with both groups improving similarly, EIBI group (ABIQ m = 74.5, SD = 14.9) and TAU group (ABIQ m =89.6, SD = 15.9). The EIBI group scored higher on ASD symptoms and lower on adaptive skills at follow-up but performed better in academic testing and had fewer internalizing behaviors.

Conclusions: Long-term follow-up of EIBI is crucial to understanding the lasting impact of the intervention regardless of what interventions and treatment may follow it. Our results indicate that children with early access to services demonstrated improved cognitive skills compared to their early assessments. EIBI appeared to have the greatest effects on academic performance and may serve as a protective factor against internalizing mental health disorders. Further, cognitive and developmental level early in life is confirmed as a predictor of long-term success in multiple outcomes, regardless of treatment received in early childhood.

Interventions - Non-pharmacologic - School-Age, Adolescent, Adult

PANEL SESSION — **INTERVENTIONS - NON-PHARMACOLOGIC - SCHOOL-AGE, ADOLESCENT, ADULT**

214 - Back to School: Identification and Treatment of Executive Function Challenges in the School Setting for Autistic Adolescents

Panel Chair: Benjamin Yerys, *Center for Autism Research, Children's Hospital of Philadelphia, Philadelphia, PA*

Discussant: Kara Hume, *Frank Porter Graham Child Development Institute, University of North Carolina at Chapel Hill, Chapel Hill, NC*

Schools are a critical setting for delivering executive function treatment. They are a setting that places the heaviest executive function demands on children and are an almost universally accessible setting for delivery of treatments, thereby reducing disparities. Two challenges in the field are finding ways to both measure and intervene with executive function skills in the school setting. In two talks, we examine the measurement of executive function with multiple methods and informant reporters for autistic children. This includes one talk examining convergence of profiles and developmental trends in teacher and parent ratings of executive function skills, and another talk assessing executive function with direct observation, and teacher ratings as part of a comprehensive ecologically-valid skill assessment. In two talks, we present feasibility and efficacy of behavioral interventions targeting executive function skill development in autistic adolescents. One talk focuses on the feasibility and initial signal of efficacy for a middle school-based intervention targeting planning/organization, monitoring, ignoring distractions, and initiating work independently (AIMS-O). The other talk focuses on the efficacy of a high school-based intervention targeting cognitive flexibility, planning, and emotion regulation skills (Flexible Futures). This symposium will summarize cutting-edge research focused on executive function skills in the school setting.

214.001 *(Panel)* Where the Rubber Meets the Road: Measuring Executive Function Outcomes in the Classroom with a Masked Observation Tool

L. Kenworthy[1], *J. Safer-Lichtenstein*[2], *A. Verbalis*[1], *C. E. Pugliese*[1], *J. F. Strang*[1], *A. B. Ratto*[1], *L. Cannon*[3], *M. A. Werner*[4], *K. C. Alexander*[5], *B. J. Anthony*[6], *K. Hardy*[7] *and L. Anthony*[6], *(1)Center for Autism Spectrum Disorders, Children's National Hospital, Washington, DC, (2)Children's National Hospital, Washington, DC, (3)Ivymount School, Rockville, MD, (4)Program Development and Training, Ivymount School, Rockville, MD, (5)The Occupational Therapy Institute, La Mesa, CA, (6)University of Colorado, Denver, Aurora, CO, (7)Children's National Health System, Washington, DC*

Background: The lack of precise, objective, ecologically-valid executive function (EF) outcome measures complicates school-based intervention trials. Objective EF tasks are critiqued for lacking ecological validity, while informant-report EF measures are subject to placebo responses of up to 40%. In the context of treatment trials, we developed the Classroom Observation Scale of Executive Function (COSEF) that can be administered in 15-20 minutes and has shown sensitivity to EF school-based treatments in two randomized controlled trails to date.

Objectives: Investigate reliability and validity of COSEF in baseline data collected as part of a randomized effectiveness trial of *Unstuck and On Target*.

Methods: Participants were 3rd-5th graders with ASD (n=47) or ADHD (n=94), who met DSM-5 diagnostic criteria as determined by an experienced clinical psychologist and cutoff criteria on the ADOS-2 (for ASD), or the Mini International Neuropsychiatric Interview-Kid (for ADHD). All participants also had: parent or teacher reported flexibility problems and a Full Scale IQ (FSIQ) score>70. See Table 1. The COSEF was collected during random academic periods of the school day by masked research assistants who had established reliability in live coding above 80%. The following behaviors were coded for presence or absence: Following Rules, Appropriate Transitioning, Getting Stuck, Expressing Negativity or Overload, Participating in Class and Social Reciprocity. Two items are reverse scored. Lower scores indicate greater problems. Because the COSEF is comprised of 6 dichotomously scored items, its internal reliability was evaluated with the Kuder-Richardson-20 statistical test.

Other baseline characterization and outcome measures included the WASI-2; Woodcock Johnson-3 Reading and Math Fluency tests; and the Swanson, Kotkin, Agler, M-Flynn, and Pelham Scale (SKAMP). The SKAMP is a teacher-report measure of classroom behavior, which includes 13 standard items, tapping EF-related skill (e.g. completing work). Two novel items (accepting criticism/feedback; having meltdowns/tantrums) were added per published instructions (Bhatara et al., 2006). Higher scores indicate more problems in the classroom. Convergent validity was investigated through partial correlations between COSEF average scores and the SKAMP and Fluency tests.

Results: The internal reliability of the 6-item COSEF is adequate given its brevity ($\alpha = 0.6$) The COSEF was not significantly related to race, gender, diagnostic group, family income, or whether the observation occurred in special or general education. The COSEF average score trended toward a significant correlation with FSIQ (p=0.12). Partial correlations controlling for FSIQ revealed that the COSEF was significantly related to teacher SKAMP report (r=-0.44; p <.001), Math (r=0.25; p=.011) and Reading (r=0.24 = p=.014) Fluency scores.

Conclusions: The COSEF shows preliminary evidence of reliability (internal and inter-rater) and convergent validity. Its medium-size correlation with teacher reported classroom learning behaviors that require EF and small correlation with academic fluency scores are encouraging indications of its relevance to specific EF related skills required for success in the classroom. Its brevity, sensitivity to change in two previous treatment trials (Kenworthy, et al., 2015; Anthony et al, 2019), and capacity for treatment-masked administration increase its value as a measure of outcome.

214.002 *(Panel)* Real-World Executive Function Profiles for Autistic Children Converge across School and Home Settings

J. E. Tschida *and B. E. Yerys, Center for Autism Research, Children's Hospital of Philadelphia, Philadelphia, PA*

Background:

Executive function (EF) is a collection of skills that allow us to regulate our thoughts, actions, and emotions in the service of goals. These skills are often impaired in children with a diagnosis of autism spectrum disorder (ASD), and they are important predictors of adaptive and academic functioning outcomes. Extant studies on real-world EF in autistic children have revealed notable impairments in the home setting. Real world EF impairments have not been assessed in the school setting for autistic children.

Objectives:

To characterize informant ratings of EF for autistic children from both the home and school setting.

Methods:

A total of 344 participants (ASD N=241 (217 Male: 24 Female), typically developing control [TDC] N=103 (90 Male: 13 Female) between the ages of 6 and 18 were enrolled. EF skills were assessed using the Behavior Rating Inventory of Executive Function (BRIEF) in home and school settings. The BRIEF captures executive function in everyday situations and is comprised of eight scales: Inhibit, Shift, Emotional Control, Initiate, Working Memory, Plan/Organize, Organization of Materials, and Task Monitor. Families chose the teacher or school professional who knew the child best as the school setting rater and the caregiver who knew the child best as the home setting rater. A MANOVA was conducted to examine differences between the ASD and TDC groups. Within the ASD group, ANOVAs were conducted to examine peak impairments and effect of age, correlations and linear mixed effects models were run to examine discrepancies between settings, and linear regressions were completed to determine whether ratings were predictive of adaptive behavior beyond age, gender, IQ, and ASD symptoms.

Results:

ASD and TDC groups differed on all BRIEF scales in both settings (F's>9, p's<0.01, η^2>0.20). The Shift scale was the peak impairment in the ASD group in both settings (p's<0.05) and scales for which there was an effect of age (Shift, Plan/Organize, Organization of Materials, and Task Monitor for the school setting and Organization of Materials for the home setting) were rated as more impaired as age increased (p's<0.05). Correlations indicated positive associations between all BRIEF scales in both settings (r's>0.23) excluding Initiate (r=0.04) while linear mixed effects models revealed rater type significantly affected the Inhibit, Emotional Control, and Working Memory scales for participants with IQ>70 (χ^2's>4.34, p's<0.05). Linear regressions revealed ratings from both settings predicted adaptive behavior in the corresponding setting (DR^2's>0.067).

Conclusions:

This study is the first to show that autistic children's real-world EF profiles in the school setting are comparable to their profiles at home. In both settings the Shift scale was the peak impairment, EF impairments increased with age, and EF skills predicted adaptive behavior. Correlations indicated moderate-to-strong associations between raters on all scales excluding Initiate. However, linear mixed effects models revealed rater type to affect ratings on Inhibit, Emotional Control, and Working Memory scales for participants with IQ>70. This study documents the stability of real world EF profiles across settings, and that within-raters teachers and caregivers are observing similar relationships with outcomes.

214.003 *(Panel)* Feasibility and Initial Efficacy of the Achieving Academic Independence in Middle School–Outpatient Intervention for Middle School Youth with ASD

A. Duncan[1], *L. Tamm*[2], *E. Kneeskern*[2], *M. D. Patel*[2] *and A. Vaughn*[2], *(1)Developmental and Behavioral Pediatrics, Cincinnati Children's Hospital Medical Center, Cincinnati, OH, (2)Cincinnati Children's Hospital, Cincinnati, OH*

Background: Youth with autism spectrum disorder (ASD) frequently experience academic problems in a variety of domains. While some of these academic struggles stem from key features of ASD, they are also strongly linked to deficits in executive functioning (EF) such as organization, time management, prioritization, and initiation. Students must be able to initiate tasks, perform multistep sequences of events, reflect, reason, plan and prioritize, sustain performance and complete tasks, be flexible in their thinking, and monitor their performance. However, 35-70% of teens with ASD without an intellectual disability (ID) present with EF deficits. Common academic EF challenges include difficulties getting started on tasks, managing distractions, planning for studying, multi-tasking, keeping materials organized, prioritizing tasks, and starting school work independently. Families and teachers qualitatively report academic EF deficits are key contributors to school problems for youth with ASD. There is a clear need for interventions targeting academic EF skills in ASD. Yet, there are no randomized clinical trials demonstrating the efficacy of EF interventions for middle-school teens with ASD.

Objectives: To assess the feasibility and initial efficacy of the Achieving Academic Independence in Middle School–Outpatient (AIMS-O) intervention. AIMS-O includes content related to the importance of EF, how to use behavior agreements, problem solving, homework and study skills.

Methods: 21 youth with ASD without ID (age M=12.2, SD=1.0, 76.2% male, 95.2% White, IQ M=109.7, SD=13.8) in the 6th (n=7), 7th (n=7), and 8th (n=7) grades with EF deficits (i.e., T>65 on parent *or* teacher planning/organization monitor, or organization of materials subscales of the Behavior Rating Inventory of Executive Functioning, BRIEF-2) participated in 3 sequential open trials. Parents and teens attended 7-weekly 90 minute AIMS-O sessions and parents and teachers completed ratings before and after AIMS-O. Feasibility and satisfaction were primary outcomes. Cohen's *d* effect sizes (small >.2, moderate >.5, and large >.8) were computed for measures of EF and academic behaviors to explore initial efficacy.

Results: Attendance was excellent (M=6.33, SD=1.0) and families completed most of the 8 homework assignments (M=5.10, SD=1.8). Satisfaction ratings were >4 on a 1 to 5 Likert scale (5=best) for effectiveness of information taught, worksheets/handouts, visuals, and instructors, and slightly lower for how well the teen understood the materials (M=3.81, SD=.24). Similarly, satisfaction ratings for each content area (problem solving, behavior agreements, organization, time management, study skills, study cards, and summarizing) were >4, and slightly lower for the ease of establishing/maintaining a behavior agreement (M=3.89, SD=.25). Moderate to large effect sizes were obtained for parent-rated BRIEF-2, Homework Problem Checklist, Children's Organizational Skills Scale (COSS), and study-developed measures. Small to moderate effect sizes were obtained for teacher-rated BRIEF-2, COSS, Academic Performance Survey, and Classroom Performance Survey. Particular gains were seen for organizational skills, homework behaviors, and academic productivity.

Conclusions: Initial data show that AIMS-O is feasible to deliver, that parents were satisfied with the content, and preliminary evidence that gains were observed in the areas targeted by AIMS-O. A randomized clinical trial is needed to rigorously assess efficacy.

214.004 *(Panel)* Preliminary Outcomes of a New School-Based Executive Function Treatment for Transition-Age Youth with ASD

C. E. Pugliese[1], *M. A. Werner*[2], *M. F. Skapek*[3], *M. D. Powers*[1], *L. Saldana*[4], *L. Anthony*[5] *and L. Kenworthy*[1], *(1)Center for Autism Spectrum Disorders, Children's National Hospital, Washington, DC, (2)Program Development and Training, Ivymount School, Rockville, MD, (3)Psychological Sciences, University of Connecticut, Storrs, CT, (4)Children's National Health System, Rockville, MD, (5)University of Colorado, Denver, Aurora, CO*

Background: Individuals without intellectual disability make up the fastest-growing subgroup of ASD, but as few as 9% reach full functional independence as adults (Farley, McMahon, & Fombonne, 2009). Executive Function (EF) problems are pivotal targets for intervention (Hume, Loftin & Lantz, 2009) because they are common (Hill, 2004), linked to independence (Pugliese et al., 2015), and responsive to treatment (Kenworthy et al., 2015). Flexible Futures (FF) is a new EF intervention for transition-age youth with autism spectrum disorders (ASD) targeting flexibility, goal-setting, planning, and self-advocacy through cognitive behavioral techniques including self-regulatory scripts, guided practice, scaffolded teaching, and visual supports. It is implemented by school personnel to maximize accessibility, intervention dosage and generalizability.

Objectives: To evaluate the effectiveness of FF on improving EF skills in high school students with ASD compared to students who received the usual care in their school environment (IEP/504 & other specialized services for ASD).

Methods: Flexible Futures (FF) was compared to treatment as usual (TAU) in 8 high schools across the DC Metro Area using a randomized, clustered, clinical trial design. All participants (*n*=47, 8 female) were in 9th-12th grade (M age=16.4, SD=1.3), had an FSIQ ³80 on the WASI-2 (see Table 1), and received prior ASD diagnoses supported in this trial by Social Communication Questionnaire scores > 11 (*n*=36) and/or ADOS-2 autism spectrum classification (*n*=19). Groups were not different on key demographic variables (see Table 1).

To account for inequality of variances between groups on two outcome variables, independent samples *t*-tests and corresponding effect sizes were used to examine between-group pre-post change on objective measures: WASI Block Design (problem-solving), EF Challenge Task (EFCT; planning & flexibility during social interaction tasks), and classroom behavior (initiation, organization, shifting, participation). Informant report was also used to examine change in: interventionist, parent, and child knowledge about intervention content; parent Behavior Rating Inventory of EF (BRIEF, Plan/Organization & Shift scales); and Adaptive Behavior Assessment System (ABAS; Global and Practical domains).

Results: The Flexible Futures group improved significantly more than TAU on the EFCT (*t*= 5.12, *p*<0.001, *d*=1.6), classroom behavior (*t*=-2.38, *p*=0.03, *d*=0.7), ABAS Global (*t*=2.09, *p*= 0.04, *d*=0.6) and Practical skills (*t*=2.10, *p*= 0.04, *d*=0.7), and interventionist (*t*= -3.74, *p*= 0.01, *d*=1.3) and student (*t*=-2.84, *p*=0.01, *d*=1.0) FF content knowledge. Medium, but not statistically significant, improvements were also made on Block Design (*t*=1.71, *p*=0.09, *d*=0.5), BRIEF Shift (*t*=1.94, *p*=0.06, *d*=0.6), and parent FF content knowledge (*t*=-1.87, *p*=0.07, *d*=0.6). No improvement difference was noted on BRIEF Plan/Organization. Significant gains on the EFCT (d=0.9), global adaptive skills (d=0.9), and students' knowledge of FF content (*d*=0.8) were maintained at 6-month follow up even though 50% of TAU students were also receiving the intervention at this time.

Conclusions: This pilot RCT demonstrated that FF implemented at school led to multi-modal improvement in flexibility, planning, problem-solving, classroom behavior, and adaptive skills with medium-large effects. Interventionists, students, and parents in FF demonstrated improved knowledge of intervention content post-treatment, and students remembered intervention content after the intervention ended. Next steps include a larger effectiveness trial.

ORAL SESSION — INTERVENTIONS - NON-PHARMACOLOGIC - SCHOOL-AGE, ADOLESCENT, ADULT
319 - Evidence-based Training and Evaluation of Life Skills

319.001 *(Oral)* The Teacch Transition Readiness and Employability Evaluation As a Transition Intervention Outcome Measure

B. Tomaszewski[1,2,3], *R. K. Sandercock*[4], *E. Wu*[5], *M. R. Klinger*[6] *and L. G. Klinger*[7], *(1)Frank Porter Graham Child Development Institute, University of North Carolina at Chapel Hill, Chapel Hill, NC, (2)Psychiatry, University of North Carolina at Chapel Hill, Chapel Hill, NC, (3)TEACCH Autism Program, University of North Carolina at Chapel Hill, Chapel Hill, NC, (4)Department of Psychology & Neuroscience, University of North Carolina at Chapel Hill, Chapel Hill, NC, (5)University of South Carolina, Columbia, SC, (6)UNC TEACCH Autism Program, Chapel Hill, NC, (7)TEACCH Autism Program; Psychiatry, University of North Carolina, Chapel Hill, NC*

Background: Transition-aged individuals with Autism Spectrum Disorder (ASD) with average intellectual skills experience challenges in postsecondary education and employment compared to their peers (Roux et al., 2015; Taylor & DaWalt, 2017). While Pre-Employment Transition Service Programs are being offered through Vocational Rehabilitation, little evidence base exists for these programs. To establish a strong evidence-base for these programs, there is a critical need to develop meaningful outcome measures (Bal et al., 2018). Currently, a majority of measurement tools rely on informant or self-report measures with few objective measurement tools used in interventions targeting transition-aged youth in ASD. The Transition Readiness and Employability Evaluation (TREE) was developed to provide an objective measure of employment readiness through behavioral observation.

Objectives: The objectives of the current study were to (a) evaluate the TREE as a measure of employment readiness in adolescents and adults with ASD without intellectual disability, and (b) examine the TREE as an outcome measure following participation in a transition intervention.

Methods: The TREE is a 20-item measure that provides a series of executive function, social communication, and emotion regulation presses during a simulated work environment appropriate for students with ASD and average or higher IQ. Two 15-minute employment tasks appropriate to office (e.g., filing, assembly of information folders) and computer data entry (e.g., accounting receipts, entry of evaluations forms) settings are presented. Items are rated from 0-2, with higher scores indicating greater difficulties. Participants included 75 adolescents and young adults ages 16-21 with ASD (Mean Age = 19.1 years) without intellectual disability who were participating in a community college-based intervention, the TEACCH School Transition to Employment and Post-Secondary Education (T-STEP) program. Confirmatory factor analysis was conducted to examine construct validity at pre-test. Participants completed the T-STEP, a community college transition readiness course, counseling services typically available on a community college campus, and an on-campus internship to practice readiness skills. Change across pre and post-testing were examined.

Results: The confirmatory factor analysis indicated that the three-factor model showed adequate fit, $\chi^2(164) = 188.4$, $p = .09$, RMSEA = .05, 90% CI [.00, .07], CFI= .92, TLI=.91. All factor loadings were significant ($p < .01$). The executive function factor was significantly associated with the social communication (B=.55, $p < .001$) and emotion regulation (B=.47, p=.001) factors. Social communication and emotion regulation were significantly associated (B=.59, $p < .001$). Following completion of the T-STEP program, participants made significant improvements across executive function from a score of , t(75) = 4.06, $p < .001$, Cohen's d= .88, social communication , t(75) = 4.77, $p < .001$, Cohen's d= 1.00, and emotion regulation t(75) = 2.20, $p = .03$, Cohen's d=. 46.

Conclusions: The results of this study provide support for the factor structure of the TREE. The TREE demonstrated sensitivity to change providing support as an intervention outcome measure to assess transition readiness and employability skills in transition aged adolescents and adults with ASD without intellectual disability. Ongoing studies are using the TREE as an objective outcome measure in RCTs.

319.002 *(Oral)* Results of an Open Trial to Evaluate the Effectiveness of Virtual Reality Job Interview Training in Transition Age Autistic Youth Engaged in School-Based Transition Services

M. Smith[1], *K. Sherwood*[2], *J. D. Smith*[3], *N. Jordan*[4] *and M. S. Atkins*[5], *(1)University of Michigan, Ann Arbor, MI, (2)University of Michigan-Ann Arbor, Ann Arbor, MI, (3)Northwestern University, Chicago, IL, (4)Department of Psychiatry and Behavioral Sciences, Northwestern University, Chicago, IL, (5)Psychiatry, University of Illinois-Chicago, Chicago, IL*

Background: Virtual reality job interview training (VR-JIT) is an efficacious internet-based intervention designed for adults with severe mental illness to improve interview skills through repetitive practice and feedback. Given the low employment rates of transition age autistic youth, VR-JIT may help enhance their employment outcomes.

Objectives: We evaluated the effectiveness and acceptability of delivering VR-JIT within school-based transition programming for transition age autistic youth and youth with other educational disabilities.

Methods: School partners (n=9) were recruited from a network of schools in Illinois or Michigan receiving state support to implement federally-mandated transition services. School administration partnered with the research team to implement VR-JIT within the transition curriculum and teachers completed surveys using individualized education plans to provide background and employment status data on n=279 autistic students and students with other educational disabilities. Also, n=115 students reported on VR-JIT acceptability and usability after completing VR-JIT training.

Results: Students (ages 16 to 22) were primarily diagnosed with autism, learning disability, other health impairment, or emotional disability. 64% of students were male and 68% were Caucasian, 16% Latinx, and 12% African-American. Regarding VR-JIT dosage, 25% of students completed a 1-5 virtual interviews (ie low dose), 46% completed 6-14 virtual interviews (ie medium dose), and 31% completed 15 or more virtual interviews (ie high dose). By six-month follow-up, 32% of student trainees obtained a new job (the uncorrected employment rate did not differ between autistic and non-autistic students; p>.10). Meanwhile, 24% of low-dose students, 32% of medium-dose students, and 40% of high-dose students with autism obtained competitive employment by 6 month follow-up; suggesting a dose-effect. A multinomial logistic regression model revealed: 1) VR-JIT use predicted a greater likelihood of employment by 6-months at OR=1.51, p=.009; CI: 1.11, 2.05 level; 2) autistic students were less likely than non-autistic students to obtain employment by 6-months at OR=0.4, p=.039; CI: 0.24, 0.96; and 3) autistic students were less likely to sustain a job between baseline and follow-up compared to non-autistic students at OR=0.40, p=.040; CI: 0.17; 0.96. This model covaried for IQ, biological sex, presence of an emotional disability, and grade level. More than 70% of students reported VR-JIT was enjoyable, helpful, and improved their skills. In turn these variables correlated with VR-JIT use (i.e., total completed trials, high score, minutes engaged in elearning, minutes engaged with virtual interviewer) (all r>0.20, p<0.05). These results did not differ by educational category.

Conclusions: These promising findings suggest that using VR-JIT to enhance transition services may lead to higher rates of competitive employment. Moreover, the more students used the tool, the more they found it to be acceptable and easy-to-use. Consistent with prior research, autistic students were less likely to obtain new jobs as compared to their peers with other educational disabilities. Future research is needed to evaluate the effectiveness and implementation of VR-JIT in a large-scale randomized trial as well as develop new interventions to help autistic students sustain employment.

319.003 *(Oral)* "Kontakt© Helped Me Reach My Goals!" the Efficacy of a Social Skills Group Training Program for Autistic Youth

B. Afsharnejad[1], *M. Falkmer*[2], *M. H. Black*[3], *T. Alach*[4], *F. Lenhard*[5], *A. M. Fridell*[5], *C. Coco*[6], *K. Milne*[7], *S. Bolte*[8] *and S. J. Girdler*[3], *(1)Autism Research Team, Telethon Kids Institute, Perth, Australia, (2)Curtin University, Bentley, Australia, (3)School of Occupational Therapy, Social Work and Speech Pathology, Curtin University, Perth, WA, Australia, (4)Cooperative Research Centre for Living with Autism (Autism CRC), Long Pocket, Brisbane, Australia, (5)Karolinska institute, Stockholm, Sweden, (6)Karolinska Institutet, Stockholm, Sweden, (7)Autism Association of awestern Australia, Perth, WA, Australia, (8)Center of Neurodevelopmental Disorders (KIND), Centre for Psychiatry Research; Department of Women's and Children's Health, Karolinska Institutet, & Stockholm Health Care Services, Region Stockholm, Stockholm, Sweden*

Background: While social skills group training (SSGT) interventions show efficacy in improving the social communication and interaction abilities of autistic youth, previous randomized controlled trials (RCTs) evaluating these interventions have emphasised parent proxy reports, largely neglecting the views of autistic adolescents themselves. Further, the efficacy of SSGT interventions is rarely considered in comparison to active controls, limiting the ability to investigate the potentially confounding effect of exposure to a supportive social context.

Objectives: This study investigated the efficacy of KONTAKT©, a manualised evidence-based SSGT program, in supporting Australian autistic adolescents in achieving their meaningful social goals in comparison to an active control group, a manualised purposely designed cooking skills program called Super Chef of equivalent dose.

Methods: Employing a pragmatic two-armed RCT design participants (N=90) were randomly assigned to either KONTAKT© (SSGT intervention) (n=46) or the Super Chef cooking group (active control group) (n=44). Participants (26 female and 64 males) were autistic adolescents aged 12 to 17, with an IQ of over 70 (m=102.38, SD=14.89). Both programs ran for 16, 90-minute sessions, were facilitated by two trained and experienced therapists from the Autism Association of Western Australia and were monitored for intervention fidelity. The primary outcome was predefined as adolescents' progress towards achieving their personally meaningful social goals, as measured by Goal Attainment Scaling (GAS). Secondary outcome measures included autistic adolescents ASD traits, their quality of life, facial emotion recognition skills, social anxiety, and feelings of loneliness. Outcomes were rated by adolescents themselves, their parents and blind experts at three time points, baseline, post-intervention and at three-month follow up (the primary analysis time point). A random-effects regression model (linear mixed model) examined changes in the dependent variables, using time (post-intervention and follow-up), age, IQ, gender, and depressive or anxious behaviour as the independent variables.

Results: While intent-to-treat analysis (N=90) demonstrated that both groups reported statistically significant progress towards their personally meaningful social goals over time (post-intervention (ES=1.39, p<0.001) and follow-up (ES=1.39, p<0.001)), KONTAKT© participants demonstrated significantly greater progress towards their goals than their peers attending Super Chef at follow-up (ES=0.21, p=0.043). The majority of secondary outcomes for both groups (ASD related traits, emotion recognition, and social anxiety) improved significantly over time, however, KONTAKT© participants demonstrated a statistically significant reduction in their social interaction anxiety compared to the Super Chef group (ES=0.23, p=0.03).

Conclusions: The design of this study addresses many of the limitations of previous research in this field. Findings suggest that KONTAKT© has efficacy in supporting autistic adolescents to achieve their personally meaningful social goals, while reducing their anxiety related to social interactions more effectively than compared to another manualised program providing a comparative social context. Further research is needed focussing on the longer term effects of SSGT interventions such as KONTAKT© and understanding those subgroups likely to benefit most from such interventions. (ANZCTR: ACTRN12617001117303, ClinicalTrials.gov: NCT03294668)

319.004 *(Oral)* Influence of Leadership Profiles on Implementation of Professional Development Model

A. Sam[1], *B. Tomaszewski*[2,3,4], *V. Waters*[5] *and S. Odom*[2], *(1)Frank Porter Graham Child Development Institute, Carrboro, NC, (2)Frank Porter Graham Child Development Institute, University of North Carolina at Chapel Hill, Chapel Hill, NC, (3)Psychiatry, University of North Carolina at Chapel Hill, Chapel Hill, NC, (4)TEACCH Autism Program, University of North Carolina at Chapel Hill, Chapel Hill, NC, (5)Frank Porter Graham Child Development Institute, University of North Carolina at Chapel Hill, Carrboro, NC*

Background: Leadership styles have been associated with implementation of evidence-based practices (EBPs) in elementary schools for students with autism (Stadnick et al., 2019) but have not been examined following the completion of a school-based intervention. This study aimed to examine how leadership profiles were influenced by implementation of the National Professional Development Center (NPDC) on autism model of professional preparation to promote EBPs in elementary schools.

Objectives: The objectives of this study were to determine (1) the leadership profiles of principals, teachers, and school staff, (2) how these leadership profiles differed by intervention group, and (3) how these leadership profiles related to attitudes and implementation of EBPs.

Methods: Participants (n = 539) included principals, teachers, and school support staff from 59 elementary schools serving students with autism. Schools were randomly assigned to the intervention group or services as usual. Schools in the intervention group received ongoing training, coaching, and materials to implement EBPs with students with autism over one school year. An Implementation Index was completed for all schools to document all features of the NPDC model throughout the school year. At the end of the school year, participants completed the Evidence Based Practices Attitudes Scale, a measure of attitudes of school personnel towards EBPs and the Multifactor Leadership Questionnaire, a measure of leadership models. Principals self-rated, and teachers and school staff rated their principals.

Results: A two-level latent profile analysis was completed, and three profiles were identified: *Optimal* (53.2%), *Suboptimal* (36.9%), and *Passive* (9.8%). The *Optimal* class demonstrated the highest transformational and transactional leadership scores and the lowest passive avoidant scores. The Suboptimal class displayed a similar profile, but their transformational and transactional leadership scores were lower, and passive avoidant scores were higher than the Optimal class. The *Passive* class demonstrated the most passive avoidant behaviors. Participants in the control group were more likely to be in the *Passive* class compared to the *Suboptimal* (OR = .310, SE = .14, $p < .001$) and *Optimal* classes (OR = .042, SE= .05, $p < .001$). Individuals in the *Optimal* class had significantly higher scores on the Implementation Index compared to the *Passive* class (B = -4.48, SE = 1.05, $p < .001$), but not the *Suboptimal* class. The *Optimal* class were more likely to have more positive attitudes towards implementing evidence-based practices compared to the *Suboptimal* (OR= .56, SE= .13, $p = .001$), and the *Passive* classes (OR= .50, SE= .24, $p = .04$).

Conclusions: Leadership styles were associated with attitudes towards evidence-based practices and the implementation of the NPDC model. Specifically, scores of the implementation index were higher for schools with *Optimal* leadership styles compared to the *Passive* style. Further, the *Optimal* leadership class was more likely to have more positive attitude towards evidence-based practices. Additionally, control schools were more likely to be in the *Passive* class. Further research is needed to determine if the implementation of the NPDC model was associated with more preferred leadership styles (i.e. *Optimal* or *Suboptimal*).

ORAL SESSION — INTERVENTIONS - NON-PHARMACOLOGIC - SCHOOL-AGE, ADOLESCENT, ADULT

320 - Novel Interventions for Individuals with ASD and their Families

320.001 *(Oral)* Behavioral Outcomes of Biofeedback-Based Videogame Training in Youth with and without Autism: A Randomized Controlled Trial

B. G. Travers[1]*, O. J. Surgent*[1]*, O. I. Dadalko*[1]*, A. Mason*[1] *and D. C. Dean*[2]*, (1)University of Wisconsin - Madison, Madison, WI, (2)Pediatrics & Medical Physics, University of Wisconsin - Madison, Madison, WI*

Background: Decreased postural stability is commonly reported in autism spectrum disorder (ASD) (Lim et al., 2017) and is linked to more severe autism symptoms (Radonovich et al. 2013; Travers et al., 2013). Further, adolescents with ASD show an early plateau in postural stability development (Minshew et al., 2004). Recently, we developed a biofeedback-based balance video game to appeal to adolescents with ASD. A quasi-experimental design found that playing this game was related to balance improvements and was perceived as beneficial and enjoyable by the participants and their families (Travers et al., 2018). A critical next step is to compare this intervention to an active control condition.

Objectives: Investigate whether a videogame-based, visual-biofeedback balance training improved postural stability, daily living skills, and autism symptom severity compared to a sedentary videogame control condition in 13-17 year-olds with and without ASD.

Methods: This pilot study was a parallel forms randomized controlled trial (RCT) pre-registered at clinicialtrials.gov (#NCT02358317). Thirty-four participants with ASD and 28 age-matched participants with typical development (TD) underwent diagnostic testing and a pre-training assessment (neuroimaging, cognitive, autism symptom severity, and motor assessments) and then were randomly assigned to the balance videogame intervention or to the sedentary videogame control training. Each participant individually completed the assigned training in the lab for 3 sessions each week over the course of 6 training weeks. At the end of training, neuroimaging, symptom severity, and motor assessments were repeated.

Results: Before training, participants with ASD demonstrated decreased postural stability compared to participants with TD, $t(60) = 2.56$, $p = .01$, but within the balance-training group, both the ASD and TD groups showed similar improvements in balance with training, $t(30) = 0.19$, $p = .85$. To test the effects of balance training, we performed 2 (pre vs. post) x 2 (balance vs. control) x 2 (ASD vs. TD) ANOVA's. Individuals in the balance-training condition showed significantly greater pre-post reductions in postural sway during visual feedback compared to individuals in the control condition, $p = .04$, and these reductions were similar across diagnostic groups, $p = .22$. Pre-post daily living scores did not change with training, $p = .99$, but SRS-2 scores decreased pre-to-post in the ASD balance training group compared to the ASD control group, $p = .02$.

Conclusions: In a highly controlled RCT, biofeedback-based video game training improved postural stability in comparison to a sedentary, videogame control group. This finding suggests that individuals with and without ASD may benefit from intensive biofeedback-based balance training framed as a video game. While balance challenges may be highly prevalent in ASD, the results suggest that balance training is as likely to benefit those with ASD as those without ASD. Within the ASD group, decreases in parent-rated autism symptom severity were observed in the balance-training group but not in the sedentary-control group, suggesting that the balance training led to decreased autism symptom severity. However, the mechanisms of this effect are unclear. Future analyses will examine the pre-post structural brain imaging measures to understand the neurobiological basis of these behavioral changes.

320.002 *(Oral)* A Pilot Randomized Controlled Trial of a Daily Living Skills Intervention for Adolescents with ASD

A. Duncan[1], *L. A. Ruble*[2], *J. Meinzen-Derr*[3], *C. Fassler*[4] *and L. J. Stark*[3], *(1)Developmental and Behavioral Pediatrics, Cincinnati Children's Hospital Medical Center, Cincinnati, OH, (2)University of Kentucky, Lexington, KY, (3)Cincinnati Children's Hospital Medical Center, Cincinnati, OH, (4)Cincinnati Children's Hospital, Cincinnati, OH*

Background: Individuals with autism spectrum disorder (ASD), even those without a comorbid intellectual disability (IQ ≥70), have bleak outcomes because of difficulties successfully navigating the transition to the adult world (Hume et al., 2014). Daily living skills (DLS) are everyday activities such as hygiene, cooking, cleaning, navigating the community, and managing money that are critical to independent functioning in adulthood. *DLS were the only significant factor found to predict a positive outcome in adulthood for individuals with high functioning ASD* (Farley et al., 2009). Despite their importance, the DLS of adolescents with ASD are often 6-8 years below their chronological age. While the acquisition of DLS should be amenable to intervention, there are currently no evidence-based group intervention packages that target DLS in adolescents with ASD. A pre-post trial (n=7) of *Surviving and Thriving in the Real World (STRW)*, a group treatment for adolescents with ASD without ID and their parent that targets specific DLS (i.e., cooking, laundry, self-care, and money management) using evidence based strategies (e.g., task analysis, video modeling). Results demonstrated that o*ver the course of a 12-week intervention, adolescent participants gained an average of 2 years of DLS (Duncan et al., 2017), which is not only clinically meaningful, but suggests that the gap between age and skill level can be significantly reduced.*

Objectives: The primary aim of the study was to conduct a feasibility pilot RCT to test the efficacy of the STRW intervention using goal attainment scaling (GAS) and the Vineland-3 as primary outcome measures.

Methods: The feasibility pilot RCT consisted of 11 adolescents with ASD between 14-18 years and their parents. Participants were randomly assigned to either the 15-week STRW group or the waitlist control group. All participants had IQs≥70 and met criteria for ASD on the ADOS-2. Information on DLS was collected using (1) the Vineland-3 and (2) a GAS protocol was created for each adolescent from a parent interview that assessed skills in the 4 main areas targeted in the STRW intervention. DLS were evaluated post-treatment and at 6-month follow-up.

Results: From baseline to post-treatment, adolescents in the STRW group gained an average of 1.5 to 2 year of DLS on the Vineland-3, while the waitlist control group did not show improvement in DLS. The STRW group had significant changes in the Personal and Domestic subdomains and DLS domain of the Vineland-3 ($p<.05$) and these gains were maintained at follow-up (all p's <.06). On the GAS, the STRW group demonstrated significant improvement from baseline to post-treatment ($p<.05$), while the control group did not. The gains on the GAS were maintained at follow-up.

Conclusions: This study demonstrates that adolescents are acquiring and maintaining DLS after completion of the STRW intervention. We are currently conducting a more rigorous RCT (n = 120) with a social skills intervention as a comparison group. A DLS intervention package for adolescents with ASD without ID that uses evidence-based strategies for teaching DLS and incorporates parental involvement has the potential to directly affect current functioning and future adult outcomes.

320.003 *(Oral)* Resilience Intervention for Parents of Children with Autism: Findings from an RCT of the Amor Method

J. M. Schwartzman[1], *M. E. Millan*[2] *and G. W. Gengoux*[2], *(1)Palo Alto University, Palo Alto, CA, (2)Psychiatry and Behavioral Sciences, Stanford University School of Medicine, Stanford, CA*

Background: Parents of children with Autism Spectrum Disorder (ASD) face unique parenting challenges. Parental stress may inhibit treatment gains for the child, particularly for parent-delivered interventions (Bekhet, Johnson, & Zauszniewski, 2012). While it is essential to enhance and sustain the well-being of parents of children with ASD, developing interventions for parents remains a prominent gap in ASD research (Weiss et al., 2013). Bridging this gap, the AMOR Method (Acceptance, Mindfulness, Optimism, Resilience) is a novel resilience intervention developed to address unique parenting challenges in ASD by enhancing parental resilience.

Objectives: A randomized controlled trial (RCT) of the AMOR Method was conducted to examine its efficacy in improving resilience and well-being in parents of young children with ASD. The study aimed to measure change in resilience among parents in the AMOR group from baseline (BL) to post-treatment (PT), relative to the waitlist (WL) group. Secondary aims were to evaluate increased positive practices, enhanced parental well-being, and improved parental perceptions of child behaviors as a result of participation in the AMOR Method.

Methods: Thirty-four parents of children with ASD (4-10:11 years) were randomized to either 8 weeks of the AMOR Method (n = 17) or to waitlist (WL; n = 17). To measure resilience changes, all parents completed the Connor-Davidson Resilience Scale (CD-RISC; Connor & Davidson, 2003) at the BL and PT timepoints. Parents completed additional measures of parental mindfulness, acceptance, optimism, as well as measures of parenting stress, internalizing symptoms, self-efficacy, self-compassion, marriage happiness, and family empowerment. Parents also completed measures of child problem behaviors, strengths and difficulties, and social impairment. Repeated measures ANOVA were employed to evaluate the pre- and post-treatment differences between and within groups.

Results: Repeated measures ANOVA revealed significant increase in resilience ($F = 10.316$, $p <0.01$) in the AMOR group (see Table 1). Additional improvements were observed in mindfulness ($F = 4.929$, $p = 0.035$), optimism ($F = 9.347$, $p = 0.005$), parenting stress ($F = 10.237$, $p = 0.004$), parental distress ($F = 5.391$, $p = 0.029$), dysfunctional interaction stress ($F = 5.866$, $p = 0.023$), general stress ($F = 4.684$, $p = 0.040$), anxiety ($F = 5.657$, $p = 0.025$), self-compassion ($F = 4.571$, $p = 0.042$), marriage happiness ($F = 9.864$, $p = 0.004$), and family empowerment ($F = 12.308$, $p = 0.002$; see Figure 1). Analyses revealed improvements in parent ratings of child inappropriate speech ($F = 4.689$, $p = 0.043$) and emotional problems ($F = 8.007$, $p = 0.013$) in the AMOR group only. No significant group differences emerged in acceptance, depression, self-efficacy, and total child problem behaviors or social impairment.

Conclusions: Findings suggest that the AMOR Method is a promising intervention for improving resilience in parents of children with ASD. Targeting resilience appears to be a pivotal treatment goal with cascading improvements in other domains of parental stress management, well-being, and positive parent functioning. Continued investigation with larger samples is needed to understand mechanisms of change and predictors of treatment response.

320.004 *(Oral)* Mindfulness-Based Therapy for Adults with Autism: Improving Disability-Related Quality of Life, Executive Functioning, and Emotional Regulation

***B. A. Pagni**, M. Walsh, E. Foldes, N. Guerithault, M. Dixon, L. Ballard, A. Sebren, E. Dominguez, C. Haynes, A. Nespodzany, L. Monahan, C. Riecken, K. Van Houghton and B. B. Braden, Arizona State University, Tempe, AZ*

Background: Emerging research suggests mindfulness-based stress reduction (MBSR) interventions reduce depression, anxiety, and autism-related symptoms in adults with autism spectrum disorder (ASD). However, treatment gains have not been compared to active control groups, making it difficult to assess the magnitude of mindfulness-specific benefits.

Objectives: We compared MBSR's efficacy to a social support/stress education control group which accounted for peer- and instructor-mediated social support and educational components of MBSR. We also sought to determine if instruments/subscales tapping into domains of executive function, emotion regulation, and mindfulness would be improved in adults with ASD, as seen after MBSR in other populations.

Methods: In two independent cohorts, a total of 54 adults with ASD were randomly assigned to an 8-week MBSR or support/education intervention. Depression and anxiety were assessed using self-report Beck Depression Inventory-II (BDI-II) and State-Trait Anxiety Inventory (STAI-1=State; STAI-2=Trait), as well as informant-report Anxiety, Depression, and Mood Scale (ADAMS) Total and subscales 'Depression', 'General Anxiety', and 'Social Avoidance'. ASD-related symptoms were assessed using self-report Adult Repetitive Behavior Questionnaire (ARBQ) subscales 'Motor, 'Sensory', and 'Insisting on sameness', Social Responsiveness Scale-2 Total, and the World Health Organization's Disability Assessment (WHO-DAS) Total and subscales 'Difficulties', 'Unable', and 'Reduce Activities/Work', as well as informant-report WHO-DAS-Total. Executive function/emotion regulation were assessed using self-report Behavior Rating Inventory of Executive Function (BRIEF) subscales 'Inhibit', 'Emotion', 'Initiate' and 'Behavioral Regulation', as well as informant-report Emotion Dysregulation Inventory (EDI) subscale 'Reactivity' and the Strengths and Difficulties Questionnaire (SDQ) subscale 'Emotion'. Finally, mindfulness traits were assessed using the Five Facets Mindfulness Questionnaire (FFMQ) Total. Repeated measures ANCOVA were performed with a within-group factor of time, between-subjects factor of group, and cohort covariate. Significant interactions were followed by within-group analyses.

Results: Main effects of time without interactions indicated improvements in both groups on self-reported BDI-II ($F(1,52)=12.57;p=0.001$), STAI-1 ($F(1,51)=5.37;p=0.03$), STAI-2 ($F(1,52)=5.70;p=0.02$), ARBQ-subscales 'Sensory' ($F(1,49)=4.04;p=0.05$) and 'Insisting on sameness' ($F(1,49)=6.69;p=0.01$), as well as informant-reported ADAMS-Total ($F(1, 31)= 9.91;p=0.004$) and subscales 'Depression' ($F(1,31)=10.60;p=0.003$) and 'General Anxiety' ($F(1,31)=5.94;p=0.02$).

Group by Time interactions were detected on self-report WHO-DAS-Total ($F(1,47)=6.93;p=0.01$), WHO-DAS-subscale 'Difficulties' ($F(1,47)=5.25;p=0.03$), ABRQ-subscale 'Motor' ($F(1,49)=5.52;p=0.02$), BRIEF-subscales 'Inhibit' ($F(1,21)=10.00;p=0.01$), 'Initiate' ($F(1,21)=5.38;p=0.03$), and 'Behavioral Regulation' ($F(1,21)=4.44;p=0.05$), and FFMQ-Total ($F(1,49)=490.12;p=0.051$), as well as informant-report ADAMS-subscale 'Social Avoidance' ($F(1,31)=7.12;p=0.01$), SDQ-subscale 'Emotion' ($F(1,31)=12.60;p=0.001$), and EDI-subscale 'Reactivity' ($F(1,16)=4.61;p=0.05$). Within-group analyses revealed that the MBSR group demonstrated significant improvements on WHO-DAS self- and informant-report Total Scores ($F(1,24)=16.79;p<0.001$; $F(1,12)=4.74;p=0.05$) and 'Difficulties' subscale ($F(1,22)=5.87;p=0.02$), ARBQ-subscale 'Motor' ($F(1,24)=6.66;p=0.02$), BRIEF-subscales 'Inhibit' ($F(1,9)=5.41;p=0.05$) and 'Initiate' ($F(1,9)=26.30;p=0.001$), and EDI subscale 'Reactivity' ($F(1,7)=8.14;p=0.03$) that were absent in the support/education group.

Conclusions: These results suggest that mindfulness training may lead to specific benefits in the domains of disability-associated quality of life, executive functioning, emotion regulation, and repetitive motor behaviors. Conversely, benefits in depression, anxiety, sensory symptoms, and flexibility can be gained through intervention programs that provide stress education with peer- and instructor-mediated social support, but do not require mindfulness training specifically. Taken together, MBSR is likely a more robust program for a breadth of symptom improvements in adults with ASD. However, community-led support groups can provide critical benefits if MBSR is inaccessible.

POSTER SESSION — INTERNATIONAL SOCIETY FOR AUTISM RESEARCH - NON-PHARMACOLOGIC - SCHOOL-AGE, ADOLESCENT, ADULT

428.001 *(Poster)* A Community-Based Motor Skill Intervention for Children with ASD Ages 4-6: An Exploratory Pilot Investigation

***M. Lloyd**[1], A. T. Ibbitson[2], T. Runge[2] and K. Cooper[3], (1)Kinesiology, University of Ontario Institute of Technology, Oshawa, ON, Canada, (2)Faculty of Health Science, University of Ontario Institute of Technology, Oshawa, ON, Canada, (3)Ontario Tech University, Oshawa, ON, Canada*

Background: Fundamental motor skills are the foundation skills required for children to engage in more complex games and activities; they include running, throwing, catching, kicking, etc. Evidence indicates that children with ASD experience delays in their fundamental motor skills, but with intervention these delays can be mitigated. However, most published motor skill interventions for children with ASD are laboratory-based, and not run in a community setting with community-based instructors.

Objectives: The purpose of this study was to pilot an 8 week, group, fundamental motor skill intervention (90 mins/week) for 4-6 year old children with ASD delivered by a community based organization. The objective was to determine feasibility of this type of delivery model and to examine if motor skills improve.

Methods: A local community-based soccer club was recruited to deliver the intervention. The instructors and volunteers were trained by the researchers on the curriculum as well as basic behaviour management. Each week a different skill was the focus (e.g. throwing, catching, kicking, running, jumping, etc.). All assessments were conducted by the research team, but the delivery of the intervention was led by the community partner exclusively.

9 children with ASD (8 male, 1 female, mean age= 5.7 ± 0.56 years) were recruited for an 8 week, 90 minutes/week, fundamental motor skill intervention. Motor skills were measured using the Test of Gross Motor Development-2 (TGMD-2) before and after the intervention. Parents were asked to provide feedback on the program in writing.

Results: At the pre-test assessment, all children with ASD were significantly delayed in their motor skills as measured by the TGMD-2. There were significant improvements as indicated by the Gross Motor Quotient, (Time 1 mean = 60.33 ± 15.35, Time 2 mean = 74.22 ± 23.91) p = .004; as well as for the Locomotor sub-score, (Time 1 mean = 10.78 ± 10.63, Time 2 mean = 19.22 ± 11.88), p = 0.014, and object control sub-score, (Time 1 mean = 12.67 ± 8.31, Time 2 mean = 22.11 ± 14.68) p= .005.

While parents were overall very happy with the pilot program, they indicated the most valuable part of the program was meeting the other families and the time to talk while watching their children participate in the program. They did suggest that the lead instructor should have a coaching and/or pedagogy background to maximize instructional time.

Conclusions: All the children demonstrated significant delays in motor skills at the baseline assessment and made improvements through the intervention. The research team learned a lot from this pilot study; specifically, about the amount of training and support required for community-based groups to deliver a motor skill intervention program for children with ASD. More, evidence-informed, programs for children with ASD are needed and more research is required on the most effective curricula and mode of delivery, particularly in the community setting.

428.002 *(Poster)* A Gaze-Driven Video Game Intervention for Attention Orienting in Individuals with ASD

L. Chukoskie[1]*, S. Hacker*[2] *and J. Townsend*[1]*, (1)University of California San Diego, La Jolla, CA, (2)Neurosciences, University of California, San Diego, La Jolla, CA*

Background: Although our group (Townsend, et al.,1996; Miller, et al., 2014) and others (Schmitt, et al., 2014; Johnson, et al., 2016) have noted the difficulties individuals on the spectrum have with orienting attention and gaze, even in very early childhood (Zwaigenbaum, et al. 2005; Elsabbagh, et al., 2013), specific interventions addressing this deficit are lacking. Here we report on a pilot clinical trial using gaze-driven video games quantify the metrics and timing of saccades using a high-accuracy video-based eye tracking system in a sample of children and adolescents.

Objectives: We sought to measure performance on an array of attention and eye movement tasks both before training and after 8 weeks of training on our purpose-designed, gaze-driven video games.

Methods: Twenty-three individuals with ASD (mean age 17.31 [4.3]) engaged in 8 weeks of at-home training using eye tracking-enabled PC computers delivered as part of the study. Participants were asked to play the games approximately 30 minutes per day, 5 days per week over the 8 week period. Three video games were available initially that trained principles of fast and accurate shifts of attention, steady fixation, and looking ahead toward the target goal in a dynamic setting. After 10 hours of game play on these games, an additional game, incorporating multiple principles, was unlocked for play. The average participant played for 22 hours at home over the trial. In the pre- and post-tests in the lab, we measured covert attention orienting, pro- and anti-saccade performance, performance on simulated driving tasks, and parent assessment using an ADHD rating scale.

Results: We observed multiple improvements in performance on our objective behavioral tasks post-training, including improved speed of attention orienting ($p < 0.0001$), speed of attention disengagement ($p < 0.003$), stability of gaze fixation ($p < 0.03$) and accuracy of the direction of saccades in an anti-saccade task ($p < 0.02$). Tasks to examine efficacy of change were a spatial attention task that controlled for motor response and processing speed to measure speed of attention orienting and disengagement (Townsend et al, 1999) and typical pro/anti-saccade tasks that requires shifting gaze to either the location of a stimulus or to the opposite side of a stimulus. Mid-level attention performance was assessed with two simulated driving tasks--a divided attention task that demanded fast and accurate responses to peripheral cues while maintaining speed and lane position on a driving course (with no other cars), and a Challenge Drive through urban, suburban and rural settings with multiple sudden occurrences that demanded a prompt response from the participant. We found significant post-training improvement on the divided attention task including fewer missed/ignored responses ($p < 0.04$) and fewer roadside/lane excursions ($p<0.05$). Finally, we used the Vanderbilt NICHQ parent report questionnaire to examine change in ADHD symptoms. We found significant improvement in inattention ($p < 0.03$) and only marginal change in hyperactivity ($p < 0.06$).

Conclusions: Our analysis suggests that gaze-driven video games can be useful for training attention orienting and that this training affects behavior in multiple related, but untrained, tasks.

428.003 *(Poster)* A Randomized Controlled Study of Compass: How Much and What Type of Coaching Is Needed to See Teacher Adherence to Intervention Plans and Student Goal Attainment Progress?

L. N. Ogle[1]*, L. A. Ruble*[2]*, J. H. McGrew*[3] *and K. Pinkman*[4]*, (1)Department of Educational, School, and Counseling Psychology, University of Kentucky, Lexington, KY, (2)University of Kentucky, Lexington, KY, (3)Psychology, Indiana University - Purdue University Indianapolis, Indianapolis, IN, (4)Department of Educational School and Counseling Psychology, University of Kentucky, Lexington, KY*

Background: The Collaborative Model for Promoting Competence and Success (COMPASS) is an evidence-based, consultation and coaching intervention that is ideal for embedding EBPs into the public school classroom. COMPASS starts with a parent-teacher consultation facilitated by a consultant producing goals and intervention plans individualized to the student with ASD, teacher, and environmental context using an evidence-based practice in psychology framework (McGrew, et al., 2015). This is followed by coaching with implementation fidelity feedback and progress monitoring.

Objectives: Three previous RCTs with COMPASS used the researchers/developers as consultants. We needed to demonstrate that school-based consultants can be trained to implement a complex intervention such as COMPASS with high fidelity. We also sought to understand how much (dosage) and what type of coaching (written vs face-to-face) is needed by teachers to achieve effectiveness and show maximum adherence to the intervention plans and student goal attainment progress.

Methods: An iterative design was applied for the development and testing of a COMPASS training package, followed by a between group design to understand the differences of dosage and coaching on teacher adherence and child outcomes.

Community consultants (n=12) were trained over three cohorts. Consultants ages' ranged from 24-60 years and averaged 11 years of consultation experience. Consultants worked with 4 teacher-student dyads. Teachers (n=36) ranged in age from 23-55 years. Students (n=36) were between the ages of 4 and 13, and all were receiving special education services under the eligibility category of autism.

After completing training, consultants provided an initial 3-hour consultation to each teacher. Follow up coaching varied across four conditions: 1) four coaching sessions, 2) two coaching sessions, 3) four written feedback emails of student's goal attainment progress and teacher intervention plan adherence, and 4) consultation only. Consultants and researchers rated teacher adherence to the intervention plans on a 0-4 scale (0 = 0%; 4 = 76-100%). Student goal attainment progress was evaluated on a scale of -2 to +2 (-2 = present level of performance; 0 = achieved annual goal; +2 = greatly exceeded goal).

Results: Full data will be available in April 2020 from all 12 consultants. Preliminary results on teacher adherence from the four coaching sessions condition demonstrated results consistent with previous RCTs of steady increased adherence to the intervention plans over the four coaching sessions (from 25% to about 60%) with goal attainment change score of 2.4. Adherence for teachers who received two coaching sessions stayed at approximately 37% with a goal attainment change score of 1.9. Adherence for teachers who received four written feedback emails increased from 37% to 50% with a goal attainment change score of 2.2. For the no coaching condition, the final goal attainment change score was 1.6.

Conclusions: Preliminary results indicate that how often coaching occurs, rather than type of coaching matters. Once final data are collected, if the findings are similar, important implications for practice are offered for the efficiency and effectiveness of coaching.

This work was supported by Grant R34 MH111783-02 from the National Institute of Mental Health

428.004 *(Poster)* A Targeted Social Communication Group Intervention for Adults on the Autism Spectrum with Limited Functional Language

E. F. Ferguson[1], *K. Hua*[1], *J. Liang*[1], *H. Feerst*[1], *K. Drapalik*[2], *A. Mallory*[1], *J. Sanford-Rodriguez*[1], *H. Nawrocki*[1] *and T. W. Vernon*[1], *(1)University of California Santa Barbara, Santa Barbara, CA, (2)Yale Child Study Center, New Haven, CT*

Background: Adults on the autism spectrum who have high support needs are critically under-represented in the autism treatment literature (Siegel, 2018; Russel et al., 2019). The exclusion of autistic individuals who are not conversationally fluent and have co-occurring intellectual disability neglects a population in dire need of targeted support. Very few adults with high support needs have regular access to appropriate social skill training or social activity programs (Gotham et al., 2015). The development of social communication interventions that promote purposeful engagement and social connection may improve quality of life for this population.

Objectives: To explore the preliminary feasibility and efficacy of a 10-week social communication skill intervention specifically designed for autistic adults with high support needs.

Methods: This study used a multiple-baseline research design to evaluate a modified version of the START socialization program (Vernon, Miller, Ko, Barrett, & McGarry, 2018), adapted and individualized for adults with ASD who have high support needs. Five autistic young adults (18-25 years) with intellectual disability (mean IQ = 50.2) and limited functional language (mean verbal IQ = 48.6) completed ten 90-minute weekly intervention sessions. The peer-mediated sessions consisted of: individual check-in/out meetings with the young adult and a parent; guided socialization time; introduction of social skill topics via popular movie examples, video modeling, and small group practice; and structured social games. Social motivation and experiential learning were crucial programmatic considerations (Pallathra et al., 2018). Prior to participation, participants were assigned to staggered baselines consisting of 2, 4, or 6 unstructured conversations with novel, untrained peers. Outcome measures were derived from both unstructured and structured conversations (with a trained peer following a social conversation script in the latter), along with parent-completed survey measures. Conversations were behaviorally-coded in Datavyu (Datavyu Team, 2014) for a number of key social communication features (κ = .65-.92).

Results: Findings from 3-minute unstructured conversations indicate that *percent of time on-topic* (duration of on-topic conversation contributions/ individual speaking duration) increased from baseline (*M* 48.7, *SEM* 17.1) to post-intervention (*M* 59.5, *SEM* 13.3; Figure 1). Similarly, *listening behaviors* (listening duration / conversation duration) increased from baseline (*M* 18.1, *SEM* 6.8) to post-intervention (*M* 33.4, *SEM* 9.2). For the structured conversations, the Wilcoxon Signed Ranks Test in R indicates that increasing numbers of *on-topic responses* from pre- to post-intervention trended toward significance ($V = 1$, $p = .06$; Figure 2). Additionally, there were significant improvements on the Social Responsiveness Scale-2 *Social Communication Index* ($V = 10$, $p < .05$). On the treatment satisfaction scale post-intervention, mean rating for helpfulness of the intervention content was 4.5 (*SD* 0.5; 1 = not helpful to 5 = very helpful).

Conclusions: Findings support the preliminary efficacy of our intervention model in improving social communication for autistic adults with high support needs. To our knowledge, this investigation is the first to evaluate a socialization program specifically designed for this population. Next steps include a randomized controlled trial to further evaluate feasibility and efficacy of our socialization program for adults who are notably under-represented in the treatment literature.

428.005 *(Poster)* ACT Based Insomnia Intervention for Autistic Adults

L. P. Lawson[1,2], *A. L. Richdale*[1], *E. Morris*[3] *and K. Denney*[4], *(1)Olga Tennison Autism Research Centre, La Trobe University, Melbourne, VIC, Australia, (2)Cooperative Research Centre for Living with Autism (Autism CRC), Long Pocket, QLD, Australia, (3)Pyschology & Counselling, La Trobe University, Melbourne, Australia, (4)Olga Tennison Autism Research Centre, La Trobe University, Melbourne, Australia*

Background: Across the lifespan, insomnia is one of the most common co-occurring conditions in Autism Spectrum Disorder (ASD), with up to 80% of children and adolescents and two thirds of adults reporting poor sleep. Insomnia symptoms in autistic individuals are associated with anxiety, depression, fatigue, poorer daytime functioning, behavioural difficulties, poorer academic performance, and underemployment. The close relationship between mental health difficulties and insomnia highlights a clear and critical need for interventions focused on insomnia treatment. Behavioural interventions, primarily parent training programs, have been shown to be efficacious in treating sleep onset and night waking in younger children. However, currently there are no published, empirically supported psychological interventions for insomnia in autistic adults. This knowledge gap contributes to risk of significant harm due to overprescribing poorly chosen medications or lack of treatment.

Objectives: Our aim was to investigate the efficacy of a combined Acceptance and Commitment Therapy (ACT)/Behavioural Therapy (BT) for insomnia in autistic adults (ACT-i).

Methods: Twelve adults expressed interest in the study and 11 met screening criteria (age 18-70 years, insomnia severity index (ISI) ≥8, autism spectrum disorder diagnosis); eight individuals were able to attend available session dates. Participants were assigned to one of two intervention groups (4/group) within a multiple baseline over time design. Each group completed questionnaires on anxiety and depression (HADS), experiential avoidance (BEAQ), psychological distress (CORE-10), daytime fatigue (FFS), pre-sleep arousal (SAAQ) and sleep (ISI [primary outcome measure], PSQI) at pre-intervention, post-intervention, and 2-month follow-up. A daily sleep diary was completed during pre-intervention, post-intervention, and again at 2-month follow-up. Actigraphy data were also collected for 7-days pre- and post-intervention. Client satisfaction was also ascertained. Intervention consists of 4 x 2-hour, therapist-led intervention sessions teaching ACT and sleep hygiene principals. It was modified from an existing sleep intervention, following feedback from three autistic adults.

Results: Six males and two females age 19-68 years, with ASD diagnosis confirmed by sighting original diagnostic reports, began intervention. At pre-intervention ISI scores ranged from 9-26 (M=17.9, SD=6.1). At post-intervention, wilcoxon signed ranks test indicated significant improvements on the ISI ($Z=-.253$, $p<.01$), PSQI ($Z=-2.13$, $p<.05$), CORE-10 ($Z=-2.31$, $p<.05$), HADS anxiety ($Z=-2.21$, $p<.05$) and BEAQ ($Z=-2.37$, $p<.05$). There was a non-significant reduction in HADS depression scores. Furthermore, majority of participants showed reliable clinical change on the ISI and treatment acceptability was good, with a modal rating of "4" (agree) on a 5-point scale. At the 2-month follow-up, there was no significant changes in any scores from post-treatment, indicating that improvements were maintained. Sleep diary and actigraphy showed considerable inter- and intra-individual variability, and no significant changes were found in response to intervention.

Conclusions: The outcomes from this pilot study indicate that ACT-i was both efficacious and acceptable in reducing self-reported insomnia symptoms in autistic adults. Significant improvements were also seen in anxiety symptoms and behavioural flexibility. Importantly, gains were maintained up to 2-months post-intervention. Next steps are to revise the group protocols based on participant feedback and clinician experiences and conduct a larger randomised control trial.

428.006 *(Poster)* Acceptability and Feasibility of Teacher-Delivered Westmead Feelings Program in Special Education Schools: A Mental Health Promotion Intervention for Children with Autism Spectrum Disorder

*M. G. Wong[1], M. Girgis[1], K. P. Haas[2], V. Gibbs[2], B. Ratcliffe[3], D. R. Dossetor[1] and **T. R. Clark**[2], (1)Psychological Medicine, Children's Hospital at Westmead, Sydney Children's Hospitals Network, Westmead, NSW, Australia, (2)Aspect Research Centre for Autism Research, Autism Spectrum Australia (Aspect), Sydney, NSW, Australia, (3)School of Social Sciences and Psychology, Western Sydney University, Bankstown, Australia*

Background: The Westmead Feelings Program (WFP) is a mental health promotion intervention for children with Autism Spectrum Disorder and co-occurring Intellectual Disability (ASD/ID) targeting emotions competence skills. Controlled trials have demonstrated that school counsellor delivered WFP improves emotions competence and reduces mental disorder symptoms in autistic children, with and without co-occurring ID (Ratcliffe et al., 2019; Ratcliffe et al., 2014). Teaching social-emotional skills in classrooms is a priority (Saggers et al., 2015). However, research has focussed on the delivery of social, rather than emotion skills interventions (Laugeson et al., 2014). Given the importance of teachers educating autistic children in emotion skills, research examining classroom-based interventions is warranted (Alexander et al., 2015; Greenway et al., 2013).

Objectives: The aims of this study were to investigate whether WFP delivered by teachers in special education schools to children with ASD/ID and their parents is acceptable and feasible and examine treatment efficacy. It was hypothesised that WFP teacher delivery would be acceptable and feasible and treatment efficacy would be demonstrated.

Methods: This is a mixed-method study utilising quantitative and qualitative methods. Participants were seventy-seven children and seventy-two parents, recruited from eight special education schools in New South Wales, Australia. The majority of children had a diagnosis of ASD/ID and were eight to 12 years old. Teachers and teacher's aides were also recruited into the study. Teachers received training to facilitate WFP over eight months to children and parents. Fidelity checks were completed in four classrooms. Feasibility data was collected from teachers and parents. Efficacy data was collected from teacher's aides, parents and children. Quantitative data was analysed using standard statistical methods: frequencies and percentages for categorical variables and means (standard deviations) and medians (interquartile ranges) for continuous variables. Qualitative data was analysed utilising a thematic approach and realist method (Braun & Clark, 2006).

Results: Teacher's aides described gains in social and emotional development in 87% of children, specifically emotions recognition, communication, regulation, and self-confidence. Analysis of quantitative data from parent and child reports indicated that WFP helped with child social and emotion skills. All parents would recommend WFP for other children. On average, teachers reported that WFP content was important for children with ASD/ID to learn and they would deliver WFP again. Teachers rated low satisfaction with parent session implementation due to a lack of teacher time and parent engagement. Despite these challenges, parent quantitative data indicated that WFP helped parents understand their child and teach their child about emotions. All parents who attended sessions indicated they would continue using WFP and would recommend parent sessions for other parents.

Conclusions: Teacher-delivery of WFP to children with ASD/ID in special education schools is acceptable and feasible. Delivery of parent sessions has low acceptability and feasibility and future studies can explore face-to-face session alternatives. There is preliminary evidence that WFP has benefit to children's emotions skills and a study that examines efficacy utilising standardised measures is warranted. This study addresses the research gap into the delivery of school-based emotion skills interventions for autistic children.

428.007 *(Poster)* Adaptation of a Virtual Reality Environment in Children with ASD to Support the Training of Executive Function Skills.

***J. Contreras**[1], E. Vera-Estay[2], R. Varas[1] and V. Y. Aguila[1], (1)Edumedica, Viña del mar, Chile, (2)Centro de Desarrollo de Tecnologías de Inclusión, Escuela de Psicología, Pontificia Universidad Católica de Chile, Santiago, Chile*

Background: Difficulties in executive functioning are frequently present in children with ASD, affecting their quality of life (Vries & Geurts,2015). Currently, intervention strategies must be innovative and adapted to children with ADS. Virtual Reality has begun to become an effective tool in the medical and educational field, however, its use in ADS are very limited and their effectiveness and safety in children with autism is poorly understood.

Objectives: The aim of this study was to explore the use of an Immersive virtual environment adapted for children with ASD, as a tool for training executive functioning skills.

Methods: For this study, a virtual environment was completely designed in Spanish, using the development platform Unity graphics engine and Oculus libraries that allow stereovision with its Oculus Gear VR glasses, following the principles of the Multiple Errands Test (Shallice & Burgess, 1991). 21 children diagnosed with ASD(M age= 10.7,SD=1.1,WISC-III,CIT,M=110,SD=15) and 21 typically developing children (M age=10.7,SD= 11.1,WISC-III, CIT,M=106,SD=20) participated in this study. Prior to first immersive session, All participants were applied the Wechsler Intelligence Scale for Children, (WISC-III v.ch), the Battery of Neuropsychological Assessment for Executive Function in Children(ENFEN)and the Perception of Differences test (CARAS-R). Parent completed the Behavior Rating Inventory of Executive Function 2 (BRIEF-2). During the following six weeks, children participated in a 15-minutes immersive activity in which they had to complete a series of errands at home, in the city and the supermarket. In each session, the children were accompanied by a psychologist who observed on another screen in real time the activities carried out by the child, being able to interact verbally with him. The data was collected by the MySQL database, and then analyzed and evaluated. At the end of the activity, a cybersickness questionnaire (Kennedy, 1993) was administered. The ENFEN, CARAS-R and BRIEF-2 were repeated after the six-week.

Results: No significant differences were observed between the ASD and typically developing group regarding intellectual performance and executive functioning before the immersive sessions, except for a poor performance in attentional control (CARAS-R), and planning skills (ENFEN), in the ASD group. Significant differences between groups were observed in daily executive functioning. The ASD group showing more difficulties in behavioral global score F(1.38)=20,722,p =.001). After the first immersive session, most participants felt little or no cybersickness (91%ASD group; 95% typically developing group). In addition, cybersickness scores were significantly reduced upon reaching the last session (MS1=22;MS2=18,t=2,606,p=.013). After the intervention, the ASD group enhanced performances in attentional control(CARAS-R,MT1=7;MT2=7.7,t=-2.870,p = .009), planning (Rings,MT1=3.5;MT2=,5,t=- 4.985,p=.001),ENFEN) and daily cognitive regulation (CRI, BRIEF-2,MT1=64;MT2=58,t=3,119,p=.005).

Conclusions: This study suggest that VR can be a safe, entertaining and effective strategy to enhance executive functioning in children with ASD. Creating a virtual environment designed for ASD also have increased de immersion experience effective during the activity and has helped in the training of executive functions.

428.008 *(Poster)* Adaptive and Maladaptive Emotion Regulation Strategies Reported By Children with Autism

***P. Tablon-Modica**, F. H. Roudbarani and J. A. Weiss, Psychology, York University, Toronto, ON, Canada*

Background: Children with autism are at a greater risk for emotional and behavioural problems compared to their peers without disabilities (Maskey et al., 2013). They have been shown to display greater emotion dysregulation in times of distress (Jahromi, et al., 2012). Many interventions have been developed to target emotion regulation problems and improve children's ability to cope with stressful situations (Soffronoff, Attwood & Hinton, 2005; Weiss et al., 2018). Traditionally, child-reported gains have been captured using standard questionnaires that assess outcomes of regulation, providing limited information on what specific regulation skills they have learned (Callear, Harvey, & Bimler, 2016). Research has yet to closely examine the content of learned strategies that children acquire from therapy to cope with distressing situations.

Objectives: To examine reported coping strategies by children with autism when asked about two hypothetical scenarios eliciting anxiety and angry feelings.

Methods: Data were collected from 32 children with autism (87.5% male) participating in a 10-session cognitive behavioural therapy program to improve emotion regulation. Children were 8 to 13 years of age (M = 9.78 years, SD = 1.66) with at least average intelligence (FSIQ; M = 105.28, SD = 15.52). At pre- and post-intervention assessments, children listened to two scenarios and were asked to identify strategies to cope with anxiety (*James and the Maths Tests* (Atwood, 2004a)) and anger (*Dylan is Being Teased* (Atwood, 2004b)). Verbal responses were transcribed verbatim and coded by two coders. Guided by the Transdiagnostic Emotion Regulation Framework (Weiss, 2014), responses were grouped into adaptive and maladaptive strategies based on the distressing scenario. Strategies were further categorized into appropriate domains identifying specific responses (i.e., *Adaptive*: help-seeking, self-regulation, etc.; *Maladaptive*: dysregulation, impractical). Coded responses were summed.

Results: Preliminary coding demonstrated good inter-rater reliability for all items (ICC = .80). Paired samples t-test showed an increase in child-reported *adaptive strategies* for the *James* task (pre-intervention: M = 1.13, SD = 1.04; post-intervention: M = 2.13, SD = 1.52; $t(31)$=-4.14, $p <$ .001) and no significant changes for the *Dylan* task. Within the *adaptive strategies* domains, self-regulation strategies increased for the *James* task (pre-intervention: M = 0.78, SD = 0.83; post-intervention: M = 1.56, SD = *1.39*; $t(31)$=-3.37, p = .002) and approached significance for the *Dylan* task (pre-intervention: M = 0.39, SD = 0.62; post-intervention: M = 0.74, SD = 0.89; $t(30)$=-2.08, p = .05). Child-reported *maladaptive strategies* significantly decreased for the *Dylan* task (pre-intervention: M = 0.28; SD = 0.66; post-intervention: M = 0.00; SD = 0.00; $t(35)$=2.53, p = .02) and no changes for the *James* task.

Conclusions: Following therapy, children were more likely to report several adaptive strategies for an anxiety-provoking scenario learned in therapy and were less likely to report on maladaptive strategies in an angry scenario. The *James* and *Dylan* open-ended tasks successfully captured acquired knowledge in therapy for children with autism and their ability to generate coping strategies. Further research may administer open-ended tasks to measure children's treatment gains and examine their capacity to demonstrate and apply learned coping strategies.

428.009 *(Poster)* Akl-T01: A Digital Intervention to Treat Inattention

***M. R. Gerdes**[1], B. C. Copeland[1], B. G. Jurigova[2], E. R. Silvers[1], J. Anguera[2] and E. J. Marco[1], (1)Cortica Healthcare, San Rafael, CA, (2)Neurology, University of California San Francisco, San Francisco, CA*

Background: Children with impaired cognitive control have challenges in their everyday life and school function. Cognitive training has previously been shown to improve attention, providing an alternative to prescription medication. Based on our previous study investigating brain training in children with sensory processing disorders (Anguera et al. 2017; PLOS ONE), we posit that attention can be improved in a clinical pediatric population with ADHD after a 4 week training period with a prescribable home-based iPad digital treatment.

Objectives: To determine whether a video game-based iPad intervention (AKL-T01) adapted for school-aged children with ADHD shows improvements in cognitive control using parent report, direct assessment, and electroencephalography (EEG).

Methods: 12 unmedicated children (10 boys), aged 8-12 years, underwent training on a provided iPad equipped with AKL-T01. AKL-T01 is a 4-week long digital intervention designed to improve cognitive control abilities (by adapting based on individual needs). Patients were recruited from the community as well as from the Marin Cortica Healthcare Center. Research inattention criteria was a parent report of ≥ 6/9 on the Vanderbilt ADHD Diagnostic Parent Rating Scale as well as a rating of ADHD-Inattentive subtype on the Mini-International Neuropsychiatric Interview for Children and Adolescents (MINI Kid) screener. Cognitive control was determined prior to and following intervention using parent report (Vanderbilt) and direct assessment (Test of Variables of Attention (TOVA)). Additionally, changes in midline frontal theta, an EEG marker associated with focused attention processing, was assessed using a custom designed perceptual discrimination task.

Results: Using the parent report measure of inattention, there was a significant decrease in symptoms ($p=0.035$) after playing AKL-T01 for 4 weeks. In addition, impulsive response time using TOVA significantly improved ($p=0.04$, $n=10$) after training. Two were excluded due to a very high false alarm rate (80%), which suggests that they did the task incorrectly. When looking at resting state midline frontal theta with EEG, there was a significant increase in activation following training during the eyes open portion. Additional investigations for task dependent EEG are ongoing.

Conclusions: This study furthers our understanding of the role of brain training for children with neurodevelopmental disorders. We replicated the improvement in parent report as well as a neurophysiologic signature of ADHD in a novel cohort. This study emphasizes the ability to guide beneficial brain plasticity with an engaging, home based digital intervention. It may have broad applications across neurodevelopmental disability cohorts who also have cognitive control challenges, such as individuals with known genetic conditions (e.g. 16p11.2 deletion) or categorical diagnoses (e.g. Autism and Sensory Processing Disorders). In addition to this preliminary analysis, enrollment is ongoing and outcomes from a larger sample will be available in May of 2020.

428.010 *(Poster)* An Evaluation of the Acceptability of the Family Check-up Intervention for Caregivers of Children with Autism Spectrum Disorder

V. Lee[1], *I. Drmic*[2], *M. Kimber*[3], *C. Roncadin*[2], *S. Georgiades*[4], *E. Duku*[4], *K. Georgiades*[4], *A. Gonzalez*[4], *M. Janus*[4], *E. Lipman*[4], *P. Pires*[4] *and T. Bennett*[5], *(1)McMaster Universtiy-Offord Centre, Hamilton, ON, Canada, (2)Autism Spectrum Disorder Service, McMaster Children's Hospital - Hamilton Health Sciences, Hamilton, ON, Canada, (3)Psychiatry and Behavioural Neurosciences, McMaster University, Hamilton, ON, Canada, (4)McMaster University, Hamilton, ON, Canada, (5)Offord Centre for Child Studies, McMaster University, Hamilton, ON, CANADA*

Background: Children with autism spectrum disorder (ASD) carry a particularly high burden of emotional behavioural problems (EBP). Although not considered core symptoms, prevalence rates of EBP (i.e. aggression, anxiety, hyperactivity) are estimated to be as high as 70%. Any intervention aspiring to alleviate EBP and improve life course-outcomes in children with ASD needs to involve caregivers in an empowering and meaningful way. But to our knowledge, there are no interventions that target parenting skills and consider ecological assessment of risk and protective factors influencing child EBP. The Family Check-Up (FCU) is a promising intervention model for families with children with ASD. The FCU is a brief, assessment-based, tailored intervention developed to decrease EBP by promoting positive parenting and family management practices. Studies of the FCU in populations of children at risk of EBP (without ASD) have demonstrated reliable reductions in childhood EBP, caregiver depression, and other outcomes.

Objectives: The objective of the current study is to investigate the feasibility and acceptability of the "Family Check-Up" (FCU) as part of a larger FCU research program aimed at reducing EBP among children with ASD. The study will use a mixed-methods approach to collect initial quantitative and qualitative data from participating caregivers regarding the acceptability of the FCU in addressing the needs of families of children with ASD.

Methods: We followed a sequential explanatory mixed methods research design and implemented the FCU program with dyads/triads of caregivers and verbal children with ASD and EBP recruited through hospital-based ASD services and community partners. Participating caregivers and children completed an initial "Get to Know you" interview with a clinician, a second assessment visit including questionnaires and videotaped interactions addressing child EBP and development, caregiver well-being, parenting and family functioning. The feedback visit concludes with review of overall family well-being, relationships, and strengthens, goal-setting and establishes a collaborative menu of available services for the family. Impact of the FCU on child EBP, and intervention dose/fidelity was assessed and estimated via descriptive quantitative measures (e.g. counts, means, rates). Qualitative interviews with caregivers were completed after completion of the FCU and focused on issues related to feasibility and applicability of the program.

Results: Recruitment is ongoing and the present results include preliminary analysis of data from 5 dyad/triads (child mean age=11 years olds, expressive and receptive language = low average to average). Using principles of interpretative description to analyze interviews, preliminary codes indicate that families find the FCU program applicable and beneficial to supporting overall well-being of families of children with ASD. Caregivers perceive the program may be particularly relevant to newly diagnosed families or families of children experiencing transitions (daycare to school, school to jobs). Caregivers described that the program validated their parenting skills, and the program provided support around defusing family conflicts.

Conclusions: Key findings from this study will inform future adaptations to the intervention, and possible clinical trials that will test the effectiveness of the FCU for families of children with ASD.

428.011 *(Poster)* An Examination of Interdisciplinary School Providers' Attitudes Toward Evidence-Based Practice

C. Middleton[1], *L. Hayutin*[1], *R. E. Boles*[1], *A. Blakeley-Smith*[2], *S. Hepburn*[3], *A. T. Meyer*[4], *N. Reyes*[2], *K. Pickard*[4], *T. Tanda*[5] *and J. Reaven*[2], *(1)University of Colorado Anschutz Medical Campus, Aurora, CO, (2)JFK Partners, University of Colorado Anschutz Medical Campus, Aurora, CO, (3)Colorado State University, Fort Collins, CO, (4)JFK Partners, University of Colorado School of Medicine, Aurora, CO, (5)Developmental Pediatrics, Children's Hospital Colorado, Aurora, CO*

Background: Many students with Autism Spectrum Disorder (ASD) struggle with psychiatric difficulties and have trouble accessing mental health services (Rotheram-Fuller and MacMullen, 2011). For these reasons, schools are the location of choice to deliver interventions; however, they often lack resources, training, and staff to be able to provide evidence-based interventions (Mychailyszyn et al., 2011). The Facing Your Fears – School Based (FYF-SB) program is an adaptation of an evidence-based, cognitive-behavioral group intervention for children with ASD and anxiety (Facing Your Fears, Reaven et al., 2011) designed to be delivered in the school setting by interdisciplinary school providers. Studies have shown that attitudes may impact a person's willingness to learn and adopt new interventions (Stahmer & Aarons, 2009). The current study examined school provider attitudes toward evidence-based interventions and explored whether there were differences between attitudes of mental health and non-mental health providers. Training non-mental health providers was a novel approach to improve access and sustainability within the school system.

Objectives: (1) To examine school providers' attitudes toward learning an evidence-based intervention; (2) To compare mental health and non-mental health providers' attitudes toward learning a new intervention; (3) To determine if provider attitudes are related to acceptability with the intervention and continuity in the second phase of the study.

Methods: Thirty-four interdisciplinary school providers from 11 elementary/middle schools were trained to deliver FYF-SB to students meeting inclusion criteria pre-treatment (e.g., SCARED, SRS-2), and those from traditionally underserved backgrounds. After a year of experience with FYF-SB, those school providers then became trainers for a new cohort of providers as part of a "Train-the-Trainer" approach to ensure sustainability of FYF-SB. Pre-training, providers completed a demographic questionnaire and a measure of attitudes toward evidence-based practices on a 0-4 Likert scale (4= most positive attitude; EBPAS; Aarons, 2004). Following FYF-SB training and implementation, school providers completed a questionnaire measuring their perceptions of the feasibility, acceptability, and appropriateness of FYF-SB on a 1-5 Likert scale (1=highly feasible/acceptable).

Results: Eight out of 11 schools completed the intervention. Of the providers enrolled in the study, 45% were mental health and 55% were non-mental health providers. School providers were generally open and willing to adopt a new evidence-based intervention (M=3.22; SD=.39). There was no difference between mental health and non-mental health providers in attitudes toward adopting a new evidence-based intervention, $t(29)=-.174$, $p=.346$. Attitudes were not related to overall acceptability with the intervention or retention of providers in year two of the study; however, overall acceptability was high (M=2.47; SD=.35) and all but two providers continued in year two.

Conclusions: These results indicate that interdisciplinary school providers in this study were generally receptive to adopting an evidence-based intervention to address anxiety in students with ASD. There were no differences between providers' attitudes (mental health vs. non-mental health). Regardless of attitude, perceptions about feasibility and acceptability of FYF-SB were high. Preliminary findings suggest that non-mental health providers may be good candidates for learning an evidence-based intervention for youth with ASD, potentially increasing capacity to treat co-occurring mental health conditions in schools.

428.012 *(Poster)* Assessing Cranial Electrotherapy Stimulation (CES) Benefits in a Clinical Cohort

B. C. Copeland[1], *M. R. Gerdes*[1], *E. R. Silvers*[1], *M. C. Steele*[1], *K. A. Shapiro*[2] *and E. J. Marco*[1], *(1)Cortica Healthcare, San Rafael, CA, (2)Cortica Healthcare, Torrance, CA*

Background: Cranial electrotherapy stimulation (CES) is a type of noninvasive transcranial pulsed-current stimulation that is intended to modify brain activity. CES has been studied in adults for anxiety, insomnia, pain, and headaches. Although the precise mechanisms of action are unknown, symptomatic benefits may be mediated by modulation of cranial nerves with parasympathetic efferents. CES has not been investigated in pediatric populations; nor is it known specifically whether CES is beneficial for other symptoms related to imbalanced autonomic nervous system function, including constipation, emotional dysregulation, sensory over-responsivity, and motor tics. We hypothesized that CES may be a promising therapy for children and adults with autism and other neurodevelopmental conditions characterized by autonomic dysregulation.

Objectives: To determine feasibility and benefit of an FDA-approved device for CES with a clinical cohort of children with neurodevelopmental disorders.

Aim 1 (feasibility): For children undergoing a 4-week CES trial, we aimed to determine the degree of compliance with and tolerance of the treatment, based on parent report.

Aim 2 (benefit): Following completion of the trial, we aimed to determine benefit based on parent report of clinical global improvement (CGI) and clinician recommendation to continue treatment.

Methods: 17 participants (12 boys and 5 girls), aged 4-18 years, underwent four weeks of at-home CES therapy for 20 minutes a night, 5 days/week at 50 microamperes (lowest possible dose/time). 16 of 17 participants completed the pre- and post-trial sessions. The initial (pre-trial) session is dedicated to training the participants on device use and determining tolerance for the treatment. A symptom questionnaire, the Repeated CES Symptom Survey (RECESS), is also completed. During the post-trial session, the RECESS is completed a second time, along with a CGI scale. The RECESS (administered online using Qualtrics) evaluates parasympathetic nervous system gated functions including: insomnia, gastrointestinal issues, headaches, involuntary movements, emotional dysregulation/autonomic hyperarousal, anxiety, and sensory over-responsivity.

Results: There was a high completion rate, with 94.1% of children completing the four-week trial. In response to the question: "Please rate how well your child tolerated the CES treatment" on a scale of 1-100, the median score was 71, with a range of 9-100. On our participant-reported measure of benefit, the median was 51, with a range of 1 to 100. Of the 17 participants, 76.5% were recommended to continue based on the CGI and clinical consultation.

Conclusions: These findings provide initial evidence that a four-week in-home treatment of CES is feasible in participants 4-18 years of age. Furthermore, it may improve clinical symptoms related to dysregulation of the autonomic nervous system. We continue to enroll participants and analyze data and will be able to present outcomes of a larger sample and details by clinical symptom in May of 2020.

428.013 *(Poster)* Autism Course for Romantic Partners – an Online Program

***E. M. Blijd-Hoogewys**, INTER-PSY, Groningen, Netherlands*

Background: Autism symptoms can have a major impact on romantic relationships. If so, their romantic partners often seek accessible individual help, before considering more intensive couples therapy.

In 2005, the Autism Course for Spouses was developed as a group training program. It was found to be effective (Blijd-Hoogewys & Talboom, 2013). Women reported significant improvements concerning the interaction with their autistic husbands, their coping style, their general wellbeing, and their self-esteem.

In 2017, an online version was developed, aimed at not only spouses but also husbands of adults with ASD.

Objectives: The objective of this study was to test whether the online Autism Course for Romantic Partners is effective.

Methods: The online Autism Course for Romantic Partners contains seven sessions. They are ideally offered in a blended fashion: four internet sessions, alternated with three face-to-face sessions with a therapist. The participant can choose between two video therapists (a man or a woman who have recorded the films), next to their own face-to-face therapist. Both participant and face-to-face therapist can follow the online progress and can chat while using this online program.

The program focuses on autism characteristics (also including the more female autism phenotype), autism information processing, partner relationship issues, parenting issues, and communication skills. These subjects are explained in short films, can be read in a script, and are accompanied by multiple exercises that can be done at home.

Over the past two years, N = 238 romantic partners from all over the Netherlands were invited to take part in this online program (98 men, 140 women), of which N = 180 romantic partners started the program (76% acceptance rate).

Results: The romantic partners reported a 33% decrease of their problems. Their therapists reported a 57% decrease of observed problems, a 78% improvement of overall therapy quality and a 67% reduction in face-to-face contacts needed.

Conclusions: Results show that the online Autism Course for Romantic Partners Spouses seems an effective training program. Further research is warranted.

428.014 *(Poster)* Biomarkers of Successful Neurofeedback Training in Children with Autism Spectrum Disorder

***M. Casanova**[1], E. M. Sokhadze[2], D. P. Kelly[3], E. V. Lamina[4] and E. L. Casanova[5], (1)University of South Carolina School of Medicine, Greenville, SC, (2)University of Louisville, Louisville, KY, (3)University of South Carolina School of Medicine Greenville, Greenville, SC, (4)Biomedical Sciences, UNIVERSITY OF SOUTH CAROLINA SCHOOL OF MEDICINE GREENVILLE, Greenville, SC, (5)University of South Carolina, School of Medicine, Greenville, SC*

Background: Neurofeedback is one of the most promising methods for training EEG self-regulation in children with autism spectrum disorder (ASD). There are several neurofeedback protocols proposed for ASD with most differences being in the type of training (e.g., theta/beta ratio, coherence), topography (Cz or Pz), guidance by quantitative EEG (qEEG) and number of sessions (e.g., 20 vs. 30, etc.). Most of studies of neurofeedback in ASD focus on behavioral and EEG outcomes and do not analyze any associated psychophysiological processes taking place during successful training. In particular, some cardiorespiratory and electrodermal effects of training are important for the understanding of neurofeedback training effects and defining their role as potential moderators.

Objectives: We proposed that 24 sessions of prefrontal neurofeedback training will be accompanied by changes in power of targeted EEG bands (e.g., 40 Hz centered gamma band) and ratios of individuals bands (e.g., theta/beta ratio), as well as by changes in electrodermal and cardiorespiratory indices. Autonomic activity patterns were hypothesized to reflect specifics of psychophysiological processes occurring during neurofeedback training in children with autism.

Methods: Outcomes measures along with EEG, ECG, pneumogram and skin conductance measures included behavioral ratings by parents. The protocol used a training for wide band EEG amplitude suppression ("InhibitAll") with simultaneous upregulation of the relative power of 40 Hz-centered gamma sub-band activity. In a pilot study on 6 children diagnosed with ASD (13.6 years, SD=1.3, 2 girls) in a 24 session-long course aimed at prefrontal 40 Hz-centered EEG gamma upregulation and theta-to-beta ratio downregulation we recorded ECG, pneumogram and electodermal activity. QEEG analysis at the training site was completed for each session of neurofeedback to determine the relative power of the individual bands (theta, beta, and gamma) and their ratios (theta/beta) within and between sessions. We analyzed Aberrant Behavior Checklist (ABC) and Achenbach's ASEBA ratings by parents (pre- and post-treatment).

Results: Dynamics of psychophysiological measures were analyzed during each neurofeedback session and across the whole course. Regression analysis revealed significant linear increase of skin conductance level (SCL, $p=0.002$) along with decrease of respiration rate (RSR, $p<0.001$) during each successful neurofeedback session without any statistical changes of SCL or RSR across the course of training. Heart rate variability (HRV) measures (e.g., HF of HRV) showed significant increase during each individual session. According to parental reports hyperactivity subscale scores of ABC ($p=0.024$) and ASEBA DSM-oriented scores of attention-related problems ($p=0.014$) decreased by the end of neurofeedback course.

Conclusions: Psychophysiological measures represent useful markers of attention and emotional engagement of children with ASD during neurofeedback and can be used as predictors of successful performance during training sessions and general behavioral outcome of the intervention. In particular, trend towards increase of electrodermal activity along with RSR deceleration and increased indices of respiratory sinus arrhythmia in HRV may reflect more active attention to training targets and/or experience of emotion states reflected in the observed pattern of psychophysiological indices.

428.015 *(Poster)* CBT Based Approaches to Intolerance of Uncertainty for Autistic Adults Experiencing Anxiety

J. Rodgers[1]*, M. Freeston*[2]*, S. Brice*[3] *and R. Herrema*[4]*, (1)Institute of Neuroscience, Newcastle University, Newcastle Upon Tyne, United Kingdom, (2)Newcastle University, Newcastle upon Tyne, United Kingdom, (3)Institute of Neuroscience, Newcastle University, Newcastle upon Tyne, United Kingdom, (4)Newcastle University, Newcastle, United Kingdom*

Background: Anxiety is a significant problem for many autistic people. There is growing evidence that some aspects of anxiety may present differently in ASD and that ASD related features of anxiety should therefore be considered during assessment and treatment. Furthermore, the presentation of anxiety is often complex and autistic people frequently present with multiple anxiety disorders concurrently, making it difficult to develop tailored packages based on specific anxiety sub-types. Effective interventions that target trans-diagnostic anxiety related mechanisms may be a parsimonious solution offering more efficient and inclusive targets for treatment. Intolerance of uncertainty (IU) described as the tendency to react negatively on an emotional, cognitive and behavioural level to uncertain situation and events is a transdiagnostic construct linked with a number of mental health conditions with a particularly strong association with anxiety disorders. Recent research indicates that IU is strongly associated with anxiety in autism and is associated with characteristics of ASD, including insistence on sameness, avoidance of unexpected events and desire to make life as predictable as possible. The first intervention programme specifically targeting IU in autistic children was published in 2017 (Coping with Uncertainty in Everyday Situations; CUES, Rodgers et al 2017, 2019). CUES aims to develop behavioural skills in coping and tolerating uncertain situations. The CUES programme has now been adapted for use with autistic adults and adolescents.

Objectives: To consider data from two recent single case experimental design studies of the CUES manualised treatment programme focusing on IU, one with autistic adults and autistic adolescents.

Methods: Four autistic adults participated in study one. Four autistic adolescents, aged between 14-18 years participated in study two. In both studies an eight session programme (Coping with Uncertainty in Everyday Situations – Adult (CUES-A) or Adolescent CUES-Adol©) was developed and delivered to participants on an individual basis. Outcome data related to IU, anxiety, restricted and repetitive behaviours and feasibility and acceptability were recorded. Analysis based on single case experimental design was used to provide evaluation of preliminary effectiveness and the feasibility, acceptability of the programmes.

Results: Analyses of outcome measures indicate that the programmes have promise as a treatment option for autistic adults and adolescents experiencing anxiety characterised by IU. Data regarding retention, acceptability and feasibility indicate that the participants valued the programmes.

Conclusions: These studies sought to take the first steps towards the development of an intervention for autistic adults and adolescents, which focuses on intolerance of uncertainty, an important transdiagnostic construct underlying anxiety.. Preliminary outcome data indicate that both programmes have promise as methods to enable autistic people to tackle the everyday challenges conferred by high levels of intolerance of uncertainty. Evaluation of the acceptability and feasibility of the CUES-A© and CUES-ADOL© programmes indicates that the programmes are feasible to deliver directly to autistic adults and adolescents, are acceptable and possess face validity. Our findings indicate that the CUES programme has promise as a treatment option for autistic adults and adolescents experiencing IU as part of their anxiety.

428.016 *(Poster)* Changes in Anterior Cingulate Cortex Surface Area Among Adolescents with Autism Spectrum Disorder over the Course of the PEERS® Social Skills Intervention

A. Arias[1]*, A. Barrington*[2]*, A. J. McVey*[3]*, A. D. Haendel*[4]*, H. K. Schiltz*[3]*, M. Carlson*[5]*, W. Krueger*[6] *and A. V. Van Hecke*[3]*, (1)Marquette University, Milwaukee, WI, (2)Biomedical Engineering, Marquette University, Milwaukee, WI, (3)Psychology, Marquette University, Milwaukee, WI, (4)Speech-Language Pathology, Concordia University Wisconsin, Mequon, WI, (5)Education, Marquette University, Milwaukee, WI, (6)Speech Pathology and Audiology, Marquette University, Milwaukee, WI*

Background: The social brain has been posited to include several areas such as the amygdala, anterior cingulate cortex (ACC; e.g., Stevens et al., 2011). fMRI studies have shown a functional connectivity between the amygdala and ACC when participants are presented with emotional stimuli (Stevens et al., 2011). Morphology comparisons of the ACC between autistic individuals and Neurotypical individuals have shown decreased surface area(e.g., Periera et al., 2018). Further study is needed to better understand these findings. Additionally, adolescents with ASD who receive a well-validated social skills intervention have demonstrated neurological changes, via EEG, coinciding with improvements in social behavior (Van Hecke et al., 2013). No known published study, has examined surface area of brain structures in ASD over the course of such an intervention.

Objectives: 1) Compare ACC surface area across sample populations of autistic adolescents and typically-developing adolescents 2) Examine changes in this regions across the Program for the Education and Enrichment of Relational Skills (PEERS®; Laugeson & Frankel, 2010) using a randomized controlled trial (RCT).

Methods: Forty-six male adolescents (37 ASD, 9 typically developing (TD) aged 11-16 participated. See Table 1 for descriptive statistics and volume means. An RCT (experimental (EXP) vs. waitlist-control (WL) vs typically-developing (TD) controls) of PEERS®was conducted for the ASD group. Structural MRI scans were collected twice (before and after PEERS®) using a GE 3T scanner. Freesurfer Autorecon Processing (Fischl et al., 2002) was used for whole brain structural segmentation. Bilateral ACC measures were extracted and analyzed.

Results: One-way ANOVAs revealed no significant difference between groups on any measure of the ACC. Repeated measures MANOVAs for Time (pretest vs. posttest) by Group (EXP vs. WL vs. TD), revealed no significant multivariate effect. However, an explorative Univariate follow-up showed a significant interaction effect (Time x Group) was present in the surface area of the right ACC. Paired sample *t*tests demonstrated a decrease ($t(15) = 2.320$, $p = .035$) of the right ACC surface area in the WL group, only, across intervention; Table 2 shows the descriptive statistics, *F*values, and significance levels for the univariate follow-ups.

Conclusions: Significant decreases were uncovered for right ACC surface area for adolescents with ASD who did not receive the intervention, whilst no significant changes were found for those who did receive PEERS® or were TD controls. Research has yet to elucidate the relation of surface area and social challenges. However, structure size is often used as an analogue for absolute neuron count which is associated with thresholds of activation prior research has shown (Herculano-Houzel et al., 2009.2012), and hypo-activation of the ACC is associated with greater social challenges (Urbain et al., 2015). The PEERS®intervention, shown to improve social behavior (Laugeson et al., 2009), may contribute a protection factor, in the form of developing appropriate social skills, against a reduction in surface area of the ACC; therefore providing the opportunity to not diminish in functional activation. Those who did not receive PEERS® may not develop these social skills targeted by the intervention; thus no protection factor is conferred unto them.

428.017 *(Poster)* Children with Autism with Lower Verbal Abilities Benefit More from Music Interventions

*A. MacDonald[1,2], M. Sharda[2,3], K. L. Hyde[3] and **A. Nadig**[1,2], (1)School of Communication Sciences and Disorders, McGill University, Montreal, QC, Canada, (2)Centre for Research on Brain, Language, and Music, Montreal, QC, Canada, (3)International Laboratory of Brain, Music and Sound Research (BRAMS), University of Montreal, Montreal, QC, Canada*

Background: Music therapy (MT) has emerged as an evidence-based therapeutic intervention for children with autism (Geretsegger et al., 2014; Thompson et al., 2014; Sharda et al., 2018). Given the heterogeneity of autism, it is important to understand which specific subgroups benefit most. A recent RCT by Sharda et al. (2018) demonstrated a significant increase in social-communication in children with autism who underwent MT, as compared to a control play-based therapy (nonMT). In another study, Crawford et al. (2017) found that children with autism with lower verbal abilities (RR: 1.45) benefited more from MT.

Objectives: Here, we explore potential differences in response to MT (or a control therapy) related to verbal abilities on two outcomes reflecting key areas of impairment in autism: a) level of triadic joint engagement, or attention to and engagement with the therapist while involved in joint activities (Adamson et al., 2009) and b) a parent-report measure of pragmatic communication and autism-related behaviors (DSM-V, American Psychiatric Association, 2013). Second, we examine if verbal ability predicts or interacts with change in triadic joint engagement and/or pragmatic communication and autism-related behaviors.

Methods: The present analysis included 51 participants with autism, 6 and 12 years old, from a prior RCT (Sharda et al., 2018). Participants were randomly assigned to receive either MT (n = 26) or nonMT (n = 25). Verbal IQ (VIQ) range was from 55 to 142. a) Videos from therapy sessions were coded by independent raters blind to timepoint using a joint engagement coding scheme (adapted from Adamson et al., 2004; Kasari et al., 2010). We analyzed the change from first to last therapy sessions in percent time spent per activity in the highest level of joint engagement, ***coordinated joint engagement*** b) Parent reported scores on the Children's Communication Checklist-2 (CCC-2, Bishop, 2003) were available pre- and post-intervention. We analyzed change on a composite score from subscales reflecting pragmatic communication and autism-related behaviors (CCC-prag-aut; Leonard et al., 2011). Verbal ability was measured by the VIQ subscore of the Wechler's Abbreviated Scale of Intelligence (WASI-II) or the WISC-IV/V. Linear fixed-effects models were used to examine the effects of Intervention Group (MT vs. nonMT), VIQ, and Intervention Group X VIQ.

Results: Children receiving MT exhibited a) significantly more time spent in coordinated-joint engagement with the therapist during the session (= -57.59, p < .01), as well as b) marginally more improvement on the CCC-prag-aut than children receiving nonMT (= -16.01, p = .08). For children receiving MT, those with lower VIQ a) experienced a significantly greater increase in percent time spent in coordinated joint attention (= 0.62, p < .01). This is illustrated in Figure 1. b) This interaction was not significant for the CCC-prag-aut (= 0.10, p = .30)

Conclusions: We provide additional evidence that music-based interventions hold benefits above non-music based interventions. Furthermore, we provide evidence that music-based interventions are particularly beneficial for children with lower verbal ability, potentially because these interventions provide a medium to target social-communication without having significant verbal interaction demands.

428.018 *(Poster)* Coaching of Parents: Promoting Occupational Performance of Children with Autism and Their Families

***A. A. Cardoso Rodrigues**, L. Freitas, I. Lambertucci Cardoso, M. L. Ricardo e Silva, H. Silva and M. Salgado, Universidade Federal de Minas Gerais, Belo Horizonte, Brazil*

Background: Autism Spectrum Disorder (ASD) is a neurodevelopmental disorder that has a major impact on the occupational performance and social participation of children and their families. Occupational Performance Coaching (OPC) is an intervention approach created by occupational therapists from Australia and New Zealand, aimed at working with parents to achieve occupational performance goals for themselves and their children. OPC is based on the premise that a better balance between person, environment and occupation leads to successful practice and subsequently improves occupational performance and transfer skills.

Objectives: The aim of this paper is to verify whether an intervention program based on OPC groups, conducted with parents or caregivers of children with ASD, contributes to increasing children's functionality and parental satisfaction with performance.

Methods: Three groups were conducted, with a total of 11 families of children (11 boys, mean age 5.75 ± 0,91 years) diagnosed with ASD, totaling 10 weekly meetings of one and a half hours with each group. Prior to the start of the intervention, parents responded to the Canadian Occupational Performance Measure (COPM) to set each child's goals, as well as performance and satisfaction scores for each goal on a scale of 1 to 10 (higher scores mean better performance and greater satisfaction). The groups were conducted according to the OPC proposal, using the Collaborative Performance Analysis and elaboration and discussion of strategies appropriate to the needs and possibilities of each family. As the intervention was carried out in group format, families could exchange experiences and collaborate in devising each other's strategies.

Results: After 10 meetings, parents reassessed performance and satisfaction against the goals set at the beginning of the program. The results show an average difference of 2.63 (±1,25) points between the final and initial performance score and 2.95 (± 1,81) points between the final and initial satisfaction score. According to the COPM user manual, a difference of 2.0 points or greater means clinically significant change, which suggests that for families participating in the groups, the OPC-based intervention contributed to increase children's performance and parental satisfaction.

Conclusions: The results of the use of OPC in Brazil are promising, which motivated the elaboration of a master's research project, whose objective will be to investigate if the coaching groups are viable for use in the public health system, for intervention with children with ASD. Because it is a low-cost and short-term intervention, OPC may be interesting for use in the Brazilian Unified Health System (*Sistema Único de Saúde – SUS*), enabling the care of a greater number of children with ASD and their families.

428.019 *(Poster)* Comparative Analysis of Child Behavior Outcomes Following Participation in Parent-Child Interaction Therapy for Children with and without Autism

K. M. Rispoli[1]*, E. W. Nathanson*[1]*, M. Norman*[1]*, S. Nelson*[1]*, N. Warren*[1] *and S. Naguib*[2]*, (1)Michigan State University, East Lansing, MI, (2)Sunfield Center for Autism, ADHD and Behavioral Health, Ann Arbor, MI*

Background: Parent-Child Interaction Therapy (PCIT) is an evidence-based intervention that uses live parent coaching to improve parent-child relationships and positive parenting, and decrease child behavioral problems (Cooley, Veldorale-Griffin, Petren, & Mullis, 2014). Efficacy is well-established for young, typically developing children (Cooley et al., 2014; Ward, Theule, & Cheung, 2016) and emerging for young children with ASD (e.g., Masse, McNeil, Wagner & Quetsch, 2016; Scudder et al., 2019). Less is known about PCIT's effectiveness for children with ASD in community settings and outcomes relative to children without ASD. One study (Zlomke & Jeter, 2019) found that PCIT improved disruptive behavior among children with ASD similarly to typically developing peers. Moreover, there is little research on fathers' participation in PCIT and ASD interventions in general (Flippin & Crais, 2011; Rankin, Paisley, Tomeny, & Eldred, 2019).

Objectives: This study examined differences in frequency (RQ1) and parent perceptions of problem behaviors (RQ2) among children with and without ASD who received community-based PCIT. Differences in mother and father ratings of these outcomes were also explored for children with ASD in this group (RQ3).

Methods: Fifty-three children (mean age = 5.9 years; boys = 31, girls = 22) with disruptive behaviors participated in PCIT through an outpatient behavioral health clinic in a small city in the midwestern US. Twenty-six children were diagnosed with ASD. Child externalizing behavior was measured at baseline and post-intervention using the Eyberg Child Behavior Inventory (ECBI; Eyberg & Pincus, 1999). This 36-item, treatment-sensitive measure has acceptable reliability and validity (Funderbunk, Eyberg, Rich & Behar, 2003). The *Intensity* scale assesses frequency of disruptive child behaviors on a 7-point scale. The *Problem* scale is a yes/no measure that assesses the extent to which parents consider child behaviors to be bothersome. Totals are reported for both scales. One-way MANOVA addressed all research questions. For children with two participating parents, primary parent ratings were used for RQ1 and RQ2 analyses. All parents of children with ASD were included for RQ3 analyses.

Results: See table for descriptive findings. For the whole group, change in frequency of child behaviors [$F(1,43) = 3.478$, $p = .069$] and parent perceptions of behavioral problems [$F(1,43) = 2.747$, $p = 1.05$] was not significantly different for children with and without ASD. Among parents in the ASD group, change in frequency of problem behaviors [$F(1,36) = 2.277$, $p = .140$] and perceptions of behavioral problems [$F(1,36) = 1.734$, $p = .196$] was similarly rated by mothers and fathers.

Conclusions: This study is among the first to compare outcomes for children with and without ASD following participation in community-based PCIT and explore differences in mother and father perceptions. Results suggest children with and without ASD evidenced similar reductions in behavioral issues and degree to which parents found behaviors problematic. Among children with ASD, mothers and fathers perceived similar improvements in behavior post-treatment. These preliminary results suggest fathers and mothers may observe similar effects of PCIT on child behavior. Additional analyses will explore fathers' participation in PCIT compared to mothers, such as time in treatment.

428.020 *(Poster)* Comparison of Physical and Virtual Robot As a Conversation Partner for Adolescent with Autism Spectrum Disorders

Y. Yoshikawa[1]*, T. Nishio*[2]*, H. Kumazaki*[3]*, Y. Matsumoto*[4]*, M. Mimura*[5] *and H. Ishiguro*[6]*, (1)Graduate school of engineering science, Osaka University, Toyonaka, Osaka Prefecture, Japan, (2)Osaka University, Toyonaka, Japan, (3)Department of Preventive intervention for Psychiatric Disorders, National Institute of Mental Health, National Center of Neurology and Psychiatry, Kodaira, Japan, (4)National Institute of Advanced Industrial Science and Technology, Tsukuba, Japan, (5)Keio University, Tokyo, Japan, (6)Graduate School of Engineering Science, Osaka University, Toyonaka, Japan*

Background: Recent advances in robotics enable us to think of robot applications as an easy communication partner for individuals with Autism Spectrum Disorders (ASD). The previous studies have shown the possibilities of robot to be a partner of conversation with children with ASD to learn gaze following (Kumazaki, Yoshikawa et al. 2018a) and consult about their daily problems (Shimaya, Yoshikawa et al. 2019). However, due to the difficulties in recognizing human utterances, no automatic robots have a sufficient capability of talking and have not yet used in the daily field of therapy or intervention. Furthermore, although a pioneering research identified a potential merit of a small physical robot to attract attention of children with ASD (Kumazaki, Yoshikawa et al. 2018b), it has been unknown which type of agent is preferable for the conversation partner of adolescents with ASD.

Objectives: We examined how long the individuals with ASD can talk to physical and virtual robots. In this study, we focused on a small humanoid robot called CommU as a physical robot, which was the same one used in the previous work (Kumazaki, Yoshikawa et al. 2018b). The CG animation program was developed to faithfully reproduce the appearance and movement of CommU and used as a virtual robot. An identical dialogue system was installed to both types of robot so that they could keep asking a variety of questions to know about the interlocutor and respond to his or her answer. We conducted an experimental conversation session where the individuals with ASD talk to either of two robots for about 15 minutes and can stop anytime when they wanted to do so.

Methods: Subjects who was diagnosed as ASD and had IQ score from 60 to 100 were included. Nine and twelve adolescents with ASD who attended to the session of the physical robot condition and the virtual robot condition, respectively, were analyzed. Each subject was asked to sit and face with a robot or a monitor display on which the CG of the robot was drawn. The subject voice was captured by a microphone array device and sent to the dialogue system to make it produce the question or the response to the interlocutor person. Every about five minutes, it asked the subject if he or she allowed it to keep talking. After fifteen minutes had passed, it told that the conversation was over.

Results: Average time that subjects spent for talking was 12.7 minute (SD=4.5). The ratio of subject who did not stop the conversation was higher in the physical robot condition than in the virtual robot condition.

Conclusions: Since the difference between two condition was whether it exists in front of the subjects or it was drawn on the screen, it is conjectured that the subjects was more willing to talk more to the physical robot than the virtual robot. The contents of utterance produced by the subjects must be examined to see whether, and to which types of questions, either of robot could promote self-disclosure.

428.021 *(Poster)* Conducting Interdisciplinary Research with Children with Autism Spectrum Disorders: Lessons Learned from an Oral Care Intervention Study

*L. I. Florindez[1], **E. Chu**[1], D. H. Como[1], M. Richter[1], D. Hudak[2], E. Isralowitz[1], L. I. Duker (Stein)[1] and S. A. Cermak[3], (1)Division of Occupational Science and Occupational Therapy, University of Southern California, Los Angeles, CA, (2)University of Southern California, Los Angeles, CA, (3)USC Mrs. T.H. Chan Division of Occupational Science and Occupational Therapy, University of Southern California, Los Angeles, CA*

Background: Research suggests that children with autism spectrum disorder (ASD) experience widespread health disparities. However, few intervention research studies include participants and their families in the research process. In addition to calling for more research to improve health outcomes, it is also necessary to understand best practices for conducting interdisciplinary intervention research while including children with ASD and their families in the research process.

Objectives: The objective of this study was to present the challenges and lessons learned in implementing an oral care intervention among a diverse pediatric population with ASD as part of an interdisciplinary research team.

Methods: Participants in the study were 220 English- or Spanish-speaking families with children aged 6-12 years with ASD who were enrolled in an oral care intervention to improve dental care experiences. The interdisciplinary study team comprised of occupational therapists, psychologists, public health professionals, pediatric dentists/residents, dental assistants, and front desk staff. Select members of the team held monthly meetings to discuss their study- and intervention-related lived experiences, identify challenges, and brainstorm strategies to facilitate research processes; all comments were documented in meeting minutes, with specific case examples noted. Meeting minutes were mined for data pertaining to strategies, with results synthesized into recommendations that were reviewed and confirmed by senior members of the research team.

Results: Results focused on the dynamics between the research team and participants, culminating in five strategies to improve care for participants and facilitate functioning of the research team. *Flexibility* was paramount, especially in relation to scheduling around family preferences; team members also needed to expect the unexpected, being prepared for abrupt changes in child behavior and modifying adaptable aspects of the intervention in response. *Patience* was also essential, emphasizing the importance of calmness when interacting with children with ASD during intervention visits, and in being patient while conducting study procedures that may fall outside typical scope of practice. Having an *open mind* when working with participants and practitioners from diverse socioeconomic, cultural, language, and practice backgrounds was crucial. By respecting and welcoming the differences inherent in the team members and participants, we acknowledged the role that these differences play in both our personal and professional lives. Clear and consistent *communication* between team members, parents, and child participants about all aspects of the research study was important to convey key messages and discuss study goals. Lastly, it was vital to *trust the experts* and rely on the expertise of the members of the research team and parents of participants; this enabled research members to perform different tasks unique to their skill sets effectively and encouraged parental support to improve rapport and facilitate intervention visits.

Conclusions: As a member of an interdisciplinary team, research members working with children with ASD need to collaborate, communicate, and share their particular skills to support participants and their families for successful delivery of interventions. This paper presents strategies to enhance rapport with participants and other researchers and facilitate study procedures to improve future research projects and help mitigate health disparities with this population.

428.022 *(Poster)* Correlation between Fear of Negative Evaluation and Familial Loneliness in Young Adults with Autism Spectrum Disorder and Other Social Challenges

***D. Mund**[1], Y. S. Lograsso[2], N. E. Rosen[3], M. Jolliffe[1] and E. A. Laugeson[2], (1)UCLA Department of Psychiatry, PEERS lab: UCLA PEERS Clinic, Los Angeles, CA, (2)UCLA Semel Institute for Neuroscience and Human Behavior, Los Angeles, CA, (3)UCLA Department of Psychiatry and Biobehavioral Sciences, UCLA PEERS Clinic, Los Angeles, CA*

Background: Research suggests that the quality of familial relationships has a bidirectional influence on the quality of an individual's social relationships (Parke & Ladd 2016).The connection between family relationships and socialization has been confirmed through recent studies showing the increased effectiveness of social skills interventions that incorporate supportive parent/caregiver assistance in the curriculum (Laugeson et al. 2015; Van Hecke et al. 2015). Additionally, studies have shown that individuals who feel shamed and ridiculed by their parents experience increased levels of social anxiety, specifically related to fear of negative evaluation (Caste, Inderbitzen, & Hope 1999). However, there are few studies examining the impact of familial dynamics, including family isolation and loneliness, upon self-perceived social anxiety.

Objectives: The purpose of this study was to examine whether greater feelings of familial loneliness among young adults correlates with higher levels of social anxiety, specifically related to fear of negative evaluation. We hypothesized that young adults reporting greater familial isolation would also experience greater feelings of negative evaluation among their peers.

Methods: Participants included 160 young adults (73% male; ages 17-35, mean age=22.21, *SD*=3.69) presenting for social skills treatment through the UCLA Program for the Education and Enrichment of Relational Skills (PEERS; Laugeson 2017), an evidence-based, caregiver-assisted social skills program for young adults with ASD and other social challenges. Baseline self-reported ratings of social anxiety, including fear of negative evaluation, were measured using the Social Anxiety Scale (SAS; La Greca 1998). Self-reported feelings of familial isolation were measured at baseline using the Social and Emotional Loneliness Scale for Adults (SELSA; DiTommaso 1993). All assessments were conducted prior to receiving the PEERS treatment.

Results: Pearson correlation coefficients revealed a significant positive correlation between feelings of familial loneliness and levels of social anxiety in relation to fear of negative evaluation [$r(160)=.202$, $p<.01$]. This finding suggests that individuals reporting greater familial loneliness experienced greater feelings of social anxiety specific to fear of negative evaluation among peers.

Conclusions: These results suggest that young adults who feel more isolated and alone within their families also tend to struggle more with social anxiety, particularly fear of being negatively perceived by their peers. This finding highlights the importance of providing more targeted interventions to improve family relationships as well as peer relationships. This broadened scope of treatment could prove beneficial in improving social interactions and reducing feelings of social anxiety, specifically, fear of negative evaluation. Given the established positive correlation between feelings of familial loneliness and social anxiety, future studies might investigate how this relationship changes following effective social skills intervention, particularly when family members are involved in treatment. We would hope to establish a similar positive correlation, such that a decrease in familial loneliness would be accompanied by a decrease in social anxiety following the completion of a social skills treatment such as PEERS.

428.023 *(Poster)* Depression As a Secondary Outcome of STEPS, a College Transition Support Program for Students with Autism

A. M. Brewe[1]*, N. N. Capriola-Hall*[1]*, J. Golt*[2] *and S. W. White*[1]*, (1)Psychology, The University of Alabama, Tuscaloosa, AL, (2)The University of Alabama, Tuscaloosa, AL*

Background: A sizeable portion of young adults with Autism Spectrum Disorder (ASD) without intellectual disability enter postsecondary education each year (Wei at al. 2016). However, there are no widely available, evidence-based programs designed to support them. Additionally, young adults with ASD experience increased rates of anxiety and depression (Lever & Geurts, 2016), which can impact students' quality of life and academic success (Smith, Ollendick, & White, 2019; Van Hees et al. 2015). The Stepped Transition in Education Program for Students with ASD (STEPS) is a transition support curriculum created to improve college adjustment for students by targeting self-determination and self-regulation using cognitive-behavioral therapy (CBT) and its guiding principles. The randomized, controlled trial demonstrated preliminary efficacy in increasing students' adjustment to college (withheld for blind review); however, additional research is needed to identify distal outcomes of STEPS related to co-occurring psychopathology.

Objectives: The current study aimed to determine whether participation in STEPS was associated with change in anxiety and depression symptoms as secondary outcomes of the program. We hypothesized that participants assigned to the STEPS group would show decreased anxiety and depression symptoms relative to the control group at post-treatment.

Methods: 24 treatment-seeking adults with ASD (mean age = 19.87 years; 70.80% male) were randomized to the STEPS condition (n=12) or waitlist control (n=12). Participation in STEPS included 12-16 weekly one-on-one counseling sessions that covered topics including goal-setting, problem-solving strategies, acceptance, and emotion regulation. All participants completed the Adult Self Report (ASR; Achenbach & Rescorla, 2003) to assess baseline and post-treatment depression and anxiety symptoms.

Results: A two (group: treatment group vs. waitlist group) x two (time: baseline vs. post-treatment) repeated measures ANOVA examining change in depression symptoms revealed a main effect of time [$F(1, 22)=6.60$, $p=.017$]. A significant Group x Time interaction was found [$F(1, 22)=7.13$, $p=.014$] such that STEPS participation was associated with lower depression symptoms at post-treatment. A second repeated measures ANOVA was run to examine change in anxiety symptoms. The model did not reveal a significant main effect for time [$F(1, 22)=3.65$, $p=.069$] or a Group x Time interaction [$F(1, 22)=.57$, $p=.457$].

Conclusions: Participation in STEPS, a CBT-based postsecondary transition support program, improved depression symptoms, but not anxiety symptoms relative to the waitlist control. It may be that the content of STEPS was better suited for distally treating depression than anxiety given the lack of anxiety-specific tasks like graded exposure to address participants' fears or worries. There is a need for evidence-based postsecondary programs that are efficient and effective in increasing positive outcomes for students with ASD. The current study demonstrates that STEPS may be a beneficial support program that provides secondary treatment of co-occurring internalizing psychopathology. Additional research is needed to identify underlying mechanisms of change in depression symptoms for STEPS, as well as within-subjects variables that may affect change, to strengthen the program.

428.024 *(Poster)* Descriptive Analysis of Law Enforcement Officers' Calls Involving Individuals with Autism

L. Gardner[1] *and J. M. Campbell*[2]*, (1)Johns Hopkins All Children's Hospital, St. Petersburg, FL, (2)Psychology, Western Carolina University, Cullowhee, NC*

Background: Little research exists to describe common interactions between LEOs and individuals with ASD. A number of highly publicized encounters between individuals with ASD and LEOs have reported on injury to caregivers or the death of an individual with ASD. Previous research offers conflicting findings as to whether people with ASD are at higher risk for involvement with the criminal justice system than the general population. It appears likely based on existing research that people with ASD are somewhat over-represented in the criminal justice system. As LEOs are the first contact between individuals and the penal system, lack of knowledge of ASD may result in LEOs misinterpreting ASD specific behavior as noncompliant, threatening, disorderly, or suspicious.

Objectives: The primary author created a bi-monthly training program for LEOs that prepares officers to respond to calls involving individuals with ASD. As part of this training, LEOs reported on calls received within the last year that include individuals with ASD. The purpose of the present study was to conduct an exploratory and descriptive analysis of LEO calls involving individuals with ASD, including the chief complaint and outcomes of calls.

Methods: One-hundred and seventy-eight LEOs attended five separate training sessions. LEOs were 61.8% male with a mean age of 40.35 years (SD = 10.0) and 12.54 years of law enforcement experience (SD = 8.8). To evaluate LEOs' prior experience with ASD, participants completed a questionnaire that included professional experiences interacting with individuals with ASD including their most recent and most stressful calls within the last 12 months. LEOs also reported on the circumstances and outcomes of the calls.

Results: Most LEOs (n=114; 64%) responded to a call involving ASD within the last 12 months, ranging in frequency from one (n=30; 16.9%) to 20 or more calls (n=21; 11.9%). For most recent calls involving an individual with ASD, LEOs reported that most individuals with ASD used words to communicate (n=68; 64.2%). The most commonly reported primary concerns included disruptive behavior (n=44; 42.7%), suspected abuse/neglect (n=20; 19.4%), and wandering/elopement (n=12; 11.7%). Most calls did not require use of physical force (n=94; 87.9%) or handcuffs (n=96; 89.7%). LEOs reported 21.7% (n=23) of calls resulted in involuntary hospitalization. For the most stressful calls, LEOs reported approximately half of individuals used words to communicate (n=41; 52.6%). Most stressful calls did not require use of physical force (n=62, 79.5%) or handcuffs (n=57; 74%), and approximately 25% resulted in involuntary hospitalization. Commons concerns for the most stressful calls included disruptive behavior (n=24; 32.4%), aggression toward self/others (n=17; 23%), suspected abuse/neglect (n=12; 16.2%), and wandering/elopement (n=11; 14.9%).

Conclusions: Most officers reported interacting professionally with individuals with ASD within the last year. Common identified concerns included disruptive behavior, wandering/elopement, suspected abuse/neglect, and aggression toward self or others. The most stressful of these incidents involved individuals with ASD who had more significant communication deficits. Stressful calls were more likely to result in use of force, handcuffs, and involuntary hospitalization. Findings provide support for the value of LEO training to respond to ASD-related calls.

428.025 *(Poster)* Direct Instruction Language for Learning Program to Promote Expressive in Children with Autism Spectrum Disorder (NCT02483910)

L. Scahill[1]*, A. Shillingsburg*[2] *and C. McCracken*[3]*, (1)Marcus Autism Center, Atlanta, GA, (2)Language Intervention, May Institute, Randolph, MA, (3)Department of Pediatrics, Emory University School of Medicine, Atlanta, GA*

Background: Language impairment is a common parental concern for children with ASD. Untreated language impairment is highly predictive of negative long-term outcomes for children with ASD. Direct Instruction-Language for Learning (DI-LL) is a commercially available intervention package with demonstrated effectiveness in children with language delays due to disadvantaged backgrounds, learning disabilities, or a primary language disorder – but it has not been carefully studied in ASD.

Objectives: Describe essential features of DI-LL and present preliminary results of a completed randomized clinical trial of DI-LL in 83 children with ASD ($\geq$4 and $\leq$ 7 years 11 months) and moderate language delay.

Methods: Children were randomly assigned in 1:1 ratio to continue treatment as usual (TAU) or to DI-LL plus TAU for six months. The primary outcome was the Clinical Evaluation of Language Fundamentals administered at baseline and endpoint by a speech pathologist who was blind to treatment assignment. The key secondary outcome was the Improvement item of the Clinical Global Impression, rated by clinician also blind to treatment assignment. DI-LL was delivered twice per week for 90 minutes per session for 6 months by bachelor-level research staff trained to reliability. The study was approved by the local IRB at the single study site.

Results: 137 children were screened; 83 (85% male, mean age of 5.6 $\pm$ 1.0 years) were randomized to TAU or DI-LL + TAU. Children with mild or severe language delay, those not in a stable TAU program or stable medication, or those in need of alternative treatment were excluded. Based on parent report, 45% were black, 22% white, 11% Asian, 16% other. The average IQ and CELF scores were 74.7 $\pm$17.1 and 53.3 $\pm$10.5, respectively. Enrollment stopped on October 1, 2019; 61 children have completed the randomized trial. The remaining 22 participants will reach endpoint by March 2020. Preliminary results will be available by May 2020.

Conclusions: DI-LL is a carefully scripted and sequenced program designed to teach basic and increasingly complex language skills. If this study supports the efficacy of DI-LL in children with ASD, it will provide an exportable intervention for a wide range of practitioners.

428.026 *(Poster)* Do Autistic Adults Benefit from Self-Guided Online Mindfulness or CBT Programs to Manage Anxiety?

M. South[1]*, S. B. Gaigg*[2]*, P. Flaxman*[3]*, G. McLaven*[4]*, R. Shah*[5]*, D. M. Bowler*[2]*, B. Meyer*[3]*, A. Roestorf*[6]*, C. Haenschel*[7] *and J. Rodgers*[8]*, (1)Psychology & Neuroscience, Brigham Young University, Provo, UT, (2)Autism Research Group, City, University of London, London, United Kingdom, (3)City University of London, London, United Kingdom, (4)Psychology, City, University of London, London, United Kingdom, (5)City University London, London, United Kingdom, (6)Psychology, City University London, London, United Kingdom of Great Britain and Northern Ireland, (7)Department of Psychology, City, University of London, London, United Kingdom, (8)Institute of Neuroscience, Newcastle University, Newcastle Upon Tyne, United Kingdom*

Background: Anxiety in autism is an important treatment target because of its consequences for quality of life and wellbeing. Growing evidence suggests that Cognitive Behaviour Therapies (CBT) and Mindfulness-Based Therapies (MBT) can ameliorate anxiety in autism. However, access to health care is often reduced for autistic adults, and cost-effective delivery of mental health treatments remains a challenge. There is an urgent need, therefore, to explore alternative strategies for delivering mental health services to the autism community (and the community at large).

Objectives: Given recent evidence that online mental health support tools can help reduce anxiety in the general population the current study examined whether such existing tools could also benefit autistic adults. We conducted a pilot randomized controlled trial to test whether online CBT and MBT self-help programmes could help reduce anxiety in autistic adults. These treatments may target difficulties with emotional acceptance suggested by previous work, though less directly towards intolerance of uncertainty.

Methods: 54 autistic adults with fluent language skills were randomly allocated to either an online CBT (n=16) or MBT (n=19) programme or to a waitlist control group (WL; n=19). Online intervention was present across different modules or sections over the course of about 8 weeks. Measures of anxiety, broader wellbeing, and potential processes of change were collected at baseline, after programme completion, and then 3 and 6 months post-completion.

Results: Baseline data confirmed that a combination of intolerance of uncertainty and emotional acceptance accounted for up to 61% of the variance in self-reported anxiety across all participants. The 23 participants who were retained in the active conditions (9 CBT, 14 MBT) showed significant decreases in anxiety at post-testing. Planned comparisons within each group separately showed that the main effect of time across all measures was significant in the MBT ($F(3,11) = 8.85$, $p=.003$; partial $\eta2 = .71$) and CBT groups ($F(3,6) = 7.71$, $p=.018$; partial $\eta2 = .79$) with large effect sizes, whereas it was not significant in the WL group ($F(3,13) = 1.56$, $p=.248$; partial $\eta2 = .26$) where the effect size was small. These results were maintained over 3 months and to some extent also to 6 months. Over 75% of participants who demonstrated moderate to severe levels of anxiety at baseline reported reliably reduced symptoms in at least some facets of their anxiety three months after completing a self-guided CBT or MBT course.. Reasons for programme dropout were diffuse.

Conclusions: Previous work regarding potential mechanisms of reduced mindfulness was supported, providing strong rationale for targeted treatments. Overall, results suggest that online self-help CBT and MBT tools may provide a cost-effective method for delivering mental health support to those autistic adults who can engage effectively with online support tools. Future treatments should also directly target intolerance of uncertainty as a mechanism for anxiety in autism. We also discuss ways in which online treatments can be modified similar to in-person treatments to better fit unique styles of autistic adults.

428.027 *(Poster)* Does Targeted Cognitive Control and Physical Exercise Training Generalize to Social Competence in Children?

M. A. Rowe[1,2], *A. Brandes-Aitken*[3], *M. R. Gerdes*[2], *B. G. Jurigova*[4], *D. R. Mittermaier*[4], *J. Anguera*[4] *and E. J. Marco*[2], *(1)Radiology, University of California, San Francisco, San Francisco, CA, (2)Cortica Healthcare, San Rafael, CA, (3)Psychology, NYU, New York, NY, (4)Neurology, University of California San Francisco, San Francisco, CA*

Background: Cognitive training and physical exercise have been posited to improve cognitive control in children and adults. Although there is still equipoise in the literature, a combined training is believed to have benefit over each intervention on its own. It is also clear that children with neurodevelopmental challenges often experience difficulties with inattention as well as with emotional regulation and social communication abilities. However, to the best of our knowledge, it has not been previously explored whether a brain and body training targeted to improved specific attention abilities and tailored for a pediatric population will have a generalized benefit to social competence.

Objectives: To examine whether an 8-week synergistic cognitive and physical training with the pediatric Body Brain Trainer (pediBBT) affects social competence. We hypothesize that school aged children will show improved emotional regulation and social communication after 24 sessions of school-based training.

Methods: Twenty children (14 boys), aged 7 to 12 years were recruited from a Northern California public school, Neil Cummins Elementary, and underwent 24 sessions (3 sessions weekly for 8 weeks) of pediBBT at the school's OT gym. PediBBT is a custom-designed, motion-capture, video game-like intervention. It consists of three modules aimed at sustained attention, working memory, and goal management in which subjects respond to stimuli by reaching, squatting, or running. Participants also completed a pre- and post-treatment battery of direct assessments and parent report forms. The Social Competence Scale (SCS) parent version, which includes Prosocial Behavior/Communication and Emotional Regulation subscales, was used as a measure of participants' social competence change with intervention.

Results: On the SCS parent version, higher scores indicate higher levels of prosocial behaviors, communication skills, and self-control. On average, overall SCS score significantly increased after 24 sessions of pediBBT ($p=0.04$). When looking at each subscale individually, the average score on the Prosocial Behavior/Communication subscale did not significantly change after treatment. However, average score on the Emotional Regulation subscale showed significant improvement following training ($p<0.01$). One outlier was excluded from analysis.

Conclusions: While these results are preliminary, they strongly suggest that cognitive and physical training targeting cognitive control—which may be preferentially right frontal parietal networks—has generalized benefit for real life social engagement. However, the finding is specific to the ability to control affective response, particularly with a negative valence rather than communication-based engagement. This finding suggests the need for further delineation of the networks subserving these functions that may be overlapping as well as a larger study in a novel cohort to replicate this potential school and home-based treatment.

428.028 *(Poster)* Does a Novel Group Parenting Intervention Reduce Emotional and Behavioural Problems in Young Autistic Children? Results from the Autism Spectrum Treatment and Resilience (ASTAR) Pilot Randomised Controlled Trial

T. Charman[1], ***M. Palmer***[2], *D. Stringer*[2], *V. Hallett*[3], *J. Mueller*[3], *R. Romeo*[4], *J. Tarver*[5], *J. Paris Perez*[2], *L. Breese*[3], *M. Hollett*[3], *T. Cawthorne*[2], *B. Beresford*[6], *M. Knapp*[7], *V. Slonims*[8], *A. Pickles*[2], *S. Scott*[2] *and E. Simonoff*[2], *(1)Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, United Kingdom, (2)King's College London, Institute of Psychiatry, Psychology and Neuroscience, London, United Kingdom, (3)South London and Maudsley NHS Foundation Trust, London, United Kingdom, (4)King's College London, Institute of Psychiatry, Psychology & Neuroscience, London, United Kingdom, (5)Aston University, Birmingham, United Kingdom, (6)University of York, York, United Kingdom, (7)PSSRU, LSE, London, United Kingdom, (8)Guy's & St Thomas' NHS Foundation Trust (Evelina Children's Hospital), London, United Kingdom*

Background: Most young children with autism display co-occurring emotional and behaviour problems (EBPs) that tend to persist over time and impact the lives of the child and their families. There is some evidence that behavioural parenting interventions are effective for reducing EBPs in autistic children as reported by parents (Postorino et al., 2017; Tarver et al., 2019). Most trials have tested individual parenting interventions, even though groups are more scalable and have the added benefit of providing a support network for parents. Also previous studies vary in the degree to which the intervention focused on externalising behaviours versus anxiety. Furthermore, convincing conclusions about the effectiveness of these approaches cannot be drawn as many trials do not employ an active control condition or use blinded outcome measures, and there is little evidence of the cost-effectiveness of these interventions.

Objectives: The ASTAR trial tested the feasibility of trialling the ASTAR group parenting intervention against an active control and will provide a preliminary indication of potential efficacy and cost-effectiveness.

Methods: As part of the Improving Autism Mental Health (IAMHealth) research programme (www.iamhealthkcl.net), 62 parents/carers (91.9% mothers) and their 4–8 year old autistic children participated in the ASTAR pilot RCT (ISRCTN91411078). Participants were randomised 1:1 to the ASTAR group behavioural parenting intervention (Predictive Parenting) or an attention control intervention consisting of psychoeducation parent groups (Psychoeducation). Both interventions consisted of 12 weekly sessions with 6 to 8 parents/carers and content was adapted based on child verbal ability (minimally verbal versus verbal). Predictive Parenting provided specific strategies to manage both externalising behaviours and anxiety and ways to promote parental self-care and reduce stress. Psychoeducation aimed to provide knowledge about autism and social support whilst not providing specific guidance on managing behaviours or emotions. The primary outcome was a blinded objective measure of the rate of child behaviours that challenge displayed during a structured parent- and researcher-child interaction was used as the primary outcome, called the Observation Schedule for Children with Autism – Anxiety, Behaviour and Parenting (OSCA–ABP). This was used to overcome biases associated with using parent reports. Secondary outcomes included observed child compliance, child-centred parenting and child-directed parenting behaviours, parent- and teacher-reported child EBPs and parental self-report of parenting practices, stress, self-efficacy and wellbeing (see Table 1 for baseline sample characteristics and primary and key secondary outcomes). Adverse events were recorded, and we also examined preliminary estimates of the cost-effectiveness of the interventions.

Results: Feasibility of the trial was demonstrated, with good retention in both arms and high completion of measures (see CONSORT diagram in Figure 1 for participant flow through the trial). Due to ongoing analysis and publication embargo, findings from the trial are not presented here but will be completed by the meeting in May 2020.

Conclusions: This trial will add to the growing literature on the effects of behavioural parenting interventions for co-occurring EBPs in autism. It highlights the need for blinded objective measures along with the use of active control intervention conditions to be included in such trials.

428.029 *(Poster)* Efficacy of Synergized Cognitive-Physical Training for Children with Inattention

J. Anguera[1], *M. R. Gerdes*[2], *B. G. Jurigova*[1], *A. J. Simon*[1], *D. R. Mittermaier*[1], *A. Gazzaley*[1] *and E. J. Marco*[2], *(1)Neurology, University of California San Francisco, San Francisco, CA, (2)Cortica Healthcare, San Rafael, CA*

Background: Children with issues of attention have difficulties in their everyday life and school function. Cognitive training and physical exercise have both been shown to improve attention, providing an alternative approach to prescribed medications. Here we posit that a synergistic training platform for children across the inattention spectrum, including children with ASD, may lead to improved cognitive control abilities as well as 'real-world' reported attentional function.

Objectives: To use a custom-designed, motion-capture, video game-based intervention (pediatric body-brain trainer (pediBBT)) adapted for school-aged children and deployed at a local elementary school to evidence potential improvements in cognitive control. Here we looked to determine if this platform improves cognitive control abilities in children with and without clinically significant inattention, as measured behaviorally and neurally via electroencephalography (EEG).

Methods: Twenty-two children (16 boys), aged 7-12 years, underwent 24 pediBBT sessions across eight weeks, with each session designed to take 45 minutes. A battery of pre and post assessments of cognition (Test of Variables of Attention (TOVA), working memory, multi-tasking), parent reported 'real-world' function (Vanderbilt parent report) and neural changes (EEG recordings) during rest and activation were obtained. The pediBBT intervention consists of three modules aimed at training attention, working memory, and goal management in which subjects respond to stimuli by reaching, squatting, or running. Critically, adaptive algorithms personalize the cognitive and physical training experience for each child by adjusting the level of difficulty to the heart rate and the level of performance.

Results: Direct assessment using TOVA showed statistically significant improvement ($p<.033$) for two measures of sustained attention (RT, RT Variability) and a measure of impulsivity (d'). Improvement was also observed on the behavioral measures of multitasking (d'; $p< .001$). By contrast, working memory did not show benefit with training. From a real-world perspective, 16 of the 22 participants showed improvements in their inattentive abilities based on the Vanderbilt parent report ($p= .010$). Of note, 7/8 participants no longer meet research criteria for inattentive subtype of ADHD following the pediBBT intervention. Finally, preliminary analyses efforts revealed that our neurophysiology measure (midline frontal theta) showed trends towards improvement both at rest and during a perceptual discrimination task ($p< .15$).

Conclusions: These findings provide initial evidence that an eight week, in-school, synergistic cognitive-physical training can lead to quantitative improvements in attention that span from behavioral assessment, neural markers and parent report. Future work will include a deeper interrogation of other EEG markers of attention and how potential improvements relate to other quantitative and subject reports of attention over time.

428.030 *(Poster)* Efficacy of an Intervention Group for Siblings of Children and Adolescents with ASD

B. Garcia[1], ***R. Calvo Escalona***[2] *and O. Puig Navarro*[3], *(1)Asperger Catalonian Association, Barcelona, Spain, (2)Hospital Clinic, Barcelona, Spain, (3)CIBERSAM, Barcelona, Spain*

Background: Autism Spectrum Disorder (ASD) is a neurodevelopmental disorder which causes severe impairments in communication, social interaction and behaviour. In addition to their increased risk for psychopathology ASD siblings may show alterations in behavioural and emotional adjustment, life quality and relationship with their affected siblings. There is scarce evidence for effective interventions programs for ASD-siblings but preliminary studies show an improvement of ASD knowledge and self-concept.

Objectives: The first aim of the present study was to measure ASD knowledge, emotional and behavioural symptoms, levels of self-concept and self-esteem and sibling relationship quality in ASD-siblings as well as parental stress in ASD-parents. The second aim was to prove the efficacy of a psychoeducational group treatment for 8-12 aged ASD-siblings in contrast to an active control group. The third aim was to measure the correlation between the variables of improvement of symptomatology in parents and children.

Methods: The final sample included 27 High-Functioning ASD siblings (HF-ASD) whose siblings were under current treatment at the Hospital Clinic in Barcelona and/or the Catalan Asperger Association. The inclusion criteria were: to be aged between 8-12, to have a sibling under 18 with a primary diagnosis of HF-ASD and a normal intellectual level, to have a normal intellectual level themselves and not to present any serious mental disorder. Self-report and parent report measures were used to assess study variables. Participants were randomly assigned to a psychoeducational intervention group (n=14) (consisting in psychoeducation on ASD symptoms, emotional management and conflicts' resolution with siblings). and active control group (n=13) (activities related to emotional education, conversation and play, not directly related to the affected sibling). Both received a seven-session pack.

Statistical analysis were used to measure whether siblings in the intervention group had a higher and significant improvement in study variables than in the control group (Student's t-test and *Mann–Whitney U test)* and to study correlation between the variables of improvement of symptomatology in parents and children (Pearson's coefficient). ANCOVA analyses were used to study differences between groups in independent variables after the treatment. Statistical analysis was performed using the SPSS ver. 20.

Results: Participants in the psychoeducational intervention group had a significant improvement ($p<.05$) in knowledge about ASD, conflict and warmth in their sibling relationship, anxiety and self-esteem towards the control group. The correlation analysis concluded a significant correlation ($p<.05$) between the improvement in ASD knowledge and anxiety.

Conclusions: There was a significant improvement in knowledge of ASD, conflict and warmth in their siblings relationship, anxiety and self-esteem of siblings participating in a psychoeducational group as compared to those who participated in a control group. These findings suggest the relevance of psychoeducational group interventions focused on ASD siblings, who are considered a risk population.

428.031 *(Poster)* Empirical Investigation of Structural and Process Treatment Fidelity in an Autism-Specific Consultation Intervention

J. A. Findley[1]*, L. N. Ogle*[2]*, L. A. Ruble*[3] *and J. H. McGrew*[4]*, (1)University of Kentucky, Burlington, KY, (2)Department of Educational, School, and Counseling Psychology, University of Kentucky, Lexington, KY, (3)University of Kentucky, Lexington, KY, (4)Psychology, Indiana University - Purdue University Indianapolis, Indianapolis, IN*

Background: Fidelity, or the extent to which an intervention was delivered as originally designed, is a critical component to intervention effectiveness (Power et al., 2005). Despite the recognized importance of treatment fidelity, it remains a poorly understood construct. Treatment fidelity is now conceptualized as a multidimensional construct that includes both structural (degree to which the intervention was implemented as designed) and process (how the intervention was delivered (Harn et al., 2017) components. Given the lack of understanding of treatment fidelity, Sanetti and colleagues (2009) suggested empirical evaluations of multiple dimensions of treatment fidelity. Thus, we evaluated the associations between multiple dimensions and multiple raters of treatment fidelity when implementing a manualized consultation intervention called the Collaborative Model for Promoting Competence and Success designed specifically for students with autism (Ruble et al., 2012).

Objectives: To better understand the structural and process components of treatment fidelity of consultants in training, we asked the following questions: (a) What were the average structural adherence and process skill ratings of novice COMPASS consultants as rated by an expert? (b) What is the association between measures of novice COMPASS consultant adherence and process skills? (c) What is the association between expert adherence ratings and novice consultant, parent, and teacher adherence ratings?

Methods: School-based ASD consultants (n=12) were recruited for a study to develop and test a training package in COMPASS. Preliminary data from five trainees who conducted 11 consultations are currently available and reported (full data will be available in April 2020). Following each consultation, researchers reviewed an audio recording of the consultation and scored the consultant's adherence to structural elements of COMPASSS and process skills. Process skills and COMPASS adherence consisted of 35 and 25 dichotomously rated items (i.e., observed, not observed). Percentages of steps completed (i.e., fidelity to research protocol) or process skills displayed were calculated by dividing the total steps or skills displayed by the total number of steps. Given the non-normality of the data, Spearman correlations were used to examine associations.

Results: Preliminary data from the first 5 trainees indicated the following. The average percentage of trainee consultant adherence to structural elements of COMPASS as rated by experts was 89.8% (range 56–100%). The average percentage of process skills displayed was 87.5% (range 58-100%). Fidelity and process skills were positively correlated ($r_s = .640$, $p = .034$). Researcher ratings of fidelity were not significantly related to teacher ($r_s = .127$, $p = .711$) or novice consultant ($r_s = -.047$, $p = .892$) ratings of fidelity. However, researcher ratings of fidelity were negatively related to parent ratings of fidelity ($r_s = -.605$, $p = .049$).

Conclusions: The data are preliminary, under powered, and highly sensitive to potential outliers. The full data will include findings from 39 consultations. Preliminarily, novice consultants achieved relatively high levels fidelity in terms of adherence to protocol and process skills. Further, ratings from parents and teachers did not correspond to research ratings of fidelity. Clearly, the source of fidelity ratings needs to be considered and discrepancies between ratings understood.

428.032 *(Poster)* Evaluating Parent and Teacher Report of Emotion Regulation in Youth with ASD Participating in CBT for Anxiety in Public Schools

A. T. Meyer[1]*, K. Pickard*[1]*, N. Reyes*[2]*, A. Blakeley-Smith*[2]*, R. E. Boles*[3]*, T. Tanda*[4]*, C. Middleton*[3]*, L. Hayutin*[3] *and J. Reaven*[2]*, (1)JFK Partners, University of Colorado School of Medicine, Aurora, CO, (2)JFK Partners, University of Colorado Anschutz Medical Campus, Aurora, CO, (3)University of Colorado Anschutz Medical Campus, Aurora, CO, (4)Developmental Pediatrics, Children's Hospital Colorado, Aurora, CO*

Background: Youth with Autism Spectrum Disorder (ASD) are at a higher risk to experience anxiety symptoms, and difficulties regulating their emotions than their typically developing peers. Emotion regulation difficulties often present as challenging and externalizing behaviors in the classroom and can significantly interfere with participation in school. Recently, emotion regulation has been a target of treatment in cognitive behavioral therapy (CBT) programs for youth with ASD. The results are promising in that emotion regulation skills seem to improve in anxious youth with ASD who receive CBT in a clinic setting (Weiss et al., 2018). However, research has yet to examine whether youth experience improved emotion regulation at school and at home when they receive CBT within school settings.

Objectives: The aims of this study were 1) to examine change in emotion regulation skills in response to a CBT program for anxiety in a public school setting; 2) to evaluate the relationship between anxiety and emotion regulation via parent- and teacher-report.

Methods: Twenty-four school-age youth (Mean age=10.5 years; SD=1.72) participated in Facing Your Fears-School Based (FYF-SB) intervention, a clinic-based CBT program for anxious youth with ASD that was adapted for schools (Reaven et al., 2019). Parents and teachers completed the Emotion Regulation Checklist (ERC; Shields and Cicchetti, 1997), a measure of emotional regulation (ER) and emotional lability/negativity (LN) at pre- and post-treatment. Higher scores on ER suggest positive affect and regulation skills while higher scores on the LN subscale suggest higher levels of negative affect. Pre- and post-treatment anxiety was measured using the Parent Screen for Childhood Anxiety and Related Disorders (SCARED; Birmaher et al., 1999) and the School Anxiety Scale-Teacher Report (SAS-TR; Lyneham et al., 2008). Only a portion of participants completed pre- and post-treatment data even with multiple reminders (n=17).

Results: There were no significant differences in either ER or LN pre- post-treatment, in parent or teacher report (See Table 1). However, according to parent and child report, significant reductions in anxiety did occur following participation in FYF-SB (ABCT presentation, Reaven et al., 2019). When evaluating the relation between emotion regulation and anxiety at pre-treatment, parent-reported ERC scores and SCARED scores were significantly correlated, ER: r= -.42, p=.046; LN: r=.52, p=.01. Teacher-reported LN was marginally correlated with SAS-TR total, r=-.40, p=.07, however ER was not significantly correlated with SAS-TR total, ER: r=-.15, p=.51.

Conclusions: At pre-treatment, parent and teacher-reported anxiety was correlated with some measures of emotion regulation suggesting that higher emotion negativity/lability and lower emotion regulation skills is related to higher anxiety at baseline. Preliminary findings from the present study suggest that although significant decreases in anxiety occurred following intervention, similar improvements in emotion regulation did not occur. Although these constructs were related at baseline, lack of improvement in emotion regulation may suggest that additional strategies that specifically target emotion regulation *may* be beneficial to address these difficulties. Limitations of the present study include a small sample size, missing data from some parents and teachers, as well as potentially limited sensitivity of the ERC to measure change.

428.033 *(Poster)* Examining Outcomes of Group CBT Targeting Anxiety in Children with Autism Spectrum Disorder

T. M. Rutter[1]*, S. Pickering*[2] *and C. Bolden*[1]*, (1)Seattle Pacific University, Seattle, WA, (2)Seattle Children's Hospital, Seattle, WA*

Background: Anxiety disorders are common in children with autism spectrum disorder (ASD), yet appear distinct from ASD deficits (Kerns and Kendall, 2012). Anxiety disorders can manifest as various clinical presentations and can lead to marked functional impairment. Several interventions targeting anxiety symptoms within the context of ASD exist, with modified cognitive behavioral therapy (CBT) showing significant improvement in anxiety symptoms among youth (Chalfant et al., 2007). *Facing Your Fears* (FYF; Reaven et al., 2011) is a manualized, evidence-based, family-focused group intervention targeting anxiety among children with ASD that has shown promising results. However, much is left to be explored in bridging the research-to-practice gap, and delineating efficacy from effectiveness in clinical settings.

Objectives: Our aim was to determine the effectiveness of *Facing Your Fears* group intervention on anxiety symptoms in children with ASD and at least one co-occurring anxiety disorder. We hypothesized there would be significant improvements across the Multidimensional Anxiety Scale for Children, Second Edition (MASC-2; March 2012) domain scores.

Methods: A total of 28 children and their parents received 90 minutes per week of FYF for 12-14 sessions. All patients had a confirmed diagnosis of ASD and an estimated Verbal IQ of 80 or above. Twelve patients (M_{age} = 10.17, SD_{age} = 1.95) were included in this preliminary analysis; those who were not included did not return measures (n = 16). Parent and child ratings on the MASC-2 were collected to determine severity of anxiety symptoms pre- and post-treatment. MASC-2 *T*-scores were assessed across the following scales: Total score, separation anxiety, generalized anxiety disorder (GAD), social anxiety, performance fears, obsessions and compulsions, panic disorder, tense/restless symptoms, and harm avoidance.

Results: Paired-sample t-tests were run to determine whether there were statistically significant mean differences across MASC-2 scores before and after FYF intervention. Among parent-reported child symptoms, results of the paired-samples t-test revealed significant improvement in *T*-scores on the separation anxiety symptom subscale (pre-test: M = 70.75, SD =10.00, post-test: M = 64.67, SD = 11.58; t(11)= 2.69, p = .021). No other significant changes were observed in parent-reported MASC-2 scales.

Among self-reported child anxiety symptoms, paired-sample t-test results also revealed significant improvement in *T*-scores on the following: Total score(pre-test M: 67.00, SD = 9.72, post-test M: 59.83, SD=8.67; t(11)=4.36, p =.001), separation anxiety symptom subscale (pre-test: M = 67.00, SD =9.72, post-test: M = 59.83, SD = 8.67; t(11)= 4.16, p = .002.), and obsessions and compulsions subscale (pre-test: M = 64.33, SD = 8.08, post-test: M = 55.17, SD = 9.72; t(11)=3.665, p= .004). No other significant changes were observed in self-reported MASC-2 scales.

Conclusions: Group CBT is effective in reducing severity of comorbid anxiety symptoms; however, this effect may vary across specific anxiety symptoms. In this sample, reduction in anxiety was demonstrated for separation anxiety (both parent and child report), total anxiety (child report), and obsessions/compulsions (child report). Future research on treatment outcomes should further assess differences in reported anxiety across children with ASD and their parents.

428.034 *(Poster)* Examining the Relationship between Organizational Climate and the Implementation of a CBT Program for Youth with ASD and Anxiety in Public School Settings

K. Pickard[1]*, A. T. Meyer*[1]*, A. Blakeley-Smith*[2]*, R. E. Boles*[3]*, L. Hayutin*[3]*, C. Middleton*[3]*, N. Reyes*[2]*, T. Tanda*[4] *and J. Reaven*[2]*, (1)JFK Partners, University of Colorado School of Medicine, Aurora, CO, (2)JFK Partners, University of Colorado Anschutz Medical Campus, Aurora, CO, (3)University of Colorado Anschutz Medical Campus, Aurora, CO, (4)Developmental Pediatrics, Children's Hospital Colorado, Aurora, CO*

Background: Access to cognitive behavioral therapy (CBT) is critical to support youth with ASD in managing anxiety symptoms that interfere with functioning across home, school, and community settings. Training school providers to deliver CBT may increase access to these programs given the high percentage of youth with ASD who receive services within public schools. “Outer” contextual factors such as school leadership, stress, and communication play an important role in the implementation of a range of evidence-based practices within community and school settings (Damschroder et al., 2009; Lyons et al., 2019). However, to date, we know little about whether these factors also contribute to the successful implementation of CBT programs within public school settings for youth with ASD and co-occurring anxiety.

Objectives: In partnership with school-based key stakeholders, Facing Your Fears (FYF), a clinic-based CBT program for anxious youth with ASD, was adapted as a school-based intervention [FYF-SB; (Reaven et al., 2019)]. This study presents data from a pilot implementation of FYF-SB in three public school districts. Specific aims are to: (1) characterize the sample with regards to organizational climate; and (2) understand how organizational factors are associated with the successful implementation of FYF-SB as measured by (a) early adoption of FYF-SB, (b) the number of FYF-SB sessions implemented, and (c) the perceived feasibility, acceptability, and appropriateness of FYF-SB following implementation.
