Methods: Thirty-four interdisciplinary school providers from 10 underserved public schools were trained to implement FYF-SB. To assess organizational readiness, all providers completed the Organizational Readiness for Change scale (ORC; Lehmann, Greener, & Simpson, 2002). The ORC contains a Climate subscale that captures school-level communication, autonomy, stress, cohesion, and leadership. All ORC items are rated on a 5-point Likert scale, with higher ratings reflecting more positive climate. Following training, school providers implemented FYF-SB. Data were collected regarding the speed that FYF-SB was started/adopted, student attendance, session fidelity, and total number of sessions completed. Following implementation, providers completed a measure of perceived feasibility, acceptability, and appropriateness of FYF-SB.

Results: School providers reported positive school communication, autonomy, cohesion, and leadership, with mean item ratings ranging from M=3.42 (SD=0.49) to M=3.78 (SD=0.45). However, high levels of stress were also reported (M=3.69; SD=0.82). The Climate subscale of the ORC was not significantly associated with the number of FYF-SB sessions implemented or the perceived feasibility, acceptability, and appropriateness of FYF-SB following implementation. However, it was marginally associated with the speed of FYF-SB adoption (r=0.34; p=0.07), with better organizational climate being associated with faster adoption. Specific domains of the ORC Climate subscale appeared to drive this relationship, with school leadership and school cohesion being significantly associated with the speed by which FYF-SB was implemented (r=0.45, p<0.01 and r=0.37; p=0.04 respectively).

Conclusions: Results from this study suggest that school climate, leadership, and cohesion may influence how quickly school-based CBT programs are initiated and implemented. These results suggest the importance of proactively capitalizing on school leadership and building school-level communication and cohesion (e.g., provider relationships) during the initial training of school providers. Limitations and future directions will be discussed.

428.035 *(Poster)* Examining the Use of a Virtual Reality Job Interview Tool in Adolescents with Autism in a School Setting: A Randomized Controlled Trial

H. Genova[1]*, M. DiBenedetto*[2]*, M. Smith*[3]*, D. Krch*[1]*, J. Morecraft*[1]*, K. L*[1] *and J. DeLuca*[1]*, (1)Kessler Foundation, East Hanover, NJ, (2)Center for Neuropsychology & Neuroscience Research, Kessler Foundation, East Hanover, NJ, (3)University of Michigan, Ann Arbor, MI*

Background: Unemployment rates are high in adolescents with ASD. Adolescents within two years of graduating high school are at particular risk of unemployment. Thus, high school represents a critical time in which interventions focused on employment outcomes should be considered. One obstacle for obtaining employment is the job interview, which may be challenging for those with ASD due to social communication difficulties. Thus, treatment aimed at improving job interview skills may be particularly helpful for adolescents, specifically as they prepare to graduate from high school.

Objectives: In the current study, we examined the effectiveness of a Virtual Reality Job Interview Tool (VR-JIT) in adolescents with ASD. While the VR-JIT has been shown to be effective in adults with psychiatric disorders, its utility has not been examined before in adolescents with ASD.

Methods: Fourteen high school students with ASD participated in the current study, which was conducted in a New Jersey school for children with mild special needs. The students (either 11th or 12th graders) were randomly assigned to either the VR-JIT intervention condition (n=7) or a services-as-usual (SAU) control condition (n=7). Participants in the intervention condition participated in 10 hours of VR-JIT during which they practiced simulated job interview skills with a virtual human interviewer, and were provided feedback on social skills. At baseline and following the intervention, all participants performed a video-recorded mock job interview. Following the study, the video recorded job interviews were rated by trained assessors who were blinded to group (intervention vs. control) and time (baseline vs. follow-up). Participants were assessed on their ability to sound professional, honest, and hardworking among other abilities. Repeated-measures ANOVA was performed. Due to the small sample size, effect sizes and p-values were considered.

Results: Compared to the SAU group, the VR-JIT group showed improved job interview performance across several domains including portraying oneself as honest and professional, as well as portraying oneself as a team player. Overall, participants in the VR-JIT group indicated they found the intervention helpful and enjoyable. Moderate to high effect sizes were observed.

Conclusions: Our results indicate that the VR-JIT improved job interview performance in adolescents with ASD. Future directions include examining whether those in the intervention group showed improved ability to obtain job offers. The study also revealed that the VR-JIT can be easily implemented in a school setting, and therefore may be helpful to adolescents with ASD as they prepare to enter the employment world.

428.036 *(Poster)* Exploratory Implementation of an in-Home Exergaming Program for Children with Autism Spectrum Disorder (ASD): Thematic Analysis of Families' Experiences and Views

H. Coo[1]*, D. Samdup*[1]*, N. King*[2]*, B. Gurd*[3]*, P. Zabojnikova*[1]*, N. Graham*[4] *and N. Golubovich*[4]*, (1)Pediatrics, Queen's University, Kingston, ON, Canada, (2)Queen's University, Kingston, ON, Canada, (3)School of Kinesiology and Health Studies, Queen's University, Kingston, ON, Canada, (4)School of Computing, Queen's University, Kingston, ON, Canada*

Background: Interventions that increase physical activity (PA) have been associated with multiple benefits in individuals with ASD, who tend to be less physically active than their typically developing peers. The Liberi exergames require players to pedal a recumbent bicycle and were developed to promote moderate-to-vigorous PA in children with cerebral palsy (CP). Specially designed controls facilitate gameplay for those with motor impairments. Players access the online games through tablets connected to the bicycles. A variety of mini-games are available for solo or group play. Arm-mounted monitors enable real-time feedback when players reach their target heart rate. Preliminary evidence supports the effectiveness of the Liberi exergames in increasing PA and fitness in children with CP. Children with ASD often have motor and other challenges that may hinder them from participating in team sports, and commercial exergames do not necessarily induce adequate exertion levels. Accordingly, the Liberi exergames could be an effective exercise intervention for the ASD population.

Objectives: Exploratory implementation of an in-home Liberi exergaming program for children with ASD to obtain feedback on the games/program.

Methods: We recruited a convenience sample of five children with ASD aged 8-12 years and one parent per household. Bikes/gaming stations were set up in participants' homes. Children were asked to play the exergames for at least 45 minutes three times per week—the games were available only on/at specified days/times—over a six-week period. A semi-structured interview guide was developed to elicit participants' experiences and views of the exergames/program during a one-hour focus group. Thematic analysis was used to identify salient themes.

Results: Four families (eight participants) attended the focus group. Four themes were identified. Motivation: Earning money to shop in the e-store, winning, playing with others (although four children did not want to use the headsets to communicate while doing so), and having fun contributed to players' enjoyment of and desire to play the games. Benefits: Three parents voiced pleasure at seeing their child engaging in PA. Other positive impacts included greater confidence, more family discussions/socializing, and establishment of a safe space for online play. Frustration: Technical difficulties were a source of frustration. Participants would have liked a larger selection of games (including more challenging/sophisticated ones), disliked the practice of rotating games such that not all were available during every session, and some experienced sensory issues (e.g., one child did not like wearing the heart rate monitor because of the sensation on his arm). Sustainability: Several parents wondered whether their child would continue exergaming once the novelty had worn off. All parents found the limited gaming windows problematic, and suggested the server be open for longer periods and at different times. Participants had mixed opinions about offering exergaming in schools. Two children voiced concerns (others may be careless with equipment, lack of a safe gaming environment), although parents were supportive of the idea (one had already broached the topic with her child's school).

Conclusions: These findings will inform the design of a more rigorous evaluation of the Liberi exergames in children with ASD.

428.037 *(Poster)* Exploring the Therapeutic Effects of a Social Skills Intervention Program Adapted for a Community-Based Children's Hospital.

C. Alcover Van de Walle[1], *M. A. Mairena*[1], *M. Diez-Juan*[2], *A. Aranbarri*[3,4], *G. Balaña*[5] *and E. Arias-Pujol*[6], *(1)Hospital Sant Joan de Déu, Barcelona, Spain, (2)UNED- Universidad Nacional Educación a Distancia, Barcelona, Spain, (3)Psychiatry and Behavioral Sciences, University of California at Davis MIND Institute, Sacramento, CA, (4)Mental Health Area, Hospital Sant Joan de Déu Barcelona, L'Hospitalet de Llobregat, Spain, (5)Sant Joan de Deu Hospital, Barcelona, Spain, (6)Blanquerna University, Barcelona, Spain*

Background:

Autism Spectrum Disorder (ASD) is characterized by challenges with social skills that imply need of help in learning how to act in different social situations. Literature suggests that social skills training groups increase social behaviors in children and adolescents with high-functioning ASD, and reduce several mental health related comorbidities. However, there is little evidence on the effectiveness of these treatments in adapted community-based hospital services.

Objectives:

The main objective of this study was to explore the effect of the MIND Social Skills Training Program (MIND-SSTP) adapted with authors' consent from Solomon, Goodlin-Jones & Anders (2004) for children and adolescents with ASD, on social conducts and several comorbid symptoms, such as anxiety, behavioral problems and mood disorders.

Methods:

This study is based on a randomized clinical trial (using a waiting-list as a control group). A total of 79 children (8-12 years old) and adolescents (13-17 years old) were recruited and divided in two groups: experimental group (n=42) and control group (n=37). Inclusion criteria included diagnosis of ASD and verbal comprehension within normal range (based on WISC-V verbal index). Diagnoses were confirmed by ADOS-2 and clinical judgement. Solomon's et al. (2004) MIND-SSTP intervention was adapted for hospital community implementation (i.e., ten consecutive weekly sessions, of 90 minutes duration, and including 15 minutes free play). Free playtime was recorded, and social conducts were codified (Lince software, Gabin et al., 2012) based on an adaptation of Bauminger (2002) observational scale applied to 39 subjects available of the initial 79. We analyzed change in the number of social conducts (coded from recoded videos), comparing experimental and control group. Coders met reliability (within 76 and 89%). Comorbid symptoms were assessed by questionnaires before and after the intervention based on the total sample (N=79).

Results:

Participants included 82,3% males (mean age: 11,92) for questionnaires data and 84,16% males (mean age: 11,39) for observational coded data. Our results showed significant improvements (pre-post coding) in social behaviors only for the experimental group. Specifically, eye contact showed a tendency of improvement ($p = 0.056$), that reached the statistical significance for participants with verbal index > 90 ($p = 0.010$), and a tendency for the sub-group of children ($p = 0.095$), not seen for adolescences. There is also a tendency of improvement in functional communication ($p = 0.057$), being more meaningful for children ($p = 0.050$). Also, children with Verbal Index > 90 showed a decrease in affective symptoms collected through questionnaires; decreasing in internalizing problems ($p = 0.022$) and within the marginal statistical significance decrease for affective problems ($p = 0.089$).

Conclusions:

Our results suggest that children under 13-years old, and participants with higher verbal skills, may be better candidates for low-intensity community social skills programs. We have also learned that by using observational methodologies, more clinically relevant changes might be captured in order to strength the validation of community interventions.

428.038 *(Poster)* Feasibility of a MULTI-Dimensional Coaching Based Intervention for Parents of Adolescents with Autism

*B. Wachspress[1], E. Kahlon[1], A. Maeir[1], I. Berger[2] and **T. Mazor-Karsenty**[1], (1)School of Occupational Therapy, Hebrew University of Jerusalem, Jerusalem, Israel, (2)Faculty of Health Sciences, Ben Gurion University, Beer Sheva, Israel*

Background: Parents of children with autism face a variety of difficulties, among which are decreased resilience and heightened stress. Recent studies have shown that parental well-being affects the child's well-being, and that parents are primary mediators of their child's development. The ***ParentShip*** protocol is a validated, short-term occupational therapy intervention for parents of adolescents with autism that aims to promote parental resilience and enhance adolescents' participation in daily life.

Objectives: The aim of this study was to examine the ***ParentShip*** feasibility and explore the modifiability of parental resilience following intervention.

Methods: We used a one-group repeated measures pretest – posttest and follow up, mixed-method, research design. Parents (n = 4 - both parents, n = 6 - mothers) of 10 adolescents with autism: five boys (M=14.32 years, SD=1.98), five girls (M=13.95 years, SD=1.06) were recruited using convenience sampling from community based autism centers and social media. Inclusion criteria: Parents - difficulties or unmet functional needs in relation to raising their adolescent; Adolescent- a score indicating non-typical functioning in at least one of the following areas: sensory processing, executive function, or social-communication skills.

An assessment of the adolescent's multi-dimensional profile in the following dimensions: sensory-motor (Sensory Profile 2), cognitive-behavioral (The Behavior Rating Inventory of Executive Function –Parent), social- communicative (Social Skills Improvement System), and motivational (A questionnaire designed for this study) was determined. Each family participated in a series of 13 individual weekly sessions of 90 minutes each. During the sessions parents and therapist analyzed the adolescent's personal profile, examined daily situations and identified barriers and bridges in the parent, the adolescent and the environment. In addition, parents set measurable and functional goals and practiced structured problem solving. Study results were analyzed at three time points: before intervention (time 1), immediately after intervention (time 2), and three months post intervention (time 3), using two outcome measures: The Autism: Parenting Questionnaire (APQ), measuring parental resilience, and the Canadian Occupational Performance Measure (COPM), measuring perception of performance. A semi-structured interview was conducted at time 2 to explore parental experience.

Results: Significant improvement in COPM performance score from time 1 to time 2 for parents (Z= 2.81, p= .005) and adolescents (Z= 2.803, p= .005). Results were maintained three months post intervention for both parents and adolescents. APQ total scores improved from time 1 (M= 98.2, SD=8.9) to time 2 (M= 105.5, SD=10.6; Z=1.582, p= .114) and showed significant improvement from time 2 to time 3 (M= 110.9, SD=8.4) (Z=2.143, p= .032). Large APQ effect size was obtained from time 1 to time 2 (Cohen's d= 1.16) and from time 2 to time 3 (Cohen's d= 1.84). Thematic analysis of qualitative results validate ***ParentShip's*** mechanisms of change.

Conclusions: Results support the ***ParentShip*** as a strength-based parent- centered intervention program that leads to significant improvement in adolescent participation and heightened parental resilience.

428.039 *(Poster)* Feasibility of a Self-Management Physical Activity Intervention with Coaching to Support Adults with Autism Spectrum Disorder and Intellectual Disability

M. Savage[1], *B. Tomaszewski[2,3,4] and K. Hume[2], (1)Educational Psychology, University of North Texas, Denton, TX, (2)Frank Porter Graham Child Development Institute, University of North Carolina at Chapel Hill, Chapel Hill, NC, (3)Psychiatry, University of North Carolina at Chapel Hill, Chapel Hill, NC, (4)TEACCH Autism Program, University of North Carolina at Chapel Hill, Chapel Hill, NC*

Background: Individuals with autism spectrum disorder (ASD) often do not engage in recommended levels of physical activity and levels continue to drop as individuals with ASD move into adulthood (Garcia-Pastor, Salinero, Theirs, & Ruiz-Vicente, 2019). Few studies have examined the impact of using family or community members as coaches to promote exercise in this population using evidence-based strategies.

Objectives: To evaluate the feasibility and acceptability of a self-management physical activity intervention with a coaching component to support adults with ASD and accompanying intellectual disability (ID).

Methods: Participants included 18 adults with ASD and ID (ages 18–47). Participants in both groups received a Fitbit Flex 2™, training on using the device, and were instructed to wear the Fitbit daily. Following a week-long baseline period to determine acceptability of wearing the Fitbit, adults with ASD and ID were randomly assigned to the Fitbit +Coaching Group or the Fitbit Only Group. Coaches in the Fitbit +Coaching group were either a family or community member who knew the adult (e.g., parent, respite provider). The coaches participated in a 2-hour web-based training, then trained participants on the project. Once the 12-week intervention began, participants met with their coach each week to determine if the weekly step goal was met, determine the next goal, and schedule exercise sessions. Researchers measured fidelity weekly and provided support as needed. When exiting, participants in both groups completed a feasibility measure and participants in intervention completed an adapted usage rating profile. Coaches also completed a feasibility and usage rating profile questionnaire.

Results: (Note: Results will be updated when 18 currently enrolled participants exit the study- total N of 36). Adults with ASD and ID in both groups reported high acceptability for using the Fitbit. Across the 12 weeks of the intervention, participants in the Fitbit +Coaching group had significantly higher average weekly step counts controlling for their baseline step counts than participants in the Fitbit Only Group, $F(1,15) = 7.55$, $p = .01$, $\eta^2 = .34$. Adults with ASD and ID in the Fitbit +Coaching group reported high ratings on the usage rating profile ($M = 3.5$, $SD = .36$, Max=4.0). Average coach fidelity was 90.0%. Coaches reported high feasibility (Max=5.0) for the coach training ($M = 4.5$, $SD = .25$), athlete training ($M = 4.4$, $SD = .52$), and overall project ($M = 4.5$, $SD = .25$) as well as high ratings on the usage rating profile.

Conclusions: These results provide some support for parents and community members implementing self-management strategies. The intervention improved physical activity outcomes above and beyond the use of the use of the Fitbit alone. High ratings of feasibility and acceptability from both participants and coaches suggest that web-based training is a promising approach to implement interventions in community settings in adulthood. Limitations and challenges that surfaced throughout the study will also be discussed.

Garcia-Pastor, T., Salinero, J. J., Theirs, C. I., & Ruiz-Vicente, D. (2019). Obesity status and physical activity level in children and adults with autism spectrum disorders: A pilot study. *Journal of Autism and Developmental Disorders*, *49*(1), 165−172.

428.040 *(Poster)* Game Day: A Novel Method of Assessing Change in Social Competence in Children with Autism Spectrum Disorder (ASD) Undergoing Social Skills Training Using the School-Based PEERS Curriculum

S. Bent[1], *M. G. McDONALD*[2], *F. Widjaja*[1], *C. Chen*[3], *J. Wahlberg*[1] *and R. Hendren*[1], *(1)Psychiatry, University of California, San Francisco, San Francisco, CA, (2)OAK HILL SCHOOL, San Anselmo, CA, (3)Psychiatry, UCSF, San Francisco, CA*

Background: Deficits in social communication and social interaction are one of the two defining characteristics of autism spectrum disorder (ASD) and contribute to numerous social difficulties throughout life. Group social skills programs have been developed and a recent systematic review of 19 studies found evidence of a medium overall positive effect but the benefits were limited to improved knowledge rather than improved frequency of enacting new social behaviors. The Program for Education and Enrichment of Relational Skills (PEERS) is the most-studied group social skills program in ASD and has shown very consistent benefits in student-reported social knowledge, parent and teacher-reported ratings of social skills, and the number get-togethers. However, none of the prior PEERS studies included blinded ratings of social interactions occurring during unstructured play times, perhaps the most robust evidence of treatment effects.

Objectives: The primary object of this pilot study was to examine whether students with ASD participating in a school-based PEERS curriculum would demonstrate improved social skills in unstructured play sessions.

Methods: Students attending a local special education school were recruited to participate in a school-based PEERS curriculum delivered in 25-30 minute group sessions four days a week for 16 weeks and delivered by a PEERS certified instructor and two assistant coaches. Students were required to have ASD with or without comorbid mild intellectual disability, be verbal, and be motivated to improve in social skills. Outcome measures included the Social Responsiveness Scale (SRS), the Social Skills Rating System (SSIS), the Test of Adolescent Social Skills Knowledge (TASSK), and a novel evaluation of an unstructured play session ("game day"). Game day occurred once a month and consisted of the instructor placing a set of board games on tables in the center of the room and then leaving the room. Videos of the game day session were rated by three reviewers who were blinded to the sequence of the videos. Raters assessed the social skills of each child using a modified version of the Contextual Assessment of Social Skills (CASS), a previously used instrument to assess social skills in ASD.

Results: Six students (age range 13-22, 5 male) enrolled and completed all PEERS instruction. Inter-rater agreement for change in social skills ratings on the modified CASS was high (0.79) for all items other than counts of initiations and responses to initiations. The total modified CASS score improved from a baseline of 38.5 to a final score of 43.6 indicating a 5.1 point statistically significant improvement ($p = 0.011$) (Figure 1). Survey outcome measures also showed statistically significant improvements in social skills knowledge (TAASK), teacher ratings of the problem behaviors (SSIS), and parent and teacher ratings of autism spectrum behaviors (SSIS).

Conclusions: This small pilot study is the first study to document improvements in social skills in unstructured play sessions for students who complete a school-based PEERS curriculum. This provides important evidence supporting the beneficial effects of PEERS that extend beyond social skills knowledge and survey-based ratings by parents and teachers.

428.041 *(Poster)* Gender Differences in Friendships, Social Behaviors and Intervention Response

M. Jimenez Munoz[1] *and T. W. Vernon*[2], *(1)University of California, Santa Barbara, Santa Barbara, CA, (2)University of California Santa Barbara, Santa Barbara, CA*

Background: Currently, the literature on both the characterization and treatment of autism largely focuses on males with ASD, whereby females with ASD remain unrepresented in clinical research (Head et al., 2014). As such, it is difficult to gain a clear understanding of friendships and sociability in females with autism. This illustrates a growing need to understand the unique socialization profiles of females on the spectrum and how they may respond differently to social skills treatment.

Objectives: The current investigation seeks to examine gender differences in both coded social behaviors and reported number of friendships before and after the completion of the Social Tools And Rules for Teens (START) intervention program for adolescents with ASD.

Methods: Twenty-nine adolescents (ages 11-16) and their parents participated in the RCT of the START program, a 20-week group experiential social competence and motivation intervention. At pre and post-intervention, adolescents engaged in 5-minute conversations with two unfamiliar, typically developing peers. Video-recorded conversations were coded for various social skills (i.e. questions asked, eye contact). Participants and their parents were asked to report an estimated number of teen friendships at each time-point. Mean number of friendships, pre-intervention social behaviors, and post-intervention changes were analyzed in female and male participant subgroups.

Results: Female participants initially asked significantly fewer questions (mean 6.8, SD 5.8) than males (mean 17.6, SD 18.5). However, both genders asked a similar number of questions post-intervention (female mean 25.9, SD 20.9; male mean 22.3, SD 18.4). Additionally, females made eye contact a mean of 41.0 seconds (SD 18.4) during a 5-minute conversation, while males exhibited a mean of 56.6 seconds (SD 19.0). Both subgroups increased eye contact duration after intervention (female mean 61.2 seconds, SD 20.3; male mean 73.9, SD 15.8). Female participants reported a greater number of friendships (mean 6.7, SD 5.4) at intake than male participants (mean 3.4, SD 4.0). After treatment, females reported a negligible increase in friendships (post mean 7.0 SD 4.5), while males endorsed a greater increase (post mean 5.6, SD 4.5). Parents reported comparable number of friendships for female (mean 1.4, SD 1.3) and male children (mean 1.4, SD 1.3), which was indicative of a greater discrepancy from female self-report. Parents also reported comparable gains in friendships post-intervention across females (mean 2.7, SD 1.5) and males (mean 2.9, SD 2.2).

Conclusions: Female participants experienced a larger gain in questions asked and a negligible change in endorsed friendship, which might be due to a ceiling effect. Furthermore, self-reported number of friendships was consistently higher than parental reports, although this discrepancy was larger for female participants. Overall, the findings of this RCT are indicative of comprehensive social improvements reflected in parent-reported, self- reported and observational social gains for both male and female teens. Additionally, these results add to the growing body of literature exploring differences in male and female presentations of autism (Hiller, Young & Weber, 2014; Lai et al., 2015) and suggest gender adaptations for the START group may be worth examining.

428.042 *(Poster)* Generalization of Clinic-Based Treatment Gains to Parents

*K. Nohelty[1], **L. Hirschfeld**[1] and D. Dixon[2], (1)Research and Development, Center for Autism and Related Disorders, Woodland Hills, CA, (2)Center for Autism and Related Disorders, Woodland Hills, CA*

Background: While applied behavior analysis (ABA) as a treatment for individuals with autism spectrum disorder (ASD) has demonstrated effectiveness across a multitude of studies, generalization of gains is an area of concern. It is necessary to consider generalization from clinicians to parents, but it is also critical to program for generalization of skills mastered in a clinic to the home. Clinicians have many options they need to consider when making treatment recommendations to achieve optimal outcomes and deciding between clinic and home-based services can be one major element of a recommendation. Both the clinic and home have several advantages (Leaf et al., 2017) and it has been demonstrated that children learn more in a clinic-based setting (Dixon et al., 2017). When recommending and providing services in the clinic, it is necessary to show that skills are generalizing to the home with parents.

Objectives: The current study examined the impact of the amount of parent training received on the percentage of skills that generalized to the home and to the parent in a within-subject group design.

Methods: The study was conducted in two parts. In the first part of the study, we recruited 13 families of individuals with ASD (2-8 years old) who received the majority of their ABA services in a clinic-based setting (70%+). A retrospective baseline was completed by identifying exemplars that were mastered within the ABA program and indicated as not known by parents via the Skills® Assessment before instruction began. Those exemplars were then probed by the parent at home. In order to control for potential confounds during training in part 1, a second part of the study was conducted. In part 2, we recruited 30 families of individuals with ASD (2-8 years old) who again received the majority of their ABA services in a clinic-based setting (70%+). For each child, 20 exemplars were identified that were not known with the parent at home and were then taught by clinicians to the children at the clinic. After the exemplars were mastered in the clinic, generalization to the children's parents at the home was assessed. Measures of treatment fidelity were scored throughout the study (i.e. pre-treatment, intervention, post-treatment). Additionally, generalization strategies used by clinicians were collected.

Results: In part 1, for all participants at least 80% of the skills generalized from the clinic setting. There was a Pearson Correlation of 0.659 between the amount of parent training and the percentage of skills generalized indicating that the amount of parent training received is significantly correlated with percentage of skills generalized to the parent. Additionally, regression analysis found an r^2=0.4348 between the hours of parent training and skills generalized. In part 2, data are presented on the generalization from the clinic to the home, in correlation with parent training.

Conclusions: The results of this study show that the amount of parent training has a direct impact on the amount of generalization to the home and adds to the growing support for parent training throughout the ABA process.

428.043 *(Poster)* Group Intervention of Social Competence (SOCO) for School-Aged Children with Autism Spectrum Disorder

***T. M. Helminen**[1], S. Häkkinen[2], S. Eränen[2], K. Rantanen[2], S. Bolte[3] and A. Kylliainen[4], (1)Faculty of Social Sciences/Psychology, Tampere University, Tampere, Finland, (2)Tampere University, Tampere, Finland, (3)Center of Neurodevelopmental Disorders (KIND), Centre for Psychiatry Research; Department of Women's and Children's Health, Karolinska Institutet, & Stockholm Health Care Services, Region Stockholm, Stockholm, Sweden, (4)Faculty of Social Sciences/Psychology, Tampere University, Tampere, Finland*

Background: Group interventions have been widely used to improve the social skills of cognitively able individuals with autism spectrum disorder (ASD). Instead of targeting of only social skills training, this study aimed to focus on a wider concept of social competence. In addition, a multilevel approach including groups for both children and parents, and the co-operation with teachers, were adopted, and the intervention program was planned to last as long as 9 months.

The Social Competence Group Intervention for Children with Autism Spectrum Disorder (SOCO) was developed and manualised based on approaches of neuropsychological rehabilitation and of cognitive behavioural therapy and the three-component social competence model. The model differentiates social competence in three components: 1) social skills 2) social performance, and 3) social adjustment (Cavell, 1990, Fig 1.). Individual goals are defined according to the analyses of deficits in three components.

Objectives: The aim of this study was to describe the SOCO intervention and examine the feasibility and preliminary efficacy of the SOCO intervention.

Methods: This study was a pilot study with n = 23 boys (n = 16 intervention, n = 7 control) with ASD with a mean age of 10.5 years (SD = 1.3; range 7.9–12.7 years). The participants were drawn from a clinical sample of two different sites and from five different SOCO groups. The parents and teachers evaluated the children's social competence with the Social Responsiveness Scale (SRS) questionnaire in baseline, in short-term outcome (right after the intervention) and in long-term outcome (after 5 months or 2-3 years, depending on the site). The subscales of SRS were divided to present the components of social competence based on clinical and theoretical judgements of the SOCO development team. In addition, observations during the group sessions (in first, second and third trimester), evaluating the overtures and reactions, were administered in two groups (n=8).

Results: In short-term outcome, the parents of the intervention group reported improvements in social skills (social awareness: $Z = 2.007$, $p = .045$; r = 0.410) and social adjustment (social motivation: $Z = 2.249$, $p = .025$, r = .460), while in long-term outcome, they reported improvements in social skills (social awareness: $Z = 2.779$, $p = .005$, r = 0.507; social cognition: $Z = 2.446$, $p = .014$, r = .447). No significant changes were found for control group. The teachers reported increases in social performance (social communication: $Z = 1.978$, $p = .048$, r = .404) in short-term outcome (Fig 2). Findings also indicated the improvement in social overtures and reactions with the peers between the first and second trimester ($Z = 2.197$, $p = .028$, r = .594).

Conclusions: Although the evidence of the pilot study should be considered as preliminary due to small sample size, it gives indications of the feasibility of the SOCO and supports the usability of the social competence model as a theoretical background for group interventions in general. The study also demonstrated how the existing, widely used SRS-instrument can be adjusted to the model of social competence.

428.044 *(Poster)* Help-Move: A Home Exercise Program Led By Parents to Improve Movement in Children with Autism Spectrum Disorder

***R. Mobley**, E. Bow, C. Rohani, E. Walsh, N. E. Fears, B. Schwarz and H. L. Miller, University of North Texas Health Science Center, Fort Worth, TX*

Background: Children with Autism Spectrum Disorder (ASD) have clinically-significant gross motor impairments, including poor postural control and coordination (Boyd et al., 2010; Miller et al., 2019), and gross motor development has been shown to predict later expressive and receptive language ability in ASD (Bedford et al., 2015). There is an unmet need for physical therapy (PT) to address motor issues in ASD early in development (Benevides et al., 2016). Exercise programs have been shown to significantly improve motor control (Bremer & Lloyd, 2016; Karanth et al., 2010), quality of life (Toscano et al., 2018), socialization (Boyd et al., 2010), and cognitive skills (Karanth et al., 2010; Sotoodeh et al., 2017). However, most exercise interventions found in the literature are performed in clinic or school settings and require a significant amount of direct interaction with a clinician. Given the time and resource limitations faced by families with ASD (Benevides et al., 2016), new approaches to delivery of motor intervention are needed.

Objectives: We aimed to determine the feasibility and efficacy of a parent-led home exercise program to improve gross motor skills in ASD, as measured by dynamic and static balance, a standardized developmental motor test, and a parent report of functional motor skills.

Methods: This ongoing intervention includes two cohorts of 5 children aged 3-7 years with ASD and an age-matched wait-list control group of children with ASD. All participants had a prior educational or medical diagnosis of ASD were screened for comorbidities related to motor control and excluded if they were taking medications known to affect movement. A standardized developmental motor test and balance tests are administered pre-, mid- (at 2 weeks and 5 weeks), and post-intervention. Parents completed the home exercise program (3 days per week for 8 weeks for a total of 30 minutes. Exercises included warm-ups, strengthening, balance, coordination, and cool down. Parents tracked adherence to the exercise program and reflected on feasibility and progress in a log provided by the research team. Researchers performed fidelity checks at 2 and 5 weeks after the start of the intervention to ensure adherence to the protocol and correct execution of the exercises.

Results: Data analysis is ongoing through completion of the second cohort. We will compare pre- and post-intervention scores on the developmental motor assessment, the balance tests, and the parent-report of motor ability. Outcome measures include postural stability data (e.g., center of pressure sway and variability) collected during balance tests, as well as scores on the developmental motor assessment and parent report of motor ability. We will also evaluate the individual trajectory of motor skills across the study period. We predict improvement across all measures over the course of the intervention, and correlations between postural stability variables and clinical assessment scores.

Conclusions: If results support our hypotheses, this will suggest that a parent-led, PT-mediated home exercise program is an effective method of improving gross motor control for young children with ASD. This approach could reduce barriers to motor intervention for families who have limited time and resources.

428.045 *(Poster)* Impacts of Aerobic Exercise Versus Relaxation on Pivotal Response Training Responder Profiles in Nonverbal and Minimally Verbal Children with Autism

***R. A. Rivera**[1], J. Jaen[2], R. Alper[3] and J. McCleery[1], (1)Psychology, Saint Joseph's University, Philadelphia, PA, (2)Communication Sciences and Disorders, Temple University, Philadelphia, PA, (3)Communication Sciences and Disorder, Temple University, Philadelphia, PA*

Background: Approximately 33% of children on the autism spectrum remain nonverbal or minimally verbal throughout their lives—resulting in decreased quality of life, reduced self-determination, and increased costs to society. There are several evidence-based interventions—including Pivotal Response Training (PRT)—for increasing speech-language skills and development for individuals with autism. However, children's responsiveness to these interventions varies. For example, research has identified social-behavioral profiles associated with less responsivity to play-based, naturalistic, behavioral speech interventions, such as PRT. Specifically, less responsive children tend to exhibit high avoidance, low approach, low rates of toy contact, high nonverbal self-stimulatory behavior, and low verbal self-stimulatory behavior. Identifying ways to increase responsiveness for these children might improve speech-language and long-term outcomes.

Objectives: Previous research has demonstrated that aerobic exercise reduces stress and anxiety, improves attentional focus and engagement, and decreases non-verbal self-stimulatory behaviors. The current study is designed to test the hypothesis that aerobic exercise will lead to improved PRT responder profiles and increased communicative acts in nonverbal and minimally verbal children.

Methods: Using a within-subjects randomized controlled trial (RCT) design, PRT response profile behaviors are scored on two separate sessions 7 to 14 days apart. One session is immediately preceded by aerobic exercise; the other is immediately preceded by relaxation in a sensory room. Condition order is randomized across participants. To date, we have completed testing 5 participants, initiated testing of 5 additional participants, and screened 4 additional qualifying participants. We will complete testing of n=24 participants by April, 2020.

Results: Descriptive statistics were conducted for all five profile behaviors across exercise and rest conditions: toy contact (Exercise *M* = 16.80, *SD* = 9.15; Rest *M* = 14.40, *SD* = 9.81), approach (Exercise *M* = 3.00, *SD* = 3.16; Rest *M* = 4.00, *SD* = 3.87), verbal self-stimulatory behavior (Exercise *M* = 16.00, *SD* = 9.62; Rest *M* = 16.40, *SD* = 10.31), avoidance (Exercise *M* = 5.80, *SD* = 6.50; Rest *M* = 9.00, *SD* = 8.54), and nonverbal self-stimulatory (Exercise *M* = 15.60, *SD* = 4.72; Rest *M* = 18.00, *SD* = 10.68). An analysis of variance (ANOVA) including condition (aerobic exercise, relaxation) and the five components of the response profile (approach, toy contact, verbal self-stimulatory behavior, reverse-coded avoidance, reverse-coded nonverbal self-stimulatory behavior) will be conducted using the final sample (n=24), in order to determine whether or not there are any main effects or interactions indicating improvements in PRT responder profiles. Figure 1 presents means and standard errors for each response profile component for the first 5 participants, which reflect non-significant mean differences in avoidant (lower), nonverbal self-stimulatory behavior (lower), and toy contact (higher).

Conclusions: Aerobic exercise has potential to be a supportive, supplementary intervention to accompany PRT. Specifically, exercise might improve responsiveness to play-based speech-language intervention by reducing stress/anxiety, increasing attentional focus, reducing nonverbal self-stimulatory behaviors, and otherwise changing social interactivity. This on-going, within-subjects clinical trial will test the hypothesis that a single bout of aerobic exercise—immediately preceding a PRT session will improve responder profiles and increase communicative acts.

428.046 *(Poster)* Impacts of Job Readiness Skills Training on Young Adults with Autism: A Qualitative Analysis

C. Okyere *and C. Sung, Department of Counseling, Educational Psychology and Special Education, Michigan State University, East Lansing, MI*

Background: Although employment is fundamental to the well-being of individuals with autism spectrum disorder (ASD), less than 20% of young adults with ASD are employed resulting in their limited employment-readiness. While employment-related intervention studies exist that focus on soft and hard skills development across employment preparation, obtainment and retention, there is no intervention that focuses on both soft and hard skill development specifically applicable to employment preparation, obtainment and retention for individuals with ASD. Employment Preparation and Application Skills Support (EPASS) is an employment readiness training program designed to improve the employment-readiness of young adults with ASD. Specifically, EPASS focuses on teaching skills important for obtaining and maintaining employment, including: searching for a job, conducting informational interviews, personal branding, applying for a job, developing a resume and cover letter, pre-employment screenings, developing job interview skills, practicing mock interviews, learning disability law and accommodations, and maintaining a job. The 12-session EPASS intervention was delivered during spring semesters at a community center conference room to three cohorts of eligible participants over the course of three years.

Objectives: The purpose of this study was to understand the experiences of transition-aged youth with employment readiness pre and post participation in the three-year pilot EPASS intervention. We explored participants experiences to assess the impact of the pilot EPASS intervention on their employment readiness.

Methods: Following approval from the university's Institutional Review Board, convenience sampling was used to recruit transition-aged youth with ASD (17-25 years of age) from a university disability resource center and a local school district. A qualitative descriptive design (Sandelowski 2010) was employed with 25 transition-aged youth with ASD and data were collected using semi-structured interviews.The data were analysed to identify themes as they emerged.

Results: Using Braun and Clark's (2006) thematic analysis, five major themes were identified: (a) Experiences with Employment pre EPASS Intervention; (b) Expectations of the EPASS Intervention; (c) Experiences with the EPASS Intervention; (d) Future Application of Acquired EPASS Skills; and (e) Recommendations for the EPASS Intervention. Overall, transition-aged youth with ASD reported significant improvement in both soft and hard skills for employment readiness post-intervention. Participants also provided recommendations that might further advance the impact of the EPASS intervention.

Conclusions: Employment-related interventions such as EPASS is significant to the employment achievements of transition-aged youth with ASD. Future intervention studies could focus on applying experiential learning strategies and video-based instruction to address additional work related and training gaps for transition-aged youth with ASD (e.g., managing personal expenses; conflict management in the workplace; securing volunteer, internships and actual job opportunities). In addition, developing instruments that measure work-related social function, job readiness and performance-based skills could assist professionals in making placement decisions relating to participation in EPASS or other employment related interventions. Finally, encouraging families and caregivers to support the employment and training needs and programs for transition-aged youth is significant to their optimal quality of life.

428.047 *(Poster)* Individualized Learning with Video-Based Instruction When Teaching How to Solve Fractions to Middle School Students on the Autism Spectrum

G. Yakubova[1]*, E. M. Hughes*[2] *and B. B. Chen*[1]*, (1)University of Maryland, College Park, MD, (2)Pennsylvania State University, State College, PA*

Background: Students with autism spectrum disorder (ASD) commonly exhibit challenges with mathematics, which is a necessary skill for not only college and career readiness, but also for everyday independent living skills. There is limited research in this area among students with ASD, with much of the literature focusing instead on strategies for students with high-incidence disabilities, e.g., learning disabilities. With the increasing number of students with ASD included in general education settings, it is necessary to determine effective mathematics support strategies that can be individualized for each student's needs and can be feasibly used in inclusive settings.

Objectives: The purpose of this study was to evaluate the effects of an individualized intervention package including point-of-view video modeling (POVM), concrete manipulatives, guided practice, and a self-monitoring checklist, on the fraction problem-solving accuracy of three middle school students with ASD.

Methods: A multiple probe across students design of single-case research design (SCRD) consisting of baseline, intervention, and generalization phases, was used to identify the effects of the intervention package on the fraction problem-solving accuracy of three students with ASD. One female and two male students, ages 12-13, who were each diagnosed with ASD and performed well below grade level in mathematics, participated in this study. During each session, students were evaluated on their accuracy on a 5-question worksheet, which included questions on adding and subtracting simple proper fractions. Baseline sessions consisted of students completing a worksheet with no instructor assistance. During intervention, students watched the POVM which demonstrated how to solve the type of fraction problems on their worksheets using concrete manipulatives (fraction tiles). After watching the POVM, students completed a guided practice session with the instructor using fraction tiles and a self-monitoring checklist that listed the problem-solving steps used in the POVM clip. Then students used the fraction tiles and self-monitoring checklist to independently complete a worksheet with different fraction problems each time. Once students reached the mastery criterion of 100% accuracy for two consecutive sessions, they completed generalization probes which followed the same conditions as baseline. The generalization probes evaluated whether students would generalize solving simple proper fractions to solving whole proper fractions.

Results: All three students improved their accuracy of fraction problem solving from baseline to intervention, and two of three students demonstrated generalization of the skills to whole proper fractions. The weighted average Tau-*U* for baseline/intervention phases was Tau-*U*= 1.0, $p<0.0001$, 90% CI= [0.6418,1], demonstrating the overall positive effect of the intervention across students. The weighted average Tau-*U* for all phases (baseline/intervention and baseline/generalization) resulted in 0.785, $p<0.0001$, 90% CI= [0.4756, 1].

Conclusions: The intervention package consisting of POVM, concrete manipulatives, guided practice, and a self-monitoring checklist was effective in improving the accuracy of fraction problem-solving among three students with ASD, suggesting that this may be an effective individualizable strategy for teachers to support students with ASD in a variety of settings.

428.048 *(Poster)* Ipads for Teaching Graphic Symbols to People with ASD

O. E. Hetzroni[1] *and E. Israel*[2]*, (1)University of Haifa, Haifa, Israel, (2)Special Education, University of Haifa, Haifa, Israel*

Background: Individuals with autism spectrum disorders (ASD) who demonstrate significant cognitive and communication needs (CCN) have been found to benefit from interventions using augmented aids such as graphic symbols for enhancing participation. Augmentative and alternative communication (AAC) has been considered to be effective for individuals with ASD and CCN as they have been considered to have enhanced visual perception. However, recent research has demonstrated differences in the process of learning graphic symbols, such as recognizing abstract similarities, that may contribute to their difficulties in their ability to use AAC successfully and in the development of social skills. Most of the studies incorporating learning of graphic symbols among individuals with ASD with CCN was conducted with children. In light of emerging research suggesting increased cognitive abilities along life trajectory, there is still little knowledge relating to learning of graphic symbols by individuals with ASD and CNN who have the potential for using AAC. Technology may enhance graphic symbol learning and participation among individuals with ASD who have CCN.

Objectives: The purpose of the study was to investigate if using an iPad equipped with an app created for the study, that included explicit strategies aimed for increasing learning of graphic symbols would increase learning of graphic symbols by children and adults with ASD, who have CCN.

Methods: 25 adults (age 18-40) and 25 children (age 7-12) with ASD, who demonstrate significant CCN were presented with a set of tests and an application for learning graphic symbols. Fifteen sets incorporating various types of symbols were presented in the application. Each symbol was presented using several screens incorporating a process developed for enhancing recognition of the symbols using various processes of symbol identification such as matching to sample and video-clips, a passive and a dynamic presentation of symbol parts, and an active assembly of the symbol.

Results: The participants were able to use the iPad with little to no assistance to learn graphic symbol recognition. All participants were able to focus for the duration of the educational software for the 30 minutes required for the fulfillments of the activity. Participants in both groups, adults as well as the children were able to identify the meaning of many of the 15 symbols by the end of the task.

Conclusions: The use of the iPad as a technology enabled control of the stimulus and the distractors, and removal of some of the communication barriers, thus, increasing the participants' ability to learn the symbols. Even participants reported to have significant limitations in their ability to sit and focus, were able to participate in the educational task presented on the iPad for 30 minutes and complete the whole activity. Results of the study demonstrate an increase in the ability to identify the meaning of new symbols learned using the iPad. The use of the iPad for learning symbols enabled participants to improve their learning of symbols though the application created for them.

428.049 *(Poster)* Job Interviewing and Vocational Outcomes Among Autistic Youth

K. Sherwood[1]*, M. Smith*[2]*, S. Blajeski*[3]*, J. D. Smith*[4]*, N. Jordan*[5]*, B. Ross*[3]*, L. E. Smith DaWalt*[6]*, L. Bishop*[7] *and M. S. Atkins*[8]*, (1)University of Michigan-Ann Arbor, Ann Arbor, MI, (2)University of Michigan, Ann Arbor, MI, (3)School of Social Work, University of Michigan, Ann Arbor, MI, (4)Northwestern University, Chicago, IL, (5)Department of Psychiatry and Behavioral Sciences, Northwestern University, Chicago, IL, (6)University of Wisconsin-Madison Waisman Center, Madison, WI, (7)University of Wisconsin - Madison, Madison, WI, (8)Psychiatry, University of Illinois-Chicago, Chicago, IL*

Background: Vocational outcomes among autistic youth are critically low. Job interviews are a particularly difficult component of the job seeking process that require complex social communication ability. Moreover, few studies highlight whether interviewing may be critical to obtaining vocational outcomes such as competitive employment or internships. Here we report on whether autistic youth have ever had a competitive job during their lifetime and if they recently interviewed for a job. Second, we will report on whether autistic youth currently have a competitive job, unpaid internship, or paid internship and whether the autistic youth completed an interview to obtain this job or internship. Third, we report on the mean hours worked and wages earned. Last, we report on the types of competitive jobs they obtained.

Objectives: Our study sought to discover whether autistic youth are participating in job interviews to secure vocational outcomes such as jobs and internships.

Methods: We conducted an open trial to evaluate the effectiveness and implementation of a virtual reality job interview training (VR-JIT) tool. This study is an evaluation of the data collected at baseline that represent student-level vocational interviewing and outcomes among the n=44 high schools that implemented VR-JIT within employment-related transition services. School staff (n=29 teachers, n=35 administrators) completed surveys reporting on the backgrounds and employment history of n=138 autistic students compared to n=518 students with non-autistic educational disabilities. Diagnoses were established using individualized education plan (IEP) classification. School teachers or administrators completed surveys assessing background characteristics (e.g., age, race, reading level, educational disability category) and employment and internship history (e.g., current and lifetime employment, interviewing history, hours worked per month).

Results: Results suggest 17.5% of autistic youth were currently employed (compared to 21.7% of non-autistic youth), and 91.7% of the employed autistic youth interviewed prior to obtaining their job (compared to 88.8% of the non-autistic youth). We also observed that autistic youth, as compared to non-autistic youth, had a lower lifetime employment rate (29.2% vs. 43.3%; X2=8.9, p=0.003) and trended towards working fewer hours (m=48.5 [sd=31.0] vs. 62.2 [sd=34.5], T=1.8, p=0.078). We observed that autistic youth, as compared to non-autistic youth, worked fewer hours at their paid internship (m=11.6 [sd=6.0] vs. 24.5 [sd=15.3], T= -4.1, p<.001); earned a lower hourly wage at their paid internship (m=4.92 [sd=0.9] vs. 6.36 [sd=2.3], T= -3.0, p=0.005); and trended towards working fewer hours per month at their unpaid internships (m=15.4 [sd=20.2] vs. 23.8 [sd=24.4], T= -1.7, p=0.092).

Conclusions: In summary, our results revealed that autistic youth receiving employment-focused transition services had a current employment rate of 17.5%. With respect to autistic youth in this study who were currently employed, we observed that the vast majority of them interviewed prior to getting hired (91.7%). It appears that the rate of participating in a job interview speaks to the importance that training in job interview skills is a critical target for transition services. The delivery of evidence-based job interviewing training is a major gap in transition services for autistic youth.

428.050 *(Poster)* Kneuroknits: Evaluating Social Participation and Anxiety Response Associated with Participation in a Knitting Group for People with Neurological Conditions (Pilot Study)

A. Kapur[1]*, M. Penner*[2]*, J. Nguyen*[2]*, L. R. Hartman*[3]*, A. Kushki*[4]*, K. Cook*[5] *and P. Waters*[5]*, (1)Autism Research Centre, Holland Bloorview Kids Rehabilitation Hospital, Toronto, ON, Canada, (2)Holland Bloorview Kids Rehabilitation Hospital, Toronto, ON, Canada, (3)Therapeutic Recreation and Life Skills, Holland Bloorview Kids Rehabilitation Hospital, Toronto, ON, Canada, (4)Bloorview Research Institute, Toronto, ON, Canada, (5)Holland Bloorview Hospital, Toronto, ON, Canada*

Background: Knitting as a creative practice has a reputation for being therapeutic. There are many programs that use crafts as a method of creating social community and reducing anxiety for youth; however, there is no existing research that demonstrates these benefits. We designed a novel study to explore the benefits of a social skills knitting group on engagement and anxiety for youth with neurodevelopmental disorders.

Objectives: 1. To evaluate the social engagement experience of youth with neurological conditions participating in the KneuroKnits program.

2. Evaluate the impact of KneuroKnits intervention on anxiety levels of participants.

Methods: We designed a 4-week knitting group for youth with neurodevelopmental disorders and acquired brain injuries. Each session included a lesson involving a knitting skill and a social skill. To evaluate social engagement, we used the Self-reported Experience of Activity Settings (SEAS) questionnaire at the first and final sessions. The five subcategories of the SEAS (Personal Growth, Psychological Engagement, Social Belonging, Meaningful Interactions and Choice & Control) were analyzed following the first and the last session. Qualitative interviews were conducted with participants, parents, and facilitators in the month following the final session and were analyzed using an interpretive phenomenological approach to outline commonly occurring themes in social engagement. To evaluate anxiety levels, participants completed the State-Trait Anxiety Inventory (STAI) at the beginning and end of the first and final sessions, respectively, and the Symptom Checklist-90-R (SCL-90) anxiety subscale; qualitative analysis included themes involving levels of anxiety from the interviews.

Results: There were 14 total participants with a mean age of 17.4 ± 2.2 years. Participants had primary diagnoses of ASD (n=9); acquired brain injury/concussion (n=4), and developmental coordination disorder (n=1). Social engagement results for the SEAS questionnaire showed a general increase in mean scores of all subcategories with a significant increase in the category of "Meaningful Interactions (p=0.02). This quantitively demonstrated that the group had an impact on creating meaningful social connection. Qualitative analysis of the interviews revealed three commonly occurring themes: The balance of organic and facilitated social interaction, a sense of community from shared experience, and direct benefits of knitting (pride, productivity, relaxation, a choice to be social). For the evaluation of anxiety levels, the STAI demonstrated a significant decrease in anxiety following both Session 1 (p=0.02) and Session 4 (p=0.006). The SCL-90-R Anxiety subsection scores significantly decreased between the first and final session (p=0.01). Participants voiced that the sessions made them feel calmer.

Conclusions: This knitting group merged a creative skill and social skill, and was novel in its approach to studying social engagement and anxiety within this population. Our study found that participants, their families and facilitators found KneuroKnits to be a valuable and rewarding program. Further study is needed in a larger sample to confirm our findings.

428.051 *(Poster)* Learning to Play and Emote: A Pilot Intervention for High-Functioning School-Aged Children with Autism Spectrum Disorder

E. A. Doernberg[1]*, A. Dimitropoulos*[2] *and S. W. Russ*[2]*, (1)Psychological Sciences, Case Western Reserve University, CLEVELAND, OH, (2)Psychological Sciences, Case Western Reserve University, Cleveland, OH*

Background: Autism Spectrum Disorder (ASD) is a neurodevelopmental disorder marked by socio-emotional deficits beginning in early childhood, greatly impacting functioning throughout development. Pretend play abilities in childhood are indicative of adaptive functioning and emotion regulation skills in later life (Russ, 1998; 2014), and the use of a pretend play intervention with typically developing children has shown to significantly increase cognitive and affective skills in play (Hoffman and Russ, 2012). Research has demonstrated that preschool-aged children diagnosed with ASD have impaired play skills compared to typical peers, but following a play intervention are able to execute improvements in these skills that generalized to increased social functioning at follow-up (Kasari, 2006; 2012).

Objectives: The present pilot study implemented an in-person pretend play intervention to a stratified sample of school-aged children diagnosed with high-functioning ASD (HF-ASD), with the goals of increasing children's cognitive and affective skills in play, while examining if these changes generalized to their learned emotional understanding abilities and social skills.

Methods: The present study involved a play intervention administered in-person to high-functioning children diagnosed with ASD, ages 6 to 9. Twenty-five children were recruited (intervention group = 18, waitlist control group = 7). Baseline and outcome visits were completed to obtain measures of cognitive and affective play skills, emotional understanding abilities, and social skills, as measured by the Affect in Play Scale (APS; Russ, 1993;2014), the Kusche Affective Inventory, Revised (KAI-R; Kusche et al., 1988), and the Social Skills Inventory System, Parent and Teacher Forms (SSIS; Gresham and Elliott, 2008), respectively. Intervention sessions were 15-20 minutes in length, administered weekly for 5 weeks. The play intervention was adapted from a validated method for typically developing children (Russ, Moore, and Farber, 2004), wherein the play facilitator uses pretend story stems to play with the child individually, employing techniques such as modeling, scaffolding, praising, reflecting emotions, and following the child's lead.

Results: A series of mixed factorial repeated measures ANOVAs were used to evaluate within and between group differences from baseline to outcome. Results indicated that children in the intervention group significantly increased their cognitive skills in play, while the waitlist control group made no changes on these variables. Additionally, the intervention group significantly increased in their ability to describe personal emotional experiences, while the waitlist control group did not demonstrate any changes. Neither group exhibited any meaningful changes in affective skills in play nor general social skills (per teacher report) from baseline to outcome.

Conclusions: Findings from the present pilot study demonstrate the positive impact of a play intervention on cognitive play skills and emotional understanding abilities in children with HF-ASD, while affective skills in play and social skills (per teacher report) were not influenced. Limitations included the small sample size for the comparison control group, as well as lacking parent report on children's social skills. Results have important implications for the efficacy of a short, easily facilitated play intervention for children with HF-ASD, indicating that increasing their play abilities can generalize to increases in children's emotional understanding abilities.

428.052 *(Poster)* Mental Health Interventions for ASD: A Systematic Review of Intervention Adaptions and Community Implementation Outcomes

K. S. Dickson[1]*, A. Jobin*[1,2,3]*, M. Kinnear*[4]*, T. Lind*[5] *and L. Brookman-Frazee*[1,3,6]*, (1)Child and Adolescent Services Research Center, San Diego, CA, (2)Rady Children's Hospital San Diego, San Diego, CA, (3)Psychiatry, University of California, San Diego, La Jolla, CA, (4)Rady Children's Hospital-San Diego, San Diego, CA, (5)University of California, San Diego, La Jolla, CA, (6)Autism Discovery Institute, Rady Children's Hospital-San Diego, San Diego, CA*

Background: Co-occurring psychiatric conditions that necessitate mental health (MH) treatment are common among youth with ASD. There has been an increasing emphasis on MH treatments for ASD over the past two decades, and data supporting the efficacy of such interventions (Vasa et al., 2018; White et al., 2018). The need to adapt or modify existing interventions prior to implementation for use with youth with ASD is common (Moree & Davis, 2014). However, the nature of such adaptations and associated impact on implementation outcomes (e.g, acceptability, feasibility, fidelity) is unknown. Further understanding of the nature and type of adaptions and key community implementation outcomes is critical to responding to calls and efforts to improve the translation of evidence-based interventions (EBIs) for ASD in the community (Wood et al., 2015).

Objectives: This systematic review examines the existing research testing intervention targeting MH outcomes for children with ASD to characterize the nature and types of adaptions to existing EBIs prior to delivery, including in the community, and implementation outcomes examined.

Methods: A systematic review was preformed to identify published articles testing interventions targeting MH systems specifically for youth ASD, including efficacy and effectiveness trials. Web of Science, Scopus, PubMed, PsychINFO, and CINAHL Plus databases were searched. Data extraction included a) study setting, design, and methodology; b) intervention target, participants, format; c) whether the intervention was developed or adapted for ASD; d) the nature and function of adaptions; e) implementation outcomes (e.g., appropriateness, feasibility, fidelity). Child, family, and provider characteristics were also extracted.

Results: 5629 articles were screened by five reviewers, resulting in inclusion of 121 articles, representing more than 35 unique or name-brand MH interventions primarily examined as part of an efficacy (67% of articles) or effectiveness (33% of articles) trial. Quantitative, qualitative, and mixed-method approaches were used in 53%, 2%, and 35% of studies, respectively. Results indicated that 38% and 30% of included articles examined an intervention with anxiety or disruptive or challenging behaviors as the primary MH target. The majority (79%) of the interventions targeted school-age youth, with 50% and 10% of interventions targeting adolescents and transition age youth, respectively. Forty-eight percent of articles included interventions that were originally developed for ASD whereas 54% examined existing MH interventions adapted for youth with ASD. The majority of adaptions were designed to make interventions more appropriate for ASD (e.g., more visuals, emphasis on generalization). Within community effectiveness trials, few of the specified adaptations aimed to improve the fit of the intervention with provider training needs or service settings. The use of existing theories or frameworks to guide these adaptations was rare. Finally, fidelity was the most commonly examined implementation outcome, with feasibility and acceptability less commonly examined.

Conclusions: This systematic review enumerated the ways in which MH interventions are adapted for ASD, and the nature and types of implementation outcomes examined. Findings point to key recommendations for future research, including further specification, reporting, and application of existing theory during intervention adaptation and examination of key implementation outcomes beyond fidelity.

428.053 *(Poster)* Mixed Martial Arts Training Improves Social Skills and Lessens Problem Behaviors in Children with Autism Spectrum Disorder

J. N. Phung[1] *and W. A. Goldberg*[2]*, (1)Psychology, California State University San Marcos, San Marcos, CA, (2)Psychology and Social Behavior, University of California, Irvine, Irvine, CA*

Background: Difficulties with social functioning are a defining feature among children with Autism Spectrum Disorder (ASD). However, adaptive social skills can be acquired, and problematic social behaviors can be lessened through the use of interventions within the community.

Objectives: The present study evaluated the effectiveness of a mixed martial arts (MMA) intervention for improving social skills and lessening problematic social behaviors in a sample of school-aged (8-11 years) children with ASD.

Methods: Children with ASD were randomly assigned to either a MMA intervention or a waitlist control (WLC) condition after an initial lab visit where parents reported on child social functioning (pre-test). Children in the MMA group then began the intervention at a local martial arts studio. The intervention ran about 13 weeks (26 sessions) and included typically-developing peers who assisted by interacting with the children with ASD and modeling appropriate social behaviors. The WLC group did not participate in any martial arts between pre- and post-test assessments. After the intervention completed, both groups returned to the lab where parents reported on social functioning again (post-test).

Results: Results indicated that the MMA group had significantly higher social skills and lower problem behaviors as reported by parents at post-test compared to the WLC group and compared to pre-test scores.

Conclusions: The peer-mediated intervention appeared to be successful in improving the social functioning of children with ASD. Implications and future directions for peer-mediated martial-arts interventions for children with ASD will be discussed.

428.054 *(Poster)* National Clearinghouse on Autism Evidence & Practice (NCAEP): Examining the Participation of Individuals with ASD across Racial and Ethnic Groups and Gender in High Quality Intervention Studies

J. R. Steinbrenner[1], *N. S. McIntyre*[2], *L. F. Rentschler*[3], *K. Hume*[1] *and S. Odom*[1], *(1)Frank Porter Graham Child Development Institute, University of North Carolina at Chapel Hill, Chapel Hill, NC, (2)University of California at Davis, Davis, CA, (3)School of Education, University of North Carolina - Chapel Hill, Chapel Hill, NC*

Background: The National Professional Development Center on ASD (NPDC) completed a review of literature published between 1990-2011 and identified 27 evidence-based practices (EBPs) for individuals with ASD from birth through age 22. A team of researchers analyzed data reported about race, ethnicity, and nationality (REN) from articles included in the previous review (West et al., 2016) and found that few articles reported information on REN (17.9%). The National Clearinghouse on Autism Evidence & Practice (NCAEP) is in the final stages of updating the previous review of literature to include articles published from 2012-2017. In addition to determining any new and emerging EBPs, it is also important to assess the reporting and inclusion of individuals with ASD across different REN, as well as examine the representation of participants across gender and/or sex.

Objectives: The objectives of this session are to (1) determine the proportion of studies that reported data on REN and sex and/or gender, and (2) examine the proportions of studies and participants within studies based on these characteristics.

Methods: The NCAEP team used the same search strategy as the 1990-2011 systematic review, using key search terms related to autism (e.g., ASD, Asperger, autistic) and intervention (e.g., education, treatment, strategies). The inclusion criteria are experimental or quasi-experimental studies that examine behavioral, educational, or developmental (i.e., non-medical) interventions with participants with ASD from birth through 22 years of age. The research team followed a rigorous systematic review process including initial search, screening, full-text reviews, quality reviews, and data extraction. During data extraction, the research team used the procedures of West et al. (2016) to extract data REN and gender/sex from all high-quality studies. Research assistants were trained to reliability. Over 90% of the articles have been coded for the REN and gender/sex data, and 25% of those articles have been coded for reliability. Coding will be complete in late fall 2019.

Results: Of the 580 articles currently coded for participant information, 530 of all articles report information on gender or sex (91.4%), including 92.5% of single-case design (SCD) studies and 87.6% of group studies. The proportion of participants who were reported as male was 84.6% overall, and 82.6% and 85.0% for SCD and group studies, respectively. Only 179 of 580 articles report information on REN (30.9%), with reporting of 25.2% in SCD studies and 48.9% in group studies. The proportion of participants who were reported as non-white was 38.0%. Table 1 has additional information about the studies and participants reporting of REN data for participants.

Conclusions: Overall, there has been an increase in the reporting of REN data between the 1990-2011 and 2012-2017 reviews, moving from 17.9% to 30.9% . However, the proportion of articles reporting REN data is still strikingly low. Notably, the reporting has greatly improved in group studies, moving from 28.2% to 48.9%.There was little difference in the proportion of non-white participants included in research between the original review (36.5%) and the recent update (38.0%).

428.055 *(Poster)* National Clearinghouse on Autism Evidence & Practice (NCAEP): Identifying New Evidence-Based Practices for Children and Youth with ASD

K. Hume[1], *J. R. Steinbrenner*[1], *S. Odom*[1], *B. Tomaszewski*[1,2,3], *K. L. Morin*[4], *S. W. Nowell*[5], *N. S. McIntyre*[6], *S. Szendrey*[7], *M. Savage*[8] *and S. Yucesoy-Ozkan*[9], *(1)Frank Porter Graham Child Development Institute, University of North Carolina at Chapel Hill, Chapel Hill, NC, (2)Psychiatry, University of North Carolina at Chapel Hill, Chapel Hill, NC, (3)TEACCH Autism Program, University of North Carolina at Chapel Hill, Chapel Hill, NC, (4)Lehigh University, Bethlehem, PA, (5)University of North Carolina - Chapel Hill, Chapel Hill, NC, (6)University of California at Davis, Davis, CA, (7)Allied Health, University of North Carolina, Chapel Hill, NC, (8)Educational Psychology, University of North Texas, Denton, TX, (9)Anadolu University, Eskisehir, Turkey*

Background: The National Professional Development Center on ASD (NPDC) completed a review of literature published between 1990-2011 and identified 27 evidence-based practices (EBPs) for individuals with ASD from birth through age 21. These findings have had a broad impact on the field since their publication in 2015 (e.g. most cited manuscript in JADD in 2017; identified by IACC as one of the top 20 scientific advances in ASD research). These findings are dated, however, and the National Clearinghouse on Autism Evidence and Practice (NCAEP) conducted an updated review of the literature and new findings related to the identification of EBPs will be available for IMFAR 2020.

Objectives: The objectives of this session are to (1) identify new practices that have met the criteria for identification as an evidence-based practice, and (2) identify for what outcomes the practices have an effect.

Methods: The NCAEP team used the same search strategy as the 1990-2011 systematic review, for peer-reviewed articles using variations of the terms (1) autism(e.g., ASD, Asperger) and (2) intervention (e.g., treatment, program, education). The inclusion criteria are experimental or quasi-experimental studies (single-case design and group design) that examine a behavioral, educational, or developmental (i.e., non-medical) intervention for individuals with ASD from birth through 22 years old. The following steps were completed for the systematic review: (1) search of 9 databases, (2) deduplication of results, (3) title/abstract review, (4) full-text review for inclusion, (5) quality review, determination of effects, and preliminary data extraction by trained external reviewers, and (6) consensus decision for quality and presence of effects as needed. The NCAEP team is currently in the process, of reviewing and finalizing the data extraction, which is combining the information about effects, interventions, outcomes, and participants across the 1990-2011 and 2012-2017 reviews.

Results: The 2012-2017 review started with over 31,000 articles in the initial search. Currently, 631 articles have met quality criteria and demonstrate at least some positive effects. The participant data indicates that more studies include 6-11.9 year-olds (59%) and 3-5.9 year-olds (45%) participants, with fewer studies including 12-14.9 year-olds (27%), 15-18 year-olds (18%), and the fewest studies including children under 3 years old (9%) and 19-22 year-olds (5%) . The data also shows that social (26%), communication (29%), and challenging behavior (20%) domains are the most common intervention targets.

Ongoing analysis indicates the identification of at least two new EBPs (behavioral momentum and Self-Regulated Strategy Development) and the reorganization and reclassification of three more (including Augmentative and Alternative Communication). Additional “named” interventions (e.g. Reciprocal Imitation Training, PEERS) that have met a threshold for evidence have been identified as well.

Conclusions: The updated systematic review of behavioral and developmental interventions is an important step as research and practice continue to move forward to facilitate the best outcomes for children and youth with ASD. New evidence will provide additional data related to the efficacy of new interventions, better identify practices that are effective with young adults with ASD, and highlight outcome areas with limited research investment (e.g. mental health, vocational).

428.056 *(Poster)* Navigation-Guided Repetitive Transcranial Magnetic Stimulation (rTMS) over Ventral Attention Network of Neurodevelopmental Disorders.

M. Nakamura[1], *J. Fujino*[1], *T. Itahashi*[1], *Y. Aoki*[2], *H. Ohta*[1], *R. Hashimoto*[3] *and N. Kato*[1], *(1)Medical Institute of Developmental Disabilities Research, Showa University, Tokyo, Japan, (2)Showa University, Tokyo, Japan, (3)Tokyo Metropolitan University, Tokyo, Japan*

Background: Attention is the initial phase of information processing and thus a neural basis of flexible behavioral adaptation. Neurodevelopmental disorders such as autism spectrum disorder (ASD) and attention deficit hyperactivity disorder (ADHD) exhibit distinct and shared attentional deficits. However, neuromodulation of the attention networks has not been sufficiently established in these neurodevelopmental disorders.

Objectives: The present preliminary study was aimed to explore any changes in attention shift, following a single session of navigation-guided repetitive transcranial magnetic stimulation (rTMS) over the ventral (bottom-up) attention network in healthy adults of typical neurodevelopment (TD), ASD adults, and ADHD adults.

Methods: As a prior brain information, structural MRI, functional MRI (fMRI), resting-state fMRI, and diffusion tensor imaging (DTI) were scanned before rTMS session. Based on structural MRI data, rTMS was navigated to right anterior temporoparietal junction (TPJ) (55, -44, 18 in MNI coordinates), a hub of the ventral attention network. rTMS protocols were intermittent theta burst stimulation (iTBS), continuous theta burst stimulation (cTBS), and sham stimulation with a sham coil. Neuropsychological test battery, including attention shift, processing speed, continuous performance test, face recognition, and spatial working memory, was evaluated before and after a rTMS session.

Results: In TD adults (n=16), attention shift scores got worse following both iTBS and cTBS, as compared with sham stimulation. In contrast, adults (N=13) with ASD and/or ADHD showed improvement of attention shift scores following iTBS and cTBS. Moreover, it should be noted that some adults responded to facilitatory iTBS, while some others responded to inhibitory cTBS. In terms of the pre-existing functional connectivity between right anterior TPJ and right middle frontal gyrus (MFG) within the ventral attention network, there was a tendency that subjects with the stronger connectivity responded to inhibitory cTBS and subject with the weaker connectivity responded to facilitatory iTBS. Neuropsychological tests of continuous performance test, face recognition, and spatial working memory did not change after any rTMS protocol over right anterior TPJ in both study groups.

Conclusions: The worsening of attention shift observed in TD adults could be attributable to a potential destabilizing effects of facilitatory and inhibitory rTMS protocols on the ventral attention network, because the network of TD adults seems to be tuned and optimized for attention shift. On the other hand, the ventral attention network of adults with ASD and/or ADHD may not be properly tuned and thus facilitatory or inhibitory rTMS could adjust the network into a normal range, resulting in improvement of attention shift scores. It could be speculated that prior MRI information may be useful to optimize and personalize rTMS protocol over the ventral attention network of neurodevelopmental disorders.

428.057 *(Poster)* Observed Effects of the PEERS Social Skills Intervention for Adolescents with ASD: A Predominantly Latinx Sample

E. Veytsman[1], *E. Baker*[2] *and K. K. Stavropoulos*[1], *(1)Graduate School of Education, University of California Riverside, Riverside, CA, (2)University of California Riverside, Riverside, CA*

Background: Adolescents with ASD have difficulty initiating and maintaining conversations with peers, affecting their ability to develop friendships (Reichow & Volkmar, 2010). Social skills interventions targeting conversational skills have demonstrated effectiveness (Laugeson et al., 2009, 2012), but few studies have utilized objective behavioral outcome measures. Using behavioral measures to assess treatment outcome can provide better evaluation of skill generalization and overcome biases in parent- and self- report (Lord et al., 2005). The Contextual Assessment of Social Skills (CASS; Ratto et al., 2011) is a commonly used observational measure of conversational skills following the PEERS social skills program (e.g., Dolan et al., 2016; Rabin et al., 2018), but its specificity to the skills targeted has been under-examined.

Objectives: The purpose of this study is to evaluate the utility of an adapted version of the CASS to measure changes in conversational skills following a social skills intervention with a Latinx sample of adolescents with ASD.

Methods: Participants included seven adolescents with ASD (six males; 71% Latinx), ages 11-16 (*M*=13.3, *SD*=1.9) with average cognitive abilities (WASI-2; *M*=104.1, *SD*=17.4). Adolescents and parents attended concurrent but separate weekly 90-minute PEERS sessions over 16 weeks. Adolescent groups were held in English; parent groups were conducted in English and Spanish simultaneously. Participants had 3-minute filmed interactions with an unfamiliar peer (i.e., a research confederate) at pre- and post- intervention, and were rated on the original nine CASS items by two blind independent raters. Seven additional items were added to coding to better represent the specific skills taught, including the number of open-ended questions and follow-up questions asked, and the appropriateness of questions and comments. Average inter-rater agreement for the combined 16 items was 0.76. Filmed interactions for a second cohort of eight adolescents (currently underway), as well as follow-ups with the first cohort, will be coded using the adapted CASS.

Results: Though paired samples t-tests revealed parent-perceived improvements in social skills (SSIS; $p<.01$) and social responsiveness (SRS-2; $p=.02$) following treatment, preliminary analyses did not demonstrate significant changes in observed conversational skills. Although the small sample size in this preliminary study limits conclusions, we offer two interpretations. First, the original CASS scores may not capture the specific skills that would be expected to change following PEERS. Second, for the newly added items, group level analyses may not reflect meaningful change in a heterogeneous group. For example, an increase in the number of questions asked may reflect an improvement for some, while a decrease may reflect a positive change for others, as their baseline levels of question asking may have been inappropriately high.

Conclusions: Informant reports of social skills gains after intervention are prone to bias, and may differ from actual performance (Mcdonald, 2008). Integrating behavioral measures with parent- and self-report provides the best evidence of treatment effectiveness. Meaningful behavioral measurement following group-based social skills intervention is challenging, due to the heterogeneity of social errors among participants. With follow-up data and a larger sample size, observed conversational improvements will be analyzed in the context of individual social needs.

428.058 *(Poster)* Open Trial of College Success Intervention: Increasing Executive Functioning and Social Skills in College Students with ASD

M. Baker-Ericzen[1] *and A. Tran*[2]*, (1)Rady Children's Hospital San Diego, San Diego, CA, (2)Child and Adolescent Services Research, Rady Children's Hospital, San Diego, CA*

Background: About 50,000 students with autism spectrum disorder (ASD) exit high school annually. Unfortunately, the outlook for the transition to adulthood is bleak, with over 66% of young adults with ASD failing to transition into postsecondary educational (PSE) institutions or employment shortly after leaving high school. For those who do participate in PSE, approximately two thirds do not obtain a degree. As the neurobiological basis of autism is further investigated, new interventions are focusing on remediating the core deficits specific to social and cognitive dysfunction in ASD. Impairments in executive functioning are considerable in individuals with ASD , and it is likely that these impairments are a leading cause of disability in ASD.

Objectives: A new, innovative program was developed, College SUCCESS to teach cognitive executive functioning and social cognitive functioning skills that are often referred to as “soft skills” necessary to succeed in college. This open trial research study investigated college students cognitive and social skills, functional ability and education outcomes as a result of receiving the College SUCCESS curriculum. Feasibility, acceptability and satisfaction data were collected.

Methods: A total of 25 students (μ= 22.6 SD=4.1 yrs; range 18-34yrs) participated. The participants were male (76%), race/ethnically diverse (64%), average IQ ((μ= 64.6 SD=15.6), 72% participated on University and 28% on Community College campuses, 76% receiving Disability Services. 32% received MH counseling and 13% on medication. The College SUCCESS curriculum was delivered 1-2xs totaling 90-180minutes per week (differing for quarter vs semester campuses) via an active group. Skills taught include executive functioning: attention, learning, memory, prospective memory, cognitive flexibility, problem solving, goal oriented thinking and contextual awareness and social cognition: social conversation (giving and receiving compliments, feedback and help), social relationships, initiations, social media, social networking and self-advocacy. Pre and post assessments included a full battery of assessments including 1) cognitive skills: self-, parent-report (BRIEF-A) & observation (Challenge Task-CT); 2) social skills: self-, parent-report (SRS-2), & observation (Social Skills Performance Assessment-SSPA); 3) academic functioning skills and 4) satisfaction. Data was gathered from standardized measures (participant and parent report) and college staff ratings.

Results: Two students had perfect attendance; average # of missed groups=3.67. Outcome analyses used paired sample t-tests. Findings reveal significant differences on cognitive (ES=.20-.63), social (ES=.30-.67) and functioning measures (ES=.37-2.05) indicating medium to large effects across informants. (Refer to Tables 1 & 2 & 3). Also, 70-75% students improved academic skills and 100% were observed by the facilitator to use new skills in course. Further, 100% of participants and 100% of parents reported the SUCCESS program overall was excellent and 92% students reported it helped them and 100% parents reported it helped their young adult.

Conclusions: This study demonstrates that a College soft skills intervention positively impacts students with ASD. This College program revealed high satisfaction and promise towards improving academic outcomes for adults with ASD.

428.059 *(Poster)* Outcome Comparison for Individual Versus Group-Based Aquatic Therapy for Treatment of Autism Spectrum Disorder: A Randomized and Controlled Clinical Trial.

T. McKinney*, B. Moseley and S. Rush, Turn Center, Amarillo, TX*

Background: There are many newly emerging therapeutic options in the treatment of Autism Spectrum Disorder (ASD). Recent studies have shown promising outcomes with regards to aquatic therapy. In this study, we aim to explore aquatic therapy strategies and compare their ability to improve pediatric quality of life.

Objectives: To compare the outcomes of an individualized, one-on-one aquatic therapy approach versus a group setting aquatic therapy approach in the treatment of ASD.

Methods: An IRB-approved prospective, randomized and controlled clinical study design was used to recruit children ages 3 to 15 presenting with DSM V diagnosis of ASD that were treatment naïve to previous aquatic therapy. Using simple randomization technique, all enrolled participants were assigned to receive standardized intervention with either one-on-one aquatic therapy (the control cohort) or group setting (consisting of 2-5 children) aquatic therapy (the study cohort) while both continuing on with any existing land-based therapies. The aquatic therapy was given forty five minutes weekly for a total of 10 weeks. Study population characteristics and various outcome measures were collected and compared among both arms of the trial at baseline and at the conclusion of the 10 week intervention period. The main outcome variable consisted of change in the PedsQL^{TM} pediatric quality of life inventory. Standard deviation of the Global PedsQL^{TM} for our study population was determined to be 12 by a pre-treatment sampling of the first five enrolled children. Using power of 90%, alpha of 0.05 and difference to detect of 20 (33% difference from the sampling mean), the sample size was calculated to be 20 total patients.

Results: The study enrolled a total of 28 children of whom there were 22 that completed the 10 week treatment regimen: fourteen children in the control cohort that received individual aquatic therapy and eight children in the study cohort that received group aquatic therapy. There were no significant differences in any of the study population demographics or baseline PedsQL^{TM} scores among the two cohorts ($p>0.05$ for all). After the intervention, both cohorts combined showed statistically significant improvement from baseline by 7.6 points in the Global PedsQL^{TM} ($p=0.0464$), with the most improvement in the Emotional ($p=0.0148$) and Social ($p=0.0201$) Functioning but not in the Physical ($p=0.2203$) or School ($p=0.6643$) Functioning. But there were no significant differences ($p=0.3962$) among the individual versus the group-based aquatic therapy cohorts when comparing change in Global PedsQL^{TM} score over the 10 week study period (+9.1 [+3.2 to +15.0] versus +5.1 [-2.7 to +12.8]; [95% Confidence Intervals]).

Conclusions: Aquatic therapy continues to show promising outcomes as an adjunctive treatment for children with ASD with respect to pediatric quality of life. Emotional and social functioning demonstrate the greatest improvement. There is no distinct clinical advantage for using either an individual versus a group-based aquatic therapy program, but it is more cost-effective for therapists to treat multiple children simultaneously as in a group setting. Future investigations with longer term follow-up are necessary to validate these findings and to determine the optimal treatment strategy when using aquatic therapy for ASD.

428.060 *(Poster)* Outcomes of the PEERS Social Skills Program in Clinical and School Settings

R. L. Hudock[1]*, S. C. Brandjord*[2]*, K. Kromminga*[1]*, C. A. Burrows*[3]*, C. M. Lee*[4] *and D. Restorff*[5]*, (1)University of Minnesota, Minneapolis, MN, (2)Educational Psychology, University of Minnesota, Minneapolis, MN, (3)Pediatrics, University of Minnesota, Minneapolis, MN, (4)Department of Pediatrics, University of Minnesota, Minneapolis, MN, (5)5605 Green Circle Drive, Lionsgate Academy, Minnetonka, MN*

Background: Many teens with autism spectrum disorder (ASD) experience increased social challenges in adolescence as the social environment becomes more complex, which can persist into adulthood (Bauminger & Kasari, 2000; Constantino, 2005; Orsmond et al., 2004). Due to the wide-reaching and long-lasting impact of social challenges, it is important to provide evidence-based interventions to minimize poor quality friendships, social isolation, peer conflict, peer rejection, as well as academic and occupational underachievement. Social skills training can occur in both regular and special education classrooms as well as in clinical settings. The Program for the Evaluation and Enrichment of Relational Skills (PEERS; Laugeson & Frankel, 2010), a curriculum using a cognitive-behavioral approach to teach age-appropriate social skills, attempts to address the social difficulties observed in teens with ASD and teaches ecologically valid social skills.

Objectives: To investigate the results of the PEERS program when implemented in a clinical and school-based setting.

Methods: The PEERS program includes 16 90-minute weekly sessions focused on teaching skills needed to make and maintain friendships. Initial descriptive analyses included 30 adolescents (ages 10-18) enrolled in PEERS an outpatient clinical setting and 40 high school students enrolled in PEERS in a charter school for students with ASD. Within the clinical sample, 90% were male and all demonstrated broadly average language and IQ. Most participants (83%) had a primary diagnosis of ASD, and over half had comorbid diagnoses of ADHD and/or anxiety. Analyses include pre- and post-test comparisons of mean scores on outcome measures, including the Social Skills Improvement System (SSIS), the Social Responsiveness Scale, 2nd Edition (SRS-2), the Test of Adolescent Social Skills Knowledge (TASSK), and the Stress Index for Parents of Adolescents (SIPA). Qualitative data gathered from educators and facilitators via brief interviews were also collected to evaluate barriers and generalization of instruction. Additional pairwise comparisons will be conducted with a larger sample when the next phase of data is collected this winter.

Results: Preliminary analysis shows increases in social skills, improvements in social communication, and improvements in emotional and behavioral outcomes as reported by parents and adolescents. Participants also showed a significant increase in social skills knowledge on the TASSK ($p=0.003$). While parents reported stable, slightly elevated levels of parenting stress, they did report improvement in parent-child relationships. See Table 1 for a summary of mean scores. Challenges within both educational and clinical settings included matching participants to appropriate groups given the heterogeneity of ASD and maintaining attendance and motivation over the course of the intervention; however, facilitators in both settings reported that the curriculum is appropriate for the large majority of participants, suggesting that PEERS can be useful as a universal intervention for students with social challenges. The clinical setting offered more flexibility for intentional group placement, while the school setting offered increased access to students who may not be able to travel to the clinic.

Conclusions: The PEERS Program shows positive outcomes when delivered in practical, real-life settings. Results are promising, as previously reported PEERS outcomes were primarily obtained within clinical research labs.

428.061 *(Poster)* Parent Training to Improve Dental Care in Underserved Children with Autism Spectrum Disorder: A Randomized Controlled Trial

R. M. Fenning[1,2], *E. Butter*[3], *E. Macklin*[4], *M. Norris*[5], *K. Hammersmith*[3], *K. McKinnon-Bermingham*[6], *J. Chan*[4], *K. G. Stephenson*[3], *C. Albright*[7], *J. M. Moffitt*[2,6], *F. Lu*[4], *R. Spaulding*[8], *J. Guijon*[8,9], *J. F. Scherr*[10], *A. Hess*[11], *D. Coury*[3], *K. Kuhlthau*[4] *and R. steinberg Epstein*[12], *(1)Center for Autism, Child and Adolescent Studies, California State University, Fullerton, Fullerton, CA, (2)Pediatrics, The Center for Autism and Neurodevelopmental Disorders, University of California, Irvine, Santa Ana, CA, (3)Nationwide Children's Hospital, Columbus, OH, (4)Massachusetts General Hospital, Boston, MA, (5)Child Development Center, Nationwide Children's Hospital, Westerville, OH, (6)Center for Autism, California State University, Fullerton, Fullerton, CA, (7)Nationwide Children's Hospital, Westerville, OH, (8)Healthy Smiles for Kids of Orange County, Garden Grove, CA, (9)John Guijon DDS Inc, Huntington Beach, CA, (10)Behavioral Health, Nationwide Children's Hospital, Columbus, OH, (11)Psychology, Nationwide Children's Hosptial, Columbus, OH, (12)Pediatrics, The Center for Autism & Neurodevelopmental Disorders, University of California, Irvine, Santa Ana, CA*

Background: Dental care is a common unmet healthcare need of children with ASD, a group vulnerable to excessive plaque, caries, and oral infections. Relative to other populations, children with ASD exhibit heightened distress during dental care and experience increased difficulty participating in home dental hygiene and dental office visits. Multiple factors impede routine dental care for children with ASD, including ASD symptoms and associated comorbidities. Demographic and systemic barriers further compound risk for children from underserved, low income, and economically marginalized families.

Objectives: To test the efficacy of a novel parent training (PT) intervention designed to improve daily home dental hygiene and oral health outcomes in underserved children with ASD.

Methods: Efficacy of our PT intervention was compared to an active Toolkit condition in a multi-site randomized controlled trial. All families received the AS-ATN/AIR-P Dental Toolkit, an electric toothbrush, a six-month supply of dental hygiene materials, and preventive dental visits at baseline, three months (immediate follow-up), and six months (maintenance). Manualized PT included seven in-person sessions and four booster sessions. Participants included 119 families of children with ASD (age *M*=7.4, *SD*=2.6; 55% Caucasian; 38% Hispanic/Latino) reporting difficulty with dental care. Families were all underserved (Medicaid-eligible). Most children presented with comorbid intellectual disability (85%), clinically-elevated behavior problems (61% CBCL Total *T*>63), and significant ASD symptoms (ADOS-2 *M*=7.3, *SD*=1.8). Parents reported on dental history and in-home dental hygiene. A blinded dental visit yielded standardized ratings of plaque (Visual Plaque Index—VPI), caries (Decayed, Missing, and Filled Teeth Index—dmft/DMFT), and gingival health (Gingival Index). Co-primary intervention targets were increased twice-daily home tooth brushing and decreased plaque. Analyses were intent-to-treat using linear and logistic mixed models.

Results: Retention of our underserved sample was high (90%). Baseline characteristics were similar between groups except that PT primary caregivers were more often female and PT families reported less frequent baseline dental hygiene, which was accounted for in analyses. Only PT significantly improved oral health as indexed by decreased plaque at three months (VPI change -0.16, 95% CI -0.29 to -0.03, *p*=.015). Relative to the Toolkit, PT led to a greater decrease in plaque (relative VPI change -0.19, 95% CI -0.36 to -0.02, *p*=.027) and caries (relative mean dmft/DMFT change -0.86, 95% CI -1.61 to -0.11, *p*=.026) at three months. Intervention-dependent oral health improvements lessened during maintenance and were not significant at six months. Frequency of twice-daily tooth brushing improved significantly within each group, but participation in PT led to greater gains at both three (ratio of OR=2.82, 95% CI 1.71 to 4.65, *p*<.001) and six months (ratio of OR=2.21, 95% CI 1.33 to 3.66, *p*=.002). See Figures 1 and 2.

Conclusions: The Toolkit and our novel PT intervention each significantly increased dental hygiene in children presenting with ASD and substantial developmental and behavioral comorbidities. Gains in daily hygiene were greater for PT and only PT enhanced oral health. Efficacy of our short-term PT program suggests avenues for promoting dental care in this high-need population. Successful study recruitment and retention demonstrates the feasibility of engaging underserved families.

428.062 *(Poster)* Physical Contact Via Hugging a Hugvie Can Reduce the Stress of Calling an Unfamiliar Person on the Phone.

H. Kumazaki[1], *H. Sumioka*[2], *Y. Yoshikawa*[3], *H. Ishiguro*[4], *T. Muramatsu*[5] *and M. Mimura*[6], *(1)Department of Preventive intervention for Psychiatric Disorders, National Institute of Mental Health, National Center of Neurology and Psychiatry, Kodaira, Japan, (2)Hiroshi Ishiguro Laboratories, Advanced Telecommunications Research Institute International, Keihanna Science City, Japan, (3)Osaka University, Toyonaka, Japan, (4)Graduate School of Engineering Science, Osaka University, Toyonaka, Japan, (5)Department of Neuropsychiatry, Keio University School of Medicine, Tokyo, Japan, (6)Keio University, Tokyo, Japan*

Background: Recent technological advancements have had a dramatic impact on the way individuals communicate, influencing how we communicate in daily life through the increasing presence of electronic devices and remote communication options, such as mobile phones. To participate in society today, it is necessary to use mobile phones to communicate with unfamiliar people in a variety of situations. Individuals with autism spectrum disorders (ASD) are not good at talking on the mobile phone to unfamiliar people. The "*Hugvie*", a cushion with a human-like shape, was designed to provide users with the tactile sensation of hugging during phone conversations to improve positive feelings (e.g., comfort and trust) toward phone partners. When hugging a Hugvie, users can strongly experience the presence of remote partners. Given the difficulty individuals with ASD have with talking to unfamiliar people on mobile phones and the social dysfunction that characterizes ASD, a Hugvie could be effectively used to decrease stress.

Objectives: The primary objective of this study is to examine whether physical contact via hugging a *Hugvie* can reduce the stress of calling an unfamiliar person on the phone.

Methods: In the present study, 24 individuals with ASD were randomly assigned to two groups. The participants in the first group (n = 12) called an unfamiliar person on the phone while hugging a *Hugvie* (Hug course) on day 1, followed by a phone call without a *Hugvie* (mobile phone-only course) on day 2. The participants in the second group (n = 12) underwent a phone-only course on day 1 and Hug course on day 2. After each phone conversation using only a mobile phone or the mobile phone plus the *Hugvie*, all participants completed questionnaires regarding their self-confidence regarding talking on the phone. In addition, they provided salivary cortisol samples four times each day.

Results: The self-confidence ratings after the Hug course was significantly greater than those reported after the Mobile phone-only course. The salivary cortisol levels of those participating in the Hug course were significantly lower after talking on the phone than the salivary cortisol levels of those participating in the Mobile phone-only course.

Conclusions: Individuals with ASD who talked on the phone with an unfamiliar person while hugging a Hugvie showed better self-confidence and decreased stress compared to those who used only a mobile phone. It is difficult for individuals with ASD to talk on the phone with an unfamiliar person. Given the results of this study, we recommend that huggable devices be used as adjunctive tools to support individuals with ASD when calling unfamiliar people on mobile phones. The findings of this study represent a meaningful contribution to the literature on interventions for communication difficulties among individuals with ASD.

428.063 *(Poster)* Pilot Implementation and Evaluation of Healthcare Transition Curriculum on Adults with ASD

G. Y. H. Lam[1,2], *M. J. Segall*[1], *H. E. Gatins*[3], *H. Abernathy*[1] *and S. N. Brasher*[3], *(1)Emory Autism Center, Emory University, Atlanta, GA, (2)Department of Educational Psychology, Chinese University of Hong Kong, Shatin, Hong Kong, (3)School of Nursing, Emory University, Atlanta, GA*

Background: Individuals with autism spectrum disorder (ASD) often have complex healthcare needs persisting into adolescence and adulthood (Perkins & Berkman, 2012; Seltzer et al., 2004). Many individuals and their families struggle to transition from pediatric to adult care due to the lack of support and preparation (Cheak-Zamora & Teti, 2015). Despite their strong desire to be independent and efforts made to manage their own healthcare, many adults with ASD do not have adequate knowledge and have limited skills confidence in navigating the complex healthcare world (Cheak-Zamora et al., 2017).

Objectives: The current study aims to evaluate the effects of a healthcare transition (HCT) curriculum on adults with ASD's understanding, skills, and confidence in healthcare management.

Methods: Six adults with ASD (22-35 years old) were recruited to participate in eight one-hour weekly sessions facilitated by two mental health and medical professionals. The intervention curriculum was adapted from the state Department of Public Health's published HCT information workbook designed for general youth to focus on the specific needs of individuals with ASD. It was modified to include lesson plans with learning activities, simulated practices, and homework for explicit teaching and modeling of the skills needed to independently manage healthcare. It also included instructional materials (e.g., visual supports) that can be differentiated to meet a range of learning needs. Lessons included topics such as roles of healthcare providers, preparation for a medical emergency, scheduling and attending an appointment, information about prescriptions and insurance plans, and goals or plans for achieving a healthy lifestyle.

This intervention is currently in the implementation phase. A mixed method evaluation approach is being used to collect data from participants with ASD pre- and post-intervention. Qualitative interviews are conducted to assess changes in participants' understanding of HCT, perceptions of their skills, and confidence in managing healthcare, and feedback about the curriculum. The Transition Readiness Assessment Questionnaire (TRAQ; Sawicki et al., 2011) is administered to measure participants' self-report skills for managing and advocating their healthcare. Follow-up TRAQ data will be collected following participants' first post-intervention doctor's appointment.

Results: Based on our initial engagement with the participants, the following observations emerged as important issues to be addressed. Participants reported being accompanied by parents in healthcare visits and not having the opportunity to speak with medical professionals directly. Participants were unaware of what to say or ask during medical appointments and had limited skills in taking charge of their own healthcare. We expect the participants will learn critical HCT knowledge and information and become more empowered to assert themselves in future healthcare tasks.

Analysis of pre- and post-data will be available for this presentation. Wilcoxon signed-rank test will be performed on TRAQ scores. Thematic analysis (Braun & Clarke, 2006) will be used to identify and compare themes pre- and post-program.

Conclusions: Findings of this pilot implementation will demonstrate the importance to address HCT needs by teaching the relevant skills and knowledge to adults with ASD. Participant feedback will assist further refinement of the curriculum and future research needs.

428.064 *(Poster)* Preliminary Results from an Online Social Media Skills Intervention for Adults with ASD: Socialization and Education Learning for the Internet (SELFI)

A. Osuna[1], *D. M. Tagavi*[2], *S. Said*[3], *J. Nguyen*[2], *M. Xie*[2], *K. Sabini*[2], *J. Whellan*[2], *N. Naranjo*[4], *C. You*[2], *C. Diaz*[2] *and T. W. Vernon*[1], *(1)University of California Santa Barbara, Santa Barbara, CA, (2)University of California, Santa Barbara, Santa Barbara, CA, (3)UCSB, Santa Barbara, CA, (4)University of California, Santa Barbara, Santa Barabra, CA*

Background: Currently, little is known about how individuals with ASD interact with peers on social media platforms. Previous research has highlighted that social media can be a useful tool for those with social challenges and/or limited confidence because online social expectations and asynchronous text-based exchanges generate less pressure and anxiety than face-to-face interactions (Goby, 2006). Additionally, online social media communication has been associated with increased quality of friendships, decreased loneliness, and benefits for individuals with social anxiety (Mazurek, 2013). These data suggest that proper social media use should be targeted in social skills interventions. Although social skills interventions are growing in popularity, no interventions have been developed specifically for social media skills. The Socialization and Education Learning For the Internet (SELFI) program was developed to evaluate and improve the online social skills and etiquette of adults with ASD in an increasingly digital world.

Objectives: The objectives of this study were to (a) gain an understanding of baseline social media activity in ASD and TD young adult populations and (b) test the feasibility and preliminary efficacy of an eight-session intervention targeting online social skills, specifically for adults with ASD.

Methods: In this pilot study, six participants with ASD (mean age: 21.12 years, 78% female) completed SELFI, an 8-week socialization intervention aimed at systematically improving individual's positive online social impression by targeting their social media interactions, responses, and initiations. To compare baseline social media experiences, social media activity samples were taken from a comparison sample of typically developing peers. The intervention package placed a specific focus on modeling, teaching, and reinforcing skill use, common strategies that are often employed in in-person autism social skill interventions. To better understand the online social experiences of participants, screenshots of their Facebook activity over the previous 7 days were collected, de-identified, and analyzed. To better understand the *quantity* of social media interactions, Facebook actions were coded either as "active" (posting, commenting, sharing) or "passive." (liking a post). Individual posts were also qualitatively rated by masked coders for overall appropriateness. To assess treatment efficacy, appropriateness scores were compared pre- and post-intervention.

Results: At baseline, individuals with ASD had fewer social media interactions than typically developing peers, with an average of 7.00 (SD = 14.75, 2.84 active, 4.16 passive) social media interactions, compared to 25.65 (SD = 28.42, 8.13 active, 25.90 passive) from TD peers. After intervention, those with ASD increased their weekly online interactions to a mean of 13.16 (SD = 16.27). Appropriateness scores also increased from 3.50 (SD = .16) to 3.68 (SD = .26) post-intervention. SELFI fidelity of implementation was 85%.

Conclusions: Preliminary SELFI outcomes are indicative of increases in social media activity and post appropriateness. This innovative format of this social media intervention has the potential to target a crucial area of social functioning that has not yet been targeted in individuals with ASD. Future directions include a randomized controlled trial to systematically test the intervention and its long-term impacts on online communication and friendships.

428.065 *(Poster)* Process Evaluation of a Randomised Controlled Trial Evaluating an Autism-Specific Workplace Tool for Employers

M. T. Scott[1]*, M. Falkmer*[2]*, T. Falkmer*[3] *and S. J. Girdler*[4]*, (1)School of Occupational Therapy, Social Work and Speech Pathology, Curtin University, Perth, Australia, (2)Curtin University, Bentley, Australia, (3)Curtin Autism Research Group, Curtin University, Perth, WA, Australia, (4)School of Occupational Therapy, Social Work and Speech Pathology, Curtin University, Perth, WA, Australia*

Background: Many adults on the autism spectrum have both the desire and ability to work, yet they continue to experience many barriers in their attempts to secure and maintain employment. A variety of environmental factors may influence the employment process, particularly employers with their attitudes, management practices and policies critical in facilitating or hindering work participation for individual on the autism spectrum. Yet, few studies exist exploring employers' capacity in hiring and supporting employees on the autism spectrum, and even fewer have considered interventions and strategies targeting employers' skills, abilities and knowledge in enhancing employment opportunities. In response to this need, the Integrated Employment Success Tool (IEST^{TM}) was developed specifically for employers. The effectiveness of the IEST^{TM} was established in a randomised controlled trial (RCT). While the RCT was useful in evaluating the effectiveness of the IEST^{TM}, it predominantly focused on pre-specified outcomes and not on the process involved in implementing the intervention. As such, a process evaluation was conducted to determine the fidelity and quality of the implementation of the IEST^{TM}.

Objectives: The primary objectives of the process evaluation were to: i) describe employers' experiences of using the IEST^{TM} in their workplace; ii) describe employers' perceptions of the usability of the IEST^{TM}; iii) explore the features of the IEST^{TM} contributing to change in the workplace, including recommendation for improvements; and iv) identify the perceived barriers and enablers in using the IEST^{TM}.

Methods: A process evaluation was conducted to obtain feedback from employers (N=29) via an online questionnaire. Of these, 11 participants were interviewed, further exploring their experiences of using the IEST^{TM} in their specific work environment. Data were analysed via descriptive statistics and thematic analysis.

Results: Descriptive statistics revealed that while participants' usage of the IEST^{TM} varied, 65% were satisfied to very satisfied using and implementing it in their workplace. More than 60% of employers had recommend the IEST^{TM} to either another manager, supervisor or co-worker in their workplace, with 14% further recommending it to a vocational rehabilitation service provider. Due to the IEST^{TM} only being a paper-based intervention, more than 60% of employers indicated a need for both a paper-based and online version. Thematic analysis revealed that participants' experiences using the IEST^{TM} could be described according to the three major themes: A 'go-to guide' empowering employers; seeing the workplace from a different perspective; and a structured approach to supporting employees on the autism spectrum.

Conclusions: The process evaluation revealed that the main benefit of the IEST^{TM} was in increasing employers' knowledge and understanding of autism in the workplace, providing clarity in relation to autism-related traits and associated workplace behaviours. It was evident that the more employers knew about autism, the more confident they felt about approaching their employee to discuss their needs. The process evaluation was a critical step in understanding *why* the IEST^{TM} was effective, and how it could be further optimised for prospective employers.

428.066 *(Poster)* Provider Perspectives on the Echo Autism: Transition to Adulthood Program

N. C. Cheak-Zamora[1]*, J. G. Farmer*[2]*, M. Crossman*[3]*, B. A. Malow*[4]*, M. O. Mazurek*[5]*, G. Stobbe*[6]*, R. L. Loftin*[7]*, M. Mirza-Agrawal*[8,9]*, M. Tapia*[10]*, A. Hess*[11]*, K. K. Davis*[12] *and K. Sohl*[13]*, (1)Health Sciences, University of Missouri, Columbia, MO, (2)General Academic Pediatrics, Massachusetts General Hospital for Children, Harvard Medical School, Boston, MA, (3)MGHfC, Watertown, MA, (4)Sleep Disorders Division, Department of Neurology, Vanderbilt University Medical Center, Nashville, TN, (5)University of Virginia, Charlottesville, VA, (6)Psychiatry & Behavioral Medicine, Seattle Children's Autism Center, Seattle, WA, (7)Department of Psychiatry and Behavioral Sciences, Feinberg School of Medicine, Northwestern University, Chicago, IL, (8)Agrawal Family Foundation, Miramar, FL, (9)Florida International University, College of Medicine/EMBRACE, Miami, FL, (10)University of Texas at Austin, Austin, TX, (11)Psychology, Nationwide Children's Hosptial, Columbus, OH, (12)Seattle Children's Autism Center, Seattle, WA, (13)Child Health, University of Missouri - School of Medicine, Columbia, MO*

Background: Each year, 50,000 youth with Autism Spectrum Disorders turn 18 years old. The current healthcare system is not equipped to care for the increasing number of transition-aged youth diagnosed with autism spectrum disorder (TAY-ASD). Despite their complex healthcare needs, TAY-ASD receive few transition services and describe difficulty finding adult providers. Pediatric and adult health care providers alike lack training in autism and report low confidence in caring for TAY-ASD.

Objectives: The current project developed and tested an adaptation of the Extension for Community Healthcare Outcomes (ECHO) model to train and mentor Primary Care Providers (PCP) in providing best-practice care for transition-age youth and young adults with ASD. The ECHO Autism: Transition to Adulthood program consisted of 12 weekly 1-hour sessions connecting PCPs to an interdisciplinary expert team via multi-point videoconferencing. Training included brief didactics, case-based learning (during which PCPs presented their cases for discussion), and guided practice.

Methods: This qualitative study aims to understand the provider's experiences while participating in the ECHO Autism: Transition to Adulthood program and better understand the healthcare providers' motivations and subsequent applications of the ECHO model training. We recruited 10 PCPs who completed the ECHO Autism: Transition to Adulthood program to participate in follow-up focus groups. Three one-hour focus groups were conducted within one month of the completion of the program utilizing a synchronized videoconferencing system. The semi-structured interview guide including questions about the participants experiences in the program, perspectives on key components of the program (e.g. case presentations, hub team recommendations, etc.), the impact of the program on provider willingness to care and confidence in caring for TAY-ASD, barriers and challenges to participating in the program, and suggestions for improvement to the program. All focus groups were recorded and transcribed verbatim by a contracted agency.

A fundamental qualitative description method was used by 3 team members with expertise in qualitative data analysis to analyze the qualitative focus group data. Each team member completed all stages of the data analysis process independently, followed by a consensus and refinement process at every level.

Results: Three unique themes arose from the PCP focus group discussions included (1) beneficial and influential aspects of the program, (2) perceived challenges within the program, and (3) suggestions for improvements and adjustments to the program. Each theme included four subthemes that further described the participants' experiences within the program. The benefits of the program included the sense of community, hub team expertise, a feeling of increased comfort, and program structure. Challenges included scheduling, session time management, access to resources, and participant characteristics. Finally, suggestions include structure adjustments, regional resources, additional technology, and formalizing acknowledgments and incentives.

Conclusions: The qualitative results indicate that the program is acceptable to provide and seems to improve PCP confidence and practice behavior. These results will be used to refine and ensure the success of the broader implementation of the ECHO Autism: Transition to Adulthood program. Further, these results can inform the development and revision of future ECHOs.

428.067 *(Poster)* Psychological Correlates of Positive Affect in Parent-Child Relationship Quality As Experienced By Parents of Children with Autism

***F. H. Roudbarani**, P. Tablon-Modica and J. A. Weiss, Psychology, York University, Toronto, ON, Canada*

Background: Parent-child relationship quality is an important aspect of both parent and child well-being. Parental positive affect, defined as the expressions of trust, affection, and respect that are expressed from parents to children, and from children to parents, is a significant contributor to parent-child relationship quality (Orsmond et al., 2006). Parental positive affect has been previously examined in relation to family characteristics (Orsmond et al., 2006); however, more studies are needed to explore how parental positive affect may be related to other psychological variables among families with autism.

Objectives: To explore how parental positive affect to and from their child are related to parent and child characteristics in families with autism.

Methods: Data were collected from 44 parent-child dyads participating at the baseline visit prior to being involved in cognitive behavioural therapy. Parents were 33 to 54 years of age (86.4% Female; M = 44.41 years, SD = 5.35), and children were 8 to 13 years of age (81.8% Male; M = 9.48 years, SD = 1.54). All children had autism and were referred as a result of difficulties managing their emotions. All measures were completed at program screening, prior to any involvement in the intervention. Parental positive affect was measured using the 10-item PAI (Bengtson & Schrader, 1982), which provides a total score and two summary scores examining: 1) positive affect *towards* their child and 2) positive affect *from* their child. Higher scores reflect more positive relationship quality. Measures of parent mental health (DASS-21; Lovibond & Lovibond, 1995), mindful parenting (BMPS; Jones et al., 2014), child autism severity (SRS-2; Constantino & Gruber, 2012), and child psychopathology (BASC-3; Reynolds & Kamphaus, 2004) were also collected at baseline.

Results: PAI total scores were negatively related to poor parent mental health (r = -.34, p = .03), and positively related to mindful parenting (r = .61, p < .001). PAI total scores were negatively related to child autism severity (r = -.44, p < .01), and child psychopathology (internalizing behaviour, r = -.36, p = .02; externalizing behaviour, r = -.47, p = .002). This poster also presents on the associations among the parent directed and child directed components of affect.

Conclusions: Greater parental positive affect is associated with better parent mental health and mindful parenting skills. Lower parental positive affect was associated with higher reports of child psychopathology and severity of autism symptoms. Future studies can investigate the directionality of these associations to further understand mechanisms of change and possible targets for interventions.

428.068 *(Poster)* Randomized Controlled Trial (RCT) of a Naturalistic Parent Training Program

***K. Nohelty**[1] and D. Dixon[2], (1)Research and Development, Center for Autism and Related Disorders, Woodland Hills, CA, (2)Center for Autism and Related Disorders, Woodland Hills, CA*

Background: Parent training can have many benefits for families of individuals with autism spectrum disorder (ASD), most notably in improving parent-child interactions. However, treatment gains noted in the research vary greatly. Naturalistic developmental behavioral interventions (NDBIs) combine the principles of applied behavior analysis (ABA) and child development with an emphasis on creating learning opportunities for the individual with ASD in the natural environment. The inclusion of NDBIs into parent training has the potential to improve outcomes for children and parents as well as increase parent involvement in their child's treatment.

Objectives: The current study expanded upon past research on the NDBI, Project ImPACT, by assessing parent-child interactions in a randomized controlled trial including clinicians with a range of experience located at a community-based ABA organization.

Methods: For the study, 36 families of individuals with ASD (2-8 years old) and 36 credentialed clinicians (i.e. Board Certified Assistant Behavior Analyst, Board Certified Behavior Analyst) with varying years of experience were recruited to participate in the study. Each clinician was paired with one family and the pairs were then randomly assigned to the active treatment or the treatment as usual control group. Clinicians assigned to the active treatment group were instructed in the study procedures using behavioral skills training (BST). For both groups, twelve weekly sessions (1.5 hours total per week) were implemented for children and their parent(s). For the active treatment group, each week the clinician reviewed the target skill(s) with the parent during a 1-hour session and then used BST to support the parent in demonstrating the target skill(s) with their child during a subsequent 30-minute session. Measures of parent-child interaction were scored by individuals blinded to group assignment and condition (i.e. pre-treatment, post-treatment, generalization to home) from a video of interaction with their child. Additionally, measures of parental self-efficacy, parental stress, and social validity were collected.

Results: Data are presented on the difference in scores of parent-child interactions, parental self-efficacy, and parental stress for each group. Additional data on social validity are compared for each group.

Conclusions: The results of this study add to the growing support for the use of naturalistic parent training strategies, specifically Project ImPACT.

428.069 *(Poster)* Reducing Physical Management in School-Age Children with ASD

B. Aaronson[1,2]*, T. Sasser*[3]*, Z. Dunne*[1]*, W. McCloud*[1]*, S. Ludeman*[1]*, L. Santillan*[1]*, C. Courshon*[1]*, J. Munson*[1,3] *and A. Estes*[1,4]*, (1)UW Autism Center, University of Washington, Seattle, WA, (2)Pediatrics, University of Washington, Seattle, WA, (3)Psychiatry & Behavioral Sciences, University of Washington, Seattle, WA, (4)Speech and Hearing Sciences, University of Washington, Seattle, WA*

Background: Children with disabilities including children with ASD are significantly more likely to experience the use of restraint in settings such as schools. The necessity of restraints are often justified by safety concerns, though restraints present inherent safety risks. The identification of de-escalation strategies effective in school-age children may increase safety for children and staff. The APEX Summer Camp program serves children with autism spectrum disorders (ASD), attention-deficit/hyperactivity disorder (ADHD), and comorbid ASD and ADHD. Physical management protocols are a component of timeout procedures, designed to maintain safety and mitigate risk. Behaviors that result in a timeout include intentional aggression, intentional destruction of property, or repeated non-compliance.

Objectives: To examine the impact of adjusting timeout procedures to include a home consequence on incidences of physical management.

Methods: The APEX program has historically implemented the timeout protocol manualized in the Summer Treatment Program (Pelham et al., 2012), but with reduced intervals starting at 2.5 minutes, and then escalating based on additional negative behavior to 5, 10, and 15 minutes (fully escalated). In 2019, we shifted to implement a “drop-the-rope” option, which coordinated a consequence at home for not serving a timeout. When a home consequence was initiated, the timeout was automatically concluded with the child being given the immediate option to return to group activities. Staff consulted with parents regarding reasonable home consequences such as losing 10 minutes of screen-time. Timeouts were categorized as requiring no physical management, minor physical management (physical guidance), and significant physical management (any use of a therapeutic hold). The number of timeouts assigned and the level of physical management required to maintain safety were examined across the summers of 2018 and 2019 respectively.

Results: No significant differences were indicated in diagnosis, age, gender, or number of participants based on Fisher’s exact test between our 2018 (n=124) and 2019 (n=136) samples. In 2018, 543 timeouts were assigned with no physical management, 106 required minor physical management, and 101 required significant physical management. In 2019, 564 timeouts were assigned with no management, 58 required minor physical management, and 30 required significant physical management. Fisher’s exact test for the 2 (years) X 3 (level of physical management) yielded a $p < .0001$.

Conclusions: Our results indicated a significant reduction in the use of physical management from 2018 to 2019. The adoption of our "drop-the-rope" procedure involving a home consequence may be a useful de-escalation strategy in school-age children. Our findings may have applicability in other settings where the use of home consequences could potentially reduce the use of physical restraints. Further replication is needed in other settings including schools.

428.070 *(Poster)* Reducing Physiological Measures of Stress through Yoga for Individuals on the Autism Spectrum

S. A. Anderson[1]*, B. G. Travers*[2]*, R. J. Davidson*[3,4] *and M. A. Rosenkranz*[4,5]*, (1)Kinesiology, University of Wisconsin - Madison, Madison, WI, (2)University of Wisconsin - Madison, Madison, WI, (3)University of Wisconsin, Madison, WI, (4)Center for Healthy Minds, Madison, WI, (5)Psychiatry, University of Wisconsin-Madison, Madison, WI*

Background: Many people with Autism Spectrum Disorder exhibit symptoms of stress and anxiety. While not every person with Autism Spectrum Disorder (ASD) is anxious, many of autism’s challenging symptoms relate to anxiety (Gillott, Furniss, & Walter, 2001; Richey et al., 2015; White, Oswald, Ollendick, & Scahill, 2009). There is a great need for effective techniques for managing anxiety in those with ASD, and the present study examines YogAutism, a Yoga-based intervention for individuals with ASD, and its short-term and long-term impact on the physiological responses that are associated with anxiety.

Objectives: The purpose of this study was to evaluate the efficacy of the YogAutism intervention in reducing the physiological correlates of stress and anxiety. Additionally, use of Wavelet Transformation was investigated as an alternative to the Short Time Fourier Transform as a means to analyze power spectra within ECG signals.

Methods: Twenty-three participants with ASD were evaluated, 10 in the YogAutism intervention group (ages 5 - 35 years, M= 13.42), and 13 in the wait-list control group (ages 6 - 20 years, M= 12.10). Each group contained participants who were identified as minimally-verbal. Salivary cortisol, salivary a-amylase and Heart Rate Variability were measured as indices of activation of the hypothalamic-pituitary-adrenal axis, sympathetic nervous system and parasympathetic nervous system, respectively. YogAutism participants received the intervention in the lab once per week over the course of 6 training weeks, and control participants viewed a nature video twice over the 6-week duration. For all participants, measurements were taken twice; before and after the intervention/video in the first 3-weeks of the study period, and again in the second 3-weeks of the study period.

Results: We found decreases in salivary cortisol in the YogAutism group at the level of medium effects ($h_p^2 > 0.059$). Levels of salivary a-amylase increased with the YogAutism intervention. This unexpected result supports observations that indices of hypothalamic-pituitary-adrenal axis and sympathetic nervous system activation may behave unexpectedly in people with autism. Heart Rate Variability was calculated from the raw ECG using Wavelet Transformation and Short Time Fourier Transform. Wavelet Transformation data were more correlated with cortisol data than were Short Time Fourier Transform data, which provided some evidence supporting the use of Wavelet Transform for calculating HRV in a sample with ASD. However, neither analysis showed significant differences in the levels of Heart Rate Variability between groups.

Conclusions: This pilot study suggested that the YogAutism intervention had a limited short-term and long-term impact on the physiological responses that correlate with anxiety. However, this was in the presence of substantial heterogeneity and potential decoupling of physiological responses. Future research would benefit from limiting the age range of participants, collecting parent/caregiver report measures and further exploration of the use of Wavelet Transform for calculating HRV in a sample with ASD.

428.071 *(Poster)* Research-Supported Intervention Strategies for Treating Externalizing Behaviors in Youth with Autism Spectrum Disorder: Implementation and Perceived Usefulness Among Community-Based Providers across Disciplines

C. Brown[1,2]*, M. D. Lerner*[2]*, C. M. Kerns*[3]*, L. Moskowitz*[4]*, E. G. Cohn*[5]*, A. Drahota*[6]*, L. Soorya*[7] *and A. Wainer*[7]*, (1)Department of Psychological Sciences, University of Missouri, Columbia, MO, (2)Department of Psychology, Stony Brook University, Stony Brook, NY, (3)University of British Columbia, Vancouver, BC, Canada, (4)Psychology, St John's University, Queens, NY, (5)Hunter-Bellevue School of Nursing, New York, NY, (6)Psychology Department, Michigan State University, East Lansing, MI, (7)Department of Psychiatry, Rush University Medical Center, Chicago, IL*

Background: Externalizing behaviors are among the most common and serious problems in youth with autism spectrum disorder (ASD; Carroll et al., 2014). More than half of youth with ASD exhibit externalizing behaviors (e.g., aggression; Kanne & Mazurek, 2011), and such behavior is linked with significant impairment across multiple domains of functioning (Brown et al., 2019; Mazurek et al., 2013). Though empirically-supported interventions do exist to treat externalizing symptoms in ASD (National Autism Center, 2015), little is known about the use and perceived usefulness of such interventions among providers who treat this population, and whether use and usefulness of these strategies varies across the range of professional disciplines these providers represent.

Objectives: The primary aim of this study was to examine the use and perceived usefulness of four research-supported intervention strategies for treating externalizing behaviors among youths with ASD by usual care providers in the community throughout the United States. The secondary aim was to compare self-reported use and usefulness of these strategies across provider discipline.

Methods: Participants were 581 community-based providers across 5 clinical sites who reported working with youth with ASD between 7-22 years of age with co-occurring externalizing problems. The Usual Care for Autism Survey (Wainer et al., 2017) was used to assess providers' self-reported frequency of use and perceived usefulness of four research-supported strategies: functional behavioral assessment (FBA), visual tools/supports, functional communication training (FCT), and token economy. These strategies were selected because they showed a high degree of consensus (i.e., 90% agreement) among ASD experts (Kerns et al., 2018) as demonstrating strong research support for treating externalizing symptoms. Generalized estimating equations were used to evaluate differences across discipline in use and usefulness while accounting for nesting of data within sites.

Results: Across disciplines, the four strategies were used "very commonly" and perceived as "very useful" by over 50% of providers. Token economy was used "very commonly" by the most providers (57.2%), and FCT was perceived as "very useful" by the most providers (71.7%). The highest proportion of "not at all" and "not at all useful" responses were for FCT (8.4%) and token economy (1.7%), respectively. Behaviorists used all strategies significantly more often than other providers across almost all comparisons (Table 2). Regarding perceived usefulness of strategies, behaviorists perceived FBA and Visual Tools as most useful. FCT was rated as most useful by "other" providers, and Token Economy was rated as most useful by allied health professionals.

Conclusions: Across disciplines, results suggest that providers report often using research-supported strategies and perceive these strategies as useful for treating externalizing behaviors in youth with ASD. Even so, there exists significant variability between disciplines regarding use and usefulness. Behaviorists used all strategies more frequently than other providers, but reported the most usefulness for FBA and visual tools/supports only. These findings are promising inasmuch as they support dissemination of key research-supported practices to address this area of challenge in the United States, and highlight extant gaps for targeting provider training in use and understanding of these practices.

428.072 *(Poster)* Self-Identified Strengths and Positive Self-Talk in Pre and Post Assessments of an Employment Skills Training for Individuals with Autism Spectrum Disorder

B. Eatchel[1]*, C. Wright*[1]*, V. D'Astous*[2] *and C. Sung*[3]*, (1)University of Utah, Salt Lake City, UT, (2)King's College London, London, UNITED KINGDOM, (3)Department of Counseling, Educational Psychology and Special Education, Michigan State University, East Lansing, MI*

Background: Individuals with autism spectrum disorder (ASD) often struggle with obtaining and maintaining employment, making interventions that target employability for these individuals crucial (Roux, Rast, Rava, Anderson, & Shattuck, 2015). However, little research focuses on the ways that these programs help to foster awareness of strengths and positive self-talk. Our research uses a qualitative approach that allows for in-depth exploration of perceived strengths and self-talk in pre and post assessments for an employment skills training program for individuals with ASD. Research in this area is needed to better understand how trainings like this can affect awareness of strengths and self-talk language.

Objectives: To examine awareness of strengths and self-talk language in individuals with ASD before and after an employment skills training program.

Methods: To explore the study objective, we analyzed qualitative pre and post interviews of individuals with ASD who participated in an employment skills training program. We collected 26 pre and post interviews. All individuals were verbally-competent. In the interviews, individuals were asked questions related to the program (e.g., what do you expect to learn, what did you learn), themselves (e.g., what are your strengths, what are your challenges) and about their needs (e.g., how do you learn best, what do you need from a group). Interviews were semi-structured, audio-recorded, transcribed verbatim, and were analyzed using multiple coders. Although self-talk was initially not a factor of the interviews, it emerged as a theme. Interviews were thematically coded and categorized to identify perceived strengths and self-talk.
Results: Initial examination suggests that participants in the program are more likely to identify strengths following participation in an employment skills training program. These strengths are likely to be more specific and clear than those identified at the pre-assessment. Further, participants were more likely to engage in positive self-talk in the post-assessment than the pre-assessment.
Conclusions: The results of this qualitative analysis suggest that interventions focused on improving job skills may help foster an awareness of strengths and increase the frequency of positive self-talk in individuals with ASD. Job skills interventions could benefit from a focus on awareness of strengths and positive self-talk as important tools for healthy independent living in individuals with ASD. Although each individual presents with unique strengths, awareness of these strengths can enhanced job readiness and self-esteem. Future research can focus on specific techniques to increase awareness of strengths with targeted interventions.

428.073 *(Poster)* Social Validity of the Autism Mentorship Program (AMP): A Mentorship Program for Adults and Adolescents with Autism

***R. L. Hudock**, A. Goerdt, J. Smith, O. Tomfohrde, K. Kremer, D. Wood and L. Weiler, University of Minnesota, Minneapolis, MN*

Background: Relationships with caring, non-parental adults (i.e., mentors) are critical to healthy development (Rhodes, 2002, 2005) and can positively influence a range of outcomes, such as peer and parent-child relationships, identity development, academic achievement, self-confidence, and prevention of problem behaviors (DuBois et al., 2011). While youth and adolescents with autism spectrum disorder (ASD) often experience challenges related to communication, social relationships, and co-occurring emotional and behavioral concerns, there are limited mentoring opportunities available for youth with ASD, and there are currently no mentoring programs that pair youth and adults with autism in mentoring relationships. Additionally, youth with ASD rarely have opportunities to form meaningful relationships with adults with ASD who can share their experience with youth during an important developmental period in their lives. The Autism Mentorship Program (AMP) was designed to meet this need.
Objectives: The aim of this study was to examine the social validity of the Autism Mentorship Program.
Methods: AMP involves one-to-one mentorship of youth with ASD by adults with ASD. Mentoring sessions consisted of 12 weekly 60-minute meetings within the teens' local high school. Pairs participated in semi-structured activities centered around common interests. Participants included 7 mentees (ages 14-17), 7 mentors (ages 19-33), 8 parents of the mentees, and 8 AMP staff. Mentees were recruited from a local high school, and mentors were recruited from a local community transition program for young adults with ASD. All participants had a diagnosis of ASD without co-occurring intellectual disability or language impairment. Multi-informant data was collected through interviews, standardized questionnaires, and focus groups to determine the acceptability and feasibility of the AMP intervention. Program data regarding attendance and satisfaction with weekly sessions were also collected.
Results: AMP was highly acceptable to all participants. Participants demonstrated a high level of attendance (92-100% for all participants). All participants (100%) reported feeling satisfied with the mentoring relationship and agreed that their participation in AMP was meaningful. Most mentors and mentees (85.7%) reported feeling satisfied with their participation in the program and the level of support they received. During interviews and focus groups, mentees described quality relationships, progress toward personal goals, learning about people and communication, learning what it is like to grow up with ASD, and gaining a better understanding of what it is like to grow up with ASD. Mentors described greater confidence, more patience, and better leadership skills as a result of participating in AMP. Parents described improvements in communication, motivation, attention, confidence and friendships for their children. AMP staff reported high satisfaction with the program (100%), and indicated that the program was able to be implemented successfully within the school setting.
Conclusions: Results from this initial pilot of AMP indicated that the program is highly acceptable to participants and feasible to implement as an after school program. In addition to enthusiastic support and acceptance for AMP, results suggest mutual benefit for both mentors and mentees. A full pilot will take place during the 2019-2020 school year with 14 mentee-mentor pairs to explore additional outcomes.

428.074 *(Poster)* Stacking the Deck to Help Adolescents with Autism Better Balance Their Group Participation

*T. P. Gabrielsen[1] and **L. E. Lees**[2], (1)Counseling & Special Education, Brigham Young University, Provo, UT, (2)Granite School District, Salt Lake City, UT*

Background: In classroom and group settings, adolescents with autism may not know how to participate in socially acceptable ways. They may talk too much (over-participating), or go silent (under-participating). Current strategies include cold-calling on under-participators as well as occasionally ignoring over-participators. Both may lead to increased anxiety, frustration, and "meltdowns" in students with ASD.
Objectives: Our goal is to create a socially acceptable self-monitoring system for adolescents with autism to help individuals balance comment levels in classroom settings and decrease disruptive group behaviors (e.g. talkouts).
Methods: Our sample consisted of males (n=25) and females (n=7) ages 11-17. All had preexisting ASD diagnoses and/or preexisting social skills difficulties; age appropriate language skills; a lack of significant classroom behavioral issues; and no more than a two years academic delay behind their age group.

During direct instruction in PEERS® (Laugeson and Frankel, 2010) sessions, the "*Stack the Deck*" intervention was used for self-monitoring participation. A differential reinforcement for high or low rates of behavior (DRH/DRL) using an existing token system with backup reinforcers allowed participants to control how many *bonus* points they receive based on their own "budgeting" of their participation behaviors using a visual, tactile system (colored slips of paper) for marking their own "turns." Some tokens (e.g., green slips of paper) are more valuable if used (answering a question). Others (e.g. red slips of paper) are more valuable if kept (refraining from answering to give someone else a turn). All participants received points for participation, but could strategize for *more* points with the intervention. The aim was to balance verbal participation in classroom settings by allowing more opportunities for students with low rates of participation to respond. Each participant was given 10 slips of paper each session "stacked" with "use" and "keep" cards as incentives to keep participation in the target (average) range.

Data were collected from videos of sessions, coded by reliable researchers, recording both group and individual behavioral trends. Variables were attempted comment frequencies (hand raises), completed comment frequencies, and talk out frequencies.

Results: *Stack the Deck* was *most effective* when it came to students with the target behavior of reducing participation. Those who were over-participators at baseline were able to keep their participation rates more consistently within the average range. Under-participators, on the other hand, did not increase their participation as much. No change was observed in participants already within the target range. Talk outs decreased overall. Therapists reported the intervention as beneficial from the viewpoint of the "teacher," waiting anxiously for each baseline completion so they could have a better group experience with the intervention in place.

Conclusions: *Stack the Deck* lowered talk outs and balanced participation during direct instruction time for adolescents, and has potential for similar effects for elementary age groups and in classrooms. It is very low cost and low effort, easy to learn, and provides opportunities for more reinforcement for self-balancing participation than current methods. Participants have complete control over their participation and choose to regulate their own behavior with minimal teacher management.

428.075 *(Poster)* Supporting Newly Identified or Diagnosed Autistic Adults: An Initial Evaluation of an Autistic-Led Programme

M. Ashworth[1]*, C. Hearst*[2]*, J. Davies*[3]*, E. L. Hill*[4] *and L. Crane*[5]*, (1)Centre for Research in Autism and Education, UCL Institute of Education, University College London, London, United Kingdom, London, United Kingdom, (2)Autism Matters, Reading, United Kingdom, (3)Centre for Research in Autism and Education, UCL, Institute of Education, London, United Kingdom, (4)Goldsmiths, University of London, London, United Kingdom, (5)Centre for Research in Autism and Education, UCL Institute of Education, University College London, London, United Kingdom*

Background: An increasing number of adults are identifying that they are autistic later in life. This process of identification (which is sometimes, but not always, accompanied by a clinical diagnosis) can have a huge impact: contributing to feelings of relief and providing an explanation for feelings of difference. However, this can also raise the question "where to from here?" (Hearst, 2019, p.5).

Following identification/diagnosis of autism there is a lack of post-diagnostic support for adults (Crane et al., 2018). The limited services that do exist tend to be provided by non-autistic professionals. Building on the evidence that peer support might be beneficial for autistic children (Gordon et al., 2015), and a community desire for autistic-led initiatives that are "nothing about us without us" (Shaprio, 1994), the current study presents an initial evaluation of an autistic-led education and peer support programme for autistic adults.

Objectives: To conduct an initial evaluation of an autistic-led post identification programme for autistic adults. The evaluation aimed to provide an evidence base upon which future such programmes can be developed.

Methods: *Exploring Being Autistic* was designed to enable autistic people to: learn about autism and discover if/how it affects them; process emotional response to identification/diagnosis; consider disclosing they are autistic; develop strategies to capitalise on the strengths and mitigate the challenges associated with autism; and socialise with peers. The autistic developer of *Exploring Being Autistic* worked with a team of researchers to conduct a preliminary, qualitative evaluation of the programme.

Sixteen participants took part in one of two iterations of the *Exploring Being Autistic* programme (iteration one: n= 9; iteration two: n= 7). Participants completed a pre-course questionnaire to gather information about their motivations for taking part in the programme. Participants were also interviewed immediately after the programme, and again six months later. Three researchers independently reviewed these data in line with an essentialist framework for thematic analysis (with no pre-existing codes), for an in-depth qualitative analysis.

Results: Questionnaire data showed that participants were motivated to take part in the *Exploring Being Autistic* programme to learn more about the associated areas of strength and difficulty in autism, become more empowered and to develop practical strategies and coping mechanisms. Three key themes were identified from the interview data. The first theme was an appreciation of the autistic-led nature of the programme: participants felt they were really understood by the autistic group facilitator. The second theme was unity in diversity: participants reported feeling a sense of belonging with the group and valued the group's diversity. The third theme was developing a positive, practical outlook on autism: better appreciating how autism made a tangible difference to participants' everyday lives, and how to use that knowledge in a tangible way.

Conclusions: This initial evaluation showed that an autistic-led post identification/diagnosis peer support programme was well received and beneficial for participants in many ways. These findings provide an important insight into aspects that could be useful for future autistic-led, peer support programmes

428.076 *(Poster)* The Development of an Interactive Musical Device for Individuals with Autism As Home-Based Sensory Integration Intervention and First Proof of Efficacy

C. Chill*, The Royal Academy of Music, Aarhus, Denmark*

Background: Music therapy and sensory integration interventions are frequently utilized to reduce sensory processing deficits and show a range of benefits. However, there are only few therapeutic tools targeting sensory stimulation in combination with music – particularly as home-based intervention.

Objectives: The goal of this project was to develop an interactive musical device in the form of a cushion that serves as a therapeutic tool. It combines both music and sensory experiences, thereby providing parents with autistic children a simple but effective way to incorporate music and sensory experiences at home. Furthermore, a pilot study attempted to assess whether the prototype might positively impact particular areas commonly affected in a negative way by high-arousal, stress, or self-stimulatory behaviour.

Methods: Eleven participants (four females, seven males), between two and a half and thirteen years, participated in the study. During a five-week period, parents were asked to integrate the device into everyday life. Before, during and after the study, parents filled out questionnaires to evaluate whether the device could be used as a tool to reduce, redirect or entirely eliminate certain symptoms and achieve positive effects.

Results: The results provide preliminary evidence suggesting that the device has great potential to be an effective and easily accessible tool for parents and individuals to positively influence certain areas that are commonly impaired or predisposed to negative outcomes in the autistic system. The findings show that the device was particularly beneficial as coping strategy for the participants to be used for stress management and as a 'mental space' in which to retreat to reduce overstimulation. Furthermore, the data indicate beneficial effects such as relaxation or distraction from negative stimuli. More than half of the test participants who showed self-stimulatory or auto-aggressive behaviour were able to redirect it during engagement with the sound cushion. In addition, the findings show that common symptoms such as sleep problems, poor concentration span or hyperactivity could be reduced by the application and thus led to a general improvement in quality of life of the participants.

Conclusions: In the treatment of autistic individuals, it is important to have access to therapeutic aids that can help to better manage the stimuli, allowing the autistic individual to experience the world on his or her own terms. Research shows that music has a positive impact on particular aspects of autistic experience, and especially on those areas in which new and alternative treatments are sought. This emphasizes the importance of including music interventions in the treatment of autism and develop new methods for therapy, such as this device. The device design makes it possible to merge many aspects of sensory integration into a new experience engaging auditory (music and sound), tactile (texture and vibrations), visual (colours and patterns) and kinaesthetic senses (movement). While the music calms and distracts, the multi-sensory experiences may be simultaneously processed more easily by the autistic system, making it possible to achieve therapeutic goals, and furthermore to improve the lives of people with autism and by extension the whole family.

428.077 *(Poster)* The Effect of Exercise on the Anxiety Levels of Children with Autism Spectrum Disorder

M. Carey[1]*, S. Kinsella*[2]*, D. Sheehan*[2] *and F. Knott*[3]*, (1)Science and Health, Institute of Technology Carlow, Carlow, Ireland, (2)Institute of Technology Carlow, Carlow, Ireland, (3)Psychology and Clinical Language Sciences, University of Reading, Reading, United Kingdom*

Background: Anxiety is a common comorbidity in children and adolescents with Autism Spectrum Disorder (ASD), with nearly 40% of youths with ASD meeting the diagnostic criteria for at least one anxiety disorder (van Steensel et al. 2011). Treatments for anxiety are severely lacking, particularly for children with severe ASD. Exercise has been proven to have a beneficial effect on decreasing anxiety symptoms in typically developing children (Ahn and Fedewa 2011; Jayakody et al. 2014) and may also have similar effects in anxiety in children with ASD. However, there is very limited research into this topic. Only one study to date has investigated the impact of exercise in ASD (Hillier et al. 2011). They found that an 8-week exercise and relaxation programme resulted in a significant reduction in salivary cortisol levels and self-reported anxiety after the exercise sessions, however this reduction was not maintained over time (Hillier et al. 2011). This shows the possible potential exercise has at decreasing anxiety in children with ASD but more studies are required.

Objectives: Therefore, the aim of this study is to assess the effects of exercise on anxiety in children with ASD.

Methods: Fourteen children (5-18 years), with moderate to severe symptoms of ASD were included in the study. A 16-week school-based exercise programme was implemented three days a week for 60 minutes per session. Parents and teachers assessed anxiety using a standardised measure, Anxiety Scale for Children with ASD (ASC-ASD) (Rodgers et al. 2016). Anxiety was measured before the programme, at week 8 and at the completion of the programme at week 16. Data was analysed using a repeated measure of variance (ANOVA) or non-parametric equivalent as appropriate.

Results: For the teacher scales, total ASC-ASD scores decreased significantly between the start and end of the program ($p = 0.001$, $h^2 = 0.42$). Analysis of individual subscales showed a significant reduction in performance anxiety ($p = 0.001$, W = 0.01), anxious arousal ($p = 0.000$, W = 0.07) and uncertainty ($p = 0.002$, $h^2 = 0.39$), but not separation anxiety ($p = 0.282$). However, total parent reported anxiety did not decline significantly, and there was a non-significant reduction in subscales.

Conclusions: The results of this study show the potential beneficial effects that exercise may have on reducing anxiety in children with ASD in a school setting. As higher anxiety levels were reported at school than at home, this may explain the greater impact of exercise seen at school. The results of this research are positive and suggest that exercise may be a beneficial treatment for anxiety in children with moderate to severe symptoms of ASD.

428.078 *(Poster)* The Effectiveness of Preventive Disclosure in Influencing Peer Engagement for the Child with Autism in Summer Camps: A Within-Case Mixed-Methods Study

L. Fan[1]*, S. Hodgetts*[2]*, A. McKillop*[3]*, S. Y. Shire*[4]*, M. Couture*[5]*, J. A. Weiss*[6] *and L. Zwaigenbaum*[3]*, (1)Rehabilitation Medicine, University of Alberta, Edmonton, AB, Canada, (2)Department of Occupational Therapy, University of Alberta, Edmonton, AB, Canada, (3)University of Alberta, Edmonton, AB, Canada, (4)University of Oregon, Eugene, OR, (5)Rehabilitation, Universite de Sherbrooke, Sherbrooke, QC, Canada, (6)Psychology, York University, Toronto, ON, Canada*

Background: Children with autism are at high risk of experiencing social exclusion, especially in community programs. Planned sharing of a child's diagnosis and information about behaviours (preventive disclosure + explanation) might be one way to reduce stigma and increase social inclusion by increasing peers' understanding of the child. All studies evaluating preventive disclosure to date have been based on hypothetical vignettes. No study has evaluated the effects of preventive disclosure in real life contexts, including community programs.

Objectives: To evaluate the influence of preventive disclosure on peer engagement and inclusion of a child with autism in a summer day camp. We hypothesized that peer engagement would increase following disclosure for a child in the disclosure condition, and decrease over the week for the same child in the non-disclosure condition.

Methods: This poster presents a sub-analysis of data from a larger mixed-method study evaluating outcomes of preventive disclosure on peer engagement and inclusion of children with autism in one type of community program, inclusive week long summer camps. This in-depth evaluation compares outcomes for one child who participated in two different summer camps, one in which he disclosed and one in which he did not disclose. For both conditions, 15-minute videos were collected on the first (baseline; pre-disclosing for that condition), second (post-disclosing for that condition) and last day of the program (follow-up). The primary outcomes were peer engagement states and reciprocal interactions (initiations and responses) for the child with autism and his peers, coded by a blinded observer using a time-interval behavioral coding system, the Playground Observation of Peer Engagement (POPE). Parents' completed the Adaptive Behavior Assessment System, third edition (ABAS-3) to describe the functional abilities of the child. Semi-structured interviews about perceived outcomes of disclosure were completed with the camp leader, the child with autism, and five peers (disclosure condition only). These data were thematically analyzed.

Results: Our participant was a 9-year-old boy with autism. He communicated verbally in full sentences. ABAS-3 scores indicated adaptive functioning in the extremely low to borderline range across domains. Peer engagement for the child in the disclosure condition increased over the week (20% of intervals jointly engaged at baseline, 30% post-disclosure/day two, 80% follow-up). Reciprocal interactions between the child with autism and peers also increased throughout the week. In the nondisclosure condition, peer engagement rates decreased over the week (60% intervals jointly engaged at baseline, 53% day two, 27% follow-up). Similarly, peers' initiations and positive responses towards the child with autism decreased over the week. Overall, interview participants indicated positive experiences related to the disclosure. Thematic analysis of interview data revealed four themes: (1) changed behavioral attribution, (2) unconditional inclusion by some peers, (3) improved inclusion for some peers, and (4) disclosure is good, autism is a part of who I am.

Conclusions: This study provides preliminary data to support the hypothesis that preventive disclosure and explanatory information may be a useful component of processes meant to improve peer engagement and inclusion of children with autism in community programs.

428.079 *(Poster)* The Effects of Creative Movement Interventions on the Motor and Social Skills of Children with Autism Spectrum Disorder (ASD)

A. Bhat[1], *I. Peace*[2], *W. C. Su*[3], *E. Manders*[4], *S. Srinivasan*[5] *and L. Overby*[2], *(1)Department of Physical Therapy, University of Delaware, Newark, DE, (2)University of Delaware, Newark, DE, (3)Physical Therapy, University of Delaware, Newark, DE, (4)Drexel University, Philadelphia, PA, (5)Department of Kinesiology, University of Connecticut, Storrs, CT*

Background: Children with Autism Spectrum Disorder (ASD) often receive Applied Behavior Analysis (ABA) interventions that are predominantly sedentary and primarily focus on improving the child's language, behavioral, and academic skills. Our lab has focused on the effects of various creative movement interventions using rhythmic movement, yoga, or dance-based activities to promote social and motor skills of children with ASD (Srinivasan et al., 2015a,b; 2016a,b; Peace et al., 2019; Kaur & Bhat, 2019).

Objectives: In the past studies, we investigated the impact of different creative movement approaches on the social communication and motor skills of children with ASD. These studies reported improvements in social skills (i.e., smiles, verbalization quality/quantity of responses), as well as motor performance (i.e., movement accuracy), post-intervention. In this talk, we will report the differential effects of the various Creative Movement approaches on the social communication and motor skills of children with ASD.

Methods: School-age children with ASD between 5.5 and 14 years of age participated. Each intervention (seated play/ABA, rhythm, yoga, or dance) was implemented over 8 weeks, with two weekly, expert-led sessions and additional parent sessions at home. Each session involved a hello song/game, warm-up/reading, 2-3 themed activities, and a farewell song/reflection. Variables coded include balance and bilateral coordination scores, praxis scores, imitation accuracy, and rates of smiling and verbalization.

Results: Our results show that post-intervention, social skills (smiles, verbalization rates) and motor skills (movement accuracy and praxis scores) improved with specific differences across groups that will be further discussed in the talk.

Conclusions: Based on our findings, we propose combining therapeutic activities across the different themes into one complex/blended intervention to maximize the positive effects on social and motor skills in children with ASD. We are now implementing a pilot randomized controlled trial (RCT) of such a complex intervention and hope to maximize the therapeutic benefits on both, social communication and motor abilities of children with ASD.

428.080 *(Poster)* The Efficacy of a Brief Career Development Program for Young Adults with Autism

J. G. Gehricke[1], *M. N. Dawson*[2], *J. A. Carriere*[3], *A. J. Griffiths*[4], *T. Tran*[4], *C. Roberto*[4] *and A. Valladolid*[4], *(1)The Center for Autism & Neurodevelopmental Disorders, University of California, Irvine, Santa Ana, CA, (2)Pediatrics, University of California - Irvine, Santa Ana, CA, (3)Attallah College of Educational Studies, Chapman University and The Center for Autism & Neurodevelopmental Disorders, Orange, CA, (4)Attallah College of Educational Studies, Chapman University, Orange, CA*

Background: The transition to adulthood is a critical and stressful time period for individuals with autism and their families. Young adults with autism face many challenges that can make it difficult to plan for a career or find and maintain a job, which often leads to un- and under-employment. Therefore, there is a critical need for services that can aid in post-secondary employment and education. However, only a few evidence-based transition programs exist for young adults with Autism Spectrum Disorder (ASD), though they are longer term and are not designed for higher functioning individuals nor do they use individual strengths and weaknesses profiles for matching skill level with postsecondary vocational planning.

Objectives: The objective of this study was to close this gap in knowledge and services by studying the efficacy of a brief career development program that includes an individualized strengths and weaknesses profile, which is commonly used with neurotypical young adults, in combination with a short term (i.e., 12-week) educational transition training program for young adults with ASD.

Methods: Twenty-one young adults, ages 16-22 years with ASD (Mean IQ Composite = 94.43, SD = 14.68), participated in two intervention modules: (1) an individualized strengths and weaknesses profile using the Strong Interest Inventory and Myers-Briggs Type Indicator and (2) a 12-week transition skills training, which included instruction in goal setting, organization, time management skills, resume building, interview skills, mock interviews, social skills in the workplace, career interests, and choosing a career path. The Vocational Index Scale, which is a broad and reliable measure of vocational and educational activities in young adults with ASD, was administered before and after the intervention. Secondary outcome measures were cognitive task performance on the Stroop Color-Word Test and the Wisconsin Card Sorting Test (WCST).

Results: Results showed significant increases in the vocational index score ($t = 2.73$, $p = 0.014$) and Stroop Color-Word Test performance ($t= 2.39$, $p = 0.027$ for color–word t score and $t = 2.61$, $p = 0.017$ for word t score) from before the intervention to post intervention. No significant differences were found in the WCST.

Conclusions: The findings of this study suggest preliminary efficacy of a brief career development program combining career counseling tools commonly used with neurotypical adults with an educational 12-week transition training program for individuals with ASD.

428.081 *(Poster)* The Impact of Training on Law Enforcement Officers' Preparation for Calls Involving Autism

L. Gardner[1] *and J. M. Campbell*[2]*, (1)Johns Hopkins All Children's Hospital, St. Petersburg, FL, (2)Psychology, Western Carolina University, Cullowhee, NC*

Background: Exposure of problematic interactions between law enforcement officers (LEOs) and individuals with autism spectrum disorder (ASD) in the media has resulted in increased attention to the need of ASD-specific training for law enforcement officers (LEOs). Given ASD affects an estimated 1 in 59 individuals 8 years and older in the US, it is likely that LEOs interact with individuals with ASD on a fairly regular basis; however, LEOs report limited knowledge, confidence, and prior training for working with individuals with ASD.

Objectives: The primary author created a bi-monthly training program for LEOs that prepares officers to recognize signs and symptoms of ASD and adapt their responses in crisis situations to meet the needs of individuals on the spectrum. The purpose of the present study was to determine if there were changes in knowledge of ASD, confidence, and self-monitoring following ASD-specific training in a sample of LEOs from the police and sheriff departments in the Tampa Bay area of the state of Florida.

Methods: One-hundred and fifty-seven LEOs attended four separate training sessions. LEOs were 66.2% male with a mean age of 39.99 years (SD = 10.1) and 12.58 years of law enforcement experience (SD = 8.9). LEOs completed a four-hour training session focused on: (a) identifying behaviors associated with ASD, (b) adapting behavior for successful resolution to calls, and (c) introduction to communication tools and strategies for use with individuals with ASD. Participants completed demographic information at pretest, and, at pretest and posttest, a 16-item measure of autism knowledge and a six-item measure of confidence in responding to an ASD-related call.

Results: For LEOs responding to calls involving ASD, those with ASD-specific training and Crisis Intervention Training (CIT) were no more likely to report feeling prepared to respond to the call. Compared to LEOs without ASD-specific training, those with prior training were equally likely to: (a) use physical force during the call, χ^2 (1, N = 95) = 0.82, p = .78, (b) use handcuffs, χ^2 (1, N = 94) = 2.13, p = .15, and (c) have the call result in involuntary hospitalization, χ^2 (1, N = 94) = 0.22, p = .64. Two, 2 (Time) x 2 (ASD Training status) x 2 (CIT Training status) mixed design ANOVAs resulted in significant main effects for Time. For *knowledge*, scores improved, F(1, 122) = 100.37, p < .001, from pretest (M = 12.28, SD = 1.9) to posttest (M = 14.16, SD = 1.3). For *confidence in responding*, scores improved, F(1, 122) = 64.15, p < .001, from pretest (M = 15.56, SD = 4.0) to posttest (M = 18.90, SD = 3.1).

Conclusions: Findings provide initial support for the value of LEO training to respond to ASD-related calls. Our design did not include a control group; therefore, we cannot conclude that gains in knowledge and confidence resulted from the training. Future work should include a control group to establish causal evidence in support of LEO training

428.082 *(Poster)* The Program to Assist Social Thinking (PAST): A School-Based Socioemotional Intervention for Children with Autism

P. Burnham Riosa[1] *and J. A. Weiss*[2]*, (1)Brock University, St. Catharines, ON, Canada, (2)Psychology, York University, Toronto, ON, Canada*

Background: It is particularly important to understand how socioemotional interventions can assist children with autism within the school setting. Many existing mental health interventions for children with autism are provided in clinical settings; however, the importance of targeting socioemotional interventions in contexts where youth spend much of their time – which is with their peers and where they typically learn – is critical. Innovations are occurring in the school system, but work is needed to understand their impact.

Objectives: The purpose of this study was to explore the experiences of students with autism who attended a school-based socioemotional intervention, the *Program to Assist Social Thinking* (PAST). The PAST program is a school-based intervention. Registered students attend the PAST program one day each week from October to June. The focus of this 3-year curriculum is on incorporating behavioural and cognitive-behavioural strategies in the context of a Social Thinking approach (Winner, 2007) to support the socioemotional development of students with autism.

Methods: A qualitative methodology was used consisting of focus groups conducted with 10 PAST students (grades 3 to 6) and individual interviews with eight parents of PAST students. Questions focused on how the program helped students with various social, emotional, and academic needs in the school setting. Interviews were audio-recorded and transcribed verbatim. All data were organized using NVivo 11. Braun and Clarke's (2006) thematic analysis was used to analyze the focus group and interview data.

Results: A description of the PAST program and findings from the qualitative analyses will be presented. Preliminary results from the parent interviews yielded 3 major themes: (1) Connection and Belonging (forming friendships and meaningful bonds with PAST students and teachers), (2) Managing Stress (learning to cope with difficult situations), and (3) Positive Changes in Social Interest and Engagement (positive interactions with others). Preliminary results from the child focus groups yielded the following themes: (1) Friendship (social relationships with other PAST students), (2) Cooperation (learning to work together to solve social problems), and (3) Socioemotional Skill Building (learning to identify emotions in self and others, using skills to manage emotions).

Conclusions: The current findings highlight the perspectives of students with autism and parents of students with autism in a school-based supportive skill-building program. Participants described a variety of social benefits of the program. Future work examining the effectiveness of PAST as a school-based socioemotional intervention is warranted.

428.083 *(Poster)* Therapist Experiences of Psychological Treatment for School Attendance Problem and Psychiatric Comorbidities in Children and Adolescents with ASD: A Qualitative Study

J. Melin[1] *and N. Choque Olsson*[2]*, (1)Child and Adolescent Psychiatry, Stockholm County Council, Stockholm, Sweden, (2)Clinical Neuroscience (CNS), Karolinska Institutet, Stockholm, Sweden*

Background: school attendance problem (SAP) is common among children and adolescents with autisms spectrum disorder (ASD). Patients with ASD with SAP is an increasing group within Child and adolescent mental health care centres in Sweden, but there is a lack of guidelines for treatment or interventions targeted to this group.

Objectives: the objective of this study was to investigate therapists' experiences of psychological treatment of SAP and comorbid psychiatric disorders in children and adolescents with ASD. The question the study addressed was the therapists' perception of treatment outcome and their view of favourable factors as well as the barriers in the treatment.

Methods: twelve therapists were interviewed using a semi-structured interview. Interviews were audiotaped, transcribed verbatim, and initially independently coded by two coders. The interviews were analyzed according to thematic analysis and using the program software N-Vivo11.

Results: the majority of therapists reported that a frequent group that they delivered psychological treatment was children and adolescents with ASD with a prolonged SAP. Insufficient adaptations in response to core impairment of ASD and lack of support in their daily life could be factors to develop the SAP. Prolonged social isolation in combination with severe psychiatric comorbidities was reported as a treatment barrier. In addition, unclear assignments and insufficient coordination between Child and adolescent mental health centres and school-services obstructed returning to the school of this group. Favourable factors to positive treatment outcome were: an accurate and sufficient survey, coordination between mental health care and schools and environmental adaptation at school as well as at home, parent support and sometimes change of schools. Concerning useful therapeutic technics behavioural activation and applied exposure from cognitive-behavioural treatment was reported. The goals for treatment when treating absence is >1 year should be carefully evaluated and restricted to the assignment at Child and adolescent mental health care centre.

Conclusions: according to therapist experiences important factors that impact the outcome of treatment was the length of the school absence and the severity of psychiatric comorbidities in patients with ASD. This entails more resources at home, school and mental health care are needed as well as better cooperation between these. According to the therapists' experiences, children and adolescents with ASD with limited societal support tends to develop SAP. We suggest that more research about SAP in children and adolescent with ASD and psychological treatment for this group is needed.

428.084 *(Poster)* Training Workplace Social Skills for Adolescents with ASD

K. Radley[1]*, K. A. Helbig*[2]*, E. H. Dart*[3]*, S. R. Schrieber*[4] *and M. E. Ware*[4]*, (1)University of Utah, Salt Lake City, UT, (2)University of South Dakota, Vermillion, SD, (3)University of South Florida, Tampa, FL, (4)University of Southern Mississippi, Hattiesburg, MS*

Background: Researchers have reported low rates of employment of individuals with ASD, with a failure to obtain employment after educational training being associated with lack of employment throughout the lifespan (e.g., Cimera & Cowan, 2009). Often, these challenges are directly associated with deficits related to social communication. More specifically, poor attendance, abusive behaviors, refusal to accept feedback, antisocial behavior, and physical appearance have been identified as social behaviors related to limited employability of individuals with ASD (Olson, Cioffi, Yovanoff, & Mank, 2001). Recent research has indicated that having well-developed social skills is predictive of employment following educational training—an unsurprising finding given that employers have rated effective social skills as one of the most important traits of employees with disabilities (Ju, Zhang, & Pacha, 2012). Despite the importance of social functioning, few interventions exist to address social skills necessary for vocational success for individuals with disabilities–with most research instead focusing on developing vocation specific behaviors.

Objectives: The purpose of the study was to evacuate an intervention package containing evidence-based strategies that school personnel can use to promote social skills in the workplace setting. Whereas a previous pilot study (Authors, 2019) had indicated the utility of such procedures in promoting social skill acquisition, this study sought to provide a systematic replication with participants with varying levels of cognitive functioning.

Methods: Five students with ASD participated in this study. All students were between the ages of 18 and 21 and were participating in a transition program. As a part of program requirements, each participant rotated across three internships during the school year where they were employed at various sites (i.e. food pantry, recreation center, dining, and child care centers). Target skills were selected via teacher interview and included Asking Questions, Following Multi-step Directions, Multitasking, Interacting with Someone Unfamiliar, and Interpreting Others Intentions. Training sessions were conducted once a week in the participants classroom and lasted an hour. The primary dependent variable was skill acquisition in the training setting with a secondary dependent variable of generalized skill acquisition to the workplace setting.

A multiple baseline design across skills was utilized to evaluate the effects of the social skills intervention package on the participants skill acquisition. Probes of skill accuracy were given across all phases of the study. Data were analyzed using visual analysis and Baseline Corrected Tau, a single case effect size estimate.

Results: Increases in level and trend were observed across participants, skills, and settings following the introduction of the intervention. Further, accurate demonstration of skills was maintained following the termination of training. Overall, this packaged intervention was effective in promoting vocational social skills.

Conclusions: Results of the study provide additional evidence of the effect of the program in promoting social skills in the workplace. Findings are of particular importance, as improvements in skill use were found to generalize to non-training settings. As such, practitioners and researchers may consider utilization of such procedures as a component of vocational preparation and transition programming for individuals with ASD.

428.085 *(Poster)* Training in-Vivo Social-Emotional Attention Improves Social Cognition: RCT of a Low-Cost EMA-Delivered Intervention.

P. Felsman[1], *A. H. Gerber*[2], *K. M. Hauschild*[3] *and M. D. Lerner*[2], *(1)Stony Brook University, Stony Brook, NY, (2)Department of Psychology, Stony Brook University, Stony Brook, NY, (3)Psychology, Stony Brook University, Stony Brook, NY*

Background: Evidence suggests that deficits in attention to social emotional stimuli in one's environment may underlie social challenges associated with autism spectrum disorder (ASD; Jones & Klin, 2013; Lerner et al., 2012). Interventions designed to facilitate social-emotional attention (SEA; e.g., by utilizing activities that require attention to/interpretation of faces) have elicited improvements in social connection and emotion identification (Lerner et al., 2011; Goldstein & Winner, 2012). While it has been hypothesized that this represents an "active ingredient" in such interventions, it is unknown whether simply potentiating alone SEA in everyday life can yield similar effects. Given challenges in these domains for those with ASD, it is likely that such changes would be greatest for those with higher ASD symptoms; if so, this could advance a low-intensity intervention for those with ASD.

Objectives: To test whether prompting SEA to interlocutors in daily life increases psychological and behavioral indices of social cognition, empathy, and prosociality, and whether autism symptoms moderate these effects.

Methods: Participants were 78 adults (M_{age}=22.35, SD_{age}=5.47) with IQ>70 (Table 1). They were randomized into one of two conditions and asked to log their social interactions via smartphone over 7 days. Those in the active condition were asked to pay attention to and report on the emotion of their interlocutor, while those in the control condition were asked to either pay attention to the hair color of their interlocutor or proceed with interactions as usual. Participants completed a variety of psychosocial measures related to social cognition and empathy pre- and post-intervention (MPDQ [Genero et al., 1992], SEIS [Schutte et al., 1998], BESA [Carré et al., 2013], DANVA-2 [Nowicki, 2004]) as well as reported how often they logged their social interactions during the intervention (i.e. compliance).

To determine whether condition predicted change in identified outcomes, we used an ANCOVA of change model, with condition moderated by compliance (to ensure participants actually engaged in SEA). Finally, we tested whether ASD symptoms as measured by the Adult Autism Spectrum Quotient (AQ; Baron-Cohen et al., 2001) further moderated the compliance x condition interaction.

Results: As compliance increased, SEA 1) marginally decreased MPDQ scores (b = -.0044, p = .0615) 2) marginally decreased total facial emotion identification errors on the DANVA-2 (b = -.0375, p = .0761) and 3) significantly decreased facial emotion identification errors for low-intensity (subtle) emotions (b = -.0375, p = .0320). AQ did not further moderate these effects.

Conclusions: Our results suggest that simply utilizing SEA in everyday life may lead people to more accurately process facial emotions, particularly subtle ones. They also appear to self-report marginally less connection to others, including the ability to pick up on their emotions. This is somewhat consistent with the Dunning-Kruger effect (Dunning, 2011) – that is, self-reported ratings of ability may actually decrease as actual performance improves via greater attunement to one's own abilities. Importantly, the effects of practicing attending to others' emotions held regardless of ASD symptoms, suggesting those with ASD may benefit equally from this approach.

428.086 *(Poster)* Translating Neuroprediction into Precision Medicine Via Brain Priming

K. Drapalik[1], *M. J. Williams*[1], *D. G. Sukhodolsky*[2], *N. Dvornek*[3], *J. S. Duncan*[4] *and P. E. Ventola*[2], *(1)Yale Child Study Center, New Haven, CT, (2)Yale Child Study Center, Yale University School of Medicine, New Haven, CT, (3)Yale School of Medicine, New Haven, CT, (4)Biomedical Engineering/Radiology, Yale University, New Haven, CT*

Background: Pivotal Response Treatment (PRT) is an evidence-based intervention for individuals with ASD; it was specifically designed to improve social communication by addressing core deficits in motivation. The neuropeptide oxytocin (OXT) plays a critical role in social functioning. Behavioral studies demonstrate that in children and adults with ASD, a single administration of intranasal OXT leads to increased willingness to interact socially, a better comprehension of affective speech, reduced repetitive behaviors, an increased understanding of others' mental states, and improved social cognition.

Objectives: The present study examines the impact of OXT and PRT on the development of language, social, and play skills in young children with ASD, specifically exploring OXT as an enhancer of response to PRT. The trial methods as well as the preliminary data are presented here.

Methods: To date, three children with ASD have fully completed the trial, ages 81, 92, and 81 months, (M= 84.67 months, SD= 6.35 months). The trial is open to children ages 5-9 years and is currently enrolling. All children have ASD as confirmed by the ADOS and expert clinical judgment. Participants complete 3 1.5- hour sessions weekly for 16 weeks. In addition, parents receive parent guidance and PRT training by a licensed clinician 1.5 hours weekly. Participants are randomly assigned to either oxytocin or a placebo and receive an intranasal spray before each PRT session. Clinical outcome measures include: SRS-II-Parent Version, Vineland-III, and ADOS. Children complete an fMRI and eye tracking at both pre- and post-intervention to assess for change in biologically-based preparedness for learning social communication skills. The fMRI task is a well-studied task of biological motion. fMRI data will be analyzed using two different machine learning algorithms to identify the regions of the brain that respond to improvement in social communication skills and predict the response to intervention. The eye tracking paradigms were developed specifically to assess changes in social attention and motivation and include clips from naturalistic social scenes.

Results: The clinical outcome measures are presented in case series format for the first 3 subjects. Specifically, Vineland-III, SRS-2, ADOS-2 scores are summarized. Please refer to Table 1.

Conclusions: This study is the first to combine oxytocin with a naturalistic behavioral intervention to determine if oxytocin has an added effect to PRT alone, at both the behavioral and neural systems-level. As seen by the Vineland-III scores, there were notable improvements in adaptive functioning. The current sample remained constant in their ADOS scores. A decrease in Child 2 and Child 3's SRS-2 scores are indicative of a decrease in ASD-related symptoms pre- to post-intervention. While the study is in its preliminary phase, it is highly novel and innovative in design and the initial findings are promising.

428.087 *(Poster)* Understanding the Daily Activities of Adolescents with Autism Spectrum Disorder and Intellectual Disability Receiving Group CBT Treatment for Anxiety

E. T. Engstrom[1]*, A. T. Meyer*[1]*, R. E. Boles*[2]*, J. Reaven*[3] *and A. Blakeley-Smith*[3]*, (1)JFK Partners, University of Colorado School of Medicine, Aurora, CO, (2)University of Colorado Anschutz Medical Campus, Aurora, CO, (3)JFK Partners, University of Colorado Anschutz Medical Campus, Aurora, CO*

Background: Adolescents with Autism Spectrum Disorder (ASD) and Intellectual Disability (ID) are at risk for significant anxiety and behavioral challenges (Helverschous & Martinson, 2011). Additionally, research suggests that teens with ASD and ID spend less time with peers and spend more time with paid professionals than teens without ID (Orsmund & Kuo, 2011). However, it is important to better understand the daily activities that this highly understudied and underserved population are engaging in, and how activities may be related to anxiety treatment outcomes.

Objectives: The purpose of the present study is to 1) identify the amount and frequency of daily activities that adolescents with ASD and ID engage in outside of school, and 2) to determine if there are changes in the total number and frequency of engagement in these activities following participation in anxiety treatment.

Methods: The present study involves data analyses from pre-intervention measures collected in an initial study that examined adolescent treatment outcomes in response to a modified group CBT program for youth with ASD, ID and co-occurring anxiety, derived from the Facing Your Fears program (FYF) (Blakeley-Smith et al.,INSAR presentation 2019; Reaven et al. 2011). A sample of 23 adolescents (*M* = 15.9, range: 12-18) with ASD and ID were included. Participants had a mean Full Scale IQ of 58.3 (SD = 12.1, range: 40-79) and a mean Adaptive Behavior Composite of 57.45 (SD= 13.2, range: 40-79). Anxiety was assessed via parent report on the SCARED (Birmaher et al. 1999) and Anxiety Depression and Mood Scale (ADAMS; Esbensen et al. 2003). Participants' parents completed the Children's Assessment of Participation and Enjoyment (CAPE; King, et.al. 2004) to measure teens' participation in recreation and leisure activities outside of mandated school activities. Dependent t-tests were conducted to examine pre-post differences in activity engagement.

Results: Results suggest that participants engaged in an average of 24.32 activities of the possible 55 on the CAPE (SD=6.61, 44.21% of activities). On average, as reported in the CAPE, participants engaged in activities with low intensity (less than 1 time per month), with a family member in their neighborhood, and with moderate enjoyment at pre-intervention (see Table 1). As previously reported in a prior presentation, there were significant decreases in anxiety as measured by the SCARED and ADAMS (Blakeley-Smith, et. al. INSAR presentation, 2019). However, there was not a significant change in the total activities endorsed on the CAPE (Diversity) from baseline (M=22.56, SD=8.04) to post-intervention (M=23.39, SD= 7.52) time points, t(18)=-0.52, p=0.61. Additionally, there were no significant changes in the frequency of activities (CAPE Intensity) from baseline (M=1.90 SD= 0.63) to post-intervention (M=1.93, SD=0.64) t(18)=-0.24, p=0.81.

Conclusions: These results suggest that while anxiety symptoms decreased following intervention, no changes were noted in engagement in recreational activities. Additional research is needed to understand factors that influence activity engagement in this population. Future research should include a larger sample size, and consider intervention components that may increase family access to recreation and leisure activities.

428.088 *(Poster)* Use of Multisensory Environments to Improve Outcomes for Individuals with Autism Spectrum Disorder: A Systematic Review

E. Isralowitz[1]*, M. E. Grager*[2]*, S. A. Cermak*[3] *and L. I. Duker (Stein)*[1]*, (1)Division of Occupational Science and Occupational Therapy, University of Southern California, Los Angeles, CA, (2)Chan Division of Occupational Science and Occupational Therapy, University of Southern California, Los Angeles, CA, (3)USC Mrs. T.H. Chan Division of Occupational Science and Occupational Therapy, University of Southern California, Los Angeles, CA*

Background: The sensory environment of education and healthcare settings have the potential to impact patient, caregiver, and provider outcomes. The Multisensory Environment (MSE) manipulates sensory features of the environment, often including adaptations to visual, auditory, tactile, and olfactory stimuli. Providing these stimuli, MSEs are reported to promote relaxation and engagement, and reduce aggression and self-injurious behaviors in users, including individuals with ASD. MSEs are popular in Europe and have been increasingly incorporated within the United States and Canada in hospitals, airports, and schools in the last decade. Despite this enthusiasm, criticism continues regarding the quantity and quality of existing MSE research.

Objectives: To systematically review available literature regarding the impact of MSEs on outcomes in individuals with ASD.

Methods: Seven databases were searched using the keywords "Snoezelen/Multisensory Environment," "sensory room," "autis*." Experimental studies utilizing an MSE, written in English, including individuals with ASD, and published from 1990 to October 2019 were included. Study characteristics, methods, and outcomes were organized and reported in tabular form. Studies wereappraised for methodological quality using a checklist with a maximum score of eight (Jinks, Cotton, & Rylance, 2010) and level of evidence via The Oxford Levels of Evidence 2 , a five-level study design rating matrix (OCEBM, 2011) by two independent researchers.

Results: The search produced 19 articles that met inclusion criteria. Of these, 11 were quantitative, 6 qualitative, and 2 mixed methodology. Of the quantitative studies the majority (82%) were non-randomized or single-subject research and 2 were randomized control trials. Participant ages ranged from 1 – 71 years, with the majority of articles focusing on a pediatric population (n=11). Studies were conducted in a variety of settings, including schools (n=9), adult day centers (n=2), residential settings (n=4), other community sites (n=3), and a dental clinic (n=1). Studies were conducted across a variety of continents including North America (n=9), Europe (n=5), Asia (n=3), and Australia (n=2). The majority of studies examined behavioral outcomes such as stereotypy, active engagement, and disruptive behaviors. Other commonly examined outcome measures included caregiver/provider and participant perceptions and anxiety, via electrodermal activity and caregiver report. Study results ranged from null to positive. Most studies reported mixed results (70%), with no negative outcomes reported. The average methodological quality score was 5 with a range of 3-8 points, indicating the majority of articles demonstrated at least two methodological issues. Based on OCEBM levels, 5 studies met a relatively high level of evidence (Levels 4-5), 6 met a moderate level of evidence (Level 3), while 8 demonstrated a lower level of evidence (Levels 1-2).

Conclusions: Based on our findings, there is preliminary evidence for the use of MSEs with individuals with ASD to promote engagement and reduce disruptive behaviors and anxiety symptoms. Despite this emerging evidence, many studies reported mixed results and few reported carryover effects beyond the MSE highlighting the need for further research. Additionally, the relative low number of randomized control studies highlights the need for more rigorous research into the efficacy and effectiveness of MSEs for individuals with ASD.

428.089 *(Poster)* Use of a Latest-Generation Multi-Sensory Interactive Room in the Intervention with Children and Adults with Autism Spectrum Disorders

***I. Basadonne**, M. Cristofolini, I. Mucchi, F. Recla and P. Venuti, Psychology and Cognitive Science, University of Trento, Rovereto, Italy*

Background: Considering the sensory peculiarities in Autism Spectrum Disorders (ASDs), some experiences with Multi-Sensory Interactive Rooms (MSIRs) have been reported over the last 20 years. These environments provide sensory stimulation calibrated on the users and the possibility to interact with the stimuli, experiencing a sense of control over the environment. According to the few studies conducted so far, MSRIs seem to favor a positive emotional state in users with ASD, a decrease in problem behaviors and longer attention spans. However, the possibility of working in MSIRs also on functions that are compromised in ASDs has not been investigated. Moreover, in the latest-generation MSRIs, physical objects have been completely replaced by digital projections, more varied and engaging but also more abstract and therefore potentially more difficult to understand for users with intellectual disabilities.

Objectives: The aim of this study was to establish whether a latest-generation MSIR is suitable for intervention on cognitive functions in ASDs, with respect to different age and functioning levels of users.

Methods: 27 subjects (18 children, mean age 5.57 years ± 1.11, 9 high- and 9 low-functioning, and 9 adults, 24.8 years ± 7.01, 3 high- and 6 low-functioning) underwent 5 sessions of 30 minutes in the MSIR. Intervention on the following functions was performed using protocols calibrated for sensory stimulation and difficulty level on the characteristics of the single participant: Maintaining instruction, Selective attention, Looking at and doing, Verbalization, Receptive communication, Turn, Memory, and Inhibition. During each session, a score (from 1 = not performed to 5 = autonomously performed) was assigned to each function in each activity that included it, calculating the average score at the session end. Wilcoxon signed-rank test on repeated measurements was conducted on the differences in performance in each function between session 1 and session 5, in the whole sample and in the subgroups Low-/High-functioning and Children/Adults.

Results: Performing the protocol has been impossible with 6 low-functioning subjects because of their difficulties in understanding the MSIR and regulating themselves inside it. Nevertheless, a reduction of the sensory stimulation and an approach based on subjects' personal exploring initiatives have allowed engaging them in some activities. For the others (13 children and 8 adults), statistically significant increases were detected in all functions, both in the whole sample and in the subgroups High-functioning and Children. In particular, in the entire sample and in the High-functioning subgroup the greatest increase was recorded for Verbalization (1.33 ± 0.75, p-value = 0.001 and 1.63 ± 1.18 p-value = 0.03 respectively) and Turn (1.30 ± 1.03, p-value = 0.002 and 1.87 ± 1.01, p-value = 0.001 respectively). Instead, for the Children subgroup in Verbalization (1.73 ± 1.22, p-value = 0.001) and Memory (1.65 ± 1.68, p-value = 0.018).

Conclusions: MSIRs solely based on interaction with digital projections seem suitable for intervention on cognitive functions in ASDs. However, possible difficulties with low-functioning subjects should be considered. Further studies are needed to fully explore the potential of MSIRs, also concerning other aspects (e.g. social interaction with peers).

428.090 *(Poster)* Utilizing Compass Supervision to Improve Intervention Plan Quality for Students with Autism

***L. N. Ogle**[1], L. A. Ruble[2], J. H. McGrew[3], A. Mitchell-Chavez[4] and K. Pinkman[5], (1)Department of Educational, School, and Counseling Psychology, University of Kentucky, Lexington, KY, (2)University of Kentucky, Lexington, KY, (3)Psychology, Indiana University - Purdue University Indianapolis, Indianapolis, IN, (4)Educational, School, and Counseling Psychology, University of Kentucky, Lexington, KY, (5)Department of Educational School and Counseling Psychology, University of Kentucky, Lexington, KY*

Background: The Collaborative Model for Promoting Competence and Success (COMPASS) is an evidenced-based, child-centered intervention that has been tested in three RCTS and improves educational outcomes for children with autism spectrum disorder (ASD). COMPASS starts with a parent-teacher consultation designed to create a holistic picture of the child at home and school. This shared understanding is then used to identify and develop personalized goals and intervention plans in the domains of social, communication, and learning skills. COMPASS is complex because the intervention plans developed are personalized based on an evidence-based practice in psychology (EBPP) approach that takes into account the specific contexts, strengths, and challenges of the student, teacher, and environment. Thus, a question concerns whether school-based ASD consultants are able to develop high quality and impactful intervention plans.

Objectives: The primary goal of this study is to describe the impact of supervision on changes in intervention plan quality over time.

Methods: School-based ASD consultants completed 16 hours of COMPASS training, then conducted consultations with 4 teacher-parent dyads. After each consultation, consultants were provided with supervision by the researchers who evaluated the quality of the intervention plans and provided qualitative feedback.

The study was conducted using an iterative design over two waves. Wave 1 included two consultants who worked with eight caregivers and special education teachers. A 16-item intervention plan quality checklist (α = .795) based on a dichotomous scale (yes/no) was developed by the researchers to assess items such as quality of the goals, inclusion of evidence-based practices for children with ASD, clarity and specificity of intervention plans, and common elements of effective teaching. This checklist was completed both by consultants and researchers. Wave 2, currently in progress, includes seven consultants and 28 dyads of parents and teachers. In addition to the 16-item consultant and researcher-rated intervention plan quality checklist developed in Wave 1, a six-item rating scale was also developed for teachers to complete after receiving the intervention plans developed during the consultation. This scale asks teachers to rate how clear, relevant, realistic to implement, appealing, consistent with values, and effective the intervention plans are from their perspective. This will also be shared with consultants as a part of supervision.

Results: Preliminary results from Wave 1 indicate that intervention plan quality improved from the first to the fourth consultation 51%, 60%, 69%, and 84% respectively. Wave 2 data is currently being collected, and will be reported in the final presentation. Once full data are available, repeated measures ANOVA will be used to evaluate the impact of supervision and teacher feedback on changes in intervention plan quality.

Conclusions: COMPASS is an EBPP intervention that has promise of widespread impact on educational outcomes of children with ASD. But the complexity of interventions may keep empirically-supported interventions from being adopted and sustained. Initial data indicate that despite the complexity with COMPASS, our supervision, feedback, and support provided to consultants enhances intervention plan quality.

This work was supported by Grant R34 MH111783-02 from the National Institute of Mental Health

428.091 *(Poster)* Virtual Reality and Video Modeling Interventions Improve Self-Reported Knowledge/Comfort during Police Interactions for Autistic Adolescents and Adults

A. Zitter[1], *M. L. Cola*[2], *L. Cordero*[2], *M. Udhnani*[2], *J. S. Miller*[2], *V. Ravindran*[3], *R. Solorzano*[3], *S. Turnacioglu*[3], *J. McCleery*[2] *and J. Parish-Morris*[2], *(1)A.J. Drexel Autism Institute, Drexel University, Philadelphia, PA, (2)Center for Autism Research, Children's Hospital of Philadelphia, Philadelphia, PA, (3)Floreo, Inc., Washington DC, DC*

Background: Individuals with Autism Spectrum Disorder (ASD) often have difficulty with novel problem solving and rapidly processing social situations in real time (Channon et al., 2001; Vanmarcke et al., 2016). Interactions with police officers are unique, unscheduled, and unplanned social situations that can introduce a high level of stress and are experienced by individuals across a wide range of functioning (Rava et al., 2016). Therefore, it is important to prepare individuals for this type of interaction. Virtual reality (VR) can be a useful training tool as it provides individuals with the opportunity to practice something multiple times under simulated conditions. In the current preliminary analysis, we compare the effectiveness of an immersive VR-based intervention versus a video-modeling intervention to teach police safety skills to adolescents and adults with ASD.

Objectives: Compare the effectiveness of two different intervention formats by assessing (1) live ratings of participant behavior during police interactions (or simulated interactions), and (2) participant self-reports of police interaction knowledge/comfort pre-/post-intervention.

Methods: Thirty-nine verbally fluent adolescents and adults with ASD were randomly assigned to complete either three sessions of the immersive VR-Based Police Safety Module (PSM) or a video modeling-based intervention (BeSAFE). To measure change in behavior and knowledge/comfort, participants engaged in a 3- to 5-minute live interaction and completed a questionnaire pre- and post-intervention. At baseline, participants interacted with a study staff member who presented as a police officer. After completing the intervention, participants interacted with an actual police officer or a uniformed security officer. During the interactions, experimentally blinded staff members and police officers completed a series of ratings on a six-point Likert scale (strongly disagree–strongly agree) about the participant's behavior. Ratings included questions about appropriateness of the participant's verbal responses, nonverbal behavior, and eye contact. The police knowledge and comfort questionnaire included questions such as, "I feel I know how to act around police officers," and "I feel comfortable being interviewed by police officers." Two generalized linear mixed effects models (lme4 in R) were used to predict (1) behavioral ratings, and (2) police knowledge scores from the interaction between condition and time (pre/post intervention).

Results: Preliminary analyses of 39 participants indicated a significant main effect of time on police knowledge and self-reported knowledge and comfort (Estimate: 10.25, SE: 1.86, t=5.50, p<.001), and no significant interaction between time and intervention format (VR vs. video modeling; p=ns). Live interaction assessment scores (conducted by staff and officers) did not significantly change from pre- to post-intervention, and there was no significant interaction between condition and time (all ps=ns). These results are preliminary and data collection is on-going (final sample N=48; complete by May 2020); final results may differ.

Conclusions: It is important to equip individuals with ASD with social skills in a format that is comfortable, motivating, and effective. In this preliminary analysis, participants reported improved police knowledge and comfort interacting with officers after completing VR-based and video modeling-based interventions. The present study is ongoing and we anticipate reporting results from the complete sample (N=48) by May 2020 (clinicaltrials.gov=NCT03605368).

428.092 *(Poster)* Vitamin D3 Combined with ABA Therapy for Treatment of Children with Autism Spectrum Disorder

C. Wang*, Department of Social Psychology, Nankai University, Tianjin, China*

Background: Autism spectrum disorder (ASD) is a neurodevelopmental disorder characterized by deficits in social interaction and communication, repetitive and stereotypic behaviors, and restricted interest. It has been regarded due to genetic and environmental risk factors. Vitamin D deficiency has recently been proposed as a possible environmental risk factor for ASD. ABA has been reported in improving social interactions of children with ASD for the last decades.

Objectives: To study the clinical effect of vitamin D3 (VitD3) combined with ABA in the treatment of children with autism spectrum disorder (ASD).

Methods: A total of 90 ASD children with VitD3 deficient, aged 7 to 12 years, were recruited and divided into three groups: ABA group (n=30), VitD3 group (n=30), and ABA+VitD3 group (n=30). Autism Diagnosis Observation Scale (ADOS), Social Communication Questionnaire (SCQ) and Childhood Autism Rating Scale (CARS) were used to evaluate social communication skills before and after 12 weeks of treatment.

Results: The ABA group had significant reductions in the total score and the scores on social communication in ADOS after 12 weeks of treatment (P<0.05) as well as a significant reduction in the total score of the SCQ and CARS (P<0.05). After 12 weeks of treatment, the ABA+VitD3 group had a significant increase in the level of 25(OH)D and significant reductions in the total score and the scores on social communication subscales of ADOS (P<0.05), as well as a significant reduction in the total score of the SCQ and CARS (P<0.05). The ABA+VitD3 group had a significantly greater reduction in the score on social interaction subscale than the other two groups (P<0.05).

Conclusions: ABA can effectively improve the clinical symptoms of toddlers with ASD, with a significantly better clinical effect in improving social interaction. ABA combined with VitD3 has a significantly better clinical effect in improving social communication skills and may be one of the best strategies for improving the clinical symptoms of toddlers with ASD.

428.093 *(Poster)* "Snack Talks": Effects of a Visual Communication Support on Increasing Conversation Engagement for Adults with Autism

K. Bateman[1], *S. E. Wilson*[2], *J. Doucette*[3], *E. Ingvarsson*[3], *W. Therrien*[2], *R. E. Nevill*[2] *and M. O. Mazurek*[2], *(1)College of Education, University of Washington, Seattle, WA, (2)University of Virginia, Charlottesville, VA, (3)Virginia Institute of Autism, Charlottesville, VA*

Background: Rates of autism spectrum disorder (ASD) diagnoses continue to rise, challenging adult service providers to support a growing number of adults with autism. Yet reviews of extant literature indicate that social outcomes for adults with ASD are typically poor. Further, few evidence-based social interventions exist for adults. As most social skills interventions are developed with children, these interventions may not be aligned with the social needs of individuals with ASD when navigating adulthood settings. Thus, targeted social skills and social communication interventions that are aligned with the needs of adults are warranted.

Objectives:

1. Describe the development and implementation of "Snack Talk", a naturalistic visual communication support used to increase social communication during mealtimes.
2. Examine potential social outcomes of mealtimes, as individuals are included in a naturally occurring routine with numerous social opportunities to build social relationships and increase overall quality of life.
3. Report findings from the implementation of "Snack Talk" with five adults with ASD and other developmental disabilities.

Methods: This intervention utilized single case research methodology. A reversal design across participants was employed to analyze the effectiveness of the intervention. Prior to intervention, participants were interviewed to identify common interests and preferences. Next, "Snack Talk" supports were developed, including a topic question and multiple visual/text possible answers in this support. Baseline conditions consisted of typical mealtimes, with no intervention implementation. Intervention conditions consisted of implementation of "Snack Talk" intervention procedures. Mealtimes were video recorded and coded to identify conversation engagement using 10-second partial interval recording. Percent of intervals engaged in conversation was reported. Upon completion of intervention, social validity surveys were distributed to interventionists and study participants.

Results: Implementation of "Snack Talk" supported increased conversation engagement across all participants during intervention and generalization phases as compared to baseline. Generalization phases indicated all participants either maintained or engaged in higher levels of conversation engagement with peers and staff. A functional relationship was established for four of the five participants. For one participant, stability was variable throughout intervention phases. This is attributed to consistent changes in medication and attendance. Social validity findings indicated staff felt the intervention was acceptable, sustainable, and effective. All participants indicated that they enjoyed participating and using "Snack Talk" cards and identified strong interest in continuing using these supports outside of intervention.

Conclusions: Targeted interventions aligned with the social needs of adults with ASD are essential to support individuals with ASD entering adulthood. "Snack Talk" is easily implemented and can be adapted to meet the individual interests and needs of adults with ASD. As a low-cost and low-tech intervention with simplistic procedures and high social validity, "Snack Talk" is a sustainable intervention that can be implemented with few resources to support social engagement. Engagement in strong social skills during naturally occurring routines, such as mealtimes, is meaningful, as it fosters peer relationships. Ultimately, these increased relationships play a large role in reducing feelings of isolation and instead ensure adults with disabilities have access to community membership.

428.094 *(Poster)* "We Can See a Bright Future": Parents' Perceptions of the Outcomes of Participating in a Strengths-Based Program for Autistic Adolescents

E. A. Lee[1,2], *M. H. Black*[1,2], *M. Falkmer*[1,2,3], *T. Tan*[1,4], *L. Sheehy*[5], *S. Bolte*[2,6,7] *and* ***S. J. Girdler***[1,2], *(1)Curtin Autism Research Group, Curtin University, Perth, WA, Australia, (2)School of Occupational Therapy, Social Work and Speech Pathology, Curtin University, Perth, WA, Australia, (3)CHILD, Swedish Institute for Disability Research, School of Education and Communication, Jönköping University, Jönköping, Sweden, (4)School of Mechanical Engineering, Curtin University, Perth, WA, Australia, (5)Autism West, Perth, WA, Australia, (6)Center of Neurodevelopmental Disorders (KIND), Centre for Psychiatry Research; Department of Women's and Children's Health, Karolinska Institutet, & Stockholm Health Care Services, Region Stockholm, Stockholm, Sweden, (7)Child and Adolescent Psychiatry, Stockholm Health Care Services, Stockholm, Sweden*

Background: Despite autistic individuals commonly possessing specific strengths, skills and abilities, young autistic people often experience poor outcomes in education, employment and community engagement. Interventions targeting the strengths and talents of autistic adolescents may improve their transition and outcomes in adulthood, building pathways to employment and further education.

Objectives: This study examines the first wave results of a three-year longitudinal survey evaluating the long-term outcomes in sense of belonging, self-esteem, health and well-being, social interaction, and activities and participation of autistic adolescents participating in a strengths-based program. This baseline study explores the principal components contributing to the success of a community strengths-based program and the outcomes for the autistic adolescents as a result of participating in the program as perceived by their parents.

Methods: An online survey was conducted with parents of autistic children who had previously or were currently participating in a strengths-based program that supports the development of special interests in Science, Technology, Engineering, Arts and Mathematics (STEAM). Activities include coding, Lego robotics, Arduino, digital media, music, visual arts and mathematic enrichment class. The survey includes both closed and open-ended questions, which will be circulated online for three consecutive years in 2018, 2019 and 2020. Fifty-two parents participated in the first year survey representing 53 autistic adolescents, with one parent reporting for her two attending children. Exploratory factor analysis was undertaken to identify the principal components of the strengths-based programs, while thematic analysis exploring parents' perceptions of the outcomes of participating in a strengths-based program for autistic adolescents was performed.

Results: Exploratory factor analysis of parents' viewpoints revealed three main factors underlying the strengths-based programs explaining a total of 64.03% of the variance: feeling accepted and engaged (37.98%), feeling at ease (16.52%), and improving social and coding skills (9.53%). Following participation in the program adolescents were more confident in asking for help, communicating and sharing what they had learnt with their autistic peers and mentors, and experienced the strengths-based program in a safe and informal learning environment. Parents perceived a positive impact on their autistic children's sense of belonging, self-esteem, health and well-being, social relationships and interactions, and activities and participation. Results demonstrate the importance of a supportive social environment in fostering adolescents' feelings of acceptance and in harnessing their unique skills and talents.

Conclusions: This initial study highlights the positive impact of strengths-based programs on participants' sense of belonging, self-esteem, health and well-being, social relationships and interactions, and activities and participation from their parents' perspectives. Understanding the strengths and abilities of autistic adolescents, and developing programs targeting and leveraging the skills, abilities and special interests of autistic adolescents is likely to improve their transition outcomes to adulthood. The principal components underlying the strengths-based programs provide a preliminary framework that may underpin future strengths-based interventions.

Interventions - Pharmacologic

PANEL SESSION — **INTERVENTIONS - PHARMACOLOGIC**

215 - Randomized Clinical Trials of Repeated Intranasal Oxytocin Treatment to Enhance Social Functioning in ASD

Panel Chair: Linmarie Sikich, *Department of Psychiatry and Behavioral Sciences, Duke Center for Autism and Brain Development, Durham, NC*

Discussant: Jeremy Veenstra-Vander Weele, *Psychiatry, New York State Psychiatric Institute / Columbia University, New York, NY*

This session will bring together investigators from around the world who are conducting randomized clinical trials of repeated doses of intranasal oxytocin in individuals with ASD. Each investigative group has taken a somewhat different approach in terms of the study population, outcome measures, context of treatment and examination of biologic factors that might inform the apparent lack of treatment response to repeated administration of intranasal oxytocin.

215.001 *(Panel)* Randomized Controlled Trial of Intranasal Oxytocin in Autism Spectrum Disorder

***E. Anagnostou**, Holland Bloorview Kids Rehabilitation Hospital, Toronto, ON, Canada*

Background: Recent evidence suggests that oxytocin (OXT) may have therapeutic potential in Autism Spectrum Disorder (ASD). Specifically, neuroimaging studies have reported that OXT enhances connectivity in the neural networks that support social functioning, with subsequent improvements in corresponding social behaviors. There has been growing interest in assessing the effectiveness of OXT treatment in ASD, although several methodological limitations exist, including sample size, varying measures of sociability and, lack of consensus on dosing, administration method and frequency of administration.

Objectives: The primary aim of this study was to examine the effect of OXT versus placebo on a measure of social function, specifically social withdrawal. A secondary aim of this study was to examine the effects of OXT on social cognition, repetitive behaviors, anxiety and, quality of life as well as assess the tolerability and safety of OXT in youth with ASD.

Methods: 60 children and adolescents (mean age: 12.4 +/- 1.8 years) participated in a 12 week, randomized, double-blind, placebo-controlled trial of OXT at 0.4 IU/kg twice a day. Participants completed: (1) the Aberrant Behavior Scale – Social Withdrawal subscale; (2) the Let's Face It! Skills Battery as a measure of social cognition; (3) The Child and Adolescent Symptom Inventory – Fourth Edition Revised (CASI-4R) as a measure of anxiety; (4) The emotional functioning subscale of Pediatric Quality of Life Inventory (PedsQL) and; (5) the Safety Monitoring Uniform Research Form (SMURF) to assess adverse effects.

Results: 54 patients completed the trial. Six patients withdrew from treatment early (5 active, 1 placebo), 1 due to adverse events and 5 due to the withdrawal of consent. There were no significant differences between active and placebo groups on social withdrawal (ABC-SW: $p = 0.60$). However, participants taking oxytocin did show significant improvement in social recognition (Let's Face it Battery: $p = 0.03$) as well as on the emotional functioning scale of the PedsQL ($p = 0.04$). A decrease in CASI anxiety scores was significantly associated with an increase in quality of life (PedsQL scores, $p < 0.001$). The effect of change in social cognition on change in quality of life was not significant. Oxytocin was overall well tolerated, with no serious adverse drug reactions reported. Furthermore, participants in the active group showed significant changes in plasma levels from week 12 to baseline ($M_{change} = 14.2$, $p = 0.03$) relative to those in the placebo group ($M_{change} = 1.5$). Preliminary results from the 30 participants who participated in an eye-tracking sub-study suggest emotion-based differences with oxytocin versus placebo on face processing tasks.

Conclusions: In our sample, oxytocin was not superior to placebo in the reduction of social withdrawal. However, participants taking oxytocin did show nominally significant improvement in social recognition and emotional functioning on the quality of life instrument. Improvements in anxiety but not social cognition partially accounted for improvements in quality of life, providing some mechanistic understandings.

215.002 *(Panel)* A Large, Heterogenous Ouble-Blinded Trial of Oxytocin to Enhance Social Behaviours in ASD

***L. Sikich**, Department of Psychiatry and Behavioral Sciences, Duke Center for Autism and Brain Development, Durham, NC*

Background: Preclinical evidence from some animal models with features of autism has demonstrated that exogenous oxytocin may improve social communicative functioning, albeit with differences in the timing and magnitude of such changes in different strains and sexes. In humans with Autism Spectrum Disorder (ASD), single doses of intranasal oxytocin have improved objective measures of social cognition as compared to placebo. However, placebo-controlled studies of repeated dosing with oxytocin have failed to demonstrate consistent improvements in social functioning of individuals with ASD. However, most of these trials have been small and relatively short. In addition, optimal dosing of intranasal oxytocin has not been established.

Objectives: The primary aim of the Study of Oxytocin in ASD to enhance Reciprocal Social Behaviors – SOARS-B was to examine the safety and therapeutic effects of oxytocin compared to placebo in a large, heterogeneous sample of children with ASD over a sufficiently long period of time to demonstrate meaningful changes in social functioning. In addition, the large sample, biologic and genetic/epigenetic measures collected were expected to facilitate identification of factors associated with oxytocin responsiveness..

Methods: 290 children and adolescents between 3 and 17 years were randomly assigned to twice daily treatment with oxytocin or placebo for 24 weeks. Randomization was stratified by the presence/absence of fluent speech. Dosing was titrated from 8 IU daily to a target of 24 IU twice daily with further increases after 8 weeks of the target dose to as much as 80 IU total daily dose. The primary outcome measure was the Aberrant Behavior Checklist – Social Withdrawal subscale (ABC-SW). Key secondary outcomes were the Social Responsiveness Scale, 2nd edition (SRS-2) and caregiver-completed Vineland Adaptive Behavior Scales, 2nd edition. The Reading the Mind in the Eyes Task was completed by subjects who verbally demonstrated understanding of different emotions. Plasma oxytocin levels were obtained prior to treatment and after 8 and 24 weeks of treatment. Adverse events were systematically elicited.

Results: The oxytocin and placebo groups were well matched. 16 participants withdrew prior to the first post-baseline assessment leaving 274 participants available for efficacy analyses. 253 participants completed the 24 week treatment period with more early withdrawals due to adverse events or clinical worsening in the oxytocin group (7) than in the placebo group (3), although more participants were lost to FU or noncompliant in the placebo group. There were 3 serious adverse events during double-blind treatment, including sedation leading to a car accident in a participant receiving oxytocin. There was no difference in the reduction in the ABC-SW or the SRS-2 total score between groups ($p=0.619$ and $p=0.595$) respectively. There was no correlation between the pretreatment plasma oxytocin level and treatment response.

Conclusions: In our sample, intranasal oxytocin was well tolerated and was not associated with significant laboratory abnormalities. However, oxytocin did not separate from placebo on multiple measures of social functioning. Further, response to oxytocin treatment was not related to pretreatment plasma oxytocin level.

215.003 *(Panel)* Randomised Controlled Trials of Oxytocin Therapy to Improve Social Learning in Young Children: Two Clinical Trial Approaches.

***A. J. Guastella**, Brain and Mind Centre, Children's Hospital Westmead Clinical School, Faculty of Medicine and Health, University of Sydney, Sydney, NSW, Australia*

Background: Early life social experiences shape neural pathways in children to develop lifelong social skills. While there have been investigations targeting social learning opportunities, and separately, neurobiological systems that underpin social development, there has been a limited number of studies that have combined both approaches. Such approaches may be important for two reasons. First behavioral social learning supports, such as the Early Start Denver Model (ESDM), show efficacy in improving social learning outcomes. There is, however, a need for better outcomes that positively impact a broader population. Second, while there is growing evidence for the potential benefits of neurobiological interventions, such as oxytocin based therapies, there have been mixed findings for efficacy. Recent studies have highlighted the importance of context and, in particular, the provision of social learning, to augment therapeutic effects.

Objectives: The aim of this talk is to present a novel approach for using behavioural and neurobiological approaches to augment social learning early in life. This talk discusses pharmacological and non-pharmacological strategies that could augment outcomes. Clinical trials are then presented that aim to improve social outcomes for children using different clinical trial designs and with social learning therapies in young children diagnosed with ASD. The role of objective and caregiver/clinician ratings in these trials are also investigated.

Methods: Two placebo controlled clinical trials are presented. The first trial presents the first trial we are aware to ultilise placebo lead designs with oxytocin and then provides 12 weeks of oxytocin treatment randomized to a placebo. In the second trial, we combine parent-led ESDM therapy with oxytocin treatment, or a placebo, to facilitate social learning in young children. A range of biomarkers were collected to evaluate the link between caregiver reports and physiological, imaging and cognitive biomarkers.

Results: Results show a very strong placebo response during placebo lead-in phase that was reported by caregivers on social responsiveness measures (Cohen's $D = 3$). Results confirm the expectation of large placebo influences on outcome measures. The presentation then examines the relationship of caregiver reports with other caregiver/clinician reports and objective markers. Results show placebo responses are not consistently reported across all measures. The presentation then focuses on the tolerability, acceptability and efficacy of oxytocin as a therpauetic on its own and when combined with behavioural therapies. Implementation, efficacy, acceptability and tolerability are discussed. Results of the trial available at the time of presentation will be presented.

Conclusions: This work highlights a novel approach to improve social learning supports for young children with ASD. This approach shifts the focus from applying possibly-related broad treatments, to specifying and targeting the relevant circuits, at the right time of learning, to optimize outcomes. It also highlights the critical importance of controlling for placebo response biases in clinical trials to improve the opportunity to demonstrate efficacy and highlights the potential impact of biases across measures.

215.004 *(Panel)* Neurobiological Mechanisms of Oxytocin's Efficacy and Its Diminishment during Repeated Administrations

***H. Yamasue**, University of Tokyo, Tokyo, Japan*

Background: Autism spectrum disorders (ASD) currently have no established pharmacological treatment for its core symptoms. Oxytocin is expected as a novel therapeutic for the core symptoms. The speaker has conducted several independent clinical trials to test oxytocin's efficacy on the core symptoms or their neural and behavioral underpinnings. These trials have revealed oxytocin-induced improvements of autistic behaviors such as difficulty in judging other's friendship based on non-verbal communicative information (JAMA psychiatry 2014), deficits in understanding other's social emotion (Brain 2014), less facial expressivity during social interaction (Brain 2019) and the core symptom itself (Brain 2015; Mol psychiatry 2018a) in adult males with ASD. Furthermore, neural effects of oxytocin were demonstrated such as enhancing activity in the medial prefrontal and anterior insular cortices during resting or conducting the tasks (JAMA psychiatry 2014; Brain 2014; 2015). In addition, a new method to predict therapeutic responses to oxytocin by utilizing information of variants in oxytocin receptor gene was developed (SCAN 2017). Although these findings have supported the potential of oxytocin as a novel therapeutic for the core symptoms of ASD, it has also been suggested that repeated administrations of oxytocin induce diminishments in the efficacy (Brain 2019) and changes in glutamatergic neural transmission (Mol psychiatry 2015; 2018b).

Objectives: To clarify the neurobiological mechanisms of oxytocin's efficacy and their decrement during repeated administrations at molecular level, the metabolomic, proteomic, and genomic data collected from these clinical trials were analyzed.

Methods: The participants with ASD of our previous clinical trials (total N=146) were genotyped using SNP arrays. Genomic data were analyzed to identify genes coding oxytocin's efficacy. The current study also examined proteomics in the plasma using Liquid Chromatography–Mass Spectrometry and metabolomics utilizing capillary electrophoresis time-of-flight mass spectroscopy in these participants with ASD. To identify metabolites and proteomics characterizing ASD individuals at baseline, plasma metabolites and proteomics levels were compared between 106 adult males with ASD and 26 age, intellectual level, parental socio-economic background and body-mass-index matched men with typical development. Furthermore, in a randomized, double-blind, parallel-group, placebo-controlled, multi-center clinical trial data, effect of 6 weeks intranasal oxytocin (48IU/day) on the metabolomics and proteomic levels was tested in 106 men with high-functioning ASD. Sub-analyses stratified with efficacy of oxytocin or its diminishment during repeated administrations were also conducted. The study protocol was approved and registered (UMIN000002241/ 000004393/ 000015264). Written informed consent was obtained from all participants.

Results: A gene was identified to be significantly associated with oxytocin efficacy indexed with neuroimaging and autistic behaviors consistently in two independent clinical trials. Furthermore, several molecules were found to be significantly associated with ASD diagnosis. The sub-analyses demonstrated a molecule showing a significant association with efficacy of oxytocin especially with its diminishment during repeated administrations.

Conclusions: The findings suggest potentials of the metabolomics and proteomics for providing surrogate markers of ASD diagnosis as well as those of oxytocin's efficacy, and also suggest that the identified genes and molecules can elucidate neurobiological mechanism of clinical improvement in individuals with ASD induced by oxytocin.

POSTER SESSION — INTERVENTIONS - PHARMACOLOGIC
429 - Interventions - Pharmacologic Posters

429.001 *(Poster)* Altering Gut Microbiota May Benefit Children with Autism Spectrum Disorder: Results from Lactobacillus Plantarum PS128 for ASD Trial

***Y. W. Liu**[1], C. W. Huang[2], J. J. Chiou[2] and Y. C. Tsai[1], (1)Institute of Biochemistry and Molecular Biology, National Yang-Ming University, Taipei, Taiwan, (2)Center for Systems and Synthetic Biology, National Yang-Ming University, Taipei, Taiwan*

Background: *Lactobacillus plantarum* PS128 (PS128), a reported psychobiotic, improved behavioral disorder in several animal models, including depression, Parkinson's disease, Tourette syndrome, and irritable bowel syndrome. A randomized, double-blind, placebo-controlled trial investigating the effects of PS128 on children with autism spectrum disorder (ASD) in Taiwan was finished recently. The results showed that PS128 benefit younger children with ASD, especially the symptoms related to anxiety, hyperactivity, and opposition.

Objectives: Gut microbiota composition was reported to be different between children with ASD and neurotypical ones. In this study, we aim to investigate the gut microbiota charcteristics in the PS128 for ASD clinical trial.

Methods: Stool sample obtained from subjects in the PS128 for ASD clinical trial were used for microbiota analysis. Total fecal DNA was extracted and the V3-V4 region of 16S rRNA was amplified by 16S amplicon PCR primers 314F' and 805R'. The amplified PCR products with Illumina adapter overhang sequences were then indexed for library construction. The sequencing was conducted with Illumina Miseq sequencer using v3 reagents (MiSeq paired-read sequencing 300 bp) in the Sequencing Core Facility of National Yang-Ming University Genome Center (YMGC). The sequencing data was analyzed on QIIME2. The LEfSe method and PICRUSt method was applied to identify the differentially abundant taxa and to predict involved functional pathway.

Results: PS128 intervention for 28 days altered the gut microbiota composition of subjects. In younger subjects, aged 7-12, increase of *Bifidobacterium* and improvement in Clinical Global Impress-Improvement (CGI-I) showed positive correlation. Results obtained from LEfSe showed that PS128 ingestion for 28 days elevated the abundance of *Lactobacillus plantarum*, Lachnospiraceae UCG_008 and Lactobacillaceae.

Conclusions: Up to date, psychological testing is the only way to diagnose ASD. Biological characteristics for ASD diagnosis and therapy are still lacking. Biomarker molecules or even specific bacterial taxa in gut are expected to be the targets for ASD therapy. In this study, we found the microbiota composition was altered by PS128 intervention and the alterations are correlated to CGI-I. Based on the results obtained from the PS128 for ASD trial, we speculated that PS128 may benefit children with ASD at least partially by gut microbiota alteration.

429.002 *(Poster)* Bumetanide Improves Social Behavior in the BTBR Mouse Model of Autism

M. Ingallinesi[1], *F. Massé*[2], *J. Combeau*[2], *S. David*[2], *J. C. Bizot*[2], *P. Baumy*[3], *G. Simonin*[4], *G. Gauderat*[3], *S. Peigne*[5], *C. Mannoury-La-Cour*[6] *and C. Gabriel*[1], *(1)Center for Therapeutic Innovation in Neuropsychiatry, Institut de Recherches Internationales Servier, Suresnes, France, (2)Key-Obs, Orléans, France, (3)Center of Excellence- Drug Safety and Pharmacokinetics, Technologie Servier, Orléans, France, (4)Biokinetics, Center of Excellence- Drug Safety and Pharmacokinetics, Technologie Servier, Orléans, France, (5)Center of Excellence- Drug Safety and Pharmacokinetics, Institut de Recherches Internationales Servier, Suresnes, France, (6)Center for Therapeutic Innovation in Neuropsychiatry, Institut de Recherches Servier, Croissy-sur-Seine, France*

Background: Bumetanide is a selective sodium-potassium-chloride (Na^+-K^+-$2Cl^-$) co-transporter inhibitor known to modulate neuronal transmembrane Cl^- gradient which drives neuronal excitatory or inhibitory function of γ-aminobutyric acid (GABA) in the brain. Previous studies in two animal models of Autism Spectrum Disorder (ASD) (fmr1 KO mice and pregnant mice treated with valproic acid) have shown the ability of a prenatal treatment with bumetanide to attenuate autism-relevant behaviors in the offspring. However, no postnatal effect of bumetanide in a relevant ASD animal model has been investigated to date. These data could be useful in the context of ongoing phase III clinical trials where a bumetanide paediatric liquid formulation is assessed for the treatment of children and adolescent with ASD.

Objectives: The present study was aimed to investigate the effect of bumetanide on social and repetitive behaviors in young BTBR T+ Itpr3tf/J (BTBR) mice, an inbred strain with high face validity for autistic-like symptoms.

Methods: Juvenile (6 week-old) male C57BL6J (B6) mice as control animals or BTBR mice received an acute intraperitoneal injection of vehicle (VEH) or bumetanide at three doses (0.3, 3 or 30 mg/kg; 8 groups; N=15 per group). After dosing, mice were tested in the 3-chamber and self-grooming/digging assays to evaluate social and repetitive behaviors respectively. The different parameters were scored by automated videotracking method and by manual scoring by a trained observer unaware of drug treatment.

Results: Both VEH- and bumetanide-treated B6 control mice exhibited a normal social behavior and a usual grooming/digging behavior in a novel environment at all tested doses. As compared to VEH-treated B6 control mice, VEH-treated BTBR mice showed a significantly impaired sociability and deficit in social novelty preference, decreased exploratory behavior and increased repetitive behaviors (grooming and digging time). Bumetanide dose-dependently attenuated the social deficit in BTBR mice in the 3-chamber test, an effect that reached statistical significance at the highest dose ($p<0.05$). However, bumetanide at tested doses did not improve exploratory behavior or deficit in social novelty preference and did not reduce the increased grooming/digging time in BTBR mice. There was no significant difference between VEH- or bumetanide-treated BTBR and B6 mice for the distance travelled in the experimental apparatus during the test session.

Conclusions: Acute bumetanide administration dose-dependently attenuated the deficit in sociability, an autism-relevant symptom, displayed by BTBR mice. Globally, the present study shows for the first time a postnatal effect of bumetanide in a relevant ASD animal model, supporting its use in clinical trials and suggesting bumetanide as a promising drug to enhance sociability deficits in ASD patients.

429.003 *(Poster)* Clinical Response to Mitochondrial Cocktail in Patients with ASD and Mitochondrial Dysfunction: A Case Series

C. Fein[1] *and M. Bauman*[2], *(1)Pediatrics, Umass Medical Center, Worcester, MA, (2)Boston University School of Medicine, Boston, MA*

Background: Autism spectrum disorder (ASD) is a neurodevelopmental disorder characterized by social, verbal and behavioral impairment which has been increasing in prevalence. Currently the cause of ASD is unknown, but the disorder is thought to be due to an interaction of environmental, biologic and genetic predisposing factors. There is a growing body of evidence showing an association between autism spectrum disorder and mitochondrial dysfunction. There is literature suggestive that children with known dual diagnosis of ASD and mitochondrial dysfunction are often difficult to distinguish phenotypically from children with idiopathic ASD. A small population study suggested that mitochondrial dysfunction may be the most common disorder associated with autism. Currently the only recommended treatment for children with ASD is ABA therapy. While the evidence regarding treatment of mitochondrial disorders with vitamin and cofactor therapy continues to be unclear, recent consensus guidelines from the Mitochondrial Medicine Society do recommend offering supplements to all patients with mitochondrial dysfunction, including Cofactor Q10 and riboflavin. While there is a significant number of publications investigating treatment for patients with mitochondrial dysfunction, there is limited research investigating the utility of and response to treatment in patients with concomitant ASD and mitochondrial dysfunction.

Objectives: This case series outlines the medical history of three patients who were diagnosed with ASD and mitochondrial dysfunction, and were subsequently treated with vitamin and cofactor therapy. We seek to demonstrate clinical improvement and regression with withdrawal of treatment through chart review and phone surveys.

Methods: Retrospective chart review was performed to identify patients being treated with vitamin and cofactor therapy who were definitively diagnosed with ASD and mitochondrial disorder. Medical records were obtained from the parents of these patients. The records were reviewed for neuropsychiatric testing and metabolic testing. Progress notes following treatment were also obtained and reviewed. A scripted phone survey was conducted with the parents of each patient to acquire current history for each case. The phone surveys conducted contained questions regarding initial symptoms prior to diagnosis, how the decision to treat was made, and what clinical response was seen with treatment.

Results: Each case included in this series outlines the onset of symptoms for each child, along with the process they underwent to be given a diagnosis of ASD and mitochondrial dysfunction. We then detail the decision to initiate therapy, and subsequent response as detailed through progress notes and medical records that were reviewed. Each case demonstrates both clinical response to treatment either in autism symptoms or mitochondrial dysfunction symptoms, as well as regression when treatment was delayed or withheld.

Conclusions: This review seeks to demonstrate that treatment of mitochondrial dysfunction with vitamin and cofactor therapy has a clinically significant impact on patients. Given the limited adverse effects of this treatment and significant potential benefit, we suggest that based on observational evidence of response, there is evidence to suggest benefit in treating patients with ASD and either diagnosed or suspected mitochondrial dysfunction.

429.004 *(Poster)* Deprescribing Benzodiazepines in ASD/IDD: Examination of Success Rates, Diagnoses and Treatment Responses in Inpatients Versus Outpatients.

J. A. Hellings[1], *S. C. Singh*[2], *C. E. Barbon-Quirante*[3], *A. Elfagir*[3], *A. L. Cheng*[3] *and S. Singh*[4], *(1)Psychiatry, University of Missouri Kansas City and Truman Behavioral Health, Kansas City, MO, (2)University of Missouri-Kansas City, Kansas City, MO, (3)UMKC, Kansas City, MO, (4)Harbor-UCLA Medical Center, Torrance, CA*

Background: Prescription of maintenance benzodiazepines (BZPs) in autism spectrum disorders (ASD) and intellectual disabilities (ID) is common. BZPs may produce disinhibition, tolerance and withdrawal, and sedation exacerbates cognitive impairments. Physicians are often presented with BZP deprescribing in such patients who also manifest ongoing aggression and self-injury.

Objectives: To examine success rates of BZP deprescribing attempts, using retrospective chart review examining demographics, diagnoses, and treatment responses in successive inpatients and outpatients with ASD/ID.

Methods: Following IRB approval, we extracted data from clinic charts of 29 consecutive patients receiving maintenance BZPs, and compared a group of chronic inpatients (IP) with outpatients (OP) for success of taper. Data extracted included IP/OP status, race, gender, age, ASD and/or ID diagnosis, presence of aggression, self-injury, and treatment resistance. Follow-up duration, DSM-5 diagnoses, attention deficit hyperactivity disorder (ADHD) history, and medications tapered were also extracted. Outcomes were measured at clinic visits using the Clinical Global Impressions (CGI) scale (Guy, 1976); with treatment response of final CGI-Improvement subscale Much Improved (2) or Very Much Improved (1).

Results: In the chronic IP group (n=15) there were 13 males, 2 females, and in the OP group (n=14) 9 males and 5 females. IP mean age was 46.7 years, and OP 27.2 years. All subjects in each group had an ASD and/or ID diagnosis, as well as often treatment-resistant (14 of IP, 10 of OP). A significant number in each group was minimally verbal (9 of IP, 4 of OP). Maintenance BZPs most commonly prescribed in IP were clonazepam (n=8), lorazepam (n=5), clorazepate (n=1), diazepam (n=1). OP received clonazepam (n=6), diazepam (n=2), and lorazepam (n=4). Two OP received BZPs as antiseizure treatment. All subjects received other medications in addition to BZPs, both psychotropic and non-psychotropic. Successful deprescribing of BZPs occurred in more IP than OP (46.7% vs 35.7%). BZP dosage reductions also occurred in more IP than OP (26.7% versus 7.1%). We will discuss other medications tapered or added to produce treatment response. Overall treatment response was achieved in 9 IP (60%) versus in 12 OP (85.7%). 10 IP (66.7%) and 12 OP (85.7%) met DSM-5 ADHD criteria. 4 IP and 1 OP met bipolar disorder criteria (26.7% versus 7.1%), 1 IP had major depression with psychosis and 1 IP schizoaffective, bipolar type. Antiseizure medications were used in 4 IP and 5 OP (28.6% vs 33.3%). No subject suffered withdrawal symptoms or seizures, using taper principle of reductions of no more than 10% per week for BZPs. BZP withdrawal was not attempted in the 2 OP receiving them as antiseizure medications.

Conclusions: Successful deprescribing of BZPs in IP and OP can be safely achieved but must be extremely slow. The groups were small and the reader is cautioned. BZP deprescribing and reduction was achieved more often in IP than OP. Clarification of ADHD, bipolar and other diagnoses, and tailoring medications to psychiatric diagnoses are useful strategies in individuals with ASD/ID, aggression and self-injury.

429.005 *(Poster)* Effect of Bacopa Monnieri on VPA Induced Neurotoxicity: An Approach Towards Preclinical Screening for Autism

S. Dwivedi[1], *A. Dusane*[2], *S. Goli*[3], *P. Kulkarni*[4] *and Y. Perumal*[3], *(1)Department of Pharmacy, Birla Institute of Technology and Sciences (BITS) Pilani Hyderabad Campus, Hyderabad, India, (2)Depatment of Pharmacy,, Birla Institute of Technology and Sciences (BITS) Pilani Hyderabad Campus, Hyderabad, India, (3)Depatment of Pharmacy, Birla Institute of Technology and Sciences (BITS) Pilani Hyderabad Campus, Hyderabad, India, (4)Department of Biology, Dr. Reddy's Institute of Life Sciences (DRILS), Hyderabad, Hyderabad, India*

Background: Autism is a complex neurodevelopmental disorder of early onset, characterized by impaired sociability, cognitive function and stereotypies. There has been no pharmacological intervention approved for the overall treatment of autism. The currently available therapies are mainly focused on disease management and symptomatic rescue. The search for herbal remedies that may conceivably act as therapeutic agents for autism has always been an active area of research.

Objectives: The present study was designed to investigate the protective role of *bacopa monnieri*, an Indian medicinal herb, towards autism like phenotypes in cell-based study as well as zebrafish model of VPA toxicity.

Methods: *Bacopa monnieri* was screened against VPA induced toxicity in neurosphere (in vitro) and zebrafish larvae model for autism (in vivo). The neurospheres were obtained from embryonic day 15 cortical neuronal cells and were co-treated for 7 days with VPA (1mM) along with *bacopa monnieri* (0.1, 1 and 10µg/ml) . The neurospheres were investigated for cell proliferation and differentiation. Zebrafish larvae were exposed to VPA (75 µM) from 4 hours post fertilization to 5 days post fertilization followed by treatment with *bacopa monnieri* (3, 10 and 30µg/ml) from 5-7 days post fertilization. After 7 days post fertilization battery of behaviour test (for anxiety, attention deficit and stereotypic behaviour) were performed followed by gene expression studies

Results: Chronic (7 days) VPA treatment in neurospheres leads to a decrease in proliferation of neurospheres followed by disrupted differentiation pattern. In the neurosphere model, co-treatment of *bacopa monnieri* with VPA, rescues VPA induced neurotoxicity as evidenced by an increase in proliferation followed by differentiation and neurite outgrowth. In zebrafish larvae model, post treatment with Bacopa monnieri was able to abrogate VPA induced behavioural despairs in a dose dependent manner observed with open field test, inattentive behaviour test and circling behaviour test. The herbal drug also rescues the effect of VPA on gene expression level of autism related genes.

Conclusions: In conclusion *bacopa monnieri* shows neuroprotective activity against VPA induced toxicity when tested in vitro and in vivo. However, further exploration may be needed to validate the use of *bacopa monnieri* as a therapeutic approach for autism.

429.006 *(Poster)* Evaluation of (±) Catechin Hydrate in Experimental Paradigm of Autism Spectrum Disorders (ASD): Exploring Possible Role of Nitric Oxide Pathway

R. Bhandari[1]*, R. Mehta*[2] *and A. Kuhad*[3]*, (1)Neuropharmacology and Drug Delivery; UIPS;Panjab University, University Institute of Pharmaceutical Sciences, Panjab University, Chandigarh, India, Chandigarh, India, (2)Neuropharmacology & Drug Delivery, University Institute of Pharmaceutical Sciences, Panjab University, Chandigarh, India, Chandigarh, India, (3)Neuropharmacology and Drug Delivery; UIPS.;PU, University Institute of Pharmaceutical Sciences, Panjab University, Chandigarh, India, Chandigarh, India*

Background: Autism spectrum disorders (ASD) is a pervasive neurodevelopmental disorder manifested in children of age 1-3 years old. The pathogenesis of autism is complex due to its heterogeneous and polygenic nature. Autism pathogenesis involves interplay of genetic, epigenetic and environmental factors. Role of gut-brain axis is considered to be of high significance in development of ASD and its associated behavioural complications . Propanoic acid which is short chain fatty acid (SCFA's), an enteric gut product produced by species of Clostridia, Sutterella, and Ruminococcus in intestine is known to worsen the behavioural complications of ASD. PPA is reported to cause oxidative & nitrosative stress, mitochondrial dysfunction and neuroinflammation hence, leading to immune system dysfunction in brain. Excess nitric oxide affects neurodevelopmental process by causing demyelination, neuroinflammation and blood brain barrier disruption. Various clinical studies indicates that levels of NO, and cytokines involved in NO production, might be high in children suffering from autism.

Objectives: The present research work aims at deciphering the involvement of nitric oxide pathway and its modulation by (±) Catechin hydrate in experimental paradigm of Autism Spectrum Disorders (ASD).

Methods: : An intracerebroventricular infusion of 4µl of 1M PPA was given in anterior region of lateral ventricle to induce autism like phenotype in male rats. Oral administration of (±) Catechin hydrate (25, 50 and 100mg/kg) was initiated from 3rd day lasting till 28th day. L-NAME (50mg/kg) and L-Arginine (800mg/kg) were also given individually as well as in combination to explore the ability of (±) Catechin hydrate to act via nitric oxide pathway. Behaviour test for sociability, stereotypy, anxiety, depression, novelty, repetitive and perseverative behaviour was carried out between 14th and 28th day. On 29th day, animals were sacrificed and levels of mitochondrial complexes and oxidative stress parameters were evaluated. We also estimated the levels of neuroinflammatory and apoptotic markers such as TNF-α, IL-6, NF-κB, IFN-γ, HSP-70 and caspase-3. To evaluate the involvement of nitric oxide pathway, levels of iNOS and homocysteine were estimated.

Results: Treatment with (±) Catechin hydrate significantly restored behavioural, biochemical, neurological and molecular deficits. Hence, (±) catechin hydrate has potential to be used as neurotherapeutic agent in ASD targeting nitric oxide pathway mediated oxidative & nitrosative stress responsible for behavioral, biochemical and molecular alterations via modulating nitric oxide pathway.

Conclusions: The evaluation of levels of iNOS and homocysteine conclusively establishes the role of nitric oxide pathway in causing behavioural, biochemical & molecular deficits and the beneficial effect of (±) Catechin hydrate in restoring these alterations.

429.007 *(Poster)* Examining Real-World ADHD Diagnosis and Pharmacologic Treatments for Challenging Behaviors in Autism Spectrum Disorders and Intellectual Disabilities: A Retrospective Case Series.

J. A. Hellings[1]*, S. C. Singh*[2]*, C. E. Barbon-Quirante*[3]*, A. Elfagir*[3]*, A. L. Cheng*[3] *and S. Singh*[4]*, (1)Psychiatry, University of Missouri Kansas City and Truman Behavioral Health, Kansas City, MO, (2)University of Missouri-Kansas City, Kansas City, MO, (3)UMKC, Kansas City, MO, (4)Harbor-UCLA Medical Center, Torrance, CA*

Background: Attention deficit hyperactivity disorder (ADHD) is frequently diagnosed in youth with autism spectrum disorders (ASD) and intellectual disability (ID), and often persists into adulthood (Hellings et al. 2017). ADHD may contribute to hyperactivity, impulsive aggression and self-injury, and mood swings related to poor affect regulation. The latter may be misinterpreted as part of bipolar disorder rather than ADHD. Treatment-resistance may relate to missed ADHD as a diagnosis to clarify and target for treatment.

Objectives: To examine a real-world clinic sample of patients with ASD/ID diagnosed with DSM-5-based ADHD for treatment responses and outcomes.

Methods: Following IRB approval, we extracted data from clinic charts of consecutive patients with ASD and/or ID who met DSM-5 ADHD diagnostic criteria, excluding verbal criteria if they were minimally verbal. Data extracted includes race, gender, age, ASD/ID level, presence of aggression and self-injury, and treatment duration and resistance. DSM-5 diagnoses, ADHD medications taken prior to and at the first visit, and medications tapered were also extracted. Final diagnoses and medications were extracted. Treatment outcomes were measured at clinic visits using the Clinical Global Impressions (CGI) scale (Guy, 1976), with treatment response of final CGI-Improvement subscale Much Improved (2) or Very Much Improved (1).

Results: We reviewed 60 charts, of 45 males and 15 females; mean age 34 years (9-69). Two were children, 5 adolescents, and 53 adults. All but 5 met DSM-5 ASD criteria. Treatment duration averaged 14.7 months (2-34.3). Fifty three patients (88.3%) were treatment-resistant (>3 previous failed psychotropic drug trials). Twenty four (40%) were minimally verbal (< 20 words of expressive language). Fifty (83.3%) had an ADHD history confirmed by relative report or previous childhood ADHD medication trials. Only 14 (23.3%) presented on ADHD medications. Baseline aggression presented in 53 (88.3%). Self-injury including self-biting, picking, scratching, slapping and head-banging presented in 47 (78.3%). Thirty-five (58.3%) had prior seizures. Response rated on CGI-I of 1 or 2 was achieved in 48 (80%); 8 (13.3%) were Minimally Improved (3). Thirty-two (66.6%) of those Much improved and Very Much Improved received ADHD medications (mostly with antipsychotics and antiseizure medications) at the final treatment point. These were amitriptyline (AMI) in 21, AMI and dextroamphetamine (DEX) combination in 5, atomoxetine (ATX) in 3, dexmethylphenidate in 1, methylphenidate in 1, and methylphenidate-ER in 1. Three of the 8 who were Minimally Improved received ADHD medications: 1 AMI, 1 ATX, 1 AMI and DEX. Three were diagnosed with bipolar disorder and 2 with rule-out bipolar disorder.

Conclusions: ADHD awareness, diagnosis and treatment may ameliorate treatment-resistance in a significant number of individuals with developmental disabilities, including in adults and minimally verbal individuals. While the tricyclic antidepressant /ADHD medication amitriptyline appeared effective for irritability and impulsive aggression in ASD/ID, randomized controlled trials are still needed. A trial of ADHD medications starting in low dose may be worthwhile, as well as clarifying early childhood history of ADHD. More studies are needed to confirm these findings.

429.008 *(Poster)* Grey Matter Volume Predicts Changes in Social Behavior Due to Single-Dose Propranolol in Autism Spectrum Disorder

C. Riecken[1], *B. J. Ferguson*[2], *A. Nieters*[1], *J. P. Hegarty*[3] *and D. Q. Beversdorf*[4], *(1)University of Missouri, Columbia, MO, (2)Health Psychology, Radiology, & Thompson Center for Autism & Neurodevelopmental Disorders, University of Missouri, Columbia, MO, (3)Psychiatry & Behavioral Sciences, Stanford University, Stanford, CA, (4)Department of Radiology, Neurology, and Psychological Sciences, University of Missouri, Columbia, Columbia, MO*

Background: Autism spectrum disorder (ASD) is characterized by persistent deficits in social communication, in addition to restricted or repetitive behaviors. Currently, there is no FDA-approved pharmacological treatment for these core symptoms of ASD. Previous research has indicated that when given propranolol, a beta-adrenergic antagonist, some patients with ASD show an increase in social behavior in a single-dose psychopharmacological challenge, as measured by the General Social Outcome Measure (GSOM). However, some individuals with ASD do not respond to propranolol. This highlights the need to develop biomarkers to determine whether propranolol will be an efficacious treatment for individuals with social communication deficits in ASD.

Objectives: In the current study, volumes of individual brain regions, measured with magnetic resonance imaging (MRI), were compared to changes in GSOM scores after propranolol administration. These relationships were analyzed to determine neuroanatomical predictors of increased social behavior when individuals with ASD are given propranolol.

Methods: 13 participants (12 male, 1 female), between the ages of 18 and 31 years old, underwent structural MRI prior to drug administration. GSOM scores were assessed separately in sessions in which participants were given either placebo or propranolol, in a double-blinded crossover manner. Freesurfer was used to determine volumes of cortical and subcortical regions from the structural MRI data. Volumes of cortical and subcortical regions were compared to the difference in GSOM scores when participants were given propranolol and placebo using R. Total intracranial volume was used as a covariate in these analyses to control for potential effects of head size.

Results: Left precentral and precuneus cortex showed significant positive relationships, after false discovery rate correction for multiple comparisons, between grey matter volume and changes in GSOM after administration of propranolol when controlling for intracranial volume. Left thalamus, pallidum, and nucleus accumbens showed significant negative relationships between volume and changes in GSOM after administration of propranolol when controlling for intracranial volume. There were no significant relationships between cortical or subcortical volumes and changes in GSOM scores in the right hemisphere, however there was a significant positive relationship between changes in GSOM score and volume of the optic chiasm.

Conclusions: Based on results from cortical regions, it is possible that higher grey matter volume in left precentral and precuneus regions, relative to total intracranial volume, is a predictor for the efficacy of propranolol in treating social communication deficits in ASD. Inversely, results from subcortical regions indicate a possibility that lower volumes in left pallidum, thalamus, and nucleus accumbens, relative to total intracranial volume, predict an increase in the efficacy of propranolol to treat social communication deficits in ASD. Larger sample sizes are needed to further validate these biomarkers, in addition to determination of their utility for predicting response to serial doses. This exploratory study has generated several potential neuroimaging biomarkers to predict changes in social behavior of patients with ASD after administration of propranolol, which will need to be confirmed and validated as predictors of treatment efficacy in follow-up studies.

429.009 *(Poster)* Preliminary Report on Results from an Open- Label Extension Trial of the Effects of Propranolol on Core Symptoms and Anxiety in Autism Spectrum Disorder

D. Q. Q. Beversdorf[1,2], *B. J. Ferguson*[3], *S. Hunter*[4], *K. Hirst*[4], *B. Lolli*[4], *P. Frye*[5], *J. E. Muckerman*[6] *and T. N. Takahashi*[6], *(1)Radiology, Neurology, Psychology, and Thompson Center for Autism and Neurodevelopmental Disorders, University of Missouri, Columbia, MO, (2)University of Missouri, Columbia, Columbia, MO, (3)Health Psychology, Radiology, & Thompson Center for Autism & Neurodevelopmental Disorders, University of Missouri, Columbia, MO, (4)Thompson Center, University of Missouri, Columbia, MO, (5)School of Health Professions, University of Missouri, Columbia, MO, (6)Thompson Center for Autism & Neurodevelopmental Disorders, University of Missouri, Columbia, MO*

Background: Propranolol is widely utilized for performance anxiety and public speaking anxiety. We previously reported single-dose psychopharmacological challenge studies revealing a significant beneficial effect of propranolol on a structured social interaction task in ASD. This led to the initiation of a clinical trial on the effects of serial doses of propranolol in ASD.

Objectives: Autism spectrum disorder (ASD) is characterized by impairments in social communication and restricted and repetitive behaviors, with a high incidence of co-occurring anxiety. We are conducting a double-blinded, placebo-controlled trial of the beta-adrenergic antagonist propranolol in ASD. Herein, we report preliminary results of the patients completing the open-label extension phase for the primary outcome measure of social communication and, secondarily, anxiety. Effects of the drug on restricted interests were also explored.

Methods: ASD patients (age 7-24) are being enrolled, titrated up to 100mg propranolol daily in divided doses over 12-weeks (body weight adjusted in children), monitoring social interaction, and secondarily anxiety and overall ASD severity. Fifteen participants have completed a 12-week open label extension. Separate Clinician Global Clinical Impression -Severity (CGI-S) scales are reported for both social interaction and anxiety as well as overall ASD severity. Clinician Global Clinical Impressions of Improvement (CGI-I) were also assessed at 12-weeks.

Results: CGI-S for social interaction at baseline was 3.81 (±0.83 sdev) (scores range from from 1-7, where 1=normal and 7=most severe), decreasing to 3.53 (±0.74 sdev) at week-12 (p=0.019). Additionally, CGI-I at 12-weeks was 2.87 (±0.99 sdev) for social interaction (where 4=no change, 1=maximal improvement, 7=maximal decline). CGI-S for anxiety at baseline was 3.81 (±1.17 sdev), decreasing to 3.4 (±1.3 sdev) at week 12 (p=0.014). CGI-I at 12-weeks was 2.8 (±1.2 sdev) for anxiety. CGI-S for overall ASD severity was 3.62 at baseline (±0.50 sdev), decreasing to 3.47 (±0.52 sdev) at week 12 (p=0.082), and CGI-I at 12-weeks was 2.87 (±0.91 sdev) for overall ASD severity. CGI-S for restrictive interests at baseline was 3.8 (±1.11 sdev), decreasing to 3.53 (±0.99 sdev) at week 12 (p=0.04).

Conclusions: A preliminary analysis of the first participants to complete open-label extension portion of the trial begins to suggest promising results for social interaction, as well as the secondary outcome of anxiety, and restrictive interests. As well, there was an initial trend toward significance for reductions in overall ASD severity. Conclusions should not yet be drawn from these findings given this small and unblinded initial open label sample.

429.010 *(Poster)* Receipt of Behavior Therapy Among Preschool Children Who Have and Have Not Taken Psychotropic Medications for Symptoms Associated with Autism

L. D. Wiggins[1], *C. Nadler*[2], *A. M. Reynolds*[3], *S. Rosenberg*[4], *J. Daniels*[5], *E. Giarelli*[6], *D. Christensen*[1], *A. Alexander*[7], *K. Thomas*[8], *N. Reyes*[9], *S. E. Levy*[10] *and E. Moody*[11], *(1)Centers for Disease Control and Prevention, Atlanta, GA, (2)Children's Mercy Kansas City, Kansas City, MO, (3)University of Colorado Denver School of Medicine, Aurora, CO, (4)University of Colorado Anschutz Medical Campus, Aurora, CO, (5)University of North Carolina at Chapel Hill, Chapel Hill, NC, (6)PhD Nursing, Drexel University, Philadelphia, PA, (7)NCBDDD, Centers for Disease Control and Prevention, Atlanta, GA, (8)University of North Carolina Chapel Hill, Asheville, NC, (9)JFK Partners, University of Colorado Anschutz Medical Campus, Aurora, CO, (10)Division of Developmental and Behavioral Pediatrics, Center for Autism Research, Children's Hospital of Philadelphia; Perelman School of Medicine at the University of Pennsylvania, Philadelphia, PA, (11)Wyoming Institute for Disabilities, University of Wyoming, Laramie, WY*

Background: Survey and administrative data suggest that between 11% and 35% of preschool children with autism spectrum disorder (ASD) are prescribed psychotropic medications to treat co-occurring symptoms, such as aggression, hyperactivity, irritability and self-injurious behaviors. The American Academy of Pediatrics (AAP) recommends that psychotropic medication only be prescribed to children with ASD when they demonstrate suboptimal response to behavior therapy. However, it is unknown how often children with ASD who are prescribed psychotropic medications ever receive behavior therapy.

Objectives: Our objectives were to: (1) Describe the number and type of psychotropic medications used by preschool children with ASD enrolled in a case-control study and (2) Explore whether children with ASD who took psychotropic medications ever received behavior therapy.

Methods: Participants were children 2.5-5 years of age enrolled in the Study to Explore Early Development Phase-2 (SEED2) during years 2012-2016. SEED2 is a multisite, community-based study of preschool children designed to investigate the development and risk factors of ASD. Children were screened for ASD risk upon study enrollment. Those with a positive ASD screen or previous ASD diagnosis received a comprehensive evaluation including the Autism Diagnostic Observation Schedule (ADOS) and Autism Diagnostic Interview – Revised (ADI-R). Results of the ADOS and ADI-R determined ASD status.

Mothers were asked to complete a services and treatments questionnaire (STQ) designed for SEED. Mothers were asked to report whether their child ever used the following classes of medications to treat symptoms of ASD: antidepressant or antianxiety, atypical antipsychotic, seizure medication (also used to stabilize mood), stimulant (to treat inattention and hyperactivity), non-stimulant (to treat inattention and hyperactivity), and other (open response). Co-authors with a background in pediatrics and psychology reviewed open response fields for medications that could be included in other categories. Mothers also reported whether their child had ever received behavior therapy.

Results: The analytic sample included 772 children classified as ASD with a complete STQ. Four hundred ninety-six (64.2%) children never received behavior therapy and 62 (8.0%) were reported to use at least one psychotropic medication. Of these 62 children, 20 (32.3%) were reported to use medications in more than one class and 37 (59.7%) never received behavior therapy. Of the medication classes reported, the most common were non-stimulant (N=23; 37.1%), seizure medication (N=24; 38.7%), and stimulant (N=23; 37.1%). Antidepressant/antianxiety and atypical antipsychotic medications were uncommonly reported (N=4; 6.5% for both classes).

Conclusions: Psychotropic medication use among preschool children with ASD was lower in our sample than reported previously in survey and administrative datasets for similar aged children, although these studies used different methods than ours. Use of non-stimulant, seizure, and stimulant medications were most commonly reported whereas use of antidepressant, antianxiety, and atypical antipsychotic medications were less frequently reported. A majority of the children in our sample were reported to have never received behavior therapy, and this was true even for children receiving psychotropic medications. Our findings are inconsistent with AAP recommendations of behavior therapy as a first-line treatment for emotional and behavioral problems in children with developmental disorders.

429.011 *(Poster)* Spectral Brain Dynamics of Pregnenolone Treatment in Adults with Autism Spectrum Disorder

D. S. Karhson[1], *J. B. Edwards*[1], *L. K. Fung*[1] *and A. Y. Hardan*[2], *(1)Psychiatry and Behavioral Sciences, Stanford University, Stanford, CA, (2)Psychiatry & Behavioral Sciences, Stanford University, Stanford, CA*

Background: Pregnenolone (PREG) is the biologically-active precursor of all endogenous steroid hormones that has been implicated the treatment of various neuropsychiatric disorders. In adults with autism spectrum disorder (ASD), therapeutic intervention with PREG may modulate neuronal excitability and be beneficial for improving core ASD features such as, maladaptive sensory reactivity and social information processing. In an open-label trial of PREG, we found that PREG was well tolerated and reduced the levels of irritability in adults with ASD. To explore the impact of PREG on brain dynamics, we examined changes in resting-state brain activity following PREG treatment using electroencephalography (EEG), which provides a high-temporal resolution of brain dynamics. Given that PREG is a robust negative allosteric modulator of several receptors critically involved in brain development (i.e., type 1 cannabinoid receptors, Ɣ-aminobutyric acid A receptors, and glutamate receptors) changes in brain dynamics following PREG may clarify the mechanisms underlying hyperexcitability in ASD.

Objectives: To investigate the changes in band power before and after 12-week trial of oral PREG in autistic adults.

Methods: Scalp-level resting-state EEG was recorded as participants were adults with ASD (N = 14) before and after PREG treatment in an open-label trial. Resting-state EEG, recorded in the absence of overt task performance, can be used to characterize oscillatory activity and reflects the excitation/inhibition (E/I) balance of neural interactions (Cornew, Roberts, Blaskey, & Edgar, 2012). PREG treatment was initiated at 50mg twice daily in weeks 1 and 2, then increased by 50mg twice daily every 2 weeks to a final dose of 250mg twice daily which was maintained from weeks 9 to 12. EEG was analyzed for changes in absolute power spectra. EEG data was filtered, segmented into 2-s epochs, before applying ICA to remove eye-blink and noise artifacts. Time/frequency analysis was performed using the standard frequency band ranges: Delta: 1- 4Hz; Theta: 4 - 8Hz, Alpha: 8 - 12Hz; Beta: 12 - 25Hz; Gamma: 25 - 50Hz; and High Gamma: 50 - 80Hz (Delorme and Makeig, 2004). Changes in theta, alpha, and gamma bands are of the greatest relevance to study the impact of PREG on hyperexcitability, sensory processing, and social information processing. Additionally, these bands are associated with deficits in cortical inhibition in ASD.

Results: Five participant with baseline and post-PREG data were examined in this preliminary analysis. At baseline, adults with ASD demonstrated *high gamma* (in low and high bands) power. This result parallels several previous studies that demonstrate increased gamma power in ASD compared to typically developing individuals. After PREG, *increased* power was observed for all bands (i.e., delta, theta, alpha, and beta), **except gamma** which *decreased* in power. Changes also appear to be spatially-specific with increased activity localized to posterior regions following treatment.

Conclusions: Although data collection and analysis are ongoing, preliminary data analysis showed changes in spectral power in low-and high-frequency bands following PREG treatment in adults with ASD. This suggests PREG may modulate hyperexcitability and the E/I balance by altering coupling between high and low frequency bands in adults with ASD.

429.012 *(Poster)* The Role of Nitric Oxide in Autism Spectrum Disorder: Towards Novel Strategies for Treatment

***H. Amal**, Institute for Drug Research, School of Pharmacy, Faculty of Medicine, Hebrew University, Jerusalem, Israel*

Background: Mutation in the *SHANK3* human gene leads to different neuropsychiatric diseases including Autism Spectrum Disorder (ASD). *SHANK3* is one of the most promising ASD candidate genes, but still significant gaps exist regarding the molecular mechanism that lead to the pathology. Recently, we showed that *Shank3* human-mutation based in a mouse model of ASD (InsG3680 model) led to a dramatic increase of nitric oxide (NO) formation and alterations in nitrergic signaling. NO is a multifunctional signaling molecule and a neurotransmitter that plays an important role in physiological and pathophysiological processes including neuronal signaling. Pioneering works showed that NO can engender nitrosative stress in the nervous system, contributing to neurodegenerative diseases. In the case of ASD, there is no evidence for a link between NO and ASD.

Objectives: Our ultimate goal is to determine and gain a deep mechanistic understanding of the molecular role of NO and derive novel strategies for treatment in ASD.

Methods: S-nitrosylated proteins in two ASD-related brain regions, cortex and striatum of young and adult InsG3680(+/+) mice (a human mutation-based *Shank3* mouse model), were identified by an innovative mass spectrometric method, SNOTRAP. To gain a systems-level insight into SNO-proteins' functionalities, and to test whether enriched processes are related to ASD, we conducted systems biology analysis. To test for functional and physical interactions among S-nitrosylated proteins in the InsG3680(+/+) mice, we used STRING to analyze protein-protein interactions. We used WB and IHC to dissect signaling pathways and discover novel drug targets.

Results: Our preliminary results showed, for the first time, that *Shank3* mutation led to significant increase of NO formation, and affects key synaptic proteins through protein S-nitrosylation, the NO-mediated posttranslational modification of cysteine thiols (SNO). Furthermore, we discovered *de novo* SNO modification on the phosphatase calcineurin (CN), which led to alterations in synaptic vesicle cycle and in CREB signaling. Finally, we found that NO amplifies mTOR and CREB signaling in mutant suggesting these pathways as a therapeutic targets.

Conclusions: This work provides novel mechanistic insights into the contribution of NO in ASD and pinpointed on pathological proteins, signaling pathways, and neurobiological processes, thereby enabling future translational studies for novel therapeutic targets.

429.013 *(Poster)* Use of Benzodiazepines in People with Autism Spectrum Disorder in the United States

*S. Roumpanis[1], M. Johnson[2], C. Liu[3] and **M. del Valle Rubido**[4], (1)Personalized Health Care, Real World Data Science, Product Development, F. Hoffmann-La Roche, Ltd., Basel, Switzerland, (2)Personalized Health Care Data Science, Real World Data, F. Hoffmann-La Roche Ltd., Welwyn Garden City, United Kingdom, (3)Personalized Health Care Data Science, Real World Data, F. Hoffmann-La Roche Ltd, Basel, Switzerland, (4)Neuroscience and Rare Diseases (NRD), Roche Pharma Research and Early Development, Roche Innovation Center, Basel, Switzerland*

Background: Benzodiazepine drugs have diverse therapeutic uses including hypnotic, anxiolytic, anticonvulsant, myorelaxant and amnesic in anesthesia, and confer a therapeutic value in a wide range of conditions. For this reason, they are a commonly prescribed class of psychotropic drugs. Psychiatric comorbidities and the use of psychotropic medications are common among patients with autism spectrum disorder (ASD) [1]. Reports of use in ASD vary and range from approximately 7% in pediatric populations in Germany [2] to 20-25% in children, adolescents and adults in the US [3,4], and for various different comorbidities among people with ASD including anxiety and epilepsy [5], sleep disturbances [6], catatonia [7] and seizures in chromosome 15q duplication syndrome [8], with inconsistent efficacy reports. However, scarce literature exists on the overall pattern of use of benzodiazepines in ASD.

Objectives: To investigate prescription patterns of benzodiazepines for people with ASD in the US and understand the differences of use by children, adolescents and adults.

Methods: We evaluated benzodiazepine claims in the Truven Marketscan database of health insurance data (both commercial and Medicaid) in the US. Medication usage was investigated throughout the calendar year 2014 among a cohort of people with ASD (≥3 years old, with at least two claims for an ASD diagnosis [of which at least one was recorded during 2014]). The prevalence and length of prescriptions, psychiatric comorbidity, class type and active principle used were described.

Results: Among the cohort of 93,639 people with ASD in the US, 10,872 (11.6%) had a benzodiazepine prescription in 2014. In terms of indication for use, the anxiolytic, sedative, hypnotic class were used more than the anticonvulsants (76.1% vs 36.6%) with diazepam, clonazepam and lorazepam being the most frequently prescribed active substances. Overall, the frequency of benzodiazepine use among adults (24.5%, ≥18 years old) was higher than among adolescents (12.3%, 13-17 years old) and children (5.4%, 3-12 years old), and more frequent for females (15.5%) than males (10.7%). From the length of the prescription, 45.6% were supplied benzodiazepines for acute use (≤30 days) while chronic use was less frequent with 33.6% and 9.9% supplied for more than 6 months and 1 year respectively.

Conclusions: Our analysis shows benzodiazepine use among people with ASD in the US is lower than previous reports and more frequently prescribed for acute/short-term use. This report sheds new light on the recent patterns of benzodiazepine prescriptions in ASD.

429.014 *(Poster)* Who Takes Medical Marijuana and Why? an Online Prospective Observational Study of Medical Marijuana Use in Autistic Children

B. E. Yerys[1]*, A. Bennett*[2]*, M. A. Diliberto*[3]*, S. Barr*[3]*, A. Cornetta*[3]*, E. Ward*[3] *and A. Zuppa*[3]*, (1)Center for Autism Research, Children's Hospital of Philadelphia, Philadelphia, PA, (2)The Children's Hospital of Philadelphia, Philadelphia, PA, (3)Children's Hospital of Philadelphia, Philadelphia, PA*

Background: Autism Spectrum Disorder (ASD) is one of 23 qualifying conditions for Medical Marijuana treatment in the state of Pennsylvania. While some research demonstrates that autistic children are taking Medical Marijuana to reduce challenging behaviors (e.g., verbal and physical aggression, self-injury, tantrums, meltdowns), these may not be the only behaviors, or even the primary behavior that providers and families intend to target with Medical Marijuana. There is also little information on the dose and caregiver perception of efficacy across symptom types and possible differences related to the autistic child's gender.

Objectives: To establish a research registry that quantifies the reasons autistic children are taking Medical Marijuana and cannabidiol (CBD) consumption, the target symptoms, the treatment dose, and perceived efficacy.

Methods: We conducted an online prospective observation study (NCT03699527) to establish a registry of children ages 3 to 19 years. Inclusion criteria included having an ASD diagnosis and receiving Medical Marijuana or CBD. Diagnosis was established with a community diagnosis of ASD and a score $\geq$ 12 on the Social Communication Questionnaire. Recruitment occurred in local clinics, social media, parent groups, and word of mouth. All procedures were conducted over the telephone, and follow-ups occurred quarterly. Caregivers completed questionnaires of the autistic child's demographics, concomitant medication, Medical Marijuana information, treatment indication, and detailed clinical information related to indication (e.g., Aberrant Behavior Checklist, 2nd Edition (ABC-2) if indication was challenging behaviors or stereotypies).

Results: The study is ongoing, but we currently have 123 participants enrolled. ~70% of the sample had a caregiver rate their intellectual functioning below their age bin (age bins were <12 months, 1-3 years, 4-5 years, 6-8 years, 9-11 years, 12-14 years, and 15-18 years), and were rated by caregivers as requiring substantial or very substantial support. ~77% had a caregiver rating on social functioning below their age bin. ABC-2 ratings (Social Engagement and Stereotypies) for those taking Medical Marijuana showed similar ratings as reported in the broader literature, whereas Behavior Rating Inventory of Executive Function – Shift scale showed an elevated rating in those taking Medical Marijuana. Caregiver ratings on Anxiety, Mood, and Irritability were elevated in those taking Medical Marijuana compared to the ASD population, whereas externalizing symptoms (ADHD, ODD) were slightly reduced in the Medical Marijuana registrants compared to an ASD+ADHD population. Those taking Medical Marijuana for sleep problems were shown to have ratings in the range of neurotypicals. Parent ratings of efficacy suggest some domains are associated with higher efficacy ratings (e.g., sleep disturbances) than others (e.g., anxiety).

Conclusions: This observational study provides insight into the general landscape of Medical Marijuana use in the pediatric autism population. While sleep problems are reported to have high efficacy and ratings are in the neurotypical range, the efficacy ratings and caregiver report of symptoms are not as convergent in other domains. Given that there is no baseline to directly establish a relationship between drug and symptom change, future research is needed to evaluate Medical Marijuana' potential therapeutic benefit in autistic children.

Medical and Psychiatric Comorbidity

PANEL SESSION — **MEDICAL AND PSYCHIATRIC COMORBIDITY**

216 - Current Trends in Suicide Prevention for Autistic Individuals

Panel Chair: Brenna Maddox*, University of Pennsylvania, Philadelphia, PA*

Discussant: Sarah Cassidy*, School of Psychology, University of Nottingham, Nottingham, United Kingdom*

The last five years have brought substantial progress in understanding the heightened risk of suicide in autistic people. Most of the published work to date has focused on risk factors, assessment, and screening. While this work has addressed many important questions, there is a dearth of research on what happens after an autistic person is determined to be at risk for suicide – how do we intervene appropriately and prevent suicide? The current panel focuses on this nascent area of suicide and autism research. Mirabel Pelton will discuss how suicide theory can inform suicide prevention efforts for autistic individuals. Lisa Morgan, co-chair of the Autism and Suicide committee of the American Association of Suicidology, will share about the development and dissemination of a crisis supports toolkit for people on the spectrum. Anne Huntjens will present on an ongoing trial of dialectical-behavioral therapy for reducing suicidal thoughts and behaviors in autistic adults. Brenna Maddox will share key stakeholder insights about modifying the Safety Planning Intervention for autistic adolescents and adults. Finally, Sarah Cassidy will lead a discussion about the clinical implications of these novel findings and future research directions for reducing suicide risk in autistic people of all ages.

216.001 *(Panel)* Suicide Prevention in Autistic Adults: What Can We Learn from the Interpersonal Theory of Suicide?

M. K. Pelton[1]*, H. Crawford*[2]*, A. E. Robertson*[1]*, J. Rodgers*[3]*, S. Baron-Cohen*[4] *and S. A. Cassidy*[5]*, (1)Coventry University, Coventry, United Kingdom, (2)Faculty of Health and Life Sciences, Coventry University, Coventry, United Kingdom, (3)Institute of Neuroscience, Newcastle University, Newcastle Upon Tyne, United Kingdom, (4)Autism Research Centre, Department of Psychiatry, University of Cambridge, Cambridge, United Kingdom, (5)School of Psychology, University of Nottingham, Nottingham, United Kingdom*

Background: Autistic people are more likely to die by suicide than the general population, but, to date, an absence of theoretically driven research provides a weak evidence base for intervention. The Interpersonal Theory of Suicide (ITS; Joiner 2005) posits that social isolation ('thwarted belonging'), worthlessness ('perceived burdensomeness') and suicidal capability (reduced fear of death resulting from trauma) enable suicidal thoughts to be actioned. Existing research associates these concepts with mental health difficulties, social exclusion and poor quality of life in autistic adults suggesting the ITS may be useful to understand suicide in this group.

Objectives: First, to explore whether autistic people report higher levels of ITS variables. Second, to explore whether the ITS explains the pathways to suicidal thoughts and behaviours in autistic adults. Third, to examine whether the strength of association of any pathway is moderated by autism diagnosis. Fourth, to examine questionnaire measurement differences between autistic and non-autistic people.

Methods: 695 autistic and non-autistic people (mean age 41.7, 58% female) were extracted from an online cross-sectional survey dataset of self-report questionnaires measuring belonging and burdensomeness (Interpersonal Needs Questionnaire-10), suicidal capability (Acquired Capability for Suicide Scale – Fearlessness about Death), traumatic life events (Vulnerabilities Experience Quotient), lifetime suicidality (Suicidal Behaviours Questionnaire revised, item 1) and autistic traits (Autism Quotient – Short Form).

Results: The autistic group reported significantly more lifetime suicidal thoughts and behaviours, stronger feelings of burdensomeness and thwarted belonging, and more frequent traumatic life events than the non-autistic group. Thwarted belonging, perceived burden, suicidal capability and traumatic life events were significantly associated with suicidal thoughts and behaviours in both groups. Path analyses (Fig. 1) reported in both autistic and non-autistic groups: (i) an indirect effect of autistic traits on lifetime suicidality through perceived burden; (ii) an indirect effect of autistic traits on lifetime suicidality through thwarted belonging; iii) a direct effect of traumatic life events on lifetime suicidality. The association of each of thwarted belonging, perceived burden and traumatic life events with suicidality was significantly attenuated by autism diagnosis. Measurement invariance analysis (Table 1) showed that all items of the burdensomeness and two items of the thwarted belonging subscales were non-invariant between autistic and non-autistic groups.

Conclusions: Results suggest that addressing feelings of thwarted belonging, burdensomeness and exposure to traumatic life events could prevent suicide in autistic adults. This could include addressing themes such as (i) double empathy problem (expectation that autistic people will communicate using non-autistic norms) to reduce the need for autistic people to engage in social camouflaging and promote mutually genuine relationships; (ii) effectively meeting autistic peoples' support needs and promoting autonomy to reduce burdensomeness; and (iii) better safeguarding autistic people to reduce exposure to trauma. Results suggest that autistic people interpreted the questionnaire items asking about perceived burdensomeness and thwarted belonging differently to non-autistic people. This suggests that conceptualizing how autistic people experience belonging and burdensomeness could contribute to new and unique suicide prevention opportunities. Overall, our results suggest that addressing the social marginalization of autistic people could reduce suicide rates.

216.002 *(Panel)* Crisis Supports for the Autism Community – a Toolkit

L. Morgan[1] *and T. W. Benevides*[2]*, (1)American Association of Suicidology, Washington, DC, (2)Occupational Therapy, Augusta University, Augusta, GA*

Background: Suicide prevention and crisis response is an important part of a national strategy to reduce suicide (U.S. Department of Health and Human Services, 2012). Materials for crisis and first responders are an essential component of prevention. For autistic individuals, who may display different risk factors and ways of communicating need, there were no crisis response tools that first responders and others could use to address suicidal ideation in autistic individuals in late 2017.

Objectives: The purpose of this presentation is to share information about the development of resources that occurred through a multidisciplinary collaboration of people and organizations, led by an autistic suicide loss survivor.

Methods: A grassroots effort to discuss suicide in autism between several organizations led to the American Association of Suicidology (AAS) forming a committee to address suicide in autism in May 2018.The initial committee was formed from individuals and representatives from AAS, Nationwide Children's Hospital and the Tragedy Assistance Program for Survivors (TAPS). A literature review was conducted by the members of the committee. As a result, the committee identified a gap in available crisis response materials specific to autistic individuals. A toolkit for crisis response individuals was developed and modified for use in crisis centers nationwide. A webinar, a press-release, and an available toolkit on AAS's website were made available in October 2018. A total of 118 crisis response centers received the toolkit at that time.

Results: The AAS Committee has received positive feedback from crisis response teams who have used the toolkit. Several first person stories have reported that the toolkit resulted in use that positively facilitated the communication between crisis responders and autistic individuals experiencing suicidal ideation. There was additional dissemination of the toolkit to the 75 members of NASCOD (National Association of Crisis Organization Directors), 63 USA accredited agencies, the Center for Autism Research Excellence, and has also been distributed through word-of-mouth.

Conclusions: Autistically developed and vetted community toolkits are essential for effective suicide prevention with autistic individuals. The feedback received has demonstrated the need for crisis response materials that can be used in the community. Although use has been high and the response has been positive, an evaluation of the toolkit is a future step. Future evaluation with end-users is important for revision and more wide-spread adoption.

216.003 *(Panel)* The Effect of Dialectical Behavior Therapy in Autism Spectrum Patients with Suicidality and/or Self-Destructive Behavior: A Randomized Multi-Center Controlled Trial

A. Huntjens[1], *W. van den Bosch*[2], *B. Sizoo*[3], *A. Kerkhof*[1,4], *M. Huibers*[1,5] *and M. van der Gaag*[6], *(1)VU University, Amsterdam, Netherlands, (2)Scelta, Apeldoorn, Netherlands, (3)Dimence, Deventer, Netherlands, (4)CLINICAL PSYCHOLOGY, Amsterdam Public Mental Health Research Institute, Amsterdam, Netherlands, (5)Amsterdam Public Mental Health Research Institute, Amsterdam, Netherlands, (6)Parnassia Psychiatric Institute, The Hague, Netherlands*

Background: Many patients with autism spectrum disorder (ASD) are treated in long-term specialized care. In this population, suicidal behavior troubles patients, families, and specialists in the field because it is difficult to treat. At present, there is no documented effective therapy for suicidal behavior in ASD. Dialectical Behavior Therapy (DBT) is an efficacious treatment program for chronically suicidal and/or self-harm behavior in patients with Borderline Personality Disorder. This study will evaluate the efficacy of DBT in patients with ASD and suicidal/ self- destructive behavior in a randomized controlled multisite clinical trial.

Objectives: The primary outcome is the level of suicidal ideation and behavior. The secondary outcomes are anxiety and social performance, depression, core symptoms of ASD, quality of life, and cost-utility. Emotion regulation and therapeutic alliance will be investigated for mediation effects.

Methods: 128 patients with autism and suicidal and/or self-harming behavior will be recruited from specialized mental healthcare services and randomized into two conditions: 1) the DBT condition in which the participants have weekly individual cognitive behavioral therapy sessions and a 2.5 hour skills training group session twice per week, and 2) the treatment as usual condition which consists of weekly individual therapy sessions of 30-45 minutes with a psychotherapist or social worker. Assessments will take place at baseline, at post-treatment (6 months), and after a follow-up period of 12 months. The mediators will also be assessed at three months.

Results: Based on previous positive clinical experiences, we expect patients to benefit from the therapy. We expect that DBT would be effective in decreasing suicidal and self-destructive behavioral and to increase quality of life and increase social functioning. Results will be disseminated unreservedly, irrespective of the magnitude or direction of the effects.

Conclusions: This is an ongoing study. The results from this study will provide an evaluation of the effectiveness of DBT treatment in patients with ASD on suicidal and/or self-harming behavior. The study is conducted in routine mental health services and this enhances the generalizability of the study results to clinical practices.

216.004 *(Panel)* Modifying the Safety Planning Intervention for Autistic Adolescents and Adults

B. B. Maddox[1], *S. R. Crabbe*[1], *M. L. Airey*[2], *D. S. Mandell*[3] *and S. Jager-Hyman*[1], *(1)University of Pennsylvania, Philadelphia, PA, (2)Children's Hospital of Philadelphia, Philadelphia, PA, (3)Center for Mental Health, University of Pennsylvania, Philadelphia, PA*

Background: Suicide is a leading cause of premature death in autistic people. Autistic individuals are significantly more likely to think about and attempt suicide than the general population. No research has examined the effectiveness of suicide interventions for autistic individuals. The Safety Planning Intervention (SPI), an evidence-based suicide prevention intervention, may be an ideal intervention, with some modifications, for autistic individuals who experience suicidal thoughts or behaviors. SPI is a brief, individually-tailored, and easy-to-use approach designed to lower the short-term risk of suicide. Little is known about the utility of SPI for autistic individuals, nor has research examined adaptations necessary to best fit this population.

Objectives: The objective of this community-partnered study is to learn from autistic adolescents and adults, their family members, and community clinicians about their perceptions of using SPI with autistic clients.

Methods: One hundred and twenty-one clinicians (82.6% female, mean age = 37 years) completed an online survey about their clinical experience managing suicide risk in autistic clients. We also completed semi-structured interviews with 17 adolescents and adults on the spectrum (59% male, mean age = 28 years), 12 family members (83% female, mean age = 56 years), and 31 community clinicians (81% female, mean age = 43 years) with a range of experience working with autistic clients. All interviews were audio-recorded and professionally transcribed for analyses.

Results: Of the survey participants, only 24% reported feeling very confident in their abilities to intervene when an autistic client is at risk for suicide, and only 17.4% reported using SPI with autistic clients. Clinicians rated SPI as a more acceptable suicide prevention strategy for clients without autism than for autistic clients ($p < .001$). During the interviews, stakeholders discussed both advantages (e.g., a written, stepwise plan) and disadvantages (e.g., difficulties with generalizing the plan outside session) of using SPI with autistic clients. As one young woman on the spectrum said, “I found it helpful having it already written down, not having to think it up on my own.” Clinicians expressed concerns about an autistic client’s impulsivity interfering with the ability to implement the plan. Autistic individuals and their family members were enthusiastic about a suicide prevention strategy that can be initiated in an outpatient therapy setting, given their negative experiences with inpatient hospitalization for suicidal thoughts and behaviors. Suggested modifications to SPI included making the text more direct and concise, decreasing the emphasis on social supports and settings, increasing education and practice about internal coping strategies, increasing the involvement of family members, incorporating visual supports (e.g., photos for each step), and leveraging technology.

Conclusions: Although some aspects of SPI are a good fit for the learning style of many autistic people, other aspects pose challenges given the core traits of autism and other common co-occurring difficulties. Our three stakeholder groups expressed support for modifying SPI for autistic individuals and provided valuable recommendations to guide this process. Next steps include pilot testing and further refining the adapted SPI.

PANEL SESSION — MEDICAL AND PSYCHIATRIC COMORBIDITY
217 - Longitudinal Examinations of Mental Health Comorbidity in Young Children with ASD

Panel Chair: Connor Kerns, *University of British Columbia, Vancouver, BC, Canada*

Discussant: Peter Szatmari, *The Hospital for Sick Children, Toronto, ON, Canada*

Mental health comorbidities (MHC) affect the majority of individuals with ASD and are associated with poorer outcomes as well as more complex and costly care (Ahmedani & Hock, 2011; Croen et al., 2006). Nonetheless, most research has focused on school-age youth and is cross-sectional, providing only a snapshot of MHC in ASD rather than an understanding of their emergence and developmental trajectory. The proposed international panel will address these limitations by presenting data from 3 longitudinal studies regarding the emergence, stability and trajectories of varied forms or psychopathology in young children with ASD and their relationship to core ASD deficits, cognitive development and sex. It is unclear when and how to best assess MHC in young children with ASD or if MHC prevention/early intervention may be warranted. The selected studies consider this knowledge gap. Learning Goals: (1) Describe whether there is evidence for an increased rate anxiety and attention deficit hyperactivity disorder (ADHD) in preschoolers with ASD despite challenges in assessment; (2) Describe how internalizing psychopathology is related to trajectories of intellectual development and ASD symptoms in young children with ASD; (3) Describe gender differences in the developmental trajectory of co-occurring psychopathology in young children with ASD.

217.001 *(Panel)* Rates and Stability of ADHD and Anxiety Diagnoses in Preschoolers with Autism Spectrum Disorder and Comorbid Intellectual Disability

***A. L. Hogan**, C. J. Black and J. E. Roberts, Department of Psychology, University of South Carolina, Columbia, SC*

Background: Psychiatric comorbidities such as attention deficit/hyperactivity disorder (ADHD) and anxiety disorders are found at elevated rates in individuals with ASD. However, most of what is known about psychiatric comorbidities in ASD has been derived from older, higher-functioning samples. Thus, the rates and stability of psychiatric comorbidities in young children with ASD and intellectual disability (ID) remains poorly understood.

Objectives: Characterize the rates and stability of ADHD and anxiety diagnoses in preschool-aged children with ASD and ID relative to typically-developing (TD) peers.

Methods: The sample included 46 children with ASD (*M* age=3.89) and 32 TD controls (*M* age=4.00). Participants were assessed at 3, 4, and 5 years of age, for a total of 129 observations (ASD: *n*=64; TD: *n*=65). Psychiatric diagnoses included the following disorders: ADHD, social anxiety, separation anxiety, specific phobia, and generalized anxiety disorder (GAD). The Preschool Age Psychiatric Assessment (PAPA) was used to measure ADHD and anxiety symptoms. Clinical best estimate (CBE) diagnoses were assigned based on review of multiple sources of data including PAPA diagnostic cutoffs, cognitive/adaptive skills, and ASD symptoms at each assessment. CBE diagnoses were determined by a multi-disciplinary team including a licensed child psychologist and those who conducted the assessments. Rates of diagnoses using the PAPA cutoffs versus clinician judgment (i.e., CBE) were compared at each age. In the children with multiple assessments (ASD: *n*=15, TD: *n*=17), stability of the number of CBE anxiety diagnoses was also characterized.

Results: Using PAPA cutoffs in isolation, the ASD group had higher rates of ADHD at 3 years (ASD: 41.2%, TD: 0%; $X^2(1)=10.60$, $p=.001$) and at 5 years (ASD: 25%, TD: 0%, $X^2(1)=3.71$, $p=.054$). In contrast, there were no group differences at any age in the rates of anxiety diagnoses according to PAPA cutoffs. However, when clinician judgment was used to assign diagnoses, distinct differences emerged. Children with ASD still had higher rates of ADHD at 3 years (ASD: 17.6%, TD: 0%; $X^2(1)=4.02$, $p = .045$) and at 5 years (ASD: 25%, TD: 0%, $X^2(1)=3.71$, $p=.054$). Children with ASD were more likely than TD children to have at least one CBE anxiety diagnosis at 3 years (ASD: 61.1%, TD: 26.1%, $X^2(1)=5.10$, $p=.023$), but not at other ages. The ASD group showed higher rates of specific phobia at 3 years (ASD: 50.0%, TD: 13.6%, $X^2(1)=3.71$, $p=.054$). Regarding anxiety diagnosis stability across age in the ASD group, 13.3% with no diagnosis remained undiagnosed (TD: 64.7%), 26. 7% maintained the same number of anxiety diagnoses (TD: 5.8%), 13.3% increased (TD: 5.8%), and 46.7% decreased (TD: 23.5%).

Conclusions: ADHD and anxiety diagnoses were diagnosed at elevated rates throughout the preschool period in children with ASD and ID. However, anxiety diagnoses in ASD appear to be less stable during this developmental period, perhaps due to the challenges of assessing and interpreting anxiety symptoms and internalizing behaviors in non- or minimally-verbal children with ASD. These results highlight the importance of examining psychiatric comorbidities longitudinally and weighing clinician judgment alongside diagnostic cutoff scores in young children with ASD and ID.

217.002 *(Panel)* Co-Occurring Trajectories of Anxiety and Insistence on Sameness Behavior in Autism Spectrum Disorder

D. A. Baribeau[1], *S. Vigod*[2], *E. Pullenayegum*[3], *C. M. Kerns*[4], *P. Mirenda*[4], *I. M. Smith*[5], *T. Vaillancourt*[6], *J. Volden*[7], *C. Waddell*[8], *L. Zwaigenbaum*[7], *T. Bennett*[9], *E. Duku*[10], *M. Elsabbagh*[11], *S. Georgiades*[10], *W. J. Ungar*[12], *A. Zaidman-Zait*[13] *and P. Szatmari*[3], *(1)University of Toronto, Toronto, ON, Canada, (2)Women's College Hospital, Toronto, ON, Canada, (3)The Hospital for Sick Children, Toronto, ON, Canada, (4)University of British Columbia, Vancouver, BC, Canada, (5)Dalhousie University / IWK Health Centre, Halifax, NS, CANADA, (6)University of Ottawa, Ottawa, ON, Canada, (7)University of Alberta, Edmonton, AB, Canada, (8)Simon Fraser University, Vancouver, BC, Canada, (9)Offord Centre for Child Studies, McMaster University, Hamilton, ON, CANADA, (10)McMaster University, Hamilton, ON, Canada, (11)McGill University, Montreal, QC, Canada, (12)University of Toronto / The Hospital for Sick Children, Toronto, ON, Canada, (13)Tel-Aviv University, Tel-Aviv, Israel*

Background: Children with autism spectrum disorder (ASD) have increased vulnerability to anxiety disorders. Emerging evidence suggests that there may be a relationship between the rigid, repetitive and routinized patterns of behavior that are core to the diagnosis of ASD, and the development of anxiety in this population. Insistence on sameness (IS) behaviors in particular (e.g., rigid adherence to rituals and routines, difficulties with transitions) have been shown to correlate with anxiety symptoms cross-sectionally. A recent study by members of our team showed that there is a longitudinal relationship as well - high restricted/repetitive behavior severity in preschool, especially IS behavior, was associated with future elevated anxiety symptoms at ages 8-11 years, even after adjusting for baseline anxiety and other confounders [1]. This analysis did not take into account potential heterogeneous longitudinal trajectories, however.

Objectives: The objective of the following study was to jointly examine heterogeneous developmental trajectories of IS and anxiety in ASD.

Methods: Data were collected through the Pathways in ASD study, a large (n = 421), longitudinal inception cohort study of children with ASD and their families that began in 2005. IS was measured using the Autism Diagnostic Interview-Revised at approximately ages 3, 6 and 11 years. Anxiety symptoms were quantified at 8 time-points between ages 3 and 11 years using the Child Behavior Checklist (CBCL) Anxiety Problems subscale. Multi-group trajectories were estimated for the continuous ADI-R IS subscale raw scores (at T1, T4, and T8) and the CBCL anxiety subscale T-scores (at T1 through T8) using group-based trajectory modelling. Clusters of participants following similar trajectories were identified using joint trajectory analysis.

Results: Three IS trajectories were identified: 1) 'low-stable' (41.7% of participants), 2) 'moderate-increasing' (52.0%), and 3) 'high-peaking' (i.e., increasing then stabilizing/decreasing behavior) (6.3%). Four anxiety trajectories were identified: 1) 'low-increasing' (51.0%), 2) 'moderate-decreasing' (16.2%), 3) 'moderate-increasing' (19.6%), and 4) 'high-stable' (13.1%). Anxiety trajectories 3 and 4 surpassed the threshold for concern (T-score >65) at one or more timepoints. Almost all children assigned to the 'high-peaking' IS trajectory were jointly assigned to anxiety trajectory 3 or 4. Anxiety and IS trajectories followed similar patterns of change for 26.2% of the sample, whereas for 18.1% opposing patterns of change were seen (e.g., decreasing anxiety and increasing IS).

Conclusions: This study revealed that the developmental trajectories of IS behavior and anxiety in ASD over childhood are associated, but the direction of the association may differ in distinct sub-groups. High IS in early development should prompt assessment/monitoring for anxiety. For some children, opposing IS and anxiety trajectories suggest heterotypic continuity, potentially reflecting a shared biologic vulnerability with evolving clinical manifestations. Overall, data suggest that there is an important opportunity for prevention of anxiety disorders in many children with ASD.

217.003 *(Panel)* Cognitive Developmental Trajectories, Social Functioning, and Internalizing Psychopathology in Preadolescents with ASD

M. Solomon[1], *A. M. Iosif*[2], *B. Heath*[1], *A. J. Gordon*[3], *M. K. Krug*[4], *C. W. Nordahl*[1] *and D. G. Amaral*[1], *(1)Department of Psychiatry and Behavioral Sciences, The Medical Investigation of Neurodevelopmental Disorders (MIND) Institute, UC Davis School of Medicine, University of California Davis, Sacramento, CA, (2)Public Health Sciences, University of California Davis, Davis, CA, (3)Psychiatry & Behavioral Sciences, University of California, Davis, M.I.N.D. Institute, Sacramento, CA, (4)Department of Psychiatry & Behavioral Sciences, UC Davis MIND Institute, Sacramento, CA*

Background: In those with typical development (TD), the period between preadolescence (ages 9-13; referred to herein as "preadolescence") is a time of cognitive and social development that prepares individuals for the profound alternations in social functioning characteristic of adolescence. A failure to develop optimally during this period may set the stage for the onset of the internalizing psychopathology known to emerge in adolescence. This period has been understudied in ASD

Objectives: Recently, our group identified trajectories of intellectual development (IQ) between early (ages 2-4 years) and later childhood (ages 4-6 years) that were associated with unique behavioral profiles. Our goal is to extend this work into preadolescence, and to investigate whether group membership is associated with changes in social functioning and internalizing psychopathology across this period.

Methods: Participants include a relatively large sample of children with ASD taken from the Autism Phenome Project (APP) cohort who were assessed in both early and preadolescence (n=90 children ages 2-13 years). They were qualified into the cohort using gold standard measurements including ADOS-2 and ADI-R administered. For this investigation, we also used scores from the Differential Abilities Scale (DAS-II), Social Responsiveness Scale (SRS-2), the Vineland Adaptive Behavior Scale-2 (VABS-2), and the Child Behavior Checklist (CBCL; Anxious-Depressed Syndrome Scale). Group-based trajectory modeling conducted in MPlus was used to identify a small number of groups of children with similar IQ trajectories from early childhood to preadolescence. Once children were classified by trajectory, we examined performance on measures of social awareness, social motivation, social adaptive functioning, and anxious depressed syndrome scale scores using general linear models with correction for multiple comparisons.

Results: We found 3 distinct IQ trajectories with very similar criteria to the 2018 manuscript. We refer to these new groups that span ages 2 to 13 years as Persistently Low (**P-Low; 45%**), which had IQ scores < 75 at all timepoints;persistently average or better as Persistently High (**P-High; 27%**), which has IQ scores > 75 at all timepoints; and Positive Changers (**+CHG; 28%)**, which started with IQs < 75 in early childhood that then increased by at least 1 standard deviation by preadolescence. Scores on social awareness of the ASD **+CHG**and **P-High** IQ groupswas comparable and higher than those of **P-Low** during preadolescence, with the social awareness of only the **+CHG**group improving from early to preadolescence. Social motivation was comparable across the 3 ASD groups and declined between early and preadolescence.The**+CHG**group versus the **P-Low**and **P-High**groups showed the steepest growth in early to middle childhood/adolescence social functioning, which leveled off at the later period, while **P-Low**and **P-High**experienced declines. Anxious-depressed symptoms increased significantly between early and preadolescence in P-High.
Conclusions: Trajectory groups found at earlier ages persisted to ages 9-13. The **+CHG**group continued to show interesting strengths, while the **P-High**group appears to be most susceptible to internalizing psychopathology, while **P-Low**was least susceptible. All ASD groups declined in social motivation between early and preadolescence suggesting an area of concern.

217.004 *(Panel)* Sex Differences in a Subgroup of Children with Autism and Co-Occurring Symptoms of Psychopathology

C. W. Nordahl[1]*, A. M. Iosif*[2]*, B. Heath*[1]*, D. G. Amaral*[1]*, M. Solomon*[3] *and S. Ozonoff*[3]*, (1)Department of Psychiatry and Behavioral Sciences, The Medical Investigation of Neurodevelopmental Disorders (MIND) Institute, UC Davis School of Medicine, University of California Davis, Sacramento, CA, (2)Public Health Sciences, University of California Davis, Davis, CA, (3)Psychiatry and Behavioral Sciences, The Medical Investigation of Neurodevelopmental Disorders (MIND) Institute, UC Davis School of Medicine, University of California Davis, Sacramento, CA*

Background: Individuals with autism often have co-occurring psychiatric conditions, but little is known about the trajectory of development of symptoms of psychopathology during early childhood, whether there are sex differences in symptom presentation, and whether early childhood symptoms are predictive of later outcomes.
Objectives: We recently identified a subgroup of 3-year-old children with high levels of psychopathology. The goal of the current study is to evaluate symptoms of psychopathology in this subgroup later in childhood, around 5.5 years of age.
Methods: Participants include a large sample of children with ASD (91 females, 209 males) assessed between 2-3.5 years of age. ASD diagnosis was confirmed using ADOS-2 and ADI-R administered by clinical psychologists with expertise in ASD. Latent profile analysis (LPA) was used to identify ASD subgroups based on symptoms of psychopathology, adaptive functioning, cognitive development, and autism severity. Psychopathology was evaluated using t-scores from the Child Behavior Checklist (CBCL) DSM-oriented scales for affective problems, anxiety problems, attention deficit/hyperactivity problems, and oppositional defiant problems. Sex differences in the proportion of girls and boys in each subgroup were evaluated. A subset of children (45 females and 99 males) returned for longitudinal assessment two years after study entry, around 5.5 years of age. CBCL DSM-oriented scales were compared across subgroups and sex. Associations between baseline and longitudinal CBCL Internalizing and Externalizing scores were also examined across sex.
Results: At baseline assessment, three LPA subgroups were identified. One subgroup comprising 27% of the sample, was classified as having higher symptoms of psychopathology than the other two subgroups and moderate impairments on the other measures (*High Psychopathology, Moderate Impairments [HPMI]*). The other two subgroups had lower symptoms of psychopathology but were differentiated by high and low levels of impairment on other measures. Distribution of sex across subgroups was significantly different ($\chi^2 = 10.4$, $p = .006$). Almost twice as many girls were classified into the HPMI subgroup as boys (40% vs 22%). At longitudinal follow-up (mean age = 66.7 months), there was a sex by subgroup interaction for the Anxiety Problems t-score (p = .06). Females in the High Psychopathology subgroup had elevated anxiety scores relative to females in the other subgroups. In contrast, anxiety scores for males in the high psychopathology subgroup were no longer different from males in the other subgroups. There were no main or interaction effects on the other DSM-oriented scales. Internalizing and Externalizing scores were significantly correlated at baseline and follow up in females (r = .73, p = .003 internalizing, r = .761, p = .002 externalizing) but not in males (r = .16, p = .62 internalizing, r = .17, p = .58 externalizing).
Conclusions: Symptoms of psychopathology at age 3 were predictive of higher levels of anxiety at age 5 in females with ASD, but not males, and internalizing and externalizing scores were significantly correlated across time in females but not males. These results suggest that symptoms of psychopathology may be more stable in females with ASD across early childhood than in males.

POSTER SESSION — MEDICAL AND PSYCHIATRIC COMORBIDITY
430 - Medical and Psychiatric Comorbidity Posters

430.001 *(Poster)* A Comparison of the DSM Structure of Anxiety and Depression Symptoms across ASD and Non-ASD Youth

T. Rosen[1]*, C. Rodriguez-seijas*[1]*, K. D. Gadow*[2] *and M. D. Lerner*[3]*, (1)Stony Brook University, Stony Brook, NY, (2)Department of Psychiatry, Stony Brook University, Stony Brook, NY, (3)Department of Psychology, Stony Brook University, Stony Brook, NY*

Background: Youth with autism spectrum disorder (ASD) are at increased risk for experiencing co-occurring internalizing symptoms (e.g., Simonoff et al., 2008). Available evidence regarding internalizing symptom presentation in ASD is mixed; that is, some presentations of internalizing symptoms in ASD conform to standard DSM or traditional classification criteria (Lecavalier et al., 2011), while others reflect altered anxiety symptom presentation resulting from epiphenomena of ASD (e.g., Kerns et al., 2014; Wood & Gadow, 2010). Additionally, studies examining anxiety symptom presentation in ASD generally have not accounted for the putative overlap of depression symptoms, which may have influenced their obtained results. Crucially, understanding the appropriate conceptualization of anxiety and depression symptoms in ASD is needed to inform accurate assessment and subsequent treatment of internalizing disorders in ASD.
Objectives: The present study examines the extent to which DSM-defined symptoms of anxiety and depression present similarly in a sample of ASD and non-ASD youth.

Methods: Participants were ages 6-18, diagnosed with ASD in an outpatient clinic (N=280; M_{age} =10.7, SD_{age}=3.4) or referred to a psychiatry outpatient clinic with no ASD diagnosis (N=1195; M_{age} = 12.1, SD_{age}=3.4). Anxiety and depression symptoms were measured using the parent CASI-4R (Gadow & Sprafkin, 2008), a DSM-IV referenced rating scale.

Confirmatory factor analysis was used to examine measurement invariance of anxiety and depression symptom structure across the ASD and non-ASD groups (Figure 1). Anxiety subscale items (e.g., PTSD, somatization, specific phobia, panic, obsessive-compulsive disorder, generalized, social, separation anxiety) were fixed to load on an anxiety factor (Scahill et al., 2019), whereas depression and dysthymia items were fixed to load on a depression factor (Uljarević et al., 2017).

Results: Fit indices from measurement invariance analyses suggested relatively poor fit of the overall model of anxiety and depression symptoms (Table 1). However, fit improved at subsequent stages of invariance testing, indicating that anxiety and depression items are functioning similarly across groups in terms of factor loadings (e.g., metric invariance) and mean item endorsement levels (e.g., strong invariance).

Conclusions: Anxiety and depression items function similarly across the ASD and non-ASD groups, suggesting that parents are interpreting anxiety and depression items comparably across the ASD and non-ASD groups. This finding is consistent with recent work suggesting that internalizing symptoms (e.g., anxiety and depression on one internalizing factor) function similarly across ASD and non-ASD samples (Rodriguez-Seijas et al., 2019). Nonetheless, fit indices suggest that the overall anxiety and depression model demonstrated unsatisfactory fit across the two groups. It may be that accounting for the influence of ASD symptoms on internalizing symptoms would yield a better fit, which would have important nosological implications, such as adding ASD-specific manifestations of anxiety and depression to the DSM. Results underscore the importance of current efforts to validate adapted measures of internalizing symptoms for youth with ASD which consider ASD-influenced forms of anxiety (Kerns et al., 2017). Future studies are needed to validate such measures for depression in ASD, while continued efforts to identify evidence-based treatments for the unique forms of depression and anxiety in ASD are also warranted.

430.002 *(Poster)* A Lasso Analysis of Maternal, Obstetric, and Perinatal Predictors of Autism

*M. Ron[1], A. Pohl[2], A. N. Ruigrok[3], M. V. Lombardo[4], P. Smith[3], C. Allison[5], S. Baron-Cohen[5] and **F. Uzefovsky**[6], (1)Ben Gurion University, Beer Sheva, Israel, (2)Washington University School of Medicine, St. Louis, MO, (3)University of Cambridge, Cambridge, United Kingdom, (4)Center for Neuroscience and Cognitive Systems, Laboratory for Autism and Neurodevelopmental Disorders, Istituto Italiano di Tecnologia, Rovereto, Italy, (5)Autism Research Centre, Department of Psychiatry, University of Cambridge, Cambridge, United Kingdom, (6)Ben-Gurion University of the Negev, Be'er-Sheva, Israel*

Background: While genetics is clearly implicated in the etiology of autism, other biological factors may also increase the likelihood of an autism diagnosis. Many of these pertain to obstetric history, prematurity, and other pregnancy complications. In addition, some studies show an association with maternal medical conditions, particularly those relating to sex-hormone imbalance. Importantly, many of these conditions co-occur, making it difficult to disentangle the relationships between individual predictors and increased likelihood of autism in the child. This is particularly difficult as most studies focus on a subset of symptoms or conditions, and do not examine them together.

Objectives: To investigate which individual symptoms or conditions are most predictive of an increased likelihood of a childhood autism diagnosis using LASSO (least absolute shrinkage and selection operator).

Methods: Women recruited online through the Cambridge autism research database (CARD) and through the Cambridge psychology website, reported medical and pregnancy history of their first-born (N=557, 34.5% of children diagnosed with autism) and second-born (N=374, 28.1% of children diagnosed with autism) children. Data collected included (1) medical conditions relating to sex-hormone imbalance, fertility, and autoimmune disorders; (2) obstetric factors relating to immune activation during pregnancy, infertility treatments, age at birth, and other obstetric complications; (3) perinatal factors relating to preterm birth and birth weight. The first-born and second-born data were analyzed separately using the LASSO procedure (including cross validation), which enables the selection of variables using regularization and normalization procedures. A total of 42 and 39 predictors were used in the first and second-child analyses, respectively (some variables were dropped due to extremely low frequency in our sample). In a follow up analysis ('siblings analysis'), obstetric course and perinatal factors were analyzed for mothers who have one child diagnosed with autism and another neurotypical child, from the same father (N mothers= 132, 61.7% males), thus allowing to control for many genetic and environmental aspects. Twenty-five predictors were analyzed using the CLOGIT-LASSO procedure, which allows a comparison between the siblings' dependent data.

Results: The main analysis revealed the maternal medical conditions, obstetric course factors and perinatal factors relating to an increased likelihood of autism in the child (20 and 11 predictors for the first and second child analyses, respectively). Factors included, parental age (both mother and father), anovulation, diabetes, child gestational age, and child sex (See all variables in Table 1). The sibling analysis revealed that high maternal BMI before pregnancy and maternal low weight gain during pregnancy differentiated the pregnancy course of children later diagnosed with autism from neurotypical children.

Conclusions: This is one of the few studies to analyze a large set of predictors, spanning maternal medical conditions, obstetric course, and perinatal factors. Analyzing these factors together, using machine learning methods, allows us to disentangle the specific factors contributing to increased likelihood of autism in the child. The follow up analysis enabled us to examine these factors within families, thus allowing to control for genetic and environmental effects. Findings show that conditions relating to sex-hormone imbalance and diabetes are important predictors of autism.

430.003 *(Poster)* A Preliminary Investigation of Fear in Those with and without ASD

***K. S. Ellison** and T. E. Davis, Department of Psychology, Louisiana State University, Baton Rouge, LA*

Background: A phobia develops when a healthy fear becomes more intense, interfering, and last longer for an individual over time (Craske, 1997). van Steensel and colleagues (2012) found that specific phobias were more common in children with Autism Spectrum Disorder (ASD) compared to other anxiety disorders. More qualitative research is needed to explore fears and phobias in children with ASD.

Objectives: This study investigated the amount of fears and types of fears reported by youth with ASD compared to youth diagnosed with Social Anxiety Disorder (SAD) and youth without a psychiatric diagnosis (NODX). Descriptives related to the types of specific phobia were explored.

Methods: Nine youths with ASD (7 males; *M=10.44* years-old), 9 with SAD (4 males; *M=10.67* years-old), and 9 with NODX (7 males; *M=12.78* years-old) were included as part of a larger IRB-approved study. Consent/assent was obtained. Diagnoses were confirmed by the *Childhood Autism Rating Scale, Second Edition (CARS-2)* or the *Autism Diagnostic Observation Schedule, Second Edition (ADOS-2)* and the *Anxiety Disorders Interview Schedule (ADIS- IV-C/P)*. Youths were matched on age and IQ. Full-Scale IQ was measured using the *WISC-V* (ASD *M*=95.66, *SD*=13.96; SAD *M*=103.44, *SD*=10.38; NODX *M*=102.56, *SD*=7.78). The *Fear Survey Schedule for Children – Revised (FSSC-R)* was completed by each youth in order to capture the individual's total amount of fear as well as specific fear domains (fear of failure and criticism, fear of the unknown, fear of injury and small animals, fear of danger and death, medical fears). Data collection is ongoing.

Results: A one-way ANOVA was performed examining the effect of diagnosis on the total fears score as well as the five fear category scores from the *FSSC-R*. The three groups differed significantly on total fear, $F(2, 24)=4.31$, $p=.03$: youth with NODX (*M*=19.78,*SD*=12.79) differed from both youths with ASD (*M*=35.11,*SD*=12.68) and SAD (*M*=39.11,*SD*=18.10). The three groups were also significantly different on fear of the unknown, $F(2, 24)=5.45$, $p=.01$, with NODX (*M*=19.88,*SD*=7.29) having significantly less fear of the unknown compared to youths with ASD (*M*=27.78,*SD*=5.89, $p=.04$) and SAD (*M*=28.89,*SD*=4.84, $p=.01$). Children with ASD and SAD did not significantly differ on fear of failure (ASD *M*=29.22, *SD*=6.74; SAD *M*=30.11, *SD*=8.13; $p=.80$), fear of injury and small animals (ASD *M*=34.00, *SD*=6.58; SAD *M*=35.67, *SD*=9.50, $p=.67$), fear of danger and death (ASD *M*=27.11, *SD*=7.30; SAD *M*=26.11, *SD*=6.82, $p=.77$), and medical fears (ASD *M*=9.56, *SD*=2.07; SAD *M*=10.55, *SD*=2.40, $p=.36$). Descriptive statistics yielded 6 of the 9 youth with SAD and 3 of the 9 youth with ASD were also diagnosed with a specific phobia. All 3 youth with ASD had a fear of wasps.

Conclusions: Contrary to previous research, children with ASD did differ in the amount of fear they endorsed compared to children with SAD, though both reported more fear than those with no diagnoses. Recruitment is ongoing to allow for additional comparisons and further exploration of group differences.

430.004 *(Poster)* ASD or Response to Childhood Trauma? How ACEs Type and Frequency Influence Symptom Presentation of Children with and without Autism Spectrum Disorder.

A. Barrett *and T. W. Vernon, University of California Santa Barbara, Santa Barbara, CA*

Background: Children with Autism Spectrum Disorder (ASD) are twice as likely to experience four or more Adverse Childhood Experiences (ACEs) than their typically developing peers (10.2% vs 5.1%; Dixon Browne & Hamilton-Giachritsis, 2009). Families affected by ASD experience several risk factors that increase their likelihood of ACEs, including parent stress, financial strain, and lack of social support (Dabrowska & Pisula, 2010). In addition, social communication impairments can prevent children with ASD from reporting, limiting access to trauma-informed interventions (McEachern, 2012). Research has found that increased ACEs is associated with widespread mental health and physical health problems (Rigles, 2017). Specifically for children with ASD, increased ACEs are associated with delayed age of diagnosis and entrance into treatment services (Levy, 2010). To date, very few studies have examined posttraumatic response in individuals with ASD to inform differential diagnosis between ASD and trauma response.

Objectives: This study examined how children with ASD process and respond to ACEs similarly or differently than (a) ASD children without ACEs and 2) typically developing (TD) children with ACEs.

Methods: Participants included a nationwide sample (n=250) of parents of children ages 3-12. The study gathered data from a culturally and socioeconomically diverse sample to measure social, emotional, and behavioral symptoms associated with posttraumatic stress response in children. Three study populations were recruited: children with ASD who experienced ACEs, children with ASD who have not experienced ACEs, and TD children who experienced ACEs. Parents completed the Trauma Symptom Checklist for Young Children (TSCYC), the Social Responsiveness Scale (SRS-2), and self-injurious and compulsive behaviors subtests of the Repetitive Behavior Scale (RBS-R). One-way MANOVAs were conducted to assess for differences in symptom presentation between groups.

Results: Preliminary data suggest that ASD participants with ACEs have significant highly number of mental health diagnoses than the other two groups ($p<.001$). Thus far, findings suggest that as children with ASD accumulate three ACEs, their posttraumatic stress symptoms cross into in the clinical range, as opposed to TD children who seem to accumulate six ACEs before reaching the same level of clinical distress. In regard to autism-related symptoms, there were significant differences between groups ($p<.001$), with children with ASD and ACEs presenting as most symptomatic in all domains. Interestingly, 54% of parents of TD children with ACEs reported ASD-related symptoms in the clinical range (M=60.3, SD=10.4). Children with ASD and ACEs demonstrated significantly higher rates of self-injurious behaviors than their TD peers with ACEs ($p=.002$). Pending analyses will explore how number and type of ACEs impact symptom presentation.

Conclusions: This investigation is part of newly emerging research investigating the diagnostic similarities and differences between TD children with ACEs and their peers with ASD. It is hoped that these results will provide novel data about the influence of ACEs on symptom presentation of children with and without ASD and will provide clarity about differential diagnosis of ASD versus trauma response. By gaining information about the unique posttraumatic symptom presentation in children with ASD, we may strive to increase timely identification of victims and adopt *appropriate* interventions.

430.005 *(Poster)* Adaptive and Behavioral Functioning in Children with Co-Morbid Down Syndrome and Autism Spectrum Disorder

K. R. Bradbury[1]*, E. I. Anderberg*[2]*, L. Huang-Storms*[3]*, J. Vasile*[1]*, R. K. Greene*[4] *and S. W. Duvall*[1]*, (1)Oregon Health & Science University, Portland, OR, (2)Oregon Health and Science University, Portland, OR, (3)Oregon Health & Science University, Seattle, WA, (4)Child Development and Rehabilitation Center, Oregon Health & Science University, Portland, OR*

Background: Down Syndrome (DS) is a genetic disorder associated with moderate to severe Intellectual Disability (ID). Approximately 16% of children with DS also have autism spectrum disorder (DS+ASD). Children with DS+ASD show more adaptive impairments than children with DS, but comparable adaptive function to children with ASD. Previous literature also indicates a general trend of children with DS+ASD showing elevated behavioral concern compared to those with DS, but reduced compared to those with ASD.

Objectives: This study aims to explore adaptive and behavioral functioning in children with intellectual disability/global developmental delay and co-morbid DS+ASD compared to children with co-morbid ASD (ASD+ID), and children with cognitive impairment alone (ID).

Methods: Children (n = 179) aged 1.5 to 18 years were evaluated at an interdisciplinary autism clinic and received diagnoses of DS+ASD (n = 22), ASD+ID (n = 112), or ID (n = 45). Since age differed across groups (ID group was older), one-way ANCOVAs were conducted comparing groups with respect to parent-reported adaptive functioning measured by the Adaptive Behavior Assessment System (ABAS) and behavioral functioning measured by the Child Behavior Checklist (CBCL). Bonferroni correction was used to control for multiple comparisons resulting in an adjusted alpha level of .004 (.05/14).

Results: Race/ethnicity and gender did not differ across groups (see Table 1). When controlling for age, all children demonstrated mildly to moderately impaired adaptive functioning on the ABAS (see Table 2). Children with DS+ASD showed the greatest impairment across almost all domains of adaptive functioning; however, differences in practical skills did not survive correction. Children diagnosed with ASD (DS+ASD and ASD+ID) showed greater social impairment than children with ID. On the CBCL, all groups had similar elevations on withdrawal and attention problems. Children with ID demonstrated greater externalizing problems, total problems, anxious/depressed symptoms, and aggression, which were lower and more similar in the ASD+ID and DS+ASD groups. These differences remained following correction. Children with DS+ASD had lower scores than children with ID across all other domains, although these findings did not survive correction. Children with DS+ASD showed significantly less oppositional/defiance than either those with ASD+ID or ID, even following correction.

Conclusions: All children showed adaptive impairment, withdrawal, and attention problems. In contrast to previous studies, lower overall adaptive function and conceptual skills were observed in children with more co-morbid diagnoses (DS+ASD<ASD+ID<ID). CBCL findings suggest similar behavioral profiles between DS+ASD and ASD groups, with the exception of decreased oppositional/defiance in children with DS+ASD relative to other groups. Children with ID showed greater behavioral difficulties on the CBCL across several scales. This finding may reflect differences in parent reporting or expectations across diagnostic groups. Children with DS are often diagnosed at or before birth which may contribute to increased parental adaption to behavioral symptoms, while challenges in children with idiopathic ID may be more attributable to emotional or behavioral factors. Future research is needed to examine profiles of cognitive functioning and ASD symptomatology in children with DS+ASD, ASD+ID, and ID to determine their impact upon adaptive and behavioral functioning.

430.006 *(Poster)* Age of Autism Diagnosis and Current Mental Health Concerns in Females. Are They Related?

C. M. Brown[1] *and M. A. Stokes*[2]*, (1)School of Psychology, Deakin University, Melbourne, Australia, (2)Deakin University, Burwood, Australia*

Background: Mental health concerns are over-represented in autistic adults. As many as 60% of all autistic individuals report at least one comorbid psychiatric diagnosis, with autistic females displaying higher levels of anxiety, depression and eating disorders. Females are also more likely to be late-identified and under-diagnosed as being autistic. It is currently unknown if historical delays in autism diagnosis worsen mental health outcomes at present.

Objectives: The purpose of this investigation was to understand if year of birth, and subsequent age of autism diagnosis influenced rates of current mental health symptomology.

Methods: We recruited 330 formally diagnosed autistic women online (M age = 33.69 years, SD = 9.97). The Autism Quotient (AQ; Baron-Cohen, Wheelwright, Skinner, Martin & Clubley 2001) was used to assess levels of autistic traits, with all participants scoring above 32. Current levels of disordered eating were assessed using the Eating Attitudes Test (EAT-26; Garner, Olmsted, Bohr & Garfinkel, 1982), and depression and anxiety symptoms were assessed using the Depression, Anxiety, Stress Scale (DASS-21; Lovibond & Lovibond, 1995). We investigated the interaction between year of birth, age of autism diagnosis, and current mental health symptom severity.

Results: Using a diagonal plot, we were able to give an approximation of the interaction between year of birth, age of autism diagnosis, and current mental health symptom severity.

We found that females who were diagnosed as autistic within particular age bands displayed the highest depression, anxiety and stress symptom burden at present (Fig. 1). These were autism diagnoses between the ages of 7 to 12 (DASS-21: M=62.33, SD=19.31), and 13 to 18 (DASS-21: M=61.26, SD=11.87) years respectively. Significant differences were found between those diagnosed with autism between the ages of three and seven years, and those diagnosed between 30 and 45 years ($F_{(12.76)}$=7.17, p=.008).

When considering current eating disorder symptomology, (Fig. 2) we again found that females displaying the highest level of eating disorder symptoms were those diagnosed with autism between the ages of 7 to 12 (EAT-26: M=19.83, SD=14.28), and 13 to 18 years (EAT-26: M=21.50, SD=16.84), though no significant differences were found between age bands.

Conclusions: It appears that delays in the identification and diagnosis of autism in females may reflect the strength of pathology. It is proposed that when females are diagnosed with autism under the age of seven, the ensuing early intervention therapies and support have a protective effect, that allow them to avoid poorer mental health outcomes in adulthood. This highlights the need for greater understanding of the female profile of autism, comorbid mental health conditions, and the development of female specific screening and assessment tools.

430.007 *(Poster)* Anxiety Problems Mediate Associations between Sleep and Gastrointestinal Problems in Hospitalized Children with Autism Spectrum Disorder (ASD)

B. J. Taylor[1]*, K. A. Pedersen*[2] *and M. Siegel*[3]*, (1)Psychiatry, Maine Medical Center Research Institute, Portland, ME, (2)Center for Psychiatric Research, Maine Medical Center, Portland, ME, (3)Maine Medical Center - Tufts School of Medicine, Westbrook, ME*

Background: Sleep and gastrointestinal (GI) problems are prevalent medical comorbidities in children with autism spectrum disorder (ASD). Sleep and GI problems are correlated with one another in both ASD and non-ASD children; however, mechanisms underlying this association are unclear. Anxiety is also highly prevalent in ASD and has been identified as a potential mediator of the sleep-GI association in non-ASD individuals. The role of anxiety in the sleep-GI association in ASD is unclear.

Objectives: To determine if anxiety symptoms statistically mediate associations between sleep problems and GI problems in a sample of psychiatrically hospitalized children with ASD.

Methods: Data from the Autism Inpatient Collection (AIC) were used for this analysis. The AIC is a multi-site study of children with ASD admitted to one of six inpatient units specialized for the psychiatric treatment of children with ASD. Caregivers provided information regarding medical comorbidities and completed the Child Behavior Checklist (CBCL). Autism diagnosis, autism severity, verbal ability, and intellectual functioning were assessed by research-reliable Autism Diagnostic Observation Schedule-2 and the Leiter International Performance Scale-3. Complete data were available in 276 patients. Logistic regressions were used to determine if caregiver-reported sleep problems predicted GI problems independent of age, sex, autism severity, verbal ability, intellectual functioning, and anxiety symptoms. Sobel tests were used to determine if anxiety symptoms statistically mediated associations between sleep and GI problems. A sensitivity analysis was used to examine if results held when the CBCL Anxiety Problem question about nightmares was removed from the total score. Exploratory logistic regressions examined items within the CBCL Anxiety Problem subscale to determine if specific indicators of anxiety were driving analyses.

Results: Prior to adjusting for anxiety symptoms, Logistic regression analyses revealed that children with ASD and a sleep problem were 78% more likely to experience a GI problem (OR=1.78, 95% CI: 1.05-3.01) after controlling for age, sex, autism severity, verbal ability, and intellectual functioning. This association was no longer significant when anxiety symptoms were entered into the model. Every point increase on the CBCL Anxiety Problem t-score was associated with a 4.7% increase in the likelihood that a participant would have a GI problem (OR=1.05, 95% CI: 1.02-1.07). Sobel tests suggested that anxiety symptoms are a statistically significant mediator of the association between sleep and GI problems (Sobel test statistic = 3.14, SE = 0.10, p = 0.002). Anxiety symptoms continued to mediate the association between sleep and GI problems after removing the “nightmare” item from the subscale. Three indicators of anxiety were found to drive the mediation results. These included being 1) nervous, high-strung, or tense; 2) too fearful or anxious; and 3) worrying.

Conclusions: Anxiety symptoms mediated associations between sleep problems and gastrointestinal problems independent of autism severity, intellectual functioning, and verbal ability. Though the current study is cross-sectional, these results suggest that sleep problems may contribute to heightened anxiety symptoms which may in turn contribute to or exacerbate GI disturbances. Sleep disturbance and anxiety may be important intervention targets in children with ASD and GI disturbances.

430.008 *(Poster)* Anxiety and ADHD in Young Children with ASD Are Associated with Distinct Patterns of Executive Function Deficits and Core ASD Symptoms

K. L. Carpenter[1], *G. T. Baranek*[2], *S. Compton*[3], *N. O. Davis*[4], *L. DeMoss*[5], *H. L. Egger*[6], *E. Glenn*[7], *S. H. Kollins*[4], *J. Howard*[1], *E. Rabinovitz*[8], *K. C. Ramseur*[1], *H. Riehl*[9], *L. Sikich*[3], *S. Sipe*[10], *M. Spanos*[7], *J. A. Summers*[10], *A. Welch*[10] *and G. Dawson*[3], *(1)Duke Center for Autism and Brain Development, Department of Psychiatry and Behavioral Sciences, Duke University, Durham, NC, (2)Chan Division of Occupational Science and Occupational Therapy, University of Southern California, Los Angeles, CA, (3)Department of Psychiatry and Behavioral Sciences, Duke Center for Autism and Brain Development, Durham, NC, (4)Department of Psychiatry and Behavioral Sciences, Duke ADHD Program, Duke University Medical Center, Durham, NC, (5)Brown Center for Children & Families, Women & Infants Hospital, Providence, RI, (6)Department of Child and Adolescent Psychiaty, New York University Langone Health, New York, NY, (7)Duke Center for Autism and Brain Development, Durham, NC, (8)Ferkauf School of Graduate Psychology, New York, NY, (9)Tufts, Boston, MA, (10)Duke University, Durham, NC*

Background: Two of the most prevalent co-occurring disorders in ASD are anxiety and ADHD, with 40-60% of children meeting criteria for one or both of these disorders (Simonoff, 2008). Executive function difficulties are proposed as a common pathway between ASD and ADHD and are also implicated in anxiety. However, little is known about how anxiety or ADHD symptoms differentially impact executive functioning or how these deficits may influence the presentation of core ASD symptoms in young children. Furthermore, the clinical implications of co-occurring anxiety/ADHD and associated executive functioning deficits remain a significant gap in the literature.

Objectives: We aimed to understand how the unique executive function difficulties associated with co-occurring anxiety and/or ADHD differentially impact the clinical presentation of ASD in young children.

Methods: Data were derived from two studies of young children with ASD: Study 1 included sixty-nine 3-6-year-old children; Study 2 included sixty-three 4-8 year old children. Both studies included children with a range of cognitive functioning. Anxiety and ADHD were assessed through parent interview using the Preschool Age Psychiatric Assessment (Study 1) and the Child Behavior Checklist (Study 2). Executive functions were assessed using the Behavior Rating Inventory of Executive Function – Preschool Version and core ASD symptoms were measured with the ADOS, Repetitive Behavior Scale-Revised, Sensory Experiences Questionnaire 3.0, and Social Responsiveness Scale. To explore the relationship between executive function difficulties and co-occurring ADHD or anxiety, we used an additive main effect general linear model. The relationship between anxiety or ADHD and core ASD symptoms was assessed via mediation models. All models included both anxiety and ADHD to account for the fact that some children experience both conditions and to explore the unique contribution of anxiety and ADHD on each outcome.

Results: In both samples, we found that greater difficulty with attentional shifting was uniquely associated with anxiety (Study 1: $F=22.6$, $p<.001$; Study 2: $F=24.3$, $p<.001$), whereas greater difficulty inhibiting behavioral responses was uniquely associated with ADHD (Study 1: $F=12.2$, $p<.001$; Study 2: $F=36.4$, $p<.001$). Additionally, the first model supported that attentional shifting mediates the relationship between anxiety and core ASD symptoms including: ritualistic behaviors (β(SE)=0.22(0.1), 95% CIs=0.05-0.5), sameness behaviors (β(SE)=0.35(0.12), 95% CIs=0.11-0.59), sensory over-responsivity (β(SE)=0.99(0.45), 95% CIs=0.11-1.9), and social motivation (β(SE)=0.20(0.11), 95% CIs=0.02-0.4). The second mediation model indicated that inhibitory control mediates the relationship between ADHD and self-injurious behaviors (β(SE)=0.37(0.17), 95% CIs=0.08-0.74).

Conclusions: Unique patterns of executive function difficulties are associated with anxiety and ADHD and mediate the relationship between these conditions and core ASD symptoms. These findings implicate executive functioning as an important cognitive process underlying psychiatric comorbidities and ASD. Future research should investigate the impact of early intervention for executive function deficits on psychiatric and neurodevelopmental outcomes in children with ASD.

430.009 *(Poster)* Assessment and Management of Attention Deficit Hyperactivity Disorder in Individuals with ASD

***G. Joshi**, Pediatric Psychopharmacology and Adult ADHD, Massachusetts General Hospital, Boston, MA*

Background: Both autism spectrum disorders (ASD) and attention-deficit hyperactivity disorder (ADHD) are severely impairing chronic conditions with high prevalence rates that manifest in early childhood, predominantly affect males, are known to be highly heritable, and characterized by distinctive clinical, cognitive, and neural correlates. Nearly half of the population with ASD suffers from symptoms of ADHD (hyperactivity, impulsivity, and inattention) that greatly adds to their morbidity and dysfunction. ADHD is the most common psychiatric condition diagnosed in children and adults with ASD (Joshi et al., 2010, 2012). In recent times there has been a surge in research aimed at promoting better understanding of the autism spectrum disorders (ASD) and related comorbidities. Management of this highly complex disorder is limited either by lack of recognition of autism in youth under psychiatric treatment or by the failure to recognize the presence of co-occuring psychiatric disorders in youth diagnosed with autism. This leads to under-recognition of reciprocal co-occurrence of ASD and psychopathology. The presence of ADHD further worsens the already compromised academic and social functioning in school children with autism. Considering that ADHD is known to respond to a variety of pharmacological and non-pharmacological interventions, identifying and treating ADHD in individuals with ASD can reduce morbidity and facilitate targeted behavioral efforts specific for ASD.

Objectives: This presentation will offer an up-to-date review of the emerging evidence on the prevalence, clinical characteristics, and management of Attention-Deficit/Hyperactivity Disorder (ADHD) in children and adolescents with autism spectrum disorder (ASD).

Methods: The literature on ASD was queried to identify published studies on: 1) the prevalence and the clinical presentation of ADHD in youth with ASD and 2) the psychopharmacological interventions for the treatment of ADHD in youth with ASD.

Results: The presentation will open with the information on the prevalence of ASD in non-referred and in psychiatrically referred populations. The first portion of the talk will underscore the burden of psychopathology associated with ASD followed by description of the clinical presentation and recognition of co-occurring ADHD. The second portion of the talk will discuss special considerations in the psychopharmacological management of individuals with ASD and provide a comprehensive overview of the available evidence on the psychopharmacology of ADHD in ASD. Presentation will emphasize best evidence practice pathways for practical, multimodal treatment of ADHD in the outpatient setting.

Conclusions: Emerging literature highlights high levels of psychopathology and dysfunction in individuals with ASD. Proper recognition of psychopathology in ASD offers the opportunity for appropriate medication intervention. An up-to-date knowledge of evidence-based pharmacotherapy for ADHD in individuals with ASD will help optimize therapeutic interventions and identify research directions.

430.010 *(Poster)* Assessment of Sleep Behaviors in Syndromic ASD

***J. N. Barstein**[1], S. Jeste[2], C. DiStefano[3], C. Hyde[4] and V. Saravanapandian[3], (1)The Help Group - University of Los Angeles, California, Los Angeles, CA, (2)University of California, Los Angeles, Los Angeles, CA, (3)University of California Los Angeles, Los Angeles, CA, (4)Semel Institute, UCLA Medical Center, Los Angeles, CA*

Background: Sleep disturbances are highly prevalent in neurodevelopmental disabilities such as autism spectrum disorder (ASD) yet many measures of sleep behaviors are inappropriate due to the inability of the individual to describe sleep-wake patterns or the lack of tools assessing behaviors that affect sleep. Recently, a modified version of the Children's Sleep Habits Questionnaire (CSHQ) was published for use in ASD. No studies to date have investigated the feasibility of the CSHQ in syndromic ASD in which cognitive and language impairment may impede item applicability and comorbidities such as hypotonia and epilepsy may differentially impact sleep. Duplication of chromosome 15q11.2-q13.1 (dup15q syndrome) is one of the most common genetic variants associated with ASD, with evidence of atypical brain activity during sleep. Thus, dup15q syndrome may serve as a model for investigating behavioral sleep symptoms in syndromic ASD.

Objectives: To examine the feasibility of using the CSHQ in a population with syndromic ASD and to identify patterns of sleep behavior in dup15q syndrome.

Methods: As part of a comprehensive phenotyping study of dup15q syndrome, 42 caregivers of individuals with dup15q syndrome ages 4 to 42 completed the original version of the CSHQ. Caregivers were instructed to skip items or mark if questions were not applicable. Participants were split into "fully completed" and "partially completed" groups and independent sample t-tests determined whether groups differed by cognitive and language skills. Chi-square analyses determined whether the rate of fully completed versus partially completed questionnaires differed between the original and revised versions. Total and subscale scores were computed for both the original and revised version and compared to the normative samples reported in the literature. Given the high prevalence of epilepsy in individuals with dup15q syndrome, scores were also compared by epilepsy status.

Results: Overall, 56% of caregivers did not skip any questions. The "fully completed" group had significantly higher cognitive abilities than the "partially completed" group. Questions most frequently skipped relied on language skills (e.g., complains about sleep problems, reports body pains at night). The revised scoring did not yield more completed questionnaires, and medically-related sleep disturbances (eliminated from the original questionnaire) were endorsed as frequently as other items. The overall average score on the CSHQ was above the normative cut-off. Participants with epilepsy had lower scores (indicating fewer symptoms) on the Bedtime Resistance and Anxiety subscales of the original questionnaire compared to those without epilepsy.

Conclusions: Results suggest that while caregivers of individuals with syndromic ASD can feasibly use the CSHQ, some items remain inappropriate, in particular for individuals with more profound cognitive impairment. Results additionally support the need for a study with a larger sample size to investigate the psychometric properties of the CSHQ in a population with significant intellectual disability. Given that use of the revised CSHQ may have resulted in an oversight of medical sleep conditions, it is advised that providers use the original questionnaire to screen for potential medical sleep comorbidities in syndromic ASD. Results also highlight the importance of considering seizure activity, as epilepsy uniquely affected caregiver ratings.

430.011 *(Poster)* Attentional and Physiological Correlates of Emotional Problems in Autistic Adolescents: Focus on Negative Social Cues

V. Carter Leno[1]*, S. Chandler*[1]*, I. Yorke*[1]*, G. Forth*[1]*, T. Charman*[2]*, A. Pickles*[1] *and E. Simonoff*[1]*, (1)King's College London, Institute of Psychiatry, Psychology and Neuroscience, London, United Kingdom, (2)Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, United Kingdom*

Background: Many autistic young people experience co-occurring emotional problems. The development of effective interventions requires greater knowledge of the causes of these problems. A key first step is to explore whether neurocognitive mechanisms reported from non-autistic populations function similarly in autistic populations. In typically developing populations, there is strong evidence to suggest emotional problems are in part driven by increased attention towards negative social cues (i.e. angry faces). There is also evidence to suggest emotional problems are associated with an increased physiological response (e.g., increased heart rate; HR) to negative social cues. Whether similar cognitive alternations are associated with emotional problems in autistic populations remains relatively unexplored.

Objectives: To test whether physiological response in response to, and attentional bias towards, negative social cues are associated with emotional problems in a well-characterised sample of autistic adolescents (QUEST sample; part of the wider IAmHealth study; n=56; 13-17 years; IQ range = 33-129). The subsample who completed the neurocognitive tasks were enriched for females (62% female).

Methods: Participants completed two computerised tasks; one measuring attentional bias through reaction times on a dot-probe task with angry and happy faces (n=56), and the other measuring HR response (average HR in the 6 second period after stimuli presentation) to happy, sad, angry and disgust faces (n=53). To account for variation in baseline HR, relative HR scores were calculated by subtracting response to happy faces from response to all other negative emotions. Emotional problems were assessed using the parent-rated Strengths and Difficulties Questionnaire (SDQ) subscale. Mixed models were used to test associations between co-occurring symptoms and differences in attentional bias and HR response to negative vs. positive social cues. Secondary analyses assessed the impact of IQ. Correlations between attentional bias and HR response were calculated.

Results: Attentional Bias: Positive values indicate bias towards (vigilance), negative values indicate bias away (avoidance) from the stimulus. A trend interaction term was found between emotion and SDQ emotional problems (β=-7.32, p=.06; see Figure 1); those with higher levels of emotional problems had a greater bias away from angry (but not happy) faces.

Physiological Response: A significant interaction term was found between emotion and SDQ emotional problems ($\chi^2(3) = 8.16$, $p<.05$); those with higher levels of emotional problems had a greater HR response to negative, as compared to positive (happy) emotions (Figure 2).

Both findings dropped to a trend when was IQ was included as a covariate (p=.07 for both interaction terms). No significant correlations were found between relative HR to angry faces and attentional bias. Relative HR to sad (r=-.32, p=.04) and disgusted (r=-.35, p=.02) faces was associated with attentional bias away from angry faces in the dot-probe task.

Conclusions: Results suggest emotional problems in autistic youth are associated with attentional avoidance of negative social cues and increased physiological response to negative relative to positive social cues. Studies testing the impact of interventions found to be effective in reducing emotional problems in typically developing population (such as attentional bias or biofeedback training) in autistic populations are required to assess directionality.

430.012 *(Poster)* Auditory Mismatch Negativity in Young Individuals Affected By High Functioning Autism Spectrum Disorder with and without Attenuated Psychosis Syndrome

G. Di Lorenzo[1]*, A. Riccioni*[2]*, M. Ribolsi*[1]*,* ***M. Siracusano***[3,4]*, F. Lucidi*[2]*, P. Curatolo*[2] *and L. Mazzone*[2]*, (1)Systems Medicine, Division of Adult Psychiatry, University of Rome Tor Vergata, Rome, Italy, (2)Systems Medicine, Division of Child Psychiatry, University of Rome Tor Vergata, Rome, Italy, (3)Biomedicine and Prevention, University of Rome Tor Vergata, Rome, Italy, (4)Department of Biotechnological and Applied Clinical Sciences, University of L'Aquila, L'Aquila, Italy*

Background: Autism Spectrum Disorder (ASD) and Schizophrenia Spectrum Disorders (SSD) represent two different psychopathological conditions characterized by common epidemiological, genetic, cognitive, and neurophysiological factors. Among electrophysiological indices, the Mismatch Negativity (MMN), an event-related potential (ERP) reflecting preattentive processing, has been widely investigated as a promising candidate biomarker for predicting development of psychosis in individuals at clinical high risk and with attenuated psychosis syndrome (APS). Within ASD population, MMN has been used to identify auditory processing deficits showing conflicting results. However, despite evidences of a strong association between the two conditions, few studies have examinated the co-occurrence rate of ASD and SSD in pediatric populations by the use of a clinical and neurophysiological approach.

Objectives:To characterize the neurophysiological and clinical phenotype of ASD patients with Attenuated Psychosis Syndrome (ASD+APS) compared to ASD patients without APS (ASD-APS) and to Typically Developing individuals (TD).

Methods:30 high functioning ASD patients (Intellectual Quotient >70; age range 9-23 years; 9 female, 22 male) and 18 typically developing controls (TD), matched for age and gender, were enrolled. A standardized clinical assessment of autistic symptoms (Autism Diagnostic Observation Schedule – Second Edition ADOS-2) and of attenuated psychosis syndrome (APS) (Structured Interview for Prodromal Syndromes (SIPS) and Scale of Prodromal Syndromes-SOPS) was performed. In all participants, a 64-channel electroencephalogram (EEG) was recorded during the listening of a passive auditory paradigm (and the watching of a silent video) with 2000 frequent tones (frequency: 1000 Hz; duration: 50 ms) and two groups of deviant tones, 200 for a higher duration (100 ms) and 200 for a higher frequency (1500 Hz). MMN waveforms to frequency deviant tones (f-MMN) and duration deviant tones (d-MMN) were obtained for the Fz channel. MMN peak latency and peak amplitude were measured.

Results: 12 ASD patients met criteria for APS (ASD+APS) whereas 18 ASD patients did not (ASD-APS). ASD patients presented significant lower f-MMN and d-MMN peak amplitudes compared to TD. In ASD+APS group f-MMN and d-MMN peak amplitudes were lower respect to those of ASD patients without APS (ASD-APS). Higher ASD clinical severity, measured with ADOS-2, was related to lower d-MMN peak amplitude in ASD-APS group, but not in ASD+APS group. MMN peak latencies did not differ between groups.

Conclusions: Current findings confirm that young individuals with ASD are characterized by impairment of neurophysiological preattentive auditory processing as measured by MMN. Our results showed that the comorbid APS affects the amplitudes of MMN in ASD, revealing a more severe impairment in preattentive auditory processing. Interestingly, the presence of psychosis seems to moderate the relation between MMN impairment and ASD clinical severity.

430.013 *(Poster)* Autism Symptoms in Gender Diverse Cohort Correspond to Mental Health, Quality of Life, and Gender-Affirming Treatment Course

R. K. Earl[1]*, F. Orlich*[2]*, C. B. Cuellar*[2]*, D. J. Inwards-Breland*[3] *and K. Ahrens*[2]*, (1)Psychiatry and Behavioral Sciences, University of Washington, Seattle, WA, (2)Seattle Children's Hospital, Seattle, WA, (3)Pediatrics, Seattle Children's Hospital, Seattle, WA*

Background: Increasing evidence suggests elevated co-occurrence of autism spectrum disorder (ASD) and gender dysphoria (GD), with individuals with ASD being 7.5 times more likely to express gender variance compared to those without ASD (Glidden et al, 2016; Strang et al, 2015; Paterski et al, 2014). As patients with ASD and GD seek gender-affirming medical treatment, it is essential that providers understand this population's clinical presentation and treatment barriers, such as intervention readiness and informed consent. Further understanding of self-reported gender identity markers and treatment trajectories for this population is also needed.

Objectives: To clinically characterize patients presenting for gender-affirming medical treatment with elevated autistic traits and to explore treatment trajectories for patients with and without elevated autistic traits.

Methods: Participants (n = 106, mean age = 14.93 years) included patients from a hospital-based gender clinic cohort enrolled in a longitudinal study of diagnostic, mental health, and psychosocial outcomes at baseline, 3, 6, and 12 months. Participants provided general information on medical treatment progress as well as self and caregiver report measures, including autistic traits (Autism Quotient (AQ)-10), depression (PHQ), quality of life (WHO-QOL), and resilience. Case review of specific treatment course for patients and coding of self-described identity markers (i.e., gender, sexuality) is ongoing. Analyses compared patients with and without elevated autistic traits on mental health, psychosocial factors, and treatment course.

Results: Clinical characterization of the cohort at baseline identified 20% (23/106) to have autistic features above the clinical cutoff on the AQ-10 ("high AQ"). High and low AQ groups did not differ in age. At baseline, high AQ patients presented with significantly higher rates of self-harm compared to low AQ patients, c^2 (1, N = 106) = 4.80, p = 0.028, and trended toward lower resilience, t(102)=1.93, p = 0.056. Results of Pearson correlation indicated a significant negative association between baseline AQ scores and baseline quality of life, r(51) = -0.37, p = 0.008, and resilience, r(100) = -0.23, p = 0.007. Additionally, there was a significant positive association between baseline AQ and baseline depression symptoms, r(94) = 0.20, p = 0.048. Preliminary findings suggest distinct trajectories for high and low AQ groups for prescription of cross-gender hormones (Figure 1). High AQ patients were less likely to be prescribed hormones over time compared to low AQ patients. Further analyses will be conducted to determine specific factors influencing differences in treatment course and to characterize self-described identity markers for high AQ versus low AQ patients.

Conclusions: Gender diverse patients with elevated autistic traits exhibited elevated psychopathology, diminished coping resources, and reduced quality of life. Furthermore, findings suggested different treatment trajectories for patients with and without elevated autistic traits. Further analysis of treatment trajectories and mental health outcomes between groups will provide critical insight into treatment course and barriers for patients with co-occurring GD and ASD symptomatology. These findings will inform gender-affirming treatment in a manner that is inclusive and personalized for patients on both gender and autism spectrums.

430.014 *(Poster)* Autonomic Startle Response and Anxiety in Preschool Children with Autism Spectrum Disorder and Fragile X Syndrome

J. A. Ezell[1]*, A. L. Hogan*[2]*, E. A. Will*[3]*, K. D. Smith*[2] *and J. E. Roberts*[2]*, (1)University of South Carolina, Columbia, SC, (2)Department of Psychology, University of South Carolina, Columbia, SC, (3)Psychology, University of South Carolina, Columbia, SC*

Background: Children with Autism Spectrum Disorder (ASD) are at an elevated risk for anxiety that emerges early in life with a profound negative impact on outcomes. Evidence suggests that 90.5% of preschoolers with ASD have at least one co-occurring anxiety disorder (Salazar et al., 2015). Fragile X syndrome (FXS) is a single-gene disorder that is the leading known cause of ASD. Children with FXS are also at an elevated risk for anxiety (Sinclair, et al, 2017). Early detection of anxiety is difficult, however, given a lack of anxiety measures validated for young or cognitively impaired children. Thus, implementation of multiple methods, including biomarkers, is ideal. Reflexive startle responses and autonomic regulation index stress and anxiety in neurotypical children (Chen et al., 2014) and require minimal compliance and effort from participants. A clearer understanding of how autonomic regulation to a startle probe is related to anxiety symptoms in ASD and FXS can provide insight into the mechanistic underpinnings of anxiety in neurodevelopmental disorders.

Objectives: The purpose of this study is to (1) compare autonomic responses to an auditory startle probe, and (2) assess the association between startle responses and anxiety symptoms across low-functioning preschoolers with ASD contrasted to FXS.

Methods: Participants included 30 children with ASD and 31 children with FXS between the ages of 3-6 years old. All children had an intellectual disability. Heart activity was measured during an auditory startle paradigm comprised of a silent movie and a brief white noise blast. For analyses, the task was assessed for 1) acute startle IBI response (5 seconds pre-startle to 2 seconds post-startle), and 2) pre-startle RSA baseline (30 seconds pre-startle). Parent-reported general anxiety on the Anxiety, Depression, and Mood Scale (ADAMS; Esbensen et al 2003) was used to assess anxiety. This study is part of an ongoing longitudinal project; thus, more participants will be added for the final INSAR dataset.

Results: The ASD group had more symptoms of general anxiety ($t(47) = 3.07$, $p < .01$). No significant group differences were seen for acute startle response or pre-startle RSA baseline. There was no relationship of acute startle IBI response to anxiety symptoms. However, elevated pre-startle RSA was marginally associated with reduced anxiety symptoms across groups ($b = -0.11$, $p = 0.05$, $R^{2=}0.09$).

Conclusions: These preliminary findings are the first to assess the relationship between autonomic regulation and anxiety in preschool children with ASD and FXS. Of particular importance, we examined these relationships in a low-functioning ASD sample. Although the ASD group showed higher parent-reported anxiety, no group differences in autonomic regulation to the startle probe were evident. Acute autonomic reactivity to the startle was not related to anxiety symptoms in either group. However, elevated baseline RSA prior to the startle was associated with reduced anxiety symptoms in both groups albeit to a modest degree. These results suggest that baseline RSA could be a sensitive early marker of anxiety in young cognitively impaired preschoolers with ASD or FXS.

430.015 *(Poster)* Biobehavioral Measurement of Autism Spectrum Disorder and Social Anxiety in Children with Neurodevelopmental Disorders

***C. A. Wall**, A. L. Hogan and J. E. Roberts, Department of Psychology, University of South Carolina, Columbia, SC*

Background: Autism spectrum disorder (ASD) and fragile X syndrome (FXS) are characterized by deficits in social communication and elevated social anxiety (SA). The phenotypic overlap between nsASD (ASD not associated with a syndrome), FXS, and SA complicates our ability to identify symptoms of SA in children with FXS and nsASD. However, biobehavioral markers such as temperament and physiological arousal (e.g., heart activity) are promising tools for distinguishing phenotypic profiles in children with neurodevelopmental disorders. Temperamental negative affect (NA) has been shown to predict anxiety (Brooker et al., 2013) and ASD (Clifford et al., 2013) early in development. Further, although heart rate has not conclusively distinguished children with ASD from their typically developing (TD) peers, children with FXS reliably present with elevated heart rate (Klusek et al., 2015). Heart rate has also been shown to distinguish anxious responses from other cognitive processes in children with ASD (Chiu, Anagnostou, Brian, Chau, & Kushki, 2016). However, no studies have integrated the measurement of NA and heart rate to predict ASD and SA symptoms in children with nsASD and FXS and most research has not included children with ASD who are low functioning.

Objectives: To investigate 1) group differences in NA and heart rate in preschoolers with nsASD, FXS without ASD, FXS with comorbid ASD (FXS+ASD), and TD controls and 2) whether baseline heart rate and NA predict SA symptoms within groups.

Methods: Participants included 33 preschoolers with nsASD (n_{males}=29; M_{age}=42.9 months), 14 with FXS only (n_{males}=6; M_{age}=45.4 months), 13 with FXS+ASD (n_{males}=11; M_{age}=45.1 months), and 23 TD (n_{males}=16; M_{age}=45.6 months). All participants in the clinical groups had an intellectual impairment. Heart rate was collected using an Actiwave ECG monitor during a 5-minute baseline video. ASD symptoms were measured using the Autism Diagnostic Observation Schedule (ADOS-2) Calibrated Severity Scale (CSS). Anxiety was measured with the Spence Children's Anxiety Scale (SCAS-P) Social Anxiety T-score.

Results: ANOVA results indicated no group differences in NA or heart rate (all *p*s > .05). Omnibus regression results indicated that NA and heart rate predicted SA in FXS ($F(3,13)=4.43$, $p=.032$, $R^2=.57$) and FXS+ASD ($F(3,9)=9.0$, $p=.012$, $R^2=.82$). Follow-up analyses indicating these effects were primarily driven by NA. No other regression analyses were significant.

Conclusions: The present study indicates that integrating both behavioral and physiological variables in a biobehavioral model holds promise for disentangling the inter-related features of ASD and SA in young children with nsASD and FXS. This is particularly important when examining these features in very young children who have limited communication skills and when features are subtle. We found that NA and baseline heart activity were not associated with SA in either nsASD or TD controls. In contrast, NA was associated with SA in the FXSonly group and both NA and heart activity were associated with SA in the FXS+ASD group. This suggests that elevated NA and atypical arousal may be unique signals for SA in FXS which is important both for early identification and targeting treatment.

430.016 *(Poster)* Characteristics Associated with Sleep Duration in Children with Autism Spectrum Disorder

*A. M. Shui[1,2], **L. A. Lampinen**[3,4], S. Zheng[3] and T. Katz[5], (1)Biostatistics Center, Massachusetts General Hospital, Boston, MA, (2)Epidemiology and Biostatistics, University of California, San Francisco, San Francisco, CA, (3)Psychiatry, University of California, San Francisco, San Francisco, CA, (4)University of California, Berkeley, Berkeley, CA, (5)Department of Pediatrics, University of Colorado School of Medicine, Aurora, CO*

Background: Sleep difficulties in children with Autism Spectrum Disorder (ASD) have been well established. Previous studies have associated sleep problems in children with ASD with sleep habits, cognitive functioning, ASD intervention, and comorbid diagnoses. Many medications have adverse side effects, and therapy to address sleep problems may be costly in terms of time and money spent. Practicing good sleep habits, such as bedtime consistency, regular exercise, and reduced screen time, may improve sleep quality. Understanding the association between sleep problems and sleep habits, cognitive functioning, ASD intervention, other therapies, and comorbid diagnoses in a large sample may inform intervention development for sleep problems in children with ASD.

Objectives: To determine the impact of the following characteristics on sleep duration in children with ASD: parent-reported bedtime consistency, exercise (ages 6-17 years), screen time, ASD severity, medication, behavioral treatment for ASD, attention deficit disorder with/without hyperactivity, intellectual disability, anxiety problems, depression, and needing or receiving physical, occupational, or speech/language therapy.

Methods: This study analyzed cross-sectional data combined from the 2016 and 2017 National Survey of Children's Health. The sample included 209 children ages 0-5 years and 1,474 children age 6-17 years with a current parent-reported autism diagnosis. Multiple linear regression was performed in each age group with sleep duration as the dependent variable. Each model adjusted for baseline covariates and included all of the target characteristics listed above. All analyses incorporated strata and weighting to produce nationally representative estimates.

Results: In the age 0-5 years model, compared to children with mild ASD, children with moderate ASD slept 0.8 hour less on an average day in the past week (p=0.013), and children with severe ASD slept 2.1 hours less (p<0.001); children who have ever had depression reported slept 2.5 hours more than children without depression (p=0.009); and compared to children who rarely or never go to bed at the same time on weeknights, those who sometimes do slept 1.7 more hours (p=0.012), those who usually do slept 1.6 more hours (p=0.001), and those who always do slept 2.4 more hours (p<0.001). In the age 6-17 years model, compared to children with mild ASD, children with moderate ASD slept 0.2 hour less on an average day in the past week (p=0.032); and compared to children who rarely or never go to bed at the same time on weeknights, those who sometimes do slept 1.2 more hours (p=0.001), those who usually do slept 1.5 more hours (p<0.001), and those who always do slept 2.1 more hours (p<0.001).

Conclusions: ASD severity is associated with shorter sleep duration, and bedtime consistency is associated with longer sleep duration. Addressing sleep problems through good sleep habits, such as bedtime consistency, may promote healthy sleep in children with ASD and help avoid medications, the adverse effects associated with them, and the need for more intensive intervention. Further research on other sleep habits, such as bedroom environment, may provide additional confirmation of the importance of good sleep practices and inform sleep treatment targets in children with ASD.

430.017 *(Poster)* Characterizing Autism Subgroups and Related Profiles of Mental Health in Transgender Youth

A. Song[1]*, E. Sadikova*[2]*, L. Kenworthy*[1]*, L. Anthony*[3]*, A. Verbalis*[1]*, S. Shakin*[1]*, A. Khawaja*[1]*, T. Maisashvili*[1]*, R. Matin*[1]*, M. Mohajerin*[1] *and J. F. Strang*[1]*, (1)Center for Autism Spectrum Disorders, Children's National Hospital, Washington, DC, (2)University of Virginia, Charlottesville, VA, (3)University of Colorado, Denver, Aurora, CO*

Background: A series of studies have identified a significant over-occurrence of ASD and autism spectrum traits among transgender youth. Clinical reports of the ASD and gender diversity co-occurrence have described a subset of transgender youth who clearly meet ASD criteria, a subgroup with notable subclinical ASD traits, and another subset with no significant ASD traits (i.e., allistic). Of particular importance is probing possible mental health differences between these groups given the extreme mental health risks experienced by transgender youth.

Objectives: Employing gold standard ASD diagnostic procedures, we aimed to assess transgender adolescents for autism symptoms and diagnosis, and investigate profiles of mental health between resulting autistic and allistic subgroups.

Methods: Transgender youth, age 13-21, who were diagnosed with ASD, suspected of having ASD, or presumed allistic were invited to participate. Sixty-six transgender youth (28 trans-feminine, 38 trans-masculine) were enrolled and completed autism and mental health assessments. ASD was assessed with the ADOS-2 and the ADI-R. Autistic traits were assessed with the self-report Broader Autism Phenotype Questionnaire (BAP-Q) and the Social Responsiveness Scale 2 (SRS-2; parent-report). Mental health was assessed with the Youth Self-Report (YSR; ASEBA), employing a composite suicidality score validated by Van Meter and colleagues (2018).

Results: Three diagnostic groups emerged based on gold-standard autism assessments: ASD (*n*=27), subclinical ASD (i.e., youth with clear autistic features and impairment but subclinical in terms of ASD diagnostics; *n*=17), and allistic (*n*=22). Self-reported BAP-Q differed between the groups ($F = 5.32$, $p < .01$), with autistic and subclinical autistic youth reporting significantly greater broader autism phenotype (BAP) characteristics than allistic youth ($t = 2.85$, $p < .01$; $t = 2.89$, $p < .01$). The autistic and subclinical autistic groups did not differ in self-reported BAP characteristics. Parent-report of autism-related social symptoms (SRS-2) differed by ANOVA Omnibus test ($F = 23.15$, $p > .01$), with significantly greater autism symptoms reported for the two autism subgroups as compared with the allistic group ($t = 7.2$, $p < .01$; $t = 4.17$, $p < .01$). The two autistic groups did not differ in SRS-2 scores. Regarding mental health, there were differences in youth reported internalizing symptoms (YSR; $F = 4.09$, $p = .02$), with greater internalizing reported in the ASD diagnosed group as compared to allistics ($p = .03$). Suicidality also differed between groups ($F = 3.54$, $p = .04$), with greater suicidality reported in both autistic groups as compared to allistics (p's = .03). Of note, 38% of autistic and 38% of subclinical autistic transgender youth reported suicide attempts as opposed to 9% of allistic transgender youth.

Conclusions: As has been described in the clinical literature, autistic and subclinical autistic youth were each identified as distinct neurodiversity subgroups among transgender youth based on gold-standard autism diagnostics. Self-report of BAP characteristics and parent-report of social autism symptoms aligned well with the diagnostic groupings. Of concern, the presence of autism at the diagnostic or subclinical level in transgender youth was related to significantly increased suicidality, and autistic transgender youth showed particularly high levels of internalizing symptoms.

430.018 *(Poster)* Characterizing Bedtime Routines in Children with ASD

S. Reimer*, E. A. Abel and J. McPartland, Child Study Center, Yale University School of Medicine, New Haven, CT*

Background: Sleep hygiene involves environmental factors, behaviors, and rituals surrounding bedtime that promote healthy sleep across development. Bedtime routines (BR's) are one aspect of sleep hygiene that prepare children for sleep by reducing sources of stimulation and implementing a predictable series of relaxing activities prior to lights out/bedtime (Mindell et al., 2018). Poor sleep hygiene (e.g., electronic device use) exacerbates sleep problems for children with autism spectrum disorder (ASD; Mazurek et al., 2015). However, there is limited knowledge of ASD-specific BR's and their role in promoting sleep for children with ASD. BR's may be uniquely valuable for families raising children with ASD given elevated sleep problems that often stem from regulatory difficulties.

Objectives: To characterize bedtime routines and their associations with sleep outcomes in ASD.

Methods: Parents of children with ASD (*n*=23) and TD (*n*=12) ages 8 to 18 (M_{age}=12.26) completed the Yale Developmental Sleep Questionnaire (YDSQ) and were asked about the timing of their child's BR. Parents' written accounts of their child's BR were qualitatively coded for content themes, deriving seven BR components (Figure 1). Fisher's Exact Tests and regressions were used to determine differences in BR practices and their influence on sleep for children with ASD and TD.

Results: 92% (*n*=32) of the sample reported following a nightly BR. BR's for children with ASD were characterized by higher levels of parental interaction and communication-based activities (e.g., reading to their child; $p < .09$). Children with ASD and TD did not differ on other BR components (Figure 1).

BR's started at 8:41PM, on average (ASD=8:31; TD=9:00) and varied by roughly 70 minutes on weekdays (ASD=72.61; TD=67.5) and 31 minutes from weekdays to weekends (ASD=27.61; TD=37.50). Earlier start times for BR's were associated with longer nighttime sleep (b=-.56, $p < .01$, R^2=.31). In contrast, increased electronic device use (including the sum of device use at bedtime, while falling asleep, and during awakenings) was associated with less nighttime sleep (b=-.57, $p < .01$, R^2=.32) and longer sleep onset latency for children with ASD (b=.66, $p < .01$, R^2=.44) but not TD. Children most commonly used electronics at the end of the BR and while in bed.

Conclusions: Bedtime routines for children with ASD include higher levels of parental involvement when compared to TD peers. This difference likely reflects ongoing parental support for children with ASD that diminishes earlier in development among parents of TD children. Establishing earlier, consistent BR's and eliminating electronic devices at bedtime/throughout the night are important first steps toward promoting healthy sleep patterns in children with both typical and atypical development.

Data collection is ongoing, and final analyses will include a larger TD sample. Future studies should utilize objective measures of child sleep (e.g., actigraphy) and ecological momentary assessments to capture the nuanced and temporal effects of BR consistency, adherence, and content on sleep outcomes and family functioning. Parent focus groups or qualitative surveys focused on BR's may facilitate better understanding of the unique challenges facing children with ASD at bedtime and thus inform targeted, family-focused sleep interventions.

430.019 *(Poster)* Child Predictors of Maternal Anxiety and Depression Symptoms: Cross-Syndrome Comparison of Autism Spectrum Disorder and Fragile X Syndrome

J. M. Burton[1], *C. G. Moser*[2] *and J. Klusek*[1], *(1)Communication Sciences and Disorders, University of South Carolina, Columbia, SC, (2)Communication Sciences & Disorders, University of South Carolina, Columbia, SC*

Background: Parents of children with autism spectrum disorder (ASD) demonstrate significantly higher rates of depression and anxiety than parents of typically developing children (Bitsika & Sharpley, 2004). Psychiatric risk in this group is thought to relate to both genetic liability and environmental stress exposure associated with parenting a child with a disability (Yirmiya & Shaked, 2005). Targeted intervention is limited by poor understanding of how psychiatric vulnerability may be moderated by specific child features, such as the severity of the communication impairment, ASD symptoms, and problem behaviors. Moreover, it is unclear whether the profile of psychiatric risk among parents of children with ASD is specific to this group or shared across parents of children with neurodevelopmental disabilities more generally, as evidence suggests that anxiety and depression are also elevated in parents of children with other types of heritable neurodevelopment conditions (Yirmiya & Shaked, 2005).

Objectives: Cross-syndrome comparison across ASD and FXS affords an opportunity determine the specificity of the psychiatric profile observed among parents of children with ASD. The present study conducted a cross-syndrome comparison of mothers of children with ASD and mothers of children with fragile X syndrome (FXS), a single-gene disorder that shows significant phenotypic overlap with ASD.

Methods: Participants included 33 mothers of children with nonsyndromic ASD and 33 mothers of children with FXS. The mean age of the children was 15 years (SD=5). Clinical diagnoses of ASD were confirmed via the ADOS-2 (Lord et al., 2012). Mothers completed the Beck Anxiety Inventory (BAI; Beck, 1993) and Beck Depression Inventory-II (BDI-II; Beck, Steer, & Brown, 1996). Child symptoms were indexed with the Social Communication Questionnaire–Lifetime (Rutter, Lord, & Bailey, 2003), Child Behavior Checklist (CBCL; Achenbach & Rescorla, 2001) and Children's Communication Checklist-2 (CCC-2; Bishop, 2006).

Results: The parent groups did not differ in the severity of depression or anxiety symptoms (ps >.344). A significant group-by-ASD symptom interaction was observed in the model predicting maternal depression symptoms (p =.004, η^2_p= .12), where elevated child ASD symptoms were associated with increased depression in mothers of children with FXS but not mothers of children with ASD. Increased child communication deficits were also associated with maternal depression in both groups (p=.011, η^2_p= .13), although a trend-level group interaction term of a medium effect size was detected that suggested that this relationship was more pronounced in the FXS group (p=.011, η^2_p= .07). None of the child factors emerged as significant predictors of maternal anxiety symptoms (ps>.295).

Conclusions: Mothers of children with ASD and mothers of children with FXS exhibited similar levels of depression and anxiety symptoms, although syndrome-specific patterns emerged in the relationships between maternal psychiatric symptoms and child features. Child ASD severity was associated with maternal depression only in the FXS parent group, with a similar pattern observed for the severity of child communication deficits. These findings suggest the presence of syndrome-specific contributors to psychiatric risk among mothers of children with ASD and FXS, underscoring the need to develop interventions targeted towards the needs of specific etiological groups.

430.020 *(Poster)* Clinicians' Perceptions of Re-Experiencing and Avoidance in Post-Traumatic Stress Disorder in Adults with Autism and Intellectual Disability

A. N. Kildahl[1,2], *S. B. Helverschou*[1] *and H. W. Oddli*[2], *(1)Oslo University Hospital, Oslo, Norway, (2)Department of Psychology, University of Oslo, Oslo, Norway*

Background: Individuals with co-occurring autism spectrum disorder (ASD) and intellectual disability (ID) seem to be at increased risk for experiencing traumatic events, and for developing post-traumatic stress disorder (PTSD) following such events. However, identification of PTSD in this population is challenging and suspected trauma or abuse may be difficult to substantiate. A recent review indicates that symptoms of re-experiencing and avoidance are particularly challenging to recognize in this population if trauma is not known to caregivers. The remaining symptoms' lack of specificity may contribute to possible PTSD being misinterpreted and attributed, instead, to ASD, ID or other co-occurring conditions. Previously, it has been suggested that the challenges in identifying re-experiencing and avoidance may be due to these symptoms' intra-psychic nature and patients' limited verbal skills. Current knowledge on identification of PTSD in ASD and ID is sparse, involving a risk that PTSD may be overlooked, or that ongoing abuse is not being detected and stopped.

Objectives: The aim of the study was to provide further knowledge on how avoidance and re-experiencing present in this population, by exploring how clinicians had experienced and perceived them as being expressed.

Methods: Interpretative phenomenological analysis (IPA) was used in an explorative, qualitative study. Eighteen clinicians with 4-29 years of conducting mental health assessments in ASD and ID were recruited for individual interviews. These were audio recorded and transcribed verbatim. Analyses were carried out in line with the recommendations for IPA.

Results: Avoidance was described by informants to be expressed in a wide range of ways. These included specific avoidance of stimuli associated with a traumatic event, as well as some individuals presenting more unspecific or global avoidance. However, specific avoidance in some cases had been challenging to differentiate from challenging behavior and apparent obstinacy. Some individuals also were described to show a conspicuous lack of planned avoidance, apparently failing to protect themselves in any observable way from being exposed to distressing reminders of trauma. Re-experiencing was described to involve co-occurring, abrupt changes to arousal and responsivity, with interpretation of behavior frequently being necessary for identification even in cases where patients had been able to verbally disclose information about re-experiencing symptoms. Examples of re-experiencing also included behavioral or verbal re-enactments that seemed uncontrolled and highly distressing, and sudden, unexpected episodes of aggression or self-injurious behavior.

Conclusions: Expressions of re-experiencing and avoidance in PTSD in individuals with ASD and ID seem to be influenced by characteristics associated with ASD and/or ID. Their intra-psychic nature and limited verbal skills do not seem to be a sufficient explanation of the challenges in recognizing these symptoms in this population, and there is a need to take account of this during clinical assessments. The results further suggest that development of these symptoms may follow different trajectories in this population, and that re-experiencing may be experienced by these individuals in particularly impactful ways.

430.021 *(Poster)* Co-Occurring Mental Health Concerns Among Youth with Autism Spectrum Disorder, Their Relationship with Social Functioning, and Moderating Effect on Social Skills Intervention

M. Matheis[1], *M. Dean*[2], *B. King*[3], *R. Landa*[4], *C. Lord*[5], *W. I. Shih*[6], *J. R. Williams*[7], *F. Orlich*[8], *A. C. Stahmer*[1] *and C. Kasari*[5], *(1)Psychiatry and Behavioral Sciences, University of California at Davis MIND Institute, Sacramento, CA, (2)Education, California State University, Channel Islands, Camarillo, CA, (3)UCSF, San Francisco, CA, (4)Center for Autism and Related Disorders, Kennedy Krieger Institute, Baltimore, MD, (5)University of California, Los Angeles, Los Angeles, CA, (6)Loma Linda University, Loma Linda, CA, (7)Biostatistics, UCLA, Los Angeles, CA, (8)Seattle Children's Hospital, Seattle, WA*

Background: Autism spectrum disorder (ASD) frequently co-occurs with mental health difficulties, including anxiety disorders, depressive disorders, and attention-deficit/hyperactivity disorder (ADHD; Salazar et al., 2015). However, limited research has been conducted examining how these comorbid conditions affect the social functioning of individuals with ASD or the outcomes of social skill intervention.

Objectives: This study had three main aims: 1) examine the co-occurrence of ASD with anxiety, depression, and ADHD amongst a diverse sample of school-aged children and adolescents; 2) determine if co-occurring mental health disorders are associated with differences in level of social functioning; and 3) examine how co-occurring mental health disorders moderate response to social skills intervention.

Methods: Participants (n = 176) included children and adolescents with ASD aged 6-18 years (M= 10.05, SD= 3.10) with IQ ranging 50-139 (M= 92.69, SD= 16.59) and diverse race/ethnicity (44.9% Caucasian, 22.2% Asian, 14.2% Hispanic, 7.4% African American) at four participating sites. Participants were randomized to one of two social skills interventions (SKILLS, didactic-based, or ENGAGE, activity-based) delivered in the school setting for 8 weeks (16 sessions). Measures of observed peer engagement, mental health symptoms via the *Behavior Assessment System for Children- 2nd Edition, Parent Rating Scale* (BASC-2 PRS), social skills and behavior problems via the *Social Skills Improvement System- Teacher* (SSIS-T) were analyzed.

Results: Baseline ratings of mental health symptoms indicated that 10.2% of the sample had elevated symptoms of anxiety, 15.3% had elevated symptoms of depression, and 34.7% had elevated symptoms of ADHD (9.1% inattentive type, 14.2% hyperactive type, and 11.4% combined type). 14.8% had more than one co-occurring mental health concern. Co-occurring inattention was found to be a significant predictor of lower social skills at baseline, b = -5.481, p = .044, model F(2, 143)= 6.566 p= .002, R^2= .084. Co-occurring depression (b= 10.830, p < .001, model F[2, 146]= 6.978, p= .001, R^2= .087) and hyperactivity (b= 9.459, p < .001, model F[2, 146]= 7.726, p= .001, R^2= .096 were significant predictors of increased problem behavior at baseline. A generalized estimating equations approach controlling for site, intervention group, age, IQ, and ASD symptom severity revealed that co-occurring mental health conditions did not have a significant moderating effect on response to social skills intervention.

Conclusions: School-aged children and adolescents with ASD have high rates of co-occurring mental health conditions, with ADHD being the most common. ADHD symptoms have a differential relationship with social functioning: inattentive symptoms were found to be related to more impaired social skills while hyperactive symptoms were found to be related to increased problem behaviors. The presence of co-occurring disorders did not appear to impact how participants responded to social skills intervention, suggesting that social skills treatment is efficacious for youth with ASD and comorbid mental health concerns. Further research is needed to examine how co-occurring mental health conditions impact response to intervention and if ASD-specific interventions result in improvement in mental health symptoms.

430.022 *(Poster)* Comorbidity and Health Services' Usage in Children with Autism Spectrum Disorder

I. Menashe[1,2], *Y. Dizitzer*[1], *H. Flusser*[2,3], *A. Michaelovski*[2,3], *I. Dinstein*[2,4,5] *and G. Meiri*[2,6], *(1)Public Health, Ben-Gurion University of the Negev, Beer Sheva, Israel, (2)National Autism Research Center of Israel, Ben-Gurion University of the Negev, Beer Sheva, Israel, (3)Child Development Center, Soroka University Medical Center, Beer Sheva, Israel, (4)Department of Psychology, Ben-Gurion University of the Negev, Beer Sheva, Israel, (5)Psychology Department, Ben-Gurion University of the Negev, Beer Sheva, Israel, (6)Preschool Psychiatric Unit, Soroka University Medical Center, Beer Sheva, Israel*

Background: Autism spectrum disorder (ASD) is a group of complex neurodevelopmental conditions that share common fundamental impairments in social communication and restricted repetitive behaviors. However, most people with ASD suffer from additional comorbidities that add to the medical burden associated with the disorder. We studied the comorbidity burden and health services' utilization of children with ASD to highlight potential etiologies and to better understand the medical needs of these children.

Objectives: To identify medical conditions that are associated with ASD among children with the disorder and to assess the burden of healthcare usage systems in these children.

Methods: We conducted a nested case-control study of ASD cases and typically developing controls that were matched to cases by age, sex, and ethnicity in a 1:5 case-control ratio. Both cases and controls were sampled from all children born between 2009 and 2016 in a single tertiary medical center. Medical diagnoses were obtained from the hospital's electronic database and were classified according to pathophysiological etiology and anatomical/systemic classification of disease. In addition, various aspects of healthcare services' utilization were assessed for each child. Standard univariate statistics were used to compare rates of medical comorbidities and patterns of healthcare usage between cases and controls. Further, multivariate conditional logistic regression models were used to assess the independent effect of ASD on the burden of the healthcare system.

Results: The research sample included 2,744 children (459 ASD cases and 2,285 controls) with a mean age of 5.5 ± 1.9 years and a Male-to-Female ratio of 4:1. ASD children had higher rates of comorbidities according to both pathophysiological and anatomical/systemic classifications ($p<0.001$). The most marked significant differences were observed for: hearing impairments (OR=4.728; 95%CI=2.207–10.127) and other auricular conditions (OR=5.040; 95%CI=1.759–14.438); neurological (OR=8.198; 95%CI=5.690–11.813), and ophthalmological (OR = 3.381; 95%CI=1.617–7.068) conditions; and ADD/ADHD (OR=3.246; 95%CI=1.811–5.818). In addition, children with ASD tended to be referred to the emergency department and to be admitted to the hospital more frequently than children without ASD, regardless of their comorbidity burden and illness severity (aOR=1.61; 95%CI =1.17–2.22 and aOR=1.68; 95%CI=1.23–2.29 for >1 referrals and admissions per year, respectively).

Conclusions: The higher comorbid burden and health care service utilization observed for children with ASD in this study highlight the greater health-related needs of these children. Increasing the awareness of healthcare professionals of these needs, and developing tools to manage difficulties associated with them, will improve the quality of healthcare provided to these children, and reduce the attendant medical, emotional, and financial burdens.

430.023 *(Poster)* Correlates of Sleep Problems in Autism Spectrum Disorder: A Meta-Analysis

E. A. Abel[1]*, D. A. Trevisan*[2] *and J. McPartland*[1]*, (1)Child Study Center, Yale University School of Medicine, New Haven, CT, (2)Faculty of Education, Simon Fraser University, Burnaby, BC, Canada*

Background: Sleep problems are among the most primary and debilitating concerns reported by individuals with ASD and their caregivers (Gotham et al., 2015). These sleep problems/concerns arise in early development (Humphreys et al., 2014; Verhoeff et al., 2018), are present throughout the life course (Ballester et al., 2019; Baker & Richdale, 2015), and are known to exacerbate daytime behavior problems and core ASD symptomology (Mazurek & Sohl, 2016; Veatch et al., 2017). However, despite a proliferation of studies documenting adverse correlates of poor sleep in ASD, little is known about the strength and consistency of these effects across samples.

Objectives: The purpose of this study was to understand the daytime correlates of poor sleep in ASD across the lifespan. Specifically, we aimed to quantify the strength of evidence for relationships between sleep and adverse outcomes likely to impact quality of life for individuals with ASD and their families. We also explored individual and familial characteristics that may contribute to greater sleep problem risk.

Methods: Preliminary findings for the current meta-analysis are based on aggregated effects from empirical studies reporting a statistical association between sleep problems and adverse daytime correlates in individuals with ASD. From a comprehensive literature search, 35 studies met inclusion criteria. Effect sizes were calculated in Comprehensive Meta-analysis software (Borenstein et al., 2013) using a random effects model, aggregating similar outcome variables across studies.

Results: Analyses are ongoing. Preliminary findings are from 25 separate effects, extracted from 9 independent samples (combined $N = 5457$). Sleep problems were associated with multiple domains of ASD symptomology (social difficulties, $r = .331$, $k = 1$, $p < .001$; sensory sensitivities, $r = .313$, $k = 2$, $p < .001$; and severity of ASD traits, $r = .288$, $k = 4$, $p = .001$). Sleep problems were also significantly associated with co-occurring psychiatric and behavior problems, such as anxiety ($r = .426$, $k = 3$, $p = .002$), somatic complaints ($r = .366$, $k = 2$, $p < .001$), ADHD symptoms ($r = .331$, $k = 3$, $p < .001$), and aggression ($r = .201$, $k = 5$, $p = .001$). Finally, lower parental education ($r = -.190$, $k = 2$, $p < .001$) was related to higher levels of reported sleep problems, but child age was not ($r = -.165$, $k = 3$, $p = .329$).

Conclusions: Sleep problems are consistently associated with a variety of daytime behaviors in ASD, though directionality cannot be ascertained from the majority of existing research. Ongoing analyses will draw from a larger, broader developmental sample, attempting to disentangle whether sleep problems precede adverse outcomes in ASD and to elucidate potential predictors of poor sleep in this population. Additionally, we are examining whether measurement methods, including objective (e.g., actigraphy) vs. subjective (e.g., questionnaires) sleep measures and sleep problem subtypes (e.g., short sleep duration, increased sleep onset latency) moderate the associations reported here. Our findings support treatment research indicating that sleep-focused interventions may also yield improvements in cognitive, behavioral, and physical functioning in ASD.

430.024 *(Poster)* Current Evidence and Research Directions for Minimally-Verbal Patients with Autism Spectrum Disorder: A Review of Technological and Behavioral Interventions.

M. Gwynette*, Medical University of South Carolina, Charleston, SC*

Background: Approximately one quarter of all patients with Autism Spectrum Disorder are minimally verbal (MVASD). This subset of patients with ASD are vulnerable, understudied and underserved despite being at high risk for challenging behaviors, co-morbid psychiatric conditions, and suboptimal long-term outcomes. In recent decades, a rising number of studies have examined MVASD, taking into account the specialized research approaches necessary and especially focusing on early interventions and the development of language. As a result, some exciting research efforts, including a number that utilize technology, have emerged which could have a profound clinical impact and improve quality of life for MVASD patients and their families.

Objectives: For both researchers and clinicians to become familiar with cutting-edge research approaches in the field of MVASD in order to guide future studies and clinical treatment.

Methods: The presenter reviewed the literature for research studies in MVASD patients with the goal of synthesizing the data for the audience according to two categories: 1) Technology-based approaches to improve outcomes in the population and 2) Non-technological interventions, including behavioral and social approaches.

Results: The presentation will begin with an in-depth discussion on language development and potential intervention strategies using speech generation devices (SGD) and augmentative and alternate communication (AAC) devices. Next, the presenter will review how these devices are being integrated with behavioral techniques to promote language and improve clinical outcomes. The presenter will then discuss the use of wearable technology and its use to limit the impact of aggression and improve safety in patients with MVASD. The presenter will next provide a review of the latest evidence and research directions for non-pharmacologic interventions, including behavioral and social interventions, highlighting outcomes data and describing in detail how these approaches aim to promote language development, improve social/communication skills, and reduce challenging behaviors in patients with MVASD.

Conclusions: Understanding the current state of research in the area of MVASD is extremely important for both researchers and clinicians. In this way, they can continue to innovate new interventions and serve the needs of minimally verbal patients with ASD and their families, a vulnerable and underserved group of people.

430.025 *(Poster)* Dental Health of Children with Autism: Controlling Anxiety Using Dental Care Training Via ICT

F. Pardossi[1], M. Bondioli[1], L. Billeci[2,3], C. Buzzi[4], M. Buzzi[4], M. Pinzino[5], V. Semucci[6], C. Senette[4], F. Uscidda[1], B. Vagelli[7], S. Pelagatti[1], M. R. Giuca[1] and ***A. Narzisi***[8]*, (1)University of Pisa, Pisa, Italy, (2)Consiglio Nazionale delle Ricerche (CNR), Pisa, Italy, (3)Istituto di Fisiologia Clinica, Consiglio Nazionale delle Ricerche (CNR), Pisa, Italy, (4)Istituto di Informatica e Telematica (IIT), Consiglio Nazionale delle Ricerche (CNR), Pisa, Italy, (5)Istituto di Neuroscienze, Consiglio Nazionale delle Ricerche (CNR), Parma, Italy, (6)Child Neuropsychiatry Unit - ASL 5, Pisa, Italy, (7)Child Neuropsychiatry Unit, Azienda USL Toscana Nord Ovest, Pisa, Italy, (8)IRCCS Stella Maris Foundation, Pisa (Calambrone), Italy*

Background: Offering dental health to children with autism is challenging because it provides various visual/aural stimulations rarely experienced in any other setting. Their different perception of the surrounding world and difficulty accepting unknown social contexts can generate anxiety and fear, which if not adequately addressed, might trigger problem behaviors. This often forces dentists to use potentially dangerous chemical sedation in order to perform dental work on the child.

Objectives: Since digital tools are natural motivators for children, our study aims to expand previous research investigating the full potential of ICT to deliver the awareness and predictability of all dental clinic environment components (settings, tools, noise, procedures).

Methods: A multidisciplinary team applied co-design to selecting and creating digital resources and tools organized in a web application called 'MyDentist' (https://mydentist.iit.cnr.it). A clinical protocol was defined and tested with a group of 59 patients (45 males and 14 females) with ASD (*ma: 9,9 years; range: 4-25 years*) to implement desensitization and anxiety control in a real dental care setting using the kit of digital resources as assistive technology. Periodic visits (45 min) were scheduled for each child over a 3-month period in the same clinical room to ease familiarization. During dental care, structured training was delivered: 1) familiarization with medical procedures (control visits, dental hygiene, tooth decay treatment, dental sealant), and 2) educational activities (in the clinic) and homework using personalized digital resources.

Results: Caregiver questionnaire analyzed using Chi square test confirm the positive role of supportive technology in anxiety control: (1) most children showed a positive response, modeling their behavior and becoming increasingly collaborative (2) caregivers strongly committed to the protocol were satisfied with their active involvement; (3) children who respected the weekly schedule successfully completed the dental protocol in the scheduled time, and their caregivers felt the child-parent relationship was reinforced.

Conclusions: This study confirms the importance of ICT tools for reducing anxiety during dental care sessions as well as for active parent involvement in the care of their children. Involving children in content creation during the clinical meeting helps them accept the dental care protocols. A few guidelines for creating accessible digital tools for anxiety reduction can be shared to benefit designers. In addition, having clear referral pathways to specialist dental services to avoid any delay and distress for families would provide a framework for a 'best practice' protocol for autism families attending primary care dental services

430.026 *(Poster)* Differences in Physical Fitness Measures between Children with and without ASD: A Study of Habits and Body Metrics

J. Mannheim[1]*, K. J. Dommer*[2] *and F. Shic*[3]*, (1)Psychiatry, Seattle Children's Autism Center, Seattle, WA, (2)Seattle Children's Research Institute, Seattle, WA, (3)Center for Child Health, Behavior and Development, Seattle Children's Research Institute, Seattle, WA*

Background: Recent research has suggested that children with ASD may be at greater risk for obesity (Curtin et al., 2010). According to the CDC, childhood obesity is associated with myriad of physical health risks (e.g. high blood pressure, type 2 diabetes, or fatty liver disease), mental health risks such as anxiety and depression, and long term health risks including adult obesity and its associated serious health consequences (CDC, 2016). A better understanding of the lifestyle or habits associated with this risk may direct interventions aimed at reducing the high prevalence of obesity in children with autism.

Objectives: To examine how structured or unstructured free-time habits, body mass index, may differ between children with and without ASD.

Methods: Data were obtained from questionnaires given to parents of children with ASD (N=117; Age M=11.0 years; 75.6% Male) and without ASD (non-ASD; N=217; Age M=10.5 years; 58.2% Male) seen at three metropolitan health clinics (general pediatric clinic, ADHD clinic and autism clinic). Children without ASD collectively encompassed a heterogeneous set of mental health conditions, including ADHD, anxiety, conduct disorder, and depression, but without ASD. Pairwise t-tests were used to compare ASD and non-ASD groups on outcome variables. Spearman's rho was used to examine relationships among variables in the ASD group.

Results: Children with ASD showed less structured weekly physical activity (e.g. sports teams) than non-ASD children ($t(138.3)=-2.94$, $p=.004$), less time spent engaged in homework or other at-home study-related activities ($t(190.8)=-8.08$, $p<.0001$), and higher BMI (ASD M=20.8; non-ASD M=18.9; $t(149.2)=2.45$, $p=.015$). Groups did not differ by time spent in physical education in schools ($p=.893$) or media use including television and video games ($p=.125$). Structured weekly physical activity in children with ASD was not significantly correlated with either time spent engaged in homework ($r=-.03$, $p=.774$) or media use ($r=-.211$, $p=.058$), but correlated with lower BMI ($r=-.25$, $p=.021$).

Conclusions: This work suggests that the children represented in this survey with ASD are getting less structured physical activity outside of school compared to their non-ASD peers. Relationships between structured physical activity and BMI suggest that this may be a factor contributing to the higher prevalence of obesity in ASD. This reduced structured physical activity does not seem to be strongly associated with either increased time spent doing homework or higher media use, suggesting: (1) other classes of free-time or structured activities may be impacting time spent in physical activities outside of school; (2) intrinsic motivational factors associated with ASD may be reducing physical activity during unregulated time; or (3) accessibility to structured physical activity may have barriers which may need to be overcome to provide more favorable health outcomes for children with ASD. Further analyses, still ongoing, of already-collected questionnaire data, will examine these factors.

430.027 *(Poster)* Early Sleep Regularity in the Context of Elevated Autism Risk

P. L. H. Chong[1]*, A. M. Kellerman*[1]*, E. A. Abel*[2] *and A. J. Schwichtenberg*[1]*, (1)Purdue University, West Lafayette, IN, (2)Yale, New Haven, CT*

Background: Up to 80% of children with an autism spectrum disorder (ASD) have comorbid sleep problems that include short sleep duration, multiple night wakings, early morning rise times, and high night-to-night sleep variability (Anders et al., 2011; Richdale & Schreck, 2009). Sleep problems are associated with both frequency and severity of daytime challenging behaviors in children with ASD (Abel et al., 2018; Cohen et al., 2017) but their role in the early developmental progression of ASD is understudied.

Objectives: This study aims to (1) assess how sleep-wake patterns in typically developing children and those with developmental concerns (including ASD) differ using a validated metric, the Sleep Regularity Index (Phillips et al., 2017) and (2) examine if differences in sleep regularity in early development precede an ASD diagnosis.

Methods: As part of a prospective longitudinal infant sibling study, infant/toddlers participated in a sleep protocol at the ages of 6-, 9-, 12-, 15-, 18-, 24-, and/or 30-month. Actigraphy data from 81 infants were scored using the Sleep Regularity Index, the percentage probability of an individual being awake or asleep at any two points 24 hours apart. Group means of the Sleep Regularity Index were created for each age. Children completed an outcome visit between 30 and 36 months and were assigned to one of three groups: ASD (n=6), typically developing (TYP) (n=46), or other developmental concerns (DC) group (n=29). Children in the DC group demonstrated developmental concerns (e.g., language delay, broader autism phenotype) but did not meet the criteria for an ASD.

Results: The mean and range of children's Sleep Regularity Index were reported for Aim 1. Children in all three groups appear to have similarly wide ranges of sleep-wake patterns (Table 1; Figure 1). Multinomial logistic regression with multiple imputation was performed to examine if sleep regularity at specific ages preceded ASD or DC outcomes at 30- or 36-months (Aim 2). Sleep regularity significantly distinguished children in the DC group from TYP peers at 18-months and 30-months, though the effects were small (Table 1). Specifically, a unit increase in sleep regularity was associated with a decrease in the log odds of being in the DC group compared to TYP group at 18- and 30-months.

Conclusions: Using a validated metric, the Sleep Regularity Index, findings demonstrate that children's sleep-wake patterns become increasingly regular across early development, regardless of developmental outcomes. Given the small sample for children with ASD outcomes in the study, this study cannot test if children with ASD are significantly different from DC and TYP peers. However, they appear descriptively comparable. Children in the DC group were more likely to have high night-to-night variability in sleep patterns (i.e., a lower Sleep Regularity Index score). Future research with larger samples of children with ASD is needed to directly address the early role of sleep in ASD development.

430.028 *(Poster)* Effect of Comorbid ADHD and Anxiety on Autism Symptoms in a Large Clinic-Referred Sample of Youth with ASD

C. A. Burrows[1]*, R. L. Hudock*[2]*, C. M. Lee*[3]*, J. Nofer*[2]*, R. K. Rumsey*[2] *and A. N. Esler*[2]*, (1)Pediatrics, University of Minnesota, Minneapolis, MN, (2)University of Minnesota, Minneapolis, MN, (3)Department of Pediatrics, University of Minnesota, Minneapolis, MN*

Background: Many children with autism spectrum disorder (ASD) experience comorbid conditions, which can cause additional impairment and reductions in quality of life (Mayes et al., 2014; Simonoff et al., 2008). In childhood, the most common comorbid psychological diagnoses include attention-deficit/hyperactivity disorder (ADHD) and anxiety disorders (Van Steensel et al., 2013). However, few studies have investigated the effects additional conditions have on ASD presentation. Understanding how comorbidities influence core autism symptoms could help better tailor interventions.

Objectives: 1. Compare autism symptoms in verbally-fluent youth with ASD with and without comorbid diagnoses of ADHD, anxiety, or ADHD and anxiety in a large clinic-referred sample. 2. Examine congruence of examiner-reported ADHD and anxiety symptoms (as rated on the ADOS) with diagnostic comorbidities.

Methods: Participants included 255 individuals aged 3-15 who were evaluated for ASD and received an ASD diagnosis in a university-based autism diagnostic clinic. Children were grouped by whether they received additional diagnostic comorbidities of ADHD (N=24) and any anxiety disorder (N=29), both ADHD and anxiety (N=20), or neither disorder (N=182). Children with other mental health diagnoses were excluded from this analysis. Children who were verbally fluent, defined as receiving modules 3 of the Autism Diagnostic Observation Schedule, 2nd Edition (ADOS-2), were selected for this study to create a sample that was homogenous in terms of language abilities. Autism symptoms in both the social affect (SA) and restricted/repetitive behavior (RRB) domains were measured using ADOS-2 domain calibrated severity scores (ADOS-CSS; Gotham, Pickles, & Lord, 2009; Hus, Gotham, & Lord, 2012). Factorial ANOVA models were used to evaluate the main effects of having ADHD and anxiety, as well as the interaction of the two, while controlling for verbal and nonverbal IQ and age. We then used a chi-square test to determine whether examiner-rated anxiety and overactivity on the ADOS-2 (e.g., E-codes) were related to comorbid anxiety or ADHD.

Results: In a full factorial model, there was a main effect of anxiety on both the SA and RRB domains, such that anxiety diagnoses were associated with lower ADOS scores, SA p=.005, RRB p=.04. There was no main effect of ADHD or interaction between the two for either domain. When examining congruence between ADOS-2 E-codes and comorbid diagnoses, those with elevated anxiety on the ADOS-2 were more likely to be diagnosed with an anxiety disorder, p<.001, though there was no significant association between overactivity on the ADOS-2 and ADHD comorbidity, p>.05.

Conclusions: This was the first study to compare autism symptoms by diagnostic comorbidity in a large clinic-referred sample of youth with ASD. Overall, having a comorbid anxiety disorder was associated with lower social communication symptoms on the ADOS. This suggests a protective effect of anxiety, in that symptoms of anxiety may reduce the appearance of autism symptoms. Children with ASD and anxiety may be more aware of how others perceive them, and thus regulate their behavior. Future work is needed to better characterize differences in other domains by comorbidity group and determine whether anxiety may influence the efficacy of treatment for social skills.

430.029 *(Poster)* Effects of rTMS on Behavioral Measures and Autonomic Nervous System Activity in Children with Autism

E. M. Sokhadze[1], *E. L. Casanova*[2], *D. P. Kelly*[3] *and M. Casanova*[4], *(1)University of Louisville, Louisville, KY, (2)University of South Carolina, School of Medicine, Greenville, SC, (3)University of South Carolina School of Medicine Greenville, Greenville, SC, (4)University of South Carolina School of Medicine, Greenville, SC*

Background: Many children with autism spectrum disorder (ASD) exhibit symptoms associated with autonomic nervous system (ANS) dysfunction indicative of low psychophysiological flexibility. It is suggested that ASD symptoms are associated with generalized abnormalities in the central nervous system (CNS) networks involved in the top-down regulation of the ANS.

Objectives: Repetitive transcranial magnetic stimulation (rTMS) has been proposed as a possible therapy to target ANS regulation deficits in ASD. The aim of this study was to investigate the effects of 18 sessions of low frequency (0.5 Hz) rTMS over DLPFC on autonomic function measures, and behavioral symptoms (based on parental behavioral reports such as Aberrant Behavior Checklist, repetitive Behavior Scale, and Social Responsiveness Scale) in children with ASD.

Methods: We used neuromodulation based on rTMS over the dorsolateral prefrontal cortex (DLPFC) to reduce sympathetic arousal and increase parasympathetic activity in children with ASD. In a study on 27 children with ASD (21 boys and 6 girls, mean age 12.52 ± 2.85 years) 0.5 Hz rTMS was administered bilaterally over the DLPFC with concurrent recording of electrocardiogram, electromyogram, pneumogram and electrodermal activity.

Results: The results of the study replicated findings of our prior studies reporting improvements in aberrant, stereotyped, and repetitive behaviors. In addition, we found improvements in social awareness, social cognition, and social motivation ratings of the SRS-2 questionnaire Statistical analysis of time and frequency domain heart rate variability (HRV) indices and skin conductance level (SCL) revealed a strong linear regression of most HRV and SCL measures. Several parental behavioral rating scores improved post-TMS and showed a correlation with autonomic outcomes, in particular parasympathetic indices of HRV negatively correlated with repetitive and stereotyped behaviors, while sympathetic arousal indices showed positive correlation with the same behaviors. Our post-TMS HRV and SCL outcomes point to a decrease of sympathetic arousal and to an increase of parasympathetic activity resulting in a trend of normalization of the autonomic balance.

Conclusions: The current theory-guided pilot study was based on a hypothesis proposing that rTMS over the DLPFC improves cortical excitation/inhibition ratio in autism, and enhances prefrontal functioning including normative prefrontal inhibitory influences on the limbic system and subcortical centers controlling level of autonomic arousal. We propose that the application of rTMS can be considered as a novel, customizable neurotherapeutic tool targeting autonomic balance that may positively affect the social and behavior deficits, as well as the hyperactivity and anxiety problems experienced by children with autism

430.030 *(Poster)* Emotional, Conduct and ADHD Symptoms in Autistic Young People and Their Parents' Mental Health: A Longitudinal, Multi-Informant Study

I. Yorke[1], *P. White*[1], *S. Chandler*[1], *V. Carter Leno*[1], *T. Charman*[2] *and E. Simonoff*[1], *(1)King's College London, Institute of Psychiatry, Psychology and Neuroscience, London, United Kingdom, (2)Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, United Kingdom*

Background: Autistic young people are likely to develop additional emotional and behavioural problems (EBP). Likewise, their parents are at heightened risk for experiencing mental health problems (MHP). According to family process theories, parent and child wellbeing are likely to influence each other reciprocally. Previous research investigating longitudinal associations has found mixed evidence for bidirectional relationships between EBP in autistic youth and their parents' MHP. However, this research largely relies on parent report of both constructs, potentially distorting observed associations due to shared method variance.

Objectives: In families of autistic children, we aimed to explore longitudinal associations between parent MHP and child emotional problems, conduct problems and hyperactivity rated by both parents and teachers, across three timepoints during childhood and adolescence.

Methods: Participants were a subsample of the QUEST cohort (n=101), a well-characterised, population-derived sample of autistic children and their parents. Data were collected at child age 4-9 years (T1), 11-15 years (T2) and 13-17 years (T3). Parents reported on their own MHP at each timepoint using the Kessler 10-item psychological distress screen. They also reported on their child's EBP at each time using validated questionnaires, such as the Developmental Behavior Checklist and the Strengths and Difficulties Questionnaire. Teachers also reported on child EBP at T1 and T2 using similar measures. Covariates were child IQ (assessed directly at T1 and T2) and ASD symptom severity (parent-report at T1 and researcher-assessed at T2). We explored longitudinal associations separately for emotional, conduct and ADHD symptoms using cross-lagged path analysis, whereby paths in a saturated model were successively dropped to achieve the most parsimonious model whose fit was not significantly worsened. Standardised path coefficients (SPCs) were examined for these models.

Results: Final models (see Figure 1) showed substantial trait stability across childhood and adolescence, except for teacher reports of child EBP. Whilst accounting for associations with child IQ and ASD symptoms and concurrent associations among all traits at each timepoint, distinct profiles of predictive associations were apparent between parent MHP and child emotional, conduct and ADHD symptoms.

Earlier child emotional problems predicted later parent MHP, but not vice versa. Specifically, T1 teacher-report emotional problems predicted T2 parent MHP (SPC .26) and T2 parent-report emotional problems predicted T3 parent MHP (SPC .28). For conduct problems, bidirectional associations were apparent. T1 parent MHP predicted T2 child conduct problems reported by both parents (SPC=.23) and teachers (SPC=.41), and T2 teacher-report conduct problems in turn predicted T3 parent MHP (SPC .30). No cross-trait predictive effects were found between child hyperactivity symptoms at T1 and parent MHP at T2; however, T1 parent-report ADHD symptoms did predict parent MHP at T3 (SPC .24).

Conclusions: The longitudinal associations between parent MHP and teacher-report emotional and conduct problems corroborate and extend previous findings in studies using parent-report only. Since these findings cannot be explained by shared method variance, they increase confidence that family-based mental health interventions may benefit the wellbeing of both autistic youth and their parents.

430.031 *(Poster)* Epilepsy in Adulthood: Prevalence, Incidence, and Associated Antiepileptic Drug Use in Medicaid Beneficiaries with Autism Spectrum Disorder

L. Bishop[1]*, K. J. McLean*[2] *and E. Rubenstein*[3]*, (1)University of Wisconsin - Madison, Madison, WI, (2)University of Wisconsin-Madison, Madison, WI, (3)Waisman Center at UW Madison, Madison, WI*

Background: Epilepsy is associated with reduced quality of life and is a strong predictor of premature mortality in autistic people. Although epilepsy commonly presents with autism in children, the extent to which it occurs in and impacts autistic adults is less understood.

Objectives: To determine prevalence, incidence, and antiepileptic drug use associated with epilepsy in a unique population of autistic adults aged 21+ in Wisconsin Medicaid. We further assessed differences between people with (N=2,738) and without (N=4,775) intellectual disability (ID) and compared both groups to adults with ID alone (N=18,429).

Methods: We identified the presence of epilepsy (here referring to all seizure disorders) using the Chronic Conditions Data Warehouse category for epilepsy using ICD-9/ICD-10 codes. Epilepsy was determined by having two unique claims for epilepsy. We used log binomial regression to calculate 11-year period prevalence (2008-2018) and two-year prevalence (2017-2018). We tested differences in prevalence by age category (<30, 30-39, 40-49, 50-59, 60+) using a Type-III F test. We used log-Poisson regression to model incidence by age category. We ran log-binomial regression to calculate prevalence ratios and log-Poisson regression to calculate incidence rate ratios. Finally, we assessed concordance between epilepsy claims and antiepileptic medication prescription claims. A Cochrane Mantel-Hanzel (CMH) test examined whether the relationship between epilepsy claims and epilepsy medication differed by case group.

Results: We found that 34.6% of autistic adults with ID and 11.1% of autistic adults without ID had epilepsy, compared to 27.0% of adults with ID alone. New incidence of epilepsy was 35.5 incident cases per 1000 person years (95% CI: 32.6, 38.5) in autistic adults with ID, 13.4 incident cases per 1000 person years (95% CI:12.0, 15.0) in autistic adults without ID, and 24.4 incident cases per 1000 person years (95% CI: 23.5, 25.3) in adults with ID alone, with differences across age strata (Table 1). Female sex was significantly associated with epilepsy in autistic adults (with and without ID; Prevalence Ratio (RR): 1.21, 1.20 respectively). For autistic adults with ID, prevalence of epilepsy was 2.65 (95% CI: 2.3, 3.0) times that of autistic adults without ID. Incidence of epilepsy in female autistic adults was 1.22 (95% CI: 1.0, 1.5) times that of male autistic adults in 2008 to 2018 and 1.20 (95% CI: 0.9, 1.5) in 2017-2018. ID was significantly associated with increased incidence of epilepsy. Comparing epilepsy claims to anti-epileptic medication claims, we found that 80.3% of beneficiaries with ASD without ID who had received anti-epileptic medications did not have a claim for epilepsy (Table 2). Case groups significantly differed in their associations between medication use and diagnostic claims (CMH: $p<0.0001$).

Conclusions: Our findings on prevalence and incidence of epilepsy in autistic adults highlight the importance of treating prevalent epilepsy and preventing and screening for incident epilepsy as autistic adults age. Intellectual disability and sex may be pivotal areas to target treatments and identify subgroup-specific etiology in future research.

430.032 *(Poster)* Exploring Genetic and Environmental Influences on Anxiety and Depressive Disorders in Twins with Autism

M. Frayne[1]*, J. P. Hegarty II*[1]*, L. C. Lazzeroni*[2]*, S. C. Cleveland*[1]*, J. M. Phillips*[1]*, J. F. Hallmayer*[1] *and A. Y. Hardan*[1]*, (1)Psychiatry & Behavioral Sciences, Stanford University, Stanford, CA, (2)Biomedical Data Science, Stanford University, Stanford, CA*

Background: Individuals with autism spectrum disorder (ASD) have an increased likelihood of comorbid psychiatric disorders (42-79%) compared to typically developing (TD) individuals (8.3-27%). In individuals with ASD, these disorders are also associated with worsened social and behavioral outcomes, which can cause considerable stress for the individuals and their families and impact treatment response. Despite serious implications, very little is known about the mechanisms involved in the etiology and presentation of comorbid psychiatric disorders in general or anxiety and depressive disorders in particular regarding ASD.

Objectives: The primary objective was to explore whether variation in internalization symptomatology (anxiety and depression), as measured by the Child Behavior Checklist (CBCL), is associated with genetic or environmental factors in twins with ASD compared to TD control twins.

Methods: Data from monozygotic (MZ) and dizygotic (DZ) twin pairs between the ages of 6 to 15 years, in which both twins were concordant for an ASD diagnosis or both were TD controls, were used for this investigation. T-scores from multiple CBCL subscales were examined and will be discussed but we highlight findings from the anxious depressed (anxious) and withdrawn depressed (withdrawn) subscales, which were compared between the groups to examine the presence of anxiety- and depression-related behaviors in children and adolescents with ASD. Intra-class correlations were also generated and the ACE model of broad sense heritability (a^2=additive genetics) and environmental (c^2=shared familial environment, e^2=unique environment) influences was examined to provide estimates for the proportion of variation associated with each factor. For both groups, the anxious and withdrawn subscales were best fit with simplified AE models.

Results: Data were available from 140 twins [35 concordant ASD pairs (MZ=19, DZ=16); and 35 concordant TD pairs (MZ=21, TD=14)]. As predicted, twins with ASD exhibited elevated anxious (M_{diff}=7.91, 95%CI [4.95, 10.86]) and withdrawn behaviors (M_{diff}=9.10, 95%CI [6.64, 11.57]) compared to TD twins. Based on ICC comparisons and ACE modeling, anxious behaviors appeared to be primarily associated with genetic factors in twins with ASD (a^2=0.67, 95%CI [0.19,1.14]) but potentially more environmental contributions in TD twins (a^2=0.26, 95%CI [-0.18,0.71]). Furthermore, genetic contributions may have exerted a larger impact on withdrawn behaviors in twins with ASD (a^2=0.59, 95%CI [0.25,0.93]) compared to TD twins (a^2=0.41, 95%CI [0.03,0.79]), albeit to a lesser extent compared to anxious behaviors.

Conclusions: Our findings support previous twin studies that reported a strong genetic influence on anxiety and depressive disorders in individuals with an ASD diagnosis or autistic-like symptoms. This study contributes novel findings by including a TD twin control sample to compare the influence of genetic and environmental factors with children and adolescents with ASD. Results from this comparison suggest that genetics may influence the presence of anxiety and depressive disorder symptomatology to an even greater extent in twins with ASD than the general population. Future research is needed to examine the specific genetic factors and associated neurobiology that contribute to these relationships in order to develop more specialized therapeutic initiatives for comorbid psychiatric disorders in general and anxiety and depression in particular in individuals with ASD.

430.033 *(Poster)* Exploring the Role of Physiotherapists in the Care of Children with Autism Spectrum Disorder

P. Jachyra[1]*, C. Campos*[2]*, M. Duck*[2]*, R. McQullan*[2]*, L. Brazill*[2]*, S. Malik*[2]*, L. R. Hartman*[3]*, A. C. McPherson*[4] *and B. Gibson*[5]*, (1)University of Toronto & Bloorview Research Institute, Holland Bloorview Kids Rehabilitation Hospital, Toronto, ON, Canada, (2)University of Toronto, Toronto, ON, Canada, (3)Therapeutic Recreation and Life Skills, Holland Bloorview Kids Rehabilitation Hospital, Toronto, ON, Canada, (4)Bloorview Research Institute, Holland Bloorview Kids Rehabilitation Hospital, Toronto, ON, Canada, (5)Physical Therapy and Bloorview Research Institute, University of Toronto and Holland Bloorview Kids Rehabilitation Hospital, Toronto, ON, Canada*

Background: Children with autism spectrum disorder (ASD) are less likely to participate in physical activity than their age related peers, and it has been suggested that physiotherapists (PT) could potentially facilitate their participation. Currently, no research has examined PTs' potential role in enhancing physical activity (PA) participation.

Objectives: The purpose of this qualitative study was to examine PTs experiences and perspectives of working

Methods: A descriptive qualitative study that used face-to-face interviews was conducted. Ten paediatric physiotherapists in Canada were interviewed. Interviews were analyzed using a thematic analysis.

Results: Three themes were identified: the role of PT, perceived lack of expertise, confidence and training, and structural and systemic barriers. The accounts highlight the social and institutional complexity and constraints in PTs potential promotion of PA for children with ASD. Participants supported a primarily consultative role whereby PTs could educate and partner with parents, teachers, and community service providers to enhance gross motor development and individualize PA needs.

Conclusions: Our study suggests PTs identify a potential role focused on consultation, providing education, gross motor assessment/treatment, and early intervention. Participants highlighted the lack of training and confidence many PTs experience in working with this group and noted that the structure of the health system in this region refers children to specific professionals/programs, limiting access to PTs. Despite these potential barriers, we highlight the role of physiotherapy in promotion of PAP and discuss how PTs might be involved in the care of children with ASD.

430.034 *(Poster)* Factors Contributing to Externalizing Symptoms in Autism Spectrum Disorder

J. Crutcher*, E. Butler, J. Burke, D. A. Fein and I. M. Eigsti, Psychological Sciences, University of Connecticut, Storrs, CT*

Background: Co-morbid psychiatric disorders are common in Autism Spectrum Disorder (ASD), with Attentional Deficit-Hyperactive Disorder (ADHD) and Oppositional Defiant Disorder (ODD) reported to be as high as 83% (ADHD) and 73% (ODD) in clinical settings (Joshi et al, 2010). Rates were lower in a population-derived cohort (28% for ADHD and 28% for ODD), though still substantially higher than in the general population (Simonoff et al. 2008). A variety of factors are thought to contribute to externalizing behaviors as symptoms of Disruptive Behavior Disorders (DBD) in general (Gremillion & Martel 2014), and more specifically to ASD (Lindor et al. 2019, Rodas et al. 2017, Vogan et al. 2018), including: IQ, ASD severity, language ability, and executive functioning (EF).

Objectives: The current study tests the independent contributions of specific processes to externalizing symptoms and diagnoses in a single large ASD sample.

Methods: Prior work established that individuals with ASD could move off the spectrum, a phenomenon termed a Loss of ASD Diagnosis, LAD (Fein et al., 2013). The current study presents a secondary analysis of psychiatric presentations in adolescents with LAD, with a current diagnosis of ASD, or with a history of typical development (TD); see Table 1. Participants completed assessments of IQ, structural and pragmatic language, parent-reported EF, and ASD symptomatology.

The Kiddie Schedule for Affective Disorders and Schizophrenia (KSADS) parent interview provided a measure of symptoms of externalizing disorders (ODD, CD, and ADHD). Poisson multiple linear regression models assessed factors as predictors of current symptoms, controlling for age and FSIQ. The model testing predictors of externalizing symptoms was run as a summation across all externalizing symptoms, and then repeated individually for ADHD, ODD, and CD. Multicollinearity was assessed; all model predictors had a VIF<3 and Tolerance>0.4.

Results: The regression model for total externalizing symptoms was significant; pragmatic language, ASD severity, and age were each significant independent predictors (Table 2). Regression models for specific diagnoses were each significant. Structural and pragmatic language were significant predictors of the ADHD diagnosis; ASD symptomatology and age were predictors of ODD; and only pragmatic language was a predictor of CD.

Conclusions: Structural and pragmatic language abilities, age, and ASD symptomatology each accounted for significant variability in externalizing symptoms; across participants, lower language scores, younger age, and greater ASD severity was associated with more symptoms. Neither IQ and EF contributed significant variance to any of the models. ADHD was the most frequent comorbid diagnosis for children with ASD, and ADHD symptoms were strongly associated with *both* pragmatic and structural language skills. Given low base rates of ODD and CD in this sample, findings are necessarily tentative. These results point towards a constellation of factors that increase the likelihood of externalizing symptoms in individuals with ASD. Specifically, age, ASD symptomology and language abilities all played an important role in comorbid externalizing symptoms. Results suggest possible mechanisms underlying difficult-to-manage externalizing behaviors, and have implications for treatment interventions and long-term outcomes.

430.035 *(Poster)* Factors Contributing to Subjective Quality of Life and Anxiety and Depression Symptoms in Autistic Adults: A Qualitative Investigation.

B. Oakley[1]*, H. L. Hayward*[1]*, D. G. Murphy*[1] *and E. Loth*[2]*, (1)Forensic and Neurodevelopmental Sciences, Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, United Kingdom, (2)Department of Forensic and Neurodevelopmental Sciences, Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, United Kingdom*

Background: Quality of life (QoL) is increasingly acknowledged as a gold standard for measuring progress and outcomes in autism (McConachie *et al.*, 2015). However, most previous studies used QoL measures developed for non-autistic individuals. It is therefore unclear which components of QoL are perceived as most important by autistic individuals, and which factors may impact them. For instance, we recently showed that frequently co-occurring anxiety and depression symptoms were a significant driver of reduced QoL for autistic people (Oakley *et al*., in prep). Consequently, understanding the determinants of elevated anxiety and depression symptoms in autism is an imperative research priority. Qualitative methods have potential for providing rich insights into these issues, however such methods have been significantly under-utilised in autism research to date.

Objectives: To take a qualitative approach to: 1) understand which aspects of QoL are most important to different autistic adults, and; 2) identify the factors that autistic individuals feel contribute to their co-occurring anxiety and depression symptoms.

Methods: 19 autistic adults (female *N*=10), aged 18-to-34 years, took part in a novel semi-structured interview about quality of life and mental health. The interview schedule was split according to several topics, each covering an aspect of well-being defined by the World Health Organisation (e.g. relationships, education/employment; WHOQoL Group, 1995). For each topic, participants were first asked to rate the importance of various statements related to that topic (e.g. "feeling supported by your friends?"). Next, the interviewer asked follow-up questions concerning the relationships between these everyday experiences, autism and mental health features. Qualitative data were thematically analysed using NVivo 12 Pro, following Braun and Clarke's six-step method (Braun and Clarke, 2006).

Results: The majority of autistic adults in our sample rated traditionally defined aspects of QoL as important, however we also noted individual variability between each participant (Figure 1a). Autistic adults in our sample stressed the impact of mental health symptoms, over core autism traits, in relation to difficulties across different aspects of everyday life. Within this context, we identified eight themes (encompassing several subthemes) that autistic adults expressed as contributing to their anxiety and depression symptoms (Figure 1b): 1. Exhaustion; 2. Loneliness; 3. Loss of Control; 4. Societal Factors; 5. Identity; 6. Stressful Life Events; 7. Negative Cognitions; and 8. Difficulties with Emotional Awareness.

Conclusions: Our study demonstrates the value of qualitative methods for providing rich insight into the lived experiences of autistic people. The eight themes that we report impacted QoL by increasing anxiety and depression for autistic adults in our sample. In particular, exhaustion from environmental 'overload' (and/ or its consequences) was frequently identified as a contributing factor for anxiety and depression. This suggests that supporting autistic adults in developing and implementing a range of coping strategies for managing different environmental demands may be beneficial. Furthermore, our findings have wider relevance for social policy and practice, highlighting that increasing autism awareness/ understanding and developing environmental adaptations to better support autistic people, may be key factors for improving mental health in this population.

430.036 *(Poster)* Familial and Socioeconomic Correlates of IQ in African-American Children with ASD

A. M. Abbacchi[1]*, Z. Hawks*[2]*, Y. Zhang*[3]*, C. A. Saulnier*[4]*, C. Klaiman*[4]*, R. Fitzgerald*[5]*, J. K. Lowe*[6]*, A. Klin*[4]*, D. Geschwind*[7] *and J. N. Constantino*[5]*, (1)Child and Adolescent Psychiatry, Washington University School of Medicine, Saint Louis, MO, (2)Department of Psychological & Brain Sciences, Washington University, St. Louis, MO, (3)Washington University School of Medicine, Saint Louis, MO, (4)Marcus Autism Center, Children's Healthcare of Atlanta and Emory University School of Medicine, Atlanta, GA, (5)Washington University School of Medicine, St. Louis, MO, (6)Semel Institute, University of California, Los Angeles, Los Angeles, CA, (7)University of California, Los Angeles, Los Angeles, CA*

Background: African-American children with autism spectrum disorder (ASD) exhibit approximately twice the rate of co-occurring intellectual disability (ID) than do non-Hispanic white children.

Objectives: The primary objective of this study is to identify correlates of cognitive disability in autism that would inform strategies to resolve racial disparities in this common comorbidity.

Methods: We enrolled 269 African-American children diagnosed with ASD into a multisite gene discovery study across two U.S. data collection sites. Cognitive assessments were conducted on first-degree relatives (biological parents and siblings) to examine familial correlates of low IQ in the sample. We collected socioeconomic demographic variables and the Vineland-II measure of adaptive functioning by parent-report interview. ASD severity was assessed using the Autism Diagnostic Observation Schedule (ADOS-2) and/or the Autism Diagnostic Interview Revised (ADI-R). We used hierarchical regression to estimate the proportion of variance in adaptive and cognitive function that was accounted for by: 1) income, gender, and estimated gestational age at birth; 2) retrospective reports of ASD severity; 3) age of ASD diagnosis.

Results: ASD probands and their first-degree relatives exhibited very broad distributions for IQ. In the context of such sample variation, we observed an *absence* of association between the IQ scores of ASD probands and those of their first-degree relatives; we obtained the same negative result in an analysis of variance which considered *categories* of cognitive impairment in the ASD-affected offspring (F=.263, df=2, 160, p<.769). No significant association was observed between proband IQ and (a) family income above versus below the median income of this group (t=-.148, df=211, p<.883); (b) maternal education with versus without a college degree (t=-1.851, df=231, p<.065); or (c) estimated gestational age at birth before versus after 37 weeks (t=-.093, df=239, p<.93). When restricting the sample to children diagnosed prior to 96 months (in keeping with the Center for Disease Control's surveillance program) and considering the complete set of predictors for IQ, only age in months at time of ASD diagnosis was statistically significant, with earlier diagnosis predicting lower IQ. The full model for IQ explained 7.5% of variance ($F = 2.1$, $p = .07$), and age at time of diagnosis uniquely explained 3.8% variance ($F = 5.2$, $p = .02$). IQ scores of the affected children, which reflected ID rates that were above national averages from epidemiologic surveillance data, were unrelated to family income or variation in the IQ scores of first-degree relatives.

Conclusions: Serious racial disparities in the prevalence of intellectual disability comorbidity in autism were reflected in this sample and not explainable on the basis of common familial and socioeconomic correlates of low IQ. These findings underscore the need to prioritize implementation of earlier diagnosis and intervention, across a range of ASD severity, to determine the potential benefit to African-American children who are disproportionately at risk for comorbid ID. Future research is necessary to explore the causes of the disproportionate burden of ID in African-American children with ASD.

430.037 *(Poster)* Feeding and Eating Issues in Children and Adolescents with Autism Spectrum Disorder

J. Baraskewich *and C. A. McMorris, Werklund School of Education, University of Calgary, Calgary, AB, Canada*

Background: Feeding issues such as picky eating and avoidance of foods due to texture or other sensory characteristics are pervasive in persons with autism spectrum disorder (ASD). Recently, however, it has also been recognized that other feeding and eating issues (e.g., disordered eating, mealtime behaviours) are also common in persons with ASD.

Objectives: The purpose of the current systematic review was to provide a comprehensive overview of the nature and extent of feeding and eating issues in children and adolescents with ASD. Specifically, we sought to identify commonly investigated feeding and eating issues, and to summarize characteristics of children and adolescents with ASD and feeding or eating issues. Additionally, given the recent literature examining the presence of ASD symptoms in individuals with eating disorders, a secondary objective of the current review was to identify the proportion of studies measuring the presence of weight, shape, and/or body image concerns in persons with ASD.

Methods: Publication dates were not restricted for the purpose of this study to ensure all possible articles examining eating issues were included up until June, 2019. Across all databases, searches were restricted to articles written in English, conducted with human participants, and published in peer-reviewed journals. The review articles had to contain empirical research with a focus on feeding and/or eating issues (e.g., eating disorders, feeding disorders, eating behaviours, picky eating), not exclusively related issues (e.g., studies primarily focusing on nutrient deficiencies, genetic markers, and parental feeding practices were not included). Samples also had to focus on children or adolescents, aged 18 years or under.

Results: Thirty-four studies were included in the current review, with the majority of studies investigating feeding issues. Amongst these studies, food selectivity was the most commonly reported feeding issue, and sensory sensitivities appeared to be a strong contributor to selective eating. Only a handful of studies examined concern over weight, shape, and/or body image in children and adolescents with ASD, but authors from these studies suggested that disordered eating thoughts and behaviours may occur more frequently in those with ASD than their peers without ASD. Importantly, there were no common demographic characteristics (e.g., similar cognitive functioning, ASD symptom severity) identified to describe children and adolescents who experience feeding or eating issues.

Conclusions: Findings from the current review highlight that no clear differentiation exists between feeding and eating issues in children and adolescents with ASD; however, clinically, the differentiation is critical for accurate identification, assessment, and treatment planning. To accurately make this distinction, further research examining disordered eating in children and adolescents with ASD is critical.

430.038 *(Poster)* Functional Brain Abnormalities Associated with Comorbid Anxiety in Autism Spectrum Disorder

J. Bartolotti[1]*, M. Huscher*[2]*, J. A. Sweeney*[3] *and M. W. Mosconi*[4]*, (1)Kansas Center for Autism Research and Training, Life Span Institute, University of Kansas, Lawrence, KS, (2)Psychology Department, University of Kansas, Lawrence, KS, (3)Psychiatry and Behavioral Neuroscience, University of Cincinnati College of Medicine, Cincinnati, OH, (4)Clinical Child Psychology Program, Schiefelbusch Institute for Life Span Studies, University of Kansas, Lawrence, KS*

Background: Anxiety disorders, including generalized anxiety disorder (GAD) and phobia, and the related obsessive-compulsive disorder (OCD) are among the most common comorbid conditions in ASD, and have been associated with more severe ASD symptoms. While challenges objectively evaluating anxiety among individuals with ASD has hindered progress in understanding and treating these issues, resting state functional magnetic resonance imaging (fMRI) is well-suited to quantify neurophysiological processes associated with anxiety in ASD. The amygdala is a structure associated with emotion, reward, and social processing, and is anatomically and functionally disrupted in both anxiety disorders and ASD; top-down control of the amygdala by anterior cingulate (ACC) and medial prefrontal cortex (mPFC) is a key locus of impairment in anxiety disorders in which amygdala-ventral prefrontal hypoconnectivity is associated with impaired emotion regulation, whereas amygdala-dorsal prefrontal hypoconnectivity is associated with impaired emotion monitoring/appraisal. Amygdala-basal ganglia networks also have been implicated in anxiety and in restricted and repetitive behaviors (RRBs) in ASD, but have not been measured systematically in individuals with ASD and comorbid anxiety.

Objectives: Our goal was to localize disruptions to amygdala functional connectivity in ASD with comorbid anxiety, and to relate brain connectivity to ASD clinical symptoms.

Methods: Resting state fMRI data were analyzed from 232 participants ages 5-18 in the Autism Brain Imaging Data Exchange, divided into three demographically matched groups: 1) ASD+Anxiety (N = 25) included individuals with a diagnosis of ASD plus GAD, phobia, or OCD and no other psychiatric disorders; 2) ASD-NoAnx (N = 68) included individuals with an ASD diagnosis but no comorbid psychiatric diagnoses, and 3) TD controls (N = 139) included individuals with no known psychiatric or developmental disorders. After preprocessing, timecourses were extracted from ROIs in left/right amygdala, medial prefrontal areas (dACC, dmPFC, rACC, sgACC, vmPFC), and left/right basal ganglia (caudate head, nucleus accumbens, putamen). Functional connectivity between left/right amygdala and each ROI was analyzed by entering normalized correlation coefficients into linear mixed effect regression models that incorporated group, hemisphere, age, ASD severity, and interactions with group.

Results: ASD+Anxiety individuals had decreased connectivity between amygdala and dorsal/rostral medial prefrontal areas (dACC, dmPFC, rACC) compared to ASD-NoAnx and TD groups. Further, higher social impairment was associated with decreased amygdala-dmPFC and amygdala-rACC connectivity, but only in the ASD+Anxiety group. RRBs were more severe in ASD+Anxiety, but were not associated with any connectivity measures. Amygdala-basal ganglia connectivity did not differ between any groups, and ASD-NoAnx did not differ from TD in any connectivity measures.

Conclusions: Results indicate that comorbid anxiety with ASD involves selective disruption to emotion monitoring/appraisal circuits, with relative sparing of the amygdala-vmPFC connection that is commonly disrupted in anxiety without ASD. The association between amygdala connectivity and social impairment only in the ASD+Anxiety group suggests that the underlying brain processes that contribute to ASD symptoms vary in relation to presence of comorbid anxiety which may require unique treatment approaches. These findings have broad implications for understanding the role of comorbid disorders on unraveling neurobiological heterogeneity in ASD.

430.039 *(Poster)* Functional Connectivity within the Anxiety Network Is Atypical in Middle-Aged Adults with Autism and Is Associated with Anxiety Symptom Severity

R. Tung[1]*, M. A. Reiter*[2]*, A. C. Linke*[3]*, J. S. Kohli*[2]*, M. Kinnear*[4]*, I. Fishman*[3]*, R. A. Carper*[2] *and R. A. Mueller*[3]*, (1)Psychology, Brain Development Imaging Laboratory, San Diego, CA, (2)Brain Development Imaging Laboratories, Department of Psychology, San Diego State University, San Diego, CA, (3)Brain Development Imaging Laboratories, San Diego State University, San Diego, CA, (4)Rady Children's Hospital-San Diego, San Diego, CA*

Background: Behavioral evidence demonstrates that anxiety is more prevalent in individuals with Autism Spectrum Disorders (ASDs) than in typically developing controls (TC). Brain regions implicated in anxiety have been found to have atypical functional connectivity (FC) in children and adults with autism, suggesting atypical communication between these regions, which could affect anxiety symptoms. However, few functional MRI studies of ASDs have taken co-occurring anxiety into account. Even fewer studies have focused on middle-aged adults with ASDs.

Objectives: The current study contrasted FC between brain regions within the anxiety network in adults with and without autism, and tested if there were differences in relationships between FC within the anxiety network and anxiety symptom severity across diagnostic groups.

Methods: 22 adults with ASDs (16 male; M_{age} = 49.5 years, SD = 6.0) and 26 TC adults (22 male; M_{age} = 51.0 years, SD = 7.0), enrolled in an ongoing study of aging in autism, and completed the Beck Anxiety Inventory (BAI) and a resting state functional MRI scan. Groups were matched on age and in-scanner head motion. An anxiety network consisting of 12 regions of interest (bilateral amygdalae and posterior insulae; left anterior insula; left globus pallidus; right fusiform, parahippocampal, superior temporal, and inferior and middle frontal gyri; left ventromedial frontal gyrus) was defined based on a large meta-analysis in TC adults and two previous studies on anxiety in autism. ANCOVA was used to test for main effects of group, as well as group by anxiety interactions on FC within this anxiety network, controlling for head motion. Results were FDR corrected and are reported at $q<.1$ (corrected), and $p<.05$ (uncorrected).

Results: Adults with ASD (compared to TC adults) showed both higher anxiety scores and underconnectivity within the anxiety network, with prominent involvement of all three insular ROIs. Connectivity within the anxiety brain network showed distinct relationships with anxiety in the ASD group, but did not relate to autism symptom severity or full scale IQ. Specifically, we found positive correlations between BAI scores and FC involving the bilateral posterior insulae in the ASD (but not the TC) group.

Conclusions: Increased levels of anxiety in middle-aged adults with ASDs were associated with atypical FC, predominantly implicating bilateral posterior insulae. Results were not related to autism symptom severity, suggesting relative independence of anxiety-related effects. Correlations between insula FC and BAI scores in the ASD group showed an opposite pattern to what has been robustly found in research on anxiety disorders conducted in adults without ASDs. In this study, adults with ASDs showed a positive correlation between insula FC and anxiety, whereas previous meta-analyses in adults without ASDs found negative correlations between insula FC and anxiety. This suggests possible distinct neurobiological mechanisms underlying anxiety in adults with ASDs. Results may relate to the prominent role of the insula in the salience network, which is involved in allocation of neural resources based on stimulus salience. However, given complexity of functional differentiations within insular cortex, involvement of other circuits cannot be ruled out.

430.040 *(Poster)* Growth Status of Children with Autism Spectrum Disorder in Shanghai and Around Area

H. Li*, Q. Xu, M. Hu, B. Zhou, C. Hu, D. Li, C. Liu, Y. Wang, J. Deng and X. Xu, Children's Hospital of Fudan University, Shanghai, China*

Background: Caused by restricted interests, repetitive behaviors, and many other reasons, autism spectrum disorder(ASD) has been found to have high risk of unhealthy growth status.Evidence showed overweight are more severe problems than wasted for kids and youth with ASD. However, the study reported that children with ASD at southwestern part of China actually had lower mean BMI z-scores than typically developing children.

Objectives: To deep understand the growth status of children with ASD, our study was designed to increase the database for growth status of Chinese children with ASD, and make up the lack of data at east and central parts of China.

Methods: Participants included 516 children diagnosed as ASD at Children's hospital of Fudan University from 2016 to 2019, aging from1 to 8 years old. Gender, age, gestational weeks, parents' enducation were recorded when they met the clinical. Physical measurement was conducted by trained pediatricians. The values were converted to BMI z-score for age using the WHO Anthro. BMI z-score >+2SD was define as overweight, and <-2SD was indicatied as wasted. Trained clinicians scored ASD symptoms during the ADOS. The second part of ADOS scale presenting restricted and repetitive behavior was defined as ADOS RB score. The fine motor score of Gesell Developmental Observation or the performance score of Wechsler Intelligence Scale had been used as the development/intelligence quotient (DQ/IQ) less impacted by verbal ability. SPSS Statistics Version 26 were employed for binary logistic regression and t test.

Results: In the whole study population, the BMI score were around 15.99 (SD=1.73). 7.17% cases are overweight. 4.46% cases are wasted. The prevalence of overweight and wasted were increased to 11.96% among children ages 5 to 8 years old, respectively. Binary logistic regression was used to find that older children (5 to 8 years old group) had 2.079 (95%CI 0.988-4.376) times higher prevalence of overweight than younger(1-4 years old, P=0.054). In addition, the prevalence of wasted was remarkably difference between these two age groups (P=0.000). 5 to 8 years old group had 4.663 (95%CI 1.989-10.932) times higher prevalence of wasted than 1-4 years old group. For the ADOS RB score, BMI z-score <-2SD patients had higher score than others (P=0.042). Binary logistic regression also supported that the cases with ADOS RB score ≥4 had 3.606 (95%CI 1.091-11.919) times higher prevalence of wasted than cases with low score (<4) (P=0.035). Gestational weeks, sex, and fine motor DQ/IQ had no significant association with unhealthy weight among children with ASD.

Conclusions: The prevalence of overweight with ASD children mostly coming from central and eastern of China is not as high as American and northern of China's data. Children over 5 years old has higher risk of unhealthy growth status, not only overweight but also wasted, than children under 5. Our results indicate that more attention should be paid to the nutrition status of older children (5 to 8 years old) and children with high ADOS RB score. Early health prevention strategies may reverse the unhealthy growth outcome.

430.041 *(Poster)* Heart Activity across the First Six Years of Life in Children with ASD and Siblings of Children with ASD

***A. L. Hogan**, K. D. Smith, C. J. Black, J. E. Roberts and E. Hunt, Department of Psychology, University of South Carolina, Columbia, SC*

Background: Previous research has clearly established that children with autism spectrum disorder (ASD) exhibit atypical physiological regulation (e.g., heart activity) that is related to impaired social-communicative functioning. However, the developmental course of physiological regulation in ASD remains largely unknown, particularly for the first few years of life. Furthermore, no studies have examined physiological regulation in non-ASD siblings of children with ASD (i.e., ASIBs), who often display subtle ASD-like characteristics (i.e., the broad autism phenotype, BAP), which are thought to reflect underlying genetic vulnerability to ASD.

Objectives: To determine whether children with ASD (Study 1) and ASIBs with and without BAP features (Study 2) differ from typically developing peers on heart activity across the first six years of life.

Methods: Participants were drawn from larger prospective longitudinal studies. Study 1 included 44 children with ASD (M_{age}=40.29 months) and 30 chronological age-matched typically-developing (TD) children with confirmed TD outcomes and no family history of ASD (M_{age}=38.40 months). Study 2 included 23 typically-developing ASIBs (ASIB-Typ; M_{age}=27.32 months), 10 ASIBs with BAP features (ASIB-BAP; M_{age}=28.10 months), and 34 TD controls (M_{age}=29.36 months), all matched on chronological age. Participants completed multiple assessments between 6 and 72 months of age, resulting in 163 total observations for Study 1 (n_{ASD}=75; n_{TD}=88) and 250 observations for Study 2 ($n_{ASIB-Typ}$=82; $n_{ASIB-BAP}$=31; n_{TD}=137). Baseline heart activity was recorded via electrocardiogram (ECG) while the child watched a 3-minute video. Mean interbeat interval (IBI, the time that elapses between heart beats) and respiratory sinus arrhythmia (RSA, the beat-to-beat variability in IBI that fluctuates with breathing), were extracted using CardioBatch software. Multilevel models (MLM) were run separately for RSA and IBI, with group, age, and the group*age interaction (when indicated by model fit parameters) included.

Results: For Study 1 (ASD/TD), the main effects model, omitting the group*age interaction term, proved to be the best-fitting model. For RSA, significant effects $F(1,72)=4.61$, $b=-0.47$, $p=.035$, and age, $F(1,88)=124.07$, $b=0.05$, $p<.0001$, were observed, suggesting lower RSA across age in ASD. For IBI, the effects of group, $F(1,72)=4.43$, $b=-21.46$, $p=.039$, and age, $F(1,88)=227.15$, $b=3.31$, $p<.0001$, were significant, indicating shorter IBI (i.e., faster heart rate) across age in ASD. For Study 2 (ASIB-Typ/ASIB-BAP/TD), the interaction model proved to be the best-fitting model. For RSA, a significant group*age interaction was observed, $F(1,180)=3.27$, $p=.04$ ($b_{ASIB-TYP}$ = -0.01, p = .086; $b_{ASIB-BAP}$=0.01, p=.180), in that RSA increased less with age in the ASIB-Typ group relative to the TD group. For IBI, a significant group*age interaction was observed, $F(1,180)=4.17$, $p=.017$ ($b_{ASIB-TYP}$=-0.26, p=.59; $b_{ASIB-BAP}$=1.74, p=.011), indicating that, relative to the TD group, IBI increased more with age in the ASIB-BAP.

Conclusions: Overall, findings suggest physiological dysregulation may not be limited to ASD but may subtly affect non-ASD siblings as well. Specifically, children with ASD exhibited lower RSA and shorter IBI starting in infancy (i.e., prior to diagnosis) and throughout the first six years

430.042 *(Poster)* Homotypic and Heterotypic Continuity of Comorbid Disorders in Autism

***V. Courchesne**[1], N. J. Wright[2], A. Ibrahim[3], T. Bennett[4], E. Duku[5], S. Georgiades[5], P. Mirenda[6], I. M. Smith[7], W. J. Ungar[8], T. Vaillancourt[9], C. Waddell[10], A. Zaidman-Zait[11], L. Zwaigenbaum[12], A. Pickles[13], P. Szatmari[14] and M. Elsabbagh[3], (1)Autism Research Group, CIUSSS du Nord-de-l'Île-de-Montréal, Montréal, QC, Canada, (2)Biostatistics & Health Informatics, Kings College London, London, United Kingdom, (3)McGill University, Montreal, QC, Canada, (4)Offord Centre for Child Studies, McMaster University, Hamilton, ON, CANADA, (5)McMaster University, Hamilton, ON, Canada, (6)University of British Columbia, Vancouver, BC, Canada, (7)Dalhousie University / IWK Health Centre, Halifax, NS, CANADA, (8)University of Toronto / The Hospital for Sick Children, Toronto, ON, Canada, (9)University of Ottawa, Ottawa, ON, Canada, (10)Simon Fraser University, Vancouver, BC, Canada, (11)Tel-Aviv University, Tel-Aviv, Israel, (12)University of Alberta, Edmonton, AB, Canada, (13)King's College London, Institute of Psychiatry, Psychology and Neuroscience, London, United Kingdom, (14)The Hospital for Sick Children, Toronto, ON, Canada*

Background: High rates of co-morbidity between psychiatric disorders are common, but their developmental origins remain poorly understood. In *homotypic* continuity, the presence of a disorder predicts the later presence of the same disorder, whereas in *heterotypic* continuity, the presence of a disorder predicts the later presence of a different disorder. Evidence from typically developing samples indicates substantial homotypic continuity, but also heterotypic continuity, in psychiatric disorders. In particular, heterotypic continuity exists between early externalizing disorders (aggression and attention problems) and later anxiety/depression (Wichstrom et al., 2017). This has been interpreted within the "failure model", whereby early behavioral problems influence interpersonal relationships, which in turn lead to anxious/depressed symptoms (Burke, Hipwell, & Loeber, 2010). In autism, trajectories of internalizing and externalizing problems were reported as relatively stable and co-occurred throughout the pre-school years (Vaillancourt et al., 2016). Furthermore, psychiatric disorders tend to persist or increase throughout childhood (Chandler et al. 2015, Midouhas et al. 2013) and adolescence (Gotham et al., 2015). However, it is unknown whether specific psychiatric symptoms seen early in autism predict the later presence of the same or different psychiatric symptoms.

Objectives: To investigate the homotypic and heterotypic continuity of specific psychiatric symptoms in autism from preschool-age to middle childhood.

Methods: Participants came from a longitudinal study of autistic children, "Pathways to Better Outcomes". Psychiatric symptoms were assessed by parent report using the Child Behavior Checklist (CBCL) at age of diagnosis (M=24.23 months, SD=8.99) and from the CBCL Teacher Report Form at 8.5 years (M=105.02 months, SD=3.14) (n=164). Continuity in symptoms from the Anxious/depressed, Attention problems and Aggressive behaviour syndrome scales were examined, using raw scores. These symptom domains reflect common co-morbid disorders in autism (Simonoff et al., 2008). A linear regression model was estimated for each outcome with the three earlier syndrome scales as predictors. The models controlled for age at completion of Time 1 CBCL, site and ADOS severity.

Results: Attention subscale scores at 8.5 years were significantly predicted by Attention scores at age of diagnosis (p<.05), but not by the other two symptom domains. Similarly, Aggressive Behavior scores at 8.5 years were only significantly predicted by Aggressive Behavior at age of diagnosis (p < .05). In contrast, there was no evidence for homotypic continuity of anxious/depressed symptoms, as anxious/depressed scores were not significantly predicted by earlier scores on the same syndrome dimension, nor Attention problems at time of diagnosis (p=.06). Regression models including and excluding ADOS severity yielded similar results.

Conclusions: These results provide evidence for homotypic continuity in problems with attention and aggressive behaviour from early to middle childhood in a sample of autistic children. Results did not show homotypic nor heterotypic continuity in Anxiety/depression problems. Given the preliminary nature of those results, next steps will include testing whether other early symptoms or difficulties could successfully predict Anxiety/Depression problems, thus confirming heterotypic continuity for this type of psychiatric problems, or if difficulties not yet evident at time of diagnosis are predictive of Anxiety/depression in later childhood.

430.043 *(Poster)* Hormonal Imbalance Among Women with and without Autism

T. Simantov[1]*, A. Pohl*[2]*, A. N. Ruigrok*[3]*, P. Smith*[3]*, C. Allison*[4]*, S. Baron-Cohen*[4] *and F. Uzefovsky*[1]*, (1)Ben-Gurion University of the Negev, Be'er-Sheva, Israel, (2)Washington University School of Medicine, St. Louis, MO, (3)University of Cambridge, Cambridge, United Kingdom, (4)Autism Research Centre, Department of Psychiatry, University of Cambridge, Cambridge, United Kingdom*

Background: There is a robust sex bias in the diagnosis of autism– more frequent in males than in females with a ratio of 2-4:1. This sex bias suggests that the sex-hormone system could be implicated in the etiology of autism. Establishing such a relationship can give insight into the biological underpinnings of autism.

Objectives: To investigate the relative prevalence of hormonal conditions and symptoms, and altered puberty course in women with and without a diagnosis of autism, hypothesizing that these will be more common in the former. Additionally, we aimed to examine whether these effects are important across the spectrum.

Methods: N = 1,230 women participated in an online study, of those, n = 361 were autistic women. Participants reported whether or not they had an autism diagnosis, as well as completing a measure of autistic traits (the Autism Spectrum Quotient (AQ)). Furthermore, participants reported endocrine-related conditions and symptomology; onset and symptoms of puberty; reproductive health, medical diagnoses, and physical symptoms related to hormonal-imbalance; physical health as reflected in current weight and height. Twenty-eight conditions and symptoms were grouped into six factors using an exploratory factor analysis: hypertension and type II diabetes (including high blood pressure, high cholesterol and type II diabetes); fertility-diagnoses (including anovulation, Polycystic ovaries syndrome, premenstrual syndrome, ovarian cancer and uterine cancer); immunology-diagnoses (including autoimmune disorder, hyperthyroidism and hypothyroidism); diabetes-symptoms (including extreme thirst, frequent need to urinate, hair loss or thinning, and sudden, unexplained weight loss); excessive menstruation symptoms (including unusually painful periods and excessive menstrual bleeding); hyperandrogenism-symptomatology (including hirsutism and severe acne). Additionally, timing of puberty as compared to peers, menstrual length, menstrual consistency and age were also included in the analyses. Together, with age and BMI as control variables, eleven predictors were used.

Results: Binomial logistic regression was performed to investigate the relationship between the above variables and the likelihood of an autism diagnosis. Six variables were statistically significant: age (ß=.026, p<0.00); timing of puberty (ß=-.456, p<0.05); hypertension and type II diabetes (ß=.411, p<0.05); diabetes-symptoms (ß=-.270, p<0.01); and fertility-diagnoses (ß=-.244, p<0.05), irregular menstrual length (ß=-.314, p<0.05). Next, a hierarchical regression was performed to investigate the relationship between the predictors and AQ scores in the combined sample of autistic and neurotypical women. Six were statistically significant: age (ß=-.184, p<0.00); BMI (ß=.091, p<0.01); diabetes-symptoms (ß=.176, p<0.00); irregular timing of puberty symptoms (ß=.151, p<0.00); excessive menstruation symptoms (ß=.073, p<0.05); hyperandrogenism-symptoms (ß=.083, p<0.05); irregular menstrual length (ß=.077, p<0.05). A second hierarchical regression was performed with neurotypical women only. The similarity of these results to those that included autistic women suggests that the general findings were not driven by the autistic group solely, and similar patterns are observed across the spectrum.

Conclusions: Autistic women have a higher likelihood for conditions and symptoms linked to hormonal imbalance. Higher levels of autistic traits are linked to hormonal imbalance. These findings are important in informing medical care for autistic women, by emphasizing medical conditions that typically co-occur with autism.

430.044 *(Poster)* Identifying the Cognitive Correlates of Social Anxiety in Autistic and Neurotypical Young People.

H. R. Pickard[1]*, C. Hirsch*[2]*, E. Simonoff*[3] *and F. Happé*[4]*, (1)Social, Genetic and Developmental Psychiatry, King's College London, London, United Kingdom, (2)King's College London, London, United Kingdom, (3)King's College London, Institute of Psychiatry, Psychology and Neuroscience, London, United Kingdom, (4)Social, Genetic and Developmental Psychiatry Centre, Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, United Kingdom*

Background: Social anxiety is one of the most common and disabling mental health problems for autistic young people, which has a significant impact on school performance and opportunities to form important peer relationships. Despite the high prevalence rates seen in this population, very little is known about the cognitive factors underpinning the development of social anxiety in autistic adolescents. Further research focusing on understanding the profile of factors that contribute towards social anxiety in autistic adolescents and how this may differ from neurotypical adolescents is imperative for understanding aetiology and informing effective disorder-specific interventions.

Objectives: Our project aims to explore the cognitive factors that may contribute towards feelings of social anxiety in autistic and neurotypical young people. The cognitive factors that were explored include Theory of Mind, negative interpretation biases (i.e. a tendency to interpret ambiguous situations negatively), intolerance of uncertainty and social insight, often defined as an individual's awareness of their own social difficulties/differences. This project aims to answer two key research questions. Firstly, are the factors underpinning social anxiety the same in young people with and without a diagnosis of autism? Secondly, are there some factors related to social anxiety in autistic young people that are specific to these individuals?

Methods: We employed a mixed experimental design, with young people completing both cognitive tasks (e.g. IQ, Theory of Mind) and questionnaires (e.g. social anxiety, intolerance of uncertainty, social insight). Parent-reported questionnaires were also completed (e.g. autistic traits, intolerance of uncertainty). In total, 61 autistic (42 boys, $mean_{age}$ = 13.46) and 62 IQ-matched neurotypical (26 boys, $mean_{age}$ = 13.52) young people took part in our research project. Questionnaire data from 119 parents was also collected.

Results: Firstly, we observed no significant difference in social anxiety symptoms for autistic and neurotypical young people. Autistic and neurotypical adolescents with elevated social anxiety symptoms reported significantly increased intolerance of uncertainty and a negative interpretation bias for social information. Theory of Mind performance was not associated with social anxiety symptoms in either autistic or neurotypical young people. In autistic young people only, elevated social anxiety symptoms were associated with better social insight. Overall, the cognitive factors driving or maintaining social anxiety in autism appear to be very similar to those in neurotypical adolescents.

Conclusions: The present research will have important implications for understanding the factors that contribute towards the development of social anxiety in autistic and neurotypical young people. Furthermore, this research has important clinical implications for prevention, early identification and subsequently informing the development and adaptation of interventions to improve the efficacy of treatments designed to target social anxiety in autistic young people.

430.045 *(Poster)* Increasing Access to Mental Health Services for Individuals with Autism and Intellectual Disability: Bridging the Gap between Research and Clinical Practice

***S. B. Helverschou**, Oslo University Hospital, Oslo, Norway*

Background:

The prevalence and burden of mental illness in individuals with autism and intellectual disability (ID) has been increasingly recognised. Identification and treatment of psychiatric disorders in these individuals is, however, challenging. Mental health services are variable in quality and often poorly integrated. Strategies to improve the quality of, and access to, specialised mental health services for autistic adults with ID are needed in countries like Norway, which have a small and scattered population and cover a large geographical area.

Objectives:

To explore the outcome, in terms of patient change, of a newly developed professional network and a standardised protocol for clinical assessment as an implementation strategy to improve services and outcome for autistic adults with ID in Norway.

Methods: Eight clinical centres, responsible for providing mental health services for autistic individuals with ID across all four health regions of Norway, participated in the development of a specialised professional network. The network emphasized professional competence and development, and the implementation of research- based strategies in clinical practice. Intervention was based on professional education, workshops and case discussions. To assess patient progress, a standardised assessment protocol was developed used and referred patients were assessed three times, at referral (T1), after one year (T2) and after two years (T3). Changes in psychiatric symptoms and behaviour problems over time were assessed with Psychopathology in Autism Checklist (PAC) and Aberrant Behavior Checklist (ABC).

Results: In the present study, 132 participants assessed at T1, T2, and T3 are included with age between 16 – 66 years (M = 28.6); 43 (32.6 %) are females and 89 (67.4 %) men, 87 (65.9 %) have mild / moderate level of ID and 45 (34.1 %) with severe / profound level of ID. All participants have been clinically diagnosed with ASD + ID.

Patients showed significant ($p \geq .001$) improvements from T1 to T2 on the psychosis, depression and anxiety subscales of PAC, but the improvement was not significant on the obsessive compulsive disorder (OCD) subscale. The improvements were maintained from T2 to T3. Patients showed significant ($p < 0.01$) improvements on the ABC total score and on all ABC subscales except inappropriate speech from T1 to T2, and the improvements were maintained from T2 to T3 – see figure 1 and 2.

Conclusions: The combination of a professional network and a standardised protocol for clinical assessment offers promise for improving professional competence and access to specialised mental health services for autistic individuals with ID and psychiatric disorders across a large geographical area.

430.046 *(Poster)* Interdisciplinary Intensive Treatment for Children with Severe Pediatric Feeding Disorders: Examining the Role of Autism Spectrum Disorders and Treatment Complexity

***R. Ma**[1,2], D. N. Dolezal[1,2], B. Stemple[2] and A. Persons-Geer[2], (1)College of Education, University of Washington, Seattle, WA, (2)Department of Psychiatry and Behavioral Medicine, Seattle Children's Autism Center, Seattle, WA*

Background: Pediatric feeding disorder (PFD) is defined by impaired oral intake that is not age appropriate and is associate with areas of dysfunctions including medical, nutritional, feeding skills, and psychosocial (Goday, 2019). Children with autism spectrum disorders (ASD) are at particular high risk for problematic feeding and associated challenges (Ledford & Gast, 2006; Maston & Fodstad, 2009; Marshall et al., 2015; Volkert & Vaz, 2010). The estimated prevalence of feeding problems in children with ASD has been reported to be as high as 90% (Kodak & Piazza, 2008). Clinical research reported positive outcomes associated with multidisciplinary intervention with emphasis on behavior treatment, particularly escape extinction (Sharp et al., 2017). Common behavior treatment procedures, such as escape extinction and positive reinforcement strategies, have been utilized alone or in combination and have shown effectiveness in decreasing challenging behaviors and increasing consumption (Freeman & Piazza, 1998; Hoch et al., 2001; Lerman & Iwata, 1996; Piazza et al., 2003; Reed et al., 2004). Although escape extinction procedures are effective in reducing food refusal, it has been associated with problematic side effects including extinction bursts (Lerman & Iwata, 1995). Ledford et al. (2018) has called for attention to appropriately adopt a "least to most restrictive" procedure when working with individuals with PFD in order to prevent possible aversive effects.

Objectives: The purpose of this study was to examine if ASD diagnosis status alone is a predictor of increased complexity of treatment components utilized per child within an interdisciplinary intensive outpatient program.

Methods: A total number of 43 children (M_{age} = 77 months) with PFD completed a two-week intensive program within the Pediatric Feeding Program at Seattle Children's Autism Center from 2012 to 2019. Among all children, 65% had a current diagnosis of ASD (N = 28, M_{age} = 82 months), 49% had anxiety disorder, not otherwise specified (N = 21, M_{age} = 77 months), and 30% had disruptive behavior disorder (N = 13, M_{age} = 92 months). The diagnostic status was coded into a binary category with effect coding. The total number of treatment components utilized were identified, grouped according to behavioral intervention, and summed per child.

Results: Pearson correlation coefficients (r) were first computed. Diagnosis status of ASD and anxiety were not correlated with increased multi-component treatments. However, a diagnosis of disruptive behavior was positively correlated with high level of multicomponent treatments utilized (r = 0.35, $p < 0.05$). Multiple linear regression with sequential predictor entry was used. ASD diagnosis ($R^2 < 0.01$, $F_{change}(1,41)$, $p > 0.05$) and anxiety diagnosis ($R^2_{change} = 0.01$, $F_{change}(1,40)$, $p > 0.05$) did not account for significant variation in total number of treatment components. Diagnosis status of behavior disorder, however, did account for 15% of the variance in the outcome, $R^2_{change} = 0.16$, $F_{change}(1,39)$, $p = 0.009$.

Conclusions: Individuals with PFD and ASD did not receive a higher number of treatment components, rather, the diagnosis of disruptive behavior disorder predicted the use of more complex treatment packages. Both groups achieved similar positive outcomes within the interdisciplinary feeding program.

430.047 *(Poster)* Investigating the Association between Heart Rate Variability and Autism Symptoms in a Sample of Low- and High-Risk Infants

A. Kushki[1], *J. Nguyen*[2], *L. A. Sacrey*[3], *V. L. Armstrong*[4], *I. M. Smith*[5], *S. E. Bryson*[6], *L. Zwaigenbaum*[7] *and J. A. Brian*[2], *(1)Bloorview Research Institute, Toronto, ON, Canada, (2)Holland Bloorview Kids Rehabilitation Hospital, Toronto, ON, Canada, (3)Autism Research Centre, Glenrose Rehabilitation Hospital, Edmonton, AB, CANADA, (4)IWK Health Centre, Halifax, NS, Canada, (5)Dalhousie University / IWK Health Centre, Halifax, NS, CANADA, (6)Dalhousie University, Halifax, NS, Canada, (7)University of Alberta, Edmonton, AB, Canada*

Background: An emerging body of literature suggests decreased heart rate variability (HRV) in autism spectrum disorder (ASD), and that these differences may emerge in infancy. Despite reports of group differences, it remains unclear how individual differences in HRV are associated with severity of early behavioural signs of ASD.

Objectives: To examine the association between HRV and ASD symptom severity in a sample of low- and high-risk infants.

Methods: Data were obtained from a sample of participants (n=32) from an ongoing longitudinal study of ASD. Participants were designated as high risk if they had an older sibling with ASD (n=20) or low risk if they did not (n=12). Behavioural signs of ASD included the total scores on the Autism Parent Screen for Infants (APSI), Autism Observation Scale for Infants (AOSI), and the Autism Diagnostic Observation Schedule (ADOS)-Toddler module. The APSI and AOSI were administered at 12 and 18 months, whereas the ADOS was only administered at 18 months. Physiological data consisted of 'baseline' HRV as well as HRV reactivity extracted from electrocardiography signals at 12 months using the Porges method (natural logarithm of the total power in the frequency band 0.24 to 1.04 Hz). For the baseline task, participants watched a 2-minute calming video clip. Reactivity was measured using a series of tasks designed to elicit negative emotions (masks, face wipe, and brushing). This was quantified as the magnitude of change from baseline relative to pre- and post-task baselines (summed). Linear regression was used to examine the association between HRV (baseline and reactivity) and the behavioural scores.

Results: There was no significant effect of group (high risk/low risk) on baseline HRV (p=0.1) or HRV reactivity (p=0.40). Linear regression revealed a significant association between HRV reactivity and APSI scores at 12 (beta=-4.04+1.6, p=0.02, adjusted R^2=0.19) and 18 (beta=-6.17+1.08, p=0.01, adjusted R^2=0.21) months, with lower HRV associated with higher scores on the APSI. No significant associations were found between HRV (baseline or reactivity) and the AOSI or ADOS scores, or baseline HRV and APSI scores.

Conclusions: Consistent with previous findings in samples of older children with ASD, our preliminary results suggest that decreased levels of HRV may be associated with increased ASD symptoms in a sample of infants at low and high familial risk of ASD. This may be related to biological differences in ASD (e.g., differences in the central autonomic network), or a by-product of other emotional and cognitive processes associated with HRV differences (e.g., emotion regulation, attention). Interestingly, the associations with HRV were only found with parent-reported ASD symptoms, and not observational measures. Future studies with larger sample sizes are needed to clarify these associations.

430.048 *(Poster)* Links between Poor Sleep and Behavior in Children with ASD and Children with ADHD

D. Crocetti[1], *C. B. Holingue*[2], *A. Spira*[3], *H. E. Volk*[4] *and S. H. Mostofsky*[5], *(1)Center for Neurodevelopmental and Imaging Research, Kennedy Krieger Institute, Baltimore, MD, (2)Center for Autism and Related Disorders, Kennedy Krieger Institute, Baltimore, MD, (3)Department of Mental Health, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, (4)Wendy Klag Center for Autism and Developmental Disabilities, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, (5)Center for Autism and Related Disorder, Kennedy Krieger Institute, Baltimore, MD*

Background: Sleep disturbances are highly prevalent in both children with autism spectrum disorder (ASD) and attention deficit/hyperactivity disorder (ADHD) presenting in an estimated 50-80% of children with ASD and 50% with ADHD. Sleep disruption in childhood has the potential for significant detrimental effects on cognition and broader aspects of behavior. Despite the prevalence of sleep disturbances in both ASD and ADHD, there have been no reported studies comparing patterns of sleep disturbance in cohorts of children with ASD to children with ADHD, nor comparing patterns of sleep dysfunction in children with ASD with and without comorbid ADHD.

Objectives: Compare sleep quality in children with ASD-only, ADHD-only, ASD+ADHD, with that of typically developing (TD) children and examine associations of sleep quality with quantitative measures of ASD- and ADHD-related traits.

Methods: Participants included 740 children (55 ASD-only, 245 ADHD-only, 133 ASD+ADHD, 307 TD) aged 8-12 years whose parent's completed the Children's Sleep Habits Questionnaire (CSHQ).

Multivariable linear models examined associations of CSHQ measures with 1) diagnosis and 2) measures of social-communicative function, using the Social Responsiveness Scale-2 (SRS-2), inattention and hyperactivity/impulsivity using the Conners scales, executive function using the Behavior Rating Inventory of Executive Functioning (BRIEF) and adaptive function using the Behavior Assessment System for Children, 3rd Edition (BASC-3). Models were adjusted for age, sex, race, ethnicity, family socioeconomic status, and use of stimulant medications.

Results: Compared with TD children, those with ASD-only, ADHD-only, and ASD+ADHD showed higher CSHQ total scores and were more likely to reach a clinical level of sleep problems (all ps<0.0001).

Poorer sleep (higher CSHQ total scores) was associated with: 1) SRS total score in all groups (ps<0.01) except ADHD-only, 2) Conners inattentive T score in all groups (ps<0.05) except ASD+ADHD, 3) Conners hyperactivity/impulsivity T score: TD (p=0.03) and ADHD-only (p<0.0001), 4) lower BASC adaptability T scores in all groups (ps<0.05) except ADHD-only, and 5) BRIEF executive function composite T score in all groups (ps<0.05).

CSHQ clinical scores were associated with 1) SRS total score: TD (p<0.0001), ASD-only (p=0.01), and ADHD-only (p=0.04), 2) Conners inattentive T score: ASD-only (p=0.01) and ADHD-only (p=0.01), 3) Conners hyperactivity/impulsivity T score: ASD-only (p<0.01) and ADHD-only (p=0.04), 4) lower BASC adaptability T scores: TD (p<0.0001), and 5) BRIEF executive function composite T score in all groups (p<0.05).

Sleep duration was largely unassociated with the behavioral outcome measures. Individuals with ADHD-only who had greater sleep duration had significantly lower (i.e. better) inattentive T scores (p=0.04) and lower (i.e. better) adaptability T scores (p=0.01).

Conclusions: This is the first large-scale study to examine the impact of sleep in children with ASD and children with ADHD. Consistent with prior reports, we observed poorer sleep quality in all groups compared to TD peers. Further, poorer sleep quality was associated with social communication deficits, inattention and hyperactivity/impulsivity, executive, and adaptive function in children with ASD and those with ADHD. We extend prior work by examining sleep quality in children with ASD with comborbid ADHD revealing distinct patterns of sleep dysfunction compared to children with ASD-only and ADHD-only.

430.049 *(Poster)* Medical Comorbidities in a Cohort of Patients with Autism Spectrum Disorder

N. Brondino[1]*, M. Vercesi*[1]*, L. Fusar-Poli*[2]*, P. Politi*[1]*, M. Rocchetti*[1]*, U. Provenzani*[1] *and S. Damiani*[1]*, (1)Department of Brain and Behavioral Sciences, University of Pavia, Pavia, Italy, (2)Department of Clinical and Experimental Medicine, Psychiatric Unit, University of Catania, Catania, Italy*

Background: subjects with ASD are often burdened by numerous medical comorbidities, sometimes hard to identify. Data on this type of comorbidities in ASD are often inconsistent. Of note, the vast majority of the studies on the topic has focused on children and adolescents with ASD. However, as ASD are life-long chronic conditions, it is plausible that an almost equal number of adults with ASD are present. Additionally, adults with ASD may display a different pattern of comorbidities compared to childhood: for instance, obesity as well as other metabolic conditions (i.e. diabetes, stroke, cardiovascular disease) tend to increase during the lifespan while childhood typical diseases (i.e. asthma, seizures) tend to decrease. Two recent reviews has observed that only a few studies have recruited also adults with ASD: of these studies, only one has actually investigated the presence of medical comorbidities in this patient group

Objectives: the identification of medical comorbidities in subjects with autism spectrum disorder (ASD) (especially if not verbal) is a challenge for clinicians but is essential for improving patient's quality of life. The aim of the present study is to evaluate the presence of medical comorbidities in a sample of adults with ASD.

Methods: this is a cross-sectional observational study. Medical history was recorded and each reported diagnosis (i.e. allergic reactions, metabolic disorders) was reinvestigated to obtain a clinical confirmation. Congenital diseases for which appropriate documentation and genetic testing was provided were not reinvestigated. Additionally, each patient underwent a complete neurological and physical evaluation. Each observed physical sign or symptom was subsequently investigated by specific instrumental testing or by referral to the appropriate medical specialist. Blood tests were prescribed if performed more than 6 months before evaluation.

Results: total sample size was 191. Presence of at least one medical comorbidity was observed in 114 subjects (59.7%). Number of comorbidities per subject varied from one to four. The more common comorbid conditions were epilepsy (n=29, 15.18%), allergic rhinitis (n=17, 8.9%) and irritable bowel syndrome (n=13, 6.8%).

Conclusions: people with ASD presented higher rate of medical comorbidities compared to general population rates. Family physicians caring for adults with ASD should be aware of the possible presence of comorbid conditions, which could go unnoticed given the communication impairment and problem behaviors inherent to ASD.

430.050 *(Poster)* Mental Health Symptoms of Children and Adolescents with Autism Spectrum Disorder

K. Robertson[1]*, S. Lau*[1]*, P. Date*[1,2] *and Z. Asher*[1]*, (1)Djerriwarrh Health Service, Melton West, VIC, Australia, (2)Murdoch Children's Research Institute, Parkville, VIC, Australia*

Background: Mental health problems are more common among individuals who have Autism Spectrum Disorder (ASD) than the general population. They are believed to negatively impact long-term outcomes of those with ASD as well as worsen the core symptoms of autism. Like most mental health difficulties, it is believed that these issues emerge during childhood and adolescence and then persist through to adulthood with early identification and treatment offering the greatest opportunity for positive long-term outcomes. Understanding the prevalence of mental health problems among individuals with ASD is notoriously difficult due to symptom overlap, validity issues with existing mental health assessment tools in this population, and differing factors such as gender, age, and IQ showing inconsistent relationships with mental health problems.

Objectives: Our research aims to provide a better understanding of the prevalence of mental health concerns in children and young people with ASD as well as explore relationships between mental health symptoms and IQ, gender, and age.

Methods: The participants were 60 children, between the ages of 3- and 18-years who were diagnosed with ASD between April 2018 to August 2019 at the Autism Spectrum Assessment Clinic at a Community Paediatrics Department in Victoria, Australia. 33% of the sample were female. The mean Full Scale IQ was 87 (*SD* = 16.34). Parents and carers of these children completed the Child Behaviour Checklist (Achenbach & Rescorla, 2001) and the Spence Anxiety Scale (Spence, 1998).

Results: For the overall sample, mean T-scores on all CBCL empirically based scales (anxious/depressed, withdrawn/depressed, somatic complaints, social problems, thought problems, attention problems, rule-breaking behavior, and aggressive behavior) fell in the borderline clinical range. Spence subscale T-scores for separation anxiety, and panic/ agoraphobia for the overall sample also fell in the elevated range, and Spence T-scores for the remaining scales (social phobia, generalized anxiety, physical injury fears, and obsessive compulsive problems) all approached the elevated range. A description of scores based on age groups (under 6 years, 6-12 years, and over 12 years), gender, and IQ groups (FSIQ<85/ FSIQ>85) is also presented although no statistically significant differences were found among these groups.

Conclusions: Very high rates of clinically significant mental health symptoms were found among the entire sample. Results of the current study indicate children diagnosed with ASD are at risk of comorbid mental health symptomology, with particular concerns in areas of anxiety, depression, social problems, attention difficulties, challenging behaviours and panic disorder. With this knowledge, it is critical that children diagnosed with ASD are also supported to manage their mental health in addition to the challenges associated with ASD. This highlights a need for diagnostic tools, clinicians and services to support children, adolescents and adults to be cognizant and holistic in assessment and treatment approaches for individuals diagnosed with ASD.

430.051 *(Poster)* Mental Health and Relationships of LGBQ Youth on the Autism Spectrum

L. Graham Holmes[1], *J. McCleery*[2], *C. C. Clements*[2], *C. J. Zampella*[2], *B. B. Maddox*[2], *J. Parish-Morris*[2], *M. Udhnani*[2], *R. T. Schultz*[2] *and J. S. Miller*[2], *(1)A. J. Drexel Autis, Drexel University, Philadelphia, PA, (2)Center for Autism Research, Children's Hospital of Philadelphia, Philadelphia, PA*

Background: Studies suggest that between 10-24% of autistic people are transgender and/or lesbian, gay, bisexual, queer (LGBQ). Both autistic teens and LGBQ teens are at higher risk for social isolation, depression, and suicide compared to other teens. Thus, autistic LGBQ teens may be at high risk for mental health issues and require targeted supports. However, there is currently little data on mental health for this population. For LGBQ teens without disabilities, family relationships and bullying by peers are linked to risk for mental health issues; this possibility has never been investigated for LGBQ youth with autism.

Objectives:

1. Do autistic LGBQ teens experience poorer mental health, higher rates of depression and anxiety, and higher rates of SSRI use than other autistic youth?
2. Do LGBQ youth experience poorer family and peer relationships than other autistic youth?
3. When accounting for family and peer relationships and adjusting for other factors, do differences between LGBQ and other autistic youth persist?

Methods: Participants were 246 parents of youth aged 14-17 years with formal diagnoses of autism. They completed a web-based survey about their child's quality of life (parent proxy sample). Measures were drawn from the National Institutes of Health Patient-Reported Outcomes Measurement Information System (PROMIS). Based on parent report, the sample included parents of youth who were LGBQ (7.7%, *n*=19) or asexual (8.1%, *n*=20). Non-parametric statistics (Kruskal-Wallis), Chi-square, and linear regression were used to address objectives.

Results: 1. Compared to non-LGBQ autistic youth, parents reported that LGBQ youth had higher depressive symptoms (p=.002), anxiety (p=.008), and stress (p=.010) and lower life satisfaction t-scores (p=.033). LGBQ youth had higher rates of depression/mood disorder (32% vs. 7% heterosexual youth; p=.006) and anxiety disorder diagnoses (53% vs. 24%; p=.021), and were more likely to be prescribed anti-depressant medication (63.2% vs. 29.7%; p=.013) than other youth.

2. There were no significant differences in PROMIS peer (p=.274) or family relationships t-scores (p=.07) for LGBQ youth. However, average family relationships t-scores fell in the mild-moderate symptom range for LGBQ youth but were within normal limits for other youth.

3. Peer and family relationship t-scores were strong predictors of depressive symptoms (R^2=.220) and life satisfaction t-scores (R^2=.349); only family relationships predicted anxiety (R^2=.147), stress (R^2=.181), and global health t-scores (R^2=.153). LGBQ status continued to predict worse depressive symptoms (p=.038) after adjusting for family/peer relationships, sex (male/female), and grade level performance (below vs. at or above); grade level performance continued to predict lower global health.

Conclusions: LGBQ autistic youth may be at higher risk for mental health difficulties compared to other youth with autism. Family relationships are a potential target for intervention. LGBQ youth did not report poorer peer relationships than others, but peer relationships were in the severe range for all autistic youth and predicted worse depressive symptoms.

430.052 *(Poster)* Night Wakings and Cognitive Functioning in School-Age Children Diagnosed with Autism Spectrum Disorder

J. G. Farmer[1], *F. Lu*[2], *K. Kuhlthau*[2], *S. Glynn*[2], *B. A. Malow*[3], *A. M. Neumeyer*[4] *and M. O. Mazurek*[5], *(1)General Academic Pediatrics, Massachusetts General Hospital for Children, Harvard Medical School, Boston, MA, (2)Massachusetts General Hospital, Boston, MA, (3)Sleep Disorders Division, Department of Neurology, Vanderbilt University Medical Center, Nashville, TN, (4)Pediatrics and Neurology, Massachusetts General Hospital, Lexington, MA, (5)University of Virginia, Charlottesville, VA*

Background: Sleep problems, which are highly prevalent in those with ASD, have been associated with deficits in several areas of cognitive functioning including learning, memory, and attention. Little is known about whether specific types of sleep problems (i.e. delayed sleep onset latency, night wakings) may differentially impact cognitive functioning in children with ASD. However, work in the general population suggests that frequent night waking is associated with compromised executive functioning. Similarly, in children with ASD, night wakings have a stronger association with daytime inattention than other aspects of sleep, including sleep latency and duration.

Objectives: To determine whether children with ASD with significant sleep problems including night wakings (SP-NW) have more problems with school functioning, attention, and working memory than those 1) with sleep problems without night wakings (SP-alone) and 2) those without sleep problems (NSP).

Methods: The sample (n=2134) included school-age children (ages 4-10) enrolled in the Autism Treatment Network Registry. This secondary analysis was limited to those with complete data for relevant measures, including the Children's Sleep Habits Questionnaire (CSHQ), the PedsQL School Functioning subscale, the Child Behavior Checklist (CBCL) Attention Problems Subscale and an IQ measure. The SP-NW (n=771) included those with CSHQ Total Scores above 40 and CSHQ Night Wakings scores above 4. The SP-alone group (n=679) consisted of those with CSHQ Total scores above 40 and CSHQ Night Wakings scores of 4 or lower. The NSP group (n=684) included those with CSHQ Total Scores of 40 or lower. Working memory scores were derived from several IQ tests (Stanford Binet-5, WISC-IV, WPPSI-III, WPPSI-IV, and WPPSI-V) for a subsample of the SP-NW (n=227), SP-alone (n=187) and NSP (n=224) groups. While significantly older (M= 7.25) than the larger sample (M= 6.67), the groups did not differ in IQ and other relevant ASD characteristics. ANOVA was used to determine if significant differences exist among the groups in any of the three main outcomes. For outcomes with significant differences, all groups were directly compared, and p-values were adjusted using a Bonferroni correction.

Results: Significant differences were found among the three sample groups for attention problems (F= 40.81; p<0.0001) and school functioning (F=46.42; p<0.0001), but not for working memory (F=0.18; p=0.8350). The SP-NW had significantly lower school functioning scores (M=55.92; SD=19.57) compared to SP-alone (M=58.50; SD=18.25; Adjusted p=0.0196) and NSP (M=65.21; SD=18.38; Adjusted p<0.0001). The SP-NW group also had higher attention problems M=68.62; SD=10.24) than the SP-alone (M=67.45; SD=10.38; Adjusted p=0.06242) and NSP (M=63.96; SD=9.75; Adjusted p<0.0001) groups. The difference in attention problems between the SP-alone and SP-NW was not significant.

Conclusions: School-age children with sleep problems show significant deficits in school functioning and attention. Night wakings appear to have a particularly strong association with neurocognitive difficulties but may not impact working memory in the ASD population. Parents and clinicians should monitor for night wakings, as they may contribute to impairments in attention and learning. More work should be done to understand the differences between sleep maintenance and sleep initiation issues and their respective relationships to cognitive functioning in this population.

430.053 *(Poster)* Prediction of the Perception of Family Relations in Youth with and without ASD

K. S. Ellison *and T. E. Davis, Department of Psychology, Louisiana State University, Baton Rouge, LA*

Background: Broadband measures have been used to identify emotional/behavioral problems in children with Autism Spectrum Disorder (ASD*)*. Children with more emotional/behavioral problems tend to have more negative family interactions and may believe their family has a negative perception of them. However, limited studies have extended this research to examine if parent's perception of their child's emotional problems predict ASD youths' report of their family relations.

Objectives: This study examined the relationship between parent-reported emotional/behavior problems on the *CBCL/6-18* and child self-reported family relational problems on the *Conners-3-Self Report Form (Conners-3-SR)* among children with ASD, Social Anxiety Disorder (SAD), and those having no diagnoses (NODX). Additionally, the child's age and gender were explored as separate predictors.

Methods: Eight youth with ASD (5 males; *M=10.88* years-old), 7 with SAD (5 males; *M=12.00* years-old), and 6 with NODX (4 males; *M=13.33* years-old) were included as part of a larger IRB-approved study. Consent/assent was obtained. Diagnoses were confirmed by the *Childhood Autism Rating Scale, Second Edition (CARS-2) or the Autism Diagnostic Observation Schedule, Second Edition (ADOS-2)* and the *Anxiety Disorders Interview Schedule (ADIS- IV-C/P)*. Full-Scale IQ was measured using the *WISC-V* (ASD *M*=93.63, *SD*=12.05; SAD *M*=104.57, *SD*=11.13; NODX *M*=105.00, *SD*=9.53). The *CBCL/6-18* was completed by the primary caretaker and for this study, the Internalizing Problems, Externalizing Problems, and Total Problems scales were utilized as primary predictors. The *Conners-3-SR* was completed by the participant (the Family Relations subscale was used to capture the youth's perception of their family's love towards him or her). Three separate hierarchal linear regressions were conducted for each of the diagnostic groups to determine if the addition of child's age and gender improved the prediction of youth's ratings of family relations over and e. Data collection is on-going.

Results: For the youth with ASD, the full model of the Internalizing Problems and Externalizing Problems scales, child's age and gender, to predict youth family relation ratings was statistically significant, R^2=.98, $F(4, 3)$=35.21, p<.001; adjusted R^2=.95. Model 1 yielded the Internalizing Problems scale as a unique predictor (b=-1.37, p=.02). When child's age and gender were added (Model 2), gender was significant (b=-.80, p=.01), the Externalizing Problems scale became a significant predictor (b=.92, p=.03) and the Internalizing Problems scale remained significant (b=-1.83, p<.001). For youth with SAD, the full model was not significant, R^2=.95, $F(4, 2)$=9.54, p=.10. The full model was not significant for NODX.

Conclusions: Caregiver ratings of both internalizing and externalizing problems in youth with ASD predicted the youth's own ratings of family relations. Higher ratings of internalizing problems were associated with lower family relational problems, whereas higher ratings of externalizing problems were associated with more family relational problems. Surprisingly, this finding was not replicated in youth with SAD. Future research should address the limitations of the current study specifically, the small sample size, in order to further explore how internalizing and externalizing problems both impact a child's perception of his or her family relations.

430.054 *(Poster)* Prevalence of Behavioral and Emotional Problems in Youth with ASD, Asthma, and Neither Condition

E. Fombonne[1]*, A. Varga*[2]*, J. Dickerson*[2]*, J. Bulkley*[2]*, L. A. Croen*[3]*, Y. Daida*[4]*, B. Waitzfelder*[4]*, M. L. Massolo*[3]*, B. Hatch*[5]*, P. Crawford*[2]*, A. Lee*[6] *and F. Lynch*[2]*, (1)Psychiatry, Pediatrics & Behavioral Neurosciences, Oregon Health & Science University, Portland, OR, (2)Kaiser Permanente Center for Health Research, Portland, OR, (3)Division of Research, Kaiser Permanente, Oakland, CA, (4)Kaiser Permanente Center for Integrated Health Care Research, Honolulu, HI, (5)Oregon Health & Science University, Portland, OR, (6)Research, OCHIN, portland, OR*

Background: Prior reports suggest that emotional and behavioral problems are elevated in children with autism (ASD) when measured both as categorical psychiatric disorders and scores of dimensional measures of psychopathology. However, many studies relied on clinical samples subjected to referral biases, and often lacked control groups of non-autistic chronic health conditions that would permit an evaluation of the specificity of the findings.

Objectives: The objectives of this study were to examine the prevalence of individual behavioral and emotional problems (BP) in youth with ASD, and to compare these patterns to two independent control groups: youth with Asthma , and youth without either of these health conditions (GENPOP). In addition, we examined age sex and other correlates of individual BP.

Methods: We used baseline data from an ongoing longitudinal study (r-Kids) that is examining the economic impact on families of raising a child with ASD. Youth with ASD ages 3 to 17 years were randomly selected from three Kaiser Permanente regions (Northwest, Hawaii, Northern California) and health clinics in the OCHIN network in the US using the electronic health record. Youth with asthma and GENPOP were matched to the ASD group distribution on age and sex of the child. A total of 1,461 parents joined the study, (564 ASD, 468 Asthma 429 GENPOP). At baseline, 1,267 parents completed the Strengths and Difficulties Questionnaire (SDQ), a standardized behavioral screening measure comprising 25 items, 5 subscales, a total behavioral score, and an impact score assessing impairment associated with behavioral problems. The prevalence of individual behavioral problems was compared across groups using chi-square tests. Total and subscale scores were compared with ANOVAs, followed by post-hoc tests. Age and sex differences were further evaluated with chi-square and ANOVAs.

Results: The sample was 79.4% male, with a mean age of 9.2 years (SD=3.9). There were no statistically significant differences between groups for both age (p=.08) and sex (p=.23). Youth with ASD had significantly higher SDQ mean scores on overall difficulties than Asthma or GENPOP youth (ASD: 18.14 (6.5); Asthma: 9.39 (6.3); GENPOP: 8.63 (6.2); p<.001); the trend was similar for externalizing and internalizing subscales and overall impact (Figure). By contrast, youth with Asthma were similar to GENPOP youth, with all SDQ scale scores comparisons being non-significant. Within each age group, youth with ASD had higher mean scores on overall difficulties than Asthma and GENPOP youth. There were no significant sex differences across groups for the SDQ total score, externalizing and impact scores. However, a significant sex effect was found for the Internalizing score; girls in the Asthma and GENPOP groups scored higher than boys on the Internalizing subscores but not in the ASD group.

Conclusions: Youth with ASD have significantly more behavioral and emotional problems than youth with asthma and youth from the general population.. This study confirms and extends previous findings on a larger and more diverse sample. These findings indicate that youth with ASD should be actively managed by primary care providers.

430.055 *(Poster)* Profiles of Internalizing Symptomatology and Social Motivation in Youth with ASD

I. Smith[1] *and S. W. White*[2]*, (1)Virginia Tech, Blacksburg, VA, (2)Psychology, The University of Alabama, Tuscaloosa, AL*

Background: Anxiety and depression are highly prevalent in children, adolescents, and adults with ASD and contribute to poor outcomes and diminished quality of life (Howlin, Goode, Hutton, & Rutter, 2004). Social motivation may vary among individuals with ASD and is likely implicated in the development of anxious and depressive symptoms (Deckers, Roelofs, Muris, & Rinck, 2014). However, the extent to which variation in social motivation contributes to distinct patterns of comorbidity remains unclear.

Objectives: The purpose of the current study was to identify clinically meaningful subgroups of youth with ASD with varying levels of anxiety, depression, social motivation, and ASD symptomatology. We hypothesized that a substantial proportion of youth would present with clinically significant anxiety and depression, and that a group would be identified with high social motivation and associated comorbid symptoms.

Methods: The sample for the current study was drawn from the National Database for Autism Research (NDAR) and consisted of 195 youth with ASD. Youth ranged in age from 6 to 17 (M = 10.08, SD = .80) and were 74% male. All participants were administered Module 3 of the Autism Diagnostic Observation Schedule (ADOS-2; Lord et al., 2012). Comorbid depression was assessed using the Withdrawn/Depressed subscale of the Child Behavior Checklist (CBCL; Achenbach & Rescorla, 2001), anxiety was indexed by the Screen for Child Anxiety Related Disorders (SCARED; Birmaher et al., 1997), and social motivation was measured using the social motivation subscale of the Social Responsiveness Scale (SRS-2; Constantino & Gruber, 2012). To identify distinct classes of youth with varying levels of ASD symptoms, anxiety, depression, and social motivation, latent profile analysis was carried out using MPlus Version 8 (Muthén & Muthén, 2017). Profile solutions were evaluated using five model fit indices. Differences across the resulting groups in primary indicators, as well as association of group membership with demographic factors (i.e., age and sex), were also examined.

Results: A three-class solution provided acceptable model fit with clear distinctions among classes. The largest class (n = 106) was characterized by low comorbidity, with subclinical scores on depression and anxiety measures and with relatively stronger social motivation. A second class (n = 66) consisted of those with significant comorbid symptomatology, with clinical elevations in depression and anxiety and diminished social motivation. The smallest identified class (n = 23) presented with low comorbidity, but significantly greater ASD symptomatology. Class membership did not differ on the basis of age or sex.

Conclusions: The proportion of our sample presenting with significant comorbid symptoms was consistent with prior literature. The hypothesized socially motivated class with elevated anxiety and depression was not identified. Notably, there was a strong correlation between social motivation and depression, but not between ASD severity and social motivation. Diminished motivation for social discourse may therefore have resulted from mood and anxiety symptoms, rather than from ASD. Longitudinal work with valid measurement of key constructs is necessary to determine whether social motivation plays a causal role in the etiology of internalizing symptoms in ASD.

430.056 *(Poster)* Profiles of Sleep Problems Among Young Children with Autism Spectrum Disorder

L. Zwaigenbaum[1], *A. Zaidman-Zait*[2], *E. Duku*[3], *T. Bennett*[4], *P. Mirenda*[5], *I. M. Smith*[6], *P. Szatmari*[7], *T. Vaillancourt*[8], *C. Waddell*[9], *M. Elsabbagh*[10], *S. Georgiades*[3], *C. M. Kerns*[5] *and W. J. Ungar*[11], *(1)University of Alberta, Edmonton, AB, Canada, (2)Tel-Aviv University, Tel-Aviv, Israel, (3)McMaster University, Hamilton, ON, Canada, (4)Offord Centre for Child Studies, McMaster University, Hamilton, ON, CANADA, (5)University of British Columbia, Vancouver, BC, Canada, (6)Dalhousie University / IWK Health Centre, Halifax, NS, CANADA, (7)The Hospital for Sick Children, Toronto, ON, Canada, (8)University of Ottawa, Ottawa, ON, Canada, (9)Simon Fraser University, Vancouver, BC, Canada, (10)McGill University, Montreal, QC, Canada, (11)University of Toronto / The Hospital for Sick Children, Toronto, ON, Canada*

Background: Sleep problems are more common and severe among young children with autism spectrum disorder (ASD) compared to typically developing peers. Previous research on sleep problems in children with ASD has mainly been variable-centered, examining associations between severity of sleep problems and child and family outcomes. An alternative approach is to use person-centered analytic methods that can identify groups of individuals with distinct sleep problem profiles. Identification of such profiles could help parse heterogeneity and help tailor intervention efforts. The goal of this study was to identify sleep problems profiles and their clinical correlates, based on a five-factor model (reported elsewhere) of the Children's Sleep Habits Questionnaire (CSHQ) among preschool children with ASD.

Objectives: (1) To describe empirically- derived patterns (i.e., latent profiles) of sleep problems among young children with ASD; and (2) To examine relations between family cumulative risk and emotional-behavioral dysregulation symptoms and sleep profile membership.

Methods: The study included 318 three- to-five years old children (M= 49.45 months; SD = 5.77). Latent profile analysis was used to identify and describe profiles of sleep problems. Sleep problems were assessed using the aforementioned CSHQ five-factor model: (1) Bedtime Routine; (2) Sleep Onset & Duration; (3) Night Waking; (4) Morning Waking; and (5) Sleep Disordered Breathing. We assess whether profile membership was associated with dysregulation difficulties derived from the Child Behavior Checklist 1.5–5 (Althoff et al., 2012), and family cumulative risk index (CRI; based on socioeconomic status, maternal distress, family functioning, and other related factors) using the three-step method (Vermunt & Magidson, 2013) with Omnibus Wald chi-squared tests to examine each predictor.

Results: A five-profile model of children's sleep problems showed the best fit (see Figure). *Profile 1, Nighttime Sleep Problems* (28%), consisted of children with scores near the sample mean, except low scores on Morning Waking. Profile 2, *Severe Sleep Problems* (25%), consisted of children with high scores relative to the entire sample across all sleep problems. *Profile 3*, *Low Sleep Problems* (18%) included children with the lowest levels of all sleep problems. *Profile 4, Moderate Sleep Problems* (17%), consisted of children with sleep problem levels near the sample mean on all factors. Finally, *Profile 5*, *Morning Waking Problems* (12%), consisted of children with low scores on Bedtime Routine problems but pronounced Morning Waking problems. Results of the multivariate model indicated that dysregulation difficulties (Wald = 13.90; p = .001) and family CRI (Wald = 13.27; p =.001) emerged as significant predictors of profile membership. Higher CRI was associated with higher odds of membership in Profile 2 (*Severe Sleep Problems*), and lower scores for dysregulation difficulties were associated with higher odds of membership in Profile 3 (*Low Sleep Problems*).

Conclusions: Children with ASD experience distinct profiles of sleep problems that differ not only by overall severity, but also by relative severity with respect to types of sleep problems. Children's dysregulation and family risk should be considered as potential correlates of sleep problems in children with ASD relevant to assessment and intervention planning.

430.057 *(Poster)* Psychopharmacologic Therapy in 4-and-5-Year-Old Preschoolers with Diagnoses of ADHD and ASD

C. A. Ochoa-Lubinoff*, M. E. A. Calabrese, M. Greene and J. Chen, Pediatrics, Rush University Medical Center, Chicago, IL*

Background: ADHD is present in 22–85% of children with ASD. Mixed results have been reported from studies examining stimulants in children with ASD and ADHD. Guanfacine, an alpha-2 agonist is a common off-label agent prescribed in preschool ADHD children. The current literature for the treatment of preschool age children with ADHD and ASD is limited.

Objectives: To determine the safety, tolerability, and efficacy of psychopharmacologic treatment in a sample of 4-and-5-year-old developmental-behavioral pediatrics (DBP) clinic patients with a diagnosis of ADHD and ASD.

Methods: All children younger than 6 years old with *DSM-5* criteria for ADHD and ASD diagnoses seen at the Rush University Medical Center DBP clinic from 2012 to 2018 were included in this study. The information on clinical response and adverse events to methylphenidate and guanfacine treatments administered to patients until they turned 6 was collected from electronic medical records. Methylphenidate and guanfacine were the first-line ADHD treatment options.

Results: Forty-eight patients with ASD and ADHD out of a 149-preschool-patient ADHD database were included in this study. Of the 48 patients with ASD, 26 received at least one drug to treat ADHD with a total of 31 drug trials (guanfacine=15, methylphenidate=16). 66% of patients receiving guanfacine and 45% of those receiving methylphenidate had a positive response: improved behavior noted in home and school environments. The positive response rate to guanfacine in patients with ASD and ADHD (66%) was similar to the general ADHD database response rate (65%). The positive response rate to methylphenidate in patients with ASD + ADHD (45%) was lower than the general ADHD database rate (63%). The rate of side effects as a cause to end treatment in ASD patients with a positive response was similar for the patients taking guanfacine (10%) and methylphenidate (14%) and was not different than the rate of ADHD patients without ASD. 33% of all the ADHD patients who received guanfacine reported lethargy and 10% reported irritability as the more common and significant side effects, which was similar to the 32% rate of lethargy and 7% irritability in patients with ASD and ADHD treated with guanfacine. From the general ADHD database, 18% of the patients who received methylphenidate were reported to present irritability, 14% decreased appetite, 7% headaches, and 4% emotional lability, whereas 50% of the patients with ASD + ADHD treated with methylphenidate were reported to present irritability, 0% decreased appetite, 6% headaches, and 13% emotional lability. No severe adverse events were reported in our database.

Conclusions: ADHD children younger than 6 years of age with concurrent ASD diagnosis had a similar rate of positive responses to guanfacine but a lower positive response rate to methylphenidate when compared to same-age children who present ADHD without ASD. The rate of side effects in all children with ADHD was not significantly different from children with ADHD and ASD who were treated with guanfacine. Irritability and emotional lability were more common side effects in children with ASD and ADHD when treated with methylphenidate and compared with all children with ADHD.

430.058 *(Poster)* Relationship between Prematurity, ASD Diagnosis, and Comorbidities in the SPARK Sample

E. Brooks[1]*, L. Green Snyder*[1] *and W. K. Chung*[2]*, (1)Simons Foundation, New York, NY, (2)Department of Pediatrics, Columbia University, New York, NY*

Background: SPARK is an online research study of individuals with a professional autism spectrum diagnosis and their families with measures of ASD symptoms and medical history. Associations have been made between autism and premature birth and other developmental co-morbidities (eg. Leavey, Zwaigenbaum, Heavner, and Burstyn, 2013), and SPARK offers the ability to confirm these trends with a very large sample.

Objectives: Our aims were to analyze the relationship between premature birth and ASD, assess frequencies of comorbid developmental diagnoses in individuals with ASD born prematurely, and assess differences in autism severity.

Methods: Participants included 35,972 individuals with ASD, ages 1-85 (M=11, SD= 8.9), and 54,317 individuals without a diagnosis of ASD (NASD), ages 1 month to 99 years (M = 32, SD= 16.21). Data for this study included a medical screener and standardized measures: Social Communication Questionnaire-Lifetime (SCQ), Developmental Coordination Questionnaire (DCDQ), and Repetitive Behavior Scale-Revised (RBS-R). Prematurity was defined as birth at less than 37 weeks gestation. Odds Ratios were calculated on frequencies of comorbidities. T-tests were done as a measure of specificity of autism symptoms in those born prematurely and full term.

Results: Within the ASD group, 77% were male at birth. In the NASD group, 36% were male at birth. In both ASD and NASD groups, the average age of gestation was 33 weeks for those born premature. ASD participants had 5.4 higher odds to be born prematurely than NASD participants (12% vs. 2.5%, 95% CI: 5.07, 5.74, $p<.01$).

Odds ratios were calculated within the ASD group to assess differences in frequencies of co-occurring diagnoses in preterm (PT) and full term birth (FT) groups. PT were only slightly more likely to have ADHD (43%) than FT (36%) (OR 1.3; 95% CI: 1.26, 1.43, $p<.01$). Similarly, likelihood of intellectual disability was only modestly associated with prematurity (31% vs. 20%, $OR = 1.19$, 95% CI = 1.11, 1.28, $p<.01$). Developmental Coordination Disorder, as determined by scores from the DCDQ, occurred in 30% PT vs. 17% FT, but this difference only increased odds to 1.15 (95% CI: 1.05, 1.26, $p<.01$).

T-tests were completed within the ASD group and found statistically significant differences in SCQ scores between PT ($M = 22.8$, $SD = 7.5$) and FT ($M = 21.7$, $SD = 7.6$) ($t(4958) = 8.13$, $p<.01$), as well as in RBS-R scores (PT M = 37.8, $SD = 21.9$; FT M = 34, $SD = 20.82$; $t(3592) = 8.6$, $p<.01$).

Conclusions: These findings from a very large sample of autistic individuals in SPARK support prior research illustrating a relationship between premature birth and developmental disabilities, including ASD. These results suggest a possible higher likelihood for those born prematurely to not only to be diagnosed with autism, but with other comorbid developmental disabilities. While statistically significant differences on social-communication markers and repetitive behaviors were found in premature and full term births, the means do not suggest a clinically meaningful difference in autism-specific symptoms. Limitations to the study include potential inaccuracies in self-reported history and adjustments were not made for potential confounds.

430.059 *(Poster)* Risk Correlates of Anxiety Symptoms in Three- to Five-Year-Old Children with and without Autism Spectrum Disorder

N. Chan[1]*, C. Callaci*[2]*, M. C. Rodriguez*[3]*, R. M. Fenning*[4] *and C. L. Neece*[3]*, (1)Department of Psychology, Loma Linda University, Loma Linda, CA, (2)Claremont McKenna College, Claremont, CA, (3)Psychology, Loma Linda University, Loma Linda, CA, (4)Center for Autism, Child and Adolescent Studies, California State University, Fullerton, Fullerton, CA*

Background: Individuals with ASD are at a significantly higher risk of developing co-occurring anxiety symptoms and diagnosable anxiety disorders compared to typically developing (TD) peers (Leyfer et al., 2006; Simenoff et al., 2008). However, because most studies focusing on anxiety in young children with ASD begin at age 5 or 6, less is known about the manifestation of anxiety in early childhood. Identifying variables associated with risk for anxiety earlier on may inform prevention and intervention efforts. A number of factors have been found to be associated with anxiety across ASD and TD populations, including behavioral inhibition, emotion dysregulation, and IQ (Bellini, 2006; Berkovits et al., 2017; Hallett et al., 2013). Among children with ASD, ASD symptoms (especially restricted and repetitive behaviors – RRBs) and communication skills have also been linked with anxiety (Kerns et al., 2014; Sukhodolsky et al., 2008).

Objectives: To examine child characteristics (i.e., behavioral inhibition, emotion regulation, IQ, communication, and ASD symptoms) associated with anxiety in children with ASD and in an age-matched TD comparison group.

Methods: Participants in our study included 61 children with ASD (M_{age}=4.46 years, 80.3% male, M_{IQ}=65.86, 72% comorbid ID), and 42 age-matched TD children (M_{age}=4.39 years, 42.9% male, M_{IQ}=105.86). Families in the ASD group were recruited as part of a larger clinical trial examining the efficacy of a stress-reduction intervention for parents of children with ASD. Measures included parent-report questionnaires (Spence Preschool Anxiety Scale, Behavioral Inhibition Questionnaire, Emotion Regulation Checklist Lability/Negative subscale, Repetitive Behavior Scale Revised (RBSR)) and clinician-administered assessments (Stanford-Binet 5, Vineland-3 Communication Domain). The RBSR and Vineland-3 were only administered to caregivers of children with ASD.

Results: We conducted linear regression analyses within each diagnostic group to determine which variables were unique predictors of anxiety symptoms on the SPAS. In the group with ASD, the following variables emerged as unique predictors of anxiety: RRB (β=.32, p<.01) and the Vineland-3 communication domain (β=.32, p<.01). IQ, emotion dysregulation, and behavioral inhibition were not unique predictors of anxiety in the group with ASD (ps>.05). In the group with TD, behavioral inhibition was the only unique predictor of anxiety (β=.54, p<.001).

Conclusions: This study sought to identify unique predictors of anxiety symptoms in a preschool-aged sample with and without ASD. It is noteworthy that the behavioral inhibition total score uniquely predicted anxiety in children with TD but not in children with ASD. Post-hoc analyses of behavioral inhibition in the group with ASD revealed that situational inhibition significantly predicted anxiety (p<.01), whereas the social inhibition subscale did not. Furthermore, results in the sample with ASD suggest that those with *fewer* deficits in communication and more repetitive behaviors are at a higher risk for anxiety symptoms, consistent with the existing literature (Davis III et al., 2011; Spiker et al., 2012). Gaining a better understanding of risk correlates of anxiety during early childhood can inform prevention and intervention for this at-risk population. Future analyses will examine correlates of DSM-5 anxiety disorders in our sample and will address the potential role of demographic and parenting factors.

430.060 *(Poster)* Shared ASD and ADHD Risk Alleles Can Contribute to Positive and Negative Polygenic Association Patterns with Educational Attainment

E. Verhoef[1], J. Grove[2,3], C. Y. Shapland[4], D. Demontis[2,3], S. Burgess[5], D. Rai[6], A. Borglum[2,3] and ***B. St Pourcain***[1,4,7]*, (1)Max Planck Institute for Psycholinguistics, Nijmegen, Netherlands, (2)Aarhus University, Aarhus, Denmark, (3)The Lundbeck Foundation Initiative for Integrative Psychiatric Research, iPSYCH, Aarhus, Denmark, (4)MRC Integrative Epidemiology Unit, University of Bristol, Bristol, United Kingdom, (5)University of Cambridge, Cambridge, United Kingdom, (6)Population Health Sciences, Bristol Medical School, Centre for Academic Mental Health, Bristol, United Kingdom, (7)Donders Institute for Brain, Cognition and Behaviour, Radboud University, Nijmegen, Netherlands*

Background: Autism Spectrum Disorder (ASD) and Attention-Deficit/Hyperactivity Disorder (ADHD) are genetically complex neurodevelopmental disorders that often co-occur. Besides some shared genetic aetiology, both conditions display apparent differences in their genetic architectures, especially in their genetic overlap with educational attainment. While increased polygenic ADHD risk has been linked to lower cognitive abilities/educational attainment, increased polygenetic ASD risk has been associated with higher scores. These association patterns could either indicate independently acting genetic factors or complex pleiotropic, mediating or confounding mechanisms that result in different directions of polygenic effects across shared loci.

Objectives: Improve our understanding of shared genetic aetiologies between ASD, ADHD and educational attainment by investigating how educational attainment-related polygenic variation is encoded within ASD and ADHD genetic architectures.

Methods: Using a multivariable regression (MVR) framework and genome-wide association study (GWAS) summary statistics, we jointly modelled the association of ASD- and ADHD-related SNP estimates with educational-attainment-related SNP estimates, across selected variants. This translates a causal modelling approach into a multivariate polygenic context, without making causal inferences. Instead, we can dissect polygenic associations between each disorder and educational attainment into either ASD-specific or ADHD-specific associations, conditional on shared ASD/ADHD cross-disorder effects. We obtained (predominantly) European descent GWAS statistics from large consortia (Psychiatric Genomics Consortium, Lundbeck Foundation Initiative for Integrative Psychiatric Research, Social Science Genetic Association Consortium), including two clinical ASD samples (N=10,610 to 32,985), a clinical ADHD (N=37,076) and a years-of-schooling (N=766,345) sample. Variants were selected at different thresholds (P_{thr}<0.05 and P_{thr}<0.0015) from ASD or ADHD GWAS statistics. Corresponding SNP estimates were extracted from ASD, ADHD and years-of-schooling GWAS statistics. MVR effects are reported as changes in genetically predictable years-of-schooling per log-odds ADHD liability and log-odds ASD liability.

Results: Our findings show that polygenic links with educational attainment are shared between ASD and ADHD, involving overlapping loci. However, at these sites the same risk-increasing alleles, irrespective of whether they were selected to increase ASD or ADHD risk, gave rise to both positive and negative polygenic association patterns with educational attainment, solely depending on the assigned SNP estimate. For example, ASD risk-increasing alleles selected at P_{thr}<0.0015 (N_{SNPs}=1973), showed a 0.009 increase (SE=0.003) in years–of-schooling per log-odds ASD liability. Conditionally, the same alleles captured a 0.029 decrease (SE=0.004) in years-of-schooling per log-odds ADHD liability. Likewise, ADHD risk-increasing alleles (P_{thr}<0.0015, N_{SNPs}=2717) showed an inverse ADHD-specific association with educational attainment (β=-0.012(SE=0.003)), conditional on ASD-related positive cross-disorder effects (β=0.022(SE=0.003)). These findings were confirmed at the relaxed variant selection threshold (P_{thr}<0.05), and replicated when modelling ASD SNP effects from independent ASD GWAS statistics. MVR effect sizes increased when variants were restricted to markers associated with both ASD and ADHD.

Conclusions: Different combinations of the same risk-increasing alleles, including alleles that increase both ASD and ADHD risk, can reveal opposite association patterns with educational attainment. This suggests pleiotropic mechanisms, where individual alleles can contribute to multiple independent polygenic effects without involving distinct sets of loci. The observed inverse association patterns across shared loci may affect the detectable net genetic overlap between ASD and ADHD.

430.061 *(Poster)* Sleep Disruptions in Individuals with 16p11.2 Copy Number Variants

H. E. Reed[1]*, A. Jutla*[2]*, J. Veenstra-Vander Weele*[3] *and W. P. Fifer*[4]*, (1)Columbia University Medical Center, New York, NY, (2)1051 Riverside Drive, New York State Psychiatric Institute / Columbia University, New York, NY, (3)Psychiatry, New York State Psychiatric Institute / Columbia University, New York, NY, (4)Division of Developmental Neuroscience, Columbia University Medical Center, New York, NY*

Background: Sleep disruptions are significantly more common in individuals with autism, with difficulty falling asleep being the most frequently reported concern. Poor sleep is associated with reduced quality of life measures in affected individuals as well as family members. Interestingly, the disrupted sleep phenotype appears consistent across multiple genetic animal models of autism, including 16p11.2 copy number variations (CNVs). Mouse models of 16p11.2 microdeletion demonstrate decreased sleep efficiency, decreased total sleep time, and decreased REM sleep compared to wild-type litter-mates. Furthermore, this disrupted sleep phenotype appears to be present only in male mice. Despite the importance of sleep in early development, there are currently no published studies on sleep in humans with 16p11.2 CNVs.

Objectives: This is the first study to characterize sleep disruptions in individuals with 16p11.2 deletions and duplications.

Methods: As part of a pilot study, participants from the Simons Variation in Individuals Project (Simons VIP) were recruited at the 2019 16p11.2-CNV family conference in Denver, Colorado. All individuals completed the Pittsburgh Sleep Quality Index (PSQI) questionnaire. The PSQI is a 19-item self-report questionnaire, widely used for sleep assessment across clinical and research settings. It has good internal consistency, test-retest reliability, and diagnostic validity. Institutional Review Board (IRB) approval was received from Columbia University Medical Center, and informed consent was obtained from all participants prior to participation.

Results: Our pilot sample includes 11 individuals, 6 of whom are 16p11.2 duplications carriers (3 females, 3 males) and 5 with 16p11.2 deletions (3 males, 2 females). The duplication group reported a mean sleep latency of 14 minutes, whereas the deletion group reported a clinically significant mean of 55 minutes to fall asleep. This between group finding approached statistical significance, $F(1,9)=3.88$, $p=0.0804$. Consistent with prior mouse models, this finding appears specific to males, with mean sleep latency of 88 minutes (SD=33) for male deletion carriers compared to a mean latency of 5 minutes (SD=0) for female deletion carriers. Duplication with a larger sample size is necessary for adequate statistical power. Further analyses will also examine specific sleep-related concerns and total PSQI scores across groups.

Conclusions: This is the first study to examine sleep disruptions in humans with 16p11.2 copy number variants. Our initial findings support prior animal data and stress the importance of further work in this population. Interpretations are limited due to the small sample size but strongly suggest an effect of male gender on sleep in 16p11.2 microdeletions. It is important to better understand sleep-related genotype-phenotype correlations, given the prevalence of sleep disruptions in developmental disorders and their impact on quality of life. We hope to bolster our pilot findings with larger sample sizes and objective sleep measures going forward.

430.062 *(Poster)* Sleep Timing Contributes to Short Sleep Duration in Adolescents with TD but Not ASD

E. A. Abel *and J. McPartland, Child Study Center, Yale University School of Medicine, New Haven, CT*

Background: Sleep problems are common for children with autism spectrum disorder (ASD), though little is known about shifts in sleep patterns that may accompany puberty and adolescence (Goldman et al., 2017). Among typically developing (TD) adolescents, sleep is referred to as 'the perfect storm'—reflecting bioregulatory (e.g., circadian phase) and psychosocial (e.g., academic) pressures that delay bedtimes. Societal pressures, including school start times, also force adolescents to wake-up earlier (Carskadon, 2012). It is unclear whether adolescents with ASD follow a similar sleep timing pattern, ultimately leading to shorter sleep.

Objectives: To elucidate sleep patterns for adolescents with ASD vs. TD, as well as characterize developmental shifts in sleep timing from school-age to adolescence.

Methods: Participants included 45 children and adolescents with ASD (n = 29; M_{age}= 12.52; 62% male) and TD (n = 16; M_{age}= 12.40; 44% male). Parents completed the Yale Developmental Sleep Questionnaire (YDSQ), a tool designed to capture sleep behaviors/patterns in individuals with developmental disabilities. Mann-Whitney tests and regression analyses were used to explore sleep differences in ASD vs. TD. Children were separated into developmental stages using age-related cutoff's consistent with the *American Academy of Sleep Medicine's* (AASM) pediatric sleep guidelines: School-Age (6-12; n=23) and Adolescence (13-18; n=22).

Results: Sleep onset latency was significantly longer in ASD (*Mdn*=20) compared to TD (*Mdn*=10), U=60.50, p=.002, r=0.48. Developmental trends in sleep are described below and in Table 1.

School-Age: Nighttime sleep was not significantly different at school-age for ASD (*mdn*=555.0) vs. TD (*mdn*=590). All children slept at least 9 hours per night, which is developmentally appropriate according to the AASM.

Adolescence: In contrast, teens with TD (*mdn*=476.50) slept significantly less than those with ASD (*mdn*=537.50), U=10.00, p=.008, r=0.59. Differences were driven by later bedtimes (*mdn*=10:00pm) and earlier rise times (*mdn*=6:00am). TD adolescents who used electronics at bedtime slept for roughly one hour less than non-device using TD peers and all adolescents with ASD, b=-.60, $p < .05$, R^2=.51. Developmental shifts toward later bedtimes, earlier rise times, and less sleep were evident in TD but not ASD.

Conclusions: Preliminary findings are consistent with pubertal shifts in circadian phase associated with naturally later bedtimes, extra-curricular activities that delay homework/bedtime, and increased bedtime autonomy in TD. Short sleep duration arises from diminished sleep opportunity, occurring when adolescents go to bed later but continue to wake early for school. Variable weekday to weekend rise times reflect TD adolescents' biologically driven sleep patterns when un-restricted by school start times, as well as recovery from sleep debt accumulated on school-nights (Carskadon, 2004).

Longer sleep for adolescents with ASD could reflect various combinations of ASD-specific, contextual, and biological factors. Earlier bedtimes mirroring those at school-age could reflect ASD traits associated with more rigid bedtimes or higher parental control of sleep timing. Reduced participation in extra-curriculars, decreased social use of electronics, and biological differences could also explain these results. Data collection is ongoing and final analyses will include a larger sample of adolescents. Future research should utilize actigraphs to more accurately capture sleep patterns in adolescence.

430.063 *(Poster)* Testing Mediators of the Link between the Broad Autism Phenotype and Mental Health: Intolerance of Uncertainty and Friendship Quality

E. J. Adler[1]*, H. K. Schiltz*[1]*, A. J. McVey*[1,2] *and A. V. Van Hecke*[1]*, (1)Psychology, Marquette University, Milwaukee, WI, (2)UCLA Semel Institute for Neuroscience & Human Behavior, Los Angeles, CA*

Background: Compared to the typically developing population, people with autism (autism spectrum disorder) are at much greater risk for having a comorbid mental health diagnosis; particularly anxiety and/or depression (Hollocks, et al., 2019). Likewise, high levels of subclinical features of autism, termed the Broad Autism Phenotype (BAP), are also associated with greater endorsement of depression and anxiety symptoms. Although some evidence points to intolerance of uncertainty (Boulter, et al., 2014) and poor friendship quality (Mazurek, 2013) as potential contributors to mental health concerns in adults with autism, no research to date has taken a broader lens to explore these as mediators between the BAP and mental health.

Objectives: The present study aimed to 1) replicate support for the mediating effect of intolerance of uncertainty on mental health outcomes and extend these findings by examining the BAP, 2) explore friendship quality as a potential mediator between BAP and mental health outcomes.

Methods: 181 college students aged 18-25 (M=18.74) completed measures assessing the BAP (BAPQ; Hurley, et al., 2007), intolerance of uncertainty (IUS; Carleton, Norton, & Asmundson, 2007), friendship quality (FQ; Baron-Cohen & Wheelright, 2004), depression (CES-D; Radloff, 1977), and anxiety (STAI Trait subscale; Spielberger, 1983). R version 3.5.1 was used to estimate direct effects of the BAP on mental health (CES-D and STAI) and indirect effects through intolerance of uncertainty (IUS) and friendship quality (FQ). Bootstrapped confidence intervals were used to interpret indirect effects.

Results: Bivariate pearson correlations revealed greater levels of BAP were associated with higher reports of anxiety, depression, intolerance of uncertainty, and lower friendship quality (Table 1). Mediation analyses indicated significant indirect effects of BAP symptoms to both anxiety (b=4.19, CI: 2.62-6.13) and depression (Figure 1: b=3.41, CI: 2.08-4.88) through intolerance of uncertainty. While there was evidence for full mediation for depression symptoms (i.e., non-significant direct effect from BAP to depression, Figure 1: b=2.14, p=0.14), the effect for anxiety was only partially mediated (i.e., significant direct effect from BAP to anxiety, b=7.47, p<.001). In contrast, although friendship quality was negatively related to BAP, it did not emerge as a significant mediator of the association between BAP and neither depression nor anxiety.

Conclusions: Findings from the present study revealed that intolerance of uncertainty, but not friendship quality, accounted for the association between BAP and mental health outcomes in a sample of college students. This may highlight that individuals with more BAP symptoms are predisposed to greater intolerance of uncertainty, which has implications for mental well-being, especially depression. Surprisingly, friendship quality did not play a mediating role in this association, suggesting that friendship quality does not seem to directly determine mental health outcomes; future work may seek to test whether this link holds true for some, but not all, adults on the spectrum. Given the added burden of living with a comorbid depression and/or anxiety diagnosis, understanding factors that might link symptoms of autism and mental health outcomes has implications for treatment avenues and bolstering quality of life for people with high levels of BAP and adults with autism.

430.064 *(Poster)* The Association between Somatic Comorbidity and Autism Among Discordant Twins—a Nationwide Population-Based Twin Study

P. Y. Pan[1] *and S. Bolte*[2]*, (1)Department of Women's and Children's Health, Karolinska Institutet, Stockholm, Sweden, (2)Center of Neurodevelopmental Disorders (KIND), Centre for Psychiatry Research; Department of Women's and Children's Health, Karolinska Institutet, & Stockholm Health Care Services, Region Stockholm, Stockholm, Sweden*

Background: Individuals with autism have higher prevalence of co-occurring somatic disorders than the general population, including immune dysregulation, gastrointestinal (GI) problems, and neurological problems. It suggests the possibility of an underlying genetic and/or environmental perturbation affecting multiple systems that might lead to both somatic disorders and autism. However, except some specific genetic disorders and the current findings of gene pleiotrophy, there is still little information regarding the relationships between somatic comorbidity and autism diagnosis or autistic traits.

Objectives: This study aimed to use a Swedish nationwide population-based twin cohort and co-twin control design, which has the advantage of well-controlled genetic background and other important shared confounders, to investigate if somatic comorbidity is involved in the etiological mechanism of autism symptoms.

Methods: A total of 16,125 twin pairs from the Child and Adolescent Twin Study in Sweden (CATSS) were included for analysis in this study (mean age 9.72 ± 1.21 yrs). The participants with autism diagnosis and the diagnose of any medical problems were identified by the International Classification of Diseases (ICD) codes through the Swedish National Patient Register (NPR). Among them, 56 pairs of monozygotic (MZ) twins and 352 pairs of dizygotic (DZ) twins discordant for autism diagnosis were identified. The ASD module in the Autism–Tics, ADHD and other Comorbidities inventory (A-TAC) was used to quantify the participants' autistic traits. The differences of somatic comorbidity among twins with autism and non-autism twins were examined. The somatic disorders identified with significant within-pair differences were then tested in relation to autistic traits in both MZ and DZ twin pairs quantitatively discordant for autism, which was defined as at least 1 point (SEM) for the intra-pair difference of ASD module score.

Results: In the whole sample analysis, the twins with autism have more infectious diseases, neurological problems, GI symptoms, and immunological dysregulation compared to non-autism twins. In addition, GI symptoms are associated with autism for both categorical diagnosis and dimensional traits, while infectious diseases and neurological problems are only associated with the severity of autistic traits. For the MZ twins quantitatively discordant for autism, the intra-pair differences of neurological problems and infectious diseases are significantly correlated with the differences of ASD module score ($r = 0.18$, $p < 0.001$, and $r = 0.08$, $p = 0.008$, respectively). However, with the conditional model for within-pair effect analysis, there is only significant association between neurological problems and ASD module score ($\beta = 0.49$, $p = 0.003$) after adjusting for ADHD and intellectual disability.

Conclusions: Our findings suggest that neurological problems could be considered as a non-shared environmental factor for MZ twins discordant for autistic traits. It may suggest that the synergic effects of organic neuropathy on a specific genetic background may compound autistic traits. On the other hand, infectious diseases and GI symptoms are also associated with autism, while might not be involved in the biological pathways. To aware these somatic comorbidities and provide adequate management is of paramount importance for clinicians working with individuals of autism.

430.065 *(Poster)* The Effect of Comorbid Anxiety and ADHD on Adaptive Functioning Among Autistic Youth in a Clinic-Referred Sample

A. J. McVey[1,2]*, E. Moulton*[2]*, P. Renno*[2] *and A. Gulsrud*[2]*, (1)Psychology, Marquette University, Milwaukee, WI, (2)UCLA Semel Institute for Neuroscience & Human Behavior, Los Angeles, CA*

Background: Research indicates that approximately 40% of youth with autism have at least one comorbid anxiety disorder (van Steensel, Bögels, & Perrin, 2011) and 30–85% have comorbid Attention Deficit-Hyperactivity Disorder (ADHD). Anxiety and ADHD are thought to exacerbate core autism symptoms (Duvekot, Ende, Verhulst, & Greaves-Lord, 2017; Leitner, 2014; Renno & Wood, 2013), particularly within the social domain. One recent study of adaptive behavior showed that ADHD symptoms among youth with autism were associated with poorer communication, socialization, and daily living skills (Yerys, Bertollo, Pandey, Guy, & Schultz, 2019).

Objectives: To examine the relation between anxiety and ADHD symptoms and adaptive functioning among autistic youth.

Methods: Twenty-five youth with autism (ages 6–18) were included in this study. The sample was drawn from a clinic database nested in an academic medical center setting. All participants met cutoffs for autism on the *Autism Diagnostic Observation Schedule, 2nd Ed.* (*ADOS-2;* Lord et al., 2012). Parent report of autism symptoms (*Social Responsiveness Scale, SRS*; Constantino & Gruber, 2002), anxiety and ADHD symptoms (*Child Behavior Checklist, CBCL*; Achenbach & Rescorla, 2001), and adaptive behavior (*Vineland Adaptive Behavior Scales, VABS*; Sparrow, Balla, & Cicchetti, 2005) were obtained. Raw scores and empirically validated indices from the SRS were used, as is recommended (Constantino & Gruber, 2012; Frazier, Georgiades, Bishop, & Hardan, 2014; Frazier et al., 2012).

Results: Pearson's correlations demonstrated negative associations between adaptive functioning and autism, anxiety, and ADHD symptoms (Table 1). Namely, the Social Communication Index (SCI) on the SRS was negatively associated with the Socialization domain and the Coping Skills subdomain on the VABS. The Repetitive Behavior Index (RBI) on the SRS was negatively associated with the Receptive subdomain on the VABS. The Anxiety Problems subscale on the CBCL was negatively related to the Receptive subdomain on the VABS, while the ADHD Problems subscale on the CBCL was negatively related to the Socialization domain and the Receptive and Coping Skills subdomains on the VABS. After partial correlations were used to control for SRS SCI and RBI, results showed no significant associations between the CBCL Anxiety or ADHD Problems subscales and the VABS (Table 2).

Conclusions: Findings from the present study demonstrate that autism symptoms explain elevations in adaptive functioning, not comorbid anxiety or ADHD. It is important to note, however, that some evidence suggests the SRS may be artificially inflated in the presence of comorbid symptoms (e.g., McVey et al., 2018). Therefore, interpretation of the original correlations was included and may suggest poorer adaptive functioning for autistic youth with anxiety or ADHD. These findings point to the importance of understanding links between autism, mental health comorbidities, and adaptive behavior in order to best address these challenges in youth to promote better quality of life in adulthood.

430.066 *(Poster)* The Effects of Emotional Control on the Relationship between Social Anxiety and Aggression in ASD

J. M. Avione[1]*, T. C. Day*[1] *and M. D. Lerner*[2]*, (1)Psychology, Stony Brook University, Stony Brook, NY, (2)Department of Psychology, Stony Brook University, Stony Brook, NY*

Background: Children with autism spectrum disorder (ASD) are at elevated risk for aggression (Kanne & Mazurek, 2010) and social anxiety (White & Roberson-Nay, 2009). Previous work has found emotion dysregulation predicts aggression in typically developing populations (Röll et al., 2012; McLaughlin et al., 2011), and there are correlations between social anxiety, physical aggression and anger control in ASD (Gaye Ambler, Eidels, Gregory, 2013). Evidence suggests social anxiety may precipitate aggression due to challenges in emotion regulation abilities (i.e., difficulties in regulating social anxiety in typically-developing youth when in social context may lead that anxiety to manifest as aggression as an escape mechanism; Aldao et al., 2016; Dixon et al., 2016; Kasdan et al., 2009; Kunimatsu & Marsee, 2012; Mazefsky et al., 2013). However, the role of emotion regulation in the relationship between social anxiety and aggression in ASD has rarely been explored.

Objectives: To determine whether emotion regulation partially explains the relation between social anxiety and aggression in children with ASD.

Methods: Participants included 133 individuals (see Table 1) with an IQ ≥ 70; 65 children met criteria for ASD based on the Autism Diagnostic Observation Schedule (ADOS-2; Lord et al., 2012) and prior history of diagnosis. Parent-reported aggression and emotion control and child-reported social anxiety was collected (see Table 1). Two hierarchical multiple regressions were performed with social anxiety (step 1) and emotion control (step 2) predicting aggression in the ASD and non-ASD group.

Results: In the ASD group, social anxiety predicted aggression (Table 2a). However, when emotion control was added, social anxiety no longer predicted aggression, but emotion control did. In the non-ASD group, social anxiety did not predict aggression (Table 2b). When emotion control was added, emotion control predicted aggression.

Conclusions: The current study found that emotion control partially explains the relation between social anxiety and aggression in children with ASD. This relationship has been previously theorized based on the relation between social anxiety and aggression in this population (Pugliese et al., 2013), but had not previously been tested. Furthermore, these findings mirror a study of non-ASD youth in which emotion dysregulation was found to predict aggression (Röll et al., 2012); however, this relationship did not explain any variance in the relationship between social anxiety and aggression (since no such relationship was found) in our non-ASD sample, suggesting the effect of interest in our models may be either unique or especially strong in ASD youth. Thus, emotion control may be a potential intervention target to reduce aggression among youth with ASD and elevated social anxiety. Given the cross-sectional nature of the current study, future work using longitudinal samples may clarify the direction and specificity of the relationship between aggression, social anxiety, and emotion control.

430.067 *(Poster)* The Nature and Impact of Executive Functioning in Mental Health Services for ASD: Perspectives from Mental Health Providers

K. S. Dickson[1], *L. Anthony*[2], *L. Kenworthy*[3] *and L. Brookman-Frazee*[1,4,5], *(1)Child and Adolescent Services Research Center, San Diego, CA, (2)University of Colorado, Denver, Aurora, CO, (3)Center for Autism Spectrum Disorders, Children's National Hospital, Washington, DC, (4)Psychiatry, University of California, San Diego, La Jolla, CA, (5)Autism Discovery Institute, Rady Children's Hospital-San Diego, San Diego, CA*

Background: Youth with autism spectrum disorder (ASD) have high rates of co-occurring psychiatric conditions, estimated at 70% versus 25% for other youth (Lai et al., 2019). Publicly-funded mental health (MH) services play a significant role in caring for school-aged youth with ASD. Yet, MH providers report limited ASD experience and knowledge (Brookman-Frazee et al., 2012). Youth with ASD in MH services have multiple co-occurring psychiatric conditions, including attention-deficit/hyperactivity disorder (ADHD), disruptive behaviors disorder, and anxiety. Executive functioning (EF) deficits play an integral role in both ASD and commonly co-occurring psychiatric conditions and increase MH symptoms in youth with ASD (Hill, 2004; Lawson et al, 2015). Little research to date has examined EF among youth with ASD receiving MH services. Research examining MH provider experience or knowledge of EF in ASD is also limited. Information from MH providers related to their knowledge and perceptions of EF deficits among youth with ASD receiving MH services is needed to inform efforts to improve MH treatment for ASD.

Objectives: The current study examined community-based MH provider's perspective regarding experience and knowledge of EF and the nature of EF deficits on MH services for youth with ASD.

Methods: Data were drawn from the first phase of a developmental study aimed to adapt and test an evidence-based EF intervention for children with ASD and co-occurring MH conditions for delivery in publicly-funded outpatient MH services. MH providers (n=42) were 83.3% female (M_{age} =32.45) and 45.2% Marriage and Family Therapists. Through a web-based survey, providers were asked about their perspectives regarding their experience and knowledge of EF, the nature of EF in youth receiving MH services, and the impact on MH services.

Results: Descriptive analyses indicated that 64% and 41% of providers report being *knowledgeable* about EF in MH conditions and the impact on EF-consistent behaviors (e.g., challenging behaviors, inflexibility) in youth on their caseload, respectively. Fewer providers (36%) reported being knowledgeable about EF specifically in ASD. Providers also reported *experience* with EF in MH conditions (55%) and EF-consistent behaviors (43%) but more limited experience with EF in ASD (31%). Providers reported that EF difficulties are more common in ASD (M=3.9, SD=2.4, Range 1-6) compared to other MH conditions (e.g., ADHD, disruptive behaviors; M=2.9, SD=1.9, Range 0-6). Difficulties with flexibility and emotion recognition and regulation were most common in ASD. Only 37% of providers reported EF as a target or focus of treatment for youth with ASD compared to 65% for other MH conditions.

Conclusions: These initial findings shed light on provider perceptions of EF deficits among youth with ASD served in MH settings. Results suggest that youth with ASD present with several EF difficulties, more than other with other MH conditions. Further, findings highlight potential targets for provider training, including further training in EF in ASD and addressing EF difficulties as a focus of MH treatment.

Rigor: This study is one of the first to examine provider perceptions of EF, a key factor in ASD, in MH services, a primary provider of services for youth with ASD.

430.068 *(Poster)* The Prevalence of Mental Health Conditions in Autistic Adults in a State Medicaid System

L. Bishop[1], *K. J. McLean*[2] *and E. Rubenstein*[3], *(1)University of Wisconsin - Madison, Madison, WI, (2)University of Wisconsin-Madison, Madison, WI, (3)Waisman Center at UW Madison, Madison, WI*

Background: Mental health conditions are more prevalent in autistic adults compared to adults in the general population. Yet, differences between autistic adults and other developmental disabilities are less understood but have the potential to inform systems level treatment approaches.

Objectives: Our objective was to determine the prevalence of mental health conditions in adults with ASD compared to adults with intellectual disability in a large, single-state Medicaid fee-for-service sample. We then assessed group differences in number of co-occurring mental health conditions.

Methods: We assessed Medicaid claims from 2008-2018 for adults (≥21 years) who had two claims for autism spectrum disorder (ASD) or intellectual disability (ID) on two different days ever during their Medicaid enrollment. Mental health condition claims were extracted from codes from Center for Medicaid Studies Chronic Conditions Data Warehouse for depression, anxiety, bipolar disorder, schizophrenia, and personality disorders. We categorized our case groups into exclusive categories (ASD without ID, ASD with ID, ID). Mental health conditions were considered prevalent if a beneficiary had two or more claims for a mental health condition at any time in the period. We then created a variable to assess the co-occurrence of depression and anxiety. Finally, we created a count variable of co-occurring mental health conditions (range: 1-5) and tested group differences in number of co-occurring mental health conditions using an ANCOVA model adjusting for age and sex.

Results: In the 11-year period assessed, Wisconsin Medicaid had 4775 unique beneficiaries with ASD; 2738 with ASD with ID; and 18429 with ID. Overall, 65.2% of the ASD group, 70.9% of the ASD with ID group, and 48.5% of the ID group had a mental health condition. The most prevalent condition in all groups was anxiety (ASD: 48.5%; ASD with ID: 48.4% ASD: ID: 30.0%). The ASD group had the highest prevalence of depression (37.3%) with similar prevalence for the ASD without ID group (28.7%) and ID group (29.3%). Bipolar disorder was more prevalent in the ASD with ID group (37%) compared to the ASD group (27.4%). Schizophrenia was prevalent in 9.6% of the ASD group; 15.0% of the ASD with ID group; and 15.2% of the ID group. Personality disorders were similar in the ASD group (11.7%), ASD with ID group (13.0%), and the ID group (9.1%). Both depression and anxiety were prevalent in 27.8% of the ASD group; 20.2% of the ASD with ID group; and 18.5% of the ID group. Mean number of mental health conditions was 1.35 (SD=1.30) in the ASD group, 1.42 (SD=1.29) in the ASD with ID group, and 1.27 (SD=1.36) in the ID group, which differed significantly by group.

Conclusions: Autistic adults are likely to have co-occurring mental health conditions. Whether this is intrinsic to autism, clinician diagnostic tendency, a result of disparity, or a yet-to be determined etiology, appropriate treatment is critical. Based on the extent of mental health services, especially in the ASD groups, investment in prophylactic mental health treatment for this population may be a way to improve outcomes and costs for a Medicaid system.

430.069 *(Poster)* The Role of Weight, Shape and Pride in Eating in Autistic Women with Anorexia Nervosa

*C. Babb[1,2], **J. Brede**[3], C. R. Jones[2], L. Serpell[3], W. Mandy[4] and J. R. Fox[5], (1)Cardiff Univeristy, Cardiff, United Kingdom, (2)Wales Autism Research Centre, Cardiff University, Cardiff, United Kingdom, (3)Research Department of Clinical, Educational and Health Psychology, University College London, London, United Kingdom, (4)University College London, London, United Kingdom of Great Britain and Northern Ireland, (5)South Wales Doctorate in Clinical Psychology, Cardiff Univeristy, Cardiff, United Kingdom*

Background: Anorexia Nervosa (AN) is a severe, restrictive eating disorder. It has consistently been found that 20-30 % of women in treatment for AN meet diagnostic criteria for autism spectrum disorder (Huke et al., 2013). AN is conventionally understood as being driven by weight and shape concerns, and research has suggested that pride in the ability to control eating and restrict food intake plays a significant role in the maintenance of AN (Skåderud, 2007; Faija et al., 2017). Our previous qualitative research, interviewing autistic women with AN, their parents and clinicians, suggests that these fundamental AN traits may be less apparent in autistic individuals, with their eating difficulties instead often stemming from their autism. Therefore, there may be an autism-specific profile of AN, which differentiates autistic women from typical AN presentations.

Objectives: The current study aims to assess the presence of typical AN behaviours (1) weight and shape concerns and (2) pride in the ability to restrict and control eating, in AN women both with and without autism, as well as in an autistic group without AN.

Methods: The current study compares three participant groups: autistic women with AN; autistic women without AN; and non-autistic women with AN. We plan to recruit 135 participants in total (45 per group), and at the time of writing have recruited more than 25 participants. Participants complete two implicit association tests (IAT; Greenwald, McGhee & Schwartz, 1998) measuring weight and shape concerns and the thin ideal internalisation. These factors are most commonly measured using self-report questionnaires, which can be susceptible to social desirability biases and impression management. Using the IAT measures allows us to disentangle these biases. In addition, participants complete a battery of self-report questionnaires related to weight and shape concerns and pride in eating disordered behaviours. We also measure general autistic and eating disorder traits and potential confounders, such as Body Mass Index, anxiety, depression and IQ. Advisors from the autistic community were consulted when developing the study protocol.

Results: Data is currently being collected and preliminary results will be presented. We hypothesise that autistic women with AN will demonstrate lower levels of weight and shape concerns and pride in eating than the non-autistic women with AN, but that autistic women without AN will show the lowest levels. To test these hypotheses, a one-way ANOVA will be used.

Conclusions: Current AN treatments and care pathways often target body image and concerns with weight and shape, but this could be unhelpful or even detrimental to autistic women's engagement with services, if these factors are not actually underlying their eating difficulties. This study will improve our understanding of AN presentations in autistic individuals and how this might differ from other women with AN. This will help eating disorder services to improve the way they engage with and treat autistic individuals.

430.070 *(Poster)* Unique Perspectives: Understanding Depression in Early Adolescents with and without Autism Spectrum Disorder through Self- and Parent-Reports

***J. M. Schwartzman**[1] and B. A. Corbett[2], (1)Palo Alto University, Palo Alto, CA, (2)Psychiatry and Behavioral Sciences, Vanderbilt University Medical Center, Nashville, TN*

Background: Depressive symptoms are common in adolescence and Autism Spectrum Disorder (ASD). Older adolescents with ASD endorse elevated severity as compared to typically-developing peers, but less is known about depression in early adolescence. Severity may vary by age in older adolescence, but the literature appears mixed for early adolescence. Additionally, differences in adolescent and parent perspectives have been documented. Therefore, it is essential to understand depression from both perspectives to improve conceptualization and intervention.

Objectives: The present study examined self-reported depression in early adolescents with and without ASD on the Children's Depression Inventory, 2nd edition (CDI-2; Kovacs, 2014). Additionally, depression ratings across early adolescents and their parents were compared to identify distinct perspectives, particularly in the ASD group.

Methods: The total sample (N = 230) included early adolescents with ASD without intellectual disability (FSIQ≥70; n = 133) and of typical development (TD; n = 97) who participated in the first year of a longitudinal study of pubertal development in ASD (PI: Corbett, MH111599). Participants were between 10:00-13:5 years old (M = 11.5, SD = 1.11) with 155 males (ASD = 99, TD = 56) and 75 females (ASD = 34, TD = 41). Depression was reported by early adolescents on the CDI-2 and by parents on domains of the Child Behavior Checklist (CBCL). Independent samples *t*-tests were employed to examine CDI scores between early adolescents with and without ASD and CBCL scores between parents in the ASD and TD groups. Intraclass correlation coefficients (ICC) were calculated for T-scores from the CDI-2 Total and CBCL Affective Problems to examine reliability between raters (early adolescent vs. parent) on depression. Additionally, Cohen's κ was calculated to estimate strength of agreement between raters on the ordinal categories of depression severity.

Results: Significant group differences emerged between early adolescents with and without ASD on the CDI for Total depression (p<.01), Emotional Problems (p<.01), and Functional Problems (p<.01) as those with ASD endorsed higher severity. Similarly, significant group differences emerged between parents on the CBCL in Internalizing Problems (p<.01), Depressed/Withdrawn subscale (p<.01), and Affective Problems (p<.01) as parents in the ASD group reported higher severity. In terms of reliability between raters (early adolescent vs. parent), ICC analyses revealed a significant, but "poor" reliability (ICC = 0.293, p<.01) between raters in the TD group, yet reliability between raters in the ASD group was nonsignificant. Furthermore, Cohen's κ analyses revealed a significant, "slight" agreement (κ = 0.132, p<.01) between raters in the TD group on depression severity, yet raters in the ASD group exhibited a nonsignificant level of agreement.

Conclusions: In this study, early adolescents with ASD endorsed greater depression severity than their typically-developing peers, which was both statistically significant and clinically meaningful. This finding was supported by elevated ratings among parents in the ASD group on a similar index of depression. However, discrepancies in severity ratings between early adolescents with ASD and their parents highlights the need for multiple perspectives. Furthermore, findings emphasize multi-informant assessment as an important method in conceptualizing and treating depression in this group.

430.071 *(Poster)* Update on the Effectiveness of Cognitive Behavioural Therapy Treatments for OCD in Individuals with ASD

***S. Bedford**, M. C. Hunsche and C. M. Kerns, University of British Columbia, Vancouver, BC, Canada*

Background: Obsessive compulsive disorder (OCD) is prevalent amongst individuals with autism spectrum disorder (ASD), with estimates of up to 37% (van Steelsel et al, 2011; Kent and Simonoff, 2017). Despite this, limited research has been dedicated to developing or evaluating treatments for OCD in ASD specifically; rather, most treatment studies have subsumed OCD under the category of anxiety disorders. Nonetheless, since OCD was distinguished from the anxiety disorders in DSM-V, more OCD-specific treatments for children with ASD are emerging in the literature.

A previous systematic review conducted in 2014 identified three pharmacological studies and one behavioural analysis and modification study as probably efficacious, but no cognitive behavioural therapy (CBT) treatments (despite its status as a well-established treatment for OCD in individuals without autism; APA Presidential Task Force on Evidence-Based Practice, 2006). Since then, a number of studies have been published examining the efficacy of psychosocial treatments for OCD in individuals with ASD. The current review is an update to Neil & Sturmey's (2014) review, using Chambless & Hollon's (1998) criteria to evaluate the efficacy of CBT treatments for OCD in individuals with ASD.

Objectives: The purpose of this review is to critically evaluate the current evidence base for the efficacy of CBT for OCD in individuals with ASD, and to provide recommendations for future research.

Methods: Studies were selected from two previous reviews (Neil and Sturmey, 2014, and Kose et al, 2018), along with a more recent PsychINFO search to include new findings. This search yielded 25 studies that were included in this review. Chambless and Hollon's (1998) criteria were applied to evaluate studies and classify treatments as possibly efficacious, probably efficacious, or well-established, based on the standards of independent replication, methodological rigor, and representativeness of studies.

Results: The present review identified 16 CBT programs for OCD in individuals with ASD that have been evaluated in case reports (13 studies), open trials (6 studies), and randomized control trials (6 studies). Most studies included a good representation of sex, but many did not report ethnicity or socio-economic status. As was found by Neil & Sturmey (2014), no treatment to date meets well-established or probably efficacious criteria. However, two new treatments have emerged in the last four years that have demonstrated promising efficacy and meet possibly efficacious criteria. Of these treatments, a newly-developed functional behaviour-based CBT demonstrated superiority to treatment as usual, and an adapted CBT for individuals with ASD demonstrated superiority to an anxiety management program. For both treatments, comparison to an established alternate treatment and replication by independent research groups is needed for these treatments to be considered well-established.

Conclusions: Though there are still no well-established treatments for OCD in individuals with ASD, attention to this area of treatment research is growing and two new treatments show promise. In general, more RCTs are needed comparing CBT for OCD to alternate treatments in individuals with ASD, as well as multi-site replication of studies examining treatment efficacy.

430.072 *(Poster)* Weight Status and Lipid Profile in Children with Autism Spectrum Disorder

***J. Lin**[1], G. R. Souza-Lin[2], G. D. Farias[2], P. G. Ambrosio[3], K. Madeira[3], L. B. Wessler[4], E. L. Streck[4] and C. Ludvig Goncalves[1], (1)Laboratory of Autism and Neurodevelopmental Research, Universidade do Extremo Sul Catarinense, Criciúma, Brazil, (2)Universidade do Sul de Santa Catarina, Tubarão, Brazil, (3)Laboratório de Pesquisa Aplicada em Computação e Métodos Quantitativos (LACOM), Universidade do Extremo Sul Catarinense, Criciúma, Brazil, (4)Laboratório de Pesquisa de Doenças Neurometabólicas (Labneuromet), Universidade do Extremo Sul Catarinense, Criciúma, Brazil*

Background: Pediatric overweight (OWT) and obesity (OBY) are significant public health concerns reaching a prevalence of up to 32% of children and adolescents in developed countries. Little is known about the prevalence and correlates of OWT and OBY among children with autism spectrum disorder (ASD). Although many risk factors for unhealthy weight are the same in ASD patients as in general pediatric population, children with ASD may have additional risk factors. ASD children may present eating disturbed behaviors such as food selectivity; they have less regular physical activities, often take psychotropic medications that can cause weight gain and may present several clinical comorbidities such as anxiety, depression, gastrointestinal problems and sleep disturbances, each one of those potentially predisposing to obesity.

Objectives: Evaluate the weight status and lipid profile in ASD children comparing to healthy controls subjects.

Methods: A comparative cross-sectional study was performed with 236 children diagnosed with ASD (118 classified into mild/moderate and 118 classified into severe autism), and 236 healthy controls. The diagnosis of ASD was confirmed by the Diagnostic and Statistical Manual of Mental Disorders, 5th Edition (DSM-V) and the severity was assessed by the Childhood Autism Rating Scale (CARS). Measured values for weight and height were used to calculate body mass index (BMI) percentiles while lipids profile (Cholesterol, triglycerides, LDL-C, HDL-C and medication data were reviewed form the medical records.

Results: Obesity was significantly higher among autistic children when compared to healthy controls (16,5% in healthy controls, 28% in mild/moderate and 29,7% in severe autistic patients). Total cholesterol levels, however, were significantly lower in severe ASD children (157,20 ± 27,07 mg/dL) when compared to healthy controls (165,95 ± 38,80 mg/dL). Overall almost 30% of ASD children met the criteria for OBY which was associated with medication use specially neuroleptics. Interestingly, lipid profile did not correlate with BMI in ASD affected population corroborating previous studies indicating hypocholesterolemia as a common feature among autistic patients. Cholesterol has multiple biological functions, some of which could plausibly contribute to ASD. Cholesterol is an important building block for the body's cell membranes and myelination of the central nervous system, it modulates oxytocin receptor function and participates in serotonin function pathways.

Conclusions: The results of this study reinforces the importance of the investigation of anthropometric data in ASD patients among with its clinical and laboratorial correlates with implications in pathophysiological investigation and treatments.

Molecular Genetics

ORAL SESSION — **MOLECULAR GENETICS**
321 - Molecular Dissection in Autism

321.001 *(Oral)* Transcriptomic Alterations Involving Synapse Maturation, Axon Guidance and MAPK Signaling Implicate Activity-Dependent Dysfunction of Isolated Purkinje Cells in the Postmortem Autism Brain

C. Brandenburg[1], *A. J. Griswold*[2], *D. Van Booven*[2], *D. Dykxhoorn*[2], *M. A. Pericak-Vance*[2] *and G. J. Blatt*[1], *(1)Hussman Institute for Autism, Baltimore, MD, (2)John P. Hussman Institute for Human Genomics, University of Miami Miller School of Medicine, Miami, FL*

Background: There is growing consensus that the cerebellum has a major role underlying autism phenotypes. This is mainly due to the consistent neuropathological findings of reduced Purkinje cell (PC) number and altered molecular profile in autism, as well as differences found in imaging studies. PCs have abundant spines, which modify their shape and function in response to stimuli and have been shown to be involved in cerebellar motor learning. In autism, many of the genes implicated by genome wide association studies (GWAS) affect synaptic stability and adhesion molecules. Since PCs have hundreds of thousands of synapses, making their dendritic branching the most complex in the brain, mutations in synaptic proteins may be particularly detrimental to PC signaling and survival and could provide a mechanism behind the PC alterations reported in human postmortem autism studies.

Objectives: To determine differences specifically in the transcriptomic profile of Purkinje cells in postmortem autism brain compared to neurotypical controls.

Methods: Age-matched brain tissue was obtained from the University of Maryland Brain and Tissue Bank. Twenty autism and nineteen control fresh frozen human lateral hemisphere (crus II) cerebellar sections were cut at 8µm onto membrane slides and briefly fixed in 75% ethanol, dipped into RNase free water, exposed to a rapid Cresyl violet solution and placed in a series of alcohols for dehydration. A Zeiss PALM MicroBeam laser capture microdissection system was used to outline PCs by morphology and cerebellar architecture and lift them from the slide to isolate ~1,500 PCs per case from the surrounding cerebellar tissue. The cells were lysed and RNA extraction performed with a Qiagen RNeasy Micro Kit. The resulting total RNA was prepped for sequencing with the NuGEN Ovation SoLo RNA-Seq system and sequenced in single end 100bp reactions on the Illumina NovaSeq 6000 generating ~25M reads. Raw reads were aligned to the hg19 human reference genome and quantified using the STAR algorithm. Differential expression between autism and control samples were determined using DESeq2 adjusting for sex, age, post-mortem interval, and self-reported race.

Results: Overall, we identified 481 differentially expressed genes between autism and control PCs using a threshold of nominal p-value 0.05 and a fold change of +/- 1.5. This includes 57 genes upregulated and 424 downregulated in autism. There are no consistent molecular pathways overrepresented in the up-regulated genes. In contrast, the downregulated genes are over-represented for gene ontology biological processes related to synapse maturation (e.g. *NEUROD2, RELN,* and *DAB2IP*) and semaphorin-plexin guidance signaling (e.g. *NRP1, SEMA3C, SEMA4C, SEMA3B,* and *PLXNA2*). Furthermore, KEGG pathways including MAPK signaling and axon guidance are enriched in the downregulated genes.

Conclusions: Identification of altered gene expression in PCs of autistic individuals compared to controls is a critical step for understanding the complex pathobiology of autism. Our data implicate downregulation of genes involved in synaptic formation, axon extension, and MAPK signaling in PCs that likely result from activity-dependent alterations in pathways reliant on proper synaptic functioning.

321.002 *(Oral)* Genomic Analysis of 10,242 Individuals with Autism Spectrum Disorder (ASD) Recruited Online Identifies 161 Risk Genes and New Insights into the Genetic Architecture of Multiplex Families

X. Zhou[1], *T. Wang*[2], ***P. Feliciano***[3], *J. Hall*[3], *S. C. Murali*[2], *N. Zhu*[1], *S. Bruce*[1], *I. Astrovskaya*[4], *L. Brueggeman*[5], *S. Xu*[4], *T. N. Turner*[6], *C. Volfovsky*[4], *E. E. Eichler*[2], *Y. Shen*[1] *and W. K. Chung*[4,12], *(1)Department of Systems Biology, Columbia University, New York, NY, (2)Department of Genome Sciences, University of Washington, Seattle, WA, (3)SFARI, Simons Foundation, New York, NY, (4)Simons Foundation, New York, NY, (5)Psychiatry, University of Iowa, Iowa City, IA, (6)Department of Genetics, Washington University, St. Louis, MO, (7)Molecular & Medical Genetics, Oregon Health & Science University, Portland, OR, (8)Boston Children's Hospital, Boston, MA, (9)SPARKForAutism.org, New York, NY, (10)Harvard Medical School, Boston, MA, (11)Division of Computational and Molecular Psychiatry, Iowa City, IA, (12)Department of Pediatrics, Columbia University, New York, NY*

Background: Previous studies have identified ~100 high-confidence risk genes for autism spectrum disorder (ASD). However, modeling of *de novo* variants suggests that the majority of risk genes remain to be discovered. For simplex families, contributions from DNMs are well-established, but this is less clear in multiplex families. Moreover, the relative contribution of rare, inherited variants in either family context has yet to be fully elucidated.

Objectives: To accelerate gene discovery and genotypic-driven research and treatments in ASD, we created SPARK (Simons Foundation Powering Autism Research for Knowledge), and have recruited and collected DNA from 39,981 individuals with ASD in addition to many first degree family members, yielding the largest single collection of autism families to date.

Methods: We have performed exome sequencing and SNP genotyping on 28,757 individuals, including 10,242 with ASD.

Results: We analyzed single nucleotide (SNV)/indel and copy number variants (CNVs) in 6,574 offspring with ASD from 4,824 simplex and 1,080 multiplex families, their biological parents and 3,040 unaffected siblings. A small percentage of families already had a known genetic diagnosis (2.8%) related to their ASD, most of which were well-established CNVs associated with increased risk of ASD. We identified variants in genes and loci that are clinically recognized significant contributors to ASD in an additional 6.7% of families and nearly doubled the number of risk genes associated with ASD. We identified 251 large *de novo* CNVs, which occur at twice the frequency in probands as in unaffected siblings. We also performed a meta-analysis on 7,039 SPARK trios and 9,216 published ASD trios using *de novo* SNVs and indels with TADA. At a false discovery rate (FDR) of 0.1, we identified 161 candidate risk genes that harbor damaging *de novo* variants in ASD cases. Of these genes, 73 are newly discovered ASD candidates. These new candidate genes converge upon functional categories similar to those previously implicated in ASD, including RNA-binding (*HNRNPD, CAPRIN1*), transcriptional regulation (*PBX1, ZBTB45, ZC3H4, RFX8, BRF1, BRF2, INTS7, INTS2,TNPO3*), and neuronal communication (*GABBR2, DLL1, TANC2*). We found evidence supporting greater inherited contribution in multiplex vs. simplex families. Parents in multiplex families carry significantly more rare protein-truncating variants in constrained genes (ExAC pLI>=0.5) than parents in simplex families (rate=0.65 vs 0.60 per person, p=7.8e-3), and multiplex cases have significant contributions from both *de novo* and rare transmitted variants (population attributable risk (PAR)=14% and 7%, respectively), whereas simplex cases have a much higher contribution from de novo (PAR=18%) compared to transmitted variants (PAR=3%).

Conclusions: Genomic analysis of the SPARK cohort has led to the discovery of a substantial number of new genetic risk factors for ASD. We have also identified a greater inherited contribution of rare severe mutations in multiplex families compared to the more heavily studied simplex families. Further analyses of the SPARK dataset will contribute to a deeper mechanistic understanding of the pathways that are disrupted in ASD and enable research studies on rare genetic etiologies.

321.003 *(Oral)* 11,364 Whole-Genome Sequences in the Cloud for Autism Spectrum Disorder Research

B. Trost[1], D. Hartley[2], B. Thiruvahindrapuram[1], J. Whitney[1], R. V. Patel[1], J. Howe[1], M. Bookman[3], J. Fuerth[4], J. Noppornpitak[4], H. Ward[4], P. Magee[4], M. Fiume[4], V. Seifer[2], M. Quirbach[2], R. K. Yuen[1], M. Zarrei[1], J. Sebat[5], D. Glazer[6], T. W. Frazier[2] and ***S. W. Scherer***[1]*, (1)The Hospital for Sick Children, Toronto, ON, Canada, (2)Autism Speaks, New York, NY, (3)Verily Life Sciences, San Francisco, CA, (4)DNAstack, Toronto, ON, Canada, (5)University of California - San Diego, La Jolla, CA, (6)Verily Life Sciences, South San Francisco, CA*

Background: Autism spectrum disorder (ASD) is a highly heterogeneous condition in both clinical presentation and genetic architecture. There are hundreds of loci associated with ASD, with multiple types of rare and common variation contributing to risk. To fully understand the genetic basis of ASD, whole-genome sequence (WGS) data are necessary, which theoretically allow the genome-wide detection of all sizes and types of genetic variants with base-pair resolution.

Objectives: Our objective is to build a WGS resource that allows researchers to better understand the relationships between genotype and phenotype in ASD-affected individuals.

Methods: We have developed MSSNG, a controlled-access resource that contains both WGS data and detailed phenotype data from individuals with ASD and their family members. Hosted on the Google Cloud Platform (GCP), MSSNG is accessible through a web-based portal (https://research.mss.ng) or, for advanced users, via GCP interfaces.

Results: The latest release of MSSNG, termed DB6, contains 11,359 genome sequences. Alignment data (GRCh38/hg38) are available in CRAM format, along with single nucleotide variants, small insertions/deletions, and mitochondrial variants. Additionally, we employed an accurate, previously-published workflow to detect copy number variants (CNVs), making MSSNG the only ASD WGS resource to make sample-level CNV calls available. The CNV data are fully integrated into the portal, allowing users to query by sample, gene, or genomic region and to filter by size, population frequency, and other attributes. Detailed CNV annotations are available, including overlap with genes, exons, and repetitive genomic regions, as well as disease-related annotations from CGD, ISCA, HPO/MPO, OMIM, and others. Users can also visualize CNVs via an Integrative Genomics Viewer browser plugin.

Compared to the previous release, DB6 includes more advanced querying capabilities, especially for phenotypes. Specifically, MSSNG includes detailed phenotype information for most affected individuals in the form of individual responses, subscale totals, and full totals on a variety of psychometric assessments (5,829 measures and growing). DB6 introduces new composite measures for Adaptive Behaviour, Socialization Scores, and General Ability that enable researchers to filter, group, and correlate by these traits without having to identify the relevant scores among the individual measures. Further, DB6 features a new data query and exploration tool that enables researchers to search by genotype and phenotype in a single query. Built atop Global Alliance for Genomics and Health (GA4GH) standards that allow querying across organizational boundaries seamlessly and securely, the data explorer provides researchers even more statistical power through connections to other databases built on the same standards.

Finally, to enable functional analysis of candidate variants, we have generated 66 iPS-derived neuronal cell lines from individuals with ASD and their familial controls, as well as another 25 lines using CRISPR modelling in an isogenic line, all available to qualified researchers upon request.

Conclusions: The Autism Speaks MSSNG project combines high-quality WGS data with detailed phenotype information to allow researchers to study the genetic architecture of ASD. WGS data generation is ongoing, and updates to MSSNG with increased sample sizes, along with additional types of information such as structural variants and epigenetic data, will be made regularly.

321.004 *(Oral)* Variation of hnRNP Encoding Genes and Shared Neurodevelopmental Disorders

Background: With the number of genes implicated in neurodevelopmental disorders (NDDs), it is unlikely that each gene has a unique molecular pathomechanism. We hypothesize that variation in gene families results in shared clinical spectrums due to shared molecular pathology, which may allow for targeted therapies. We identified a gene family, the heterogeneous ribonucleoproteins (hnRNPs), a large family involved in RNA processing, as a family fitting our model, with significantly more *de novo* variants than expected among 10,927 NDD exomes.

Objectives: We aim to explore the impact of hnRNP variation in neurodevelopmental disorders and determine the molecular consequences of such variation.

Methods: We identified additional hnRNP-variation probands through targeted sequencing data from our Autism Spectrum/Intellectual Disability network (n = 16,377), exome data from the SPARK consortium (n = 6,499), clinical sequencing data generated by Baylor Genetics Laboratories (n = 9,536), collaborations through GeneMatcher and international collaboration (n = 15), exome data from GeneDx (n = 15,180), rare variants from Geno2MP (n = 10,892), as well as the literature (in total, 74,004). We identified 197 probands with variation in 13 hnRNP-encoding genes.

Human fetal transcriptomic data was generated from single cell RNA-seq (scRNA-seq) of cortex samples. Using Cas9 gene-edited induced pluripotent stem cells and differentiated neuronal and glial cells, we are investigating changes in cell viability/proliferation, neuronal morphology and activity, as well as hnRNP-specific functionality, including effects on splicing and expression, as well as RNA/protein trafficking.

Results: Our cohort has significantly higher burden of hnRNP variation compared to gnomAD (non-neuropsychiatric subset, n = 114,704), supporting their pathogenicity. Using two statistical models, three hnRNPs meet genome-wide significance ($p < 5x10^{-7}$) for likely gene disrupting (LGD) and/or missense variants, while and additional five meet nominal significance ($p < 0.05$). Clinically, we have found a shared spectrum of intellectual disability/developmental delay (78%), autism spectrum disorder (ASD, 35.6%), and MRI abnormalities (40.8%). ASD is significantly more prevalent with LGD variants ($p < 0.05$) and seen primarily among *HNRNPUL2* and *SYNCRIP* probands (62.5% and 61.5%, respectively).

scRNA-seq of fetal human cortex samples shows high levels of expression of these NDD-related hnRNPs among excitatory neurons, radial glia, ventral progenitor cells, and intermediate progenitor cells, with decreased expression among inhibitory and newborn neurons. This shared expression is notable, as hnRNPs are implicated in many processes, including neuronal development, and often work cooperatively. Molecular modeling has shown changes in expression of ASD-relevant genes as well as other functional impacts, such as changes in protein localization.

Conclusions: We show that the hnRNPs have clinical relevance for NDDs. Additionally, we have shown that it is effective and efficient to study gene families in order to expedite NDD research. Finally, we have determined some of the molecular characteristics of the hnRNPs as well as pathomechanisms of variation this gene family. These results will contribute to identifying shared, druggable targets that may have utility for NDD probands.

POSTER SESSION — **MOLECULAR GENETICS**

431 - Molecular Genetics Posters

431.001 *(Poster)* An Integrated Deep Mutational Scanning Approach Provides Clinical Insight on PTEN Genotype-Phenotype Relationships

*T. L. Mighell[1], S. T. Thacker[2], E. Fombonne[3], C. Eng[4] and **B. J. O'Roak**[1], (1)Molecular & Medical Genetics, Oregon Health & Science University, Portland, OR, (2)Genomic Medicine Institute, Lerner Research Institute of Cleveland Clinic, Cleveland, OH, (3)Psychiatry, Pediatrics & Behavioral Neurosciences, Oregon Health & Science University, Portland, OR, (4)Genomic Medicine, Cleveland Clinic, Cleveland, OH*

Background:

Germline *PTEN* variants lead to heterogenous clinical presentations including overgrowth and cancer predisposition syndromes collectively known as PTEN Hamartoma Tumor Syndrome (PHTS) as well as neurological presentations such as autism spectrum disorder, developmental delay, and intellectual disability (referred to here as ASD/DD). Despite decades of research, it remains unclear why certain *PTEN* variants lead to PHTS versus ASD/DD outcomes. Recently, a novel experimental paradigm known as deep mutational scanning (DMS) has been applied to PTEN. These data provide the biochemical effects of thousands of protein variants, which have been measured in parallel. For PTEN, two datasets were generated in which the lipid phosphatase activity (fitness score), or the general cellular abundance (abundance score) were empirically estimated for thousands of variants. These datasets represent measurements for 86% and 54% of all single amino acid substitutions for fitness and abundance scores, respectively.

Objectives:

In this study, we leveraged two DMS datasets, along with the largest well-curated clinical cohort of PTEN-variant carriers, to uncover clinically relevant genotype-phenotype relationships for PTEN.

Methods:

A custom machine learning approach was used to learn patterns of variant tolerance from the measured variants, and then predict scores of un-measured variants with high accuracy. These complete datasets were then explored to identify relationships between variant effect and clinical outcome.

Results:

First, we found that fitness and abundance scores are related to quantitative clinical traits, including head circumference and CC score (Cleveland Clinic score, a semi-quantitative measure of disease burden). These relationships validate that our DMS datasets reflect clinical outcomes. Fitness and abundance scores, along with CADD scores, were used to build a model that accurately identifies pathogenic versus benign *PTEN* variation (AUC = 0.892). Next, we sought to understand how the fitness or abundance score of a *PTEN* variant modulated lifetime cancer risk. We identified a ~10-fold increased lifetime risk of cancer for individuals with compromised fitness and abundance scores versus individuals with wild-type like fitness and abundance scores. We also observed increased risk of early onset cancer in highly damaging missense variants as compared to nonsense, potentially indicating a dominant negative mechanism. Finally, we find that classes of functional scores have significantly different risk levels for developing core features of PHTS with odds ratios ranging from ~10–100 depending on the variant effect. In striking contrast, ASD/DD risk does not change significantly across variant severity classes with odds ratios of 5-10.

Conclusions:

We show here that combining DMS datasets and well-curated clinical cohorts can lead to powerful clinical insights. We generated a *PTEN* pathogenicity predictor that outperforms all prior tools. We find that lifetime risk of cancer is strongly dependent on the severity of *PTEN* variant. This framework can inform clinicians as they make decisions regarding screening and treatment, and will help herald time and resources. Finally, we demonstrate that the risk pattern for developing ASD/DD versus PHTS features is strikingly different, providing further evidence that the penetrance of these phenotypes is driven by different underlying molecular or cellular processes.

431.002 *(Poster)* Characterizing Germline and Mosaic Mutations and Their Integrated Roles in the Biological Mechanisms Underlying Autism Risk

A. Nishida[1], *L. Brueggeman[2], J. Michaelson[3] and B. J. O'Roak[1], (1)Molecular & Medical Genetics, Oregon Health & Science University, Portland, OR, (2)Psychiatry, University of Iowa, Iowa City, IA, (3)Division of Computational and Molecular Psychiatry, Iowa City, IA*

Background: Studies on autism spectrum disorder (ASD) cohorts have identified a strong burden of germline *de novo*mutations (GDMs). We and other have also identified postzygotic mosaic mutations (PMMs) within these ASD cohorts. From our analysis of data from the Simons Simplex Collection (SSC), we estimated that PMMs contribute risk to at least 3-4% of simplex ASD cases. The roles and overlaps of the targets of these mutation classes remain to be fully elucidated. However, we previously found preliminary evidence that GDMs and PMMs show different geneset enrichments. For example, missense PMMs were enriched for disrupting chromatin remodelers while missense GDMs were not. We hypothesized that germline and mosaic mutations are enriched within distinct biological pathways, developmental time points, and cell types. Here, we test this hypothesis evaluating germline and mosaic mutations in the SSC using new ASD risk gene scoring approaches and single-cell datasets.

Objectives: To characterize the role of mosaicism in ASD and the underlying biological mechanisms altered by germline mutations, mosaic mutations, or both.

Methods: Mutation calls from the SSC were obtained from Krupp et al. 2017. Scores from forecASD, a random forest machine learning framework trained on known risk genes and diverse genome-scale datasets (Brueggeman et al., 2018), were used to rank mutations.Single-cell RNA-seq data of cortex development were obtained across 4,261 cells (Nowakowski et al. 2017). Early newborn excitatory neurons were compared against late newborn excitatory neurons using a Wilcoxon rank sum test. Enrichment analyses were performed for germline and mosaic mutations by comparing probands to unaffected siblings.

Results: Unlike other ASD risk gene approaches,forecASD scores are predictive of risk genes implicated by diverse datasets and have been highly predictive of new ASD risk genes that appeared after the development of the tool [e.g., 12/16 genes new genes in the iHART study are in forecASD's top decile (Ruzzo et al., 2018)]. In the SSC, we found forecASD score rankings were strongly biased for proband nonsynonymous PMMs compared to siblings (Wilcoxon rank sum, p = 0.0049), further suggesting these mutations are contributing to ASD risk. Moreover, proband PMMs were enriched in the top forecASD decile (binomial; pro: 44/195 [22.6%], p = 2.5 x 10^{-7}; sib: 18/138 [13%], p=0.25). Within single-cell RNA-seq data, proband nonsynonymous PMMs showed an ~2-fold enrichment genes that are differentially expressed in early versus later born neurons, while GDMs had no enrichment. We are in the process of replicating these results within the SPARK cohort.

Conclusions: These findings demonstrate that forecASD is robust against preference of genetic risk mechanisms, making it an ideal choice for interpreting putative risk from both GDMs and PMMs. Our integrated approach allows us to validate and capture a wider breadth of mutations contributing to ASD and classify their likelihood of ASD risk, developmental trajectories, and functional cell-types. This increased level of specificity gives deeper insight into the genetic architecture and pathophysiology of ASD and establish an analysis framework for future large-scale ASD datasets such as SPARK.

431.003 *(Poster)* Comprehensive Integrative Analyses Identify TIGD5 As a Risk Gene for Autism Spectrum Disorder

*X. Xie[1], L. Li[2], H. Wu[1], F. Hou[2], Y. Chen[2], Q. Xue[1], Y. Zhou[1], J. Zhang[3], J. Gong[2] and **R. Song**[1], (1)Department of Maternal and Child Health and MOE Key Lab of Environment and Health, School of Public Health, Tongji Medical College, Huazhong University of Science and Technology, Wuhan, China, (2)Maternity and Children Health Care Hospital of Luohu District, Shenzhen, China, (3)Department of Epidemiology and Biostatistics, Arnold School of Public Health, University of South Carolina, Columbia, SC*

Background: The past decade has witnessed tremendous progress in genome-wide association studies (GWAS) on autism spectrum disorder (ASD), and a number of genome-wide significant variants/loci have been identified. However, due to the limitations of GWAS, such as the issue of false-positives that results from multiple hypotheses, how to pinpoint the causal genes at the reported loci remains a challenge.

Objectives: This study aimed to pinpoint the potential causal genes for ASD and explored the possible susceptibility and mechanism.

Methods: The convergent functional genomics (CFG) method was used to prioritize the candidate causal genes for ASD by combining the lines of evidence from different analyses. The evidence from different layers included *Sherlock* integrative analysis using large-scale Psychiatric Genomics Consortium (PGC) GWAS and brain eQTL from Myers et al., spatio-temporal expression pattern, expression analysis from Gene Expression Omnibus, protein-protein interaction, and co-expression. Evidence from each analysis contributed one point to the studied genes and a higher total score in CFG approach suggested that more evidence supported this gene as an ASD risk gene. For the identified causal genes with higher CFG scores, we tested whether the variants in the candidate causal genes were associated with ASD in a Chinese Han population with the sample size of 602 ASD cases and 604 healthy controls. The functional effect of risk polymorphisms was characterized with a dual-luciferase reporter assay system. A workflow diagram was provided to illustrate the above analyses in Fig. 1.

Results: We identified five genes (*MAPT, ZNF285, TIGD5, SMAD9, RGS16*) as candidate causal genes for ASD using the CFG approach. The genotyping experiment showed that the *TIGD5* rs75547282 polymorphism was significantly associated with an increased risk of ASD for the T allele and TC genotype (respectively OR=1.253, 95% CI=1.051-1.493, *P*=0.030; OR=1.328, 95% CI=1.036-1.702, *P*=0.042) after adjustment for multiple tests using the Benjamin-Hochberg method. The mutant-type of rs75547282 activated the expression of *TIGD5* comparing to the wide-type in dual-luciferase reporter assay.

Conclusions: The comprehensive integrative analyses suggested that *TIGD5* was the most promising candidate gene for ASD. Rs75547282 polymorphism of *TIGD5* might confer susceptibility to ASD in the Chinese Han population.

431.004 *(Poster)* DNA Copy Number Variants Analysis from Whole Genome Sequencing in Families with Non-Syndromic Autism Spectrum Disorders

*Y. Qiao[1], K. Calli[1], S. Martell[1], H. MacRitchie[1], C. Chijiwa[2], S. Jones[3], E. Rajcan-Separovic[4], S. W. Scherer[5] and **M. S. Lewis**[1], (1)Medical Genetics, University of British Columbia, Vancouver, BC, Canada, (2)University of British Columbia, Vancouver, BC, Canada, (3)Canada's Michael Smith Genome Sciences Centre, Vancouver, BC, Canada, (4)Pathology, University of British Columbia, Vancouver, BC, Canada, (5)The Hospital for Sick Children, Toronto, ON, Canada*

Background: De novo pathogenic DNA copy number variants (CNVs) contribute to the causes of Autism Spectrum Disorder (ASD) in ~10% of cases, standardly identified by chromosome microarray analysis (CMA). Whole genome sequencing (WGS), as a state-of-the art and high throughput technology, has improved ASD diagnosis by an additional 20%, mainly by discovering single nucleotide variants (SNVs) and small insertions and deletions (indels). The ability to detect CNVs from WGS is becoming more and more important in promoting WGS as an all-inclusive first-tier genetic test for neurodevelopmental disorders in the clinic setting.

Objectives: To compare the CNVs identified from WGS and clinical diagnostic CMA in families with ASD.

Methods: A total of 38 probands with ASD were screened for CNVs using both CMA from clinical diagnostic service laboratories (using the Affymetrix CytoScan as the gold-standard platform for CNV detection) and WGS (Illumina HiSeqX)coupled with analysis via commercial VarSeq software from Golden Helix.

Results: By CMA, 42 CNVs (4 de novo, 4 paternal, 11 maternal and 1 unknown origin) were reported as pathogenic or as variants of unknown significance (VUS) in 14 out of 36 patients. The size ranged from 110 Kb to 3.5 Mb. Normal array results were reported in 22 subjects. Using our VarSeq CNV algorithm (WGS-VarSeq) (setting 10Kb segments as minimum detection distance in the genome), all of the 42 CNVs were identified by WGS except one, a 110 Kb duplication at 2q31.2(179397560-179508251, hg19) of unknown origin involving *TTN* found in one of 3 autistic children in one family. In addition, WGS-VarSeq also detected 3 additional non-redundant CNVs in 7 patients who already had VUS CNVs identified from clinical CMA: 1) arr[hg19] Xq11(38480001-38580000)x3, mat, 100 Kb, involving single gene *TSPAN7*. 2) arr[hg19]17p11.2(18560001-18930000)X3 mat, 370Kb in size, shared by all 3 affected, within the Smith-Magenis Syndrome region. 3) arr[hg19]17q11.2(29300001-29330000)X3 pat, 30Kb in size, involving a single gene *RNF135*, shared by all 3 affected children within the NF1-microdeletion syndrome region. However, no additional positive CNVs were detected by WGS-VarSeq among the 22 patients with reported normal CMA results.

Conclusions: CNVs reported by clinical diagnostic service laboratories can be reliably detected from WGS data using VarSeq software. A limited number of additional CNVs were detected by WGS-VarSeq, however, this does not increase the CNV detection rate due to the co-existence of these CNVs with other CNVs reported by CMA in the same patient. In addition, small CNVs, especially <10Kb, cannot be identified using the current algorithm of VarSeq.

431.005 *(Poster)* Differences in the Genetic Background Contribute to Risk and Resilience to Autism

T. Rolland[1], F. Cliquet[1], R. J. Anney[2], A. Mathieu[1], G. Huguet[3], A. Vaysse[4], C. Leblond[5], E. A. Douard[3], A. Maruani[6], F. Amsellem[7], A. Packer[8], S. Jacquemont[3], R. Delorme[9,10] and ***T. Bourgeron***[11]*, (1)Institut Pasteur, Paris, France, (2)MRC Centre for Neuropsychiatric Genetics and Genomics, Cardiff University, Cardiff, United Kingdom, (3)UHC Sainte-Justine Research Center, University of Montreal, Montreal, QC, Canada, (4)Human genetics and cognitive functions, Institut Pasteur, Paris, France, (5)Institut PASTEUR, Paris, France, (6)hopital robert debre, paris, FRANCE, (7)Pasteur, Paris, France, (8)Simons Foundation, New York, NY, (9)Excellence centre for Autism and Neurodevelopmental disorders, Paris, France, (10)Pasteur Institute, Human Genetic and cognitive function, Paris, France, (11)Human Genetics and Cognitive Functions, Institut Pasteur, Paris, France*

Background: The genetic architecture of autism spectrum disorders (ASD) is complex. If rare deleterious variants in more than 100 genes are now well-accepted risk factors for ASD, the genetic basis of the incomplete penetrance of the variants remains poorly understood.

Objectives: Here, we investigated the genetic architecture of "resilient" individuals, carrying ultra-rare deleterious variants in ASD-associated genes or loci from the SPARK gene list without being diagnosed with the condition.

Methods: We designed a framework to assess the risk associated to ultra-rare deleterious mutations in parents and children of 1,201 quadruplet families with one affected and one unaffected child of the Simons Simplex Collection. We investigated hallmarks of mutation intolerance (haploinsufficiency, probability of loss-of-function mutation intolerance, z-score for missense mutation or deletion intolerance) to discriminate mutations likely to affect gene function. We also used clinical records available for each family to focus on mutations identified in children displaying a clear discordance in ASD phenotype.

Results: We identified ultra-rare deleterious variants affecting ASD-associated genes in approximately 8% of non-ASD relatives. Within children with inherited ultra-rare deleterious variants, we observed a slight enrichment of girls among resilient individuals, in line with the reported sex-specific penetrance of rare mutations in ASD. In addition, probands received higher genome wide polygenic score for ASD than expected ($p = 4.5x10^{-8}$) whereas the siblings received less ($p = 0.0034$). We propose a model according to which the penetrance of ultra-rare deleterious variants in ASD-associated genes strongly depends on the sex and the genetic background of each individual.

Conclusions: The genetic background significantly influences the clinical trajectory of siblings carrying similar deleterious mutations in ASD-associated genes. We are currently investigating other ASD cohorts as well as control populations to further investigate the genetic factors contributing to resilience for ASD. This work provides new insights into the molecular mechanisms of ASD, ultimately allowing the development of novel therapeutic strategies.

431.006 *(Poster)* Genetic Architecture of Autism Spectrum Disorder without Intellectual Disability

J. Zhang[1]*, A. Ghorai[2], S. C. Taylor[3], H. C. Dow[2], B. N. Gehringer[2], A. Langer[2], E. Rawot[2], L. S. Perez[2], M. Goodman[2], A. A. Pallathra[4], S. D. Elkhatib Smidt[2,5], D. J. Rader[6], L. Almasy[6], E. S. Brodkin[7] and M. Bucan[6], (1)Graduate Group in Epidemiology and Biostatistics, University of Pennsylvania, Philadelphia, PA, (2)University of Pennsylvania, Philadelphia, PA, (3)Graduate Group in Neuroscience, University of Pennsylvania, Philadelphia, PA, (4)Department of Psychiatry, Catholic University of America, Washington, DC, (5)Children's Hospital of Philadelphia, Philadelphia, PA, (6)Department of Genetics, University of Pennsylvania, Philadelphia, PA, (7)Department of Psychiatry, University of Pennsylvania, Philadelphia, PA*

Background: The genetic architecture of autism spectrum disorder (ASD) is complex and involves a combined effect of common and rare variants that are either inherited or arose *de novo*. Prior efforts to understand the genetic etiology of ASD have focused on the recruitment of children with ASD and their first-degree relatives, specifically parents and siblings. To complement ongoing large-scale efforts, The Autism Spectrum Program of Excellence (ASPE) at the University of Pennsylvania is focusing on the recruitment and genetic analysis of adults with ASD without intellectual disability (ID) and their extended families.

Objectives: The goal of the program is to study the genetic basis of variation in phenotypic expression within and across families with ASD by integrating the effects of common and rare variants on a wide range of ASD behavioral traits, including sleep.

Methods: We have recruited over 200 families and obtained whole genome sequence (WGS) on 189 individuals. Pathogenic and likely pathogenic single-nucleotide variants (SNVs) and insertions and deletions (indels) were identified from WGS data using InterVar, which generates automated interpretation of the clinical significance of each variant based on the guidelines of the American College of Medical Genetics and Genomics and the Association for Molecular Pathology. We also used integrated Copy Number Variation detection algorithm (iCNV) to detect copy number variants (CNVs) in WGS. All SNVs, indels, and CNVs were validated using Integrative Genomic Viewer in the context of family pedigrees. Pathogenic and likely pathogenic SNVs and indels in known ASD risk genes, defined by the Transmitted And De Novo Association test on larger datasets, were identified.

Results: ASPE is ongoing with 189 individuals (81 ASD without ID probands and 108 relatives) with WGS currently. The average age of probands is 35 years old and 67% of them are male. The average age of relatives is 45 years old and 48% of them are male. We identified 299 pathogenic and likely pathogenic SNVs and indels in 160 genes. When comparing probands and relatives, 65% of the probands carried at least one of these variants compared to 44% of the relatives, $\chi^2(1, N=189)=8.194, p=.004$. In 10 individuals in ASPE (5.5%), 7 pathogenic and likely pathogenic SNVs and indels were found in 7 known ASD risk genes (*KMT2C, MAP1A, PTEN, TSC1*, *EIF3G, PHF21A, PHF2*). CNV analysis identified 1568 exonic CNVs that are absent from the Database of Genomic Variants. Of these CNVs, 700 are found in probands (8.64/person) while 868 are found in relatives (8.04/person).

Conclusions: In ASPE, ASD without ID probands are associated with a higher burden of pathogenic and likely pathogenic SNVs and indels compared to their relatives. Among 7 of the pathogenic and likely pathogenic SNVs and indels found in known ASD risk genes, 3 of them are found in *KMT2C*, which is a gene involved in histone methylation activity. The integrative analysis of variants of varying frequency, inheritance pattern and type (SNV, indel, and CNV), and a polygenic load for ASD will help us to better understand the genetic basis of ASD without ID.

431.007 *(Poster)* Integration of Polygenic Scores, Copy-Number Variants, Inbreeding and Ancestry Increases the Yield of Genetic Diagnostics for Neurodevelopmental Disorders in a Large Group of >13,000 Individuals

Tabet*[17], *(1)Institut PASTEUR, Paris, France, (2)Institut Pasteur, Paris, France, (3)Human genetics and cognitive functions, Institut Pasteur, Paris, France, (4)Université de Bordeaux, Bordeaux, France, (5)Hopital Pitié Salpétrière, Paris, France, (6)Hôpital Trousseau, Paris, France, (7)Hôpital Jean Verdier, Paris, France, (8)Hôpital Robert Debré, Paris, France, (9)hopital robert debre, paris, FRANCE, (10)CHU La Pitié Salpétrière,, paris, France, (11)CHU La Pitié Salpétrière,, Paris, France, (12)Hopital Jean-Verdier, Paris, France, (13)AP-HP, Robert-Debré Hospital, Child and adolescent Psychiatry unit, Paris, France, (14)Excellence centre for Autism and Neurodevelopmental disorders, Paris, France, (15)Pasteur Institute, Human Genetic and cognitive function, Paris, France, (16)Human Genetics and Cognitive Functions, Institut Pasteur, Paris, France, (17)AP HP, Robert Debre Hospital, Paris, France*

Background: Neurodevelopmental disorders (NDDs) are heterogenous, characterized by delays in global development, motor skills, and cognition, as well as intellectual disability and affect more than 3% of children worldwide.

Objectives: Over than 1000 loci have been associated to NDD but delineating the heritable genetic components or defining individual factors that predispose to NDD risk is still a challenge. Our study aims to dissect the genetic architecture of NDD.

Methods: We analyzed the largest group to date of individuals from France with neurodevelopmental disorders (NDD) coming from four hospitals of AP-HP, France (Robert Debré, Trousseau, La Pitié Salpétrière, Jean Verdier). The data from 8,300 patients, 2,000 relatives and 2,955 controls were collected from two Illumina SNP array platforms over 5 years (2013-2017). Patients were grouped according to the biomedicine agency categories: syndromic intellectual disability (S-ID; N=3047), multiple congenital anomalies (N=1025), isolated ID (N=1058), autism (N= 1864) and other (N=1742). The CNVs were called using QuantiSNP and PennCNV and then compared to CNV partition, the algorithm used for diagnosis. Genotyping data were also used to estimate the ancestry and to compute the inbreeding coefficient as well as the polygenic score for different traits such as autism and intelligence.

Results: The analysis of this large sample of patients with NDD revealed several important results: First, QuantiSNP and PennCNV outperform CNV partition for the detection of CNVs. The new algorithms could increase the yield of genetic diagnosis (e.g. three patients with SHANK3 deletions were identified). Second, patients with S-ID, ID or autism had a higher burden of CNV affecting genes associated with NDD/autism or expressed in the brain or intolerant for deleterious mutation (pLI>0.9) compared to controls. Interestingly patients with autism had also higher polygenic scores for autism compared to controls ($p<10^{-22}$) or other diagnostic categories ($p<10^{-3}$), confirming the strong polygenic contribution to autism. Third, we could find that a high level of inbreeding was a risk for S-ID and ID, but not for autism. Finally, the role of several genes will be discussed such as TRPM1, SHANK3, PTGER3, OTUD7A, MTMR10, PTGER3, SDHA, PIGW, HNF1B, GGNBP2, CCDC127, ACACA, KLF13, VPS37D, SPNS1, RIMBP3, BAZ1B and ATXN2L. These genes might be important to understand the shared and specific mechanisms leading to different clinical trajectories.

Conclusions: Our large-scale French study of NDD, combining new genetic approaches, provides a better yield of genetic diagnostic for NDD. It results from the collaboration between clinicians and quantitative geneticists through data sharing, standardization and multi-level analyses. In order to go further, more data such as whole genome sequencing and standardized clinical data from deep phenotyping will be necessary to provide better diagnostic and prognostic insight. We also observed a very high degree of heterogeneity in the ancestry of the population, which will require match ancestry controls in order to provide diagnostic to all individuals attending to the hospital in France, not only those from European descents for which we have control data.

431.008 *(Poster)* Multi-Model Functionalization of 106 PTEN Missense Mutations Identifies Multiple Molecular Mechanisms Underlying Protein Dysfunction

K. L. Post[1], *M. Belmadani*[2], *P. Ganguly*[2], *F. Meili*[2], *R. Dingwall*[2], *T. A. McDiarmid*[2], *W. M. Meyers*[2], *C. Herrington*[2], *B. P. Young*[2], *D. B. Callaghan*[2], *S. Rogic*[3], *M. Edwards*[2], *C. H. Rankin*[2], *T. P. O'Connor*[2], *S. X. Bamji*[2], *C. J. Loewen*[2], *D. W. Allan*[2], *P. Pavlidis*[2] *and* ***K. Haas***[2], *(1)University of British Columbia, Vancouver, BC, CANADA, (2)University of British Columbia, Vancouver, BC, Canada, (3)MSL and Department of Psychiatry, University of British Columbia, Vancouver, BC, Canada*

Background: Sequencing efforts of individuals with autism spectrum disorder (ASD) have identified large numbers of gene variants of unknown significance (VUS) to protein function, yet this knowledge is critical for linking genetic variation to disease expression, outcome and treatment. The utility of investigations to assess variant impact is dependent on application of appropriate assays to evaluate all aspects of a protein's function.

Objectives: Here, we seek to fully assess the effects of 106 missense and nonsense variants of PTEN associated with ASD, somatic cancer and PHTS.

Methods: We take a deep phenotypic profiling approach using 18 assays in 5 model systems spanning diverse cellular environments ranging from protein stability and molecular function to neuronal morphogenesis and behavior. Model systems include yeast, fly, worm, rat primary neuronal culture, and human cell lines.

Results: We find that protein instability is a major mechanism of dysfunction for variants altering amino acids across the entire protein structure. Other variants, located in discrete functional domains including the N-terminus substrate binding and the catalytic domains exhibited impacts ranging from loss of function to dominant negative phenotypes independent of effects on stability. Results indicate that 31 of the 48 variants tested from ASD individuals are likely pathogenic and 2 are likely benign and not causal.

Conclusions: Our results indicate that full characterization of variant impact requires assays sensitive to instability and a range of protein functions.

431.009 *(Poster)* Predictive Impact of Rare Genomic Copy Number Variations in Siblings of Individuals with Autism Spectrum Disorders

L. D'Abate[1], *S. Walker*[1], *R. K. Yuen*[1], *K. Tammimies*[2], *J. A. Buchanan*[1], *R. W. Davies*[3], *B. Thiruvahindrapuram*[1], *J. Wei*[1], *J. A. Brian*[4], *S. E. Bryson*[5], *K. R. Background: Identification of genetic biomarkers associated with autism spectrum disorders (ASDs) could improve recurrence prediction for families with a child with ASD.

Objectives: To use clinical microarray - the first-tier diagnostic test for developmental disabilities - to assess if copy number variants (CNVs) affecting ASD-related loci correlate (pre- and post-symptomatically) with phenotypic outcomes in the Baby Siblings Research Consortium (BSRC) cohort of infant siblings whose family history is associated with a higher probability of developing ASD.

Methods: We describe clinical microarray findings for 253 longitudinally phenotyped ASD families from the BSRC, encompassing 288 infant siblings.

Results: By age 3, 103 siblings (35.8%) were diagnosed with ASD and 54 (18.8%) were developing atypically. Thirteen siblings have copy number variants (CNVs) involving ASD-relevant genes: 6 with ASD, 5 atypically developing, and 2 typically developing. Within these families, an ASD-related CNV in a sibling has a positive predictive value (PPV) for ASD or atypical development of 0.83; the Simons Simplex Collection of ASD families shows similar PPVs. Polygenic risk analyses suggest that common genetic variants may also contribute to ASD.

Conclusions: CNV findings would have been pre-symptomatically predictive of ASD or atypical development in 11 (7%) of the 157 BSRC siblings who were eventually diagnosed clinically.

431.010 *(Poster)* Umbilical Cord Blood Gene Expression and 36-Month Autism-Related Quantitative Traits from an Autism-Enriched Cohort

J. I. Feinberg[1], *A. E. Jaffe*[2], *C. Ladd-Acosta*[1], *L. A. Croen*[3], *I. Hertz-Picciotto*[4], *C. J. Newschaffer*[5], *A. P. Feinberg*[6], *M. D. Fallin*[1] *and H. E. Volk*[1], *(1)Wendy Klag Center for Autism and Developmental Disabilities, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, (2)Lieber Institute for Brain Development, Baltimore, MD, (3)Division of Research, Kaiser Permanente, Oakland, CA, (4)University of California at Davis, Davis, CA, (5)College of Health and Human Development, Pennsylvania State University, University Park, PA, (6)Johns Hopkins University, Baltimore, MD*

Background: Few studies have used next generation sequencing to examine differential gene expression in cord blood specifically related to autism (ASD)-related outcomes. The EARLI Autism Risk Longitudinal Investigation (EARLI) is an ASD enriched-risk pregnancy cohort that provides a unique opportunity to study this tissue source in a high-risk set of individuals, an approach which might elucidate potential mechanisms of ASD etiology better than might be found in the general population.

Objectives: To examine the potential association between differential gene expression in umbilical cord blood collected at birth and three ASD-related quantitative outcomes assessed at 36 months in the EARLI cohort.

Methods: Cord blood RNA samples from 72 newborns in the EARLI cohort were used to measure genome-wide transcripts via the Illumina HiSeq 3000. Using the *limma* and *edgeR* packages in R we identified genes showing differential expression in relation to three autism-related quantitative traits at 36-months of age: the Social Responsiveness Scale (SRS) total score, the Mullen Scales of Early Learning (MSEL) composite score, and the Vineland Adaptive Behavior Scales (VABS)-2 composite total.

Results: After filtering out genes with low expression levels in preprocessing, only one gene (*EXOC7*) showed differential expression in relation to the MSEL composite total scores and passed a significance threshold of FWER $P < 0.05$. Further comparison of mean expression levels of *EXOC7* in cord blood between 36-month outcomes of ASD versus typical development did not show a significant difference. No differential expression in relation to SRS and VABS scores passed this threshold. However, using a relaxed significance threshold of $p<0.01$, we found 113 and 185 differentially expressed genes for SRS and MSEL, respectively. Further analyses exploring ASD gene enrichment, weighted gene correlation network analysis (WGCNA), and sex-stratified models are currently ongoing and will be reported.

Conclusions: Our work shows promising results in examining potential associations between differential gene expression levels in cord blood samples collected at birth and ASD-related quantitative traits at 36-months, however our ability to detect individual transcripts with global significance may be limited by sample size. Further analyses of gene networks and sex-specific models may identify new mechanisms related to ASD and cognitive development.

Molecular Neuroscience

POSTER SESSION — **MOLECULAR NEUROSCIENCE**
432 - Molecular Neuroscience Posters

432.001 *(Poster)* A Model for Neural Development of FOXP1 Syndrome Using Patient-Derived iPSCs

S. Stathopoulos[1], *M. S. Breen*[2], *N. Yang*[3], *J. Buxbaum*[4] *and E. Drapeau*[5], *(1)Psychiatry, Mount Sinai School of Medicine, New York, NY, (2)Psychiatry, Genetics and Genomic Sciences, Icahn School of Medicine at Mount Sinai, New York, NY, (3)The Friedman Brain Institute, Black Family Stem Cell Institute, New York, NY, (4)Department of Psychiatry, Icahn School of Medicine at Mount Sinai, New York, NY, (5)Seaver Autism Center for Research and Treatment, Icahn School of Medicine at Mount Sinai, New York, NY*

Background: Autism Spectrum Disorder (ASD) is characterized by high heritability and both phenotypic and genetic heterogeneity. One way to unravel some of the complexity of ASD is by focusing on single-locus disorders with high penetrance for causing ASD. Haploinsufficiency of the forkhead-box protein P1 (*FOXP1*) gene leads to FOXP1 syndrome, a neurodevelopmental disorder with a broad range of manifestations including ASD, intellectual disability, language impairment and psychiatric features. While animal models have provided valuable insight into the pathways that are dysregulated in *FOXP1* deficiency, human neuronal models are the closest proxy to study its underlying biology in a disease-relevant tissue. Induced pluripotent stem cells (hiPSCs) retain the full genetic background of the individual they derived from and have the advantage of being expandable and the possibility to differentiate into neural progenitor cells (iNPCs) and iNeurons.

Objectives: The overarching goal of this study is to improve our understanding of FOXP1 syndrome and identify candidate genes and pathways that could be targeted pharmacologically to alleviate its symptoms. To do this, we applied a multi-step approach that aimed to: 1) generate high-quality iPSC clones derived from *FOXP1* patients and siblings; 2) differentiate them into iNPCs and iNeurons, to capture their neurodevelopmental phenotype; 3) identify *FOXP1*-associated transcriptomic and methylomic signatures at different stages of development in iNPCs and iNeurons, by RNA sequencing and whole-genome DNA methylation screen.

Methods: Blood samples from 6 individuals with FOXP1 syndrome and their unaffected siblings were reprogrammed to iPSCs using a modified non-integrating Sendai virus to express reprogramming factors. For each individual, 2-3 clones were expanded for quality control (QC) and banking; those that passed QC were i) differentiated into iNPCs using a monolayer approach with PSC Neural Induction Media (Fisher) and ii) differentiated into inhibitory and excitatory iNeurons by viral transfection. To make GABAergic iNeurons, iPSCs were transduced with three viruses expressing a fused Ascl1-T2A-puromycin resistance gene, a Dlx2-hygromycin resistance gene and rtTA. To make glutamatergic iNeurons, lentiviruses expressing rtTA and a fused Ngn2-T2A-puromycin resistance gene were used. RNA and DNA were isolated from iNPC and iNeurons at three different timepoints of neural development, for RNA sequencing and whole-genome methylation screen.

Results: Six FOXP1 patient/sibling pairs were successfully reprogrammed to iPSCs with 2-3 clones per individual, subsequently used for iNPC and iNeuron generation. iNPCs and iNeurons were subjected to RNA sequencing and whole-genome DNA methylation assays for preliminary investigation into the early developmental molecular profiles of *FOXP1* syndrome. We find distinctive transcriptomic and DNA methylation signatures associated with *FOXP1* haploinsufficiency at different developmental stages, consistent with a central role for *FOXP1* in neurodevelopment and ASD etiology.

Conclusions: This is the first report of hiPSCs for FOXP1 syndrome, offering valuable insight into the early neurodevelopmental deficits associated with its etiology. Generating epigenomic and transcriptomic profiles for patient-derived iNPCs and iNeurons provides a unique perspective on the molecular pathways associated with FOXP1 syndrome, which can be used in conjunction with other models of the disease and known drug expression profiles to identify new therapeutics.

432.002 *(Poster)* Changes in the Developing and Mature Brain in Chd8 Heterozygous Mutant Mice

A. A. Wade[1], *C. P. Canales*[2], *C. E. Moyer*[3], *S. Frank*[4,5], *J. Bennett*[6], *Y. Zuo*[7], *D. G. Amaral*[8] *and* ***A. S. Nord***[1], *(1)Center for Neuroscience, Department of Neurobiology, Physiology, & Behavior, University of California, Davis, Davis, CA, (2)Center for Neuroscience | MIND Institute, Department of Psychiatry and Behavioral Sciences, University of California Davis, Davis, CA, (3)Molecular, Cell and Developmental Biology, UC Santa Cruz, Santa Cruz, CA, (4)MIND Institute, UC Davis, Davis, CA, (5)Department of Molecular Biology, Princeton University, Princeton, NJ, (6)UC Davis, Davis, CA, (7)UC Santa Cruz, Santa Cruz, CA, (8)Department of Psychiatry and Behavioral Sciences, The Medical Investigation of Neurodevelopmental Disorders (MIND) Institute, UC Davis School of Medicine, University of California Davis, Sacramento, CA*

Background: The gene encoding chromodomain helicase DNA binding protein 8 (*CHD8*) has one of the highest observed de novo loss-of-function mutation rates in patients with autism spectrum disorder (ASD). Mutations to *CHD8* have been suggested to drive pathology through global disruptions to gene expression and chromatin state. Neurobiology and pathological mechanisms associated with CHD8 haploinsufficiency remain to be fully elucidated and appear extend from embryonic development through the mature brain. Mouse models provide a system to examine impacts of ASD-relevant mutations on the mammalian brain, spanning the interval from early embryonic development to mature brain structure and function.

Objectives: We aim to define the pathological mechanisms associated with heterozygous mutation to *Chd8* through identifying convergence between *Chd8*-dependent gene regulation and dysfunction in the developing and mature brain using the mouse as a model. Here we focus on identifying phenotypes present in the mature cortex to determine neuronal pathology in *Chd8*$^{+/-}$ mice.

Methods: We previously identified differential RNA expression across brain development in *Chd8*$^{+/-}$ mice, which continues into the mature brain and is accompanied by increased brain size via structural MRI and neuroanatomy. Here, we have continued to examine phenotypes in the mature brain. In this work, we combined functional genomics, neuroanatomy and experimental characterization of synapse dynamics in adult mice that harbor heterozygous mutation to *Chd8*.

Results: Differential expression signatures were strong in adult cortex and implicate deficits in neuronal maturation and synaptic dysfunction. *In vivo* analysis of spine dynamics in *Chd8*$^{+/-}$ cortex showed that spine density was significantly lower and spine outgrowth was significantly increased with no change in spine elimination. Previously reported brain overgrowth in *Chd8*$^{+/-}$ mice was validated via stereological analysis of cerebral cortex, finding increased volume but no change in neuronal cell counts or nuclear volume. Studies in conditional mice with neuron-specific Chd8 haploinsufficiency are ongoing.

Conclusions: From these data we conclude that impacts of *Chd8* haploinsufficiency extend to mature brain and specifically in cortical neurons. Understanding underlying molecular mechanisms and the connection between stage-specific requirements for *Chd8* and ASD pathology will be important to help overcome current barriers in elucidating mechanisms underlying neurodevelopmental disorders.

432.003 *(Poster)* Hydrogen Peroxide and Estradiol Might be Associated with Autism Via Altered BCL2 Expression Level

***Y. Wen**, Neurology, Massachusetts General Hospital, Charlestown, MA; ietheory institute, Burlington, MA; Harvard Medical School, Boston, MA*

Background: Our previous studies investigated the overlaps between autism spectrum disorders (ASDs) and cancer in genes, signaling pathways, and mitochondria, and we found that BCL2 might play an important role in autism/cancer mechanisms. Several published studies found that the expression level of BCL2 was significantly decreased in autistic brain (45-47% less). Further, a study reported that rats with rapid eye movement (REM) sleep deprivation had decreased level of Bcl-2; while another study found that children with autism have less time in or even no REM sleep at all. These evidences showed that BCL2 had multi-level linkage to ASDs at gene, protein, pathway, and symptom.

Objectives: To examine the role of BCL2 in ASD pathophysiology, we set out to identify the compounds that may alter the expression level of BCL2 and their associations with ASDs.

Methods: We used a chemical-gene-disease database, Comparative Toxicogenomics Database (CTD), as our data source to investigate gene-chemical interactions in relation to BCL2-associated chemicals. 1) We used “BCL2” as the search term under the “Gene” category in CTD. Gene-chemical interaction data was downloaded under the “Chemical Interactions” sub-category for BCL2, we chose the top 10 chemicals that were intensively studied, which indicates that these gene-chemical interactions have been well-established. 2) Then, for each top interacting chemicals of BCL2, we investigated the interaction type “decreases^expression” and “increases^expression”. 3) We examined the “reference count” for each interaction type and determined if the chemical was more likely to decrease or increase the expression level of BCL2. 4) We searched PubMed for those top 10 interacting chemicals to see if they had any association to ASDs.

Results: The top 10 interacting chemicals to BCL2 are Arsenic Trioxide, Doxorubicin, Resveratrol, Cisplatin, Quercetin, Sodium Arsenite, Hydrogen Peroxide, Curcumin, Paclitaxel, and Estradiol. Among them, estradiol is more likely to increase the expression level while others are more likely to decrease the expression level of BCL2. arsenic trioxide, doxorubicin, cisplatin, sodium arsenite or paclitaxel have no published evidence suggesting any links to ASDs. Resveratrol and curcumin are reported to suppress neuroinflammation in animal models of ASD, while quercetin is reported to have anti-inflammation effect in children with ASDs when included in a luteolin-containing dietary intervention. Most interestingly, children with ASDs had higher (2 fold) mitochondrial rates of hydrogen peroxide production comparing to normal children, while hydrogen peroxide is more likely to decrease the expression level of BCL2. Estradiol is a form of estrogen (a sex hormone), which could reverse autism-like features in mice.

Conclusions: Overall, estradiol results in increased expression of BCL2 and may reverse autism-like features in mice; hydrogen peroxide results in decreased expression of BCL2 and its level in autistic children were found to be twice as high as in normal children. This is logically consistent with the finding that BCL2 level is decreased in autism brain by 45-47% less from previous studies. These findings support the idea that Bcl-2 level might be altered in autism and it could be a potential biomarker and therapeutic target.

432.004 *(Poster)* Shankopathies from Mechanisms to Treatments

*E. Ey[1], R. Delorme[2,3], C. Leblond[4], F. Cliquet[5], A. T. Ferhat[5], F. de Chaumont[5], K. Mouzat[6], A. Biton[7], M. Rachid[8], E. Verpy[8], A. Mathieu[5], F. Campana[5], J. Fumey[8], A. Bourgeron**[1], (1)Human Genetics and Cognitive Functions, Institut Pasteur, Paris, France, (2)Excellence centre for Autism and Neurodevelopmental disorders, Paris, France, (3)Pasteur Institute, Human Genetic and cognitive function, Paris, France, (4)Institut PASTEUR, Paris, France, (5)Institut Pasteur, Paris, France, (6)Laboratoire de Biochimie, CHU Nîmes, Nîmes, France, (7)Bioinformatics and biostatistics hub, Institut Pasteur, Paris, France, (8)Human genetics and cognitive functions, Institut Pasteur, Paris, France, (9)Human Genetics and Cognitive Functions Unit, Institut Pasteur, Paris, France, (10)hopital robert debre, paris, FRANCE, (11)Pasteur, Paris, France, (12)AP-HP, Robert-Debré Hospital, Child and adolescent Psychiatry unit, Paris, France, (13)Centre National de Recherche en Génomique Humaine, Evry, France, (14)Labex GENMED, Centre National de Génotypage-IG-CEA, Paris, France, (15)Laboratoire de biochimie et biologie moléculaire, CHU Nîmes, Nîmes, France, (16)AP HP, Robert Debre Hospital, Paris, France*

Background: The SHANK protein family is composed of three proteins SHANK1-3, which are synaptic scaffolding proteins located at glutamatergic synapses. Mutations in all SHANK genes have been associated with neurodevelopmental disorders (NDD), but with a gradient of cognitive severity. *SHANK1* mutations are associated with autism without intellectual disability (ID), *SHANK2* mutations are associated with autism and mild cognitive deficits and *SHANK3* mutations cause ID with autism in >60% of the cases. SHANK3 point mutations or deletions are detected in 1-2% of patients with autism and ID. The gene is located on chromosome 22q13.3, a region deleted in patients suffering from Phelan-McDermid syndrome (PMS), characterized by ID, severe language deficit, dysmorphic features and frequently autism (>60%). Remarkably, *de novo SHANK3* mutations were also detected in patients with schizophrenia and bipolar disorders, but the prevalence of these mutations remains to be better estimated.

Objectives: To develop better diagnostic and new treatments, our collaborative groups investigate SHANKOPATHIES from patients to mouse models. We aim at better understanding the variance in the clinical severity of patients with SHANK3 mutations. We use the mouse model mutated in exon 11 of Shank3 to explore the molecular bases of the phenotype. Finally, we aim at setting up a framework for the future clinical trial with Shank3 patients.

Methods: We first hypothesized that the variance in the clinical severity of the patients carrying SHANK3 point mutations or 22q13.3 deletions could be due to additional mutations. We therefore performed the whole genome sequence (WGS) of 20 patients with *SHANK3* point mutations/deletions. We then characterized the behavior of *Shank3Δ11* mutant mice at 3, 8 and 12 months of age, and performed transcriptome analyses on different brain regions of adult male mice after behavioral testing. Finally, we will present the framework of a new clinical trial that will be launched in 2020 using lithium in patients with autism carrying SHANK3 point mutations/deletions.

Results: The pilot WGS study on a relatively small sample could already identify multiple hits including one patient with a *de novo* mutation of the *MED13L* gene. The complete list of the most relevant multiple hits as well as the computation of the polygenic scores of the patients for ASD will be presented. In *Shank3Δ11* mice, male and female *Shank3Δ11* mutant mice display excessive grooming that exacerbates with increasing age as well as reduced exploratory activity. RNAseq analyses revealed that, while the cortex, the hippocampus and the cerebellum display few genes differentially expressed, the striatum displays a massive change of its transcriptome. The genes differentially expressed will be presented and their role on the excessive grooming of the mice will be discussed.

Conclusions: Our collaborative group investigate SHANKOPATHIES at different levels from genes to clinical trials and a website to share the data with the scientific and medical community will be soon available. We are now extending this study to other European countries to increase the statistical power and to identify knowledge-based treatments for SHANKOPATHIES. More information to join the collaborative group can be found here: https://research.pasteur.fr/fr/project/phelan-mcdermid-syndrome-from-mechanisms-to-treatments/

432.005 *(Poster)* Signal Transduction through the mTOR Protein Interaction Network Is Disrupted in Fragile X Syndrome

D. Wehle[1] *and S. E. Smith*[2]*, (1)University of Washington, Seattle, WA, (2)Seattle Childrens Research Institute, Seattle, WA*

Background: The mTOR pathway is a central signaling cascade that is linked to many types of autism. Multiple syndromic forms of autism such as TSC, PTEN, and Fragile X syndrome are the result of mutations in genes involved in mTOR signaling. Mouse models of Fragile X syndrome have shown an increase in phosphorylation of AKT, mTOR and p70S6K as well as an upregulation of PI3K and PIKE expression (Sharma et al 2010; Hoeffer et al 2012). This suggests that a key part of the Fragile X phenotype is abnormal signal transduction in the mTOR pathway.

Objectives: To test the hypothesis that disruptions in the mTOR protein interaction network contribute to abnormal signaling outcomes in Fragile X syndrome.

Methods: We have developed a proteomic method known as Qualitative Multiplex Immunoprecipitation (QMI) that can simultaneously measure changes in hundreds of protein interactions. Target proteins for the mTOR QMI antibody panel were chosen based on two criteria. The first is the target's importance to the mTOR pathway and the number of known interactions with other pathway members. The second criterion is the target's association to autism as determined by their SFARI gene score, where highly associated autism genes were added to the panel. We screened for a pair of commercially available antibodies that could capture a target onto CML beads and probe for that target through flow cytometry. We screened the detergents NP40, Deoxycholate, Digitonin, and Lubrol to determine the optimal detergent for solubilizing the proteins of interest. We stimulated cortical slices of wildtype and FMR1 knock-out mice with Insulin Growth Factor-1 (IGF-1) and DHPG to characterize how the loss of FMRP affects signaling through the mTOR protein interaction network.

Results: We successfully identified antibody pairs for seventeen key signaling or autism related proteins. We found that Digitonin best captured the protein interactions that occur between our selected targets. The loss of FMRP produced a pattern of protein interactions that was distinct from the wildtype when given no stimulation. Stimulation with DHPG or IGF produced unique rearrangements of the mTOR network in wildtype slices. However, these rearrangements were different in FMR1 mutant mice.

Conclusions: We developed a QMI antibody panel that can quantify changes in protein interactions between member proteins of the mTOR pathway. We found that the detergent Digitonin was best used to solubilize the targets of our panel after screening for the most effective detergent. Different stimulating inputs yielded different patterns in the protein interaction network. Fragile X mice displayed different protein network states than their wildtype counterparts. We hypothesize that the differences in protein network states leads to abnormal signaling outputs and contribute to deficits in protein translation observed in Fragile X syndrome.

432.006 *(Poster)* Synaptic Scaffolding Proteins Associated with Autism Are Required for Homeostatic Plasticity in Vitro and In Vivo

W. E. Heavner[1]*, H. Speed*[1]*, J. Lautz*[1]*, E. Gniffke*[1] *and S. E. Smith*[2]*, (1)Center for Integrative Brain Research, Seattle Children's Research Institute, Seattle, WA, (2)University of Washington, Seattle, WA*

Background: In order to adapt to changes in input, neurons adjust their synaptic strength and/or firing rate up or down so that cell-wide excitability remains stable. This capacity is known as homeostatic plasticity and is disrupted in several mouse models of autism. Recent studies have used high-throughput methods to identify newly synthesized transcripts and proteins after homeostatic up-scaling and down-scaling; however, how such changes interact to maintain homeostasis remains unclear. Moreover, how protein interaction networks critical for homeostatic plasticity are disrupted in autism has not been demonstrated.

Objectives: We aim to establish a ground truth for the synaptic protein network state during homeostatic synaptic up-scaling, homeostatic synaptic down-scaling, and whisker deprivation of the barrel (somatosensory) cortex. We will compare the protein network state during the above modes of homeostatic plasticity in mice mutant for the autism-associated genes Homer1 and Shank3.

Methods: We use quantitative multiplex immunoprecipitation (QMI), a semi-high-throughput method, to detect widespread changes in multi-protein complexes during homeostatic up- and down-scaling in cultured mouse cortical neurons, thereby establishing a ground truth for the protein network states that modulate synaptic homeostasis. We then use QMI to evaluate changes in multi-protein complexes in the whisker-deprived barrel cortex, an established model of in vivo homeostatic plasticity. Finally, we evaluate protein network state in the whisker-deprived barrel cortex of mice lacking the autism-associated genes Shank3 and Homer1.

Results: We find that many multi-protein complexes change bidirectionally with up-scaling versus down-scaling in cultured neurons over time, while the overall level of several key proteins stabilizes by 48 hours. Many of these multi-protein complexes involve Homer1, Shank1, and Shank3. Moreover, the whisker-deprived barrel cortex replicates many of the changes observed with in vitro down-scaling. Mice lacking Homer1 or Shank3 do not undergo normal protein interaction changes in response to whisker deprivation, demonstrating that disruption of a structural hub protein broadly inhibits protein network activity.

Conclusions: These results highlight the extensive, interconnected network of structural alterations that constitute homeostatic plasticity and demonstrate that in vitro and in vivo models of homeostatic plasticity engage similar mechanisms and require the autism-associated genes Homer1 and Shank3.

433.001 *(Poster)* Chandelier Cells and an Altered Gabaergic Synaptic System in the Human Prefrontal Cortex in Autism

T. Hong[1], *C. Falcone*[1], *S. Amina*[1,2], *R. Perez Castro*[1], *J. E. Regalado*[1], *W. Pearson*[1], *S. C. Noctor*[2,3] *and V. Martinez-Cerdeno*[1,2], *(1)Pathology & Laboratory Medicine, UC Davis School of Medicine; Institute for Pediatric Regenerative Medicine and Shriners Hospitals for Children of Northern California, Sacramento, CA, (2)MIND Institute, UC Davis Medical Center, Sacramento, CA, (3)Psychiatry & Behavioral Sciences, UC Davis School of Medicine, Sacramento, CA*

Background: Autism has been correlated with dysregulation of the excitation/inhibition balance in the cerebral cortex. We previously found a significant decrease in the number of a GABAergic inhibitory interneuron subtype called the chandelier cell (Ch) in the human prefrontal cortex in autism. Ch cells play a synchronizing role in regulating excitation, as a single Ch cell forms synapses with hundreds of excitatory pyramidal cells and does so exclusively on the axon initial segment (AIS) of pyramidal cells. We herein investigated this crucial link between chandelier cells and pyramidal cells to help uncover changes leading to imbalanced brain activity in autism.

Objectives: Currently available data indicates a downregulation of GABA system components in autism, but cellular localization of these alterations is not yet known. Thus, we hypothesized that in autism, the postsynaptic pyramidal cell contains reduced $GABA_A$ receptor subunit α2 protein in its AIS. We also hypothesized that there is a decreased number of Ch cell terminal boutons on each pyramidal cell AIS in autism.

Methods: Using human prefrontal cortex tissue from 20 control and 20 age- and sex-matched cases with autism, we performed immunohistochemistry to label Ch cell terminal boutons as well as $GABA_A$ receptor subunit α2 protein in the pyramidal cell AIS, and we used ImageJ (NIH) to quantify the amount of protein. We are examining Brodmann Areas (BA) 9, 46, and 47, as these are areas associated with the cognitive abnormalities in autism.

Results: We found a reduction of $GABA_A$ receptor subunit α2 protein in the pyramidal cell AIS in specific areas of the prefrontal cortex in autism. In addition, our preliminary findings show no difference in the number of Ch cell terminal boutons on each pyramidal cell AIS in control cases vs. cases with autism.

Conclusions: The downregulation of receptor protein in pyramidal cells may be a response to the overall decreased GABA synthesis in the prefrontal cortex, or a compensatory response to modified activity among remaining Ch cells. Overall, reduction of receptor protein may contribute to an excitation/inhibition imbalance in autism, and our findings support the potential for GABA receptor agonists as a therapeutic tool for autism.

433.002 *(Poster)* Patterns of Cortical Gyrification in Individuals with 22q11.2 Deletion Syndrome and Idiopathic Autism Spectrum Disorder

Ecker*[2], *(1)Department of Forensic and Neurodevelopmental Sciences, and the Sackler Institute for Translational Neurodevelopment, Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, United Kingdom, (2)Department of Child and Adolescent Psychiatry, Psychosomatics and Psychotherapy, Goethe-University Frankfurt am Main, Frankfurt, Germany, (3)Department of Forensic and Neurodevelopmental Sciences, Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, United Kingdom, (4)Behavioural Genetics Clinic, Adult Autism Service, Behavioural and Developmental Psychiatry Clinical Academic Group, South London and Maudsley Foundation NHS Trust, London, United Kingdom, (5)Department of Child and Adolescent Psychiatry, Institute of Psychiatry, Psychology and Neuroscience, King's College, London, United Kingdom, (6)University of California, Los Angeles, CA, (7)Forensic and Neurodevelopmental Sciences, Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, United Kingdom, (8)National Autism Unit, Bethlem Royal Hospital, London, United Kingdom*

Background: In order to fully capture the complex neuroanatomical underpinnings of autism spectrum disorder (ASD), it is important to consider the neurobiological determinates of ASD across disorders. For example, 22q11.2 deletion syndrome (22q112.DS) is a genetic condition that is associated with a high prevalence of ASD (Schneider et al., 2014). Even though recent studies suggest that individuals with 22q11.2DS and ASD are neuroanatomically distinct from 22q11.2DS without (Gudbrandsen et al., 2019; Jalbrzikowski et al., 2017), no studies to date have examined how closely the neurobiological phenotype of ASD in 22q11.2DS resembles the phenotype of ASD in idiopathic ASD. Moreover, no studies to date have focused on regional differences in cortical folding across disorders, which is key to both 22q11.2DS and idiopathic ASD.

Objectives: To establish whether ASD symptomatology in 22q11.2DS is underpinned by the same or different regional patterns of cortical folding compared to those without the micro-deletion.

Methods: We measured cortical gyrification based on the local gyrification index (*l*GI) across 131 individuals (6-25 years). These included (1) 50 individuals with 22q11.2 deletion syndrome (n=25 with ASD and 25 without), and (2) 81 non-deletion individuals (n=40 with ASD and 41 without). In accordance with previous studies (Gudbrandsen et al., 2019; Jalbrzikowski et al., 2017), all individuals with ASD met diagnostic cut-offs in the reciprocal social interaction and communication domain of the Autism Diagnostic Interview (ADI-R: (Lord, Rutter, & Lecouteur, 1994)), but were allowed to fall below threshold in the repetitive behaviors domain. We employed a multivariate approach using canonical correlation analysis (CCA), which allowed us to treat ASD as a continuous clinical construct spanned by multiple symptom domains assessed via the five subscales of the Social Responsiveness Scale (SRS; (Bölte & Poustka, 2008; Constantino & Gruber, 2012)), and to examine the multivariate association between inter-individual clinical profiles and neuroanatomical variability between 22q11.2 deletion carriers and non-carriers.

Results: In both groups (i.e. carriers and non-carriers) clinical variability across the five subdomains of the SRS could be reduced to a single latent trait variable that was (1) highly predictive of group (i.e. ASD vs. non-ASD), and (2) significantly associated with neuroanatomical variability in *l*GI (see Fig. 1 for ASD vs Controls & Fig. 2 for 22q11.2DS). However, although clinical variability was represented by a similar factor structure in both groups, the multivariate association between ASD symptomatology and neuroanatomical variability in *l*GI was significantly reduced in individuals with 22q11.2DS. Furthermore, we found that the spatially distributed patterns of neuroanatomical variability associated with this latent trait clinical factor significantly differed between groups, particularly in the left anterior cingulate cortex, the bilateral inferior parietal cortex, and the bilateral superior parietal cortex.

Conclusions: Our results suggest that while there is a high degree of clinical similarity between groups, ASD symptomatology appears to be mediated by different patterns of cortical folding in individuals with 22q11.2DS compared to those without.

433.003 *(Poster)* Serotonergic Innervation of the Amygdala Is Increased in Autism Spectrum Disorder and Decreased in Williams Syndrome

C. H. Lew[1], *K. Groeniger*[1], *K. L. Hanson*[1], *D. Cuevas*[1], *D. Greiner*[1], *B. Hrvoj-Mihic*[1], *U. Bellugi*[2], *C. M. Schumann*[3] *and* ***K. Semendeferi***[1], *(1)Anthropology, UC San Diego, La Jolla, CA, (2)Salk Institute, La Jolla, CA, (3)Psychiatry and Behavioral Sciences, UC Davis MIND Institute, Sacramento, CA*

Background: Williams syndrome (WS) and Autism Spectrum Disorder (ASD) are neurodevelopmental disorders that demonstrate overlapping genetic associations, dichotomous sociobehavioral phenotypes, and dichotomous pathological differences in neuronal distribution in key social brain areas, including the prefrontal cortex and the amygdala. The serotonergic system is critical to many processes underlying neurodevelopment, and is additionally an important neuromodulator associated with behavioral variation. The amygdala is heavily innervated by serotonergic projections, suggesting that the serotonergic system is a significant mediator of neuronal activity. Disruptions to the serotonergic system, and atypical structure and function of the amygdala, are implicated in both WS and ASD.

Objectives: To quantify the density of serotonergic axons in the four major subdivisions of the amygdala in the postmortem brains of individuals diagnosed with ASD and WS, and neurotypical (NT) brains.

Methods: Serial sections through the amygdala from 22 postmortem human brains (six age-matched pairs of ASD, WS, and NT) ranging from 19-69 years of age were immunohistochemically stained for the serotonin transporter (SERT) involved in serotonin reuptake into the presynaptic terminal. Adjacent sections were stained with cell-body stain (nissl) to determine amygdala nuclei boundaries, which were then overlaid onto SERT-ir stained sections. Stereological methods were used to estimate SERT-ir axon length and density. Nonparametric statistical methods were employed due to small sample size.

Results: We found opposing directions of change in serotonergic innervation in the two disorders, with ASD displaying an increase in SERT-ir axon density compared to NT, and WS displaying a decrease. Significant differences ($p<0.05$) were observed between WS and ASD data sets across multiple amygdala nuclei.

Conclusions: Differential alterations to serotonergic innervation of the amygdala may contribute to differences in sociobehavioral phenotype in WS and ASD. These findings will inform future work identifying targets for future therapeutics in these and other disorders characterized by atypical social behavior.

Neurochemistry

POSTER SESSION — **NEUROCHEMISTRY**
434 - Neurochemistry Posters

434.001 *(Poster)* Children with Autism Spectrum Disorder Show Differential Glutamatergic Response in the Pons during Affective Face Discrimination Task.

O. J. Surgent[1]*, B. G. Travers*[1] *and B. Nacewicz*[2]*, (1)University of Wisconsin - Madison, Madison, WI, (2)Department of Psychiatry, University of Wisconsin - Madison, Madison, WI*

Background: Children with ASD often face challenges with interpreting emotion from faces and motor ability. It is possible that an imbalance of neural excitation and inhibition underlies both of these symptoms (Rosenberg et al., 2015). In order to investigate the role of affective context on the relationship between neurochemistry and motor ability, we assessed the neurochemical signature of bilateral hand gripping in response to pictures of hands and faces (neutral and emotional) using event-related, high-temporal resolution functional Magnetic Resonance Spectroscopy (ht-fMRS). ht-fMRS has the capacity to quantify second-by-second accumulation of neurotransmitters within a specific brain voxel. The present study focused on the neurochemistry of the median pontine nuclei during grip due to its known role in integrating top-down motor cues with visual and emotional information and prior findings of microstructural pontine abnormalities that were related to motor ability and core symptoms in ASD (Travers et al., 2015).

Objectives: 1) Characterize the glutamatergic pontine neural signature of grip responses in children with ASD and TD, and 2) examine the differential pontine responses to affective versus non-affective visual stimuli in children with ASD and TD.

Methods: While collection is ongoing, data reflect functional spectroscopic and behavioral information collected from 18 children with ASD and 25 children with typical development (TD), ages 6-10 years. Participants completed a task that involved squeezing dynamometers (hard or light) in response to visual cues (hands, neutral faces [non-affective], or emotional faces [affective]). While participants performed the task, glutamatergic concentrations were measured with a jittered 1.5 second repetition time. A general linear model was applied to the raw spectroscopic data that deconvolved glutamatergic signatures associated with the presentation of cues.

Results: No significant group differences in maximum grip were found during responses to hands (p=.14), neutral faces (p = .26), or affective faces (p = .41). However, children with ASD showed unique glutamate signatures in all conditions (Figure 1). For hands, there was an interaction between diagnostic group and hard vs. light grip trials (p = .008). Specifically, the ASD group showed elevated glutamate compared to the TD group in the “grip hard” trials, but diminished glutamate during the “grip light” trials. For faces, there was an interaction between diagnostic group and hard vs. light trials (p = 0.02) and glutamatergic signatures were similar in directionality to those of the hand trials.

Conclusions: This study found that pontine glutamate in ASD differed as a function of squeezing hard or light. Despite similar behavioral performance, elevated glutamate response in the brainstem during hard grips and diminished glutamate response during light grips suggests an altered subcortical mechanism of motor execution in ASD. Results also indicate that this glutamatergic pontine activity in ASD is not affected by the affective context of visual stimuli, thus indicating that this altered mechanism is relatively emotion-independent. However, it is possible that emotional cues affect the neuronal behavior elsewhere in the circuit, therefore further characterization of the neurochemical dynamics of the motor circuit may help to fully elucidate the underlying impact of emotion on motor ability.

434.002 *(Poster)* Correlation of Oxidative Damage Associated with Glutathione Status and Attention Switching/Tolerance of Change in ASD.

C. D. Jimenez-Espinoza*, Physiology, University of La Laguna, Santa Cruz de Tenerife, Spain*

Background: Autism is a complex, behaviorally defined neurodevelopmental disorder characterized by significant impairments in social interaction, verbal and non-verbal communication, and by restrictive, repetitive and stereotypic patterns of behavior. Numerous indicators of oxidative stress have been documented previously in the blood from children with autism, including decreased antioxidant enzyme activities. Glutathione (GSH; γ-L-glutamyl-L-cysteinyl-glycine) is the primary antioxidant responsible for maintaining the reducing intracellular microenvironment that is essential for normal cellular function and viability. Previously, we described the kinetic imbalance of glutathione biosynthesis in the cingulated cortices as target of oxidative stress in individuals with ASD. Taken together, the findings of this study support our hypothesis and a role for glutathione redox imbalance and oxidative stress in the attention switching/tolerance of change in autism, which lead the next step in our investigation to correlate of imbalance neurochemistry linked to cingulated cortices with attention switching/tolerance of change in the autism spectrum disorders.

Objectives: To study imbalance of glutathione in the cingulated cortices correlated with the AQ domains attention switching/tolerance of change associated with ASD using ^{1}H-MRS.

Methods: Single voxel (^{1}H-MRS) in bilateral ACC and PCC, in adults with a clinical diagnosis of ASD (n=21) and controls (TD) typically development (n=46), matched for age, gender. Autism quotients (AQ) score were assessed. Statistic one-way ANOVA and Bonferroni correction were applied.

Results: The results of the Pearson correlation were represented graphically, where it was observed that there is no correlation between the change in attention and the deregulation of glutathione in the ACC in ASD (Fig.1). These results make us suggest the relation of the deficit in the change of attention with the deficiencies in the network of the executive function; in accordance with that described by (Pascualvaca et al., 1998); who demonstrated the relation of the deficits in the care path with the deficiencies in the network of the executive function. Comparatively, the subjects of the control group were negatively correlated with the relative proportions of glutathione in both cortices. On the other hand, it was recently demonstrated that the deficiencies of the executive network in the subjects with ASD originate in the central lobes, being one of its central nodes the ACC (Watanabe & Rees, 2016); what sustains our neurochemical findings.

Conclusions: This imbalance in the levels of GSH in ACC and PCC, could contribute to the decrease of antioxidant defenses and therefore increase the susceptibility of astrocytes, generating a poor glial defense, contributing to the existing neuronal damage in ASD caused by oxidative stress, mitochondrial dysfunction and neuroinflammation that have been identified as determining causes in the appearance of ASD.

434.003 *(Poster)* Parietal GABA in Children with Autism Spectrum Disorder and Typically Developing Peers: Distinct Age-Related Changes

M. DeMayo[1], *I. Pokorski*[1], *A. D. Harris*[2,3], *Y. J. Song*[4], *R. Thapa*[1], *Z. Ambarchi*[1], *S. Patel*[1], *I. Hickie*[4] *and A. J. Guastella*[1], *(1)Brain and Mind Centre, Children's Hospital Westmead Clinical School, Faculty of Medicine and Health, University of Sydney, Sydney, NSW, Australia, (2)Department of Radiology, University of Calgary, Calgary, Alberta, Canada, Calgary, AB, Canada, (3)Cumming School of Medicine, University of Calgary, Calgary, AB, Canada, (4)Brain and Mind Centre, Central Clinical School, Sydney Medical School, University of Sydney, Sydney, NSW, Australia*

Background: Gamma-Aminobutyric acid (GABA) acts as the brain's primary inhibitory neurotransmitter for most of life. A lack of GABA-mediated inhibition has been proposed to contribute to the development of Autism and explain specific behavioural differences. Previous research has found reductions in GABA concentrations for children and adolescents with Autism across a number of brain regions. The younger the participants, the more consistent the reductions appear to be. Further, no differences in GABA concentration have been found in adults. This suggests a potential influence of age on GABA concentration. The impact of age has shown inconsistent results, with some studies reporting age-related changes, while others did not find these associations.

Objectives: We sought to investigate the developmental trajectory of GABA concentration in the left parietal lobe, a region key for social cognition and language. A cross-sectional design was used to compare children with Autism to their typically developing peers to assess group differences and age-related effects on GABA concentration to better understand the brain biology accompanying Autism.

Methods: Twenty-four children with Autism (age 9.11± 2.3, range: 4-12 years) and 35 typically developing children (age 8.81 ± 2.26, range: 4-12 years) participated in the study. Imaging was conducted on a 3-Tesla GE Discovery MR750 scanner. A T1-weighted detailed anatomical scan was completed for voxel placement and segmentation. A single voxel (size: 3x3x3 cm^3) MEGA-PRESS was acquired in the left parietal lobe for GABA quantification. A typical voxel placement and example spectrum is shown in Figure 1.

Processing was conducted using Gannet, version 3.1 to estimate the concentration of GABA within the voxel. The voxel is segmented using spm12, with the proportion of grey matter, white matter and cerebrospinal fluid used to correct for differences of tissue type contribution to the measured GABA signal. An ANCOVA was used to examine group differences in GABA concentration, with age included as a covariate to investigate its influence on GABA.

Results: There was a significant influence of diagnosis ($p = 0.033$), age ($p = 0.005$) and interaction of diagnosis and age ($p = 0.029$) on GABA concentration. Participants with Autism showed lower GABA concentrations at younger ages compared to TDC ($B = -0.835$, $p = 0.033$) and participants with Autism show a significant increase in GABA with age ($B = 0.092$, $p = 0.029$) whereas GABA levels in TD children do not change with age. The GABA and age association is illustrated in Figure 2.

Conclusions: This study provides further evidence for differences in GABA concentration in children with Autism compared to their typically developing peers. Specifically, children with ASD showed age-related increases in GABA concentration while TD participants did not. Our data suggests GABA levels in younger children with ASD are lower when compared to TD but in older groups, this group difference does not persist. We found that at age 9, the ASD group attained typical GABA levels. This finding offers a potential explanation for why reductions in GABA are seen in children and adolescents with ASD but not in adult populations.

Neuroimaging

PANEL SESSION — **NEUROIMAGING**

218 - Disentangling Clinical and Biological Heterogeneity in ASD Using Data-Driven Approaches

Panel Chair: Stephanie Ameis, *The Margaret and Wallace McCain Centre for Child, Youth, & Family Mental Health, Campbell Family Mental Health Research Institute, Centre for Addiction and Mental Health, Toronto, ON, Canada*

Discussant: Evdokia Anagnostou, *Holland Bloorview Kids Rehabilitation Hospital, Toronto, ON, Canada*

Heterogenity in autism remains an enormous barrier to the biomarker discovery needed for clinical innovation. Here, four speakers will present on different approaches to parse heterogeneity in autism using different large neuroimaging datasets including infants, children, and youth with autism, and related neurodevelopmental disorders (NDDs, attention-deficit/hyperactivity disorder, ADHD, obsessive compulsive disorder, OCD). Presenter #1 will present studies of relationships between distinct functional brain connectivity patterns and specific behavioural domains from the Infant Brain Imaging Study that set the stage for testing whether first-year-of-life fcMRI can be used to predict autism behaviors at 24 months. Presenters #2 and #3 will each present clustering results from two different samples indicating that verbal/nonverbal IQ profiles (Presenter #2: ASD sample) and executive function/ADHD symptoms (Presenter #3: ASD/ADHD sample) can be used to identify subgroups of children featuring distinct clinical presentations and brain imaging profiles (including structural and functional connectivity measures). Presenter #4 will present 4 novel participant similarity subgroups cutting across children with ASD, ADHD or OCD identified using integration of multimodal structural imaging and behavioural data that feature distinct behavior profiles not found using diagnostic labels. The discussant will discuss the potential clinical relevance of presented efforts to disentangle heterogeneity across NDDs.

218.001 *(Panel)* fcMRI Correlates for ASD-Related, Intervention-Relevant Behaviors in Infants and Toddlers

***J. Pruett**, *Co-senior author, **For the IBIS Network, Washington University School of Medicine, St. Louis, MO*

Background: Recent research on brain and behavior development in infants at risk for autism spectrum disorder (ASD) has identified group-based differences in infants at high familial risk (HR: have an older affected sibling) who do and do not later develop ASD and also in comparison to low risk (LR) control infants. The field, however, has yet to identify clinically actionable first-year-of-life predictive behavioral features. On the other hand, investigators in the Infant Brain Imaging Study (IBIS) Network have reported MRI findings in HR infants in the first year of life that have over 80% positive predictive value for a later diagnosis. In addition to replicating these important categorical outcome prediction results, it will be crucial to identify MRI-based biomarkers for dimensionally measured aspects of ASD-related behaviors that are candidate targets for future presymptomatic interventions.

Objectives: We seek to understand better associations between brain functional connectivity and ASD-related behaviors that may fit these criteria.

Methods: Infant Brain Imaging Study (IBIS) investigators collected fcMRI scans during natural sleep from HR and LR infants (overlapping sets of subjects for different analyses with Ns ranging from 87-130 per age group: 12 and 24 months). Image processing included rigorous motion artifact mitigation procedures. fcMRI correlates of ASD-related behaviors, joint attention (the coordinated orienting of two people toward the same object), motor function, and restricted and repetitive behaviors, were characterized using a novel-for-fcMRI statistical approach, fcMRI enrichment, and significance was evaluated using randomization.

Results: We have produced initial descriptions of functional brain networks that associate with initiation of joint attention (IJA), walking and gross motor behavior, and three different subcategories of restricted and repetitive behavior: e.g., visual network – dorsal attention network (DAN) connectivity and visual network – default mode network connectivity for IJA at 12 months ($p < 0.05$ at the brain-wide level via randomization). Unpublished preliminary findings with N=37 subjects contributing clean fcMRI at both ages suggest we may be able to model fcMRI associations with multiple developmentally linked behaviors, e.g., IJA at 12 months and expressive language at 24 months: within DAN connectivity ($p = 2.38 \text{ X } 10^{-8}$ using FDR).

Conclusions: fcMRI-behavior associations across multiple studies in infants at risk for ASD implicate specific functional brain networks at different ages that are specific for different domains of behavioral functioning – IJA, motor function, RRB – and for specific subtypes of behavior within these broader domains, e.g., walking, reaching and grasping; and restricted, stereotyped, and ritualistic-sameness behavior. The demonstration of fcMRI correlates for ASD-related behaviors suggests the future possibility of predicting individual behavioral profiles with an eye to personalized interventions. These initial fcMRI-behavior findings need to be replicated, and we have new funding that will allow us to do so in an independent sample of 250 HR infants, where we will test the power of first-year-of-life fcMRI to predict individual levels of language, social responsiveness, joint attention, and repetitive behaviors at 24 months.

218.002 *(Panel)* Functional Random Forest Reveals Transdiagnostic Hyperactive and Inattentive Subtypes Tied to Executive Function

***E. Feczko**, Emory University, Atlanta, GA*

Background: Overlap between Autism spectrum disorder (ASD) and attention deficit hyperactivity disorder (ADHD) diagnoses exemplifies the heterogeneity problem, where different mechanisms may lead to the same diagnosis, and childhood outcomes may depend on factors unrelated to mechanism. Multifactorial approaches hope to identify sub or biotypes that overcome this heterogeneity problem, however, most methods employed do not assess whether newly discovered subtypes are relevant to a given childhood outcome.

Objectives: To model the association between executive function and ADHD symptoms across ADHD and ASD children, assess model robustness and then identify subtypes from the model. Subtypes are assessed for stability and characterized by clinical diagnosis and executive function measures, and measures of functional brain organization are used to assess subtype validity.

Methods: Executive function (EF) measures derived from parental assessments (e.g. BRIEF) and cognitive tasks were acquired on an OHSU sample of children aged 7-16 with research-reliable diagnoses with ASD and ADHD. T1-weighted and resting state functional magnetic resonance imaging data were acquired on a subset of these participants alongside a typically developing (TD) sample for a comparative analysis. A Functional Random Forest was used to identify subtypes tied to ADHD hyperactive and inattentive symptom totals from 158 children. EF measures were used as inputs to predict the ADHD symptom totals using a random forest model. The models were assessed via cross-validation and compared to null models. A proximity matrix was derived from each model and Infomap, a community detection algorithm, was used to identify subtypes from the proximity matrix. Subtype stability was assessed via a modularity permutation test. An enrichment analysis and ANOVA tests were used to measure differences in resting state functional connectivity between subtypes and the TD cohort to assess the external validity.

Results: Two sets of transdiagnostic subtypes were identified from hyperactive and inattentive ADHD symptoms. The modularity permutation test showed that subtypes were stable (Q=0.234, p = 0.001). For both hyperactive and inattentive model subtypes, one subtype showed consistently lower performance on tasks and greater severity on assessment measures when compared to the other subtype. Functional connectivity differences between subtypes showed variable patterns, where some networks were more similar to controls for one subtype but not another.

Conclusions: Hybrid methods like the functional random forest provide a framework to discover and assess unknown subtypes relevant to mental health outcomes. Because multifactorial approaches and subtypes remain controversial within the field, such hybrid methods can provide statistical frameworks for resolving this controversy. Here, we found two sets of transdiagnostic subtypes with consistent differences in executive function. However, differences in functional connectivity patterns suggest that these subtypes are not merely examples of more and less severe, but rather may arise from different mechanisms. Out of sample replication of these subtypes remains critical for validation; large-scale samples such as from the adolescent brain cognitive development (ABCD) study may be ideal for such replication.

218.003 *(Panel)* Cognitive Imbalances in Autism Differentially Affect Macroscale Brain Organization

***S. J. Hong**, Child Mind Institute, New York, NY*

Background: Autism spectrum disorder (ASD) is characterized by heterogeneity in a wide range of cognitive functions such as language and perception. Notably, the strengths in one domain appear to co-exist with deficits in other domains, indicating potential atypical cross-modal plasticity. One important example is reduced language skills that tend to co-occur with normal or increased perceptual abilities in non-syndromic ASD. Previous work has assessed a relationship between these behavioral competencies by analyzing verbal and nonverbal intelligence quotient (IQ) in ASD. Yet, its neurobiological underpinnings have not been systematically investigated.

Objectives: To find macro-scale brain substrates for atypical verbal/nonverbal IQ (vIQ/nvIQ) profiles in ASD, and to decompose their variable patterns to find multiple homogeneous subtypes.

Methods: The vIQ/nvIQ measures, symptom severity (calibrated Autism Diagnostic Observation Schedule [ADOS] scales) and magnetic resonance imaging (T1-weighted and resting-state fMRI) in 155 individuals with ASD and 151 neurotypical controls. We assessed the ratio of vIQ/nvIQ to see its imbalance in individuals with ASD, comparing to the neurotypical controls. We also clustered the individuals with ASD based on this ratio using hierarchical clustering. We then associated these cognitive phenotypes to whole-brain cortical thickness and functional connectivity, and decoded the significant brain areas using Neurosynth to identify related cognitive terms.

Results: Compared to neurotypical individuals, ASD showed reduced vIQ/nvIQ ratio, and the lower scores generally correlated with overall symptom severity. Assessing interactions between vIQ/nvIQ and diagnostic group on cortical thickness observed a strong effect in the language areas (*i.e.* inferior frontal areas) in ASD, which functional specificity was confirmed by Neurosynth. Moreover, ASD showed decreased functional connectivity in bilateral temporal areas when seeding from the areas showing thickness associations. Unsupervised clustering of vIQ/nvIQ profiles converged on two different subtypes (ASD1: a group of severely affected vIQ/nvIQ ratio, ASD2: a group of a normal range of the IQ ratio), each related to differential whole-brain cortical thickness and functional connectivity patterns.

Conclusions: Our multimodal imaging correlation analyses suggest convergent anatomical and functional network substrates underlying verbal and non-verbal dimensions of IQ in ASD. Atypical maturation and incomplete pruning of frontal and language-related networks in ASD may be associated to intrinsic functional reconfigurations, and may contribute to autism subtypes with verbal impairment yet relatively intact visuospatial components of intelligence.

218.004 *(Panel)* Integration of Brain and Behavior Measures for Identification of Data-Driven Subgroups Cutting across Children with ASD, ADHD, or OCD

*G. Jacobs[1], A. Voineskos[1], C. Hawco[1], L. Stefanik[2], N. Forde[1], E. W. Dickie[1], M. C. Lai[3], P. Szatmari[4], R. Schachar[5], J. Crosbie[6], P. Arnold[7], M. J. Taylor[4], A. Goldenberg[4], L. Erdman[8], J. P. Lerch[9], E. Anagnostou[10] and **S. Ameis**[11], (1)The Centre for Addiction and Mental Health, Toronto, ON, Canada, (2)Pediatrics, Mount Sinai Hospital, Toronto, ON, Canada, (3)Autism Research Centre, Department of Psychiatry, University of Cambridge, Cambridge, ON, United Kingdom, (4)The Hospital for Sick Children, Toronto, ON, Canada, (5)Psychiatry, The Hospital for Sick Children, Toronto, ON, Canada, (6)Psychology, The Hospital for Sick Children, Toronto, ON, Canada, (7)University of Calgary, Calgary, AB, Canada, (8)sick kids, Toronto, ON, Canada, (9)Wellcome Centre for Integrative Neuroimaging (WIN), University of Oxford, Oxford, ON, United Kingdom, (10)Holland Bloorview Kids Rehabilitation Hospital, Toronto, ON, Canada, (11)The Margaret and Wallace McCain Centre for Child, Youth, & Family Mental Health, Campbell Family Mental Health Research Institute, Centre for Addiction and Mental Health, Toronto, ON, Canada*

Background: Autism spectrum disorder (ASD), obsessive-compulsive disorder (OCD) and attention-deficit/hyperactivity disorder (ADHD), are heterogeneous neurodevelopmental disorders (NDDs) with overlapping clinical and biological features. Conventional case-control research using current DSM labels have failed to yield opportunities for clinical translation.

Objectives: To integrate different structural brain imaging and behavioral measures and then apply clustering to define subgroups of children with different NDDs featuring similar brain-behavior profiles and evaluate subgroup stability, validity, and prospective clinical utility.

Methods: Cross-sectional T1-weighted and diffusion weighted magnetic resonance imaging, as well as behavioral/cognitive measures were acquired through the Province of Ontario Neurodevelopmental Disorder (POND) Network (Sick Kids, Holland Bloorview Kids Rehabilitation Hospitals, Toronto, Canada). POND participants aged 6-to-16 with primary ASD, ADHD, or OCD clinical diagnoses were included. Cortical thickness, subcortical volume, and white matter fractional anisotropy neuroimaging metrics, as well as behavioral scores from 182 children with different NDDs were integrated using Similarity Network Fusion. Spectral clustering was applied to a fused participant similarity matrix to delineate data-driven participant similarity subgroups. Normalized mutual information was used to determine top contributing model features. Data-driven subgroup stability, distinguishing features, and potential validity using out-of-model outcome measures were examined. Supervised machine learning was used to examine subgroup identification using top contributing model features.

Results: Four transdiagnostic data-driven subgroups were identified featuring neurobiological distinctions not present in DSM-defined groups. Subgroup differences were stable across resampling and independent of age effects. Identified subgroups also featured distinctions in adaptive (everyday) functioning and structural covariance network efficiency measures that were not included in the subgroup detection model. Using subsets of top contributing model features, participant similarity subgroups were identified with sensitivities ranging from 60-90%.

Conclusions: Integration of multivariate imaging and behavioural data across different NDDs yielded novel transdiagnostic data-driven subgroups that were stable and featured more distinct brain-behaviour profiles on both in and out-of-model outcome measures suggesting their potential utility outside of the current sample. Out of sample replication and longitudinal outcome tracking is needed to evaluate whether data-driven participant similarity subgroups feature the diverging prognostic/treatment response trajectories needed for clinical translation.

322 - Brains, Genes, and Behaviour

322.001 *(Oral)* Non-Replication of Functional Connectivity Differences in ASD across Multiple Sites and Denoising Strategies

*Y. He[1], L. Byrge[1] and **D. Kennedy**[1,2,3], (1)Psychological and Brain Sciences, Indiana University, Bloomington, IN, (2)Cognitive Science Program, Indiana University, Bloomington, IN, (3)Program in Neuroscience, Indiana University, Bloomington, IN*

Background: Resting-state functional connectivity MRI (fcMRI) has often been used to describe differences in the functional organization of the brain in ASD, and is touted as an approach that may identify biomarkers of ASD. However, despite over 10 years of investigation and hundreds of studies, findings remain largely inconsistent and robustly replicable results have yet to be identified. It remains an open question whether inconsistencies across studies are primarily due to differences in methodology (i.e., denoising strategy/preprocessing pipeline), or whether site-level effects (e.g., non-harmonized procedures and sample characteristics) may account for discrepancies.

Objectives: Our goals were to: (1) determine the relationships between the different denoising strategies, (2) determine whether ASD-control differences are replicable across independent sites when the same preprocessing pipelines are applied, and (3) determine whether any particular denoising strategy leads to greater replication across sites.

Methods: We analyzed 4 datasets (sites) from the Autism Brain Imaging Data Exchange (ABIDE I and II) comprised of equally-size control and ASD groups ranging from 34 to 44 participants per group. Groups were well-matched within and across sites on multiple characteristics including age, IQ, handedness, and motion. Each of the 4 datasets were analyzed according to 33 different denoising procedures, which included combinations of common preprocessing steps (e.g., motion regression with 6, 12, or 24 parameters, global signal regression (GSR), scrubbing, spike regression, white matter and CSF signal regression, ICA-AROMA). Correlations between functional connectivity matrices were calculated, and the results were visualized using multidimensional scaling (MDS).

Results:

Across sites, we found clear and reliable relationships between different denoising strategies, with the largest effects for the use of GSR vs. not. We also found that the basic functional architecture of the brain was highly replicable across pipelines and across sites, with mean correlations of r = 0.92 (0.06) and r = 0.88 (0.02), respectively. However, group differences, while consistent across pipelines within a single site, were highly inconsistent across sites, regardless of the choice of denoising strategies [mean r = 0.07 (0.04)]. The MDS plot shown in Figure 1 shows that the effect of pipeline is dwarfed by the much larger effect of site. The lack of replicable differences persisted when examining the data at the large-scale network level or when only considering the edges with the largest effect sizes.

Conclusions:

Our results help to identify the sources of variance that likely underlie the inconsistent findings in the literature. While there are reliable effects of the various preprocessing strategies employed, these effects are quite small relative to the large site effects (which may include scanner, acquisition, procedural or cohort differences). Another possibility that should be considered is that functional connectivity differences are small, hard to detect, heterogeneous, or even possibly non-existent at the spatiotemporal scales measured. These results highlight the importance of examining replicability in future studies of ASD, and call for extra caution when interpreting results based on single datasets.

322.002 *(Oral)* Genetic and Environmental Influences on White Matter Integrity in Twins with Autism

***J. P. Hegarty II**[1], J. C. Monterrey[1], L. C. Lazzeroni[1,2], J. A. McNab[3], S. C. Cleveland[1], J. M. Phillips[1], J. F. Hallmayer[1] and A. Y. Hardan[1], (1)Psychiatry & Behavioral Sciences, Stanford University, Stanford, CA, (2)Biomedical Data Science, Stanford University, Stanford, CA, (3)Radiology, Stanford University, Stanford, CA*

Background: Reduced white matter (WM) integrity is reported in a multitude of studies comparing individuals with autism spectrum disorder (ASD) to typically-developing (TD) controls. However, the type and degree of these alterations are heterogeneous across individuals, which may be associated with the variable effects of genetic and environmental influences on brain development.

Objectives: The primary objective of this investigation was to examine WM integrity in twins with ASD compared to TD control twins to identify tract-specific differences in the impact of genetic and environmental factors.

Methods: Same-sex monozygotic (MZ) and dizygotic (DZ) twin pairs in which at least one twin was diagnosed with ASD or both were TD controls (aged 6-15 years) were recruited to participate. Diffusion weighted MRIs were obtained and processed with the FSL Diffusion Toolbox to extract skeletonized fractional anisotropy (FA) images from each participant. Intra-class correlations were computed within twin pairs and compared between the diagnostic and control groups. ACE modeling for broad sense heritability (a^2=additive genetics) and environmental influences (c^2=shared family environment, e^2=unique environment) was also examined to provide estimates for the proportions of variation associated with genetic and environmental factors. FA was best fit with either the AE or CE model in all instances for both groups.

Results: Good quality data were available from 154 twins [29 concordant ASD twin pairs (15 MZ,14 DZ); 15 discordant ASD twin pairs (3 MZ,12 DZ); and 33 concordant TD twin pairs (20 MZ,13 DZ)]. Average FA was reduced in twins with ASD compared to TD controls (M_{diff}=-0.01, 95% CI [-0.02,-0.004]) as well as in twins with ASD compared to unaffected co-twins (M_{diff}=-0.01 [-0.02,-0.002]). Although average FA was primarily genetically-mediated in both the TD (a^2=0.80 [0.57,1.02]) and ASD twin pairs (a^2=0.71 [0.33,1.09]), there were also ASD-related differences in the impact of genetic and environmental influences on tract-specific measures. FA in all of the tracts that were assessed was primarily genetically-mediated in TD twins (a^2=0.52 to 0.80), except for the superior longitudinal fasciculus, corticospinal tract, and cerebellar peduncles (c^2=0.41 to 0.74). Conversely, tract-specific FA was predominantly associated with environmental factors in twins with ASD, including the superior longitudinal fasciculus, corticospinal tract, and cerebellar peduncles (c^2=0.56 to 0.77) as well as the posterior thalamic radiation, sagittal stratum, and internal/external capsules (c^2=0.34 to 0.60). Twin pair differences in FA were also associated with differences in symptom severity.

Conclusions: Previous twin studies reported that WM is predominantly genetically-mediated in TD adults but our findings suggest that some WM tracts may be more heavily influenced by environmental factors earlier during typical development. Environmental factors may also have a more pervasive impact on WM development in children and adolescents with ASD, which in addition to our preliminary examinations of structural grey matter measures in this pediatric twin sample suggest that children with ASD may be more susceptible to environmental influences during development. Future studies should examine the critical periods and specific environmental factors that are associated with this increased susceptibility to help identify new potential therapeutic pathways for children with ASD.

322.003 *(Oral)* Examining Neural Habituation to Repeated Sounds in Children, Adolescents and Adults with and without Autism Spectrum Disorder

D. V. Crawley[1], *P. Garces*[2], *L. Mason*[3], *E. J. Jones*[3], *J. F. Hipp*[4], *C. L. Ellis*[1], *A. San Jose Caceres*[1], *E. Kong*[1], *E. McGregor*[5], *J. Cooke*[1], *B. Oranje*[6], *J. K. Buitelaar*[7], *D. G. Murphy*[1], *J. Ahmad*[1], *E. Loth*[8] *and E. U. AIMS LEAP*[9], *(1)Forensic and Neurodevelopmental Sciences, Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, United Kingdom, (2)Neuroscience, Ophthalmology, and Rare Diseases (NORD) Roche Pharma Research and Early Development. Roche Innovation Center Basel, Hoffmann-La Roche, Basel, Switzerland, (3)Centre for Brain and Cognitive Development, Birkbeck, University of London, London, United Kingdom, (4)Neuroscience and Rare Diseases (NRD), Roche Pharma Research and Early Development, Roche Innovation Center, Basel, Switzerland, (5)University of East London, London, United Kingdom, (6)Department of Psychiatry, Brain Center Rudolf Magnus, NICHE Lab, University Medical Center Utrecht, Utrecht, Netherlands, (7)Karakter Child and Adolescent Psychiatry University Centre, Nijmegen, Netherlands, (8)Department of Forensic and Neurodevelopmental Sciences, Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, United Kingdom, (9)EU-AIMS Consortium, London, United Kingdom*

Background: Autism spectrum disorder (ASD) is often characterised by behavioural rigidities and sensory processing atypicalities that can significantly impact daily functioning and quality of life. These behaviours may manifest as a result of reduced habituation to sensory stimuli. Habituation describes the process whereby neural responses to frequently repeated stimuli diminish over time. If habituation is reduced, the stimuli may be experienced as repeatedly novel, prompting sensory overload/hypersensitivity. Insistence on sameness behaviours may in turn be coping responses to atypical experiences of sensory sameness.

Objectives: To examine neural habituation to repeated sounds in ASD and comparison individuals and investigate whether reduced habituation relates to sensory atypicalities and/or restricted, repetitive behaviour (RRB) in ASD.

Methods: Participants were individuals from the EU-AIMS LEAP cohort both with (N=256) and without (N=191) ASD, aged 6-30 years (*M*=16.37, SD=5.49) with IQs ranging from 40-148 (*M*=99.2, SD=19.45). EEG was recorded during an auditory oddball paradigm, comprising 82% 'standard tones' (1000Hz, 50ms) and 18% 'deviant tones' (3 deviant types: 6% frequency, 6% duration, 6% combined frequency/duration). Event-related brain responses were compared across first, second and third presentations of standards after a deviant and between diagnostic groups using linear mixed-effects models to investigate habituation to repeated sounds (S1, S2, S3). Both amplitude and latency of the P1 component were estimated at Fz from the most positive amplitude within the time period of 50ms to 150ms. Sex, age and IQ associations were also examined. In the ASD group, associations between S1-S3 difference scores and both RRB (Repetitive Behaviour Scale-Revised, RBS-R) and sensory atypicalities (Short Sensory Profile, SSP) were analysed using Spearman's correlations.

Results: For amplitude, a significant interaction between diagnosis and response type was observed ($F_{(2,888)}$=5.36, p=.0050; Fig1A). Post-hoc tests revealed a larger amplitude on first responses compared to second responses in the control group (t=3.45, p=.0077, d=0.23; Fig1B), but no significant differences between responses 1 and 3 or 2 and 3 (p=.2 and p=.9, respectively). In the ASD group, no differences between response types were observed (ps>.9). For latency, the effect of diagnosis was approaching significance ($F_{(1,443.91)}$=3.58, p=.059, d=-0.12), however there was no main effect of response type nor interaction (ps>.2). Older age was significantly associated with larger amplitude (b=-0.12, p=6.72e-16) and did not interact with diagnosis (p=.8), whilst diagnosis interacted with IQ on latency, such that higher IQ was related to shorter latency only in the control group (b=-0.30, p=0.017). In the ASD group, reduced habituation (a smaller S1-S3 difference) was significantly associated with more RRB symptoms (RBS-R total r_s=-0.19, p=.0052), specifically RBS-R Ritualistic-Sameness (r_s=-0.18, p=.0074; Fig1D) and RBS-R Restricted Interests (r_s=-0.21, p=.0017; Fig1E). These correlations remained significant when controlling for age (Ritualistic-Sameness r_s=-0.16, p=.019; Restricted Interests r_s=-0.19, p=.0046). Associations with sensory symptoms were not significant (SSP total r_s=0.11, p=.2).

Conclusions: There was evidence of initial habituation in the TD group but not in the ASD group. Within the ASD group, reduced habituation was associated with increased ritualistic-sameness behaviour and restricted interests. Behavioural rigidities may act as coping strategies for reduced neural habituation, here in the auditory domain.

322.004 *(Oral)* ADHD Comorbidity Modulates the Association between Cumulative Genetic Load for Autism Spectrum Disorder and Amygdala Structural Development

G. Bussu[1], *V. Trindade Pons*[2], *C. B. Beckmann*[3], *C. Ecker*[4], *T. Bourgeron*[5], *F. Campana*[6], *C. Leblond*[7], *F. Cliquet*[6], *J. Tillmann*[8], *T. Charman*[9], *E. Loth*[10], *D. G. Murphy*[11] *and J. K. Buitelaar*[12], *(1)Donders Institute for Brain, Cognition and Behaviour, Radboudumc, Nijmegen, Netherlands, (2)Radboud University, Nijmegen, Netherlands, (3)Centre for Functional MRI of the Brain (FMRIB), University of Oxford, Oxford, United Kingdom, (4)Department of Child and Adolescent Psychiatry, Psychosomatics and Psychotherapy, Goethe-University Frankfurt am Main, Frankfurt, Germany, (5)Human Genetics and Cognitive Functions, Institut Pasteur, Paris, France, (6)Institut Pasteur, Paris, France, (7)Institut PASTEUR, Paris, France, (8)King's College London, London, United Kingdom, (9)Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, United Kingdom, (10)Department of Forensic and Neurodevelopmental Sciences, Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, United Kingdom, (11)Forensic and Neurodevelopmental Sciences, Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, United Kingdom, (12)Karakter Child and Adolescent Psychiatry University Centre, Nijmegen, Netherlands*

Background: Autism Spectrum Disorder (ASD) is a highly heritable disorder with a complex polygenic architecture(Huguet, Benabou, & Bourgeron, 2016). Polygenic scores for ASD (PS-ASD) measure the cumulative genetic load for ASD at an individual level, allowing the investigation of the association between the polygenic component of ASD and its biological features. Core social symptoms have been associated to alterations in brain regions modulating social behaviour, like the amygdala, a central structure in emotional cognitive processing. In particular, neuroimaging studies have reported lower amygdala volume in ASD(van Rooij et al., 2018).

Objectives: To test the potential role of amygdala structural alterations as intermediate phenotype for ASD, we investigated the association between polygenic scores for ASD and amygdala volume. Furthermore, given the high genetic overlap between ASD and attention-deficit/hyperactivity disorder (ADHD), we investigated the effect of ADHD comorbidity on the association between PS-ASD and amygdala volume.

Methods: Polygenic scores for ASD were computed on 343 ASD cases and 241 typically developed controls from the EU-AIMS Longitudinal European Autism Project (Loth et al., 2017). Amygdala volumes were obtained from automatic subcortical segmentation on 348 individuals between 7 and 31 years of age (240 males), from four different outcome groups: typically developed individuals (TD, n=137), ASD cases (n=176), individuals with intellectual disability but not ASD (ID-controls, n=9), and ASD cases with intellectual disability (ID-ASD, n=26). We used a regression model to test whether PS-ASD would predict amygdala volume while accounting for age, gender, intelligence quotient (IQ), outcome group, site of data acquisition, and ADHD comorbidity. Amygdala volumes were corrected for intra-cranial volume.

Results: We found a significant correlation between polygenic liability for ASD and for ADHD ($r=0.23$, $p<10^{-3}$), supporting the idea of shared genetic liability between the disorders. The regression model showed a significant interaction between PS-ASD and ADHD comorbidity ($b=12.25$, $p=0.04$). In particular, PS-ASD had a negative marginal effect on amygdala volume in non-ADHD individuals ($b=-0.35$, $p=0.06$), while the effect was reversed but not significant in individuals with ADHD ($b=0.38$, $p=0.22$; Figure 1). We also found a significant main effect of site ($b_{site2}=-0.33$ and $b_{site5}=-0.25$ $ps<10^{-3}$), and a marginal effect of IQ ($b=-0.12$, $p=0.065$). Of note, adding PS-ADHD as a covariate did not improve model fit ($F(1,333)=1.82$, $p=0.18$), and its main effect was not significant ($b=-0.07$, $p=0.18$).

Conclusions: We conceptualize that cumulative effects of common genetic variants associated with ASD lead to changes in amygdala structure, in turn influencing social development and resulting in the ASD social phenotype. ADHD comorbidity interplays with the cumulative genetic load for ASD to modulate its association with amygdala structure. In particular, there was a marginally significant association only without ADHD comorbidity, with higher polygenic load for ASD linked to smaller amygdala volume. While previous studies report no difference between ASD and ADHD in subcortical volumes(Baribeau et al., 2019), our findings suggest a more complex interaction between the two disorders at a genetic level, affecting the resulting association with the structural brain phenotype. Further analysis of single variants might help disentangle the comorbidity effect on amygdala structure.

POSTER SESSION — **NEUROIMAGING**
435 - Neuroimaging Posters

435.001 *(Poster)* A Cross-Species Link between mTOR-Dependent Deficient Synaptic Pruning and Functional Hyper-Connectivity in Autism

M. Pagani[1], *A. Bertero*[1,2], *A. De Felice*[1], *A. Locarno*[3], *I. Miseviciute*[3], *S. Trakoshis*[4,5], *C. Canella*[1], *K. Supekar*[6], *V. Menon*[6], *A. Galbusera*[1], *R. Tonini*[3], *M. V. Lombardo*[5], *M. Pasqualetti*[1,2] *and A. Gozzi*[1], *(1)Istituto Italiano di Tecnologia, Functional Neuroimaging Lab, Centre for Neuroscience and Cognitive Systems, Rovereto, Italy, (2)University of Pisa, Department of Biology, Unit of Cell and Developmental Biology, Pisa, Italy, (3)Istituto Italiano di Tecnologia, Neuroscience and Brain Technologies Department, Genova, Italy, (4)Department of Psychology, University of Cyprus, Nicosia, Cyprus, (5)Center for Neuroscience and Cognitive Systems, Laboratory for Autism and Neurodevelopmental Disorders, Istituto Italiano di Tecnologia, Rovereto, Italy, (6)Stanford University, Stanford, CA*

Background: Post-mortem examinations have revealed an excess of excitatory synapses in the brains of children with autism spectrum disorders (ASD). Recent investigations have linked this trait to hyper-activity of the mTOR pathway, resulting in synaptic pruning deficits [1]. ASD is also characterized by alterations in brain functional connectivity as measured with resting state functional MRI (rsfMRI). These observations raise the question of whether and how mTOR-related deficient pruning affects rsfMRI dysconnectivity observed in ASD.

Objectives: Our work probes a mechanistic link between mTOR dysfunction and fMRI dysconnectivity in ASD. To this aim, we mapped dendritic synaptic density, rsfMRI connectivity [2] and social behavior in tuberous sclerosis 2 deficient ($Tsc2^{+/-}$) mice, a mouse line that mechanistically reconstitutes mTOR-dependent dendritic spine surplus observed in ASD [1]. A separate cohort of animals was subjected to a daily treatment with the mTOR inhibitor rapamycin with the aim to rescue the synaptic surplus, and establish a link between synaptic traits and brain-wide connectivity.

Methods: ***Mouse studies***. Animal studies were conducted in accordance with the Italian Law (DL 26/2014). We used a cross-sectional treatment protocol with four cohorts of n=20 animals each: control $Tsc2^{+/+}$ mice treated with rapamycin; control $Tsc2^{+/+}$ mice treated with vehicle; mutant $Tsc2^{+/-}$ mice treated with rapamycin; mutant $Tsc2^{+/-}$ mice treated with vehicle. After daily treatment during pre-pubertal phase [1], $Tsc2^{+/-}$ and control mice underwent rsfMRI mapping as previously described [2]. Inter-group differences in rsfMRI connectivity were mapped using weighted degree centrality (WDC) and seed-based analysis (SBA) [3]. Post-mortem dendritic spine density was measured as in [1]. ***Human studies:*** We used WDC and SBA to map rsfMRI connectivity in pre-pubertal (age range 7-13) children with ASD (n=163) and typically developing controls (n=168) from ABIDE-1 collection [4].

Results: We observed increased spine density and long-range rsfMRI over-connectivity in basal ganglia and polymodal cortical areas of $Tsc2^{+/-}$ mice, and found that hyper-synchronization of insular and striato-prefrontal regions was predictive of motor sterotipies in these mice. Developmental treatment with rapamycin completely normalized synaptic density, rsfMRI hyper-connectivity and behavioral alterations in $Tsc2^{+/-}$ mice. These results implicate a possible causal link between mTOR-related pruning deficits, rsfMRI hyper-connectivity and fronto-insular dysfunction. Given the prominent implication of mTOR pathway dysfunction for human ASD [1], we hypothesized that a similar hyper-connected phenotype should be identifiable in clinical ASD populations. In keeping with mouse findings, rsfMRI connectivity mapping in pre-pubertal children revealed increased long-range connectivity in the anterior insula, basal ganglia and prefrontal cortices in children with ASD with respect to typically developing controls. Furthermore, insular prefrontal over-connectivity was significantly associated with repetitive behaviors, reconstituting the phenotype observed in $Tsc2^{+/-}$ mice. We finally found that TSC2/mTOR-network genes appear to be expressed in a similar topological pattern as the identified ASD hyper-connectivity phenotype, establishing a putative mechanistic link between the observed hyperconnectivity and mTOR-related aberrant activity in ASD.

Conclusions: Taken together, our results establish a possible mechanistic link between mTOR-dependent deficient synaptic pruning and rsfMRI over-connectivity in ASD.

435.002 *(Poster)* A Longitudinal Diffusion Weighted Imaging Study of White Matter Development in Autism across Early Childhood

D. S. Andrews[1], *J. K. Lee*[1], *D. J. Harvey*[2], *M. Solomon*[1], *S. J. Rogers*[1], *D. G. Amaral*[1] *and C. W. Nordahl*[1], *(1)Department of Psychiatry and Behavioral Sciences, The Medical Investigation of Neurodevelopmental Disorders (MIND) Institute, UC Davis School of Medicine, University of California Davis, Sacramento, CA, (2)Public Health Sciences Division of Biostatistics, University of California Davis, Davis, CA*

Background: Diffusion weighted magnetic resonance imaging (DWI) studies of autism indicate atypical white matter (WM) microstructure in autism spectrum disorder (ASD). While a large body of evidence suggests older children, adolescents and adults with autism have decreased fractional anisotropy (FA) across several commissural, projection, and associative fiber tracts, a smaller literature in young preschool aged children (i.e. <30-50 months) suggests autistic individuals have increased FA earlier in development.

Objectives: We sought to characterize the longitudinal trajectory of WM diffusion properties associated with autism in a sample of male and female children across early childhood.

Methods: We analyzed 135 individuals with ASD diagnoses (91♂,44♀) and 83 typically developing controls (46♂,37♀), who successfully completed at least two DWI acquisitions over the course of three annual follow-up visits from ~2-6½ years of age. DWI were acquired in 30 independent directions with five interleaved *b*0 images. Images were pre-processed using MRtrix3, including; 1) image denoising, 2) Gibbs artefact correction, 3) eddy current correction, 4) outlier detection and replacement, and 5) between and within volume motion correction. A longitudinal registration protocol was used to map individual's FA maps to the JHU-ICBM WM atlas and extract median FA values across 13 tracts of interest. Linear mixed effects modeling was used to investigate diagnostic differences in developmental trajectories. Each model included diagnostic group, sex, pre-post scanner update, and ROI as categorical fixed effect factors, age, cerebral volume, absolute and relative movement as continuous covariates, and individual as a random effect with age as a random slope. For each tract, age was modeled by selecting from series of fractional polynomials [-3, -2, -1, -0.5, 0.5, 1, 2, 3] shown to have the lowest log likelihood and thus provide the best fit.

Results: The corpus callosum and bilateral cingulum, superior longitudinal fasciculi (SLF), internal capsules, and sagittal striatum all showed significant (FDR $p<0.05$) age-by-diagnosis interactions in measures of FA. By 6½ years of age, these tracts showed decreased FA in both males and females with ASD. However, trajectories within several WM regions including the body and splenium of the corpus callosum, SLF and internal capsules suggest an inflection point around 30-35 months where younger individuals with ASD showed increased FA.

Conclusions: Our findings provide longitudinal evidence that individuals with ASD have an altered WM developmental trajectory characterized by increased FA in young childhood and decreases later in life. The inflection point for this transition appears to be around 30-35 months of age, but varies by tract and for some regions may occur prior to the age of diagnosis. Next steps will be to investigate the behavioral consequences associated with altered WM development in autism, including associations with autism severity and intellectual ability.

435.003 *(Poster)* A Machine Learning Approach for Grading Autism Severity Levels Using Task-Based Functional MRI

R. Haweel[1], *O. Dekhil*[1], *A. Shalaby*[1], *A. Mahmoud*[1], *G. Barnes*[2] *and A. S. El-Baz*[3], *(1)Bioengineering, University of Louisville, Louisville, KY, (2)Neurology, University of Louisville School of Medicine, Louisville, KY, (3)University of Louisville, Louisville, KY*

Background: Some autism characteristics can be observed as early as 12 months old with the advent of brain medical imaging modalities and the recent state of the art machine learning algorithms. In general, task-based fMRI is used for addressing evoked blood oxygen level-dependent (BOLD) signals in all brain regions with response to certain tasks belonging to a range of different task domains. Studies in literature statistically examined the hemodynamic effects associated with task-control using the general linear model (GLM). The focus of previous studies was to analyze or diagnose autism disorder in two groups of ASD or normal, which is not sufficient for addressing differences among subjects across the wide autism spectrum.

Objectives: The goal of this study is to utilize brain processing and analysis tools as well as machine learning algorithms for developing an autism severity grading approach to diagnose each autistic subject as mild, moderate or severe autistic. Hence, presenting a more specialized objective computer aided diagnosis (CAD) system to provide a better early diagnosis and treatment plan for each autistic subject individually having different autism severity.

Methods: A novel framework for grading the severity level of autistic subjects using task based fMRI in a speech experiment (Fig. 1), consisting of four audio stimulus, is presented with the following steps: 1) preprocessing using fMRI expert analysis tool (FEAT) included in fMRIB's software library (FSL). 2) feature extraction with multi-level general linear model (GLM) averaged for each brain area according to the Brainnetome atlas (BNT). 3) classification and severity grading according to ADOS reports using recursive feature elimination (RFE) and random forest (RF) classifier. To validate our results, we applied higher level analysis to have more insightful analysis about the overall group differences and match with selected features of each brain area

Results: This study is conducted on" Biomarkers of Autism at 12 Months: From Brain Overgrowth to Genes" dataset obtained by the National Database for Autism Research (NDAR). The adopted dataset consists of 39 subjects (13 subjects per group). we use random forest classifier in both RFE and classification. We used a 10-folds cross validation technique and calculated the accuracy of classification. The achieved accuracy is 76%. We have validated our selected features in our classification by comparing them with the most activated areas in the group analysis. High intersection between the selected areas by RFE, in the feature selection step, with the top activated areas in each group is revealed.

Conclusions: In this study, we introduce a machine learning based approach for autism severity grading on the autism spectrum. To the best of our knowledge, this is the first effort to utilize task based fMRI for this goal. With a limited number of subjects (n = 39), our algorithm achieved accuracy of 72% using random forest classifier following recursive feature elimination. We also applied group analysis to validate selected features and study common group brain activation.

435.004 *(Poster)* A Twin Study of Sensory Processing in Children with Autism Spectrum Disorder

J. Gong[1], *J. P. Hegarty*[2], *L. C. Lazzeroni*[3], *S. C. Cleveland*[2], *J. M. Phillips*[2], *J. F. Hallmayer*[2] *and A. Y. Hardan*[2], *(1)Psychiatry and Behavioral Sciences, Stanford University, Stanford, CA, (2)Psychiatry & Behavioral Sciences, Stanford University, Stanford, CA, (3)Biomedical Data Science, Stanford University, Stanford, CA*

Background: Differences in sensory processing are associated with autism spectrum disorder (ASD) and may be related to structural differences in the primary sensory processing regions in the brain, such as auditory processing difficulties and the primary auditory cortex. Neurobiological variation across individuals in these brain regions is linked with different genetic and environmental factors during brain development.

Objectives: The primary objective was to examine the relationship between sensory processing difficulties and brain regions involved in sensory processing in twins with and without ASD to determine whether brain-behavior relationships are related to genetic or environmental factors.

Methods: Monozygotic (MZ) and dizygotic (DZ) twin pairs aged 6-15 years participated in this study. FreeSurfer was used to process T1-weighted MRI scans and generate structural neuroimaging measures of the brain. The Short Sensory Profile (SSP) was used as a measure of sensory processing. Intra-class correlations and ACE modeling (a2=additive genetics, c2=shared environment, e2=unique environment) for broad sense heritability was used to estimate the influence of genetic and environmental factors these measures. Brain-behavior relationships were also examined between structural brain measures and the domain-specific subscales of the SSP.

Results: Analyses included data from 148 twins [26 concordant ASD twin pairs (13 MZ,13 DZ), 17 discordant ASD twin pairs (3MZ,14DZ), and 31 concordant TD twin pairs (18 MZ,13 DZ)]. Brain-behavior relationships were observed across several sensory domains but one of the most prominent was between auditory filtering and the superior temporal gyrus, a region integral to auditory processing. Auditory filtering difficulties were more severe in twins with ASD (M=13.33,SD=5.12) than TD controls (M=24.98,SD=3.65); $p<0.001$. These difficulties were also more severe in twins with ASD (M=18.75,SD=4.55) compared to their unaffected co-twins (M=26.44, SD=3.61); $p<0.001$. Grey matter (GM) in the left and right STG was also thicker in twins with ASD (M_{left}=3.18,SD=0.19; M_{right}=3.18,SD=0.18) compared to TD twins (M_{left}=3.09,SD=0.17, $p<0.04$; M_{right}=3.09,SD =0.17, $p<0.05$) as well as twins with ASD (M_{right}=3.21,SD=0.13) compared to their unaffected co-twins (M_{right}=3.09,SD=0.19); $p<0.03$. Additionally, GM thickness exhibited significant genetic contributions in TD twins (a2=0.44[0.11,0.78]) but was primarily environmentally mediated in twins with ASD (c2=0.80[0.68,0.93]). GM differences between twin pairs were also associated with auditory filtering differences in MZ (r=-0.36,p=0.003) but not DZ twin pairs, $p>0.05$, further supporting environmental influences on these brain-behavior relationships.

Conclusions: Our findings indicate that the presence of some sensory processing difficulties in children with ASD may be associated with the impact of environmental factors on GM development in the primary sensory processing cortices in the brain. These observations also support previous studies implicating the STG with differences in auditory processing as well as our preliminary examination of global level GM thickness in which twins with ASD exhibited greater environmental influences across the brain compared to TD controls. Future research into the specific environmental factors that impact sensory processing difficulties in children with ASD may provide useful therapeutic targets for minimizing these difficulties.

435.005 *(Poster)* Absence of White Matter Abnormalities in Males with Autism: A Quality-Controlled, Diffusion Tensor Imaging Study

J. S. Jurayj[1], *H. B. Koene*[1], ***A. B. Fanta***[1], *K. A. Pelphrey*[2] *and R. J. Jou*[3], *(1)Yale Child Study Center, Yale School of Medicine, New Haven, CT, (2)University of Virginia, Charlottesville, VA, (3)Yale University, New Haven, CT*

Background: Diffusion Tensor Imaging (DTI) has been used to investigate the neural phenotype of autism spectrum disorder (ASD) by detecting potential differences in structural brain connectivity. Previous DTI studies report widespread, although heterogeneous, white matter (WM) differences in individuals with ASD. Many of these studies supported reductions Fractional Anisotropy (FA) in males with ASD compared to typically developing (TD) controls (Aoki et al., 2013). However, in later studies which follow stringent data quality control protocols (Kwondelyn et al., 2014; Yendiki et al., 2014), these findings were not replicated. In fact, Lei et al. (2019), which implemented stringent data quality control, suggests that females with ASD exhibit widespread reductions in FA compared to female TD controls, while males with ASD exhibit no differences when compared to male TD controls. These inconsistent findings highlight the need for future investigation on differences between the neural phenotype of males with ASD compared to TD males.

Objectives: To evaluate differences in WM between males with ASD and TD males using DTI.

Methods: Subjects included 35 males, 21 subjects with ASD (age = 21 ± 7.7 years), and 14 TD controls (age= 25.4 ± 7.6 years). T1-weighted and diffusion-weighted MRI (directions = 6 and b0 = 1) were acquired using a 1.5-Tesla scanner. FMRIB Software Library (FSL) was used to process/analyze diffusion-weighted data and compute the following WM microstructure metrics: fractional anisotropy (FA), mean diffusivity (MD), axial diffusivity (AD) and radial diffusivity (RD). Voxel-wise analysis of multi-subject diffusion data was conducted using FSL's Tract Based Spatial Statistics (TBSS). Areas of significant difference were computed using Threshold-Free Cluster Enhancement (TFCE) and displayed as p-value images, where $p < 0.05$ corrected for multiple comparisons across space.

Results: The groups did not differ on age ($p = .076$). ASD males had significantly lower FSIQ (M=103.1+/-10.9) than TD controls (M=112.6+/-9.8) ($p=.013$). There were no significant group differences on FA, MD, AD, or RD between ASD groups and TD controls.

Conclusions: No significant between group effects were observed between male ASD and TD participants. These null results are consistent with recent findings by Lei et al. (2019) suggesting that using stringent data quality control measures, abnormalities exist between ASD females and TD females, but are not apparent between ASD males and TD males. Lack of statistically significant differences does not preclude that aberrant WM microstructure exists in ASD males, especially if the effects are small. Future studies should investigate whether current findings replicate in much larger studies with closely-matched comparison groups.

435.006 *(Poster)* Altered Social Cognition and Connectivity of Default Mode Networks in the Co-Occurrence of Autistic Spectrum Disorder and Attention Deficit Hyperactivity Disorder

*K. Wang, M. Xu, X. Du, **J. Yu** and F. Li, Developmental and Behavioral Pediatric Department & Child Primary Care Department, Brain and Behavioral Research Unit of Shanghai Institute for Pediatric Research and MOE Shanghai Key Laboratory for Children's Environmental Health, Xinhua Hospital, Shanghai, China*

Background: As two common neurodevelopmental disorders, autistic spectrum disorder and attention deficit hyperactivity disorder frequently occur together.

Objectives: Until now, only a few studies have investigated the co-occurrence of attention deficit hyperactivity disorder and autistic spectrum disorder, this is due to restrictions associated with previous Diagnostic and Statistical Manual of Mental Disorders, Fourth Edition, Text Revision. Most previous research has focused on the developmental trajectories for autistic spectrum disorder and attention deficit hyperactivity disorder separately, while the neural mechanisms underpinning the co-occurrence of autistic spectrum disorder and attention deficit hyperactivity disorder remain largely unknown.

Methods: We studied 162 autistic spectrum disorder individuals (including 79 co-attention deficit hyperactivity disorder and 83 non-attention deficit hyperactivity disorder patients) and 177 typical developing individuals using resting-state functional magnetic resonance imaging data from the Autism Brain Imaging Data Exchange II, an aggregated magnetic resonance imaging dataset from 19 centers. Independent component analysis was used to extract sub-networks from the classic resting-state networks. Functional connectivity values within (intra-iFC) and between (inter-iFC) these networks were then determined. Subsequently, we compared the ASD_coADHD group with the ASD_nonADHD group in relation to the abnormal intra-iFC and inter-iFC of autistic spectrum disorder group relative to the typical developing group.

Results: The ASD_coADHD group showed more severe social impairment and decreased intra-iFC in the bilateral posterior cingulate cortex of the default mode network (independent component 17) and increased inter-iFC between the default mode network (independent component 8) and the somatomotor networks (independent component 2) compared to the ASD_nonADHD group. In addition, the strength of the intra-iFC in the default mode network was associated with the severity of autistic traits across the entire autistic spectrum disorder group and particularly the ASD_coADHD group.

Conclusions: Our results showed that dysfunction of the default mode network is a central feature in the co-occurrence of autistic spectrum disorder and attention deficit hyperactivity disorder, including connectivity within the default mode network as well as between the default mode network and the somatomotor networks, thus supporting the existence of a clinically combined phenotype (autistic spectrum disorder + attention deficit hyperactivity disorder).

435.007 *(Poster)* Anomalous Auditory Object Binding in Autism Spectrum Disorder

*H. M. Bharadwaj[1], S. Khan[2], A. Losh[3,4], M. S. Hämäläinen[2] and **T. Kenet**[5], (1)Purdue University, West Lafayette, IN, (2)Massachusetts General Hospital, Boston, MA, (3)Graduate School of Education, University of California Riverside, Riverside, CA, (4)MGH, Boston, MA, (5)Massachusetts General Hospital, Charlestown, MA*

Background: Auditory processing deficits have been extensively documented in ASD, and neurophysiological signatures of these abnormalities have been mapped using a variety of paradigms. To date, the vast majority of such studies focused on the neural signatures resulting from the processing of stimuli such as tones or speech sounds. Tones, simple or complex, presented in isolation, do not elicit synchronous activity or require binding. Speech sounds, in contrast, are highly complex and meaningful auditory structures, and can be referred to as "auditory objects". Organizing auditory information into coherent auditory objects, i.e. the binding of acoustic features into auditory objects, is fundamental to the proper decoding of auditory information, but we do not fully understand the nature of the deficits associated with type of processing in ASD.

Objectives: The objective of the study was to understand the extent to which abnormal perceptual binding of acoustic features may contribute to perceptual auditory deficits in ASD.

Methods: A novel auditory stimulus was developed, where the temporal coherence of different acoustic features could parametrically manipulated such that the acoustic features formed into auditory objects with increasing salience as the temporal coherence was increased. We then used magnetoencephalography (MEG) to study the neurophysiological responses to this stimulus at varying levels of temporal coherence, in 26 typically-developing (TD) children and 21 children with ASD, who were age (8-17), sex, and IQ matched.

Results: We found that children with ASD showed impaired sensitivity to the temporal coherence that promotes perceptual binding of acoustic features into auditory objects. The extent of the auditory processing deficits varied directly with the ability to neurophysiology bind auditory objects. While evoked responses increased in magnitude with increasing coherence in the TD group, the evoked responses flattened with increasing coherence in the ASD group. The extent to which this was the case correlated significantly with both the sensory processing score, obtained using the Sensory Processing Questionnaire, and the severity of communication deficits, measured using the ADOS communication subscore.

Conclusions: These findings offer novel insights into the mechanisms underlying auditory perceptual deficits of ASD. Given that temporal coherence is an important binding cue in natural sounds, the reduced sensitivity in ASD to temporally synchronized auditory stimuli likely contributes to poorer object binding. In scenarios with multiple sound sources, this could lead to poorer segregation of the sounds into individual objects, contributing to sensory overload and impaired auditory selective attention. The reduced ability to bind the stimulus into objects in the ASD group is also consistent with the atypical activity of GABAergic neurons, given the role of the GABAergic system in object binding. Our observations thus also contribute to our understanding of the specific mechanisms underlying the ways in which abnormal GABAergic function might ultimately lead to some of the most common sensory processing deficits in ASD.

435.008 *(Poster)* Anxiety but Not Sensory over-Responsivity Is Associated with Attrition in Resting State fMRI Research in School Age Children with Autism and Developmental Delay

E. Glenn[1]*, F. Sabb*[2] *and L. L. McIntyre*[1]*, (1)Special Education and Clinical Sciences, University of Oregon, Eugene, OR, (2)Lewis Center for Neuroimaging, University of Oregon, Eugene, OR*

Background: Prevalence studies suggest 40% of children with autism spectrum disorders (ASD) will develop an anxiety disorder. One pathway through which anxiety disorders are hypothesized to develop is sensory over-responsivity. Children with developmental delay (DD), while experiencing similar levels of sensory over-responsivity, exhibit lower rates of anxiety than children with ASD, while still higher than the general population. Resting state fMRI (rs-fMRI) research could provide an essential lens into neurobiological mechanisms through which sensory over-responsivity differentially contributes to the development of anxiety. However, due to the nature of MRI acquisition, it's possible anxiety and sensory over-responsivity could also uniquely contribute to attrition in this sample of children.

Objectives: This study aims to investigate patterns of attrition within a sample of children with ASD and DD participating in a rs-fMRI protocol, and to examine if clinical profiles predict which children will be unable to attempt or complete an MRI.

Methods: This sample consisted of 86 school-age children (M=110mo; SD=22mo) participating in a study exploring shared neurobiological etiology between ASD and DD. Participants completed clinical assessments, a mock scan, and an rs-fMRI protocol lasting approximately 25 minutes involving a fixation crosshair and a standardized movie. Autism diagnosis and severity were obtained using the ADOS, with additional diagnoses collected via parent checklist. Anxiety, sensory over-responsivity, and sensory over-responsivity to sound were measured using the CBCL, SSP, and SensOR, respectively.

Attrition occurred in 3 distinct ways: 1) ten families declined to participate in the MRI protocol, including the mock session, 2) six participants completed a mock session but declined an MRI visit, and 3) six participants attempted an MRI but were unable to complete the full rs-fMRI protocol. As participants in these attrition groups demonstrated relative homogeneity across variables of interest (p's > 0.5), we collapsed these participants into a singular group to compare to children who completed the full rs-fMRI protocol. Fisher's exact tests and generalized linear models were used to determine if clinical variables predicted scan completion.

Results: When comparing MRI completers to the attrition group, no statistically significant differences were found related to age, elevated sensory over-responsivity, sensory over-responsivity to sound, or number of co-occurring diagnoses. Participants unable to attempt or complete the scan were significantly more likely to have elevated anxiety scores than those who completed the MRI (72% versus 46%; p= 0.035; OR: 0.33). For participants with ASD, ASD symptom severity did not significantly predict MRI completion rates.

Conclusions: Although 91% of our sample of children with ASD and DD who attempted an MRI successfully completed our rs-fMRI protocol, 29% of children from the original sample were lost to attrition in various forms. Children with elevated anxiety were at greater risk for attrition, however, sensory over-responsivity did not predict attrition. Future research should target approaches for engaging participants in MRI research during various stages of the process, and explore additional desensitization procedures that effectively reduce the effects of anxiety on MRI participation.

435.009 *(Poster)* Association of Self-Regulation with White Matter Microstructural Property in Boys with and without Autism Spectrum Disorder

H. Y. Lin[1]*, H. C. Ni*[2] *and S. S. F. Gau*[3]*, (1)Department of Psychiatry, University of Toronto, Toronto, ON, Canada, (2)Psychiatry, Chang Gung Memorial Hospital at Linkou, Taipei, TAIWAN, (3)Department of Psychiatry, National Taiwan University Hospital & College of Medicine, Taipei, Taiwan*

Background: Self-regulation, the ongoing and dynamic modulation of action, emotion and cognition, plays an important role in co-occurring psychopathology in individuals with autism. Previous studies demonstrated distinct neural correlates underpinning impaired self-regulation (dysregulation) between individuals with autism spectrum disorder (ASD) and typically developing controls (TDC). However, white matter (WM) correlates of dysregulation in ASD and TDC remain unclear.

Objectives: To investigate WM correlates of dysregulation in intellectually able boys with ASD and TDC boys, we leveraged recent advances in multivariate analysis, canonical correlation analysis, CCA, and the diffusion spectrum imaging (DSI) tractography.

Methods: Diffusion spectrum imaging was acquired in 59 ASD and 62 TDC boys. We investigated the relationship between participants' dysregulation levels and microstructural property of 76 WM tracts in a multivariate analysis (canonical correlation analysis), across diagnostic groups. CCA was used to identify the maximum co-variation between individuals' behavioral characteristics related to self-regulation and WM property.

Results: The application of CCA identified one significant mode (r = 0.59, FWE-corrected p = 0.005) of interdependences between WM property patterns and the diagnosis, diagnosis by dysregulation interaction and general cognitive function (FIQ). his mode corresponds to diagnosis-distinct correlates underpinning dysregulation, which showed higher generalized fractional anisotropy (GFA) associated with less dysregulation in ASD but greater dysregulation in TDC, in the tracts connecting limbic and emotion regulation systems. Moreover, higher GFA of the tracts implicated in memory, attention, sensorimotor processing, and perception associated with less dysregulation in TDC but worse dysregulation in ASD. No shared WM correlates of dysregulation between ASD and TDC were identified.

Conclusions: These findings not only support a notion that self-regulation encompasses multiple cognitive processes, but also suggest indispensable diagnosis-specific strategies when advancing therapeutics for dysregulation in individuals with ASD.

435.010 *(Poster)* Associations between Elicited Motor Imitation and Visual-Motor Cortical System Morphology in Children with and without Autism Spectrum Disorder

C. Chen[1], *D. Crocetti*[1], *R. N. Rochowiak*[1], *C. Pacheco*[2], *A. Y. Herstic*[1], *R. Vidal*[2], *B. Tuncgenc*[3] *and S. H. Mostofsky*[4], *(1)Center for Neurodevelopmental and Imaging Research, Kennedy Krieger Institute, Baltimore, MD, (2)Johns Hopkins University, Baltimore, MD, (3)Psychology, University of Nottingham, Nottingham, MD, United Kingdom, (4)Center for Autism and Related Disorder, Kennedy Krieger Institute, Baltimore, MD*

Background: Studies show that children with Autism Spectrum Disorder (ASD) demonstrate poorer elicited motor imitation compared to typically-developing (TD) controls, with associations of greater symptom severity and impaired social behaviors. Investigations of the neural correlates involved in elicited motor imitation reveal recruitment of motor and visual-motor networks. However, there lacks brain-behavior investigations using objective, quantitative assessment of motor imitation.

Objectives: To examine diagnostic effects on motor imitation, measured using a novel, highly-reliable, Computerized Assessment of Motor Imitation (CAMI), and associations with brain morphologies of motor and visuomotor network regions in children with ASD and TD controls.

Methods: The present study included data from 52 participants (27 ASD) ages 8-12 years old. Motor imitation was assessed using CAMI applied to a task during which children imitated a sequence of limb and whole-body movements performed by an avatar. Volume, surface area (SA), and thickness of the inferior parietal lobe (IPL), superior temporal sulcus (STS), supplementary motor complex (SMC) and primary motor cortex (M1) were defined in FreeSurfer v6.0 for both hemispheres (LH and RH). All analyses covaried for total cerebral volume. ANCOVAassessed effects of diagnosis on CAMI and brain morphologies.

Results: A multivariate GLM revealed a significant diagnostic effect on CAMI ($p<0.001$), such that children with ASD demonstrated worse imitation than TD controls ($\bar{X}_{ASD}=0.31$, $\bar{X}_{TD}=0.54$). Analyses also revealed a significant diagnostic effect on RH STS SA ($p=0.014$), RH SMC SA ($p=0.042$), and LH M1 thickness ($p=0.044$), such that children with ASD show greater SAs and thickness ($\bar{X}_{ASD}=4166.15$, $\bar{X}_{TD}=3855.17$; $\bar{X}_{ASD}=1749.25$, $\bar{X}_{TD}=1603.17$; $\bar{X}_{ASD}=2.76$, $\bar{X}_{TD}=2.67$ respectively). No significant correlations between CAMI and brain morphology were observed in the whole group. Looking within diagnostic groups, a significant positive correlation was found in TD controls between CAMI and LH SMC SA ($r=0.36$, $p<0.05$). Further, positive correlations trending toward significance were observed between CAMI and the following morphologies in the TD group: RH SMC SA ($r=0.35$, $p=0.05$), LH SMC volume ($r=0.32$, $p=0.07$), and RH M1 SA ($r=0.34$, $p=0.06$). Positive and negative correlations trending toward significance were found in between CAMI and the following morphologies in the ASD group: LH STS volume ($r=0.361$, $p=0.059$), RH STS volume ($r=0.365$, $p=0.057$), and RH M1 SA ($r=-0.349$, $p=0.066$).

Conclusions: Findings confirm previous reports revealing increased regional visuomotor cortical system SA and thickness in children with ASD compared to TD controls. Examination of motor imitation correlates suggest that for children with ASD poorer imitation is associated with reduced STS volume but increased M1 SA. In contrast, associations for TD children appear localized to motor/premotor regions with poorer imitation associated with reduced SA in SMC/M1. The findings suggest dissociable brain-behavior relationships underlying motor imitation in children with ASD vs. TD children.

435.011 *(Poster)* Associations of Inferior Parietal Cortex Structure with Behavioral and Linguistic Measures of Social Communication Impairments in Children with Autism

A. Y. Herstic[1], *C. A. Koch*[1], *M. J. Stabile*[2], *C. Chen*[1], *I. M. Eigsti*[2], *S. H. Mostofsky*[1,3] *and B. Tuncgenc*[4], *(1)Center for Neurodevelopmental and Imaging Research, Kennedy Krieger Institute, Baltimore, MD, (2)Psychological Sciences, University of Connecticut, Storrs, CT, (3)Department of Neurology, Johns Hopkins University School of Medicine, Baltimore, MD, (4)Psychology, University of Nottingham, Nottingham, MD, United Kingdom*

Background: Social communication impairments in autism spectrum disorders (ASD) manifest in both behavioral and linguistic domains. Within the behavioral domain, mimicry of others' gestures, known to facilitate prosociality and interpersonal rapport is observed less frequently and synchronously in individuals with ASD as compared to typically-developing (TD) individuals (Helt et al., 2010). Within the linguistic domain, children with ASD produce more poorly-constructed narratives than their TD peers (Baixauli et al, 2016). Individuals with ASD show increased gray matter volume (GMV) and thickness in the inferior parietal cortex (IPC) (Brieber et al, 2007; Hyde et al, 2010), an area implicated in social cognition, language, and gesture imitation/praxis. Given these differences in early brain development in ASD, altered IPC structure may be associated with these behavioral and linguistic social-communicative impairments.

Objectives: This study examined the relationships among mimicry, narrative storytelling structure, and IPC structure (i.e., thickness and GMV), and how these relationships differ in children with ASD compared to TD children.

Methods: Participants included children aged 8-12 years (22 ASD, 24 TD); groups did not differ on age, sex, or total cerebral volume. Participants completed a story narration activity, during which they watched a video of a narrator telling a brief story and performing specific actions (yawning, arm scratching, face rubbing). Children's retellings were coded for the *proportion of story elements retold* (narrative structure) and *frequency of mimicked actions*. Structural metrics of IPC morphology were derived using FreeSurfer, applied to T1-weighted images acquired using a 3T Phillips scanner.

Results: Children with ASD showed reduced mimicry (p=.04) and presented fewer story events (p=.02) than TD children. There was a significant group difference in IPC, with increased thickness (p=.04) and GMV (p=.03) across hemispheres in the ASD group. A multiple regression test revealed a significant interaction between IPC GMV and diagnosis on story event production, such that increased IPC volume was associated with *poorer* story event production in children with ASD, but *better* story event production in TD children (F(1,45)=5.37, p=.03). The opposite pattern was found for the interaction effect of IPC thickness and diagnosis on story event production: TD children with increased IPC thickness produced fewer story events (F(1,45)=5.64, p=.02). Additionally, there was a significant interaction effect of IPC thickness and diagnosis on mimicry, such that TD children with increased IPC thickness showed increased mimicry (F(1,42)=4.35, p=.04). Figure 1 illustrates the diagnosis effect on, and interactions between IPC volume, IPC thickness, story event production and mimicry.

Conclusions: Children with ASD exhibited less spontaneous mimicry, produced fewer story events, and had increased IPC GMV and thickness relative to TD children. Examination of brain-behavior associations indicated that volumetric differences in the IPC may contribute to poorer narrative structuring abilities and impaired gesture mimicry in children with ASD. These findings elucidate the involvement of the IPC in behavioral and linguistic impairments in ASD.

435.012 *(Poster)* Atypical Deactivation Order Associated with Posterior Default Mode Network in Autism Spectrum Disorder

A. Kotila[1], *M. Järvelä*[2], *V. Korhonen*[2,3], *S. Loukusa*[1], *H. E. Ebeling*[4], *T. Hurtig*[4], *V. Kiviniemi*[2,3] *and V. Raatikainen*[2,3], *(1)Research Unit of Logopedics, University of Oulu, Oulu, Finland, (2)Research Unit of Medical Imaging, Physics and Technology, University of Oulu, Oulu, Finland, (3)Department of Diagnostic Radiology, Oulu University Hospital, Oulu, Finland, (4)Clinic of Child Psychiatry, University of Oulu and Oulu University Hospital, Oulu, Finland*

Background: Earlier studies have reported differences in resting state network (RSN) function between individuals with autism spectrum disorder (ASD) and neurotypical (NT) individuals but have not fully considered the temporal propagation patterns across the brain. Recent studies have shown atypical time lag variations across brain regions in ASD. These studies have analyzed the lag structure by computing cross-correlation function for the full-time series (Mitra et al. 2015) or by dynamic lag analysis (DLA) method (Raatikainen et al. 2019) which measures time lag variations peak-by-peak between RSNs and statistically defines how the lag patterns are altered between NT and ASD. Despite the growing interest in temporal propagation patterns, the nature of dynamic deactivation patterns in ASD is still unknown.

Objectives: The aim of this study was to investigate dynamic negative phase lag variations between RSNs in ASD compared to NT individuals by utilizing the DLA method.

Methods: The study population consists of 20 young adults (age 23.7[3.2]; 5 females) who had been diagnosed with ASD in their childhood based on ICD-10 criteria and 20 NT controls (age 25.3[6.2]; 4 females). Resting state data were acquired using a Siemens 3T Skyra scanner with fast fMRI sequence (10Hz). Preprocessing was performed using a typical FSL pipeline as described in Raatikainen et al. (2019). Group level ICA (independent component analysis; model order 40) was used to identify 16 resting-state networks (RSNs) for dynamic lag analysis (DLA). DLA was applied to groupwise concatenated very low frequency (VLF) time signals to reveal the time lag variation between RSNs pairs as in Raatikainen et al. (2019), in exception that lags were measured between negative peaks of the time signals (Fig.1A).

Results: After investigating 120 combinations of RSNs pairs applying the DLA method, statistically significant differences in negative-to-negative lag patterns between the NT and ASD groups were found in three network pairs including posterior default mode network (DMN): DMN_{pcc} (posterior cingulate cortex) - V1 (primary visual network; p= .001), $DMN_{precuneus}$ – Salience network (p< .001) and $DMN_{precuneus}$L (left) – CEN (central executive network; p= .002), see Fig.1B. When examining dynamic lag distributions in these network pairs, there was a distinct directionality in the deactivation pattern in the NT group: in majority of the lags negative phase of the posterior DMN follows negative phase of V1, Salience network and CEN (median lag positive). Furthermore, order between these RSNs was less evident in ASD, especially between interplay of $DMN_{precuneus}$-Salience network pair. Moreover, the lag count was 29%, 20% and 9% higher in the NT than ASD group in DMN_{pcc}-V1, $DMN_{precuneus}$L-CEN and $DMN_{precuneus}$-Salience, respectively.

Conclusions: The NT group showed a robust directionality in deactivation where the posterior DMN deactivation followed deactivations of three other RSNs. In the ASD group the directionality was more random between the posterior DMN and other networks. Weaker directionality in connectivity may be linked to restricted attention shifting in ASD.

435.013 *(Poster)* Atypical Development of Language Network Functional Connectivity in Infants at High Risk for ASD

J. Liu[1], *N. J. Okada*[2], *K. K. Cummings*[2], *J. Jung*[2], *G. Patterson*[1], *S. Y. Bookheimer*[2], *S. Jeste*[1] *and M. Dapretto*[2], *(1)University of California, Los Angeles, Los Angeles, CA, (2)Dept of Psychiatry and Biobehavioral Sciences, University of California, Los Angeles, Los Angeles, CA*

Background: Altered functional connectivity is characteristic of developmental disorders involving language impairment such as autism spectrum disorder (ASD). Individuals with ASD show altered connectivity in several resting-state networks compared to neurotypical controls. In particular, youth with ASD show altered interhemispheric functional connectivity between primary and secondary auditory cortices as well as atypical temporo-thalamic connectivity associated with social behavioral symptoms. Toddlers with ASD display disrupted synchronization of language areas, suggesting that early disruptions in functional connectivity may be predictive of later language impairments associated with the disorder. Prior studies have examined the emergence of functional network atypicalities in infants at high familial risk for ASD, but little is known about the development of functional connectivity within auditory-language networks in at-risk infants.

Objectives: We used resting-state fMRI (rsfMRI) to characterize the development of functional connectivity networks underlying auditory and language processing during the first year of life in infants at high (HR) and low familial risk (LR) for ASD.

Methods: During natural sleep, 8-minute rsfMRI scans were collected in infants at 1.5 and 9 months of age. Preprocessing was performed using FSL. To correct for effects of head motion, an advanced ICA-based strategy for automatic removal of motion artifacts (ICA-AROMA) was used. We first examined seed-based connectivity of primary and secondary auditory cortices (left/right Heschl's gyrus and posterior superior temporal gyrus) at 1.5 and 9 months of age. Time-series extracted from processed residuals in standard space were correlated with every other voxel to generate functional connectivity maps. We examined group differences for functional networks associated with each seed separately. Next, we modeled longitudinal changes over time in network connectivity using linear mixed models in R to examine emerging differences in the functional connectivity between auditory and language-processing regions as well as the thalamus. More specifically, we investigated the effects of risk group within each time point, the effects of time point within each risk group, and the interaction between risk group and time point.

Results: As early as 1.5 months of age, functional connectivity underlying the integration of auditory and motor representations, which is crucial for language development, was already atypical in HR infants. By 9 months of age, HR infants showed hyperconnectivity with somatosensory regions whereas LR infants displayed greater connectivity with higher-order cortical regions. Over the first year of life, widespread changes with increasing long-range connectivity and decreasing short-range connectivity were observed in the LR group, whereas HR infants showed limited developmental changes. More specifically, the LR group exhibited increasing connectivity between frontotemporal language regions and decreasing temporo-thalamic connectivity from 1.5 to 9 months of age, whereas HR infants displayed relatively static developmental profiles.

Conclusions: Extending prior work showing altered functional connectivity in infant siblings at high risk for ASD, this is the first study to characterize longitudinal development of language-related networks in this population. Collectively, our findings suggest that emerging differences in language-related network connectivity can be detected across the first year of life, which may provide an early marker of risk for ASD or other suboptimal developmental outcomes.

435.014 *(Poster)* Atypical Intrinsic Visual Motor Functional Connectivity Is Associated with Imitation Deficits in Autism

R. N. Rochowiak[1]*, D. E. Lidstone*[1]*, B. Tuncgenc*[2]*, C. Pacheco*[3]*, R. Santra*[4]*, S. R. Santos*[4]*, S. H. Mostofsky*[5] *and M. B. Nebel*[1]*, (1)Center for Neurodevelopmental and Imaging Research, Kennedy Krieger Institute, Baltimore, MD, (2)Psychology, University of Nottingham, Nottingham, MD, United Kingdom, (3)Johns Hopkins University, Baltimore, MD, (4)Center for Neurodevelopmental and Imaging Research; Kennedy Krieger Institute, Baltimore, MD, (5)Center for Autism and Related Disorder, Kennedy Krieger Institute, Baltimore, MD*

Background: Motor imitation, commonly reported to be impaired in autism spectrum disorder (ASD), is critical for social-communicative skills and requires simultaneously integrating visual and motor input. Abnormal functional connectivity (FC) between networks comprising brain regions responsible for higher-order visual processing and motor control has been shown in children with ASD (Nebel et al., 2016). Moreover, this visuo-motor asynchrony was found to be associated with increased autism severity and predicted better imitation of recognizable hand gestures in typically developing (TD) children. In this study, we explored how visual-motor processing deficits are related to motor imitation during a task comprising unfamiliar, limb and whole-body movements and measured using a novel and highly reliable, Computerized Assessment of Motor Imitation (CAMI).

Objectives: To investigate the relationship between visual-motor FC and imitation ability using a novel, highly-scalable videogame task.

To explore the relationship between visual-motor FC and autism severity.

Methods: Resting-state functional magnetic resonance imaging (rsfMRI) scans were acquired from 30 children (14 ASD and 16 TD) aged 8-12 years. Imitation performance was assessed using CAMI applied to a brief, highly-engaging task, during which children imitated unfamiliar dance moves of a video avatar in three one-minute trials. CAMI algorithm, validity-checked by comparisons with human coding in a previous study, automatically detected the important joints and returned a score considering the spatial and temporal differences between the child and the avatar. Group Independent Component Analysis (ICA) was applied to rsfMRI data. Previously-generated spatial map templates corresponding to visual components (VC1, VC2, VC3) and two motor components (upper-limb: UL, and lower-limb: LL) were used to extract those components with the highest spatial similarity to each component of interest. FC between each pair of participant-specific motor and visual component time-courses was computed. Brain-behavior associations were examined between FC of each visual-motor component pair and: (1) motor imitation (mean CAMI score), and (2) impaired social-communicative function core to autism (Social Responsiveness Scale, SRS-2). Age, mean framewise displacement, and number of image volumes used to calculate FC were included as covariates in the regression models.

Results: As compared to TD, children with ASD displayed poorer imitation (p=0.0001) and greater FC between the VC2-UL visual-motor pair (p= 0.06, d= -0.70; Figure 1A). In addition, children with ASD who demonstrated more in sync VC2-UL intrinsic activity were worse at imitation (t= -2.380, p= 0.041; Figure 1B), such that a 0.1 increase in VC2-UL synchrony in the ASD group was associated with a 0.15 decrease in imitation score compared with the TD group. No other visual-motor pair was a significant predictor of imitation (all ps> 0.14) and no visual-motor pair significantly predicted SRS-2 scores.

Conclusions: Our findings reveal that children with ASD show an anomalous pattern of increased visuo-motor synchrony. Moreover, this increased visuo-motor synchrony significantly predicted poorer motor imitation of unfamiliar, limb and whole-body movements in ASD as compared to the TD group. These findings add to our understanding of the interplay of altered visual-motor integration and imitation skills in ASD.

435.015 *(Poster)* Auditory Evoked Magnetic Fields and Language Performance in Young Children with ASD

Y. Yoshimura[1]*, T. Ikeda*[2]*, C. Hasegawa*[2]*, K. M. An*[3]*, K. Yaoi*[3]*, D. N. Saito*[3]*, S. Tanaka*[4]*, S. Iwasaki*[3]*, T. Hirosawa*[5] *and M. Kikuchi*[6]*, (1)Institute of Human and Social Sciences, Kanazawa University, Kanazawa, Japan, (2)Kanazawa University, Kanazawa, Japan, (3)Research center for child mental development, Kanazawa University, Kanazawa, Japan, (4)Rsearch Center for Child Mental Development, Kanazawa University, Kanazawa, Japan, (5)Department of Psychiatry and Neurobiology, Graduate School of Medical Science, Kanazawa University,, Kanazawa, Japan, (6)Research Center for Child Mental Development, Kanazawa University, Kanazawa, Japan*

Background: Atypical auditory neuromagnetic responses have been reported in children who have autism spectrum disorder (ASD). Some studies have reported the relationship between these brain responses to sounds and human voices and language ability. However, there are still many questions regarding the relationship between language development and brain function in young children with ASD.

Objectives: The purpose of this study is to investigate brain responses evoked by sound using magnetoencephalography (MEG) in young children and to investigate the relationship with language ability.

Methods: 35 typically developing (TD) children (70.8±4.0 month) and 38 children with ASD (73.4±10.4 month) participated in this study. MEG data were recorded using a 151-channel superconducting quantum interference device (SQUID), whole-head coaxial gradiometer MEG system for children (PQ 1151R; Yokogawa/KIT, Kanazawa, Japan). We used the oddball paradigm consisting of two types of sinusoidal tone (standard 523Hz and deviant 1046Hz). Brain responses (P1m, N1m and N2m) evoked by standard stimuli were used in this analysis. The intensity and latency in P1m, N1m and N2m were compared between TD children and children with ASD. Furthermore, the relationship between brain responses (P1m and N2m) and language abilities were investigated in each group. As an index of language abilities, we used the language subtest (i.e. riddles) in K-ABC and Japanese version of picture vocabulary test – revised (PVT-R).

Results: For P1m, components met the criteria were detected 28/35 in the left hemisphere and 17/35 in the right hemisphere in TD children, 32/38 in the left hemisphere and 25/38 in the right hemisphere in children with ASD. For N1m, 5/35 in the left hemisphere and 12/35 in the right hemisphere in TD children, 6/38 in the left hemisphere and 8/38 in the right hemisphere in children with ASD. For N2m, 34/35 in the left hemisphere and 35/35 in the right hemisphere in TD children, 33/35 in the left hemisphere and 31/35 in the right hemisphere in children with ASD. As a result of independent samples t-test, there was no significant difference in any brain responses in both hemispheres between TD children and children with ASD. In the relationship between the brain response and language abilities, there was a significant positive correlation between N2m intensity in the left hemisphere and the standard score of PVT-R (N= 33 r=0.444 *P*=0.010) and negative correlation between N2m latency in the right hemisphere and standard score of PVT-R (N=34 r=-0.412 *P*=0.016) in TD children. In children with ASD, there was no significant correlation between brain responses and language abilities in children with ASD.

Conclusions: The current results showed that there was no significant difference in brain responses (P1m, N1m and N2m) to tone between TD children and children with ASD children aged 5 to 8 years. In TD children, the shorter latency and larger intensity in N2m components correlated with the higher the language comprehension ability, however the same relationship was not seen in children with ASD. This result suggests that the possibility that an abnormality of maturation of infantile myelination affects language development.

435.016 *(Poster)* Autism Diagnosis Framework Using Diffusion Tensor Imaging

Y. ElNakieb[1]*, O. Dekhil*[1]*, M. T. Ali*[1]*, A. Shalaby*[1]*, A. Soliman*[1]*, A. Mahmoud*[1]*, R. Keynton*[1]*, M. Ghazal*[2]*, G. Barnes*[3] *and A. S. El-Baz*[4]*, (1)Bioengineering, University of Louisville, Louisville, KY, (2)Electrical and Computer Engineering, Abu Dhabi University, Abu Dhabi, United Arab Emirates, (3)Neurology, University of Louisville School of Medicine, Louisville, KY, (4)University of Louisville, Louisville, KY*

Background: Autism Spectrum Disorder (ASD), commonly known as autism, is developmental disorder associated with a broad range of symptoms depicted as difficulties in social interaction, communication skills, and behavioral patterns. Being caused by differences in the brain, numerous studies were presented suggesting abnormal development of neural networks in the brain in shape, functionality, and/ or connectivity. The aim of this work is to present our automated computer aided diagnostic (CAD) system for accurate diagnosis of autism based on the connectivity of the white matter (WM) tracts. To achieve this goal, two levels of analysis are provided for local and global scopes, where diffusion tensor imaging (DTI) data is utilized. A local analysis using Johns Hopkins WM areas' atlas is exploited for DTI segmentation. The proposed system was tested on a large data set of 263 subjects.

Objectives: To use DTI to achieved global accuracy and local diagnostic accuracies to allow for a better understanding of ASD-related brain abnormalities.

Methods: Anonymized MRI scans were obtained for 263 subjects (131 females and 132 males, 122 autistics and 141 typically developed) from NDAR database. The framework mainly consists of three stages: first, a preprocessing step to reduce artifacts and eliminate non-brain tissues, including skull stripping and eddy current correction. In the second stage, feature extraction, WM integrity is examined by extracting most prominent features representing WM connectivity from DTI. Six different features (fractional anisotropy, axial and radial diffusivities, mean diffusivity, and skewness) are calculated based on the 3 eigenvalues λ_1; λ_2, and λ_3 on each voxel, and atlas-based segmentation technique is used to allocate features for each area, on John-Hopkins white matter atlas. After that, interactions of WM features between different areas in the brain, demonstrating correlations between WM areas' features were used, and feature selection among those correlations are made. Finally, a Leave-one-subject-out classifier is employed to get the final diagnosis, as well as spotting the brain areas correlations with ASD vs normal behavior.

Results: To ensure system robustness, we used Leave one subject out approach (LOSO) for validation at all runs. For each WM area, overall accuracy, sensitivity, and specificity were calculated. To obtain the subject global diagnosis decision, two steps are used. First, features are ranked based on the s2n score, then iteratively first *n* is fed to next step, with n starting from 1 to 250. Selected features are concatenated, and SVM classifiers are used to obtain probabilities of being autistic given these features, providing a single global decision per subject, which achieved a diagnostic accuracy of 71%, sensitivity of 0.72, and specificity of 0.7.

Conclusions: This promising work provides not only fast and high early-stage diagnostic accuracy, but also allows identifying the localized abnormalities for each individual subject, characterized by the areas of highest rank, which may aid in understanding the autistic subject behavior and help the clinician to deliver a tailored personalized treatment. More medical interpretation to map the impacted regions to the corresponding expected behaviors is needed to validate the personalized maps.

435.017 *(Poster)* Autism Polygenic Risk Is Associated with Larger Caudate and Cerebellar Cortex Volume in Youth with ASD

L. M. Hernandez[1]*, K. E. Lawrence*[1]*, D. Geschwind*[1]*, S. Y. Bookheimer*[2]*, M. J. Gandal*[3] *and M. Dapretto*[2]*, (1)University of California, Los Angeles, Los Angeles, CA, (2)Dept of Psychiatry and Biobehavioral Sciences, University of California, Los Angeles, Los Angeles, CA, (3)Psychiatry, UCLA-Semel Institute, Los Angeles, CA*

Background: Genetic liability for autism spectrum disorder (ASD) is mostly conferred through the additive effects of common genetic variants across the genome (Gaugler et al., 2014). Only very recently have genome-wide association studies (GWAS) of ASD achieved sufficient power to detect ASD-associated single nucleotide polymorphisms (SNPs) reaching genome-wide significance (Grove et al., 2019). A number of previous imaging-genetics studies have investigated the effects of common SNPs on neuroimaging measures in ASD, but have been limited by small sample sizes and/or have focused on ASD candidate genes. To date, there has been no large-scale study incorporating well-powered ASD GWAS to examine the effects of polygenic risk for ASD on brain structure in children.

Objectives: To examine the relationship between polygenic risk for ASD and magnetic resonance imaging (MRI) measures of brain volume, surface area (SA), and cortical thickness in a large sample of youth with/without ASD.

Methods: Participants were of European ancestry and consisted of 81 youth with- and 4,465 unrelated youth without ASD. Data were acquired and processed as part of the multi-site Adolescent Brain and Cognitive Development study; curated data were accessed through the National Data Archive. Genetics data were imputed to the TOPMed reference panel using the Michigan Imputation Server (Das et al., 2016). Polygenic risk scores (PRS) were computed from publicly available summary statistics (Grove et al., 2019) using PRSice-2 (Choi et al., 2019), covarying for age, sex, and 20 ancestry principal components. To test the association between PRS and 80 bilateral measures of brain structure, linear mixed effects models were generated using the lme4 package in R, covarying for age, sex, 20 ancestry principal components, IQ, whole brain volume (WBV), and scan site as a random effect. FDR corrected results at $q<0.05$ and standardized betas (B) are reported.

Results: ASD youth had higher PRS for ASD relative to non-ASD youth ($t=-2.02$, $q=0.04$); ASD PRS explained 0.7% of the variance in case-control status (Nagelkerke R^2). In ASD youth, higher PRS was associated with reduced mean SA (B= -0.200) and WBV (B=-0.204). At the regional level, higher PRS was associated with greater volume in the left and right cerebellar cortices (B=0.319 and 0.316, respectively) and left caudate (B=0.322). No significant associations were observed in youth without an ASD diagnosis between PRS and brain structure measures.

Conclusions: These findings indicate that, in high-functioning 9-10-year-old youth with an ASD diagnosis, polygenic risk for autism is associated with increased volume of subcortical brain regions, particularly of the cerebellar cortex. These findings are in agreement with mounting evidence from human postmortem studies, animal models, and molecular neuroscience suggesting a critical role for the cerebellum in the etiology of ASD (Fernandez et al., 2019).

435.018 *(Poster)* Characterizing Cerebellar-Thalamic-Cortical Structural Covariance in 125 Mouse Models of Autism Spectrum Disorder

F. Morgado[1]*, J. Ellegood*[2] *and J. P. Lerch*[3]*, (1)University of Toronto, Toronto, ON, Canada, (2)Mouse Imaging Centre, Hospital for Sick Children, Toronto, ON, Canada, (3)Wellcome Centre for Integrative Neuroimaging (WIN), University of Oxford, Oxford, ON, United Kingdom*

Background: The cerebellum is a frequent site of dysfunction in Autism Spectrum Disorder (ASD). It is also a highly integrated structure with connections throughout the brain, particularly to the cortex via the thalamus. Deficits within this circuitry have been shown to negatively affect neurodevelopment and lead to ASD-related behaviours such as social withdrawal (Wang et al., 2014).

By measuring how changes in volumes covary between regions, the strength of covariance can be used as a proxy for connectivity (Alexander-Bloch et al., 2013). This could provide insight into how cerebellar connectivity differs in ASD compared to typically developing brains. This exploratory analysis is well-suited for brain imaging using mouse models of ASD, which can be imaged at high resolution and high throughput.

Objectives: To characterize patterns of cerebellar-thalamic-cortical structural connectivity across mouse models of ASD.

Methods: 125 ASD models comprised of 3231 adult mice (32.8% female) were imaged on a 7-Tesla MRI scanner with a T2-weighted fast spin echo sequence. A 40um isotropic atlas with 434 segmented structures (Watson et al., 2017; Dorr et al., 2008) was registered to the brain scans using ANTS (Avants et al., 2010). Pairs of cerebellar and cortical structures were tested for statistically significant covariance by fitting a linear model to the volumes. If a pair of structures were found to significantly covary, thalamic regions were tested to assess whether they mediated this covariance (Barron & Kenny, 1986). An interaction model was used to compare 10 clusters of ASD mouse models against their respective wild-type controls (clusters were established using hierarchical clustering based on median change in regional volumes, originally presented in an Ellegood et al. 2018 INSAR abstract). P-values were False Discovery Rate-adjusted across all tests. To validate this approach, positive and negative controls were also tested, consisting of well-established thalamus-mediated pathways (e.g. medial lemniscus, ventroposteromedial thalamic nucleus, somatosensory cortex) and random trios of brain regions, respectively.

Results: 96.2% of all significantly mediated cerebellar-thalamic-cortical trios were attributed to cluster nine (Table 1), which also had the greatest median mediation effect size. Effect size was defined as the difference in the normalized absolute values of $\beta_{Crus1,a}$ and $\beta_{Crus1,b}$ from the equations in figure 1, where V denotes volume and m_{mut} is a binary factor for mutant/wild-type status. Figure 1 illustrates the most significant cortico-cerebellar covariance from this cluster and its mediating thalamic nucleus ($|\beta_{Crus1,b}|<|\beta_{Crus1,a}|$, and the difference plus-or-minus its standard error did not contain zero). Crus 1 volumes covaried with the right cingulate cortex with the greatest statistical significance compared to other cortico-cerebellar pairs. Mediating thalamic nuclei included the ventral anterior nucleus, paraxiphoid nucleus, anteromedial nucleus, paracentral nucleus (which have connections to the prefrontal cortex), ventral lateral nucleus, and pregeniculate nucleus. 87% of positive control pathways were significant, and all negative control pathways were non-significant.

Conclusions: Crus 1 volumes significantly covary with the cingulate cortex in a cluster of ASD models, particularly left crus 1 to right cingulate cortex. This covariance is mediated by thalamic nuclei with diffuse connections throughout the frontal, prefrontal and cingulate cortices.

435.019 *(Poster)* Children with ASD Show Atypical Electrophysiological (EEG) Responses to Processing Pragmatic and Semantic Incongruencies.

A. V. Marquez[1]*, G. Iarocci*[2]*, V. Vakorin*[1]*, S. Moreno*[1] *and S. Doesburg*[1]*, (1)Simon Fraser University, Burnaby, BC, Canada, (2)Psychology, Simon Fraser University, Burnaby, BC, Canada*

Background: Studies have demonstrated that even with intact language skills people with autism spectrum disorder (ASD) still experience difficulties with processing contextual linguistic information and pragmatic language prossesing. ERP studies have previously reported a negative deflection in the ERP signal around 400 milliseconds post-stimulus onset (the N400) in participants who were typically developing (TD) and diagnosed with Asperger's syndrome, but not in those diagnosed with autism (Pijnacker, Geurts, van Lambalgen, Buitelaar & Hagoort, 2010).

Objectives: The present study used event-related potentials to investigate potential alterations in how children with ASD process semantic and pragmatic (contextual) incongruencies when compared to TD children.

Methods: Data were collected from multiple children during four single-day summer camps using methods previously developed by our research group (Moreno et al., 2015, 2011). We recruited a population of 75 children, 33 ASD participants (mean age [years] 9.7 ±5.6) and 42 TD participants (mean age [years] 9.3 ±2.51). Individuals with an IQ less than 70 were excluded from the study. The EEG was recording using ENOBIO systems with eight channels (EOG1, EOG2, Fz, Cz, Pz, F7, F8, CP6). On each trial, participants saw an image on a computer screen and listened to two word sentences that might describe the present image correctly (congruent condition, e.g. “rubbing eyes”), might make no sense (semantic incongruent condition, e.g “rubbing sky”) or would make sense but not correspond to the image (pragmatic/context incongruent condition e.g. “rubbing lips). Participants were asked to respond by selectinga tick if the sentence corresponded to the image, and a cross, if it did not, as schematically illustrated in the Figure 1. EEG data were band-pass filtered between 1 and 30 Hz, epoched between 200 ms before and 600 ms after the onset of second word presentation, and filtered using Independent Component Analysis (ICA) by removing components which were highly correlated with the EEG dynamics recorded by ocular channels (EOG1 and EOG2). The ERPs were computed for each participant, condition, and channel. A multivariate analysis was applied to compare the ERP signals across conditions, separately for each group and EEG channel.

Results: Our preliminary results showed no statistically significant differences in the ERP across conditions in the ASD group for any of the EEG channels. However, we found robust differences in the ERP between conditions in the TD group, for four out of six EEG channels. Specifically, performing the congruent task condition elicited a greater positive response when compared to the semantic incongruent and pragmatic incongruent conditions in the TD group. The most robust differences in the ERP response across conditions were observed between 300 and 600 ms after the onset of the second word presentation.

Conclusions: The children with ASD showed an atypical electrophysiological response to the semantic and pragmatic incongruencies (i.e. showed larger N400 for incongruent than congruent conditions). These results support clinical observations of the difficulties that individuals with ASD often have understanding the meaning of words in context and point to potential differences in language processing between children with and without ASD.

435.020 *(Poster)* Corneal Confocal Microscopy: A Surrogate Marker for Neuro-Degeneration in Autism

A. Khan[1], *M. Kamal*[2], *M. A. Adan*[3], *A. M. Alhothi*[3] *and R. A. Malik*[4], *(1)Weill Cornell Medicine-Q, Doha, Qatar, (2)Sidra Medicine, Doha, Qatar, (3)Hamad General Hospital, Doha, Qatar, (4)Weill Cornell Medicine-Qatar, Doha, Qatar*

Background: Autism spectrum disorder (ASD) is a developmental disorder characterised by difficulty in communication and interaction with others. Most studies have focused on central alterations with postmortem studies showing cerebral neuronal loss and diffusion tensor imaging showing small fibre loss in face-perception and inter-hemispheric regions of the brain. However, recent studies show altered peripheral sensory perception thresholds and intraepidermal nerve fibre loss in ASD.

Objectives: To determine whether there is corneal nerve loss in children with ASD.

Methods: Corneal confocal microscopy is a rapid non-invasive ophthalmic imaging technique that has demonstrated corneal c-fibre loss in peripheral (diabetic neuropathy, CIDP, CIPN) and in central (Parkinson’s disease, multiple sclerosis, stroke, dementia) neurodegenerative disorders.

Results: Eight children with ASD (age: 14.13 ± 3.30 years) and eighteen age-matched children without ASD (age: 13.55 ± 2.82 years) underwent corneal confocal microscopy (CCM) to quantify corneal nerve fiber density (CNFD), corneal nerve branch density (CNBD) and corneal nerve fiber length (CNFL).

There was a significant reduction in CNBD (46.03 ± 24.00 vs. 85.97 ± 26.71, $p = 0.0001$), CNFL (16.51 ± 3.58 vs. 24.71 ± 4.06, $p = 0.01$), with no difference in CNFD (29.75 ± 5.58 vs. 33.21 ± 7.60, $p = 0.277$) in children with ASD compared to children without ASD.

Conclusions: Corneal confocal microscopy identifies distal corneal nerve fibre loss in children with ASD compared to children without ASD. Larger studies are required to determine the utility of CCM as a surrogate imaging biomarker for neuronal loss in relation to MRI abnormalities and behavioral alterations in patients with ASD.

435.021 *(Poster)* Correlations between fNIRS-Based Cortical Activation and Synchronized Sway, Social Communication Skills, Adaptive Functioning, and Motor Skills in Children with and without Autism Spectrum Disorder (ASD)

W. C. Su[1], *M. Culotta*[1], *D. Tsuzuki*[2] *and* ***A. Bhat***[3], *(1)Physical Therapy, University of Delaware, Newark, DE, (2)Department of Language Sciences, Tokyo Metropolitan University, Tokyo, Japan, (3)Department of Physical Therapy, University of Delaware, Newark, DE*

Background: Children with ASD have impaired social communication skills and motor performance that together affect their ability to engage in socially-embedded actions, such as interpersonal synchrony (IPS). Using functional near infrared spectroscopy (fNIRS), we have reported atypical cortical activation in children with ASD as they synchronized whole-body sway motions with an adult over the Observation-Execution Matching Systems (OEMS) including lower activation in the Inferior Frontal Gyrus (IFG) and Superior Temporal Sulcus (STS) and greater activation in the Inferior Parietal Lobe (IPL) activation. However, we do not know the relationships between cortical activation patterns and their IPS behaviors, social communication skills, adaptive functioning, and motor skill performance in children with/without ASD.

Objectives: We correlated cortical activation during synchronized sway to IPS variables (coherence and phase lag), social communication, adaptive functioning, and motor performance in children with/without ASD.

Methods: Seventeen school-age children with and without ASD participated in this study. The children were asked to a) sway face to face with an adult partner (Face condition), and b) sway with an adult and with their fingertips touching (Touch condition). Each participant wore a cap embedded with a 3x11 fNIRS probe set that covered the bilateral middle frontal gyrus (MFG), pre- and postcentral gyrus (PCG), IFG, STS, and IPL. Inertial measurement units were placed on the center of mass of the child and the adult to calculate the coherence and phase lags between partners during synchronized sway. The caregivers of the children completed the Social Communication Questionnaire (SCQ) and Vineland Adaptive Behavioral Scales (VABS) questionnaires. We also administered the manual dexterity and the upper-limb coordination subtests of the Bruininks-Oseretsky Test of Motor Proficiency (BOT-2) to assess the children's manual coordination skills. Parametric and non-parametric correlations were conducted to investigate associations between cortical activation and sway behaviors, SCQ, VABS, and BOT-2 scores.

Results: We are still analyzing our data. Our pilot data are based on correlation findings in children with ASD. For the IPS behaviors, we found that children with ASD who showed greater phase lag during Touch had greater left MFG activation (r=0.34, $p<0.01$). Children with ASD with greater SCQ scores (more impairment) had lower right IPL activation during Face (r=-0.38, $p<00.1$). Children with ASD with lower VABS total scores had lower left IPL, right PCG, and right STS activation during Face and lower left STS and lower right IFG activation during Touch (rs>0.30, $p<0.05$). Lastly, children with ASD with lower manual coordination scores had lower left PCG activation during Face (r=-0.353, $p<0.01$) and lower left MFG and right STS activation during the Touch (r=0.31 and -0.34 respectively, $ps<0.05$).

Conclusions: Children with ASD who had greater IPS impairments relied on greater executive functioning. Children with ASD who showed lower OEMS activation also had lower social communication scores, lower adaptive functioning, and poor motor coordination skills. We may have identified fNIRS-based cortical neurobiomarkers that could be used as treatment response measures to determine who will benefit and what to expect following synchrony-based interventions.

435.022 *(Poster)* Cortical Gyrification Morphology in Individuals with ASD and ADHD across the Lifespan: A Systematic Review and Meta-Analysis

A. Gharehgazlou[1], *S. Ameis*[2], *C. P. De Barros Freitas*[3], *M. J. Taylor*[4], *J. P. Lerch*[5] *and E. Anagnostou*[6], *(1)Institute of Medical Science, University of Toronto, Toronto, ON, Canada, (2)The Margaret and Wallace McCain Centre for Child, Youth, & Family Mental Health, Campbell Family Mental Health Research Institute, Centre for Addiction and Mental Health, Toronto, ON, Canada, (3)Bloorview Research Institute, Toronto, ON, Canada, (4)The Hospital for Sick Children, Toronto, ON, Canada, (5)Wellcome Centre for Integrative Neuroimaging (WIN), University of Oxford, Oxford, ON, United Kingdom, (6)Holland Bloorview Kids Rehabilitation Hospital, Toronto, ON, Canada*

Background: Autism Spectrum Disorder (ASD) and Attention-Deficit Hyperactivity Disorder (ADHD) are relatively common neurodevelopmental disorders (NDDs) with a high rate of symptom overlap. Magnetic Resonance Imaging (MRI) has been used extensively to study atypical brain development in both NDDs, however, cortical gyrification as a specific measure derived from MRI has not been thoroughly investigated in ASD and ADHD literature.

Objectives: To the best of our knowledge, no systematic review or meta-analysis has been conducted to qualitatively and quantitatively synthesize cortical gyrification findings simultaneously in ASD and ADHD literature. We are conducting a systematic review to synthesize existing literature on cortical gyrification morphology in both NDDs with the aim of enhancing our understanding of what is known regarding shared and disorder-specific gyrification features in these two disorders. We are also quantitatively synthesizing local gyrification findings in ASD literature by conducting a meta-analysis, and further conducting a meta-regression to explore whether differences found in gyrification between individuals with ASD and typically developing (TD) peers depend on the potential contributing effects of age, sex, intelligence (IQ) and/or sample size.

Methods: Guidelines of Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) methodology was implemented for study identification and selection. Seed-based d Mapping, formerly "Signed Differential Mapping" (SDM), meta-analytic software was used for conducting the meta-analysis on ASD studies focusing on the computation of the local gyrification index (lGI) measure.

Results: Twenty-nine studies, investigating cortical gyrification morphology in ASD and ADHD relative to typical development across the lifespan, met the inclusion criteria for the systematic review. The findings are highly contradictory with evidence of greater, reduced, or no different cortical gyrification in individuals with ASD and ADHD relative to TD peers across different cohorts. Although the direction of change and specific regions of atypicality are not clear, studies in this review point towards heterogeneity in the atypicality of cortical gyrification in both NDDs. Ten ASD studies met the inclusion criteria for the meta-analysis, consisting of a total of 527 participants with ASD and 450 TD participants. The results are not statistically significant after correction for multiple comparisons, perhaps due to insufficient statistical power resulting from the limited number of included studies. However, with a more liberal threshold ($p<0.1$) trends are observed, specifically greater lGI in individuals with ASD compared to TD peers in clusters located in the temporal (p=0.06), frontal (p=0.07) and occipital (p=0.07) lobes. The meta-regression yielded no significant effects of age, sex, IQ or sample size.

Conclusions: The highly contradictory findings of the systematic review and null results of the meta-analysis may reflect insufficient statistical power as a result of the limited number of included studies, the heterogeneous nature of ASD and ADHD or high variability of cortical gyrification construct itself observed even in normative data. Future large-scale studies are needed to identify specific regions of large effects and to adequately address contributions of age, sex and intelligence in this phenomenon in ASD and ADHD.

435.023 *(Poster)* Cortical Volume Truncation – a New Freesurfer Measure to Capture the Asymmetric Distribution of Grey Matter Volume between Brain Surfaces

C. Mann[1], *T. Schäfer*[1], *A. Bletsch*[1], *E. Daly*[2], *J. Suckling*[3], *E. Bullmore*[4], *M. C. Lai*[3], *M. V. Lombardo*[3], **. MRC AIMS Consortium*[5], *S. Baron-Cohen*[3], *D. G. Murphy*[6] *and C. Ecker*[1,2], *(1)Department of Child and Adolescent Psychiatry, Psychosomatics and Psychotherapy, Goethe-University Frankfurt am Main, Frankfurt, Germany, (2)Department of Forensic and Neurodevelopmental Sciences, Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, United Kingdom, (3)Autism Research Centre, Department of Psychiatry, University of Cambridge, Cambridge, United Kingdom, (4)Institute for Behavioural and Clinical Neuroscience, Department of Psychiatry, University of Cambridge, Cambridge, United Kingdom, (5)University of Cambridge, Cambridge, United Kingdom, (6)Forensic and Neurodevelopmental Sciences, Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, United Kingdom*

Background: Autism Spectrum disorder (ASD) is a complex neurodevelopmental condition accompanied by manifold differences in brain morphometry. Among others, neuroanatomical abnormalities in ASD include differences in the development of grey matter volume, which has extensively been studied in the past (Courchesne et al., 2001; Hazlett et al., 2011; Ecker et al., 2017). However, traditional analyses do not assess how grey matter volume is distributed along the depth of the cortical mantle (i.e. across cortical layers). This is of importance as ASD-related genes have been shown not to be equally expressed across all cortical layers, but may affect either the superficial (Parikshak et al., 2013) or the inner (Willsey et al., 2013) layers differentially, which in turn may impact on cortical lamination and folding.

Objectives: In the present study, we aimed to (1) develop a new feature assessing the surface-based distortion of grey matter volume across cortical surfaces, and (2) to utilize this feature to characterize differences in brain morphometry between individuals with ASD and typically developing controls (TD).

Methods: We included 92 adults with ASD and 92 neurotypical controls, aged 18-52 years. For all 184 participants, T1-weighted volumetric images were acquired. Cortical surface models were extracted using FreeSurfer (http://surfer.nmr.mgh.harvard.edu/). Vertex-wise estimates of 'Cortical Volume Truncation' (CVT) across layers were calculated as the ratio of the expected volume based on the outer grey-matter surface (V_E) and the actual (i.e. analytical) volume (V_A) (Winkler et al., 2018). Initially, we examined the relationship between CVT and other cortical measures to explore its biological plausibility. Subsequently, we examined differences between ASD and TD by regression of a GLM at each vertex with (1) group, gender, and site as categorical fixed-effects factors, (2) an age-by-group interaction term, and (3) age and FSIQ as continuous covariates.

Results: The spatial distribution of CVT appeared to approximate the normal distribution, capturing information on both cortical volume and brain geometry, and followed the outline of primary and secondary gyri and sulci (Figure 1A). More specifically, measures of CVT were significantly positively associated with surface area, cortical thickness, and cortical volume ($p<0.05$), and significantly negatively correlated with mean curvature (Figure 1B). Following correction for multiple comparisons (RFT-based cluster-corrected, $p=0.05$), we found that the degree of CVT was significantly increased in ASD relative to TD in many cortical clusters, including inferior parietal, superior temporal, and cingulate regions (Figure 2A). In several areas, vertex-wise measures of CVT were also significantly positively correlated with symptom severity measured by the Autism-Spectrum Quotient (AQ) (Figure 2B). Furthermore, we were able to replicate the results of the between-group differences in gender-specific analyses (Figure 2C&2D).

Conclusions: Our findings suggest a larger contribution of supragranular, rather than infragranular, layers to regional differences in cortical volume in ASD compared to TD. We also replicated our initial finding in males and females with the condition. The degree of CVT might therefore serve as a novel in vivo proxy measure assessing volumetric gradients along the depth of the cortical mantle and may guide future studies into the genetic underpinnings of ASD.

435.024 *(Poster)* Decreased Activation of Executive Control Network during Driving Hazard Detection in Autism Spectrum Disorder

H. M. Bednarz[1]*, D. Stavrinos*[2]*, A. M. Svancara*[3]*, G. M. Sherrod*[4]*, H. D. Deshpande*[4] *and R. K. Kana*[5]*, (1)Psychology, University of Alabama at Birmingham, Birmingham, AL, (2)Psychology, UAB, Birmingham, AL, (3)The University of Alabama at Birmingham, Birmingham, AL, (4)University of Alabama at Birmingham, Birmingham, AL, (5)University of Alabama, Tuscaloosa, AL*

Background: Driving difficulties of adult drivers with autism spectrum disorder (ASD) are well documented in the literature, including difficulty responding to hazards on the road. In particular, previous studies have indicated that individuals with ASD have difficulty responding to social hazards (e.g., pedestrians) within the traffic environment compared to other hazard types (objects on the road). Differences in several social and cognitive skills have been purported to underlie driving difficulty in ASD, including attention, executive function, and theory of mind. The purpose of this study was to characterize the neuropsychological and neurobiological mechanisms underlying driving hazard detection in ASD drivers using functional neuroimaging.

Objectives: To examine differences in functional brain responses between ASD and typically developing (TD) adult drivers in response to various hazards during a driving hazard detection task.

Methods: Twenty-nine participants (13 ASD, 16 TD, 16-30 years, matched on age and sex) completed a driving hazard detection task in a Siemens Prisma 3 Tesla MRI scanner. Participants watched a video of a simulated driving scene from the perspective of a driver in which potential hazards approached the roadway intermittently. Hazard events were presented in a jittered, event-related design. Hazards differed in whether they contained a human component (social versus nonsocial hazards). Social hazards consisted of pedestrians, bicyclists, and other drivers; nonsocial hazards consisted of a barrel, ball, and tumbleweed. Participants pressed a button, akin to braking while driving, at the time that they would react to hazards if they were actually driving. Whole-brain within-group and between-group differences in functional activation for the social versus nonsocial condition were examined (Monte Carlo Simulation correction p=.005, cluster=84).

Results: Within-groups results indicated that the ASD participants recruited regions within the bilateral temporal/parietal lobes and bilateral inferior frontal gyrus. The TD group exhibited broader activation patterns, encompassing inferior, medial, and superior frontal regions, temporal/parietal regions, as well as cerebellar and occipital regions. Compared to the TD group, the ASD showed greater activation in the right inferior parietal lobule (RIPL) for the social versus nonsocial hazard contrast. On the other hand, the ASD group showed reduced activation, relative to TD, in the bilateral medial prefrontal cortex (MPFC), right cingulate gyrus, and the right pre and post central gyri for the social versus nonsocial contrast.

Conclusions: The ASD group showed greater RIPL recruitment while processing social hazards; this region has been implicated in bottom-up attention processes and social cognition. In comparison, the TD group seemed to rely more on brain regions commonly implicated in cognitive control, including executive function and motor planning regions. This suggests different cognitive approaches between the ASD and TD groups, with ASD participants devoting more resources to lower-order attention and social processing and TD utilizing higher order cognitive processes to predict and plan for social hazards. Findings provide insights into the difference in quality of driving performance in ASD drivers compared to TD drivers.

435.025 *(Poster)* Delayed Auditory Evoked Responses in Autism Spectrum Disorder: Across the Lifespan

J. Matsuzaki[1], *M. Ku*[1], *M. DiPiero*[1], *T. Chiang*[1], *J. Saby*[1], *L. Blaskey*[1], *E. S. Kuschner*[1], *M. Kim*[1], *J. I. Berman*[1], *L. Bloy*[1], *Y. Chen*[1], *J. Dell*[1], *S. Liu*[1], *E. S. Brodkin*[2], *D. Embick*[3] *and T. Roberts*[1], *(1)Lurie Family Foundations MEG Imaging Center, Department of Radiology, Children's Hospital of Philadelphia, Philadelphia, PA, (2)Department of Psychiatry, University of Pennsylvania, Philadelphia, PA, (3)Department of Linguistics, University of Pennsylvania, Philadelphia, PA*

Background: Previous magnetoencephalographic (MEG) studies have shown abnormal auditory cortical responses in superior temporal gyrus (STG) such as delayed auditory response components in primary/secondary auditory processing (e.g., M50, M100) in Autism spectrum disorder (ASD) cohorts compared to typically developing (TD) peers. Although a number of studies have revealed delayed early auditory responses in ASD, prior work has measured MEG in different developmental stages (i.e., age range) or using different paradigms (i.e., different types of stimuli, duration, frequency, inter stimulus interval).

Objectives: To better understand neural correlates of auditory processing in ASD *across the lifespan*, the present study used MEG to measure cortical responses to auditory tone stimuli identical to those used in Roberts et al., (2010), and compared them with responses from a TD cohort with similar age-range.

Methods: One hundred and thirty-two participants (aged 6 to 42 yrs) were included into the final analyses (children and adolescents; TD, n=36, 9.21±1.6 yrs; ASD; n=58, 10.07±2.38 yrs, adults; TD, n=19, 26.97±1.29 yrs, ASD, n=19, 23.80±6.26 yrs). Social Responsiveness Scale, Wechsler Intelligence Scale - Fourth Edition, Wechsler Abbreviated Scale of Intelligence-II were used. 200, 300, 500 and 1,000 Hz sinusoidal tones of 300 msec duration (105 at each frequency) were presented binaurally. MEG data were obtained in a magnetically shielded room using a 275-channel whole-cortex CTF magnetometer (CTF MEG, Coquitlam, Canada). Left and right M50 (50-125ms) and M100 (100-250 ms) peaks in STG were defined from the source waveform using BESA. The study was approved by the Children's Hospital of Philadelphia IRB.

Results: A linear mixed model (LMM) revealed statistically significant main effects of group on M50/M100 latency ($p < 0.001$) over hemisphere and frequency across the lifespan. Delayed M50/M100 latencies were found in participants with ASD compared to the TD group and earlier M50 /M100 latency were associated with increased age. Furthermore, there was a statistically significant association between verbal aptitude (VIQ) and both M50/M100 latency ($p < 0.001$).

Conclusions: In the present study, delayed M50/M100 latencies were found across the lifespan and suggest that findings of latency delays in both M50/M100 perhaps indicate that abnormalities in maturation of the local neural circuits generating these responses persist into adulthood. Another finding is the association between verbal aptitude and M50/M100 latencies. The M50/M100 responses are primarily generated in the STG, and activation of this region has figured prominently in models of receptive language function and impairment, suggesting basic non-speech auditory processing is specifically linked to oral language functioning, and that latency delays evident at this early stage of auditory perception may specifically contribute to impaired language development across the lifespan.

435.026 *(Poster)* Development of Visual Evoked Responses in Typically Developing Infants and Implications for at-Risk Infant Studies

T. Chiang[1], *J. C. Edgar*[1], *S. Lam*[1], *H. L. Green*[1], *L. Bloy*[1], *E. S. Kuschner*[1,2], *M. Kim*[1], *J. Lebus*[1], *T. Yount*[1], *M. Ouyang*[1], *H. Huang*[1], *T. Roberts*[1] *and Y. Chen*[1], *(1)Lurie Family Foundations MEG Imaging Center, Department of Radiology, Children's Hospital of Philadelphia, Philadelphia, PA, (2)Department of Psychiatry, Children's Hospital of Philadelphia, Philadelphia, PA*

Background: Visual processing abnormalities are a common sensory impairment in autism spectrum disorder (ASD) (Siper et al., 2016), specifically primary visual evoked responses (VERs). Few studies, however, have examined the maturation of primary visual responses in typically developing (TD) infants, particularly changes in the latency of VERs. To understand visual processing deficits in infants at risk for ASD, studies characterizing the maturation of VERs in TD infants are needed.

Objectives: Study goals were: (1) to determine maturation rates for left and right primary visual latency; (2) to explore associations between cognitive abilities and the speed of VERs via a cross-sectional sample (2 to 40 months).

Methods: MEG data were obtained from 58 TD infants (mean age=346±307 days, 27 males) using an infant MEG system (Artemis 123). Cognitive composite scores were obtained using age equivalent scores from Mullen Scales of Early Learning (MSEL) -Visual Reception domain or Bayley Scales of Infant and Toddler Development -III (BSID) - Cognitive domain. VERs were measured in response to black-and-white checkerboard stimuli contrast reversing at a 1Hz rate, and with each square subtending a visual angle of 1°. MEG data were co-registered to an age-appropriate MRI template. Artifact-free epochs 200ms pre- to 500ms post-stimulus were averaged. Peak latency of the infant left and right hemisphere VERs were obtained by fitting dipoles at left and right primary visual cortex. Associations between left and right VER peak latency and age evaluated whether the latency of the M100 VER decreased as a function of age. Associations between left and right VER peak latency and cognitive composite scores evaluated whether the speed of VERs was related to cognitive ability.

Results: The infant's VERs were composed of a positive peak (~50 to 100ms post-stimulus), a negative trough (~100 to 180ms post-stimulus, infant M100 VER), and a positive peak (~160 to 300ms post-stimulus). Given that the infant M100 VER was the largest component, analyses focused on the infant M100 peak latency. The peak latency of the M100 response decreased as a function of age between 2 to 12 months (R^2=0.38 ($p<.0001$) and 0.32 ($p<.0001$), left and right respectively). No age-related M100 latency change was evident after 12 months. No Hemisphere by Age interaction on M100 latency was observed. In the full sample, the peak latency of the M100 response was associated with cognitive ability (R^2=0.24 (p=.001) and 0.22 (p=.002), left and right respectively).

Conclusions: The peak latency of the infant M100 VER decreased at a rate of 4.64ms/month for the left hemisphere and 4.31ms/month for the right hemisphere between 2 and 12 months, and then stabilized at an adult-like M100 latency by ~1 year of age in both hemispheres. Earlier M100 responses were associated with better cognitive ability. Present data indicate that studies seeking to examine the maturation of visual M100 responses in infants at risk for ASD should focus on at-risk infants from birth to 1 year old.

435.027 *(Poster)* Distinct Effects of Sensory over-Responsivity and Anxiety on Brain Response to Aversive Sensory Stimuli in Youth with Autism or Anxiety Disorders

K. K. Cummings[1]*, L. M. Hernandez*[2]*, K. E. Lawrence*[2]*, M. Dapretto*[1]*, S. Y. Bookheimer*[1] *and S. A. Green*[1]*, (1)Dept of Psychiatry and Biobehavioral Sciences, University of California, Los Angeles, Los Angeles, CA, (2)University of California, Los Angeles, Los Angeles, CA*

Background: Heightened sensory over-responsivity (SOR) is common among individuals with an autism spectrum disorder (ASD), and is associated with increased anxiety (Bitsika et al., 2016). SOR symptoms are evident in toddlers with autism and predict later emergence of anxiety symptoms (Green et al., 2012). SOR in autism has been linked to over-active brain responses to aversive sensory stimulation after covarying for anxiety (e.g. Green et al., 2015) but the unique effects of anxiety and SOR symptoms on brain responses to sensory stimulation have not been examined. While SOR and anxiety symptoms are correlated in other clinical groups, including those with anxiety disorders (Hofmann et al., 2007), it remains unclear whether the neural mechanisms underlying these symptoms are similar across diagnostic groups.

Objectives: To examine the unique contributions of anxiety/SOR to brain activation during exposure to aversive tactile/auditory stimuli in children with autism compared to children with anxiety disorders.

Methods: Participants were 19 youth (13F) with anxiety disorders (social, separation, or generalized anxiety; ANX), and 19 age-, IQ-, and sex-matched youth (13F) with ASD, aged 8-17. A matched typically-developing (TD) group was used to compare behavioral SOR and anxiety. While undergoing fMRI, participants experienced six 15-sec blocks each of auditory, tactile, and joint (auditory+tactile) aversive sensory stimulation. Stimuli consisted of pulsing white noise and a scratchy sponge rubbed on participants' inner left arm at 1-sec/stroke. Parent-reported SOR (Sensory Over-responsivity Inventory; Miller et al., 2004) and anxiety symptoms (Screen for Child Anxiety Related Disorders; Birmaher et al., 1995) were entered as simultaneous regressors in bottom-up, whole-brain analyses to examine the relative contributions of SOR and anxiety to neural activation during the joint condition in each group. Contrasts were thresholded at $z>2.3$, corrected for multiple comparisons at $p<.05$.

Results: Anxiety and SOR were significantly elevated in the ANX and ASD groups compared to the TD group, but the ANX and ASD groups did not differ on either symptom type. Anxiety and SOR were highly correlated across the sample ($r=.53$, $p<.01$).

SOR was correlated with increased activation to sensory stimulation in the precuneus and occipital cortex for the ASD group, but was not significantly correlated with brain response for the ANX group. Anxiety symptoms were associated with increased activation in the insula, temporal regions, and the postcentral gyrus for the ASD group, and the lingual gyrus and occipital regions for both the ASD and ANX cohorts. In the ANX group, anxiety symptoms were correlated with increased activation in multiple subcortical regions, including amygdala, hippocampus, and thalamus, and these correlations were significantly stronger in ANX compared to ASD.

Conclusions: While both groups showed atypically elevated anxiety and SOR, these symptoms related differently to neural sensory processing in each group. SOR and anxiety symptoms uniquely contributed to brain responses to aversive sensory stimulation in ASD, but only anxiety symptoms related to brain responses during sensory stimulation for ANX participants. Results suggest that anxiety may play a primary role in sensory responsivity for children with anxiety and support the development of targeted treatment approaches.

435.028 *(Poster)* Divergent Connectivity Patterns in a Social Hub Region in Youth with Autism Spectrum Disorder Compared to Early Onset Psychosis

R. Jalal[1]*, A. Nair*[2]*, J. Jung*[3]*, K. K. Cummings*[3]*, M. Rshtouni*[4]*, K. Karlsgodt*[4]*, M. Dapretto*[3] *and C. Bearden*[5]*, (1)Semel Institute, University of California Los Angeles, Los Angeles, CA, (2)University of California Los Angeles, Los Angeles, CA, (3)Dept of Psychiatry and Biobehavioral Sciences, University of California, Los Angeles, Los Angeles, CA, (4)University of California, Los Angeles, Los Angeles, CA, (5)University of California, Los Angeles, CA*

Background: The anterior cingulate cortex (ACC) is thought to be an integrative social brain hub (Lavin et al., 2013), critically implicated in social cognition (Apps et al., 2016; Mao et al., 2017). Cross-sectional neuroimaging studies have found that altered functional and white matter connectivity of the ACC has been implicated in developmental neuropsychiatric disorders characterized by social impairments, notably autism spectrum disorder (ASD) and psychosis (Demonte et al., 2013; Yan et al., 2012). However, few studies have examined ACC connectivity in a group of ASD adolescents relative to age-matched individuals with early-onset or adolescent-onset psychosis (EOP) to identify any shared or distinct patterns of ACC connectivity unique to each diagnostic group.

Objectives: The goal of the current study is to examine whole-brain resting-state functional connectivity of the ACC with the whole brain in age-matched adolescents with ASD and EOP, compared to typically developing (TD) adolescents.

Methods: Resting-state functional magnetic resonance data were acquired on a 3T Siemens scanner for 25 adolescents with ASD aged 12-21 years (Mean age = 15.87; % female = 12%), 9 age-matched EOP adolescents (Mean age = 16.37; % female = 55%), and 12 age-matched TD controls (Mean age = 16.45; % female = 50%). Data were preprocessed in FSL (Smith, 2004), and ICA-AROMA (Pruim et al., 2015) was used to remove motion confounds. Nuisance regressors (mean white matter, cerebrospinal fluid, as well as their derivatives) were included to further reduce potential confounds. A bilateral ACC mask was derived from the Harvard-Oxford Cortical Atlas in FSL. Global timeseries were extracted from this ACC mask using AFNI for whole brain analysis. *t*-tests were conducted between each group separately to examine group differences in ACC connectivity. These whole-brain analyses were thresholded at $Z>2.3$ and corrected for multiple comparisons at $p<.05$.

Results: Between-group comparisons revealed that the ASD group exhibited underconnectivity of the ACC with the precuneus compared to both the TD and EOP groups. Additionally, the EOP group exhibited ACC overconnectivity with the precuneus and posterior parietal cortex (PPC), compared to the ASD and TD groups.

Conclusions: Our results suggest distinct patterns of disrupted ACC connectivity in both the ASD and EOP groups. While the ASD group evidenced underconnectivity of the ACC with the precuneus, the EOP group showed overconnectivity with the precuneus and PPC regions. Notably, the ACC and precuneus are both part of the default mode network (DMN), and these findings may suggest that disrupted connectivity within the DMN network may be relevant to the social impairments common to both these neuropsychiatric groups. Additionally, the EOP group also demonstrated overconnectivity between the ACC and the PPC- a brain region involved in attention and working memory (Behrmann et al., 2004; Nee & Brown, 2012). This suggests further disruptions in connectivity in the EOP group that may potentially underlie cognitive deficits observed in this disorder, and this hypothesis will be investigated in our ongoing studies.

435.029 *(Poster)* Effects of Oxytocin on Neural Response to Social and Non-Social Reward in Autistic and Neurotypical Women

T. L. Procyshyn[1]*, M. V. Lombardo*[2]*, M. C. Lai*[3]*, B. Auyeung*[4]*, S. Crockford*[5]*, J. B. Deakin*[6]*, S. Soubramanian*[7]*, A. Sule*[8]*, S. Baron-Cohen*[1] *and R. A. Bethlehem*[1]*, (1)Autism Research Centre, Department of Psychiatry, University of Cambridge, Cambridge, United Kingdom, (2)Center for Neuroscience and Cognitive Systems, Laboratory for Autism and Neurodevelopmental Disorders, Istituto Italiano di Tecnologia, Rovereto, Italy, (3)Autism Research Centre, Department of Psychiatry, University of Cambridge, Cambridge, ON, United Kingdom, (4)University of Edinburgh, Edinburgh, United Kingdom, (5)University of Cambridge, Cambridge, United Kingdom, (6)Cambridgeshire and Peterborough NHS Foundation Trust, Cambridge, United Kingdom, (7)Liaison Psychiatry, South West London St.George's Mental Health NHS Trust, Carshalton, United Kingdom, (8)Department of Psychiatry, University of Cambridge, Cambridge, United Kingdom*

Background: Intranasal administration of oxytocin has been shown to promote social interactions, leading to interest in its therapeutic potential for autism spectrum conditions. However, the neurological underpinnings of oxytocin's effects on social behaviour remain unclear. One hypothesis is that oxytocin enhances social motivation via effects on neural reward processing, although this has not been tested in diverse autistic samples.

Objectives: To test the effect of intranasal oxytocin relative to placebo on brain responses to social and nonsocial rewards in autistic and neurotypical women and to explore biomarkers predictive of individual responses to oxytocin.

Methods: In this randomized, double-blind, cross-over functional magnetic resonance imaging (fMRI) experiment, 40 women (24 neurotypical, 16 autistic) underwent scanning (3T Siemens scanner, TR = 2400 ms, TE = 12, 29, 46 ms, FOV = 40 mm; alternating slice acquisition, slice thickness 3.8 mm, 11% slice gap; flip angle 80°) once after intranasal administration of 24 IU oxytocin and once after placebo. During scanning, participants completed 30 rounds each of the monetary incentive delay (MID) and social incentive delay (SID) tasks. Each round comprises presentation of a symbol indicating whether a successful response earns a reward; a variable time window during which participants must press a button; and, in case of successful response, presentation of an image indicating the reward (MID = money; SID = smiling face). Task-based neural activation in response to the anticipation and outcome of monetary and social rewards was denoised using multi-echo independent component analysis and analysed using fMRI Expert Analysis Tool v6.00 (part of FSL). Whole brain analyses were thresholded using clusters determined by Z>2.3 and a corrected cluster significance threshold of P=0.05. Pre-treatment salivary oxytocin levels were quantified by radioimmunoassay.

Results: Under placebo, neurotypical women showed significantly greater neural activation during both tasks compared to autistic women in brain regions including the ventral striatum, amygdala, cingulate cortex, and orbitofrontal cortex (Fig 1a,b). Among autistic women, there were significant increases in brain activation under the oxytocin vs. placebo condition for the anticipation of social and monetary rewards and the outcome of monetary reward (Fig 1c,d). Notably, the regions showing increased activity under the oxytocin condition in autistic women overlapped with the areas in which neurotypical women showed significantly greater activity under placebo. Finally, pre-treatment salivary oxytocin level had a significant negative effect on changes in brain activation under the oxytocin condition among autistic women, such that individuals with lower salivary oxytocin levels showed greater increases in neural activation in response to receipt of social reward in the cingulate cortex and medial prefrontal areas associated with theory of mind.

Conclusions: This study extends the evidence of reduced neural responses to both social and nonsocial reward in autistic relative to neurotypical individuals to specifically include women. The observed effects of oxytocin relative to placebo support that oxytocin influences reward processing, but that the effect is not specific to social reward. Finally, this study provides further evidence that pre-treatment oxytocin levels may be a useful predictor of responses to oxytocin administration in autistic individuals.

435.030 *(Poster)* Emerging Atypicalities in Cortico-Cerebellar Connectivity across the First Year of Life in Infants at High Risk for ASD

N. J. Okada[1]*, J. Liu*[2]*, T. Tsang*[2]*, E. Nosco*[3]*, K. K. Cummings*[1]*, J. Jung*[1]*, G. Patterson*[2]*, S. A. Green*[1]*, S. Y. Bookheimer*[1]*, S. Jeste*[2] *and M. Dapretto*[1]*, (1)Dept of Psychiatry and Biobehavioral Sciences, University of California, Los Angeles, Los Angeles, CA, (2)University of California, Los Angeles, Los Angeles, CA, (3)UCLA, Los Angeles, CA*

Background: Cerebellar atypicalities are a consistent finding in autism spectrum disorders (ASD). While the cerebellum is traditionally known for its role in motor control, it is also involved in many non-motor functions including higher order cognition, language, and social learning. There is great heterogeneity in the specific regions of the cerebellum recruited to support these different behaviors. Youth with ASD show altered functional connectivity in cortico-cerebellar networks, but the development of these networks in early infancy remains poorly characterized. Specifically, little is known regarding the emergence of distinct cortico-cerebellar networks underlying separate social/cognitive and sensorimotor functions in infancy and how these networks relate to later ASD symptomatology.

Objectives: We used resting-state fMRI to characterize developing functional connectivity in two distinct cortico-cerebellar networks during two timepoints in the first year of life in infants at high (HR) vs. low familial risk (LR) for developing ASD. We then examined how early group differences in cortico-cerebellar networks that support sensorimotor vs. social/cognitive functions predict social and language skills as well as ASD symptomatology in the second year of life.

Methods: Eight-minute rs-fMRI scans were collected during natural sleep in infants at 1.5 and 9 months of age. ICA-AROMA was used to correct for head motion. Seed-based connectivity of bilateral crus I (social/cognitive) and lobule I-IV (sensorimotor) cerebellar ROIs was examined at each time point. Group differences in functional networks associated with each seed were examined separately. Next, early differences in cortico-cerebellar connectivity were related to measures on the Early Social Communication Scales collected at 12 months and the MacArthur-Bates Communicative Development Inventories and the Autism Diagnostic Observation Schedule–Toddler Module collected at 18 months of age.

Results: At 1.5 months, whole-brain connectivity maps generated from lobule I-IV demonstrated functional connectivity with subcortical regions and sensorimotor cortex in both groups. LR infants additionally showed robust connectivity between crus I and subcortical regions and sensorimotor cortex. At 9 months, connectivity maps in both groups indicated a functional segregation of these networks, with robust connectivity between lobule I-IV and both subcortical and sensorimotor regions, as well as emerging connectivity between crus I and both subcortical and higher order frontal regions (Fig.1). At 1.5 months, the LR group showed greater connectivity between crus I and thalamus and basal ganglia compared to HR infants. Within LR infants, greater connectivity between these regions at 1.5 months was related to better joint attention and language comprehension at 12 and 18 months respectively. By 9 months, LR infants showed greater connectivity between lobule I-IV and supplementary motor area compared to the HR group. Within HR infants, greater connectivity between these regions at 9 months was related to better joint attention at 12 months and less severe ASD symptomatology, including fewer restricted and repetitive behaviors, at 18 months (Fig.2).

Conclusions: Taken together, these findings demonstrate that the emergence of cortico-cerebellar networks is already atypical in infants at high risk for developing ASD. Early differences in functional connectivity may predict altered developmental trajectories before overt behavioral delays and the onset of ASD symptomatology.

435.031 *(Poster)* Examining Relations between Anxiety Symptoms and Amygdala Activity Among Autistic Adolescents Using fMRI

A. J. McVey[1]*, J. D. Herrington*[2]*, A. Barrington*[3]*, H. K. Schiltz*[1]*, B. Dolan*[4]*, A. D. Haendel*[5]*, K. Willar*[6]*, A. Arias*[7] *and A. V. Van Hecke*[1]*, (1)Psychology, Marquette University, Milwaukee, WI, (2)Perelman School of Medicine, University of Pennsylvania, Philadelphia, PA, (3)Biomedical Engineering, Marquette University, Milwaukee, WI, (4)Medical College of Wisconsin, Milwaukee, WI, (5)Speech-Language Pathology, Concordia University Wisconsin, Mequon, WI, (6)Stanford University, Stanford, CA, (7)Marquette University, Milwaukee, WI*

Background: Approximately 40% of youth with autism experience at least one anxiety disorder (van Steensel, Bögels, & Perrin, 2011). A budding area of research demonstrates links between anxiety and amygdala activity among autistic youth (Herrington et al., 2017; Herrington, Miller, Pandey, & Schultz, 2016), preschool-aged children (Ventola et al., 2014), and adults (Corden, Chilvers, & Skuse, 2008; Kleinhans et al., 2010). Findings thus far are sparse and therefore further exploration is necessary to clarify these potential associations.

Objectives: To examine links between self- and parent-reported anxiety symptoms and amygdala activity among youth with autism. We hypothesized that anxiety symptoms would be positively associated with amygdala activity.

Methods: Thirty-eight autistic adolescents ages 11–16 were included in the present study. This subsample was drawn from a larger randomized clinical trial of a social skills intervention for autistic youth. All adolescents underwent an fMRI at two timepoints; only data from the first timepoint are included here. Given the difficulty of measuring anxiety in autism and following prior recommendations (Spain, Sin, Linder, McMahon, & Happé, 2018), several measures of anxiety were collected including the Anxiety Problems subscale on the *Child Behavior Checklist* (CBCL; Achenbach & Rescorla, 2001) and *Youth Self-Report* (YSR; Achenbach & Rescorla, 2001), *Spence Children's Anxiety Scale* (SCAS; Spence, 1998), *Social Anxiety Scale for Adolescents* (SAS; La Greca & Lopez, 1998), and *Social Interaction Anxiety Scale* (SIAS Heimberg, Mueller, Holt, Hope, & Liebowitz, 1993). fMRI data were collected using a GE MR750 3T using a 1-back, affective face processing task. Data were preprocessed using FSL (Smith et al., 2004); data included here were determined to be useable following preprocessing including motion correction. Amygdala activity was examined using contrasts of faces vs. houses and single-group average was conducted using FSL. Amygdala ROI data were identified with the Harvard-Oxford Subcortical Atlas (https://identifiers.org/neurovault.collection:262) and a binarized mask. Average amygdala values were extracted using z-stat maps.

Results: Pearson's correlations were conducted. Although the right and left amygdala were significantly related to one another, and there were significant links among several anxiety measures, no significant associations between anxiety symptoms and amygdala activity emerged (see Table 1). One link, between the right amygdala and SAS parent-report of fear of negative evaluation showed a trending positive correlation ($r = 0.311$, $p = 0.061$).

Conclusions: Contrary to our hypotheses, no significant links between anxiety symptoms and amygdala activity were found. One trending correlation showed a possible link between parent-report of fear of negative evaluation on the SAS and activity in the right amygdala. Because parsing by specific anxiety disorder diagnosis was not possible in the current sample, it is unknown whether a more fine-grained approach would reveal associations. Lastly, neural activity may be tied to a more proximal measure of symptoms, such as state anxiety measures (e.g., the State Trait Anxiety Inventory; Spielberger, Gorsuch, & Lushene, 1970), as more distal questionnaires such as the CBCL might not reliably capture the true latent construct of anxiety in autism.

435.032 *(Poster)* GABA and Glx Levels in Adults with High Functioning Autism Versus Major Depressive Disorder

A. Mulhall[1]*, **T. C. Day***[2]*, R. A. Vogel*[3]*, J. P. Giacomantonio*[4]*, M. Batra*[5]*, H. Garman*[4]*, C. DeLorenzo*[6]*, X. He*[7] *and K. D. Gadow*[8]*, (1)Psychiatry, Stony Brook University, Stony Brook, NY, (2)Psychology, Stony Brook University, Stony Brook, NY, (3)Neurobiology and Behavior, Stony Brook University, Stony Brook, NY, (4)Stony Brook University, Stony Brook, NY, (5)College of Osteopathic Medicine, New York Institute of Technology, Glen Head, NY, (6)Psychiatry and Behavioral Science, Stony Brook University, Stony Brook, NY, (7)Radiology, Stony Brook University, Stony Brook, NY, (8)Department of Psychiatry, Stony Brook University, Stony Brook, NY*

Background: Adults with high functioning autism (HFA) often experience social anhedonia (SA) and depression (Gadow, 2012; Gadow, *et al.*, 2012). Furthermore, SA is a core feature of HFA and major depressive disorder (MDD; Kanner, 1943; Gadow & Garman, 2018; Blanchard *et al*., 2001). Abnormalities in gamma-aminobutyric acid (GABA) and glutamate+glutamine (Glx) are found in major depressive disorder (MDD) and autism, and although findings are mixed, research suggests decreased levels in both populations (Shur *et al.,* 2016; Yuksel & Ongur, 2010; Horder *et al.,* 2013). Nevertheless, little is known about how they compare to one another.

Objectives: To examine similarities and differences in adults with HFA and MDD in behavioral phenotypes, and brain GABA and Glx levels.

Methods: Participants comprised adults with HFA (*n*=30; age=18-45 years) with IQs ≥ 80 and adults with MDD (*n*=21; age=18-45 years), with prior MDD diagnosis and score of 22+ on the Montgomery- Åsberg Depression Rating Scale. Adults with HFA (*n*=16) and MDD (*n*=18) were scanned using (1) Single voxel J-editing H-MRS was acquired on Siemens Biograph 3T scanner for the metabolites GABA and Glx, which was performed with one voxel (30×30×20 mm 3) in the anterior cingulate cortex using a TR/TE of 2000/68 ms with a spectral bandwidth of 2 kHz, 384 spectral average and 16 water reference. Measures included the self-administered Social Responsiveness Scale Second Edition (SRS-2) and the Revised Social Anhedonia Scale (RSAS) and the Hamilton Depression Rating Scale (HAM-D).

Results: The MDD group was significantly more depressed than the HFA group per the Ham-D (*p*<.001; Cohen's d=1.84), Groups did not differ in overall autism severity (SRS-2 total score; *p*=.267) or in SRS-2 Awareness, Communication, and Motivation (*p*s>.05) subscales, but there were significant group differences for Mannerisms and Cognition (*p*s<.02) subscales. Groups did not differ in social anhedonia (RSAS, *p*=.445). HFA had higher levels of Glx than MDD (*p*=.002; Cohen's d=1.17), which remained significant after controlling for severity of depression (HAM-D; *p*=.004; Cohen's d=1.24). Group differences in GABA levels were not statistically significant (*p*=.104).

Conclusions: Adults with HFA and MDD each exhibited comparable levels of social anhedonia and overall autism severity but nevertheless differed with regard to reciprocal social interaction and repetitive behaviors. Collectively, our findings support both transdiagnostic and disorder-specific phenotypic features in these clinic populations. Adults with HFA had significantly higher brain levels of Glx than MDD, which supports the notion that the biologic substrates of the two disorders differ. However, brain GABA levels were comparable. Additional research that includes typically developing adults may help us better understand the biological basis of autism with comorbid depression, which could have important implications for treatment.

435.033 *(Poster)* Identifying Brain Areas Correlated with Autism Diagnostic Observation Schedule

O. Dekhil[1]*, R. Haweel*[1]*, Y. ElNakieb*[1]*, A. Shalaby*[1]*, A. Mahmoud*[1]*, G. Barnes*[2] *and A. S. El-Baz*[3]*, (1)Bioengineering, University of Louisville, Louisville, KY, (2)Neurology, University of Louisville School of Medicine, Louisville, KY, (3)University of Louisville, Louisville, KY*

Background: Altered functional connectivity patterns are believed to play an important role in explaining autism spectrum disorder related impairments. In order to examine such connectivity, resting state functional MRI is the most commonly used technique. To the moment, the majority of effort in this area tends to examine the whole time series of brain activation as a signal generated by a stationary process. In this study, we are providing a more detailed insight of how functional connectivity fluctuates over time, by quantifying the instances where over-connectivity and under-connectivity happens. We are using a novel approach that utilizes non-parametric surrogates test to examine the stationary nature of the activation time series. This study identifies the areas where under-connectivity or over-connectivity are correlated with the autism diagnosis observation schedule.

Objectives: To correlate the most significant areas and neural circuits with subject behaviors.

Methods: In this study, 166 subjects having ADOS module 3 data and 72 subjects having ADOS module 4 data are used. The ADOS reports used are the total, communication, social and behavior reports. We developed an algorithm to quantify the moment of over-connectivity and under-connectivity between the time courses of different brain regions (shown in Fig.1). The extracted feature represent the number of moments falling within top 5% and 10% and bottom 5% and 10% of proposed connectivity null distribution. These features are then used in correlation analysis with the 4 reports of the 2 ADOS modules.

Results: In this study, two main experiments were conducted: (i) to study the correlation between the extracted percentiles features and ADOS module 4, and (ii) to study the correlation between the extracted percentiles features and ADOS module 3. To check if the correlation is significant, FDR is used with adjusted p-value significance level set to 0.1. For ADOS module 3, only two pairs of areas were found to be significant, and these two pairs were correlated only with the behavioral domain: right cerebellar lobules IV–V and right pars opercularis ($r = 0.4$, $p = 0.03$), right caudate and right medial orbitofrontal cortex ($r = 0.39$, $p = 0.033$). They were correlated with over-connectivity moments, 90–95%, 95–100%, respectively. For ADOS module 4. For the communication domain, the most significant pair is right temporal pole and left middle occipital gyrus. The most significant pair in the behavioral domain is right cerebellar lobule III and left thalamus ($r = 0.59$). Correlation of $r = 0.5$ was observed in the paired inferior occipital and superior frontal gyri in the left hemisphere. Finally for the ADOS total severity score, the most significant correlation was seen with left inferior occipital gyrus and right precentral gyrus. This pair is known to be implicated in autism.

Conclusions: This methodology better estimates regional functional connectivity (under-connectivity or over-connectivity) with observed behaviors on the AODS than a stationary process. This work is believed to be an important next step towards personalized autism diagnosis and treatment, where each subject impairments are better understood and addressed.

435.034 *(Poster)* Implementation of a System to Reduce in-Scanner Head Motion in Pediatric Participants with Autism Spectrum Disorder Undergoing a 60-Minute fMRI Protocol

C. Horien[1]*, S. Fontenelle*[2]*, K. Joseph*[2]*, N. Powell*[2]*, C. Nutor*[2]*, D. M. Goncalves Fortes*[2]*, M. Butler*[2]*, K. K. Powell*[2]*, D. Macris*[2]*, J. McPartland*[2]*, F. R. Volkmar*[3]*, D. Scheinost*[4]*, K. Chawarska*[2] *and R. T. Constable*[5]*, (1)Yale Interdepartmental Neuroscience Program, New Haven, CT, (2)Child Study Center, Yale University School of Medicine, New Haven, CT, (3)Child Study Center, Yale School of Medicine, New Haven, CT, (4)Radiology & Biomedical Imaging, Yale School of Medicine, New Haven, CT, (5)Yale University, New Haven, CT*

Background: Performing fMRI scans of children with autism spectrum disorder (ASD) can be a difficult task, as participants tend to move in the scanner. Head motion represents a confound in functional connectivity analyses (e.g. Power et al., 2012), and methods are needed to limit the impact of movement. One approach has been to use shorter fMRI protocols, though this potentially sacrifices reliability of results.

Objectives: We describe steps we have taken to limit head motion in children undergoing a 60-minute MRI scan. We assess if the protocol limits movement, if the system is generalizable, and if it is efficacious in children with ASD.

Methods: We leverage data from an ongoing study. The experimental group (n=12) underwent a formal mock scan, used a weighted blanket, and earned prizes during the scan for limiting head movement; the control group (n=7) did not undergo these steps. No subjects in either group had ASD. To test generalizability, we used a validation group (n=16; 5 with ASD): these subjects underwent the same steps to limit motion as the experimental group, except a separate team of researchers conducted the mock scan and fMRI protocol.

We conducted two-sample *t*-tests to compare demographic factors and a two-tailed Fisher Exact Probability test to compare the number of females. For each participant, we calculated the mean frame-to-frame displacement (FFD) in mm for each functional run. To determine if the mean FFD values differed due to scan condition (movie, attention task ('gradCPT'), and rest), we calculated Hedge's *g* to determine effect sizes. To determine statistical significance, we performed two-sample *t*-tests on the average mean FFD value for a condition and across all scans per participant. Significance was assessed at a *P*-value < 0.05 after correcting for multiple comparisons using the Benjamini-Hochberg procedure. We also classified scans as either low or high motion after applying movement thresholds and used a Chi-square test of association to determine if there was a significant difference among the groups.

Results: All three groups were similar demographically, except there were more females in the validation group relative to the control group (Table 1); we found no significant correlations among IQ and mean FFD values. When we compared mean FFD values, we found the experimental and validation groups tended to have significantly lower mean FFD values compared to controls ($P < 0.05$ in 6/8 comparisons) and effect sizes tended to be large (Hedge's $g > 0.08$ in 18/20 comparisons). When we classified scans as either high or low motion, we found the experimental and validation groups had more scans classified as low motion (all $P < 0.05$; see Figure 1 for a comparison of the control and experimental groups).

Conclusions: Compared to the control group, our steps to reducing motion in both the experimental and the validation group did indeed lead to less head motion. With appropriate measures, these data suggest it is possible to obtain low motion data in participants with ASD undergoing a long scan protocol.

435.035 *(Poster)* Intrinsic Functional Connectivity Versus Fluid Reasoning Abilities in Autistic Children

J. Degré-Pelletier[1], *E. Danis*[2], *E. B. Barbeau*[3] *and I. Soulieres*[4], *(1)Université du Québec à Montréal, Montreal, QC, Canada, (2)University of Quebec in Montreal, Montreal, QC, Canada, (3)Cognitive Neuroscience Unit, Montreal Neurological Institute, McGill University, Montreal, QC, Canada, (4)Département de Psychologie, Université du Québec à Montréal, Montréal, QC, Canada*

Background: Strengths in fluid reasoning have been documented in autistic children, such as greater performance at Raven's Progressives Matrices (RPM) than predicted by Wechsler IQ (Dawson et al., 2007). In typical adults, intrinsic functional connectivity during rest has been associated with individual differences in reasoning abilities (Yuan et al., 2012). Knowing that differences in intrinsic functional connectivity have been reported in autism (Assaf et al., 2010; Monk et al., 2009), do different patterns of intrinsic functional connectivity support reasoning abilities in autistic children?

Objectives: The current study aims to investigate the associations between the pattern of intrinsic functional connectivity in autistic children and individual differences in fluid reasoning, by 1) Exploring patterns of functional connectivity at rest in autistic versus typical children and 2) Examining the links between functional connectivity during rest and fluid reasoning performance.

Methods: 27 (2F) autistic and 26 (7F) typical children equivalent in age (*M*=11.60, *SD*=2.73), RPM percentile scores (M=59.69, SD=29.71) and laterality were scanned in a 3T MRI scanner. Each participant completed a resting state sequence (6min) fixating a white dot on a black background. CONN toolbox was used for preprocessing and seed-to-voxels analyses (few corrected *p*=.05). The posterior cingulate cortex (PCC) was taken as seed for the analyses, as it is a central component of the default mode network (DMN), active during rest (Monk et al., 2009; Fox et al, 2005).

Results: The pattern of functional connectivity involving PCC was similar in both groups, with significant connectivity with precuneus, angular gyrus (bilateral), insular cortex (bilateral), medial prefrontal cortex, superior frontal gyrus (bilateral), lateral parietal cortices (bilateral), temporal lobe (bilateral), lateral occipital complex, parahippocampal gyrus (bilateral) and paracingular gyrus (bilateral). There was no significant between-group difference of functional connectivity among these DMN regions. In all participants, RPM scores were positively associated with functional connectivity between PCC and parahippocampal gyrus (r = .321, *p*<.05). In autistic children, RPM scores were negatively associated with functional connectivity between PCC and left middle temporal gyrus (r = -.383, *p*<.05), left and right angular gyrus (r respectively -.429 and -.415, p<.05). In typical children, RPM scores were positively correlated with functional connectivity between PCC and left middle temporal gyrus (r = .412, *p*<.05) and right superior frontal gyrus (r = .401, *p*<.05).

Conclusions: In line with previous findings, we found that the same network of regions were interconnected with PCC in autistic and typical children (Monk et al., 2009). Previous studies found between-group differences in the level of connectivity, typical participants showing over-connectivity between PCC and superior frontal gyrus, and autistics showing stronger connectivity between PCC and temporal lobe (Monk et al., 2009). Going further, we found that functional connectivity in these regions was associated with fluid reasoning abilities in each group: connectivity between PCC and superior frontal gyrus predicted reasoning abilities in typical children only, while connectivity between PCC and middle temporal gyrus predicted reasoning abilities in both groups but in different directions. Different intrinsic functional connectivity patterns seem to support fluid reasoning in autistic versus typical children.

435.036 *(Poster)* Investigation of Cortical Development in ASD Using Motion-Corrected R1 Relaxometry

A. L. Alexander[1], *G. R. Kirk*[2], *S. R. Kecskemeti*[2], *D. C. Dean*[3], *A. Freeman*[4], *B. A. Zielinski*[5], *M. D. Prigge*[6], *J. S. Anderson*[7], *N. Lange*[8], *E. Bigler*[9] *and J. E. Lainhart*[10], *(1)Medical Physics & Psychiatry, University of Wisconsin - Madison, Madison, WI, (2)Waisman Brain Imaging Lab, University of Wisconsin - Madison, Madison, WI, (3)Pediatrics & Medical Physics, University of Wisconsin - Madison, Madison, WI, (4)University of Wisconsin - Madison, Madison, WI, (5)Pediatrics and Neurology, University of Utah, Salt Lake City, UT, (6)Developmental Network Neurobiology Laboratory, University of Utah, Salt Lake City, UT, (7)Radiology and Imaging Sciences, University of Utah, Salt Lake City, UT, (8)McLean Hospital, Cambridge, MA, (9)Brigham Young University, Provo, UT, (10)Psychiatry, University of Wisconsin - Madison, Madison, WI*

Background: Recent neuroimaging and pathology studies suggest that cortical development is affected in autism spectrum disorders (ASD). In particular, most ASD structural neuroimaging studies have focused on measures of cortical thickness, surface area and gyrification from T1-weighted (T1w) images. The boundary contrast between gray matter (GM) and white matter (WM) on T1w images has also been reported to be reduced in ASD. we utilized a novel whole-brain, high resolution quantitative R1 mapping method to investigate the developmental changes of quantitative R1 (=1/T1) relaxometry in the cerebral cortex, which should provide more direct indicator of both structural and microstructural changes.

Objectives: The primary objective was to investigate the developmental age-related changes of quantitative R1 relaxometry in the cerebral cortex.

Methods: High functioning (IQ >70) participants included 46 with ASD [mean age: 16 years, age range: 5-42 years] and 66 typically developing (TD) [mean age: 16.4 years, age range: 5.75-31 years]. Neuroimaging with 3T MRI included whole-brain MPnRAGE [Kecskemeti et al. 2016], which generated multiple inversion recovery contrasts used to fit quantitative R1 maps with 1mm isotropic spatial resolution. Total imaging time was approximately 8.5 minutes. Retrospective motion correction was used to generate images with consistent high contrast between GM and WM and minimal motion blurring [Kecskemeti et al. 2018]. Cortical parcellation was performed using Freesurfer on the MPnRAGE T1w images, which are inherently coregistered to the quantitative R1 maps. Individual R1 measurements were mapped to the cortical surface, assessed at the half-thickness of the cortex, and resampled onto a standardized cortical template within Freesurfer. Statistical testing was performed at each surface vertex using a general linear model in Freesurfer. First, R1 versus age regression was performed independently for each group. A follow-up model analysis was performed to evaluate R1 versus age, group and age x group effects. Statistically significant effects were assessed following False Discovery Rate multiple comparisons correction at $p<0.05$.

Results: For the TD cohort, there was a significant positive relationship between R1 and age over the majority of the medial and lateral cortical surfaces. Conversely, R1 versus age relationships in the ASD cohort were weaker, with many ventral frontal, temporal, and occipital regions not exhibiting a significant age relationship. In the second model, significant age x group interactions for cortical R1 were observed in bilateral temporal pole, bilateral fusiform gyrus, and right primary auditory cortex.

Conclusions: To our knowledge, this is the first study to investigate quantitative R1 relaxometry in the cerebral cortex in ASD. We observed significant group differences in age-related R1 trajectories, particularly in ventral frontal and temporal regions. The differences in age-trajectories may help to explain the diminished T1w cortical GM versus WM contrast reported in ASD [Andrews et al. 2017]. One potential mechanism for cortical R1 changes is myelination [Glasser et al. 2011]. However, other potential mechanisms include inflammation, iron accumulation, and the distributions of macromolecules in the tissue. In summary, R1 mapping with MPnRAGE is a promising tool for investigation of cortical microstructure in ASD across the lifespan.

435.037 *(Poster)* Lateralization of Precision Motor Behavior and Physiology in ASD

W. S. McKinney[1,2], *K. E. Unruh*[1] *and M. W. Mosconi*[1,2], *(1)Kansas Center for Autism Research and Training (K-CART), University of Kansas, Lawrence, KS, (2)Clinical Child Psychology Program, Schiefelbusch Institute for Life Span Studies, University of Kansas, Lawrence, KS*

Background: Individuals with ASD show atypical patterns of motor lateralization characterized by higher rates of mixed handedness. Systematic comparisons of precision sensorimotor behaviors across right and left hands are needed to characterize the extent to which atypical lateralization affects different motor abilities. Task-based functional MRI studies right and left hand motor behavior are needed to clarify neurodevelopmental processes associated with atypical lateralization of motor function in ASD.

Objectives: To (1) characterize precision motor behavior across right and left hands in ASD, and (2) define functional brain networks associated with right and left hand precision sensorimotor control in ASD.

Methods: Twenty-three individuals with ASD, including three left-handed individuals, and 20 typically developing controls, including three left-handed individuals, matched on age (range: 10-34 years), sex, and nonverbal IQ completed a visually guided precision gripping task during fMRI. During the task, participants gripped a force transducer while viewing two horizontal bars. Their task was to press on the transducer to move the lower bar upwards to the height of the static target bar. The target bar was set at 45% of their maximum voluntary contraction (MVC). Participants completed three 26-s blocks of gripping each separated by 26-s of rest. They completed one run of the task with each hand. Grip strength, mean force, force regularity (approximate entropy, or ApEn), and force variability (SD) were examined separately for each hand. Percent BOLD signal change during gripping vs. rest was examined. These preliminary analyses use a voxel-wise threshold of $p < .05$ with a cluster threshold of 20 voxels. Data collection is ongoing, and data of additional subjects will be presented.

Results: Relative to controls, individuals with ASD showed reduced grip strength and mean force with their left hand and reduced ApEn with their right hand. Individuals with ASD also showed increased force variability across both hands. When using their left hand, individuals with ASD showed reduced BOLD activation relative to controls in multiple sensorimotor regions, including bilateral M1, contralateral S1, anterior cingulate cortex, left V1, and pons. When using their right hand, individuals with ASD showed greater activation in left precuneus, left angular gyrus, and right superior temporal gyrus.

Conclusions: Lateralized reductions in grip strength and mean force in ASD suggest atypical development of motor cortical circuits. Reduced force complexity (ApEn) in right but not left hand implicates left-lateralized difficulties with the online integration of sensory feedback. When using their left hand, individuals with ASD also showed reduced activation in contralateral M1 and S1 implicating atypical hemispheric specialization as a critical neurophysiological feature of ASD. Reductions in contralateral precuneus and angular gyrus during right hand control indicates lateralization of cortical motor alterations and suggests abnormal sensory feedback processing contributes to atypical sensorimotor behavior in ASD.

435.038 *(Poster)* MEG Predictors of Cognitive and Language Impairment

L. Bloy[1], *J. Matsuzaki*[2], *L. Blaskey*[1], *M. Kim*[1], *H. L. Green*[1], *E. S. Kuschner*[1], *D. Embick*[3] *and T. Roberts*[1], *(1)Lurie Family Foundations MEG Imaging Center, Department of Radiology, Children's Hospital of Philadelphia, Philadelphia, PA, (2)Children's Hospital of Philadelphia, Philadelphia, PA, (3)Department of Linguistics, University of Pennsylvania, Philadelphia, PA*

Background: Autism Spectrum Disorder (ASD) is a heterogenous neurodevelopmental disorder presenting with a range of cognitive and language deficits. Prior studies have identified associations between magnetoencephalography (MEG) measures of auditory cortex activity and both general cognitive ability (IQ) and domain-specific language ability. Specifically, measures of auditory encoding processes (e.g., M50 latency) are more sensitive to measures of nonverbal IQ, while post-stimulus event related desynchronization (ERD) of auditory cortex has higher sensitivity to language function. However, with the growing use of imaging (including MEG) in high risk infant cohorts to *'predict'* functional outcome, it becomes important to investigate the ability of MEG measures to explain variance of behavioral functional outcome measures such as IQ or language.

Objectives: In order to better understand the potential utility of MEG to predict functional outcome measures we used general linear models (GLMs) to investigate the ability of a brief battery (<30 minutes) of MEG tasks to explain variance in nonverbal IQ and parent reports of language ability. Participants had a wide range of intellectual and language abilities but for descriptive purposes can be described of coming from 4 cohorts: 1) Minimally-Verbal/Nonverbal children with ASD, 2) lower Intelligence Quotient (IQ) Intellectual Disability/Developmental Disability (ID/DD, non-ASD), 3) Verbal children with ASD, and 4) Verbal typically developing children.

Methods: Fifty six participants (aged 7-13yrs) were included in the final analysis (MVNV children with ASD, n=24, 10.1±1.4yrs; lower IQ ID/DD (non-ASD) children, n=10, 10.0±1.4yrs; Verbal children with ASD, n=10, 9.5±1.4yrs; typically developing children, n=13, 9.5±0.9yrs). The MEG battery consisted of two tasks. Auditory Pure Tone Exam: 500 Hz tones presented with a random ISI between 600ms-2000ms. The latency of middle auditory evoked response (**M50**) was determined bilaterally. Language Task: Stimuli consisted of monosyllabic words and pronounceable nonwords. Bilateral auditory **ERD** was measured between 5-20Hz and 200-1650ms. Cognitive ability was operationalized as the Nonverbal IQ (NVIQ) of the Leiter-3 or Perceptual Reasoning Index of the WISC-IV. Language ability was assessed using the communication domain of the Vineland-3 (Vineland-Comm). GLMs were used to separately investigate the relationship of NVIQ and vineland-comm using fixed effects of M50, ERD and hemisphere.

Results: MEG measures were able to explain significant amounts of variance for both NVIQ (R^2=0.23; $p<0.01$) and Vineland-Comm (R^2=0.36; $p<0.001$). For the NVIQ model, effects of both M50 ($p=0.016$) and ERD ($p=0.001$) were significant and their interaction was marginally significant ($p=0.088$). Effects of hemisphere and its interactions were not significant. Similarly, both M50 ($p=0.009$) and ERD ($p<0.0001$) were significant in explaining Vineland-comm, with a potential trend ($p=0.1$) observed for their interaction. Effects of hemisphere and its interactions were all not significant.

Conclusions: These findings demonstrate a significant association between measures of IQ and language ability with MEG measures derived from a brief battery of passive MEG tasks. While the observed associations were between measures obtained at a single timepoint and in school aged children, these positive results over a large range of functional abilities, are encouraging for future applications to infant subjects and for predicting future measures of cognitive and language ability.

435.039 *(Poster)* Magnetic Resonance Imaging Findings in a Sample of Uruguayan Adolescents with Autism Spectrum Disorder

J. Irigoyen[1]*, C. Amigo*[2]*, G. Garrido*[3]*, L. Buschiazzo*[1]*, M. Garcia Fontes*[4]*, L. Valuntas*[5] *and M. E. Rodriguez-Parodi*[6]*, (1)Centro Hospitalario Pereira Rossell, Montevideo, Uruguay, (2)Clinica de psiquiatria pediátrica Facultad de medicina, UDELAR, Montevideo, Uruguay, (3)Universidad de la República, Montevideo, Uruguay, (4)PET TC and MRI, Centro Uruguayo de Imagenologia Molecular, Montevideo, Uruguay, (5)MRI, Centro Uruguayo de Imagenologia Molecular, Montevideo, Uruguay, (6)RADIOLOGY, Centro Uruguayo de Imagenologia Molecular, Montevideo, Uruguay*

Background: Autism spectrum disorder (ASD) refers to a neurodevelopmental disorder characterized by impairment in social communication and restricted repetitive behaviors and interests. In children and adolescents diagnosed with ASD, multiple structural and functional variations have been identified in sMRI as well as in fMRI, compared to neurotypically developed population. Nevertheless, the growing neuroimaging literature in ASD has not yet identified neuroanatomical or functional markers that specifically and consistently accompany an ASD diagnosis. The limitations to advance in this field are multiple, making international efforts and collaboration between scientists fundamental to achieve better results; in this context is that we initiate our project.

Objectives: Our purpose is to contribute to define more consistently the neuroanatomical features of ASD in adolescents, and considering that the amount of evidence that comes from South American population is scarce, we aim to establish to what extent the variations in sMRI and fMRI described in the international literature are also identified in our patients. Therefore, we aspire to show new data obtained from a sample of patients that participate in our project.

Methods: Participants included are adolescents between 14 and 17 years old, with an ASD diagnosis done by doctoral-level clinicians based in DSM-5 criteria. None of them have medical, neurologic or genetic illness; if this was the case, the participant was excluded. To every participant the Autism Diagnostic Observation Schedule (ADOS), the Autism Diagnostic Interview-Revised (ADI-R) and the Wechsler Intelligence Scale for Children (WISC-IV) or the Wechsler Adult Intelligence Scale (WAIS-IV) were administered. All images were acquired using a 3.0-Tesla MRI (General Electric Discovery 750W). Morphological and functional sequences were done (3D T1,3D Flair, DTI and Resting State fMRI); magnetic resonance imaging was performed without sedation in all cases.

Results: The Resting State fMRI showed normal functional connectivity. The morphological sequence and DTI showed an asymmetry between right and left subcortical white matter, with the identification of multiple white matter tract distortions. In regards to the clinical evaluation, impairments in language, executive functions, as well as in facial and emotional processing were identified.

Conclusions: Encephalic volumetric asymmetry and diverse nervous tracts distortions are described in ASD and our first sample of participants show results that support this fact. The latter could also explain the impairments in language, executive functions, as well as in facial and emotional processing. To advance in the knowledge of these possible associations, research with a bigger number of patients is required, as well as the introduction of neurotypically developed participants to our project.

435.040 *(Poster)* Mapping Neural Correlates to Language and Biological Motion in School-Aged Children with Autism Using High Density Diffuse Optical Tomography

A. Svoboda[1]*, T. Burns-Yocum*[2]*, A. Sherafati*[1]*, M. L. Schroeder*[1]*, S. Rafferty*[1]*, J. P. Culver*[1] *and A. Eggebrecht*[1]*, (1)Washington University School of Medicine, St. Louis, MO, (2)Indiana University Bloomington, Bloomington, IN*

Background: Autism Spectrum Disorder (ASD) is a neurodevelopmental disorder characterized by marked impairments in social communication and heightened restrictive and repetitive patterns of behavior. Understanding the disruption to neural systems underlying ASD will be crucial in early diagnosis and for developing novel targeted interventions. However, traditional neuroimaging modalities like functional magnetic resonance imaging (fMRI) require participants to remain still in a loud, enclosed environment that can be challenging for children, especially those with ASD. To overcome these challenges while acquiring fMRI comparable images, we have developed high-density diffuse optical tomography (HD-DOT), a silent, wearable, and minimally constraining neuroimaging modality that can map brain function in an open, naturalistic environment more amenable to studies on children with ASD.

Objectives: In the current study, we aim to establish the use of HD-DOT in school-aged children with ASD using a hierarchical paradigm of language processing and also a biological motion processing paradigm previously shown with fMRI to exhibit ASD-associated differences in brain areas known for socially-relevant processing.

Methods: We imaged 30 children with ASD age 9-17 years old and 40 typically developing (TD) age-matched children. Each participant was imaged using HD-DOT while completing three stimulus paradigms. First, participants listened passively to nouns presented over speakers in a block design. Second, participants generated an associated verb in response to nouns presented visually in a block design on a monitor. Third, participants watched alternating 24-seconds of scrambled and coherent point-like animations of biological motion. This paradigm is well-validated in fMRI and eye-tracking studies to evaluate altered patterns of social perception and processing in those with ASD.

Data was processed using the NeuroDOT pipeline (Eggebrecht et al., 2014) in MATLAB, with HD-DOT data (ΔHbO contrast) registered to the MNI atlas for group analyses. Standard GLM analyses were used with an HD-DOT-derived adult hemodynamic response function (Hassanpour et al., 2013) and contrast maps were assessed within and across groups.

Results: Both cohorts exhibit bilateral activations over auditory cortex in response to hearing words presented via room speakers at a volume of normal conversation. In response to the cognitive task of generating words, the groups show two interesting differences. The TD exhibit strong activations in right- and left-lateralized dorso-lateral prefrontal cortex (rdlPFC & ldlPFC), while the ASD cohort exhibits diminished activations in visual cortex and heightened activity in rdlPFC. Results of the biological motion task replicate previous studies in healthy adults as well as in TD and ASD adolescents, demonstrating stronger contrasts of biological-vs-scrambled motion in TD than ASD in right-lateralized temporal-parietal junction (r-TPJ), right posterior superior temporal sulcus (r-STS), and rdlPFC, key nodes of the social brain.

Conclusions: This study shows school-aged children with and without ASD can be successfully imaged with HD-DOT to map brain function with high fidelity in a silent and naturalistic environment. These results show HD-DOT is sensitive to differential responses to biological motion in children with ASD as compared to TD. Future analyses will relate the variation in these contrast maps across participants to variation in assessments of social responsiveness.

435.041 *(Poster)* Measuring Motor Networks in Children with Autism Spectrum Disorder: A Systematic Review of EEG Techniques and Research Designs.

F. Acluche[1]*, A. Augustiniak*[2]*, N. Ditchfield*[3]*, J. Bo*[2] *and E. A. Sunde*[1]*, (1)Clinical Psychology, Eastern Michigan University, Ypsilanti, MI, (2)Psychology, Eastern Michigan University, Ypsilanti, MI, (3)Neuroscience, Eastern Michigan University, Ypsilanti, MI*

Background: Motor deficits (e.g odd gait, clumsiness, rigidity) and delays in fine and gross motor skills have been observed in children diagnosed with Autism Spectrum Disorder (ASD). Impairments in the motor domain have been documented as impacting the diagnostic features of ASD, such as language acquisition. As the use of electroencephalography (EEG) in research with this population increases, to better understand behavioral and neural correlates of the motor network, so does the need for research guidelines that: 1) are specialized for the complex symptomatology in this population and; 2) inform methodological approaches of future studies. There are currently no formal guidelines for examining neural correlates of the motor network that account for the special considerations needed in this population. A lack of homogeneity in behavioral measures, EEG techniques and overall study design leads to difficulty replicating findings and identifying factors essential for determining appropriate analytical approaches.

Objectives: To describe and compare EEG techniques and research methods implemented; and describe and compare reported brain activity associated with the motor network in children diagnosed with ASD.

Methods: Systematic review were conducted via PubMed, PsychInfo, and Web of Science, for the terms *electroencephalography OR eeg*; *autis* OR ASD*; *motor*; and *child OR childhood OR children*. Inclusion criteria: English-language articles, use of EEG technique, indirect or direct discussion of the motor network; and participant age 5-12 years old diagnosed with ASD.

Results: A total of 154 articles were reviewed. 13 articles were included in the full text analysis. 18 domains were identified as pertinent factors to consider when determining relevant study designs for examining the motor network in children diagnosed with ASD: (1) Clinical Sample characteristic; (2) Control sample characteristic; (3) Diagnostic measure; (4) Assessment measures; (5) Medication; (6) Behavioral paradigm detail; (7) Experiment setup; (8) Experiment task; (9) EEG system; (10) EEG electrode; (11) EEG recording-online; (12) EEG recording-offline; (13) EEG Analysis: (14) EEG component(s); (15) Temporal characteristics; (16) Quantified EEG; (17) EEG activity; (18) EEG activity function. The domains are displayed in tables. Using the domains, we observed that related articles focused neural activity of: *Movement Related Potential (MRP); Event Related Potentials (ERP); Mu / Mu wave Suppression; Event-related Spectral perturbations (ERSP); Intrinsic Connectivity Network (ICN); Event-related Desynchronization (ERD); and alpha hemispheric activation*. EEG activity was characterized concerning: *Amplitude, Slope and Latency; Amplitude, Slope and ERP; Frequency band rhythm/oscillation; Time frequency oscillation; Functional connectivity;* and *Hemispheric activation*. Behavioral paradigms included: *internally / externally cued movement tasks; modified Posner Cued spatial attention task; Praxis imitation task; motor imitation task; motor observation and execution tasks; and passive resting tasks*.

Conclusions: Although there were commonalities in study designs among articles that used the same analytical approach to characterize the motor network EEG activity, future studies would benefit from study development that accounts for information captured in the 18 domains. Further literature reviews should be conducted to refine the domains and determine its generalizability to other imaging techniques.

435.042 *(Poster)* Motion Matters: An Analysis of Motion Bias Correction in Diffusion MRI

J. Robinson[1]*, V. Vattipally*[1]*, S. H. Mostofsky*[2] *and D. Crocetti*[3]*, (1)Kennedy Krieger Institute, Baltimore, MD, (2)Center for Autism and Related Disorder, Kennedy Krieger Institute, Baltimore, MD, (3)Center for Neurodevelopmental and Imaging Research, Kennedy Krieger Institute, Baltimore, MD*

Background: Diffusion MRI (dMRI) is commonly applied to examining white matter (WM) microstructure and integrity and is often used to examine WM abnormalities in Autism Spectrum Disorder (ASD). DMRI is particularly susceptible to motion-induced artifact, common to children with ASD and those with related disorders, particularly Attention-Deficit Hyperactivity Disorder (ADHD). Prior work suggests that motion systematically alters commonly-reported diffusion metrics in anisotropic (WM) regions, with resulting reductions in fractional anisotropy (FA) and increases in mean diffusivity (MD). Several techniques to control for these biases are commonly employed, but there is little work investigating relative efficacies.

Objectives: To evaluate the performance of motion-bias control methods commonly used in dMRI analyses, comparing impacts on FA and MD in 7 regions of interest (ROIs) in children with ASD, with ADHD and typically-developing (TD) peers.

Methods: This study included 559 children (99 ASD, 187 ADHD, 273 TD) aged 8-12 years. Diffusion scans were corrected for scanner and motion artifacts using FSL, and FA and MD were extracted for 7 WM ROIs, collapsed across hemisphere. Scans were visually inspected for signal loss and assigned the following quality ratings: “Excellent” = 0 volumes with signal loss, “Good” = 1-15 volumes, and “Poor” = >14 volumes. Average frame-wise displacement (FWD) was also calculated for each scan. FA and MD for each hemisphere were estimated after applying 3 different methods for controlling motion-induced bias: 1) “removing poor-quality” (RPQ) data, 2) co-varying for FWD, and 3) matching diagnostic groups on FWD; these findings were compared to each other and to those using “no motion-control” (NMC).

Results: Repeated-Measures ANOVA revealed that RPQ consistently outperformed the two other methods. For left and right hemisphere, when comparing RPQ and NMC, FA and MD significantly differed for TD children (*ps<0.001)*, those with ASD (*ps<0.01)* and those with ADHD (*ps<0.001)*, such that FA increased and MD decreased in both hemispheres. In contrast to RPQ, for children with ASD, FWD co-varying and FWD matching produced no significant changes in FA or MD; for TD and ADHD cohorts, while there were some significant effects observed, these were inconsistent and less robust than changes with RPQ. Given our findings suggesting the superior efficacy of RPQ compared to other methods, we then examined effects of diagnosis on FA and MD for each ROI after applying RPQ. Findings revealed a significant effect of diagnosis on FA in left Supramarginal Gyrus, such that children with ASD showed lower FA compared to TD (*p=0.036*) and a significant effect of diagnosis on MD such that children with ASD showed significantly higher MD than children with ADHD, but not TD, in the left (*p=0.029*) and right (*p=0.013*) Anterior Corona Radiata.

Conclusions: Our findings suggest that RPQ is the most effective method for reducing bias induced by head motion in dMRI. Further, the two other commonly used methods do not produce findings that reliably differ from baseline, and may result in spurious findings. Applying RPQ should help to increase the reliability and validity of dMRI findings in ASD, ADHD and other motion-susceptible populations.

435.043 *(Poster)* Neural Correlates of Autism Spectrum Disorder with Psychotic-like Symptoms in the Adolescent Brain Cognitive Development (ABCD) Cohort

A. Jutla[1]*, J. H. Foss-Feig*[2]*, M. R. Donohue*[3] *and J. Veenstra-Vander Weele*[4]*, (1)1051 Riverside Drive, New York State Psychiatric Institute / Columbia University, New York, NY, (2)Seaver Autism Center, Department of Psychiatry, Icahn School of Medicine at Mount Sinai Hospital, New York, NY, (3)Washington University School of Medicine, St. Louis, MO, (4)Psychiatry, New York State Psychiatric Institute / Columbia University, New York, NY*

Background: The neural correlates of autism spectrum disorder (ASD) and the psychotic disorder schizophrenia are divergent. However, the disorders are clinically associated, with ASD individuals at 3 to 4 times greater risk of developing schizophrenia than members of the general population. It is unknown whether ASD with co-occurring psychosis has a distinct neural signature, dissociable from those of ASD and schizophrenia alone. Identifying such a signature may help identify which youth with ASD are at risk of schizophrenia, allowing for individualized treatment and determination of prognosis.

Objectives: Using data collected from the Adolescent Brain Cognitive Development (ABCD) study (n = 11,875; 47.84% female; age mean = 9.91 years, SD = 0.62 years), we compared resting-state functional connectivity measures among three groups: 1) youth with ASD without psychotic-like symptoms, 2) youth with ASD and psychotic-like symptoms, and 3) youth with psychotic-like symptoms but not ASD. We hypothesized that each group would show a distinct pattern of connectivity among large-scale cortical networks.

Methods: To eliminate inter-scanner variability, we restricted the ABCD sample to participants with neuroimaging data collected by a Siemens scanner. We defined ASD by parent report during the screening interview, and defined psychotic-like symptoms by a Prodromal Questionnaire – Brief Child Version score ≥ 6, a cutoff based on previous literature. We then estimated random forest models to predict group status. The feature space for each model comprised 100 measures of resting-state connectivity strength between 10 large-scale cortical networks (auditory, visual, dorsal attention, ventral attention, default mode, salience, cinguloparietal, cingulo-opercular, frontoparietal, and retrosplenial-temporal). We addressed class imbalance using synthetic minority over-sampling and assessed performance using out-of-bag error scores. We calculated global feature importance using the Gini method, and compared top features across models, verifying model predictions by training local surrogate models to explain select predictions.

Results: 5,374 ABCD paricipants met our scanner criterion. 53 had ASD without psychotic-like symptoms, 16 had ASD with psychotic-like symptoms, and 737 had psychotic-like symptoms without ASD. All models predicted group status with low out-of-bag error rates (ASD without psychotic-like symptoms: 0.36%; ASD with psychotic-like symptoms: 0.21%; psychotic-like symptoms without ASD: 7.60%). ASD without psychotic-like symptoms was most strongly predicted by retrosplenial-temporal - salience, retrosplenial-temporal - fronto-parietal, and within-network retrosplenial-temporal connectivity. ASD with psychotic-like symptoms was predicted by dorsal attention network - cinguloparietal, salience - cinguloparietal, and cingulo-opercular - visual connectivity. Psychotic-like symptoms without ASD was predicted by within-network cingulo-opercular, cingulo-opercular - visual, and cingulo-opercular - auditory connectivity.

Conclusions: Within the ABCD cohort, ASD with psychotic-like symptoms, ASD without psychotic-like symptoms, and psychotic-like symptoms without ASD were characterized by distinct patterns of functional connectivity. Our finding that retrosplenial-temporal connectivity predicted ASD without psychotic-like symptoms is consistent with reports that retrosplenial-temporal connectivity is involved in social cognition and is altered in ASD. Our finding that dorsal attention and salience network connectivity predict ASD with psychotic-like symptoms is consistent with potentially altered interpretation of sensory cues in this sub-group. These results suggest that ASD with psychotic-like symptoms may be a sub-type of ASD with distinct neural correlates.

435.044 *(Poster)* Neural Substrates of Sensory Perception in Autism: An ALE Meta-Analysis

***N. Jassim**, S. Baron-Cohen and J. Suckling, Autism Research Centre, Department of Psychiatry, University of Cambridge, Cambridge, United Kingdom*

Background: Sensory sensitivities occur in up to 90% of autistic individuals. It has been hypothesized that on the one hand this may contribute to talent in areas such as attention to detail and systemizing, but it is also recognized that it may contribute to high levels of anxiety or feeling overwhelmed with information (for a review, see Robertson & Baron-Cohen, 2017). Sensory sensitivities is one of the DSM-5 core diagnostic criteria for autism, acknowledging its central role in autism. There is therefore a need to have a clearer understanding of its neurobiological correlates.

Objectives: To examine the existing functional neuroimaging evidence of sensory processing in autism compared to neurotypical individuals, via an activation likelihood estimation (ALE) meta-analysis.

Methods: Using ALE, we synthesized information from task-based functional MRI (fMRI) studies of non-social sensory perception in autism published before October 2019. Details were recorded in accordance with PRISMA guidelines. Following systematic literature review, 20 whole-brain task fMRI studies met our inclusion criteria for testing differences in neural activity between autistic (n=379) and neurotypical (n=381) participants during sensory processing. The ALE map was thresholded at $p<0.001$ uncorrected, with a minimum cluster size of $100mm^3$.

Results: Compared to neurotypical participants, autistic individuals showed enhanced activity in parietal (x=-54, y=-22, z=-52), somatosensory (x=48, y=-20, z= 38) , and occipital cortices (x=-16, y=-82, z=26) and in regions including the caudate nucleus (x=16, y=18, z=18), thalamus (x=-18, y=-28, z=4), and primary visual cortex (x=-22, y=-91, z=19) *(Fig. 1A)*. Meanwhile, neurotypical participants showed more activation in the frontal (x=36, y=46, z=28) and temporal (x=64, y= -40, z= 6) cortices *(Fig. 1B).* Coordinates are reported in MNI space.

Conclusions: These results suggest that autistic individuals, compared to the neurotypical population, on average show distinct engagement of sensory-related neural circuits during sensory perception. This meta-analysis may help guide future research to focus on relevant brain networks, regions and neurobiological mechanisms to better understand the causes of sensory sensitivity in autism.

435.045 *(Poster)* Neuroanatomical Trajectories across Age and Association with Clinical Outcome in Autism Spectrum Disorder (ASD)

***C. M. Pretzsch**[1], T. Schäfer[2], C. Mann[2], A. Bletsch[2], J. Tillmann[3], A. Yousaf[4], C. M. Freitag[5], D. G. Murphy[6], C. Ecker[2] and L. G. EU-AIMS[7], (1)IoPPN King's College London, London, United Kingdom, (2)Department of Child and Adolescent Psychiatry, Psychosomatics and Psychotherapy, Goethe-University Frankfurt am Main, Frankfurt, Germany, (3)Institute of Psychiatry Psychology & Neuroscience, London, United Kingdom, (4)Goethe University Frankfurt, Frankfurt, Germany, (5)Department of Child and Adolescent Psychiatry, Psychosomatics and Psychotherapy, University Hospital Frankfurt, Goethe University, Frankfurt am Main, Germany, (6)Forensic and Neurodevelopmental Sciences, Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, United Kingdom, (7)EU-AIMS Organization, London, United Kingdom*

Background: Autism spectrum disorder (ASD) and associated behavioural difficulties, such as impaired adaptive functioning, incur a high cost to affected individuals. Nonetheless, the neurobiological underpinnings of these symptoms remain poorly understood. A wealth of studies has associated ASD with differences in neuroanatomy assessed via a variety of structural features such as cortical thickness (CT), surface area (SA), and cortical volume (CV). These features and their differences in ASD are likely to vary across the lifespan and may contribute to clinical outcome.

Objectives: However, no study has examined yet how neuroanatomical differences in ASD across the human lifespan relate to a meaningful change in clinical outcome, such as change in adaptive behaviour. This was the aim of the present study.

Methods: Here we conducted a study in one of the largest longitudinal ASD samples available (n = 639, ASD n = 360, TD n = 279). We examined age-related between-group differences in CT, SA, and CV. Moreover, in the ASD group, we investigated the association between brain structure at timepoint 1 (T1) and change in adaptive behaviour between T1 and timepoint 2 (T2, 12-24 months later). First, we tested if age-related between-group differences predict change in adaptive functioning. Secondly, we grouped individuals into 'Improvers' and 'Worseners' based on the change in their adaptive behaviour (using recently published Minimal Clinically Important Difference [MCID] measures) and compared their brain structure at T1.

Results: In our sample, we established significant between-group differences in the developmental trajectories of CT, SA, and CV in cortical and subcortical areas, including frontal, temporal, parietal and central regions. Among these, CV in frontal and temporal-parietal regions significantly predicted outcome in adaptive functioning scores from T1 to T2 with an accuracy of up to 75%. Moreover, 'Improvers' and 'Worseners' differed significantly in CT, SA, and CV at T1, predominantly in frontal, temporal, parietal, central, and occipital regions.

Conclusions: Our findings of atypical neurodevelopment in ASD based on a variety of morphometric features are largely consistent with previous reports. Moreover, our observation that specific brain structural anomalies in ASD precede and predict subsequent behavioural change has important implications for future studies aimed at utilizing neuroanatomy to predict outcome in ASD.

435.046 *(Poster)* Patterns of Functional Hypo- and Hyperconnectivity in an Autism Subtype with High Social-Communicative but Low Restricted Repetitive Behavior Symptom Severity

Background: Heterogeneity is one of the biggest challenges for better understanding autism. Amongst the most important priorities are to better understand how phenotypic variability maps onto intrinsic functional neural circuit organization.

Objectives: Use unsupervised data-driven stratification methods to subtype autism by ADI-R social-communication (SC) and restricted repetitive behavior (RRB) scores and then identify replicable subtype-specific differences in functional connectivity measured with resting state fMRI (rsfMRI).

Methods: ADI-R data was identified for n=3,380 autistic individuals across 72 independent datasets in the National Database for Autism Research (NDAR). Each of the 72 datasets were randomly split in half to generate independent Discovery and Replication datasets (n=1,690). Unsupervised hierarchical clustering was used to stratify autism by the DSM-5 symptom dyad SC and RRB algorithm scores. Identical clustering methods were applied to the EU-AIMS LEAP dataset. The LEAP dataset was split into independent Discovery and Replication sets, while preserving proportion of individuals across different scanning sites in each set. Subtypes in EU-AIMS LEAP were then examined for replicable rsfMRI connectivity differences (autism n=274; typically developing (TD) n=243). Functional connectivity was estimated as partial correlations between ICA components from FSL group-ICA and dual regression. Linear mixed effect models were used to identify differences between autism subtypes and TD. These models included sex, age, and mean framewise displacement as other fixed effect covariates and site as a random effect modeled with random intercepts. Replicable differences were required to show significant effects ($p<0.05$) across both Discovery and Replication sets and to have a replication Bayes Factor statistic (repBF) greater than 10.

Results: Six autism subtypes were replicably identified in NDAR Discovery and Replication datasets. Five of these 6 subtypes are also identified in EU-AIMS LEAP data. Replicable functional connectivity differences were isolated for 4 component pairs for a specific autism subtype with very high levels of SC severity and correspondingly low levels of RRB severity (e.g., autism SC>RRB). A fronto-temporal network centered on the bilateral posterior superior temporal sulcus was functionally hypoconnected in this autism SC>RRB subtype with a right-lateralized somatomotor network (Discovery d= -0.58, Replication d= -0.45, *repBF*= 11) and a network centered on visual association cortex that spans midline occipital and temporal cortical areas (Discovery d= -0.43, Replication d= -0.50, *repBF*= 184). This autism SC>RRB subtype also showed functional hyperconnectivty between the default mode network and right-lateralized executive control network (Discovery d= 0.34, Replication d= 0.50, *repBF*= 66) as well as the salience network and a left-lateralized somatomotor network (Discovery d= 0.34, Replication d= 0.38, *repBF*= 11). No other subtypes showed similar replicable functional connectivity differences.

Conclusions: Unsupervised data-driven subtyping by phenotypic patterns reveals consistent subtype population stratification in autism. An autism subtype with high SC but low RRB severity on the ADI-R showed replicable functional connectivity differences that are a mixture of hypo- and hyperconnectivity patterns. These differences in connectivity may help to explain phenotypic and cognitive differences that may be apparent in this particular SC>RRB autism subtype.

435.047 *(Poster)* Scmri Confirms Brain Network Abnormalities in Children with ASD

B. A. Zielinski[1,2], *Y. J. Kim*[2], *M. D. Prigge*[2] *and J. E. Lainhart*[3], *(1)Pediatrics and Neurology, University of Utah, Salt Lake City, UT, (2)Developmental Network Neurobiology Laboratory, University of Utah, Salt Lake City, UT, (3)Psychiatry, University of Wisconsin - Madison, Madison, WI*

Background: Background: Autism is a complex neurological condition characterized by childhood onset of dysfunction in multiple cognitive domains including socio-emotional function, speech and language, and processing of internally- versus externally-directed stimuli. Accumulating evidence suggests that autism is a network-based disease, and that abnormalities in brain network structure underlie the abnormal brain function at the core of the disorder. However, large-scale brain network structure has yet to be fully characterized in autism.

Objectives: Using an emerging technique known as structural covariance MRI (1), this study sought to confirm whether specific abnormalities in large-scale brain network organization are associated with autism, and whether previously reported network-level abnormalities in brain architecture (2) can be reliably detected and replicated with standard clinical MRI in an independent sample.

Methods: We used scMRI to interrogate network-level differences in gray matter structure within eight canonical large-scale 'intrinsic connectivity networks' (ICNs) strongly implicated in autism, in 116 high-functioning autistic subjects and age-, gender-, and IQ-matched controls (mean age 9.67 yrs, range 3-12 yrs, all male). T1-weighted 3.0 Tesla anatomical MRI scans were realigned, segmented, normalized to a customized template, modulated, and smoothed. To study network structural covariance, we derived 4-mm radius spherical seed regions-of-interest (ROIs) within core hubs of canonical ICNs. Extracted mean ROI gray matter intensities provided covariates-of-interest for whole brain condition (diagnosis)-by-covariate analyses based on the General Linear Model. Resulting seed covariance maps for each age group were thresholded at $p < 0.05$, corrected for family-wise error. Direct between-group comparisons were performed using ROI, diagnosis group, and neuropsychiatric test scores as covariates of interest.

Results: Seed-based scMRI confirmed specific perturbations in brain network architecture within distinct ICNs, consistent with phenotypic manifestations of autism. Structural covariance maps in controls were consistent with canonical ICN topologies. Extent and topology of the salience network, involved in social- emotional regulation of environmental stimuli, is markedly underdeveloped in autism. In contrast, the default mode network (DMN) is larger in autism, but demonstrates 'posteriorization'. Moreover, discrete nodes outside of canonical DMN boundaries are present in the autism group, including many regions commonly associated with autism. Other networks demonstrate concurrent over- and under-development, regional decoupling, or remain unaffected.

Conclusions: Specific abnormalities in large-scale brain network structure underlie autism. Our findings are consistent with a network-based 'selective vulnerability' model of autism, provide a plausible substrate for phenotypic features of the disorder, and suggest a unifying interpretation of previous work. Structural brain network abnormalities in autism are quantifiable using standard clinical MRI, and abnormalities are both reliable and replicable.

435.048 *(Poster)* Sex-Related Heterogeneity of Intrinsic Neural Temporal Signal Complexity in Autism

S. Trakoshis[1], *A. Yang*[2], **. MRC AIMS Consortium*[3], *S. Baron-Cohen*[4], *M. C. Lai*[5,6] *and M. V. Lombardo*[7], *(1)Department of Psychology, University of Cyprus, Nicosia, Cyprus, (2)Harvard Medical School, Boston, MA, (3)University of Cambridge, Cambridge, United Kingdom, (4)Autism Research Centre, Department of Psychiatry, University of Cambridge, Cambridge, United Kingdom, (5)Autism Research Centre, Department of Psychiatry, University of Cambridge, Cambridge, ON, United Kingdom, (6)Centre for Addiction & Mental Health, University of Toronto, Toronto, ON, Canada, (7)Center for Neuroscience and Cognitive Systems, Laboratory for Autism and Neurodevelopmental Disorders, Istituto Italiano di Tecnologia, Rovereto, Italy*

Background: Evoked responses to sensory stimuli are more unreliable in autism, suggesting an enhancement of neural noise. Enhanced neural noise could be a consequence of intrinsic excitation-inhibition (E:I) imbalance. Given that sex-related mechanisms can affect E:I-relevant biology, we examined how neural noise may modulated by sex-related heterogeneity in autism. To examine intrinsic neural noise, we used resting state fMRI data (rsfMRI) and estimated multiscale entropy (MSE).

Objectives: Examine how MSE differs in autism and typically developing (TD) individuals and identify which cortical areas express sex-related heterogeneity.

Methods: Age-matched adult males and females with and without autism (male autism n = 23, age = 27.13 years; female autism n = 25, age = 27.35 years; male TD n = 29, age = 28 years; female TD n = 33, age = 26.99 years) were scanned at 3T for over 13 minutes (TR = 1302 ms; 620 volumes) with an eyes-closed resting state acquisition. Preprocessing was conducted in AFNI, with motion parameters and their derivatives plus CSF signal regressed out and wavelet denoising was used to further remove residual artefact signals. Mean time-series for 180 regions from the HCP-MMP parcellation were computed and MSE was estimated across 4 scales (m = 2) and with an r parameter estimated for each scale. Hypothesis tests were implemented with a linear mixed effect model that also included mean framewise displacement and full-scale IQ as other fixed effects of no interest. MSE scale was included as a random effect in the model. FDR $q < 0.05$ was used to correct for multiple comparisons.

Results: All MSE estimates were within the range typically observed for pink to red noise. Sex-by-diagnosis interactions were identified in frontal (e.g., ventromedial prefrontal cortex (vMPFC), primary motor cortex (M1)), temporal (e.g., superior temporal sulcus), and occipital cortices. These effects were complex and dependent upon brain region. For example, vMPFC and M1 were characterized by a large TD sex difference (Females>Males), but an absence of this sex effect in autism. Diagnosis effects were widespread across all lobes and generally manifested as higher sample entropy across scales in TD compared to autism. Sex effects were also particularly widespread and manifested as higher sample entropy in females compared to males.

Conclusions: Sex-related heterogeneity in intrinsic MSE is restricted to specific cortical areas and can be described as attenuation or absence of normative sex differences in autism. Other diagnosis differences not affected by sex-related heterogeneity are characterized by decreased complexity and enhanced regularity in autism. These effects may be linked to E:I imbalance and future work should investigate MSE modulations during experimental manipulations to E or I in-vivo.

435.049 *(Poster)* Shared or Distinct? - Neuroanatomical Underpinnings of ASD in Carriers and Non-Carriers of the 22q11.2 Microdeletion

A. Bletsch[1], *M. Gudbrandsen*[2], *C. Mann*[1], *E. Daly*[2], *C. M. Murphy*[2,3], *V. Stoencheva*[2,3], *C. E. Blackmore*[2,3], *M. Rogdaki*[4,5,6], *L. Kushan*[7], *C. Bearden*[7], *D. G. Murphy*[2,3], *M. Craig*[2,8] *and C. Background:

There is increasing interest in using human genetic models to better understand the mechanistic underpinnings of autism spectrum disorder (ASD).A crucial step in this process, however, is to demonstrate that the biological underpinnings of ASD in genetic high-risk conditions are similar to those in idiopathic illness. 22q11.2 deletion syndrome (22q11.2DS) is a genetic condition with complex clinical phenotypes that include ASD. Evidence from *in vivo* neuroimaging studies (Antshel et al.,2007; Jalbrzikowski et al.,2017; Gudbrandsen et al.,2019) suggests that 22q11.2DS individuals with ASD symptomatology are neuroanatomically distinct from those without, and may represent a distinct neurobiological subgroup. None of these previous studies, however, included individuals with idiopathic ASD. It therefore remains unknown how closely the neurobiological phenotype of ASD in 22q11.2DS resembles the ASD phenotype in those without the microdeletion.

Objectives: To establish whether ASD symptomatology in 22q11.2 deletion carriers is underpinned by the same – or distinct – neural systems that mediate these symptoms in non-carriers.

Methods: We examined vertex-wise estimates of regional cortical volume, surface area, and cortical thickness (CT) across 131 individuals (6-25 years). We included (1) 50 22q11.2 deletion carriers (n=25 ASD, n=25 without ASD), and (2) 81 non-carriers (n=40 ASD, n=41 healthy controls). In accordance with previously published studies (Jalbrzikowski et al.,2017; Gudbrandsen et al.,2019), all individuals with ASD met diagnostic cut-offs in the reciprocal social interaction and communication domain of the ADI-R (Lord et al.,1994), but were allowed to fall below threshold in the repetitive behaviors domain. We employed a multivariate dimensional approach using canonical correlation analysis (CCA). This allowed us to; 1) treat ASD as a continuous clinical construct spanned by multiple symptom domains assessed via the five subscales of the Social Responsiveness Scale (SRS; Bölte & Poustka,2008; Constantino & Gruber,2012), and 2) to examine the multivariate association between inter-individual clinical profiles and neuroanatomical variability in 22q11.2 deletion carriers and non-carriers.

Results:

Initially, CCA was performed across individuals without the microdeletion (see **Fig.1**) where clinical variability across the five subdomains of the SRS could be reduced to a single latent trait variable that was (1) highly predictive of group membership (i.e. ASD vs. controls), and (2) significantly associated with neuroanatomical variability across multiple morphometric features. In contrast, in 22q11.2 deletion carriers (see **Fig.2**) the multivariate association between ASD symptoms and neuroanatomical variability was very significantly decreased relative to non-carriers (RV_{coef}=0.06, p<0.7 vs. RV_{coef}=0.196, p<0.0001), even though clinical variability was represented by a similar latent factor structure. Moreover, the spatially distributed patterns of neuroanatomical variability associated with this factor significantly differed between groups particularly for measures of CT in the right lateral and medial orbitofrontal cortex, the right rostral middle frontal cortex, and the left precuneus and superior parietal cortex.

Conclusions: ASD symptomatology is mediated by distinct neuroanatomical substrates in individuals with and without the 22q11.2 microdeletion, even when taking inter-individual variability in SRS subdomains of ASD into account. Brain mechanisms underlying ASD associated with specific genetic etiology may thus diverge from those in idiopathic illness.

435.050 *(Poster)* Shifted Phase of EEG Cross-Frequency Coupling in Individuals with Phelan-Mcdermid Syndrome

M. G. Mariscal[1], *E. Berry-Kravis*[2], *L. E. Ethridge*[3], *J. H. Foss-Feig*[4], *A. Kolevzon*[4], *M. E. Modi*[1], *C. A. Nelson*[5], *M. W. Mosconi*[6], *C. M. Powell*[7], *P. M. Siper*[4], *A. Thaliath*[8], *M. Sahin*[5] *and A. R. Levin*[1], *(1)Neurology, Boston Children's Hospital, Boston, MA, (2)Pediatrics, Neurological Sciences, & Biochemistry, Rush University Medical Center, Chicago, IL, (3)Pediatrics, University of Oklahoma Health Science Center, Oklahoma City, OK, (4)Seaver Autism Center, Department of Psychiatry, Icahn School of Medicine at Mount Sinai Hospital, New York, NY, (5)Boston Children's Hospital/Harvard Medical School, Boston, MA, (6)Clinical Child Psychology Program, Schiefelbusch Institute for Life Span Studies, University of Kansas, Lawrence, KS, (7)Neurobiology, UAB School of Medicine, Birmingham, AL, (8)Rush University Medical Center, Chicago, IL*

Background: Phelan-McDermid Syndrome (PMS) is one of the most well-characterized genetic subtypes of Autism Spectrum Disorder (ASD). PMS is a rare disorder caused by deletion or mutation of the *SHANK3* gene. *SHANK3* encodes an important structural component of excitatory synapses, thus disrupting the balance between neural excitation and inhibition in both thalamic and cortical neurons,[1,2] potentially altering processing of feedforward (“bottom-up”) versus feedback (“top-down”) neural activity. Feedforward:feedback imbalances may contribute to phenotypes frequently seen in PMS, including ASD, seizures, and other neurodevelopmental concerns.

In this context, we hypothesize that individuals with PMS may exhibit abnormalities in an electroencephalography (EEG) based measure termed "phase bias." Phase bias reflects the cross-frequency coupling between neural oscillations, and a more positive phase bias reflects the degree to which the amplitude of the faster oscillation increases at the peak (versus the trough) of the slower oscillation[3]. Feedforward and feedback activity can increase at different points in the slower oscillation; phase bias thus may reflect the overall balance between feedforward and feedback neural network activity.

Objectives: We examine whether individuals with PMS display differences in resting EEG phase bias, compared to age-matched typically developing controls.

Methods: Resting EEG data were collected at multiple sites (n = 16 controls, n = 35 PMS). Among EEG electrodes in a standard 10-20 configuration, we examined cross-frequency coupling between alpha (8-12 Hz) and gamma (20-60 Hz). Positive phase bias was calculated as the proportion of amplitude of the high frequency (gamma) signal occurring in the positive phases of the low frequency (alpha) signal, - .5. Therefore, a positive phase bias >0 or <0 indicates gamma amplitude increasing at the peak or trough, respectively, of the alpha waveform. Among all possible channel and frequency combinations, statistically significant clusters were identified using a permutation based clustering algorithm.

Results: Positive phase bias in individuals with PMS (mean = .0005, SD = 0.0010) is increased relative to controls (mean -.0005, SD = 9.3e-05; p = .00004). This reflects a tendency for gamma amplitude to increase at the trough of the alpha oscillation in the control group, but at the peak of the alpha oscillation in PMS group. Clusters demonstrating increased positive phase bias are primarily located at posterior channel locations.

Conclusions: We find individuals with PMS demonstrate increased positive phase bias, possibly reflecting an altered ratio of feedforward:feedback activity in this population. Future work aims to determine whether abnormal phase bias may portend ASD (or other specific behavioral phenotypes) more broadly, assess for similar findings in other genetic populations at high risk for ASD, and better understand the biological underpinnings of this EEG-based finding.

435.051 *(Poster)* Somatosensory-Evoked Potentials in Young Children with Autism Spectrum Disorder

S. Espenhahn[1,2,3,4], *K. J. Godfrey*[1,2,3,4], *S. Kaur*[2,3,4], *C. A. McMorris*[3,5], *D. Dewey*[3,4], *S. Bray*[1,2,3,4] *and A. D. Harris*[1,2,3,4], *(1)Cumming School of Medicine, University of Calgary, Calgary, AB, Canada, (2)Child and Adolescent Imaging Research (CAIR) Program, University of Calgary, Calgary, AB, Canada, (3)Alberta Children's Hospital Research Institute, University of Calgary, Calgary, AB, Canada, (4)Hotchkiss Brain Institute, University of Calgary, Calgary, AB, Canada, (5)Werklund School of Education, University of Calgary, Calgary, AB, Canada*

Background: More than 90% of children with autism spectrum disorder (ASD) show atypical responses to sensory stimuli (e.g. hyper- or hypo-sensitivity) that affect their everyday functioning. Impaired tactile processing has been proposed to exacerbate deficits in communication and social skills. Sensory tactile abnormalities in ASD are often measured with parent questionnaires. While clinically relevant, these do not inform the underlying neurophysiological mechanisms. Electroencephalography (EEG) provides insight to cortical excitation and inhibition with excellent temporal resolution and is an ideal tool for paediatric populations (e.g. easy-to-apply, no loud noises, less sensitive to movement compared to MRI). Increasing evidence suggests that an excitation-inhibition imbalance results in atypical sensory processing in ASD. While evidence of inhibitory dysfunction in older children with ASD exists, little is known about tactile processing in young children under the age of 8, despite early emergence of sensory symptoms (<age 3).

Objectives: Using EEG, we are investigating tactile processing in young children aged 3-6 years with ASD compared to typically developing (TD) children and the relationship with parent-reported sensory, behavioral and social symptom severity.

Methods: Twenty-four children with ASD of varying cognitive and verbal abilities and forty TD children aged 3-6 years participated in the study (Table). All participants with ASD had a clinical diagnosis. During EEG recording, children received tactile fingertip stimulation at different rates (1050ms and 150ms interstimulus interval (ISI) in blocked presentations) while watching a movie. Latency and amplitude measures for somatosensory-evoked potentials (SEPs) elicited with the 1050ms ISI were derived and the difference between SEP amplitudes elicited by 1050ms and 150ms ISIs was used as a measure of adaptation.

To assess intellectual functioning, the Wechsler Non-Verbal Scale of Ability (non-verbal IQ) was utilized, and parents completed standardized questionnaires that assessed sensory (SP, Sensory Profile 2), behavioral (BASC-3, Behavior Assessment System for Children 3) and social (SRS-2, Social Responsiveness Scale 2) symptoms.

Properties of SEPs and adaptation were compared between ASD and TD groups using ANCOVA models controlling for age, biological sex, and non-verbal IQ, and Pearson correlations were used to determine associations with sensory, behavioral and social symptom severity.

Results: Preliminary results show that ASD and TD groups were comparable in terms of age and sex, but children with ASD had lower IQ, and showed significant sensory, behavioral and social difficulties. The latency and amplitude of the early prominent SEP, ~50ms post-stimulus (P50), did not differ between groups (p>0.4). Similarly, there was no significant group difference in P50 adaptation (p>0.4); however, the amount of adaptation was significantly different from zero only in the TD group (p=0.004). Specific to the ASD group, greater P50 amplitude was associated with stronger sensory seeking behavior (r=0.48, p=0.019, Figure).

Conclusions: We have >80% success rate of collecting EEG in children with ASD at this challenging age range, including those with low cognitive and/or verbal abilities. This represents a highly novel dataset to better understand tactile processing in early childhood ASD, which is important for informing future therapies for sensitivities. Our investigations will continue with a larger sample by 2020.

435.052 *(Poster)* Thalamic Resting-State Connectivity Mediates the Relationship between Thalamic GABA and Sensory Over-Responsivity in ASD

E. T. Wood[1], *K. K. Cummings*[1], *J. Guo*[2], *J. O'Neill*[3], *M. Dapretto*[1], *S. Y. Bookheimer*[1] *and S. A. Green*[1], *(1)Dept of Psychiatry and Biobehavioral Sciences, University of California, Los Angeles, Los Angeles, CA, (2)Department of Psychiatry & The Zuckerman Institute, Columbia University, New York, NY, (3)Division of Child & Adolescent Psychiatry, UCLA Jane & Terry Semel Institute For Neuroscience, Los Angeles, CA*

Background: Sensory Over-Responsivity (SOR) is a highly prevalent and impairing feature of ASD. 50-75% of children with ASD experience SOR, ranging from discomfort to distress in response to stimuli (e.g., clothing tags, loud sounds), and these symptoms are among the most disruptive in their everyday life (Ben-Sasson et al., 2007). A better understanding of the physiological mechanisms and underlying neurochemistry of SOR may translate to psychopharmacological and psychotherapeutic interventions for individuals with ASD and SOR, thereby dramatically improving their lives. Genetic studies of GABA receptor function, biochemical analyses of GABA synthesis and degradation, as well as computational models have suggested that core features of ASD are driven by an excitatory-inhibitory imbalance of neuronal activity (Rosenberg et al., 2015). Work from our laboratory shows reduced modulation of thalamocortical connectivity in autism in response to mildly aversive sensory stimulation, suggesting altered thalamic sensory gating that could be related to neurochemical imbalance.
Objectives: Examine how GABA in the thalamus 1) differs between youth with and without ASD; 2) correlates with behavioral measures of SOR; and, 3) relates to intrinsic brain connectivity.
Methods: Subjects were 29 youth with ASD (21 males; mean age 15.0±2.6 years) and 26 typically developing youth (15 males; mean age 13.4±3.1 years). Single-voxel edited 1H-MR spectra were acquired from the bilateral thalamus (8.75ml voxel) using a Siemens prototype MEGA-PRESS sequence (TE/TR 68/2000ms; 256 averages) and post-processing in MATLAB (Guo et al., 2018) to yield high accuracy GABA ([GABA] = GABA/Cr) concentrations. For resting-state fMRI, the bilateral thalamus was the seed in a bottom-up whole-brain connectivity analysis with [GABA] entered as a regressor to determine how metabolite concentrations predicted intrinsic connectivity (thresholded at $Z>2.3$ and corrected for multiple comparisons at $p<0.05$). The Sensory Over-Responsivity (SenSOR) Inventory (Schoen et al., 2008) – a child sensory responsivity questionnaire – was completed by parents.
Results: [GABA] was not statistically different between groups (Student's t-test). In the ASD group, a negative correlation was found between [GABA] and SOR scores (SenSOR Total $r=-0.47$, $p=0.01$). Thalamic [GABA] predicted lower thalamic-somatosensory (SMS) connectivity in ASD as opposed to greater thalamic-SMS connectivity in TD (Fig 1). Thalamic [GABA] was correlated with greater thalamic-insula connectivity only in the ASD group (Fig 2). Furthermore, thalamic-insula connectivity mediated the effect of Thalamic [GABA] on SOR in youth with ASD.
Conclusions: These results demonstrate a relationship between lower thalamic [GABA] and greater severity of SOR symptoms in youth with autism that is mediated by intrinsic connectivity between the thalamus and insula. This suggests that in ASD youth, higher GABA may reduce the risk of SOR through increased thalamic connectivity with the insula, a Salience Network hub. Importantly, these variations in GABA and associated network connectivity in the ASD group highlight the potential role of GABA as a mechanism underlying SOR, a major source of phenotypic heterogeneity in ASD. For ASD youth, abnormalities of the thalamic neurochemical balance could interfere with the thalamic role in integrating, relaying, and inhibiting attention to sensory information. Results have implications for GABA-modulating pharmacologic interventions.

435.053 *(Poster)* The Imaging Validity Questionnaire: Development of a Novel Methodology

N. Nadwodny[1], *A. Verbalis*[1], *J. Bascom*[2], *S. daVanport*[3], *G. L. Wallace*[4], *J. Eilbott*[5], *J. F. Strang*[1], *L. Anthony*[6], *A. B. Ratto*[1], *C. E. Pugliese*[1], *C. Jeppsen*[1], *L. Kenworthy*[1] *and K. A. Pelphrey*[7], *(1)Center for Autism Spectrum Disorders, Children's National Hospital, Washington, DC, (2)Autistic Self Advocacy Network, Washington, DC, (3)Autistic Women & Nonbinary Network, Lincoln, NE, (4)The George Washington University, Washington, DC, (5)Yale Child Study Center, Yale University School of Medicine, New Haven, CT, (6)University of Colorado, Denver, Aurora, CO, (7)University of Virginia, Charlottesville, VA*

Background: Social validity of neuroimaging findings is a largely under-utilized tool in studying autism, as it is a critical link between imaging and real-world experiences. Although the neuroimaging literature makes generalized claims about autistic experiences, rarely does this research ask autistic people if findings fit their own experiences. The superiority of autistic individuals' self-reports vs. parent-reports in evaluating multiple psychological domains suggests that the validity of imaging findings may be compromised by failing to consider the autistic perspective (Benetto et al., 2018).
Objectives: To bring together autistic self-advocates, clinical researchers, and neuroimagers to create a novel measure for autistic individuals to report their own experience of traits identified in previous neuroimaging studies of autism. This measure can be used to validate participants' resting state data, thus framing findings within the autistic perspective and providing context for interpreting future neuroimaging studies.
Methods: Resting state fMRI imaging data from a multi-site NIMH Autism Center of Excellence (ACE) Network study (n=112) was used to identify cortical nodes showing the greatest differences in connectivity between autistic males and females and corresponding control groups. These nodes' accompanying coordinates were entered into Neurosynth.org, an application for large-scale fMRI data synthesis, from which we extracted lists of associated concepts, along with values indicating strength of association. Neurosynth identified neuroimaging studies related to autism and combined reported activation in brain areas with terms that appear alongside in the texts to generate these lists. Self-advocates led the development of a questionnaire, translating functional constructs into accessible language. Once items were finalized, a brief cognitive interviewing process with autistic adolescents was conducted to ensure comprehensibility. To further prepare for use in the ACE study, test-retest data was collected online from adults within the US; participants were recruited via targeted Facebook postings and self-reported their diagnostic status.
Results: A 20-item measure was generated from the constructs identified by Neurosynth. Its overall Flesch Kincaid reading level was grade 4.7. Test-retest data, completed by autistic (ASD), non-autistic mixed-clinical (MC), and control (C) participants (n=58; nASD=14; nMC=24; nC=20, ages 18-27) showed adequate reliability for both absolute and relative stability. Relative stability of the measure was high (r=0.68) and absolute stability of the measure was moderate (ICC=0.67).

Conclusions: This imaging validity questionnaire provides early promise of a new methodology that integrates the expertise of autistic self-advocates, neuroimagers, and clinical researchers through a novel interdisciplinary partnership. This questionnaire will be used to contextualize claims for future, related neuroimaging studies. The novel approach used to develop this measure is original in that specific questions were generated based on neuroimaging findings; this process can be used with related imaging studies to validate results. This process is also innovative in that self-advocates directly collaborated with psychologists and neuroimagers to produce the resulting measure. Future research can use this collaboration as a model to continue including the input of autistic participants in brain-imaging studies to both reflect on their own experiences and provide social validity for imaging results.

435.054 *(Poster)* Title: Examination of Regional Cerebellar Volumes and Associations with Core ASD Traits

M. R. Plotkin[1]*, R. N. Rochowiak*[1]*, J. Bernal*[2]*, S. H. Mostofsky*[3] *and D. Crocetti*[1]*, (1)Center for Neurodevelopmental and Imaging Research, Kennedy Krieger Institute, Baltimore, MD, (2)Johns Hopkins University, Baltimore, MD, (3)Center for Autism and Related Disorder, Kennedy Krieger Institute, Baltimore, MD*

Background: One of the most consistent neuroanatomical findings reported in ASD has been alterations in cerebellar structure, as described in neuroimaging, animal model, and post-mortem dissection studies. Further, regional differences in cerebellar structure have been linked to core features which characterize the disorder. Prior studies examining cerebellar structure have primarily relied on gross cerebellar boundary definitions and from neuroanatomical atlases not validated against the high accuracy manual delineation approach. As such, the ability to examine detailed cerebellar morphology using validated methods is essential to advance our comprehension of ASD etiology.

Objectives: To examine the relationship between functionally-distinct cerebellar regions and associations with core ASD deficits, specifically social communication deficits and repetitive and restrictive behaviors.

Methods: Participants included 50 male children aged 8-13 (25 ASD & 25 TD) balanced on age, scan quality, and scanner head coil. Autism-associated traits were assessed using the Social Responsiveness Scale-2 (SRS-2), the Autism Diagnostic Observation Scale-2 (ADOS-2) and the Repetitive Behavior Scale-Revised (RBS-R). Lobular volumes were generated using a cerebellar atlas developed at the Center for Neurodevelopmental and Imaging Research. The cerebellar atlas (Figure 1.) is based on a highly reliable manual parcellation with interclass correlation coefficients ranging from .86-.99 across eleven anatomically defined subdivisions including: the Corpus Medullare, Hemisphere Lobules I-V, VI, Crus I, Crus II/VIIB, VIII, IX, and X, and Vermis Lobules I-V, VI-VII, and VIII-X. We applied our parcellation schema to a high-resolution human cerebellar template, the Spatially Unbiased Infratentorial (SUIT) template allowing for automation with a high level of spatial correspondence to the manual “gold-standard” technique. The SUIT toolbox was used to align each subject to the SUIT-template space using nonlinear normalization. The cerebellar atlas was back-projected into native-space for regional calculation. Tissue segmentation interrogated gray and white matter within each cerebellar label. Multivariate linear models were used to examine the diagnosis effect on cerebellar volume and associations with autistic traits. Total cerebral volume was included as a covariate in all models.

Results: Pairwise comparisons revealed a significant diagnosis effect in regional GM volumes, with decreased volumes in ASD for: left lobule VI ($p=0.021$), right lobule VI ($p=0.023$) and left crus I ($p=0.047$). Further, correlation analyses revealed a significant correlation between the ADOS Communication total score and right lobule X GM ($r= -0.539$, $p=0.008$,) such that decreased volume was associated with greater communication impairment. In contrast, the ADOS social interaction total score correlated with both the left crus II/VIIB ($r= 0.539$, $p=0.049$) and the left lobule VIII ($r= 0.415$, $p=0.008$) such that increased volume was associated with greater social impairment. Analysis of the RBS-R and SRS-2 with regional cerebellar volumes revealed no significant effects.

Conclusions: Consistent with prior findings we observed structural alterations in regional cerebellar volumes involved in sensorimotor integration and higher-order functions including language and gestural communication. Further, we observed associations with measures of social and communicative function in children with ASD. Future studies, with larger samples sizes, could examine additional behavioral ASD components in order to develop a greater understanding the role of cerebellar structure in ASD etiology.

435.055 *(Poster)* Transdiagnostic Data-Driven Patterns of Emotion Regulation in Functional Resting State Connectivity

L. Antezana[1]*, J. A. Richey*[2] *and M. Coffman*[2]*, (1)Virginia Polytechnic Institute and State University, Blacksburg, VA, (2)Virginia Tech, Blacksburg, VA*

Background: The ability to modulate the intensity of one’s emotional responses to adaptively fit the context or achieve one’s goals is known as emotion regulation (ER; Mazefsky et al., 2013). ER difficulties are associated with various mental health outcomes in adolescence (Weinberg and Klonsky, 2009). Examining resting state brain connectivity transdiagnostically in adolescents at various risk for ER difficulties may reveal ER-specific neural signatures. Recent work by Burrows and colleagues (2017) hypothesized that the salience network (SN), which relates to attention allocation, and default mode network (DMN), which underlies self-referential cognitions and inflexible thinking, may be linked to ER difficulties, i.e., repetitive negative thinking.

Objectives: Thus, we aimed to determine whether transdiagnostic data-driven SN-DMN connectivity subgroups relate to common and distinct patterns of ER difficulties in a sample of adolescents with autism, social anxiety, and controls.

Methods: Participants completed the Difficulties in ER Scale (DERS) and a resting state brain scan. The DERS has six subscales (i.e., Nonacceptance, Goals, Impulsivity, Awareness, ER Strategies, Clarity) with higher scores indicating greater ER difficulties. Functional and structural Magnetic Resonance Imaging (MRI) were collected on a Siemens 3T scanner. Preprocessing was conducted using the Configurable Pipeline Analysis of Connectomes (C-PAC; https://fcp-indi.github.io/). The dataset consisted of 55 adolescents. Participant characteristics are detailed in Table 1.

Four DMN and three SN nodes were chosen using Neurosynth (http://neurosynth.org/). Thus, a total of seven 5mm spherical regions were extracted for each participant. Group Iterative Multiple Model Estimation (GIMME), a graph theory approach (Gates and Molenaar, 2012), was applied on time series data in order to identify individual connectivity patterns. Subsequently, a community detection algorithm was used on individual patterns to identify subgroups characterized by distinctive SN-DMN connectivity patterns.

Results: All participants were characterized by within-SN and within-DMN connections (Figure 1). Two data-driven subgroups were identified: Subgroup A (n=30) was characterized by one additional path, while Subgroup B (n=18) had four additional paths. Data-driven subgroups did not differ in IQ or age (*p*s>.16). When examining the subgroups transdiagnostically, a MANOVA revealed no differences in ER (all *p*s >.19). When examining ER patterns by subgroup within diagnostic group, analyses revealed that controls in Subgroup B demonstrated greater difficulties in ER Clarity than those in Subgroup A ($p<.001$). Additionally, in ASD, a trend ($p<.10$) emerged for difficulties in Goal-directed behavior, such that adolescents with ASD in Subgroup B had greater difficulties than those in Subgroup A. No subgroup differences existed within the social anxiety group (*p*s>.20).

Conclusions: These results suggest that the hyperconnectivity of SN-DMN processes may subserve group-specific patterns in ER dysfunction during typical vs. atypical adolescence. More specifically, adolescent controls with SN-DMN hyperconnectivity had difficulties in clearly identifying their emotions, while adolescents with ASD with hyperconnectivity had a trend toward greater difficulties in goal-directed behavior. This work highlights the importance of understanding ASD-specific and trandiagnostic patterns. This information may aid in identifying neural markers for tailoring ASD-specific ER-targeted treatments (e.g., mindfulness, biofeedback).

435.056 *(Poster)* Variability Quenching in Adults with Autism

Y. Paz[1]*, A. Arazi*[2] *and I. Dinstein*[3]*, (1)Cognitive and Brain Sciences Department, Ben-Gurion University of the Negev, Be'er-Sheva, Israel, (2)Department of Cognitive and Brain Sciences, Ben Gurion University, Beer Sheba, Israel, (3)Psychology Department, Ben-Gurion University of the Negev, Beer Sheva, Israel*

Background: Previous research has demonstrated that children and adults with autism exhibit excessive cortical response variability across trials when examined with either electroencephalogram (EEG) or functional magnetic resonance imaging (fMRI) recordings. A universal characteristic of cortical neural activity is that trial-by-trial variability is reduced (i.e., "quenched") by stimulus presentation. For example, EEG variability across trials is reduced by ~30% after presentation of visual stimuli. Previous studies have not examined whether neural variability quenching may differ in autism.

Objectives: The goal of the current study was to quantify trial-by-trial EEG variability before and after stimulus presentation and identify potential differences across autism and control groups.

Methods: 43 adults, ages 18-45, 23 with ASD and 20 controls, participated in this study. EEG was recorded using a 64 channel Biosemi II system while subjects performed a contrast discrimination task with a two-interval forced-choice (2IFC) design. Each trial contained two checkerboard stimuli that were presented one after the other. One stimulus always had 100% contrast while the contrast of the other stimulus was 50% on the first trial and then adjusted according to the subject's abilities using a 2-down-1-up staircase procedure. All subjects completed six blocks of 80 trials each, yielding 480 trials with 100% contrast. Trials with eye-blinks, saccades, and other artifacts were removed. The remaining trials were used to estimate trial-by-trial variability in the pre-stimulus (-200ms to 0) and post-stimulus (150ms to 400ms) periods. The ratio between the two, normalized into units of percent change, was used to estimate variability quenching. In addition, all subjects completed the Autism Quotient to assess social-communication difficulties and the Raven test to assess performance IQ.

Results: There was a trend for larger absolute trial-by-trial variability in the ASD group in comparison to the control group in both pre-stimulus ($t(41)=1.27$, $p=0.21$) and post-stimulus ($t(41)=1.57$, $p=0.12$) periods. The mean magnitude of variability quenching was similar in both groups (ASD = -18.8%, control = -17.2%) and did not differ significantly ($t=-0.325$, $p=0.746$). Nevertheless, individual magnitudes of variability quenching were correlated with the severity of ASD symptoms as estimated by the ADOS ($r(23)=0.45$, $p=0.03$).

Conclusions: These findings demonstrate a trend for larger neural variability across trials in adults with ASD along with similar magnitudes of variability quenching across groups. Intact quenching suggests that basic cortical mechanisms that act to suppress neural variability following stimulus presentation are acting in a similar manner in adults with ASD as in controls.

435.057 *(Poster)* White Matter Compromise in Children and Adolescents with ASD Detected By Tracula

A. Schadler[1]*, J. Hau*[2]*, R. A. Carper*[3]*, I. Fishman*[4] *and R. A. Mueller*[4]*, (1)San Diego State University, San Diego, CA, (2)Brain Development Imaging Lab - SDSU, San Diego, CA, (3)Brain Development Imaging Laboratories, Department of Psychology, San Diego State University, San Diego, CA, (4)Brain Development Imaging Laboratories, San Diego State University, San Diego, CA*

Background: Both functional and structural connectivity findings from MRI suggest that symptoms of Autism Spectrum Disorders (ASDs) are linked to disruptions in distributed brain networks. Aggregate findings from diffusion weighted imaging (DWI) have suggested that children younger than 4-5 years have higher fractional anisotropy (FA) and lower mean diffusivity (MD) in white matter throughout the brain, compared to typically developing (TD) controls, whereas older children and adolescents show predominantly lower FA and higher MD, considered indices of reduced white matter integrity. However, findings in this later period have been mixed, particularly with regard to localization, possibly due to insufficient motion-matching and methodological differences.

Objectives: To broadly test across several major white matter tracts for differences in white matter microstructure between samples of children and adolescents with ASDs and TD peers tightly matched for in-scanner motion.

Methods: We collected diffusion MRI data from participants aged 7-19 years: 60 with ASDs (mean age=13.1±2.9; 13 female, 6 left-handed) and 56 TD controls (mean age=13.2±2.9; 15 female, 7 left-handed). Groups were matched for age, non-verbal IQ (ps>.51), and head motion (ps>.83). ASD diagnoses were confirmed using the Autism Diagnostic Observation Schedule (ADOS-2). Automated tractography was performed using TRActs Constrained by UnderLying Anatomy (TRACULA), which estimates probable locations for 18 white matter tracts in individual subject space. Data from each participant were carefully inspected to ensure each tract reconstructed properly. To test for group and age effects, general linear models were run for each diffusion measure (FA and MD) of each tract, fitted with age, diagnostic group, average rotation, and average translation as model terms. Follow-up tests on axial and radial diffusivity (AD, RD) were performed for tracts with significant group effects. To investigate potential brain-behavior relationships, partial correlations were performed between diffusion measures and autism symptom severity (Social Responsiveness Scale 2), adjusting for age and motion. All reported effects were FDR-corrected (at $q < .10$).

Results: Compared to the TD group, the ASD group had lower FA in bilateral uncinate fasciculus (UF), left parietal superior longitudinal fasciculus (SLFp), and right cingulum angular bundle (CAB), and higher MD in bilateral UF, right CAB, right inferior longitudinal fasciculus (ILF), as well as both of the right parietal and temporal superior longitudinal fasciculi (SLFp and SLFt respectively).
Follow-up tests for RD and AD revealed that differences in all reported tracts were driven by larger RD in the ASD group. No significant correlations were found between diffusion measures and autism symptom severity.
Conclusions: In a sample of children and adolescents, we found evidence of reduced tract integrity in several association tracts in ASD. Many of the tracts implicated are associated with functions such as socio-affective processing (UF), language functioning (both branches of the SLF), and working memory (CAB). – domains known to be affected in individuals with ASDs. These analyses were performed on samples that were well matched for subject motion and support the presence of altered tract microstructure in white matter tracts pertinent to autism symptomatology.

435.058 *(Poster)* Who Can Participate in Neuroimaging Research? Considering Temperament As a Factor for Maximizing Scan Success

***E. S. Kuschner**, M. Kim, L. Bloy, M. DiPiero, J. C. Edgar and T. Roberts, Lurie Family Foundations MEG Imaging Center, Department of Radiology, Children's Hospital of Philadelphia, Philadelphia, PA*

Background: Clinical and behavioral protocols to support neuroimaging scan experiences for children who have autism spectrum disorder (ASD) (Gabrielsen et al., 2018; Nordahl et al., 2016; Kuschner et al., 2019) have advanced the field and expanded participation in neuroimaging studies. Children who have limited language and cognitive ability have often been excluded from neuroimaging studies due to assumptions of difficulties remaining still, tolerating novel sensory experiences, inhibiting repetitive behaviors, and understanding/following the directions associated with the exam. Current clinical and behavioral protocols have supported children with limited language and cognitive ability to complete neuroimaging scans, with scan success rates from 75-100%.
Objectives: To consider temperament as a child trait that will help optimize protocols and, ultimately, predict likelihood of scan success.
Methods: Participants included 42 children 8 to 12 years (mean age=10.3 years, SD=1.4; Nonverbal IQ mean=54.5, SD=15.8). Children were minimally verbal/nonverbal with ASD or had a neurodevelopmental disorder/genetic syndrome and intellectual disability. With the support of the *MEG Protocol for Low-Language/Cognitive Ability Neuroimaging* (MEG-PLAN; Kuschner et al., 2019), magnetoencephalography (MEG) data were obtained using a 275-channel CTF MEG system. We report on a pure tone paradigm. Sinusoidal tones (300 ms duration; 10 ms ramps) with a pseudo-randomized 600-2000ms inter-trial interval were presented using a freefield loudspeaker (and thus binaurally). Parents completed the Carey Temperament Scales (Carey & McDevitt, 1995) to report their child's behavioral style across nine categories of temperament. Questionnaire version was chosen based on nonverbal mental age, with 35 parents completing the Behavioral Style Questionnaire (for 3-7 years) and 7 parents completing the Toddler Temperament Scale (for 1-35 months). Participants were groups into "Successfully" and "Unsuccessfully" scanned participants, with success operationalized as reaching a point where MEG data were *acquirable* (i.e., MEG machine was turned on and an exam administered). Dependent variables were Carey temperament category scores, including Activity level, Adaptability, Approach to novelty, Distractibility, Emotional intensity, Persistence, Quality of mood, Rhythmicity, and Sensory sensitivity. Temperament ratings between groups were compared with independent samples t-tests.
Results: Using MEG-PLAN, a 76% success rate was achieved. Temperament scores were examined between the 32 children who scanned "successfully" (n=32) versus those with "unsuccessful" scans (n=10). Children with unsuccessful scans were more likely to have elevated scores on the Distractibility scale (i.e., external stimuli alter their ongoing behavior; p=.03, Cohen's d=.8) and the Emotional Intensity scale (i.e., show greater energy level in response to their environment; p=.03, d=.7), and to be rated by their parent as more globally difficult to manage (p=.03, d=.7). There were no other group differences.
Conclusions: Temperament features related to distractibility, intensity of emotional responses, and general manageability were associated with difficulty completing neuroimaging protocols. As the field seeks to expand participation in neuroimaging research, executive control and regulation weaknesses will limit successful scanning. Clinical and behavioral protocols to target these skills are needed.

435.059 *(Poster)* Whole-Brain Resting State Lag Structure Is Similar in Adolescents with and without Autism Spectrum Disorders

***L. E. Mash**[1,2], A. C. Linke[1], M. Wilkinson[1,2] and R. A. Mueller[1], (1)Brain Development Imaging Laboratories, San Diego State University, San Diego, CA, (2)SDSU/UC San Diego Joint Doctoral Program in Clinical Psychology, San Diego, CA*

Background: Atypical functional connectivity (FC) has been widely reported in autism spectrum disorders (ASDs). Conventional functional connectivity MRI (fcMRI) methods typically assume that activity within shared brain networks is synchronous. However, recent research suggests that lagged blood oxygen level-dependent (BOLD) correlations may better characterize functional brain networks by accounting for neural propagation or differences in hemodynamic latency. In typical development, reliably 'early' and 'late' regions have been identified within some functional networks; e.g., posterior cingulate and ventromedial prefrontal cortices are early and late, respectively, within the default mode network (Mitra et al., 2014). A few studies have reported atypical resting-state BOLD lag structure in high-functioning adults with ASDs (King et al., 2018; Mitra et al., 2017). However, it remains unclear whether or how BOLD latency structure differs at rest in adolescents with ASDs.
Objectives: We aimed to (i) establish the relationship between FC and BOLD latency in adolescents with and without ASDs; (ii) characterize regional BOLD latency structure in each group, and (iii) compare regional BOLD latency between groups.
Methods: Low-motion, multi-echo, multi-slice resting-state functional MRI data (TR = 1.1 or 1.25s) from 22 ASD and 20 typically developing (TD) participants was included, group-matched for age, sex, handedness, and cognitive ability. A functional cortical atlas (Schaefer et al., 2018) and the Harvard-Oxford subcortical atlas were combined to yield 114 regions of interest (ROIs) covering the whole brain. FC was calculated for each ROI pairing at zero-lag. Cross-covariance was then used to examine synchronicity at different latencies ranging from -2 to 2 TRs. The optimal lag corresponding to the maximum absolute covariance between each ROI pairing was determined using parabolic interpolation. For each ROI, average latency with respect to all other ROIs was computed to identify putative sources and sinks of neural activity. Zero-lag FC, ROI-ROI lag matrices, and average ROI latencies were compared across groups.

Results: A one-sample t-test showed predominant overconnectivity across all ROI pairings in ASDs ($t(6440) = 70.7$, $p < .001$) at zero-lag, largely driven by increased positive correlations between default-mode and other networks. No significant differences were found with respect to average whole-brain latency for any of the 114 ROIs. The average ROI-ROI lag matrices for the ASD and TD groups were highly similar ($r = .70$, $p < .001$). Among the ten 'earliest' ROIs for both groups were occipital cortex, posterior parietal cortex, and precuneus. Among the ten latest ROIs for both groups were higher-order regions, such as frontal eye fields and prefrontal cortex.

Conclusions: Zero-lag FC was overall increased in ASDs, particularly between default-mode and other networks. On average, ASD and TD participants showed highly similar regional 'early' and 'late' patterns of BOLD latency across the brain, suggesting absence of dramatic differences in neural propagation or regional hemodynamic latency during the resting-state in high-functioning adolescents with ASDs.

436.001 *(Poster)* Self-Reported Parkinsonism Symptoms in Older Autistic Adults: A Descriptive Study

H. M. Geurts[1], *S. Begeer*[2] *and B. A. Schmand*[3], *(1)Dutch Autism & ADHD Research Center, Brain & Cognition, University of Amsterdam, Amsterdam, Netherlands, (2)VU University Amsterdam, Amsterdam, Netherlands, (3)University of Amsterdam/AMC, Amsterdam, Netherlands*

Background: Parkinson disease (PD) is thought to be prevalent in the autistic population[1,2], but recognizing PD related parkinsonism in autistic populations is a challenge. It is unknown what characterizes the autistic adults who do show this Parkinsonian complex of motor symptoms (i.e., parkinsonism). For example the high observed prevalence in previous studies might be large driven by the prevalent intelectual disabilities in the autistic samples included, and might not be related to autism perse. We will, therefore, focus on parkinsonism in autistic adults without an intelectual disability.

Objectives: In this study we explore: (a) the prevalence of self-reported motor symptoms associated with parkinsonism in autistic adults with a late adulthood diagnosis of ASD; (b) the age of onset of symptoms; and (c) whether there are differences between those who screen positive or negative for parkinsonism.

Methods: A total of 296 autistic adults aged 50 to 81 years of age (M 58.4, SD 5.9; 183 males; 113 females) filled out a new, six-item, parkinsonism screening questionnaire (PSQ)[3]. Information was collected, through self-report, regarding mental health problems, physical health problems, and use of psychotropic medication. We also measured subjective cognitive functioning with the *cognitive failures questionnaire.*

Results: Of the older autistic adults, 64.5% gave an affirmative answer to at least one of the questions of the PSQ with a mean age of onset ranging from 35.9 to 50.4. A subgroup (16.9%; N=50) scored above the cut-off of the PSQ screening score. The estimated percentage of true positives is between 15.9 to 16.2%. People screening positive encountered more physical and mental health problems, but less cognitive failures, then people who screened negative. As especially the use of anti-psychotics is associated with parkinsonism symptoms, we explored whether the use of anti-psychotics differed between those who screened positive and those who screened negative, but no significant differences emerged.

Conclusions: We conclude that (a) self-reported parkinsonism is prevalent in middle and older autistic adults with a late adulthood diagnosis; (b) self-reported motor symptoms are not likely to be an intrinsic part of autism; and (c) are not likely to be due to psychotropic drug use. It needs to be determined whether adults who screen positive for parkinsonism need to receive a follow up neurological examination. Put differently, while we can conclude that subjective parkinsonism is prevalent in older autistic adults without an intelectual disability, it needs to be determined, by means of longitudinal studies including neurological examinations, if self-reported parkinsonism is a red flag for neurologically validated parkinsonism and idiopathic Parkinson disease.

437.001 *(Poster)* "I Bet There Comes a Beat". an ERP Study of the Effects of Positively and Negatively Violated Expectations in an Auditory Oddball Task in Young Adults with ASD.

A. Piatti[1], ***E. Pashchenko***[2], *L. Pashchenko*[2] *and J. K. Buitelaar*[3], *(1)Department of Experimental-Clinical and Health Psychology, Ghent University, Ghent, Belgium, (2)Tyumen State University, Tyumen, Russian Federation, (3)Karakter Child and Adolescent Psychiatry University Centre, Nijmegen, Netherlands*

Background: The study of the neural correlates of predictive coding in individuals with autism spectrum disorder (ASD) has given interesting insights into the cognitive processes from which some of the distinctive behavioural features of people with ASD may originate.
Previous studies have used different paradigms to investigate predictive coding in ASD, including adapted versions of the oddball paradigm. Such studies generally involve the use of standard, frequent deviant and infrequent deviant stimuli. However, they often do not differentiate between the effect of unexpected stimuli when specific expectations are present (negatively violated expectations) or absent (positively violated expectations). Moreover, the differential processing of infrequent deviant stimuli may be caused by different sensitivity to physical stimulus properties.
Objectives: We designed an auditory oddball paradigm to disentangle the effects of negatively violated expectations from those of positively violated expectations, and the effects of expectedness from those of acoustic stimulus features.
Methods: Participants with ASD (n = 16, 6 women, mean age 20.5 ± 3.3, mean non-verbal IQ 112 ± 7) and typically developing (TD) controls (n = 16, 6 women, mean age 21 ± 3.5, mean non-verbal IQ 113 ± 7) heard 210 series of four pure tones (duration: 190 ms, silence between tones: 500 ms, silence between series: 2500 ms). In 70% of cases, the series consisted of 3 low tones (500 Hz sinusoidal) and one high tone (800 Hz sinusoidal) occurring in position 3. In 15% of cases, the high tone occurred in position 2 (positively violated expectation: an unexpected deviant tone plays when a standard one normally occurs and participants do not formulate specific expectations). In the remaining 15% of cases the series consisted of 4 identical low tones (negatively violated expectation: listeners specifically expect a deviant tone in position 3, but a standard one plays). EEG activity was recorded using a 32 electrode 10-20 montage.
Results: For negatively violated expectations, we found a group difference in the effect of expectedness over the amplitude of the N1 peak to low tones (Expectedness x Group: $F(1,30) = 4.680$, $p = .039$). The effect of Expectedness was only significant in the ASD group ($F(1,15) = 12.092$, $p = .003$). Exploratory analysis showed good sensitivity (87.50%) but lower specificity (68.75%) of this effect to discriminate between ASD and TD participants.
The response to positively violated expectations did not differ between the two groups, who showed an N2 and P3 effects.
Conclusions: Our results suggest that existing expectations and top-down mechanisms can have a stronger impact over sensory processing in individuals with ASD than in their TD peers. For negatively violated expectations, participants with ASD showed an effect of expectedness over the processing of acoustically identical stimuli at an early stage (100-200 ms time-window), when effects are generally due to physical stimulus properties and bottom-up processes. However, participants in both groups processed positively violated expectations in a similar way. Overall, this might signify that it is particularly problematic for individuals with ASD to cope with non-fulfilled expectations rather than with unexpected events.

437.002 *(Poster)* Altered Error-Related Negativity (ERN) in ASD May Result from between- Rather Than within-Subject Variability of the Timing and Magnitude of Neural Response.

T. Clarkson[1]*, A. Carpenter*[1]*, S. Casini*[2]*, A. Arora*[2]*, B. Frempong*[2]*, M. D. Lerner*[3] *and J. M. Jarcho*[1]*, (1)Psychology, Temple University, Philadelphia, PA, (2)Temple University, Philadelphia, PA, (3)Department of Psychology, Stony Brook University, Stony Brook, NY*

Background: The error-related negativity (ERN), an index of threat monitoring measured via electroencephalogram (EEG), is generated from theta-band oscillations from the anterior cingulate cortex (Cohen, 2011). The ERN is different, but not consistently so, in autism spectrum disorder (ASD) compared to non-ASD youth (Groen et al., 2008; Rosen & Lerner, 2018; South, et al., 2010; Vlamings et al., 2008). One plausible explanation for these mixed findings is that individuals with ASD may have greater within-subject variability in the ERN (Milne et al 2011). However, no study to date has examined whether within-subject variability of the timing or magnitude of theta oscillations of the ERN account for observed differences in the ERN in ASD. Inter-trial phase coherence (ITPC) can isolate within-subject variability in the *timing* of trial-level theta oscillations during the ERN. Time-frequency analyses can be used to calculate within-subject variability of the *magnitude* of trial-level theta oscillations during the ERN. Thus, they represent ideal tools for determining whether mixed ERN findings in ASD can be explained by greater within-subject variability of the timing and magnitude of neural response.
Objectives: We examined whether group differences in the ERN are due to within- or between-subject variability in the timing and magnitude of theta oscillations during the ERN.
Methods: Forty-four youth (M_{age}=11.61, SD_{age}=2.92; 32male) with ADOS-2-confirmed ASD diagnosis and seventy-two typically-developing (TD) youth (M_{age}=12.39, SD_{age}=1.89; 34male) completed the Flanker Task (Eriksen & Eriksen, 1974). 15 artifact-free trials were randomly selected per participant. The ERN was calculated using the difference between the mean amplitude of Error-Correct responses between -25-to-75ms post-response. Morlet-wavelet transformation (.5Hz resolution; m=4) were conducted on single trials in the theta-band (4-7Hz) to calculate within-subject variability of magnitude. Then, ITPC were extracted (Trujillo & Allen, 2007). A one-way ANOVA examined group differences in the ERN, ITPC, and magnitude of theta oscillations. A repeated-measure ANOVA examined differences in within-subject variability of the magnitude of theta oscillations between groups.
Results: The ERN differed between groups ($F(1,109)=4.86$, $p=.03$), such that the ERN was less negative in ASD compared to TD. Groups did not differ on theta-band ITPC ($F(1,108)=1.55$, $p=.22$), yet the ASD group exhibited a bi-modal distribution (Fig1). Groups differed in the magnitude of theta oscillations ($F(1,115)=11.22$, $p=.001$), such that the magnitude of theta oscillations was smaller in ASD compared to TD (Fig2). There were no group differences in within-subject variability of the magnitude of theta oscillations ($F(1,109)=.85$, $p=.36$).
Conclusions: The ERN was less negative in ASD relative to TD youth, replicating previous literature (Rosen & Lerner, 2018; Vlamings et al., 2008). In contrast to current theories suggesting that greater within-subject variability contribute to inconsistent ERN findings (Milne et al., 2011), our results suggest ASD and non-ASD youth have similar levels of variability in the timing and magnitude of theta oscillations during the ERN. Rather, the ASD group overall had less theta activation during the ERN. Additionally, the bi-modal distribution ITPC of the ERN suggests there may be greater between-subject variability in in timing of neural response in ASD relative to non-ASD youth.

437.003 *(Poster)* An EEG Study of Music and Speech Processing in Children with Autism Spectrum Disorder

S. Goldman[1], *J. R. Isler*[2], *N. M. Yamane*[1], *S. Wyne*[1], *M. M. Myers*[3] *and N. Tottenham*[4], *(1)Department of Neurology, Division of Child Neurology, Columbia University Irving Medical Center, New York, NY, (2)Pediatrics, Columbia University Irving Medical Center, New York, NY, (3)Psychiatry & Pediatrics, Columbia University Irving Medical Center, New York, NY, (4)Psychology, Columbia University, New York, NY*

Background: *"My child has autism; he doesn't speak, but he can sing."*

Strong musical abilities are commonly reported in verbal and nonverbal children with autism spectrum disorder (ASD), such as perfect pitch or rhythmicity. Furthermore, most intervention programs include music-based sessions to enhance social responsiveness and emotion regulation. Yet, few neurophysiological studies have investigated the neurobiological mechanisms involved in music processing in the context of speech anomalies in ASD children. Neuroimaging studies report an overlap among brain regions involved in music and speech and higher fronto-temporal connectivity in adolescents/adults with ASD compared to their typically developing (TD) peers during singing than speaking, suggesting alternate mechanisms for music processing in ASD. However, neural findings on young children with ASD are critically missing, as imaging techniques are often burdensome and challenging to implement on younger participants. Thus, this study focuses on the neurophysiological underpinnings of musicality in young children with ASD.

Objectives: The goal of this study was to use EEG, a convenient, non-intrusive method, to examine neuronal response such as differential patterns of electrocortical activation, to musical and matched spoken stimuli in young children with ASD.

Methods: Participants included two groups of children with ASD (n=15) and TD children (n=6) matched on sex and age (4 to 6 years). All children were evaluated for diagnostic (ADOS) and intellectual functioning, followed by testing with EEG. In the same testing room, children were asked to sit in their parents' laps in front of a low-impact visual stimulus and fitted with a 128-electrode cap connected to the Net Station EEG acquisition system (Electrical Geodesics, Inc., Eugene, OR) for approximately 6 minutes. After 1 minute of silent baseline, two counterbalanced, randomized blocks of sung and spoken forms of four popular nursery rhymes (i.e. "Twinkle, Twinkle, Little Star", "Row Your Boat", "Clean Up", and "ABC") were presented using a stimuli presentation software. Physiological artifacts were removed, and data were filtered and average referenced. *T*-statistics were used to analyze differences in EEG spectral power across groups (unpaired tests) and stimuli (paired tests).

Results: All children except three with ASD were able to complete the experiment (ASD: n=12; TD: n=6). Widespread significant differences in music minus speech EEG spectral power ($|t| > 2.4$, $p < .05$) between children with ASD and TD children were found, with a high degree of spatiotemporal clustering in response to music at 10, 31, and 52 Hz in children with ASD. Overall, our results reveal a less scattered, more spatially localized pattern of spectral power differences between ASD and TD while listening to music.

Conclusions: Our findings confirm significant differences in patterns of neural activation in response to music and speech between ASD and TD children. These results suggest differential brain patterns that may contribute to high musicality frequently reported in ASD. This study provides preliminary neurophysiological evidence for music and speech processing pointing to a potential, novel electro-cortical signature of ASD. These biologically based findings may help in the development of targeted music-based therapy and the search for electrophysiological biomarkers in ASD.

437.004 *(Poster)* Attentional Allocation to Auditory and Visual Stimuli in Autism Spectrum Disorder

C. McLaughlin[1], *S. B. Guillory*[1], *H. Grosman*[1], *E. Isenstein*[2], *K. Keller*[3], *O. Jones*[4], *J. Fagan*[5], *A. Rouhandeh*[1], *D. H. Mathalon*[6] *and J. H. Foss-Feig*[1], *(1)Seaver Autism Center, Department of Psychiatry, Icahn School of Medicine at Mount Sinai Hospital, New York, NY, (2)University of Rochester, Rochester, NY, (3)Department of Psychiatry, Icahn School of Medicine, Seaver Autism Center, New York, NY, (4)Fordham University, Bronx, NY, (5)McGill University, Montreal, QC, Canada, (6)Psychiatry, University of California, San Francisco, San Francisco, CA*

Background: Autism Spectrum Disorder (ASD) is commonly characterized by sensory abnormalities; many individuals with ASD display hyper- or hyposensitivity to sensory stimuli in both auditory and visual domains. It remains unclear, however, whether individuals with ASD attend to sensory stimuli differently than typically developing (TD) individuals, and whether attentional allocation in ASD is related to sensory symptoms. We utilized oddball paradigms during continuous electroencephalograph (EEG) recording to measure attention to task-relevant "target" and task-irrelevant "novel" sensory input.

Objectives: Our aim was to quantify differences in neural markers of attention to visual and auditory stimuli between ASD and TD.

Methods: EEG was recorded during visual and auditory oddball tasks (VOD and AOD). Each task consisted of three blocks of 150 trials in pseudorandom order; 80% of trials presented a "standard" stimulus (VOD: small blue circle; AOD: 500Hz tone), 10% presented a "target" stimulus (VOD: large blue circle; AOD: 1000Hz tone), and 10% presented a "novel" stimulus (VOD: fractal image; AOD: animal noises, bells). Participants responded with a button press to target stimuli only. Amplitudes of P3a (novel) and P3b (target) event-related potentials (ERPs) were assessed. EEG was recorded from participants with ASD (VOD: n=11 (27.3% female), mean age=22.97 years; AOD: n=11 (36.4% female), mean age=21.80 years) and TD (VOD: n=15 (60.0% female), mean age=22.32 years; AOD: n=17 (52.9% female), mean age=22.56 years). Participants with ASD also completed the Adolescent/Adult Sensory Profile to measure self-reported sensory symptoms.

Amplitudes of P3a (novel) and P3b (target) event-related potentials were compared between groups using independent samples t-tests. Correlations between ERP amplitude and sensory symptoms were calculated for ERP variables that showed significant differences between groups.

Results: During the VOD task, ASD (9.53μV) and TD (8.96μV) groups displayed similar P3a amplitude to novel stimuli (p=0.75), but P3b response to target stimuli was significantly enhanced in ASD (ASD: 11.42μV; TD: 8.12μV; p=0.04). During the AOD task, ASD and TD individuals did not differ significantly in either P3a amplitude to novel stimuli (ASD: 9.25μV; TD: 7.16μV; p=0.19) or P3b amplitude to target stimuli (ASD: 9.29μV; TD: 6.91μV; p=0.13). Behavioral performance of target detection accuracy did not differ between groups in either task.

Within the ASD group, P3b amplitude in response to VOD target stimuli had a significant negative correlation with self-reported measures of visual sensory symptoms (r=-.76, p=.01), as well as sensory sensitivity across modalities (r=-.64, p=.05).

Conclusions: Our findings identify a significant group difference only in visual P3b, suggesting individuals with ASD attend more strongly to visual target stimuli than TD individuals. This result indicates a difference in how ASD individuals allocate attentional resources in response to visual but not auditory, and target but not novel, stimuli. It is consistent with enhanced perceptual functioning in ASD in the visual domain.
We further identify an inverse relationship between attentional allocation to visual target stimuli and sensory symptoms within the ASD group. This suggests that individuals with ASD who allocate more attention to behaviorally-relevant visual stimuli may be less likely to have clinically-impairing sensory symptoms.

437.005 *(Poster)* Children with ASD Show Abnormally Delayed Left-Hemispheric Sustained Field Neuromagnetic Response to 40 Hz Click Trains.

*K. S. Komarov, D. E. Goiaeva, T. S. Obukhova, T. M. Ovsiannikova, A. O. Prokofyev, T. A. Stroganova and **E. V. Orekhova**, MEG-Center, Moscow University of Psychology and Education (MSUPE), Moscow, Russian Federation*

Background: ASD is often associated with delayed or abnormal language development. The neural mechanisms of language deficits in ASD are poorly understood, but may involve degraded capacity for processing of low-level properties of sounds in the left hemisphere. The acoustic features such as periodicity and spectrum are encoded by two types of neuronal populations in the auditory cortex – one fires in synchrony with individual acoustic events, and the other increases firing non-synchronously with the individual events within a periodic sound (Wang et al, Neuroscience, 2008,154:294). Periodic 40Hz clicks engage both these neural populations and induce two concurrent responses in magnetoencephalogram (MEG): the auditory steady state response (ASSR) time-locked to each click and the sustained field (SF) – a deflection of the magnetic field that follows the transient response and is sustained during the whole interval of the stimulation. ASSR and SF originate from different cortical sources and may respectively reflect activity of the 'synchronized' and 'non-synchronized' neural populations. While previous ASSR studies in ASD were generally inconclusive, the SF has never been studied in ASD.
Objectives: We aim to investigate in children with ASD and neuro-typical (NT) children both ASSR and SF responses to periodic 40 Hz click trains using MEG and individual MRI-derived brain models.
Methods: Participants were 35 NT and 37 ASD children aged 7-12 years. Their IQs (KABC-II) range was 45-128 in ASD and 94-145 in NT. Autism severity was assessed using parental questionnaires (SCQ, SRS, Child-AQ) and the 1st PCA component was used as an autism severity score. The 500 ms trains of 40 Hz clicks were presented monaurally with 1000 ms intervals. The brain sources of the evoked auditory responses (ASSR and SF) contralateral to the presented sound were localized using S-Loretta.
Results: The ASSR originated from the Hershel gyrus, with higher prominence in the right hemisphere. In accordance with the previous report (Edgar et al, Dev Neurosci, 2016), the 40 Hz ASSR inter-trial phase coherence (ITPC) increased with age in both NT and ASD participants (NT: left R=0.41,p=0.012, right R=0.43,p=0.008; ASD: left R=0.28,p=0.09; right R=0.39,p=0.02), while between-group differences in the ITPC or its developmental courses were absent.
The cortical source of the SF in the Hershel gyrus was positioned rostral to that of the ASSR. The SF started at approximately 150 ms after stimulus onset, and then, after initial rise, sustained over time until 100 ms post-stimulus. Age did not affect the SF amplitude and timecourses in either group (all p's>0.1). The rmANOVA with factors Group, Hemisphere and Time revealed significant 3-way interaction (p=0.0005) due to an abnormally slow rise of the SF in ASD in the left hemisphere. The degree of the SF delay correlated with higher severity of autism (R= 0.41, p<=0.026), but not with IQ (p=0.8).
Conclusions: The delayed SF response in the left primary auditory cortex in children with ASD may reflect abnormal processing of periodic sounds in the 'language-dominant' hemisphere. Further studies are needed to investigate the consequences of this neuro-functional deficit for speech processing in ASD.

437.006 *(Poster)* Detection of an Autism EEG Signature from ONLY Two EEG Channels through Advanced Machine Learning

***E. Grossi**[1], M. Buscema[2], C. Olivieri[1] and R. J. Swatzyna[3], (1)Autism Research Unit, Villa Santa Maria Foundation, Tavernerio, Italy, (2)Semeion Research Centre, Roma, Italy, (3)Tarnow Center for Self-Management, Huston, TX*

Background: In previous studies we have shown the ability of a novel method of machine learning system named MS-ROM/IFAST to extract interesting features in digital EEG with standard 19 electrodes montage that allow very good distinction of ASD children from those who are developing typically and from those affected by other neuro-psychiatric disorders. If this signature is already present already at birth, then a screening program could be afforded in general hospitals registering EEG signals in the newborn. Since the equipment routinely available in neonatology units employ often few channels (2-8 electrodes), we were curious to check if features extracted from just two channels were enough to allow a good diagnostic performance in the same cases of the above-mentioned studies.
Objectives: The aim of this study is to evaluate the information load present in just two EEG channels to distinguish autistic subjects from typically developing ones and from those affected by other neuro-psychiatric disorders.
Methods: C3 and C4 time-series were isolated from EEG data sets used in two previous studies, the first carried out in Italy on 25 subjects (15 ASD and 10 typicals) and the second carried out in US on 40 subjects (20 ASD and 20 with other neuropsychiatric disorders)A continuous segment of artifact-free EEG data lasting 10 minutes in ASCCI format was used to compute multi-scale entropy values and for subsequent analyses. A Multi-scale ranked organizing map (MS-ROM), based on the self-organizing map (SOM) neural network, coupled with the TWIST system (an evolutionary system able to select predictive features) created an invariant features vector input of EEG on which supervised machine learning systems acted as blind classifiers.
Results: After MS-ROM/I-FAST preprocessing, ninety features were extracted from C3-C4 timeseries of study 1 and of study 2 representing the EEG signature. Acting on these features the overall predictive capability of different machine learning systems in deciphering autistic cases from typicals (study 1) and from other NP disorders (study 2) ranged between 93% and 94. % (study 1) and from 80 and 88% (study 2) These results were obtained at different times in separate experiments performed on the same training and testing subsets.

Conclusions: The results of this study suggest that also a minor part of EEG contain a precious information useful to detect autism if treated with advanced computational algorithms. This could allow in the future to use standard EEG from newborn to check if ASD signature is already present at birth.

437.007 *(Poster)* Different Eye Tracking Patterns in Autism Spectrum Disorder in Toddler and Preschool Children

*X. Kong[1] and **G. Wan**[2], (1)Radiology, Massachusetts General Hospital, Charlestown, MA, (2)Department of Child Psychiatry and Rehabilization, Shenzhen Maternity & Child Healthcare Hospital, Shenzhen, China*

Background: Although the aforementioned studies have demonstrated the potentials of eye tracking, few studies have investigated the eye tracking differences in ASD children of different ages. Elucidating these differences will significantly enhance our understanding of the development of ASD. Recently, machine learning techniques have been successfully applied to identify biomarkers for ASD. As a subset of artificial intelligence in the field of computer science, machine learning is a procedure that trains the computer algorithm to analyze a set of observed data and statistically learn the latent patterns without being explicitly programmed. Different markers such as behavior, brain structure, activity and connectivity, and eye tracking has been used to distinguish individuals with ASD and TD and has achieved encouraging results.

Objectives: We applied a paradigm consisting of several pictures and short videos to 1) systematically investigate the eye tracking patterns of children with ASD across different ages and their association with clinical symptoms and 2) apply a machine learning method to explore the features distinguishing ASD from TD across different ages.

Methods: In this study, we recruited two cohorts of children with ASD (1-3 years old toddlers and 4-6 years old preschoolers) and two cohorts of age- and gender-matched typically developing (TD) children to investigate eye tracking changes across different ages using video and picture paradigms.

Results: We found that compared with TD children, fixation times of children with ASD on non-biological motion (moving helicopter and duck), electronic fan picture and eye area of a woman sitting still and mouthing the alphabet is normal in toddler years, but significant lower in preschool years compared with age matched TD. Support vector machine analysis showed that the classifier could discriminate ASD from TD in toddlers with an accuracy of 80%, a sensitivity of 80.0%, and a specificity of 81.8%; and could discriminate ASD from TD in preschoolers with an accuracy of 75.7%. a sensitivity of 89.2%, and a specificity of 62.2%.

Conclusions: Our results suggest that toddler years may be an important developmental period for ASD, and our findings may shed light on the development of new screening methods for the early detection of ASD.

437.008 *(Poster)* EEG Correlates of Excitatory/Inhibitory Balance during Visual Perception in Autism and Schizophrenia Spectrum Disorders

K. Keller[1], *H. Grosman[2], A. Naples[3], S. Kala[3], A. Bagdasarov[3], E. Cummings[3], C. Carlos[3], J. Wolf[3], V. Srihari[4], A. Anticevic[4], J. McPartland[3] and J. H. Foss-Feig[2], (1)Department of Psychiatry, Icahn School of Medicine, Seaver Autism Center, New York, NY, (2)Seaver Autism Center, Department of Psychiatry, Icahn School of Medicine at Mount Sinai Hospital, New York, NY, (3)Child Study Center, Yale University School of Medicine, New Haven, CT, (4)Division of Neurocognition, Neurocomputation, and Neurogenetics (N3), Yale University School of Medicine, New Haven, CT*

Background: Excitatory/Inhibitory (E/I) imbalance theory purports to explain dysfunction in both autism spectrum disorder (ASD) and schizophrenia (SZ). E/I neurotransmitter balance facilitates center-surround interactions within receptive fields of neurons in the visual cortex. Surround suppression reflects the effect whereby neural responses to a central stimulus are suppressed by input from the surrounding visual field. This study assesses integrity of surround suppression effects across ASD and SZ by comparing neural responses to central vertical gratings in parallel and perpendicular surround conditions.

Objectives: This study aimed to use EEG to (1) assess event related potential (ERP) indices of surround suppression in adults who met diagnostic critera for ASD, SZ, or were typically developing (TD) and (2) evaluate associations between neural response and diagnostic features across disorders.

Methods: Participants included 17 ASD (15 males; age: M=25.94±6.05 years; IQ: M=106.71±17.17), 14 SZ (12 males; age: M=23.96±4.22 years; IQ: M=92.64±16.05), and 39 TD adults (21 males; age: M=26.46±5.99 years; IQ: M=112.24±15.89). EEG data were recorded using a 128-channel net. Participants observed vertical sinusoidal grating filling a central annulus, either alone, surrounded by perpendicular gratings, or surrounded by parallel gratings (Fig. 1). With intact surround suppression, attenuated ERP amplitudes are expected in parallel vs perpendicular surround. We focused on N1 and P2 components over occipital scalp. Participants were administered the Autism Diagnostic Observation Schedule (ADOS) and the Positive and Negative Syndrome Scale (PANSS) to assess current ASD and psychosis symptoms, respectively. Between-group differences were examined with repeated measures ANOVAs. Associations between neural activity and clinical variables were explored with bivariate correlations.

Results: For the N1 response, there was a main effect of condition ($F(1,67)=46.58$, $p<.001$) with N1 amplitude suppressed during the parallel condition across groups. There was also a groupXcondition trend ($F(2,67)=2.69$, $p=.075$), wherein ASD adults showed enhanced N1 suppression during parallel vs perpendicular surround, particularly relative to TD ($p=.030$). For P2, we saw the opposite effect, wherein P2 amplitude was greater in the parallel versus perpendicular condition across groups ($F(1,67)=11.54$, $p=.001$). A main effect of group was also observed ($F(2.67)=3.61$, $p=.032$) where P2 amplitude was larger in ASD vs both SZ ($p=.028$) and TD ($p=.016$) across conditions. With regard to clinical variables, greater N1 suppression correlated with fewer positive psychosis symptoms transdiagnostically ($r=.36$, $p=.05$). Weaker suppression of the P2 response correlated with greater ASD symptoms ($r=.39$, $p=.032$).

Conclusions: Results reveal evidence for surround suppression effects in the N1 ERP response during visual perception across ASD, SZ, and TD. We did not find clear evidence for global suppression deficits in either ASD or SZ. Rather, relative strength of N1 suppression was related to degree of positive psychosis symptoms across groups. This finding suggests that, rather than corresponding directly to diagnostic categories, E/I imbalance may represent a state-specific property of neural function that corresponds to period of increased delusions, conceptual disorganization, and hallucinations transdiagnostically. Further work to understand the amplification of P2 response during parallel surround conditions, and its association with ASD traits, is warranted.

437.009 *(Poster)* Early Neural Difference in Auditory Processing of Speech in Children with ASD: Is It Habituation or Discrimination?

E. L. Cary[1]*, B. Prieve*[2]*, E. A. Kaplan*[1]*, D. Pacheco*[2]*, E. C. Masters*[1]*, A. Rodrigues*[1]*, E. Matsuba*[1]*, A. Madrid*[2] *and N. Russo*[1]*, (1)Department of Psychology, Syracuse University, Syracuse, NY, (2)Department of Communication Sciences and Disorders, Syracuse University, Syracuse, NY*

Background: Key diagnostic criteria of autism spectrum disorder (ASD) include social impairment, and one important aspect of social functioning is the ability to encode, perceive, and attend to relevant speech cues. Research suggests that the auditory processing pathway is disrupted in ASD, particularly to speech. However, the nature of this difference is less well interrogated. On the one hand, individuals with an ASD may show differences in their habituation to speech sounds, with some evidence suggesting that speech and non-speech are treated similarly in ASD but not in TD. On the other hand, individuals with autism demonstrate consistent enhanced discrimination abilities, and as such may attend to different aspects of speech cues than TD children. Here we attempt to tease apart these two perspectives by examining differences in early auditory evoked responses to speech in ASD, focused on the P1 ERP component. Working to determine the nature of early auditory processing differences between TD and ASD children in discrimination of and habituation to speech will enhance our understanding of auditory processing in ASD.

Objectives: The current study seeks to examine auditory habituation and discrimination by looking at P1 ERP responses to speech sounds presented in an auditory oddball paradigm among TD and ASD children.

Methods: Participants currently include 9 children with Autism Spectrum Disorder (ASD) and 17 Typically Developing (TD) children, ages 7-16, and data collection is ongoing. ASD diagnosis was confirmed by administering the Autism Diagnostic Observation Schedule 2nd Edition (ADOS-2) and Autism Diagnostic Interview-Revised (ADI-R), and TD participants had no psychological diagnoses. Participants were excluded if their hearing thresholds were elevated, their IQ was below 80, or if they had a history of epilepsy, neurological, genetic, psychiatric, or learning disorders. The P1 was evoked by speech stimuli “ba” and “da” and recorded via an electrode net. There were 1000 trials, 80% standard and 20% deviant, presented in random order. Participants were seated in a sound-insulated room and stimuli were presented via two speakers at an intensity of 60 dB sound-pressure level, while a visual distraction task engaged the participants’ attention. The P1 was measured as the mean amplitude of the most positive peak at about 100ms at the FCz cite, discrimination was measured by the difference between standard and deviant waveforms, and habituation measured by the difference of the response to standard auditory stimuli over repetitions.

Results: Preliminary data suggest that ASD children have a significantly larger P1 response to standard minus deviant stimuli than TD children and did not differ from TD children in their response to repetitions of standards.

Conclusions: Our results suggest that TD children may encode speech within a broader category, such that similar speech sounds are not discriminated at the early neural level. In contrast, discrimination was evident for very similar speech sounds for the ASD participants. Habituation was similar for both groups in response to the repetition of the speech sounds. Results suggest that it is discrimination, not habituation that is driving the ASD-related differences.

437.010 *(Poster)* Exploring Physiological Profiles Associated with Challenging Behavior in Adolescents with ASD

J. Lantz*, T. Villavicencio and T. Hamlin, The Center for Discovery, Harris, NY*

Background: Those with autism spectrum disorder (ASD) can display challenging behaviors that interfere with skill development and negatively impact quality of life. Electrodermal activity (EDA) refers to changes in the electrical conductivity of the skin in response to sweat secretion and is associated with activation of the sympathetic nervous system. When looking at the alignment of EDA responses with challenging behaviors in those with ASD, findings have been inconsistent. Some researchers have found that physiological arousal can be used to predict aggressive behavior in individuals with ASD (Goodwin et al., 2018) and in individuals without ASD who display aggression (Looff et al., 2018), while others have found that a significant build-up of physiological arousal is not always present prior to a behavior in those with ASD (Ferguson et al., 2019). Better understanding the timing of physiological responding around behavior onset and offset can help guide intervention efforts.

Objectives: This exploratory study aims to further examine the alignment of behaviors and EDA responses within and across individuals with ASD who display high-impact behaviors such as elopement, disruption, self-injury and aggression.

Methods: The participants include four minimally-verbal adolescents with ASD and moderate-to-severe intellectual disability who live and attend school in a residential setting. EDA data were collected in a temperature controlled classroom during normally planned lessons using the Q-Sensor by Affectiva or the E-4 by Empatica. Behavior data were retrieved from video and coded by research assistants. After visual inspection of the EDA, we used the web-based tool EDA Explorer (Taylor et al., 2015) to classify the data into peaks (skin conductance responses) and artifacts. The threshold for the amplitude of the peaks was set at 0.05 μS. We set the maximum number of artifacts to 25%. Data not meeting this criterion were discarded. We calculated the total number of peaks, peaks per minute (PPM), mean EDA, standard deviation and EDA mean difference for 30 minutes preceding and following the behavior of interest. In order to determine whether there was an immediate anticipatory physiological response, we calculated peaks per minute for the 5 minutes preceding the problem behavior.

Results: Data collection is finished for all four students. At the time of this proposal, data analysis is complete for 21 sessions across two behaviors for one student. For Student 1, the average total number of peaks was greater in the 30 minutes *afte*r the behavior compared to the 30 minutes *prior* to behavior onset. Only 38% of sessions had more than 1 PPM in the 5 minutes prior to behavior onset, meaning that an immediate anticipatory physiological response was not significant for most behaviors.

Conclusions: Our initial analysis is consistent with findings from our previous research. Significant physiological arousal is not always present before behavior onset in people with severe forms of ASD. Furthermore, the amount of arousal that remains following behavior offset is concerning and has implications for treatment. Patterns of physiological responding around behaviors may not be dependent on behavior topography.

437.011 *(Poster)* Face Processing Hemispheric Specialization Differences between ASD, ASD + ADHD, and Typically-Developing School-Age Children: The Autism Biomarkers Consortium for Clinical Trials

H. M. Borland[1], *M. Santhosh*[1], *J. T. Benton*[1], *A. Naples*[2], *C. Sugar*[3], *S. Jeste*[3], *G. Dawson*[4], *R. Bernier*[5], *F. Shic*[1], *S. Faja*[6], *J. Dziura*[7], *S. J. Webb*[5] *and J. McPartland*[2], *(1)Center for Child Health, Behavior and Development, Seattle Children's Research Institute, Seattle, WA, (2)Child Study Center, Yale University School of Medicine, New Haven, CT, (3)University of California, Los Angeles, Los Angeles, CA, (4)Department of Psychiatry and Behavioral Sciences, Duke Center for Autism and Brain Development, Durham, NC, (5)Psychiatry and Behavioral Sciences, University of Washington, Seattle, WA, (6)Boston Children's Hospital, Boston, MA, (7)Yale University, New Haven, CT*

Background:
While ASD and ADHD are considered separate disorders, between 40 to 70% of children with ASD also have a co-occurring diagnosis of ADHD (e.g., Antshel & Russo, 2019). It is suggested that ERP responses may be informative in understanding the neural similarities and distinctions in the two disorders (Lau-Zhu et al., 2019).
The N170 Event Related Potential (ERP) component is associated with early-stage face processing. In typically-developing (TD) populations, the N170 is right lateralized. The response is less consistently lateralized in individuals with ASD (Kang et al., 2018). For example, Tye et al. (2013) found that the N170 in participants with ASD-only and ASD+ADHD was not lateralized, while it was right biased in an ADHD-only or TD group. The Autism Biomarker Consortium for Clinical Trial (ABC-CT) study poses a unique opportunity to study the distribution of N170 laterality responses in children with ASD: (1) as the N170 to upright faces is a primary outcome variable; (2) the ABC-CT has 280 participants with ASD and 119 with TD; and (3) the EEG battery is collected at three time periods.
Objectives:
(Aim 1) To examine patterns of N170 lateralization to upright faces in a large sample of children aged 6 to 11 years of age with ASDonly, ASD+ADHD, and TD. (Aim 2) To examine possible subcategorization based on subgrouping of symptoms or stimulant medication usage.
Methods:
Participants, ages 6-11yrs, completed a high-density EEG battery that included watching pictures of upright and inverted faces and upright houses. Parents completed the Aberrant Behavior checklist with the Hyperactivity/Noncompliance domain and the Child and Adolescent Symptom Inventory Inattentive and Hyperactivity sub-scales. Analyses used a difference score for the N170 latency to upright faces Temporal Parietal (TP) right minus TP left. A negative difference reflects a faster right region response.
Results:
Analyses focus on our interim sample of 84 children with ASDonly (20 female), 38 with ASD+ADHD (5 female), and 62 with TD group (22 female). ANOVA analysis yielded significant main effect between the groups for Face Upright Right TP N170 Latency $F(2,181)=7.3$ $p<0.05$. The ASDonly (M=215.00 SD=27.90 [141-298]) did not differ from either the ASD+ADHD (M=202.50 SD=37.46 [131-308]) or the TD (M=195.97 SD=28.69 [140-276]) group.
As seen from the mean values and the reported range, the response in the ASDonly group was suggestive of no hemisphere bias. The ASD+ADHD group also demonstrated a response that was similar.
Conclusions:
Kang et al. (2018) found that 8 studies demonstrated a right lateralized group (mean) response in ASD, while 12 did not. We found response ASD children during perception of upright faces to be similar to TD children as well as ASD+ADHD and does not support the findings of Tye et al. (2013). Our sample was significantly larger than these studies and focuses on elementary school age children, which may account for the differences in findings. Additional analyses will extend these group differences to ADHD subtypes and include the P100, a perceptual-attention response that precedes the N170. Further analyses will control for medication, specifically stimulant use.

437.012 *(Poster)* Implicit Processing of Happy and Fearful Expressions in Individuals with High and Low Autistic Traits: An EEG Fast-Periodic Visual Stimulation Study

S. Naumann*, T. Weinstein, M. Matyjek, M. Bayer and I. Dziobek, Berlin School of Mind and Brain, Humboldt-Universitaet zu Berlin, Berlin, Germany*

Background: Individuals with autism spectrum conditions (ASC) often have difficulties with processing visual information from faces such as recognizing emotional expressions. These deficits have been related to altered sensory perception, implying an interdependent relationship between social functioning and sensory processing. With the help of a fast-periodic visual stimulation (FPVS) paradigm, our study investigated the link between autistic traits and the ability to detect brief changes in emotional expressions.
Objectives: We aimed to quantify the sensory differences in the processing of happy and fearful facial expressions as a function of autistic traits.
Methods: Twenty-eight neurotypical participants (15 females, age M = 31.68, SD = 10.02) completed the Autism-Spectrum Quotient (AQ). During electroencephalogram (EEG) recordings, we showed two variations of a FPVS paradigm. In the first variant, participants were presented with neutral faces at a rate of 6.00 Hz (base frequency) for a period of 40 s; while every fifth face (deviant, presented at a rate of 1.2 Hz) was either a happy or fearful face (maximum emotion intensity). In the second variant, happy or fearful faces were presented with parametrically increasing emotion intensity (every 20 s in 20% steps until 100 %). The resulting 1.2 Hz EEG response and its harmonics were used for quantifying the detection of facial expression change. Based on FFT-transformed, baseline-corrected amplitudes, we calculated linear mixed models with emotion, emotion intensity and AQ as fixed factors and participant and electrode as random factors. Analyses focused on occipital-temporal sites.
Results: In the maximum emotion intensity variant of the paradigm, no effects of emotion or a significant interaction with AQ were found. In the variant with gradual increase in emotion intensity for deviants, we detected a significant effect for emotion. Happy deviants elicited larger amplitudes compared to fearful deviants ($p < 0.01$). We also detected a significant interaction of emotion and AQ ($p < 0.05$). Increased AQ values led to a decrease in amplitude for both emotions. There was, however, no significant difference between the different emotion intensities.

Conclusions: We found partial evidence for sensory differences modulated by autistic traits. Individuals with higher autistic traits may be less susceptible to brief changes in emotion expressions as indicated by lower EEG amplitudes, which is in line with former studies employing an emotional face FPVS paradigm with individuals with autism.

437.013 *(Poster)* Intraindividual Variability in Spectral Power Slope and Spectral Band Power Demonstrates Concordance with Sensory Processing Deficits in Adults with Autism Spectrum Disorder

C. Carlos[1]*, A. Bagdasarov*[1]*, E. Cummings*[1]*, S. Kala*[1]*, A. Naples*[1]*, T. McAllister*[1]*, J. Wolf*[1]*, J. H. Foss-Feig*[2]*, V. Srihari*[3]*, A. Anticevic*[3] *and J. McPartland*[1]*, (1)Child Study Center, Yale University School of Medicine, New Haven, CT, (2)Seaver Autism Center, Department of Psychiatry, Icahn School of Medicine at Mount Sinai Hospital, New York, NY, (3)Division of Neurocognition, Neurocomputation, and Neurogenetics (N3), Yale University School of Medicine, New Haven, CT*

Background: Autism Spectrum Disorder (ASD) is characterized, in part, by reports of atypical sensory experiences. However, the expression of atypical sensory symptoms is heterogenous among the ASD population, and their mechanisms remain unknown. Currently, symptomology is captured by clinical interviews or questionnaires, yet no objective biological markers of these symptoms exist. Recent research indicates that the balance of excitation and inhibition (E/I) across the cortex, which can be indexed by the slope of the electroencephalographic (EEG) power spectrum, may associate with individual differences in sensory processing. Here we explore, for the first time, how within-individual variability in E/I balance, which indexes more global shifts in brain activity, may associate with sensory sensitivity.

Objectives: Characterize the relationship between within-person neural variability and atypical sensory processing in adults with ASD.

Methods: Resting EEG was collected from 38 adults with ASD (7 female, mean age of 25). EEG was cleaned of artifact and power spectral density was calculated over 2-second epochs. The slope of power spectra was computed as a linear fit on logarithmically transformed data between 2 and 55hz. The slope of the loglog power spectrum was calculated in a given 2s epoch for each channel in a scalp region of interest and then an average slope per epoch was created by taking the mean of all the slopes across channels in the region. Intraindividual slope variability was calculated as the standard deviation of slopes across all epochs. Power band variability was calculated by taking power from each canonical frequency band (delta, theta, alpha, beta, gamma) per channel, averaging across channels in the scalp region of interest, and calculating the standard deviation across all epochs for each frequency band.

Results: Intraindividual variability in EEG slope significantly correlated with the "tactile hyposensitivity" subscale of the *Glasgow Sensory Questionnaire* (GSQ) in the left occipital ($p < .01$, $r = .44$) and right occipital ($p < .01$, $r = .49$) regions, indicating that more variable E/I balance at rest may be associated with sensory hyposensitivity. Intraindividual variability of EEG power also correlated with tactile hyposensitivity, including gamma power variability in occipital left ($p < .01$, $r = .44$) and right ($p < .01$, $r = .43$) as well as alpha power variability in frontal right ($p < .01$, $r = .44$). Additionally, the "gustatory hypersensitivity" subscale of the GSQ displayed a significant negative correlation with theta band variability in the parietal left region ($p < .01$, $r = -0.47$). These changes in specific band power may be what is captured, in part, as the EEG slope changes over time.

Conclusions: Our results demonstrate that intraindividual variability in EEG activity is a useful metric, unto itself, for capturing meaningful variability in symptomology. Furthermore, differential relationships across the scalp suggest a level of regional specificity for these effects. Through analyzing variability in EEG measures by lateralized region, spatio-temporal patterns of sensory processing may thus be further mapped.

437.014 *(Poster)* Microstate Analysis of Resting-State Electroencephalography in Autism Spectrum Disorder

A. Bagdasarov[1]*, C. Carlos*[1]*, E. Cummings*[1]*, S. Kala*[1]*, T. C. Parker*[1]*, A. Naples*[1]*, J. Wolf*[1]*, J. H. Foss-Feig*[2]*, A. Anticevic*[3]*, V. Srihari*[3] *and J. McPartland*[1]*, (1)Child Study Center, Yale University School of Medicine, New Haven, CT, (2)Seaver Autism Center, Department of Psychiatry, Icahn School of Medicine at Mount Sinai Hospital, New York, NY, (3)Division of Neurocognition, Neurocomputation, and Neurogenetics (N3), Yale University School of Medicine, New Haven, CT*

Background: Variability in the electroencephalogram (EEG) across the scalp can be parsed into a small set of canonical topographies, or "microstates," that shift every 80-120ms. These topographies (labeled A, B, C, and D) are evident across studies and clinical populations and reflect activity in different brain networks. Combined EEG and functional magnetic resonance (fMRI) studies have shown microstate A to index signal in the auditory resting-state network; B in the visual network; C in the default mode network; and D in the dorsal attention network. However, temporal parameters of microstates have not been well characterized in adults with autism spectrum disorder (ASD) and hold potential to provide useful information about activation of functional networks.

Objectives: 1) Identify the four canonical microstates and compare their temporal parameters between groups of individuals with ASD and typical development (TD). 2) Assess the relationship between microstate parameters and clinical characteristics within the ASD group.

Methods: Participants were 22 adults with ASD and 37 TD controls aged 18 to 39 years. Demographic and clinical characteristics are presented in Table 1. Microstate analysis of eyes-closed resting-state EEG was performed using the *Microstate EEGlab Toolbox* and identified the four canonical microstates (Figure 1). Each microstate was characterized by three temporal parameters: 1) The duration a given microstate remained stable before switching to a different microstate; 2) The frequency of occurrence of each microstate; and 3) The fraction of time for which a given microstate was dominant (i.e., coverage).

Results: Between-group independent-samples *t*-tests demonstrated that the occurrence of microstate B was significantly greater in ASD (M=3.79) compared to TD (M=3.55), $t(57)$=-2.222, p=.030, and had significantly greater coverage in ASD (M=.30) compared to TD (M=.27), $t(57)$=-2.084, p=.042. The opposite pattern was found for microstate C, for which the occurrence was significantly greater in TD (M=2.69) compared to ASD (M=2.27), $t(57)$=2.64, p=.011, and had significantly greater coverage in TD (M=.18) compared to ASD (M=.15), $t(57)$=2.167, p=.034. Within-group linear regression analyses revealed that lower microstate C duration significantly predicted greater ADOS CSS scores in ASD, R^2=.188, p=.044. Also, greater microstate B duration [R^2=.201, p=.042], occurrence [R^2=.279, p=.014], and coverage [R^2=.235, p=.026] significantly predicted higher GSQ visual hypersensitivity scores in ASD.

Conclusions: Greater occurrence and coverage of microstate B in ASD may reflect increased visual processing load. This is corroborated by our finding that greater microstate B duration, occurrence, and coverage predicted greater self-reported hypersensitivity to visual stimuli in ASD. Less occurrence and coverage of microstate C in ASD may reflect suppressed brain activity in the default mode network, which is consistent with previous research. Lower duration of microstate C predicted greater ASD symptomatology in ASD, suggesting that time spent in microstate C rather than its occurrence and coverage is a significant predictor of default mode network activity in ASD. Together, these results suggest that microstates may serve as markers for abnormal visual and default mode networks in ASD. Future directions include using different EEG preprocessing strategies as well as different microstate clustering algorithms to further explore these relationships.

437.015 *(Poster)* Neural Correlates of Own Name and Own Face Processing in Neurotypical Adults Scoring Low Versus High on Symptomatology of ASD.

D. Oomen[1]*, R. El Kaddouri*[2]*, M. Brass*[3] *and J. R. Wiersema*[4]*, (1)Department of Experimental Clinical and Health Psychology, Ghent University, Ghent, Belgium, (2)Experimental Clinical and Health Psychology, Ghent University, Ghent, Belgium, (3)Department of Experimental Psychology, Ghent University, Ghent, Belgium, (4)Department of Experimental-Clinical and Health Psychology, Ghent University, Ghent, Belgium*

Background: It has been argued that self-referential processes are altered in ASD. On the neural level, people with ASD show a reduced enhancement of the P3 in response to self-related stimuli such as their own name or face. A limitation of current work is that different types of self-related stimuli are mainly studied in isolation, while they might differ in crucial aspects. There is only one study that looked at own name and face processing in the same sample. They found visual name and face processing to be altered in ASD. However, this study presented the name stimuli visually, stripping the stimuli from its ostensive feature; for spoken names are mostly used to grab someone's attention to engage in social interaction. Moreover, they did not investigate whether the (absent) self-referential effect present for both stimuli can be ascribed to overlapping or distinct underlying mechanism.

Objectives: To overcome previous limitations, we directly compared the neural response to hearing the own name and seeing the own face in the same sample. We presented the names auditory, which allows us to compare two self-related stimuli of which one is also an ostensive cue. In order to test whether the underlying mechanisms are similar for different self-related stimuli we correlated the neural response to both types of stimuli.

Methods: 60 neurotypical adults scoring low versus high on ASD symptomatology (n_{low} = 30, n_{high} = 30) completed an auditory oddball task with own name stimuli and a visual oddball task with own face stimuli. Close-other names and faces and unknown names and faces were used as control stimuli. Brain activity was recorded with EEG.

Results: P3 amplitudes were larger for own names and faces (than close-other names and faces) indicating a self-referential effect for both types of self-related stimuli. However these effects were present irrespective of group. We found no relationship (correlation near 0) between self-referential processing of own names and faces

Conclusions: The absent relationship between self-referential processing of the own name and face suggest that two distinct mechanisms may underlie the self-referential effects seen for own names and faces. Interestingly, we did not find the self-referential effect to be diminished in individuals that score high on ASD symptomatology. This would imply that an absent self-referential effect for own names and own faces is specific for ASD and not a dimensional feature of ASD symptomatology. This finding warrants further investigation applying a dimensional approach (i.e. sample that includes low, and high scoring individuals as well as individuals with ASD) before firm conclusions can be made.

437.016 *(Poster)* Pathways of Perceptual Primacy: ERP Evidence for Relationships between Autism Traits and Enhanced Perceptual Functioning

E. A. Kaplan*, E. L. Cary, E. C. Masters, E. Matsuba and N. Russo, Department of Psychology, Syracuse University, Syracuse, NY*

Background: Individuals with autism spectrum disorder (ASD) show enhanced perceptual functioning on a range of behavioral tasks. Neurophysiological evidence from fMRI investigations also corroborates the conclusion that persons with ASD utilize perceptual processes in reasoning and problem solving to a greater extent than neurotypical (NT) comparisons; despite robust behavioral and neuropsychological evidence for enhanced perceptual functioning among individuals with ASD, the cognitive and behavioral consequences of such early perceptual processing differences remain unclear.

Objectives: The first goal of the present study was to explicitly examine the relationship between the size of participants' early perceptual (P1 component) and late cognitive (N400 effect) event related potentials (ERPs). In order to associate ERP indicators of processing to levels of ASD traits, the second goal was to assess whether the size of participants' P1 and N400 effects were related to participants' self-reported levels of Attention to Detail as measured by the Autism Spectrum Quotient (AQ) using path analyses.

Methods: 62 NT adults (28 female) between the ages of 18 and 23 years participated in the study. Participants watched a computer screen while pictures of animals were presented simultaneously with an animal sound. Congruent trials consisted of trials in which the animal picture and audio were the same (i.e., a dog picture presented with a bark and a frog picture presented with a ribbit). Incongruent trials consisted of trials in which the animal picture and audio were mismatched (i.e., a dog picture presented with a ribbit and a frog picture presented with a bark). Participants' ERPs were recorded during the task. Following the ERP portion of the experiment, participants were administered the AQ. Causal relationships between ERP components and self-reported levels of Attention to Detail on the AQ were examined using path analysis models.

Results: The size of participants' perceptual ERPs (P1 effects) were positively correlated with the size of their late cognitive ERPs (N400 effects) and self-reported levels of Attention to Detail on the AQ. Path model comparisons indicated that variation in levels of Attention to Detail predicted meaningful variation in participants' ERP waveforms. Specifically, the relationship between Attention to Detail scores and the size of the N400 effect was significantly mediated by the size of the P1 effect.

Conclusions: Findings indicate that individuals with higher levels of Attention to Detail show larger perceptual ERP differences, which correspond to larger cognitive ERP effects. Results support the Enhanced Perceptual Functioning model of autism, suggesting that perceptual processing differences cascade forward and result in modifications of cognitive mechanisms. The positive relationship between P1 and N400 effect sizes suggests a strong feed-forward flow of information from perception to higher-order levels of processing in NT individuals. Future research should explore whether the strength of such processes is moderated by ASD status.

437.017 *(Poster)* Reduced Frontal Spectral Power in Infants at High Familial Risk for ASD

M. Daniel[1]*, A. H. Dickinson*[2]*, S. Jeste*[2] *and A. Marin*[3]*, (1)Semel Institute for Neuroscience, UCLA Center for Autism Research and Treatment, Los Angeles, CA, (2)University of California, Los Angeles, Los Angeles, CA, (3)University of California San Diego, San Diego, CA*

Background: Infant siblings of children diagnosed with ASD demonstrate increased risk of developing ASD compared to the general population (Ozonoff et al., 2011). Using electroencephalography (EEG) to measure neural synchrony through spectral power, neurophysiological differences can be detected in high risk infants prior to onset of atypical development (Tierney et al., 2012). As early as age 3 months, familial risk infants demonstrate reduced frontal power across multiple frequency bands compared to low risk controls, particularly in the gamma (30-50 Hz) range (Levin et al., 2017). This early difference in gamma power has been linked to cognitive and language skills in early childhood (Benasich et al., 2008).

Objectives: (1) To examine frontal spectral power in the gamma frequency band (30-50 Hz), acquired during spontaneous resting state EEG from 3 month old infants at familial risk for ASD compared to low risk controls. (2) To examine correlations between gamma power at 3 months and later cognitive function in familial risk infants.

Methods: As part of a longitudinal study of neurodevelopment in high risk infants, resting spontaneous EEG was acquired in a sound attenuated, dimly lit room using a 128-channel Hydrocel net (Electrical Geodesic Net Inc.) for 3 to 5 minutes, while infants sat in a caregiver's lap and a hidden experimenter blew bubbles. Usable data were obtained at 3 months from 29 low risk controls and 36 familial risk infants. Data were processed using EEGLAB (Delorme and Makeig, 2003) and cleaned using Artifact Subspace Reconstruction (ASR) (Chang et al., 2018). A Laplacian filter was applied to remove electromyogram artifact that may obscure electrophysiological activity in the gamma band. Independent samples t-tests were used to analyze differences in spectral gamma power according to familial risk status and ADOS-T concern classifications at 18 months. A Pearson correlation test was used to analyze the relationship between spectral gamma power and behavioral Mullen subscores at 18 months.

Results: Relative spectral power was reduced in the gamma frequency band in familial risk infants compared to low risk controls ($t = 2.047$, $p = .045$). Relative spectral gamma power was reduced in infants showing increased ASD symptomatology at 18 months compared to infants with no ASD concern ($t = 2.927$, $p = .005$). Relative spectral gamma power was significantly correlated with the visual reception ($p = .039$), receptive language ($p = .005$), and expressive language ($p = .036$) Mullen subscores.

Conclusions: Results from this study suggest that reduced relative frontal power in the gamma frequency band is an electrophysiological marker of risk for ASD. However, as reduced gamma power was also indicative of concern for ASD at 18 months, it suggests that underlying atypical neurodevelopment due to ASD symptomatology is driving differences in risk groups. Furthermore, relative gamma power is associated with both nonverbal and verbal cognition, suggesting that these early physiological changes may impact early learning and further neurodevelopment. EEG is a scalable tool that can facilitate early prediction of neurodevelopmental disabilities and improve early screening and monitoring of those infants at highest likelihood of atypical development.

437.018 *(Poster)* Resting EEG As a Predictor of Autism Severity in School-Aged Children with below Average Head Circumference: Results from the ABC-CT

S. Kala[1]*, A. Eiland*[1]*, A. Bagdasarov*[1]*, C. Carlos*[1]*, E. Cummings*[1]*, A. Naples*[1]*, T. McAllister*[1]*, K. Chawarska*[1]*, G. Dawson*[2]*, R. Bernier*[3]*, S. Jeste*[4]*, S. J. Webb*[3]*, C. Sugar*[4]*, M. Murias*[5]*, F. Shic*[6]*, J. Dziura*[7]*, C. Brandt*[7] *and J. McPartland*[1]*, (1)Child Study Center, Yale University School of Medicine, New Haven, CT, (2)Department of Psychiatry and Behavioral Sciences, Duke Center for Autism and Brain Development, Durham, NC, (3)Psychiatry and Behavioral Sciences, University of Washington, Seattle, WA, (4)University of California, Los Angeles, Los Angeles, CA, (5)Duke Center for Autism and Brain Development, Department of Psychiatry and Behavioral Sciences, Duke University, Durham, NC, (6)Center for Child Health, Behavior and Development, Seattle Children's Research Institute, Seattle, WA, (7)Yale University, New Haven, CT*

Background: Autism spectrum disorder (ASD) is a developmental disorder with complex, heterogenous etiology involving atypicalities in a variety of neural systems. Historically, electroencephalography (EEG) has been used to understand neurophysiological substrates underlying the disorder. A growing body of research is using EEG to understand the abnormalities of the resting brain in individuals with ASD. For example, research has identified differences in alpha and gamma power between individuals with ASD and typical development (TD). The manner in which atypical head circumference, a common finding in ASD, may influence EEG is poorly understood.

Objectives: (1) Characterize EEG power in the low alpha, high alpha, and gamma bands across head circumferences in school-aged children with ASD and TD. (2) Examine relationships among EEG power, head circumference, and ASD symptomatology.

Methods: Participants were children with ASD (n=133) and TD controls (n=58) aged 6-11 (Table 1). ASD diagnoses were confirmed using the Autism Diagnostic Observation Schedule (ADOS-2) and the Autism Diagnostic Interview (ADI-R). Parents completed the Social Responsiveness Scale (SRS-2), a measure of ASD symptom severity. Head circumference data obtained prior to EEG was grouped into three categories based on a standardized head circumference growth chart: small (<-1SD), average (-1SD to +1SD), and large (>+1SD). Participants viewed a resting paradigm in which non-social, abstract moving images were presented in 30 second blocks (n=6). Power spectra for low alpha (8-10 Hz), high alpha (10-12 Hz), and gamma frequency (30-55 Hz) were obtained.

Results: The age-matched ASD and TD groups showed no significant difference in their average head circumference (p>.05). Within the small head circumference group, ASD participants exhibited significantly greater low alpha power than TD participants (p=.033). This difference did not exist in the average or large head circumference groups (p>.05). Additionally, no significant differences between ASD and TD participants emerged for high alpha or gamma power in any of the three head circumference groups (p>.05). Linear regressions were used to understand the relationship between low alpha power and ASD symptom severity transdiagnostically (Table 2). Within a linear regression model, low alpha power and age explained 40.4% of the variance in SRS T-scores across all participants in the small head circumference group (R^2=.404, $F(2,12)$=4.060, p=.045). When controlling for age, low alpha power independently predicted SRS T-scores (β=.804, p=.016). However, age did not independently predict SRS T-scores (p>.05). The same model did not predict SRS T-scores in participants with average or large head circumferences (p>.05). Additionally, neither high alpha nor gamma power predicted SRS T-scores in any of the head circumference groups (p>.05).

Conclusions: Preliminary results suggest that global low alpha power at rest is distinct in individuals with ASD and TD who have head circumferences more than one standard deviation below average. Across participants in this head circumference group, low alpha power significantly predicted severity of ASD symptomatology when controlling for age. These results suggest that head circumference, specifically small head circumference, must be carefully considered when understanding the relationship between EEG spectral power and symptom severity in school-aged children with ASD and TD.

437.019 *(Poster)* Sensory Features and EEG Connectivity in Young Males with ASD

K. Sarmukadam[1]*, C. F. Sharpley*[2]*, V. Bitsika*[1]*, M. McMillan*[3] *and L. Agnew*[1]*, (1)University of New England, Armidale, NSW, Australia, (2)Brain-Behaviour Research Group, University of New England, Armidale, NSW, Australia, (3)School of Science and Technology, University of New England, Armidale, NSW, Australia*

Background: 'Sensory features' (SF), manifesting as atypical behavioural responses to sensory stimuli (Dunn, 1999; Schaaf et al., 2014), affects 90-95% of individuals with Autism Spectrum Disorder (Baranek, Little, Parham, Ausderau, & Sabatos-DeVito, 2014). SF also reflects a threshold of internal neurological and self-regulatory processes (Baum, Stevenson, & Wallace, 2015; Schauder & Bennetto, 2016). However, there are limitations upon external observation of these neurological phenomena, which may also restrict clinical and research understanding of SF and its effects. Consequently, some researchers have used psychophysiological recording techniques to study SF in ASD, including electroencephalography (EEG). Although some previous studies have inferred brain connectivity (which typically describes the strength of the communication between two EEG signals obtained from different areas of the brain) to study sensory processing via the detection of event-related potentials (ERPs) (Brandwein et al., 2013; Bruneau, Bonnet-Brilhault, Gomot, Adrien, & Barthelemy, 2003; Cascio, Woynaroski, Baranek, & Wallace, 2016; Kang et al., 2018; Marco et al., 2011; Whitehouse & Bishop, 2008), they have not directly investigated the association between neural connectivity and SF *per se*.

Objectives: To directly investigate the relationship between EEG connectivity and SF features in an *a priori*-justified sample of children and adolescents with ASD, using data obtained from a standardised scale of SF.

Methods: Forty male participants aged between 6 and 17 years, with an IQ of at least 70 and who were diagnosed with Autism Spectrum Disorder (ASD) underwent audiovisual stimulus conditions which consisted of three naturalistic videos varying in intensities of illuminance (visual) and weighted decibels (auditory). EEG responses to the low-, medium-, and high-intensity audiovisual stimulus conditions were analysed via Granger Causality (GC).

Results: At the lateral (averaged connectivity values separated by left and right hemispheres) and non-lateral (total averaged connectivity values) levels, there was a medium-sized negative relationship between the *CSP-2* Quadrants and GC between the Frontal and Temporal regions at medium beta (β2 = 18 to 23.75 Hz) and high beta (β3 = 24 to 30 Hz) frequencies. In addition, there were significant ($p < .05$) main effects between lateral right T→F using GC connectivity and dominant (i.e., participants' highest Quadrant score) Sensory Quadrant *CSP-2* scores. There were also significant ($p < .05$) main effects for non-lateral F→T and non-lateral T→F connectivity and the *CSP-2* dominant Quadrants.

Conclusions: The results above indicated deficits in neural connectivity between Frontal and Temporal brain regions, particularly in the right hemisphere, in response to varying audiovisual stimulus conditions. These findings have the potential to provide more avenues for neurophysiological interventions such as transcranial direct current stimulation (tDCS) or neurofeedback to strengthen neural connections (particularly in relation to Frontal and Temporal brain regions) and reduce the adverse effects associated with sensory features in young people with ASD.

437.020 *(Poster)* Social Perception in High-Functioning Adolescents with ASD: A MEG Study

A. Korisky[1]*, A. Goldstein*[1,2] *and I. Gordon*[1,2]*, (1)Gonda Brain Research Center, Bar-Ilan University, Ramat Gan, Israel, (2)Department of Psychology, Bar-Ilan University, Ramat Gan, Israel*

Background: Autism spectrum disorders (ASD) are neurodevelopmental conditions characterized partly by core social dysfunction, impaired social motivation and interaction. Recent discoveries highlight the impact that intranasal administration of the neuropeptide Oxytocin (OT) may have on social behavior and perception in ASD. Several brain imaging studies in individuals with ASD show OT's capacity to modulate "the social brain", however, there is a gap in the literature regarding the effect of OT on neural temporal dynamics in ASD as compared to typical developing (TD) individuals.

Objectives: This study explored brain responses to faces in adolescents diagnosed with ASD using magnetoencephalography (MEG) and the impact of OT administration on the time course of brain activity. This is the first ever study to explore OT's neural effects via MEG in children with ASD. As a first stage in our research, following previous studies that examined social perception we focused on the M100, M170 and M250 components which tend to show atypical patterns in ASD. We hypothesized that OT will modulate the amplitudes of the above components so that they resemble those of an aged matched TD group.

Methods: We present data from 28 adolescents with ASD (aged 12-18), who received a single dose of intranasal OT (24IUs) in a double-blind placebo-controlled study. Forty-five minutes following administration, participants were scanned in the MEG. During each scan participants were presented with pictures of emotional eyes or vehicles and asked to identify the picture theme. Twenty-five TD aged-matched individuals served as a comparison group. For ethical reasons, TD participants did not receive OT/placebo.

Results: Whole head analysis revealed significant differences in the M170 component between TD and ASD groups with TD showing higher amplitude in response to the social stimuli. We also found marginal group differences in M100 amplitude, mainly over posterior sensors. In this specific analysis for the mentioned components we did not find effects for OT.

Conclusions: Our study provides evidence for distinct patterns of neural activity in response to social stimuli in ASD individuals. In this preliminary analysis, and contrary to our hypothesis, we did not find major effects of OT on the components tested here. However, since OT effects tend to be subtle, more detailed analyses will follow.

437.021 *(Poster)* Tactile Processing in Children with ASD: A Behavioral and Electrophysiological Study

G. Kadlaskar[1]*, S. Bergmann*[1]*, R. McNally Keehn*[2]*, A. Seidl*[1] *and B. Keehn*[1]*, (1)Speech, Language, and Hearing Sciences, Purdue University, West Lafayette, IN, (2)Indiana University School of Medicine, Indianapolis, IN*

Background: Touch plays a key role in facilitating social communication. Individuals with autism spectrum disorder (ASD) show atypical tactile responsivity, which is associated with increased ASD symptomatology. However, the neural mechanisms associated with responsivity to touch in ASD remain unknown. Additionally, it is unclear whether tactile cues may facilitate behavioral responses in individuals with ASD (as is observed with visual and auditory cues). The current study investigates the neural indices of tactile processing in children with ASD and how these relate to behavioral response patterns.

Objectives: (1) To identify neural processes underlying novel tactile stimulation and determine whether tactile cues facilitate behavioral responses in ASD. (2) To examine the relationship between neural and behavioral indices of touch-related processing and socio-communicative impairments in ASD.

Methods: To date, participants include 8, 6-to-12-year-olds with ASD and 14 age- and non-verbal IQ matched typically-developing (TD) children (Projected N= 20 ASD; 20 TD). ASD diagnoses are confirmed using the ADOS-2 and the SCQ. Caregivers also complete the SRS-2. For the neural task, children participate in an ERP oddball paradigm during which they watch a silent video while being presented with auditory and tactile stimuli (i.e., 80% standard speech sound /a/; 10% oddball speech sound /i/; 10% novel vibrotactile stimuli on the fingertip with standard speech sound /a/; Figure 1). Participants also complete a behavioral tactile-cueing task in which they are instructed to respond with a button press to a target speech sound. Tactile cues are presented at 200, 400, and 800ms (25% each) prior to the onset of the target sound. The remaining trials (25%) are presented without tactile cues.

Results: For the ERP task, preliminary analyses suggested that there was a significant main effect of ROI (frontal, central, parietal) (p<.001), and an interaction between Condition (standard, oddball, novel) and ROI (p<.001). N2b amplitudes in response to novel touch were greater in the frontal compared to central and parietal ROIs (p<.001). However, there were no between-group differences (p=.93; Figure 2). In the ASD group, there was a negative correlation between frontal N2b amplitudes to novel touch and SRS-2 scores (p=.02). Results of the behavioral tactile-cueing task showed that there was a main effect of Cue Interval (no cue, 200, 400, 800ms; p<.001), but no main effect of Group (p=.35) or interaction between Cue Interval and Group (p=.84). Last, in the ASD group, behavioral facilitation to tactile-cues was not related to neural indices of tactile processing or ASD symptomatology.

Conclusions: Children in both the ASD and TD groups responded to perceptual novelty as indicated by increased N2b amplitudes in response to novel tactile stimulation. Presentation of tactile-cues facilitated behavioral performance in both groups. In the ASD group, decreased response to perceptual novelty was associated with increased ASD symptomatology. Preliminary results indicate that children with ASD may show similar performance in detecting novel tactile stimuli and in using tactile-stimulation as cues to facilitate behavioral performance compared to TD children. Last, reduced neural response to perceptual novelty may be related to increased socio-communicative impairments in ASD.

437.022 *(Poster)* Testing 1/f As a Proxy Marker of E/I Ratio in EEG Using Arbaclofen: Evidence from Adults with and without Autism Spectrum Condition (ASC)

C. L. Ellis[1]*, J. Ahmad*[1]*, A. Zoumpoulaki*[2]*, H. E. Velthuis*[3]*, A. C. Pereira*[3]*, N. M. Wong*[4]*, M. Dimitrov*[5]*, L. Kowalewski*[3]*, E. Daly*[6]*, E. McGregor*[7]*, P. Garces*[8]*, D. G. Murphy*[1] *and G. M. McAlonan*[9]*, (1)Forensic and Neurodevelopmental Sciences, Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, United Kingdom, (2)Cardiff University, Cardiff, United Kingdom, (3)Department of Forensic and Neurodevelopmental Sciences, Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, United Kingdom, (4)Biomedical Research Centre for Mental Health at the Institute of Psychiatry, Psychology and Neuroscience and South London and Maudsley NHS Foundation Trust, London, United Kingdom, (5)Forensic and Neurodevelopmental Sciences, Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, United Kingdom, (6)Department of Forensic and Neurodevelopmental Sciences, Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, United Kingdom, (7)University of East London, London, United Kingdom, (8)Neuroscience, Ophthalmology, and Rare Diseases (NORD) Roche Pharma Research and Early Development. Roche Innovation Center Basel, Hoffmann-La Roche, Basel, Switzerland, (9)NIHR-Biomedical Research Centre for Mental Health at the Institute of Psychiatry, Psychology and Neuroscience, South London and Maudsley Foundation NHS Trust, London, United Kingdom*

Background: Excitatory (E) glutamate signalling and Inhibitory (I) GABA signalling ensure efficient information processing in the brain. E-I regulation is thought to be disrupted in neurodevelopmental conditions such as autism spectrum condition (ASC). However, methods for investigating E-I systems in the living human brain, such as positron emission tomography (PET) and magnetic resonance spectroscopy (MRS), are predominantly invasive and/or expensive, constraining their general application. In contrast, EEG is a cheap and non-invasive method that can reveal subtle alterations in brain oscillating activity. As the frequency of these oscillations increases, their power decreases; this relationship is captured in the 1/f frequency spectrum. Evidence from computational modelling and animal studies suggest that this 1/f exponent is a proxy of E/I ratio. However, we do not know if this translates to typical humans, let alone those with a neurodevelopmental condition, namely ASC.

Objectives: In this Proof-of-Concept study we tested the hypothesis that there would be a correlation between 1/f and MRS measures of E/I ratio in ASC and Typically Developing (TD) individuals. We then examined whether this 1/f measure was sensitive to (i.e. correlated with) a shift in E/I, elicited by the GABAB receptor agonist Arbaclofen, in TD and ASC individuals.

Methods: Participants were 15 ASC males (M_{age}: 29.09 years) and 12 TD males (M_{age}: 33.19 years). Using MRS, we quantified GABA+macromolecules (GABA+), Glutamate+Glutamine (Glx) and E/I ratio (Glx/GABA+) levels in the medial occipital cortex (mOCC). We further conducted EEG recordings during an auditory odd-ball paradigm. Data were collected at baseline (after placebo) and following a single dose of 30mg of Arbaclofen. EEG data were segmented into 4 consecutive standard tones lasting 24 seconds. Power Spectral Density (PSD) slopes were extracted and a regression line was fitted to the PSD slopes to characterize the 1/f slope function. We examined the association between MRS metrics and 1/f at baseline, and after pharmacological challenge across the entire sample, as well as within each group separately.

Results: Across groups, baseline 1/f measures correlated significantly with MRS metrics of E/I (r=-0.470, p=0.013). Similarly, across groups, the drug-induced shifts in 1/f and E/I correlated significantly (r=0.365, p=0.034). Our sample size precluded further analyses of group differences between correlations but an initial post-hoc analysis within each group suggested that the relationship between E/I shift and 1/f change appeared to be driven primarily by the neurotypical control group, (r=0.649, p=0.005), and was not statistically significant in the ASC group (r=0.130, p=0.618).

Conclusions: Here, we provide Proof-of-Concept that 1/f correlates with MRS metrics of E/I at baseline and is sensitive to change. This metric may thus be a non-invasive, candidate proxy marker of E/I. Our observation of a qualitatively stronger relationship between E/I and 1/f shift in TD group compared to the ASC group might indicate a difference in the E/I control of the activity underpinning 1/f in ASC and will be examined during the on-going data collection.

437.023 *(Poster)* The Respiratory Sinus Arrhythmia in Young Children with Developmental Delay and Prominent Features of Autism Spectrum Disorder: A Follow-up Study

A. Kylliainen[1]*, J. Lauttia*[2]*, K. Eriksson*[3] *and T. M. Helminen*[4]*, (1)Faculty of Social Sciences/Psychology, Tampere University, Tampere, Finland, (2)Faculty of Social Sciences/Psychology, Tampere Univeristy, Tampere, Finland, (3)Tampere University and Tampere University Hospital, Tampere, Finland, (4)Faculty of Social Sciences/Psychology, Tampere University, Tampere, Finland*

Background: Respiratory sinus arrhythmia (RSA) i.e., heart rate variability in synchrony with respiration has been associated to social engagement and emotion regulation. Earlier research has found lowered RSA in cognitively able adults, adolescents and school-aged children with ASD and it has been suggested as one of the potential biomarkers for ASD. There have, however, been also contradictory findings showing no ASD specific differences in RSA, especially in young children with ASD and intellectually impaired children with ASD. In addition, it is not clear how stable the atypical RSA findings are in development of ASD.

Objectives: The aim of the study was to investigate longitudinally baseline RSA in young children with developmental delay and prominent features of ASD. To ensure that the possible abnormal findings were autism-specific, the RSA were measured also from a developmental-age matched comparison group of children with developmental delay (DD) without ASD and from a normative comparison group of age-matched typically developing children (TD).

Methods: The sample of 47 children (14 children with ASD, 17 TD children and 16 children with DD) participated in the study. Every group included 2 girls and the age ranged from 29 to 81 months. ADOS-2 and ADI-R evidenced prominent features of ASD and IQ estimate ranged between 45 to 88. The follow-up after two years consisted of 43 children (14 ASD, 17 TD & 12 DD children). Heart rate was measured whilst the children looked at a neutral video about a person building with blocks for 3 minutes. Data was carefully offline video analysed in order to reject artefacts. Measurement segments for the analyses varied between 54-169 seconds. There were no significant differences in the length of the segments between the groups. RSA was analysed in 0.24–1.04 Hz using a Matlab-based in-house program.

Results: The findings revealed significant difference in RSA between the groups at the initial (Kruskal-Wallis H = 6.324, $p = .042$) and tendency of difference at the follow-up (Kruskal-Wallis H = 5.355, $p = .069$) measurement. Paired comparison revealed that the children with ASD had significantly lower RSA than TD children and children with DD in both time points. There were no differences in RSA between TD and DD children in either of the time points (Figure 1). There was a tendency of increase in RSA during the two-year follow-up period all the children (Z = -1.652 $p = .099$). There was a strong correlation in RSA between the first and the follow-up measurement (r = .807, $p = .000$).

Conclusions: The findings suggested that lowered RSA is detectable in young children with developmental delay and prominent features of ASD, and seems to show ASD specificity. The findings showed that baseline RSA seemed to be constant measure within an individual. Future studies with larger sample size could examine whether RSA has predictive value of different developmental trajectories.

437.024 *(Poster)* Variation in Early Vocal Emotion ERPs By Age and Autism Symptom Severity

T. C. Day[1]*, K. M. Hauschild*[1] *and M. D. Lerner*[2]*, (1)Psychology, Stony Brook University, Stony Brook, NY, (2)Department of Psychology, Stony Brook University, Stony Brook, NY*

Background: Evidence suggests that the ability to identify another's emotion from prosodic cues, vocal emotion recognition (VER), is impaired for some individuals with ASD (Fridenson-Hayo et al., 2016; Globerson et al., 2014). However, relatively little is known about the neural underpinnings of this impairment or its emergence across development. Previous work suggests an ensemble of early event-related potentials (ERPs; N100, P200, N300) are implicated in VER, reflecting attention to vocal stimuli, integration of prosodic acoustic cues, and early emotional evaluation, respectively (Paulmann et al., 2009; Paulmann & Kotz 2008). A small literature has examined these in ASD, suggesting the N100 may differ (Korpilathi et al., 2007) and be associated with decreased VER behavioral task performance (Lerner, McPartland & Morris, 2013) in this population. These components have likewise been associated with corresponding ERPs in the facial emotion recognition domain (Lerner et al., 2013), wherein ample research suggests the N170 face-responsive component gets faster with age and is delayed as a function of ASD symptoms (Kang et al., 2018). However, little is known about how these VER-related ERPs may vary by age or ASD symptom severity. Such understanding is crucial for disentangling whether processes underlying VER are modality-specific, or reflect more general underlying differences in processing social-emotional information.

Objectives: To examine whether age and ASD severity are related to N100, P200, N300 ERP responses to a VER task.

Methods: 108 adolescents and adults with and without ASD completed a standardized VER task while electroencephalography (EEG) was recorded (Table 1; Figure 1). A mixed ASD and non-ASD sample was used to maximize variation in ASD symptomology and, thus, consequent relations with the target ERPs. ASD symptom severity was measured by the Autism Diagnostic Observation Schedule-2 (ADOS-2; Lord et al., 2012) comparison score (CS; Gotham, Pickles, & Lord, 2009; Hus & Lord, 2014). Pearson correlations were used to examine variation in ERP (N100, P200, and N300) responses during the VER task by participant age and ASD symptom severity.

Results: Faster N100 latency was associated with lower autism symptom severity (r(108)=.192, p<.05). Larger P200 amplitude was related to younger age (r(108)=-.370, p<.01). No associations with the N300 emerged.

Conclusions: Consistent with prior work (Lerner & McPartland, 2013; Korpilathi et al., 2017), a slower N100 latency was associated with greater ASD symptom severity suggesting possible decreased attention to emotional prosodic cues. Additionally, smaller P200 amplitude was related to older age indicating that the processing of emotional information may require more effort for adolescents than adults (Garrido-Vásquez et al., 2013). Taken together, these findings suggest that initial orientation to vocal emotions may be delayed for individuals with greater ASD symptom severity and that efficient emotional salience detection likely continues to develop through adolescence into adulthood. Furthermore, VER-related ERP responses did not differ by ASD diagnostic status thus reflecting a continuity in processing vocal emotion information across ASD and non-ASD populations.

Neuropsychology

POSTER SESSION — **NEUROPSYCHOLOGY**
438 - Neuropsychology Posters

438.001 *(Poster)* A Pilot Study on Executive Functioning in Mainland Chinese Autistic Preschoolers

***V. Zhou**, J. Strom, K. Drafton and B. J. Wilson, Seattle Pacific University, Seattle, WA*

Background: There is a robust literature on the positive benefits of executive functions (EFs) on academic (Blair & Razza, 2007; Bull, Epsy, & Weibe, 2008; Clark, Pritchard, & Woodward, 2010) and social-emotional development (Carlson & Wang, 2007) in neurotypical preschool- and school-aged children from Western countries. Studies over the last two decades also offer emerging support for higher EF ability in East Asian children compared to same-aged peers in the US (Imada, Carlson, & Itakura, 2013; Lan, Legare, Ponitz, Li, & Morrison, 2011) and UK (Ellefson, Ng, Wang, & Hughes, 2017; Oh & Lewis, 2008). Given the social and academic challenges experienced by autistic individuals, there is great interest in furthering our understanding of EF in this population. However, there is mixed evidence regarding EF dysfunction in autism (Faja & Dawson, 2014; Griffith, Pennington, Wehner, & Rogers, 1999; Pellicano et al., 2014) and very few studies have investigated EF skills in East Asian autistic children. Further research is necessary to understand the EF profile of East Asian autistic children.

Objectives: The purpose of this study was to compare whether preschool-aged, autistic children and neurotypical peers in mainland China differed on iPad-delivered measures of EF, specifically inhibitory control, visuospatial working memory, and cognitive flexibility.

Methods: Forty-nine, 36- to 83-month-old preschoolers in Beijing, China participated in this study. The sample included 21 autistic preschoolers and 28 age- and sex-matched neurotypical preschoolers. Eligibility criteria included a Verbal Comprehension Index (VCI) score above 70 on the Weschler Preschool and Primary Scales of Intelligence – Fourth Edition (WPPSI-IV; Weschler, 2012). All autistic children had a clinical diagnosis of autism spectrum disorder from a child psychiatrist based on DSM-5 criteria and no other comorbid neurodevelopmental disorders. Children were administered an iPad-based EF assessment battery (Go/No-Go, Mr. Ant, and Card Sort tasks) from the Early Years Toolbox (EYT; Howard & Melhuish, 2017) to measure inhibitory control, working memory, and cognitive flexibility. Linear regression analyses were conducted to evaluate the unique associations between autism and inhibitory control, working memory, and cognitive flexibility.

Results: Diagnostic status significantly predicted inhibitory control (B = -0.19, $t(47)$ = -2.96, $p < .001$, working memory (B = -0.88, $t(47)$ = -4.27, $p < .001$), and cognitive flexibility (B = -3.50, $t(47)$ = -3.52, $p < .001$). Specifically, neurotypical children outperformed autistic children on all EF tasks.

Conclusions: This study provides preliminary evidence for EF impairment in Chinese autistic preschoolers compared to neurotypical peers. It is also the first study to utilize iPad-administered tasks to assess for EF in young autistic children. Currently, early intervention for Chinese autistic children focuses largely on core autistic symptoms. However, it is evident that autistic preschoolers may benefit from accommodations and interventions that support their EF challenges. Further research on the efficacy of EF interventions for autistic preschoolers is needed. Cross-cultural studies are also needed to determine the generalizability of these findings to other preschool populations.

438.002 *(Poster)* Behavioral and Neural Profiling of School-Aged Children and Adults with Non- or Minimally Verbal Autism Spectrum Conditions (ASC)

***D. Slušná**[1], E. Canales-Rodríguez[2], A. Rodríguez[3], B. Salvado[4], E. Càmara[5], A. Gómez[5], A. Rodriguez-Fornells[5], J. Muchart[6] and W. Hinzen[7], (1)Universitat Pompeu Fabra-CIBERER, Barcelona, Spain, (2)Fundació per a la Investigació i la Docència Maria Angustias Giménez (FIDMAG), Barcelona, Spain, (3)COADI, Barcelona, Spain, (4)COADI, BARCELONA, SPAIN, (5)Cognition and Brain Plasticity Group, Bellvitge Biomedical Research Institute (IDIBELL), Barcelona, Spain, (6)Department of Pediatric Neurology, Hospital Sant Joan de Deu, Barcelona, Spain, (7)Department of Translation and Language Sciences, Universitat Pompeu Fabra, Barcelona, Spain*

Background: Up to 30 % of individuals with ASC are estimated to remain non- or minimally verbal throughout their lifetime. Due to difficulties in assessment, little is known about their neuropsychological and neuroanatomical profile.

Objectives: To explore cognitive variability in this population using a series of behavioural - linguistic and non-linguistic - standardised measures and, in a subset, the neural basis of absence of language using a structural and functional MRI-protocol.

Methods: 48 children and adults (chronological age, CA, range=5;11 – 57;1, M=20;3) participated in this study. ASC diagnosis was confirmed with ADOS-2 or ADOS-Adapted and, in the case of 24 participants, the ADI-R as well. Their non- or minimally verbal status was determined on the basis of the vocalisations produced during the ADOS assessment. Depending on the type and number of vocalisations, the participants were classified as either having less than 5 words (N=29) or more than 5 words or simple phrases (N=19). Standardised tests were applied to determine their verbal mental age (VMA) (PPVT-III), nonverbal IQ (Leiter-R), and capacity of forming abstract mental representations of daily objects (ComFor). A structural and functional MRI-protocol was applied to 8 children of the sample under propofol sedation, using a protocol that has previously demonstrated that neural responses to auditory stimuli can still be detected. We targeted the integrity of language-related white matter tracts and neural responses to heard speech and reversed-speech.

Results: The neuropsychological profiling yielded floor-level variation VMA (M=1;11, SD=1;3) and nonverbal IQ (NVIQ; M=50, SD=17). Approximately 92% of the sample had intellectual disability (ID, defined as NVIQ<70). Participants' ComFor scores fell into three levels (a) no attribution of meaning to objects (N=11), attribution of functional meaning (N=15), attribution of generic meaning (N=18). Correlational analyses showed that variability in abstraction levels was significantly related to VMA ($r_s(44)=.660$, p=.01), and to NVIQ ($r_s(44)=.521$, p=.01), while VMA and NVIQ did not correlate ($r_s(48)=.156$), as assessed by Mann-Whitney sign rank tests. When dividing the group by productive language (having less or more than 5 words), differences showed between them in both VMA (U=459,5, d=1,352, p<.005) and ComFor (U=357,5, d=1,226, p<.005), but not CA. All seven participants participating in the MRI study showed anomalous right lateralisation of fractional anisotropy scores in the arcuate fasciculus (t-test: p=0.0312; Wilcoxon signed-rank test: p=0.0156). They also showed neural BOLD responses to speech condition in the canonical language network at p=.01 uncorrected. When activations to reverse speech were subtracted from normal speech, only three children maintained, although diminished, language-network activations.

Conclusions: Near-absence of language development is accompanied by floor level nonverbal IQ and language comprehension, though some variation remains. A residual capacity to form abstractions covaries with both word comprehension and nonverbal IQ, and improves with even minimal language production differences. Differences in white matter language-related connectivity and failure to recognise the difference between forward and reversed speech in most but not all individuals, suggest fundamental differences in language organisation in the brain.

438.003 *(Poster)* Characterizing the Executive Functioning Profile of Females with ASD, ADHD, and Comorbid ASD+ADHD

*L. A. Katz[1], **N. Berger**[2], A. Davis[3] and E. Chin[3], (1)Psychology, Roosevelt University, Chicago, IL, (2)Rush University Medical Center- AARTS Center, Chicago, IL, (3)AMITA Health Neurosciences Institute, Hoffman Estates, IL*

Background: Executive functioning (EF) deficits are well established both in individuals with Autism Spectrum Disorder (ASD; O'Hearn et al., 2008) and Attention-Deficit/Hyperactivity Disorder (ADHD; Willcutt et al., 2005). While findings vary depending on methodology, overall, children with ASD tend to present with more difficulties in cognitive flexibility, whereas problems with inhibitory control are typically more pronounced in children with ADHD (Antshel & Russo, 2019). Children with comorbid ASD+ADHD generally present with more significant EF problems with characteristic deficits of both disorders (Craig et al., 2016). However, research characterizing EF in these populations is biased by use of participant samples that are predominantly male. Given research identifying sex differences in ASD symptomatology, it is important to determine whether the extant research characterizing patterns of EF deficits across ASD and ADHD is representative of females with these diagnoses.

Objectives: This study is the first, to our knowledge, that characterizes and compares the specific EF profile of females with ASD, ADHD, and ASD+ADHD. It was hypothesized that females with ASD+ADHD will exhibit more pronounced EF deficits compared to participants with ASD or ADHD only.

Methods: Participants included 200 females (8-18 years) diagnosed with ASD only (n=20), ADHD only (n=150), or comorbid ADHD+ASD (n=30). EF was assessed via parent report on the Behavior Rating Inventory of Executive Function, 2nd Edition (BRIEF-2; 9 subscales), as this measure has been identified as having greater ecological validity than performance based measures of EF, particularly in ASD (Kenworthy et al., 2008).

Results: A MANCOVA with IQ as covariate identified a main effect of group on EF. Follow-up ANCONVAs showed significant differences on Inhibit, Shift, Plan/Organize, and Task-Monitor subscales. Post-hoc multiple pairwise comparisons using adjusted means and Bonferroni correction indicated that on the Inhibit and Shift subscales, ADHD+ASD was more impaired compared to ADHD only. On the Plan/Organize and Task Monitor subscales, ADHD+ASD was more impaired compared to ASD only.

Conclusions: Paralleling prior work with predominantly male samples, we found that females with ASD+ADHD exhibited a more severe EF profile compared to females with ASD or ADHD alone. However, the pattern of specific EF deficits observed across groups differed compared to what would be expected based on research with male participants. Unlike prior research, we found no significant differences when comparing EF profiles of girls with ADHD only and ASD only. This suggests a greater degree of overlap in EF deficits across diagnostic groups in females compared to males. Further, while research with ASD+ADHD males has typically found that this group shares deficits in shifting and flexibility with ASD and inhibition with ADHD, we instead found that ASD+ADHD females shared deficits in shifting and inhibition with ASD and deficits in planning and monitoring with ADHD. This study is the first to identify unique EF profiles in females with ASD, ADHD, and ADHD+ASD, and underscores the importance of explicitly targeting females in research characterizing neurocognitive phenotypes of ASD and ADHD.

438.004 *(Poster)* Characterizing the IQ-Adaptive Functioning Gap in Autistic and Typically-Developing Girls and Boys

G. A. McQuaid[1], *G. L. Wallace*[2], *A. Jack*[2], *K. Ankenman*[3], *E. H. Aylward*[4], *R. Bernier*[5], *S. J. Webb*[5], *J. Eilbott*[6], *J. McPartland*[7], *P. E. Ventola*[6], *J. Wolf*[7], *C. A. Nelson*[8], *T. Apelian*[9], *K. Best*[10], *S. Y. Bookheimer*[11], *M. Dapretto*[11], *Z. Jacokes*[12], *J. Van Horn*[13] *and K. A. Pelphrey*[14], *(1)George Mason University, Fairfax, VA, (2)The George Washington University, Washington, DC, (3)University of California San Francisco, San Francisco, CA, (4)Seattle Children's Research Institute, Seattle, WA, (5)Psychiatry and Behavioral Sciences, University of Washington, Seattle, WA, (6)Yale Child Study Center, Yale University School of Medicine, New Haven, CT, (7)Child Study Center, Yale University School of Medicine, New Haven, CT, (8)Boston Children's Hospital/Harvard Medical School, Boston, MA, (9)UCLA CAN Clinic, Los Angeles, CA, (10)University of California, Los Angeles, CA, (11)Dept of Psychiatry and Biobehavioral Sciences, University of California, Los Angeles, Los Angeles, CA, (12)Georgia Institute of Technology, Atlanta, GA, (13)University of Southern California, Los Angeles, CA, (14)University of Virginia, Charlottesville, VA*

Background: Cognitively-able individuals with autism spectrum disorder (ASD) show a gap between IQ and adaptive functioning, or the skills critical to successful independent living. This gap suggests cognitive skills captured by IQ do not serve to bolster adaptive skills among autistic individuals without an intellectual disability. Further, there is increasing evidence that this gap between intellectual potential and adaptive functioning widens with age, and is associated with markers of poor outcome, including greater autistic symptomatology and elevated rates of co-occurring psychopathology.

Objectives: The IQ-adaptive functioning gap has been documented in predominantly male ASD samples; therefore, it is unknown if such a gap exists among ASD girls, and if so, whether the gap differs from ASD boys. Additionally, it is unknown whether the gap is found in typically developing (TD) individuals. To address these understudied aspects of the IQ-adaptive functioning gap, we leverage a unique, sex-balanced sample of ASD and TD youth.

Methods: We assessed 177 ASD (mean age: 12.5±2.9; 75 female) and 178 TD (mean age: 13.0±2.9; 87 female) youth 8 to 17y with full-scale IQ (FSIQ)>70. Expert clinicians confirmed ASD diagnoses using the Autism Diagnostic Observation Schedule, Second Edition and the Autism Diagnostic Interview-Revised. Parents of participants reported on their children's adaptive skills (Vineland Adaptive Behavior Scales-II [VABS-II]). FSIQ was estimated using participants' General Conceptual Ability Standard Scores on the Differential Abilities Scales-II. Difference scores between estimated FSIQ and the VABS-II Adaptive Behavior Composite score were calculated for each group as a measure of the IQ-adaptive functioning gap.

Results: One-sample *t*-tests showed the IQ-Adaptive functioning gap differed significantly from zero for each group (ASD girls: t=11.3, p<.001; ASD boys: t=15.7, p<.001; TD girls: t=4.4, p<.001; TD boys: t=9.8, p<.001). Groups did not differ in age (F=1.49, p=.22). Collapsing across sexes within each diagnostic group, the IQ-adaptive functioning gap is positively associated with age (ASD: r_s=.21, p<.01; TD: r_s=.25, p<.001); however, considering the sexes separately, this association appears to be driven by ASD boys (r_s=.19, p<.05) and TD girls (r_s=.29, p<.05), with non-significant associations for ASD girls and TD boys. An ANCOVA controlling for age revealed a main effect of group (F=30.6, p<.001), but no main effect of sex (F=0.91, p=.34), and no group by sex interaction (F=1.9, p=.17). Post-hoc follow-up tests indicated both ASD girls (t=-5.5, p<.001) and boys (t=-4.0, p<.001) showed a greater IQ-adaptive functioning gap than their same-sex TD counterparts.

Conclusions: Corroborating the extant literature, ASD youth show a greater IQ-adaptive functioning discrepancy than their same-age TD peers, and this discrepancy widens with age. However, we provide novel evidence for a smaller but significant gap occurring in TD youth as well. Additionally, *both* autistic girls and boys demonstrate a greater discrepancy in IQ-adaptive functioning than their same-sex TD peers. Fully characterizing the discrepancy between IQ and adaptive functioning in ASD girls and boys promises to yield a better understanding of factors that contribute to or are consequent of difficulties in independent living despite high intellectual potential in cognitively-able autistic individuals.

438.005 *(Poster)* Comparing the Cognitive Flexibility of Adolescents with Intellectual Developmental Disorder (IDD) with and without Autism

S. Lung *and A. Bertone, McGill University, Montreal, QC, Canada*

Background: Rigidity is one of the core diagnostic features of autism and is related to difficulty with cognitive flexibility (i.e., CF; the ability to move freely between information, concepts or tasks). A review of 122 studies which assessed CF in autism reveals inconsistent findings, contingent on the choice of CF measures and participant characteristics (Lung et al., in prep.). Studies that use performance-based tasks (e.g., Wisconsin Card Sorting Task; WCST) to assess CF were more discordant about the presence of CF difficulty in autism than studies that use questionnaire-based assessments (e.g., Behavioural Rating Inventory of Executive Function; BRIEF). Moreover, most of the studies concluded findings based on comparisons of autistic children and adults against their typically developing peers (111 studies), as well as on autistic participants with average or above intelligence (117 studies), see *Tables 1 and 2*. CF studies that focus on autistic adolescents with comorbid intellectual developmental disorder (ASD-IDD) remain scarce.

Objectives: Given the scarcity of CF studies on autistic adolescents with intellectual developmental disorder identified from the review of 122 related studies, this study aims to examine CF of adolescents diagnosed with ASD-IDD by comparing their CF abilities with adolescents with IDD but no autism.

Methods: Thirty-nine adolescents diagnosed with IDD, M_{age} = 14.65 (1.08), M_{FSIQ} = 53.15 (9.65) were recruited; fourteen of whom also had an autism diagnosis (ASD-IDD). They completed the computerized WCST since it was found to be the most frequently used measure of CF (41 of the 122 studies; or 34% of studies) in the review. Both ASD-IDD and IDD groups were matched for chronological age and Full-Scale IQ measured by Wechsler Abbreviated Intelligence Scale – Second Edition (WASI-II). T-test was used to compare between-group difference in WCST performance and Pearson correlation was used to examine the relationship between WASI-II and WCST performance in each group.

Results: Between-group comparison between the autistic (ASD-IDD) and non-autistic (IDD) groups suggested no CF difference, $t_{perseverative\ errors}$ (36.818) = -.571, p = .571 and $t_{conceptual\ responses}$ (37) = .053, p = .958. Despite the comparable between-group performance on CF, relationship between cognitive abilities and WCST performance differed between groups. Notably, a positive relationship between fluid reasoning abilities (as measured in Matrix Reasoning subtest "MR" of WASI-II) and WCST performance is only found in the ASD-IDD group, $r_{MR\text{-}perseverative\ errors}$ (14) = -.644, p = .013; $r_{MR\text{-}conceptual\ responses}$ (14) = .621. Interestingly, it was the verbal categorical skills (as measured in Similarities subtest "SI" of WASI-II) that was positively associated with higher conceptual responses for in the IDD group, $r_{SI\text{-}conceptual\ responses}$ (25) = .399, p = .048.

Conclusions: Given respective CF difficulty in IDD and ASD, no aggregate CF deficit was found in the ASD-IDD group. This may be explained by the limited detectability of variances in CF in extremity of cognitive functioning, and/or floor effect of standardized tests. Moreover, the ASD-IDD group may be more dependent on nonverbal skills compared to the IDD group while making conceptual responses.

438.006 *(Poster)* Dual Language Learning Does Not Hinder Cognitive Functioning in Youth with Autism Spectrum Disorder

*G. Reimann[1] and **A. B. Ratto**[2], (1)National Institute of Mental Health, Bethesda, MD, (2)Center for Autism Spectrum Disorders, Children's National Hospital, Washington, DC*

Background: Dual-language learning has been associated with advantages in cognitive skills and executive functioning (EF) in neurotypical individuals (Barac et al., 2014). Yet, families are routinely told by providers to avoid dual-language exposure in individuals with Autism Spectrum Disorders (ASD), due to concerns about hindering language and cognitive development (Yu, 2013). However, few studies have systematically evaluated the effects of dual-language learning on cognitive development in youth with ASD.

Objectives: To assess the hypothesis that among youth with ASD, dual language learners (DLL) will show no deficits in broad cognitive skills (IQ) and advantages in EF relative to monolinguals

Methods: Participants were drawn from a sample of >2,000 individuals (ages 6-25) seen for neuropsychological testing through clinical and research evaluations at a center specializing in ASD in the Washington, DC metropolitan area. A final sample was identified (n=354) who met Lainhart criteria for ASD and had known language learning history. Participants were designated as monolingual if they had no or very minimal exposure to a second language, and as DLLs if they had substantial exposure ($\geq$30%) to a language other than English. All participants were tested in English only and considered English dominant at the time of testing. Socioeconomic status (SES) was ordinally-defined as highest level of parent education achieved, where lower numbers indicate higher education. Full-scale IQ and verbal and nonverbal reasoning were assessed by a standardized IQ measure (e.g., Wechsler Intelligence Scale for Children). Global EF was assessed via parent report on the Behavior Rating Inventory of Executive Functioning (BRIEF). Verbal working memory was evaluated via the Sentence Memory subtest of the Wide Range Assessment of Memory and Learning-2 (WRAML-2). Independent sample t-tests were used for initial comparisons of DLLs (n = 75) and monolinguals (n = 279), followed by multiple linear regression analyses to control for the effects of gender, age, and SES.

Results: DLLs scored significantly lower on unadjusted comparisons of verbal IQ (t=2.12, p = 0.04) and verbal working memory (t=*2.38,* p = 0.02) and showed trend-level advantages in global EF (t=1.86, p=.07). However, when adjusting for the effects of age, gender, and SES using multiple linear regression, cognitive and EF skills were not predicted by language learning status. SES significantly predicted WRAML Sentence Memory (*β= -.68, t= -2.17, p=.03*) and predicted verbal IQ at the trend level (*β= -5.87, t= -1.76, p=.08*), such that higher SES was associated with better performance. DLL status was associated with reduced EF deficits at the trend level (*β= -5.25, t= -1.84, p=.07*).

Conclusions: Findings show dual-language exposure does not impair cognitive skills in youth with ASD and may show EF advantages. Future studies are needed to explore these findings, using additional performance-based measures of EF and other neuropsychological domains, and to monitor cognitive development of autistic DLLs longitudinally. Preliminary findings suggest that families should not be discouraged from exposing autistic youth to multiple languages.

438.007 *(Poster)* White Matter Structure Relates to Delayed Processing Speed for the Planning Task and in ASD without Intellectual Disability.

***M. Takahashi**[1], Y. Matsubara[2] and K. Nakamura[2], (1)Research Center for Child Mental Development, Graduate School of Medicine, Hirosaki University, Hirosaki, Japan, (2)Department of Neuropsychiatry, Graduate School of Medicine, Hirosaki University, Hirosaki, Japan*

Background: Impaired executive function has been well demonstrated in individuals with autism spectrum disorder (ASD). However, many neuroimaging studies for examining executive function in ASD and neural correlates have not been adequately considered symptoms and diagnosis of Attention-deficit hyperactivity disorder (ADHD), although ADHD has been able to diagnose in individuals with ASD from DSM-5 (2013).

Objectives: The aim of this study is to examine dysfunction and neural basis of executive function in individuals with ASD after controlling ADHD symptoms adequately.

Methods: We used a test battery that is consisted of 8 neuropsychological tests for comprehensibly assessing various executive function domains including planning, set-shifting, flexibility, cognitive control, and divergent thinking. Some of the neuropsychological tests were conducted on a PC tablet using a cloud-based test, namely CANTAB and measured performance speed besides performance results. Additionally, we collected T1 weighted image and diffusion tensor imaging (DTI) with a 3T scanner. Analyses of neuroimaging data were conducted cloud-based system (MRI cloud). These data acquired form 11 individuals with ASD having no intellectual disabilities (ID) (FSIQ $\geq$ 80) and 37 sex-, handedness and intelligence matched neurotypical subjects (NT).

Results: When controlling ADHD symptoms, individuals with ASD did not show a lower performance of any neuropsychological tests. Whereas, it was observed a slower performance speed on the test of One Touch Stockings of Cambridge (OTSC) that measure planning domains of executive function compared to NT ($p < 0.0049$). In the comparison of T1 weighted image data, individuals with ASD showed reduced gray matter volume of the right middle frontal gyrus and right inferior temporal gyrus and increased white matter volume of the right superior frontal gyrus. In the DTI, individuals with ASD exhibited lower fractional anisotropy value in the right precentral gyrus and the temporal part of the right superior longitudinal fasciculus (all $p < 0.005$). Then, partial correlation analyses showed that white a matter volume of the superior frontal gyrus positively correlated a performance speed on the OTSC (partial correlation $r = 0.514$, $p < 0.001$), indicating a larger white matter volume of the superior frontal gyrus associated with a slower performance speed on the planning task. These results suggest that an abnormality of white matter structure in the right superior frontal gyrus closely relates to delayed performance speed of activity that required planning skills.

Conclusions: Individuals with ASD having no ID had difficulties in performance speed in planning but not the performance itself, when controlling ADHD symptoms. In the brain volume, the white matter volume of the superior frontal gyrus was increased in ASD. Additionally, it was observed that the delayed performance in the task which required a planning skill related to an increased white matter volume in the right superior frontal gyrus. These results indicate that delayed planning performance is the true condition of executive dysfunction in ASD, and this dysfunction is related to the abnormality of white matter structure in the frontal lobe.

ORAL SESSION — NEUROSCIENCE: AFFECTIVE, BEHAVIORAL, COGNITIVE
323 - Brain-Behaviour Relationships

323.001 *(Oral)* Saccade Velocity Dysmetria during Naturalistic Visual Exploration in Autism Spectrum Disorder

N. Bast[1], *L. Mason*[2], *C. M. Freitag*[3], *A. M. Portugal*[4], *T. Smith*[5], *L. Poustka*[6], *T. Banaschewski*[7] *and M. H. Johnson*[2], *(1)Department of Child and Adolescent Psychiatry and Psychotherapy, University Hospital Frankfurt, Frankfurt, Germany, (2)Centre for Brain and Cognitive Development, Birkbeck, University of London, London, United Kingdom, (3)Autism Research and Intervention Center of Excellence Frankfurt, University Hospital Frankfurt, Frankfurt am Main, Germany, (4)Birkbeck College, London, United Kingdom, (5)Department of Psychological Sciences, Birkbeck, University of London, London, United Kingdom, (6)Child and Adolescent Psychiatry and Psychotherapy, University Medical Center Goettingen, Goettingen, Germany, (7)Child and Adolescent Psychiatry, Central Institute of Mental Health, Medical Faculty Mannheim, University of Heidelberg, Mannheim, Germany*

Background: Visual exploration in Autism Spectrum Disorder (ASD) is characterized by attenuated social attention. However, the underlying oculomotor function that shapes visual exploration is understudied, although laboratory studies during restricted viewing indicated aberrant saccade features in ASD. Specifically, saccade velocity dysmetria was reported that suggested different (oculo-)motor modulation by the ponto-cerebellar motor network.

Objectives: We wanted to characterize oculomotor function during naturalistic visual exploration in a large and heterogenous ASD sample. We expected to replicate saccade velocity dysmetria, which would outline an underlying mechanism of altered visual exploration in ASD (see figure 1): A subcortical network of ponto-cerebellar motor modulation that has been underutilized in previous ASD imaging research.

Methods: Oculomotor function was recorded using infrared remote eye-tracking in 279 ASD participants (age = 16.1/5.7 [6-30][1]; IQ = 99.5/18.1 [46-148]; gender = 194/85 [m/f]) and 156 neurotypical controls (age = 15.8/5.8 [6-30]; IQ = 104.2/16.7 [50-139]; gender = 102/54 [m/f]) during free viewing of naturalistic videos with and without social content. Groups were matched within age subgroups (children: 6-11 y, adolescents: 12-17 y, adults: 18-30 y) by age, IQ, and sex. Oculomotor function was defined as well established saccade, fixation, and pupil-dilation features that were compared between groups in linear mixed models. Combined features were investigated for their potential as ASD classifier in Receiver Operating Characteristic curves.

[1] Mean / SD [Min – Max]

Results: ASD oculomotor function is characterized by increased variation in peak saccade velocity ($d = 0.19$, CI [0.01, 0.37]) and velocity main sequence, which is saccade velocity corrected for saccade amplitude ($d = 0.27$, CI [0.06, 0.48]). These characteristics of saccade velocity dysmetria were independent of social video content. We also found ASD oculomotor function with decreased pupil dilation variation for average IQ ($85 \leq IQ \leq 115$; $d = -0.24$, CI [−0.47, −0.01]), and decreased saccade duration and amplitude for social video content ($d = -0.29$, CI [-0.47, -0.05]; $d = -0.29$, CI [−0.51, −0.07]). Oculomotor function is outlined as a valid ASD classifier across the heterogenous sample (AUC = .689 CI [.638, .740]) with increased power in age- and IQ-stratified subgroups (adolescents: AUC = .765 CI [.691, .839]; IQ < 85: AUC = .840 CI [.711, .969]; IQ > 115: AUC = .822 CI [.734, .909]). Oculomotor function is comparable to “attenuated social attention” as ASD classifier concerning discriminative power.

Conclusions: Saccade velocity dysmetria during visual exploration is confirmed across a heterogenous ASD sample that emphasizes generalizability to the ASD population. Our findings extend previous restricted-viewing findings to naturalistic gaze behavior that provides ecological validity. Thus, saccade velocity dysmetria likely contributes to attenuated social attention in ASD. This is supported by subgroup-specific findings in average IQ and social video content that suggested attenuated visual exploration. Overall, saccade velocity dysmetria indicates altered ponto-cerebellar motor modulation, which provides a promising underlying mechanism of altered visual exploration in ASD.

323.002 *(Oral)* Alterations in Gray Matter Covariations in Autism Spectrum Disorder Compared to Controls. Results from the EU-AIMS Longitudinal European Autism Project

T. Mei[1], *A. Llera*[1], *D. L. Floris*[2], *S. Durston*[3], *C. Moessnang*[4], *T. Banaschewski*[5], *R. Holt*[6], *S. Baron-Cohen*[6], *E. Loth*[7], *T. Charman*[8], *D. G. Murphy*[9], *C. B. EU-AIMS*[12], *(1)Donders Institute for Brain, Cognition and Behaviour, Nijmegen, Netherlands, (2)Donders Centre for Cognitive Neuroimaging, Nijmegen, Netherlands, (3)Department of Psychiatry, Brain Center Rudolf Magnus, University Medical Center Utrecht, Utrecht, Netherlands, (4)Department of Psychiatry and Psychotherapy, Central Institute of Mental Health, University of Heidelberg, Mannheim, Germany, (5)Child and Adolescent Psychiatry, Central Institute of Mental Health, Medical Faculty Mannheim, University of Heidelberg, Mannheim, Germany, (6)Autism Research Centre, Department of Psychiatry, University of Cambridge, Cambridge, United Kingdom, (7)Department of Forensic and Neurodevelopmental Sciences, Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, United Kingdom, (8)Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, United Kingdom, (9)Forensic and Neurodevelopmental Sciences, Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, United Kingdom, (10)Centre for Functional MRI of the Brain (FMRIB), University of Oxford, Oxford, United Kingdom, (11)Karakter Child and Adolescent Psychiatry University Centre, Nijmegen, Netherlands, (12)EU-AIMS Organization, London, United Kingdom*

Background: Voxel-based Morphometry (VBM) provides a voxel-wise characterization of gray matter (GM) densities commonly used to examine brain structural differences in psychiatric disorders. VBM studies in Autism Spectrum Disorder (ASD) have yielded inconsistent results of GM differences, which could partly be attributed to structural abnormalities depending on inter-regional covariations.

Objectives: To detect the GM structural covariation alterations of ASD, we applied Independent Component Analysis (ICA) on VBM data from EU-AIMS (European Autism Interventions) Longitudinal European Autism Project. Further, we were interested in the relationship between the obtained independent components set of GM variations and the categorical diagnostic labels, and continuous measures of the core ASD symptoms.

Methods: The sample comprised 347 individuals with ASD (72.9% male) and 252 typically developing individuals (64.7% male), between 6 and 30 years of age, and a full-scale IQ (FIQ) > 50. Each subject's T1-weighted structural image was used to obtain subject VBM measures. All subjects' VBM data was then decomposed into 100 spatially independent components using ICA. A Generalized Linear Model (GLM) was used to examine case-control differences between subject loadings of each component while correcting for age, sex, FIQ, and sites. A GLM was also utilized to explore the univariate relationships between each component and each symptom profile in the ASD group. Furthermore, Canonical Correlation Analysis (CCA) was performed to separately examine the integrated effects between all brain components and ADI, ADOS (N = 325), and between all brain components and Social Responsiveness Scale (SRS), Repetitive Behaviour Scale-Revised (RBS), and Short Sensory Profile (SSP) (N = 194) in the ASD group. The statistical significance of each canonical variate was determined by permutation testing (number of permutations = 10000).

Results: GLM analyses showed significant case-control differences at two independent components, i.e., component number 10 (IC10, $p = 8.850X10^{-5}$), and component number 14 (IC14, $p = 5.450X10^{-4}$) (FDR corrected, $q = 8.072X10^{-4}$). As shown in Figure 1, IC10 primarily was related to structural variations in bilateral insula, inferior frontal gyrus, orbitofrontal cortex, and caudate nuclei. IC14 mainly involved variations in the bilateral hippocampus, parahippocampal gyrus, and amygdala. No further corrected significant linear association with pathology symptoms was found. Considering the results of the two CCA analyses, in both cases, IC14 was one of the components with the strongest loadings in all components on symptom profiles (Figure 2e, g). On the first CCA analysis (Figure 2a), the ADOS RRB subscale loaded most among the symptom profiles (Figure 2f) in the significant Bonferroni corrected CCA mode (permutation $p = 0.008$, Figure 2c). In the secondary analysis (Figure 2b), the SSP weighted most in this case (Figure 2h) for the again significant Bonferroni corrected CCA mode (permutation $p = 0.002$, Figure 2d).

Conclusions: We demonstrate ASD-driven inter-regional covariation changes of the insula, frontal area and caudate, and highlight a strong effect of the hippocampus, parahippocampal gyrus, and amygdala on ASD symptoms, which indicate the brain morphometry abnormalities could be a part of the consequence of affected brain regions' covariations, and could be linked to the phenotypes of ASD.

323.003 *(Oral)* Brain Activation during Emotion Regulation Predicts Anxiety in Women but Not Men with Autism Spectrum Disorder

M. Walsh[1], *C. Haynes*[2], *B. A. Pagni*[1], *A. Nespodzany*[1], *E. Foldes*[1] *and B. B. Braden*[3], *(1)Arizona State University, Tempe, AZ, (2)Temple University, Philadelphia, PA, (3)College of Health Solutions, Arizona State University, Tempe, AZ*

Background: Women with ASD show higher rates of psychiatric co-morbidities, especially depression and anxiety. Emotion regulation difficulties may partially explain the high prevalence of psychiatric co-morbidities in ASD and lead to poorer quality of life and reduced functional independence. Sex differences in emotion regulation and its neurocircuitry have been observed in neurotypical and clinical populations, but have received limited attention in ASD.

Objectives: We provide a preliminary characterization of sex differences in emotion regulation neurocircuitry in adults with ASD and associations with anxiety and depression.

Methods: Participants included men and women (18-72 years, mean: 32.5[13.9]) of average intellectual ability (mean IQ: 102.9[16.9]) with ASD (female ASD: *n*=21; male ASD: *n*=38) participating in a larger intervention study. Behavioral dependent measures included self-reported Beck Depression Inventory-II and State/Trait Anxiety Inventory and the informant-reported Strength and Difficulties Questionnaire emotional difficulties subscale. Participants completed a cognitive reappraisal emotion regulation fMRI task (Richey et al., 2015). Statistical parametric mapping was used for whole-brain, family-wise error corrected (p=0.01) activation group-level and sex differences analyses. Task-modulated connectivity using generalized psychophysiological interaction was used for seed regions showing significance in the activation analysis. Mean activation and connectivity values from significant regions were extracted and correlated with anxiety and depression scores. Age and IQ were used as a covariates in all brain and behavioral analyses.

***Results**:* Women with ASD had greater depression ($F_{1,53}$=6.417;p=.014) and emotional difficulties ($F_{1,46}$=7.207;p=.010) than men with ASD, and greater trait anxiety approached significant ($F_{1,53}$=2.882;p=.095). During cognitive reappraisal, significant activation across all participants with ASD was observed in bilateral insula/orbitofrontal cortex (OFC), anterior-mid cingulate (aMCC), dorsomedial prefrontal cortex (dmPFC), caudate, and cuneus; left dorsolateral prefrontal cortex (dlPFC), inferior parietal lobe (IPL)/temporoparietal junction (TPJ), pre/post-central gyrus; and right middle temporal gyrus. No sex differences in activation were observed at the whole brain level. Women but not men showed associations between state anxiety and task activation in the IPL/TPJ (r_{17}=.543;p=.016), left dlPFC (r_{17}=.483;p=.036), pre/post-central gyrus (r_{17}=.591;p=.008), bilateral insula/OFC (left: r_{17}=.591;p=.008, right: r_{17}=.458;p=.048), right caudate (r_{17}=.466;p=.045), and dmPFC (r_{17}=.477;p=.039). Across all subjects, increased task-modulated connectivity was observed for 1) aMCC with the left superior parietal lobe, and 2) right insula/OFC with right posterolateral temporal cortex, which correlated with reduced emotional difficulties (r_{46}=-.281;p=.05; r_{46}=-.384;p=.007, respectively). Men but not women with ASD showed greater task-modulated connectivity with multiple seed regions, including dmPFC, aMCC, left insula/OFC, and left IPL/TPJ. Increased task-modulated connectivity between the left insula and right cerebellum in men but not women predicted reduced state (r_{32}=-.362;p=.035) and trait (r_{32}=-.409;p=.016) anxiety and depression (r_{32}=-.418;p=.013).

***Conclusions**:* Brain activation during emotion regulation predicts anxiety in women but not men with ASD. While profiles of brain activity are similar across sexes, men show increased task-modulated connectivity compared to women. Interestingly, connectivity between the left insula and right cerebellum during cognitive reappraisal may be protective against anxiety/depression in men with ASD, compared to women with ASD. These findings highlight the importance of characterizing sex differences in ASD neurocircuitry to inform sex-tailored interventions.

323.004 *(Oral)* The Maturation of Functional Emotional Neural Networks in Autism Spectrum Disorder

***K. Safar**[1], M. M. Vandewouw[2], B. T. Dunkley[3] and M. J. Taylor[4], (1)Diagnostic Imaging, Hospital for Sick Children, Toronto, ON, Canada, (2)Neuroscience & Mental Health Program, The Hospital for Sick Children Research Institute, Toronto, ON, Canada, (3)Hospital for Sick Children, Toronto, ON, Canada, (4)The Hospital for Sick Children, Toronto, ON, Canada*

Background: Autism spectrum disorder (ASD) is characterized by social impairments, which may be related to deficits in processing emotional faces. Altered functional connections among brain regions critically involved in affective processing have been reported using magnetoencephalography (MEG) in different developmental cohorts. However, few studies have examined the maturation of functional networks underlying emotion processing in ASD, and differences between ASD and typical development.

Objectives: Using MEG, we investigated changes from childhood to mid-adulthood in functional connectivity of eight ROIs (bilateral insulae, fusiform gyri, amygdalae and anterior cingulate cortex; ACC) during the implicit presentation of emotional faces in 190 children, adolescents and adults: 83 with ASD (*M* age=19.5±9.17 yrs, range=7.02-39, 59 males) and 107 age-and sex-matched controls (*M* age=19.92±8.83yrs, range=6.6–39, 74 males).

Methods: Happy or angry faces and a scrambled pattern (target) were presented simultaneously for 80ms on either side of a central fixation cross while MEG was recorded. The location of the target (left or right) was indicated as rapidly as possible by a button press. MEG data were epoched by emotion. Time-series were derived from 90 cortical and subcortical sources of the AAL atlas using the LCMV beamformer. The phase difference derivative was used to assess phase synchronization of ongoing neural oscillations among sources.

Results: In ASD, increased functional connectivity to happy faces across age 0-400ms was found in the theta band (F=7.7, 36 edges, 35 nodes, p_{corr} <0.008). The network included interregional connections anchored in the left insula and left amygdala and spanned primary visual, parietal, and temporal brain regions. Increased theta band connectivity across age was also found to angry faces in ASD (F=9.5, 37 edges, 33 nodes, p_{corr} <0.008). The majority of connections were anchored in the right hemisphere, particularly in the right fusiform gyrus and right ACC.
Likewise, in the control group, we found a positive correlation between functional connectivity and age in the theta band, 0-400ms to happy faces (F=6.6, 35 edges, 31 nodes, p_{corr} = 0.04). The most important nodes were the right ACC and left fusiform. To angry faces in controls, we also found a positive correlation between connectivity and age in theta (F=7.7, 35 edges, 30 nodes, p_{corr} <0.008), with the majority of connections anchored in the left amygdala and left fusiform. Decreased functional connectivity with age to happy faces in beta (F=7.6, 35 edges, 32 nodes, p_{corr} <0.008) was also found in controls; anchored in the right ACC, left insula and fusiform. No significant interactions were found between age and group, or significant between-group differences either to happy or angry faces.

Conclusions: We found age-related changes in functional connectivity of brain regions important for emotion processing in typical controls and in ASD. Both those with and without ASD showed increased connectivity with age in the theta band to happy and angry faces. Findings of increased theta band connectivity across age may reflect greater communication and recruitment of these networks across development, while decreasing recruitment of a happy face-specific beta band network in controls suggests automaticity in processing.

Novel Therapeutic Approaches (gene, protein or RNA targeted therapies)

POSTER SESSION — NOVEL THERAPEUTIC APPROACHES (GENE, PROTEIN OR RNA TARGETED THERAPIES)
439 - Novel therapeutic approaches (gene, protein or RNA targeted therapies) Posters

439.001 *(Poster)* Explore the Effect of Multi-Session Intermittent Theta Burst Stimulation over Bilateral Posterior Superior Temporal Sulci in Adults with Autism Spectrum Disorder

H. C. Ni[1], *H. Y. Lin*[2] *and Y. Z. Huang*[3], *(1)National Taiwan University, Taipei, Taiwan, (2)Department of Psychiatry, National Taiwan University Hospital & College of Medicine, Taipei, Taiwan, (3)Neurology, Chang Gung Memorial Hospital, Taoyuan, Taiwan*

Background: Although the therapeutic potential of repetitive transcranial magnetic stimulation (rTMS) for individuals with autism spectrum disorder (ASD) has been proposed for years, the results are quite limited. Theta burst stimulation (TBS) is a modified rTMS method with shorter simulation duration and lower stimulus intensity than conventional rTMS. TBS may be more suitable than conventional rTMS for individuals with ASD. However, the therapeutic benefits of TBS on ASD remain unclear.

Objectives: Our study aimed to explore the impacts of intermittent TBS (iTBS) over the bilateral posterior superior temporal sulcus (pSTS) for 5 consecutive days in adults with ASD. The outcomes included the clinical symptoms and executive functions.

Methods: In our randomized, single-blinded, sham-controlled crossover trial, 13 adults with ASD received iTBS for 5 consecutive days over the bilateral pSTS and inion (as a sham control) in a 4-month interval and in a randomly assigned order. The executive function was measured with the Wisconsin Card Sorting Test (WCST) for cognitive flexibility. The clinical outcomes were measured with the Autism Spectrum Quotient (AQ) by participants themselves and their parents before and after 5-day iTBS interventions.

Results: Our results did not find significant direct effects of multiple-sessions iTBS over the bilateral pSTS on clinical symptoms and neuropsychological performances in adults with ASD. However, our further analysis revealed several moderators might modify the effects of iTBS on the clinical symptoms and cognitive flexibility in adults with ASD. Specifically, the immediate impacts of iTBS were moderated by the concurrent medication use and baseline severity of restricted and repetitive behaviors (RRB) on the total errors in the WCST. In addition, the immediate effects of iTBS on the self-reported AQ scores were moderated by the baseline intelligence, baseline severity of RRB and concurrent medication use. Moreover, the effects of iTBS on the parents-reported AQ scores were moderated by the baseline intelligence and baseline severity of language.

Conclusions: Although modulating pSTS activities may be a potential therapeutic target in treating ASD, we did not find definite impacts of multiple-sessions iTBS over the pSTS in adults with ASD. However, several important factors, which should be noticed in the future study, might moderate the effects of iTBS over the pSTS on adults with ASD.

Patients, Families, and Clinical Services

ORAL SESSION — PATIENTS, FAMILIES, AND CLINICAL SERVICES
324 - Autism at the Point of Care: Informing Services for Patients and Families

324.001 *(Oral)* Utilization of a Best Practice Alert (BPA) at Point-of-Care for Recruitment into a US-Based Autism Research Study

K. Ahmed[1], *A. R. Simon*[2], *G. Marzano*[3], *G. Duhon*[1] *and* ***R. P. Goin-Kochel***[1], *(1)Baylor College of Medicine, Houston, TX, (2)Autism Center, Texas Children's Hospital, Houston, TX, (3)Psychology, Autism Center, Texas Children's Hospital, Houston, TX*

Background: Recruitment for research studies is challenging and can thus limit the rate of scientific progress. A survey of research participants indicated that provider referral is one of the most influential reasons a family enrolls in a study. To ease referral burden on providers and researchers, we developed a Best Practice Alert (BPA) that fires during a clinical visit if the patient meets basic eligibility criteria for the study.

Objectives: To determine the efficacy of using a BPA for in-clinic recruitment of individuals with Autism Spectrum Disorder (ASD) for the SPARK (Simons Foundation Powering Autism Research for Knowledge) study.

Methods: The BPA was developed with the Epic Team at Texas Children's Hospital (TCH) to include a brief description of the SPARK study and multiple response options (*interested, decline, enrolled, dismiss*). The BPA was activated in four pediatric sections at TCH (Neurology, Developmental Pediatrics, Psychiatry, and Psychology). Once a provider recorded a response, an Epic inbox message was sent to the research team with the response and patient's information. This information was transferred to a spreadsheet where follow-up information was recorded. "Interested" patients received an email invitation within 72 hours of the response, followed by up to two phone calls and three reminder emails. For referrals received from 9/12/18-9/12/19, referral information, such as visit date, pediatric section, all contact attempts, patient response, and enrollment status, were tracked from 9/12/18-10/12/19.

Results: During the assessment period, 111 providers recorded 1879 BPA responses, including 1203 (64.0%) "Interested," with a weekly average of 23 "Interested" responses. Of these, 233 (19.4%) enrolled in SPARK. The largest number of enrollments (88) came after the email invitation (37.8%) and the first phone call (21.5%); 12.0% of new enrollments from the BPA occurred without any contact from the study team. Referral numbers differed widely across departments (from 1020 in Neurology to 64 in Psychology). Although providers from the Neurology department had the lowest "Interested" rate (56.8%), they had the highest rate of enrollment (21.4% of "Interested" patients). The Psychology Department, which had the highest "Interested" rate (90.6%), had the lowest rate of enrollment (14.0%).Throughout the assessment period, we received 861 additional enrollments from participants who did not receive the BPA, and 258 (30.0%) of these returned the saliva kit for the individual with ASD. However, 56.0% of participants recruited through the BPA returned the saliva kit for the individual with ASD, which was a significantly higher proportion (p <.0001, Fischer's exact).

Conclusions: A best practice alert (BPA) can be highly effective in identifying patients with ASD and recruiting them into a research study during a clinic visit. Participants recruited through the BPA were more likely to complete the study by sending back the saliva kit for the individual with ASD, indicating that families who hear about a study at the doctor's office may be more engaged and likely to complete study involvement. By improving recruitment and engagement processes for participants with ASD, we can more quickly execute research to speed up our understanding of ASD and improve patient outcomes.

324.002 *(Oral)* Inclusion, Acceptance, Shame and Isolation: Attitudes to Autism in Aboriginal and Torres Strait Islander Communities in Australia

R. Lilley[1]*, M. Sedgwick*[2] *and E. Pellicano*[3]*, (1)Department of Educational Studies, Macquarie University, Sydney, NSW, Australia, (2)National Centre for Epidemiology and Population Health, Australian National University, Canberra, ACT, Australia, (3)Macquarie University, Sydney, Australia*

Background: This research investigates attitudes towards autism in Aboriginal and Torres Strait Islander communities in Australia. Overall, Aboriginal and Torres Strait Islander peoples, who constitute 3.3% of the total Australian population, experience widespread socioeconomic disadvantage and health inequality, including being 1.8 times more likely to be living with disabilities than other Australians. Such disparity is especially evident in rates of childhood disability. The qualitative research presented contributes to the growing literature on cross-cultural and pluralistic understandings of autism and family experience.

Objectives: This is the first research to explicate attitudes towards autism in Aboriginal and Torres Strait Islander communities in Australia. Understanding the complexity of these attitudes is crucial because they influence recognition of autism as well as support and management. We cannot simply assume that Western biomedical conceptualisations of autism are accepted in these diverse communities or that current diagnostic practices and services will meet their needs. The overall research objective was to provide a detailed understanding of family experiences of supporting children diagnosed with autism in Aboriginal and Torres Strait Islander communities. This understanding can contribute to the design of services that are culturally safe and relevant to these communities.

Methods: Families with Aboriginal and/or Torres Strait Islander children on the autism spectrum were recruited through the networks of our partner organizations, Positive Partnerships and First Peoples Disability Network. Twelve families from diverse parts of Australia – including eleven mothers and one grandmother – agreed to participate in a semi-structured interview. These women talked about their experiences of supporting 16 children diagnosed with autism, who ranged in age from 2 to 22 years. The research team was comprised of two non-Aboriginal and one Aboriginal researchers, whose disciplinary backgrounds span psychology, anthropology and Indigenous policy and health. Interview transcripts were thematically analyzed using the six-step process outlined by Braun and Clarke (2006). Here we report on a group of themes related to attitudes towards autism in Aboriginal and Torres Strait Islander communities that emerged as a distinct data set within the overall data corpus.

Results: We identified four themes relating to Aboriginal and Torres Strait Islander attitudes towards autism: inclusion, acceptance, shame and isolation. Overall, there was a marked tension in these accounts between the growing acceptance of autism in these communities and the stigmatisation of autistic individuals and their families as well as between feeling supported, especially by family, and being socially isolated because of child preferences and shame associated with atypical behaviour.

Conclusions: The findings of this study demonstrate that there are multiple attitudes towards autism in Aboriginal and Torres Strait Islander communities. On the one hand, some of these attitudes potentially point towards under-identification or misdiagnosis. On the other hand, this study found that a widespread ethos of 'looking after each other' and of accepting individual differences may be contributing to some good outcomes for autistic children and adults. In this respect, Aboriginal and Torres Strait Islander attitudes towards autism provide a positive model of support for and acceptance of autistic children and their families.

324.003 *(Oral)* Inside the Portrait of Autism in Africa: Understanding Diagnostic Profiles and Comorbidities in Mental Health Clinics in National Referral Hospitals in Uganda

E. Bonney[1,2]*, C. Abbo*[2]*, C. Ogara*[2]*, M. E. Villalobos*[3] *and J. T. Elison*[4]*, (1)Institute of Child Development, University of Minnesota, Minneapolis, MN, (2)Psychiatry, Makerere University, Kampala, Uganda, (3)Psychiatry, UNC Chapel Hill, Asheville, NC, (4)University of Minnesota, Minneapolis, MN*

Background: Autism Spectrum disorder (ASD) is a behaviorally defined neurodevelopmental disorder of increasing prevalence and global concern. Recent estimates in the United States show that as many as 1 in 59 school-aged children are affected. It is believed that the prevalence of ASD in low- and middle-income countries (LMICs) may be comparable to Western estimates. The average age of diagnosis for children in developed nations is around 5 years of age. Further, ASD is reported to co-occur with many developmental disabilities. However, there is little empirical evidence on the average age of ASD diagnosis in children in Sub-Saharan Africa. Additionally, studies characterizing comorbidities associated with ASD in African populations are limited. Understanding the clinical profiles of children with ASD living in low resource settings such as Uganda may provide insights to inform early detection, intervention, and research priorities in this part of the world.

Objectives: The purpose of this study was to determine the age of diagnosis and to describe common comorbidities associated with ASD in a clinical sample of young people receiving treatment in mental health clinics at National referral hospitals in Uganda.

Methods: Demographic and clinical profiles were collected through retrospective chart review for all children diagnosed with ASD at two tertiary mental health facilities in Uganda between 2014 and 2019. ASD and related comorbidities were diagnosed by child and adolescent psychiatrists using the DSM 5 diagnostic criteria. Descriptive statistics were computed to estimate the average age of diagnosis and to summarize the proportion of children with ASD and related comorbidities.

Results: A total of 237 (156 males, 81 females) children with ASD were identified over the five-year period. The average age of first-time diagnosis was found to be [6.99±4.04 years], which was significantly different between males and females [t= -2.106, p=0.036]. Out of the 237 who were diagnosed with ASD, 54.9% [n=130, mean age 6.7 years SD (3.8)] were identified as having ASD only, 18.9% [n=45, mean age 6.5 years SD (3.4)] had ASD and ADHD, 12.6% [n=30, mean age 8.7 years SD (4.7)] were found to have ASD and Epilepsy [n=30, mean age 8.7 SD (4.8)], and 2.9% [n=7, mean age 5.0 years SD (2.4)] were found to have ASD and Global Developmental Delay. 2.9% [n=7, mean age 6.3 years SD (5.3)] were also diagnosed with ASD and language delays, and less than 1% of the sample had ASD in addition to other psychiatric comorbidities such as depression, psychosis and challenging behaviors.

Conclusions: Findings suggest that African children receive formal diagnosis of ASD later compared to peers in developed countries. Furthermore, while a large proportion of children in these settings experience ASD only, the results show that ASD often co-occurs with other psychiatric and developmental problems. The study demonstrates that early identification remains a daunting challenge in Africa, underscoring the need to maximize screening and surveillance efforts across the region. Lastly, culturally appropriate and effective interventions need to be developed to address not only the symptoms of ASD but also related behavioral problems.

324.004 *(Oral)* Preliminary Outcomes of a Culturally Responsive Peer Counselling Program for Parents of Children with Autism in the South Asian Community

A. S. Mills[1]*, K. Vimalakanthan*[2]*, S. Sivapalan*[2]*, N. Shanmugalingam*[2] *and J. A. Weiss*[1]*, (1)Psychology, York University, Toronto, ON, Canada, (2)South Asian Autism Awareness Centre, Toronto, ON, Canada*

Background: Parents of children with autism routinely report high levels of stress, which can impact their mental health (Hayes & Watson, 2013). In addressing these mental health challenges, it is important to consider how culture influences beliefs and practices related to raising a child with autism. Peer volunteers have been found to be effective in delivering psychosocial interventions when they come from the same culture and share similar experiences (Atif et al., 2016). The South Asian Autism Awareness Centre (Toronto, Canada) developed a manualized intervention (the CARES Program) to address the need for culturally responsive counselling for parents in the South Asian community.

Objectives: 1) Evaluate the preliminary mental health outcomes of this 6-week group-based peer counselling program. 2) Evaluate changes in parent self-reported wellbeing across sessions.

Methods: Findings are based on 63 parents (M_{age}= 43.7 years, 68 % mothers) who participated in the group counselling program (2 - 6 parents per group). Peer facilitators were volunteers from the community who were selected based on their experience working with vulnerable populations and shared experiences caring for someone with autism. The sessions addressed understanding and acceptance of children's diagnosis, coping skills, and goal setting. Parents completed the following measures before and after the program to assess changes in mental health and quality of life: the *Depression Anxiety Stress Scale* (DASS-21), the *Quality of Life Enjoyment and Satisfaction Questionnaire* (QLESQ-SF), the *Parental Stress Scale* (PSS), and *the Brief Family Distress Scale* (BFDS). Additionally, participants completed the Outcome Rating Scale (ORS) at each of the 6 sessions to evaluate changes in wellbeing.

Results: Wilcoxon signed-rank tests and paired sample t-tests were conducted to evaluate change in parent-reported mental health outcomes. Results demonstrated significant improvements on the DASS Depression Scale (Z = - 3.79, $p < .001$), Anxiety Scale (Z = -3.02, $p = .002$), and Stress Scale (Z = -4.38, $p = < .001$), as well as the QLESQ-SF ($t = 2.13$, $p = 0.03$), PSS ($t = -2.80$, $p = 0.007$), and BFDS (Z = -3.87, $p < .001$). McNemar tests indicated significant differences in clinical levels on the DASS Depression Scale (60% pre-intervention, 41% post-intervention, $p = 0.01$), Anxiety Scale (73% pre-intervention, 35% post-intervention, $p < 0.001$) and Stress Scale (54% pre-intervention, 35% post-intervention, $p = 0.004$). Multilevel modelling was used to assess change in parent reported overall wellbeing (ORS ratings) across sessions. The Session 1 score was used as the control timepoint, and compared with each subsequent session to assess change over time. Results demonstrated improved ORS scores from the initial session to each other time point (all $p < .001$), with posthoc analyses indicating significant changes after the first and second session, and stable high ratings across all other sessions.

Conclusions: Findings demonstrate the clinical utility of using trained peer volunteers to support the mental health of parents of children with autism in the South Asian community. There are implications for considering the kinds of adaptations that can allow for effective and accessible support services for families in other diverse communities.

Pediatrics

POSTER SESSION — **PEDIATRICS**
440 - Pediatrics Posters

440.001 *(Poster)* Assessing Caregivers' Perceptions about the Impact of Psychotropic Medication Treatment in a National Sample of Children with Autism Spectrum Disorder (ASD)

J. S. Anixt[1,2], *J. K. Law*[3,4], *E. Pedapati*[5], *R. Adams*[5], *A. C. Gile*[1] *and P. H. Lipkin*[6], *(1)Division of Developmental & Behavioral Pediatrics, Cincinnati Children's Hospital Medical Center, Cincinnati, OH, (2)Pediatrics, University of Cincinnati College of Medicine, Cincinnati, OH, (3)Maryland Center for Developmental Disabilities, Kennedy Krieger Institute, Baltimore, MD, (4)Johns Hopkins University School of Medicine, Baltimore, MD, (5)Cincinnati Children's Hospital Medical Center, Cincinnati, OH, (6)Neurology and Developmental Medicine, Kennedy Krieger Institute, Baltimore, MD*

Background: The Medication Outcomes for Developmental Delays (MODD) questionnaire was developed as a clinical tool to efficiently assess a caregivers' perceptions of the impact of psychotropic medications on their child's target symptoms in a population of children with autism spectrum disorder (ASD) and related developmental disabilities. The MODD has been found to significantly correlate with the Clinical Global Impression Severity Scale (CGI-S), and Clinical Global Impression Improvement Scale (CGI-I), indicating agreement between caregivers and clinicians regarding symptom control and side effects. The 16-item MODD includes 4 domains: Functional Impairment (FUNC; degree to which behaviors interfere with daily living), Developmental (DEV; symptoms related to core ASD features), Symptoms (SX; common co-occurring conditions in ASD), and Medication Impact (MED).

Objectives: To use the Medication Outcomes for Developmental Delays (MODD) questionnaire to assess caregivers' impressions about psychotropic medication treatment and compare outcomes between commonly prescribed classes of medication.

Methods: Caregivers of children with ASD enrolled in the Interactive Autism Network (IAN), a well-established, family-centered online research network, completed questionnaires, including the MODD, a demographic survey, and a questionnaire about psychotropic medication use. Descriptive statistics included proportions and means. Scores on the MODD were summed for each of the 4 domains and reported as a severity score (sum of FUNC, DEV, and SX) and Medication Impact Score (MED). Linear regression modeling was conducted controlling for gender, age, and ethnicity to determine the relationship between MODD scores and classes of psychotropic medications.

Results: Caregivers of 644 children with ASD (mean age 12.3 years, 82% male) completed the MODD survey. Of these, 351 children were taking psychotropic medication and the 4 most common classes included: anti-depressants (44%), alpha adrenergic agonists (35%), atypical antipsychotics (34%), and stimulants (31%). Caregivers viewed the impact of psychotropic medications favorably, with 69% indicating it was "very true" that positive benefits of medication outweighed negative side effects, and 58% reporting that their child's overall well-being improved since starting behavioral medication. Use of atypical antipsychotics and alpha agonists were each significantly associated with the MODD severity score (sum of FUNC, DEV, and SX scales) (β=0.309 and β=0.127, $p<0.001$), controlling for gender, age, and ethnicity, indicating these 2 classes of medication were associated with a greater degree of developmental disability / functional impairment. On the MED scale, use of stimulants was significantly associated with improved learning (β=0.171, $p<0.01$) and independence (β=0.20, $p<0.001$), and the total medication impact score (β=0.189, $p<0.001$). Use of antidepressants was associated with improved overall well-being (β=0.133, $p<0.05$).

Conclusions: The MODD questionnaire is a useful clinical tool for assessing caregiver perspectives about behavioral pharmacotherapy in children with ASD and related developmental disabilities with the potential to improve shared decision-making and track healthcare outcomes. While decisions to use psychotropic medications to address challenging behaviors are difficult, most caregivers view the impact of psychotropic medications positively.

440.002 *(Poster)* Caregiver Confidence in Reporting Anxiety Symptoms in Children with Autism Spectrum Disorder

L. I. Duker (Stein)[1], *M. E. Williams*[2], *C. Wylde*[3], *F. Choudhury*[4] *and S. A. Cermak*[5], *(1)Division of Occupational Science and Occupational Therapy, University of Southern California, Los Angeles, CA, (2)Univ. of Southern California/Children's Hosp. of Los Angeles, Los Angeles, CA, (3)Private Practice, Jackson, TN, (4)Preventive Medicine, University of Southern California, Los angeles, CA, (5)USC Mrs. T.H. Chan Division of Occupational Science and Occupational Therapy, University of Southern California, Los Angeles, CA*

Background: Up to 40% of children diagnosed with autism spectrum disorder (ASD) also meet criteria for an anxiety disorder. As children with ASD and anxiety disorders are at higher risk for self-injury, depression, and parental stress than children with ASD without comorbid anxiety disorders, it is important for anxiety to be properly identified in this population so children can receive appropriate treatment.

Objectives: Anxiety is often assessed through parent questionnaires; however, due to the nature of the questions and verbal limitations often present in children with ASD, caregivers may experience difficulty completing such measures. Therefore, the objective of this study was to examine caregiver confidence in reporting anxiety symptoms in children with ASD.

Methods: English- or Spanish-speaking caregivers of children 6-12 years with an ADOS-confirmed ASD diagnosis (n=143) completed the CASI-4 ASD Anxiety Scale and rated their level of confidence responding to each item on a 1-4 point Likert scale (not at all confident, not so confident, somewhat confident, very confident).

Results: Overall, parents reported that they had high confidence in their anxiety ratings (average 3.75 score). However, when examining parental confidence on individual items, differences emerged based on question type. Behavior-based items were highly endorsed by parents. For example, more than 90% of parents reported that they were *very confident* of their choice of anxiety rating for their child on items such as your child has difficulty falling asleep and your child is afraid to go to sleep without a parent nearby. However, feeling- or thought-based questions were less confidently endorsed. For example, less than 70% of parents were *very confident* regarding their responses to questions about the child's difficulty controlling worries, having distressing thoughts, and experiencing nightmares about being separated from a parent.

Conclusions: Results indicated that parents had high overall confidence in rating their child's anxiety symptoms. However, parents reported lower confidence on items requiring verbal skills and/or inquiring about children's thoughts or feelings. Future analyses should examine confidence scores in relation to autism severity, communication ability, IQ, and anxiety score.

440.003 *(Poster)* Characterising Sleep Problems in Children with ASD and Intellectual Disability: An Exploration of Child and Family Factors.

N. Papadopoulos[1], *C. Emonson*[2], *C. A. Martin*[3], *N. Rinehart*[1], *J. McGillivray*[2] *and E. Sciberras*[4], *(1)Deakin University, Burwood, VIC, Australia, (2)Deakin University, Melbourne, VIC, Australia, (3)Deakin University, Geelong, VIC, Australia, (4)Faculty of Health, School of Psychology, Deakin University, Burwood, VIC, Australia*

Background: Approximately, 40-80% of children with Autism Spectrum Disorder (ASD) experience behavioural sleep problems (Cortesi et al., 2010). In addition to sleep problems, children with ASD commonly experience co-morbidities such as emotional and behavioural disturbances (Maskey et al., 2013) and Intellectual Disability (ID), with approximately 36.8% of children with ASD experiencing a co-morbid ID (Braun et al., 2015). The mechanisms that underlie sleep problems in ASD are largely unknown, however several biopsychosocial factors related to the child have been proposed (Rzepecka et al., 2011). Family factors have also been shown to be related to sleep problems in ASD (Hodge et al., 2013; Tilford et al., 2015), although few studies have explored this association accounting for ID.

Objectives: The aim of this study was to compare the sleep profiles of individuals with ASD with and without ID. Additionally, this study aimed to examine commonly occurring parent and child factors (ID, ASD symptom severity, emotional and behavioural disturbance, parent psychological distress and parenting stress) and their impact on sleep problems in children with ASD.

Methods: Parents of 56 children with ASD (34 ASD+ID, 22 ASD) aged 6-13 years were recruited from a community sample. Children's ASD and ID diagnoses were confirmed by sighting clinical reports. Parents reported on their child's sleep problems (Children's Sleep Habits Questionnaire - ASD version), emotional and behavioural disturbances (Developmental Behaviour Checklist; DBC) and ASD symptom severity (Social Communication Questionnaire- Lifetime form). Parents also reported on their own parenting stress (Parenting Stress Index – Short Form) and psychological distress (Kessler Psychological Distress Scale). T-tests and regression analyses were conducted.

Results: Preliminary analyses revealed there were no significant group differences for total sleep problems or individual sleep problem subscales. There were also no significant group differences for parent psychological distress. Whilst there were no significant group differences for overall emotional and behavioural disturbances, significant differences between groups were evident for the self-absorbed subscale (p= .009) and the communication disturbance subscale (p <.001) of the DBC, with the ASD+ID group reporting significantly worse psychopathology. Additionally, whilst there were no significant group differences for total parenting stress, significant differences between groups were evident at the subscale level, with the ASD+ID group being significantly higher than the ASD only group for both the parent-child dysfunctional interaction (p= .004) and difficult child (p= .024) subscales. Regression analyses revealed there was a significant independent association between child sleep problems and experiencing emotional and behavioural disturbances *(β= 0.75, p <.001)*. There were no significant independent associations between total parenting stress, overall parent psychological distress or ASD symptom severity and total child sleep problems.

Conclusions: Our results demonstrate the importance of considering the influence of emotional behavioural disturbances when treating behavioural sleep problems in children with ASD. Future research should investigate the specific emotional and behavioural difficulties that may be contributing to sleep problems in larger samples of children with ASD.

440.004 *(Poster)* Echo Autism - Improving Primary Care Self-Efficacy in Educating Caregivers on Safety Skills and Injury Prevention in Children with Autism Spectrum Disorders

S. C. Bauer[1], ***C. Roestel***[2], *K. Fried*[3], *V. Castro Padilla*[3], *M. Castro*[4], *J. Gattuso*[5], *L. Mulford*[5], *S. Solomon*[2], *L. N. Osborne*[3], *L. Velazquez*[3], *Y. Li*[6], *J. Weedon*[7], *C. Hvala*[8], *J. Palmer*[9] *and A. McNulty*[10], *(1)Pediatric Developmental Center at Illinois Masonic Medical Center, Advocate Children's Hospital, Chicago, IL, (2)Pediatric Developmental Center, Children's Advocate Hospital, Chicago, IL, (3)Pediatric Developmental Center, Advocate Children's Hospital, Chicago, IL, (4)Pediatric Developmental Center, Adocate Children's Hospital, Chicago, IL, (5)Advocate Children's Hospital, Pediatric Developmental Center at Illinois Masonic Medical Center, Chicago, IL, (6)Advocate Center for Pediatric Research, Advocate Children's Hospital, Oak Lawn, IL, (7)Advocate Children's Hospital, Park Ridge, Advocate Children's Hospital, Park Ridge, IL, (8)Pediatric Developmental Center, Advocate Children's Hosptial, Chicago, IL, (9)Advocate Children's Hospital - Park Ridge, Park Ridge, IL, (10)Advocate Children's Hospital - Oak Lawn, Oak Lawn, IL*

Background: Individuals with autism spectrum disorders (ASD) are at increased risk for death secondary to preventable injuries, including those that result from wandering and elopement. In fact, nearly half of parents of children with ASD report that their children wander or elope from safe places. Wandering and elopement behavior increases a child's risk of requiring medical attention due to sustaining bodily injury and may even result in accidental death. Primary care physicians are on the front lines to empower caregivers about ways to keep their children safe and to build safety skills yet have little training and few resources to do so.

Objectives: The purpose of this pilot study was to examine primary care physician self-efficacy in counseling families of children with ASD about injury prevention and safety skills as part of ECHO (Extension for Community Healthcare Outcomes) Autism in Primary Care.

Methods: The study design was a pre- and post-survey of primary care physician self-efficacy in assessing risk for injury and educating caregivers about safety measures and injury prevention for children with ASD. With permission from the authors, the *Primary Care Assessment of Self-Efficacy* (Mazurek et al, 2017) was adapted to assess physician knowledge of assessing risk of injury and safety skills as well as providing resources to families of children with ASD. This survey was done before and after specific ECHO Autism teleclinics focused on injury prevention and safety skills.

During these specific ECHO Autism teleclinics, the Hub team included a dedicated Safety Team comprised of developmental pediatricians, psychologists, behavior therapists, nurses, speech and language pathologists, occupational therapists, social workers, and the hospital injury prevention coordinator. As part of these teleclinics and in line with the ECHO model, primary care physicians presented cases about wandering and elopement. The didactic portion of the teleclinics focused on injury prevention and safety for children with developmental differences, including ASD.

Statistical analyses utilized Mann-Whitney U tests to compare confidence levels pre- and post-session. A two-sided p value ≤ 0.05 was considered statistically significant. Qualitative data in the form of physician responses were also included in the study.

Results: 11 primary care clinicians participated in the ECHO Autism Safety teleclinics, and data collection is ongoing. All were pediatricians from the greater Chicago metropolitan area. Of the participants who filled out the survey pre-ECHO, 17-50% stated they had little to no confidence in assessing risks for injury and educating families about safety. After these specific ECHO teleclinics, their confidence significantly improved to 80-100% (p <0.02 for all topics).

Conclusions: This ongoing pilot study provides emerging evidence that ECHO Autism is an effective format to improve primary care self-efficacy in safety and injury prevention for children with developmental differences, including ASD. Future research includes assessing telementoring and telemedicine as intervention strategies to address safety and injury prevention for children with all developmental differences, including ASD.

440.005 *(Poster)* Examining Potential Benefit of Autism Webinars on Screening, Diagnosis, and Referral Practices for Pediatric Primary Pediatric Health Care Professionals

M. L. Ayala[1], *K. C. Bergez*[2], *S. S. Mire*[3], *L. Berry*[4], *K. Ahmed*[4] *and R. P. Goin-Kochel*[4], *(1)Psychological, Health and Learning Sciences, University of Houston, Houston, TX, (2)University of Houston, Houston, TX, (3)Psychological, Health, & Learning Sciences, University of Houston, Houston, TX, (4)Baylor College of Medicine, Houston, TX*

Background: Early identification of autism spectrum disorder (ASD) facilitates earlier intervention and is a strong predictor of better outcomes (Rhoades, Scarpa & Salley, 2007). However, early identification of ASD (i.e. ASD-screening, diagnosis) is often delayed in the pediatric setting (Self, Parham, Rajagopalan, 2014). While rates of ASD-screening at well-child visits are high, few pediatric primary care providers (PPCPs) make ASD-specialist referrals following a failed screen, and even fewer evaluate for ASD themselves (Monteiro et al., 2019). Although PPCPs report an eagerness to improve services for patients with ASD, barriers include a lack of adequate diagnostic training and insufficient knowledge of treatment information (Rhoades et al., 2007; Mazurek, Brown, Curran, & Sohl, 2017). Accessible, evidence-based educational tools are greatly needed to address these barriers and increase early identification and treatment.

Objectives: To evaluate PPCP perspectives on the value and utility of an ASD educational webinar series, as well as changes in knowledge and confidence about ASD-screening, diagnostic, and referral practices following participation.

Methods: PPCPs from a hospital-affiliated pediatric network were invited via email to participate. A subsequent group of providers from an integrated medical home were invited following their request for ASD-diagnostic training. Pre- and post-test measures of knowledge and confidence were collected for each webinar (Screening, Diagnosis, Referral). Participants had the option of providing open-ended feedback following each post-test. PPCPs were incentivized with 1 continuing medical education (CME) credit for each webinar completed and the ability to download each presentation following post-test.

Results: Of 291 PPCPs invited, 37 (12.7%) completed Screening; 31 (10.7%) completed Diagnosis; and 28 (9.6%) completed Referral. Paired samples t-tests revealed statistically significant pre-post increases ($p< .001$) in knowledge and confidence scores for each webinar. Chi-square analyses comparing pre-post proportions of correct versus incorrect responses showed larger proportions of correct responses post-test. Additionally, themes and subthemes identified in analyses of provider feedback reflected high utility and acceptability, though inclusion of community resources was requested for improvement.

Conclusions: Results indicated substantive gains in both knowledge and confidence across webinars, suggesting their value as an educational tool. Although providers consistently request ASD- specific training (Carbone, Norlin & Young, 2016), as was the case for the current sample, response rates in the present study were surprisingly low. Future research investigating the discrepancy between the demand for training and the limited uptake of such freely available programs is warranted. Qualitative provider feedback suggested high utility and acceptability, which will assist in addressing this question and improving future webinars. Additional future directions include novel delivery methods (e.g., Podcasts) that would allow for access and reference 'on-the-go.' Additionally, future research should evaluate the usefulness of supplemental resources to assist providers with implementation of best practices in-clinic. For example, the utility of best-practice alerts (BPA) in combination with the educational webinars to provide immediate, in-clinic support to facilitate PPCPs' ASD diagnostic and referral practices should be investigated.

440.006 *(Poster)* Exploring Experiences and Support Needs of Parents of Children with Newly Diagnosed Autism Spectrum Disorder in Singapore: A Descriptive Qualitative Study.

J. X. Goh[1], *H. G. He*[1] *and* ***R. Aishworiya***[2,3], *(1)Alice Lee Centre for Nursing Studies, National University of Singapore, Singapore, Singapore, (2)Paediatrics, National University Health System, Singapore, Singapore, (3)Paediatrics, National University of Singapore, Singapore, Singapore*

Background: Autism Spectrum Disorder (ASD) is a lifelong disorder that impacts a child and family in numerous ways. It is important to understand the experiences of these families so as to identify their support needs and subsequently design support networks for them. Although parental stress among children with ASD in general is known to be higher, literature in terms of experiences within this specific cultural context is limited.

Objectives: To explore the experiences and support needs of parents of children with newly diagnosed ASD in Singapore and to identify ways of better supporting them.

Methods: This was a qualitative descriptive design study undertaken at the Child Development Unit of a tertiary university hospital. Inclusion criteria was 1. Parent with a child with ASD aged between 2 to 10 years 2. Child diagnosis of ASD by formal psychological assessment (using the Autism Diagnostic Observation Schedule) within the last 2 years 3. Parent being one of the child's caregivers since birth. Exclusion criteria was: 1. Parent with another older child with ASD 2. Parent with mental health disorders or terminal medical illness and 3. Parent being unable to comprehend interview questions in either English or Mandarin. Parents who met eligibility criteria were purposively sampled from the outpatient clinics between October to December 2018. Semi-structured face-to-face individual interviews were conducted with the parent until data saturation was reached. Common themes were subsequently analyzed using constant comparative method to generate results.

Results: Data saturation was achieved after 13 interviews; which comprised of 11 interviews with the mother and 2 with the father. Parents reflected the major ethnicities in Singapore with 9 of Chinese ethnicity, and 2 each of Malay and Indian ethnicity. Mean age of children of parents interviewed was 4.6 years. Parent's experiences centered around three main themes with their respective sub-themes as follows: (1) Adjusting psychologically to the diagnosis (parent's own negative emotions and stigma and expectations from society), (2) Changing lifestyle of self and family (having to plan around the child, financial/employment adjustments and juggling needs of other family members), (3) Contending with hurdles to services (difficulty accessing educational resources and frustration with services in the healthcare system). Support needs centered on the areas of informational support, tangible support (time, financial) and emotional support. Parents also highlighted a lack of formal and informal support networks to address their needs.

Conclusions: Parents of newly diagnosed children with ASD experience multiple challenges post diagnosis. Services can be improved to provide targeted support for these parents; especially informational resources and affordable access to services. Establishing dedicated support networks for these parents and educating society on the condition could also be beneficial.

440.007 *(Poster)* Food Responsiveness and Attentional Bias to Foods in Autism

***K. Beyer**, E. L. Richard, A. Wolff, M. Nadeau, A. Job Said and G. L. Wallace, The George Washington University, Washington, DC*

Background: People with Autism Spectrum Disorder (ASD) are at substantially elevated risk of developing obesity (Curtin et al., 2014), which cascades to negatively impact their broader health (Croen et al., 2015). The mechanisms contributing to and driving these adverse health outcomes are unclear. Appetitive traits, such as food responsiveness, likely play a role. Among non-ASD children with higher than normal body mass index, evidence suggests an attentional bias towards food stimuli (Rojo-Bofill et al., 2019). To date, food responsiveness, broadly construed (including attentional bias towards food stimuli), has not been examined among children with ASD.

Objectives: Examine food responsiveness via parent report of appetitive traits and a selective attention task in children with ASD.

Methods: Study 1: Participants consisted of parents of children with ASD (n=188; M age=8.6; 136 males) and parents of typically developing [TD] children (n=113; M age=9.2; 53 males) who completed the well-validated and psychometrically sound Children's Eating Behavior Questionnaire (CEBQ; Wardle et al., 2001). Specifically, scores were derived from the Food Responsiveness subscale of the CEBQ. Study 2: An overlapping (with Study 1) group of children with ASD (n=15; M age=12.53; 12 males) and TD children (n=25; M age=11.44; 14 males) were invited to complete an in-person computerized task examining attentional bias to food using a dot probe paradigm. The primary task consisted of 144 trials with 96 food trials and 48 filler trials. Images were presented at a rate of 500 ms. Participants were asked to focus on a plus sign ("+") in the center of the screen. Then the subjects were presented with two images at different screen locations (top and bottom). Participants were instructed to look at the top picture. The picture then disappeared and a probe (either "E" or "F") appeared on either the top or bottom. The participants were instructed to match the probe to the labeled keyboard keys. Data were analyzed for accuracy and latency.

Results: Study 1: Parents rated children with ASD as more food responsive (CEBQ) than TD children (t=2.28, p<.05). Study 2: There was a significant interaction (p=.03) between group and condition wherein children with ASD demonstrated attentional bias to food (vs. non-food) stimuli while TD children did not in the context of the dot-probe task. Adding self-reported hunger ratings (even though groups did not differ at the time of testing) as a covariate in the ANOVA did not alter results.

Conclusions: In sum, this study was the first to examine food responsiveness in children with ASD. In contrast to their TD counterparts, children with ASD demonstrated increased food responsiveness per parent report and in the dot probe paradigm. These findings could pinpoint one of several underlying contributors to the increased risk for development of obesity in ASD. Future research could examine treatment approaches that seek to mitigate this attentional bias to food, as has been done in TD groups, in order to address risk of obesity development in children with ASD.

440.008 *(Poster)* Grey and White Matter Alterations in Rett Syndrome

***D. Li**, Q. Xu, H. Li and X. Xu, Children's Hospital of Fudan University, Shanghai, China*

Background: Rett syndrome (RTT) is a devastating genetic disorder representing the most common genetic causes of severe intellectual disability in females. Most cases are caused by X-linked MECP2 gene mutations. Patients with RTT usually lose the ability to use words and experience poor hand use with severe cognitive and motor deficits. Pathologic studies showed reduced brain weight in RTT. Regional brain volume measurements reported decreased grey matter volume and reduced FA values compared to healthy controls. In this study, we employed voxel-based morphometry (VBM) and tract-based spatial statistics (TBSS) to investigate the grey matter and white matter alterations in RTT, the idiopathic ASD, and typically developing children as controls respectively. Compared to traditional region-of-interest based analytic method, VBM is automated full-brain analysis without manually delineations; while TBSS provides advantages with higher spatial comparability.

Objectives: To investigate the grey and white matter alterations in children with Rett Syndrome based on the structural MRI imaging, so as to provide reference for targeted treatment.

Methods: 73 children were included in the present study, including 22 with Rett Syndrome, 24 ASD children without pathogenic gene variation or pathogenic Copy Number Variations and 27 typically developed children. MR scans were obtained on a GE 3.0T Discovery 750 system with T1 BRAVO and EPI (15 directions) sequences. VBM analysis: TOM8 toolbox was used to create study specific TPM maps. These maps were utilized on CAT12 software in the DARTEL algorithm to create final templates for normalization and segmentation. Resulting statistical maps were thresholded at P<0.01 FWE corrected. TBSS analysis: All DTI datasets were first corrected for eddy current distortions and head movements using FSL. Then DTIFIT fitted a diffusion tensor model at each voxel to generate FA maps. The TBSS analysis was then performed. All FA images were aligned to form the target image then transform into MNI standard space. Tract-based spatial statistics were then tested with FA maps to create the "skeleton". Permutation tests were applied to the general linear model. Resulting statistical maps were thresholded at P<0.01 FWE corrected using TFCE approach.

Results: VBM post-statistical analysis between Rett group and ASD group, as well as Rett group and typical developed controls, clearly showed significant brain volume decreases mainly on left frontal gyrus, including left Frontal_Mid, Frontal_Sup, Frontal_Mid_Orb and Frontal_Sup_Orb (Figure 1). No significant altered brain volumes were found between ASD and typical developed controls. TBSS results demonstrated decreased FA values mainly on the corpus callosum and corona radiata in Rett group, including Genu_of_corpus_callosum, Body_of_corpus_callosum, Splenium_of_corpus_ callosum, Anterior_corona_radiata and Posterior_corona_radiata (Figure 2). Interestingly, no significant different FA values were found between ASD and typical developed controls.

Conclusions: This work demonstrated that, in children with Rett Syndrome, the brain volume decreases were mainly found at left MFG, SFG, OMF and OSF and the white matter abnomalities were at the corpus collosum and corona radiata. These brain structure alterations may elaborate the clinical manifestations of Rett Syndrome, including language, cognition and motor developmental delays. Further functional MRI studies may provide more evidence for the current conclusions.

440.009 *(Poster)* Iron and Vitamin D Deficiency in Young Children with Autism Spectrum Disorder in Singapore

M. Y. Koh *and R. Aishworiya, Paediatrics, National University Health System, Singapore, Singapore*

Background: Iron and vitamin D have been implicated to play an important role in cognition and neurodevelopment respectively. Existing evidence suggests that correcting deficiencies in both these nutrients can improve Autism Spectrum Disorder (ASD) symptoms. Children with ASD are also at greater risk for these deficiencies due to behavioural difficulties and food selectivity. Extant literature shows highly variable rates of these deficiencies and variable practices in routine screening among different populations.

Objectives: The objectives of this study were to 1. Determine occurrence of iron and vitamin D deficiency in the sample population, 2. Identify predictors of the presence of these deficiencies if any and 3. Elucidate factors influencing screening for these deficiencies in children with ASD.

Methods: This was a retrospective cross-sectional review of case records of all patients with ASD who were seen at a tertiary developmental paediatric centre in Singapore from January 2018 to June 2018. Inclusion criteria was 1. Child age 0 to 7 years and 2. Diagnosis of ASD following clinical evaluation by a developmental paediatrician or formal psychological evaluation with the Autism Diagnostic Observation Schedule. Exclusion criteria was 1. Chronic medical conditions and 2. Genetic syndromes. Information on demographic variables, ASD-related variables and other medical conditions was abstracted using a structured data collection form. Presence of iron deficiency (serum ferritin < 12µg/L or transferrin saturations < 10%), vitamin D deficiency (25-hydroxyvitamin D [25(OH)D] < 10 µg/L) and vitamin D insufficiency (25(OH)D between 10.1-29.9 µg/L) was determined from review of laboratory investigations. Descriptive statistics were used to assess for prevalence of iron and vitamin D deficiencies. Logistic regression was used to identify predictors of iron and vitamin D deficiencies and chi square tests were used to compare children who were and were not offered screening for these deficiencies.

Results: The sample consisted of 480 children (81% males, 19% females) with a mean age of 4.5 years (SD 1.3). Of this, only 20.2% (N=97) of children were screened for iron deficiency and 18.3% (N=88) were screened for vitamin D deficiency using blood tests. The prevalence of iron deficiency was 19% (N=18). Younger children were more likely to have iron deficiency (B=1.06, p=0.02). The prevalence of vitamin D insufficiency was 38% (N=33) and that of vitamin D deficiency was 1.1% (N=1). Older children were more likely to have vitamin D deficiency or insufficiency (B=1.07, p=0.01). Only 20.8% (N=100) of children from the entire sample were offered screening blood tests; children with greater severity of disease ($\chi 2$= 9.80, p=0.002) and those with a history of selective feeding ($\chi 2$= 8.27, p=0.004) were more likely to be offered screening tests.

Conclusions: The prevalence of both iron deficiency and vitamin D deficiency/insufficiency was high in this sample compared to the general population. Of note, only a small proportion of children were offered screening and eventually screened for these deficiencies. Apart from child age, there were no significant child or disease characteristics that predicted these deficiencies. Routine screening of all children with ASD for iron and vitamin D deficiency is recommended.

440.010 *(Poster)* Results from a Multidisciplinary Self Injurious Behaviour Clinic - 2 Years Later

A. Richardson*, BC Children's Hospital, Vancouver, BC, Canada*

Background: Self Injurious Behaviours (SIB) is a distressing Restrictive and Repetitive Behaviour (RRB) that can impact up to 30% of those with autism; severe SIB is much less common but is an incredibly distressing behaviour. Identification and early specialised intervention of those who are at risk of severe SIB is a key component to reducing this RRB. Currently, in North America, there are few clinics that specialise in severe SIB. The multidisciplinary SIB Clinic has been operational in Vancouver for two years. We employ a novel approach to assessment of the most affected children in our province (British Columbia). It is a clinic that brings together general pediatrics, neuropsychiatry, pediatric neurology, pain, sleep specialists, psychology as well as allied health with a behavioural analyst, speech and language pathologist, occupational therapy and a social worker. Children are referred to the clinic by psychiatrists through British Columbia's Children's Hospital and we have been seeing approximately 1 patient per month.

Objectives: As we have been operational for two years and have assessed 17 patients this is an opportune time to review the patients we have assessed to date.

Methods: Demographic, intervention and investigational data has been gathered and has been reviewed. We have identified themes in presentation, treatment and assessment of severe SIB.

Results: The average age of children seen was 9.7 years, with the youngest being 4 and the eldest being 16. Almost all (15/17) of the children seen for assessment are male. The majority had a diagnosis of autism at presentation (15/17). Three patients had a genetic syndrome known to be associated with autism and while these children had been seen by multiple subspecialists (up to 7), many of the others were managed by psychiatry and pediatrics. Sleep issues, including insomnia, parasomnias, biphasic sleep and restless sleep affected most of the patients (14/17). 1/3 of the children were living the care of social services due to their behaviours. Many children were managing polypharmacy and had trialled multiple psychiatric medications (0-14) and over the counter medications. Few (2/17) had a prior Brief Functional Analysis completed, although all had some Behavioural Intervention in place. All had major deficits in communication, most (15/17) were non-verbal. In terms of prior investigations including bloodwork, imaging, and genetics only 3/17 had a reasonable workup for causes of SIB.

Conclusions: Through our novel 2 year operation we have identified several themes which are informative to practice. First, multidisciplinary clinics such as ours are rare and labour intense. Second, most of those affected by severe SIB are male, and although we see a range in age, the SIB has been a long standing issue. Third, likely based on behaviours, these children have had little to no investigations to assess causes of their SIB, or the underlying autism. Fourth, although we know that SIB is a form of RRB that requires interventions aimed at reducing the RRB, children have limited access to this specialised treatment. Finally, sleep and poor communication are common comorbidities in those affected by severe SIB.

Rare Genetic Disorders

POSTER SESSION — **RARE GENETIC DISORDERS**
441 - Rare genetic disorders Posters

441.001 *(Poster)* A Study of the Impacts of AB-1224 on the Rett-like Phenotype and Intestinal Permeability in the Mecp2tm1.1Bird Mouse Model of Rett Syndrome

J. M. McLellan[1]*, S. Campbell*[2]*, D. H. Donabedian*[1]*, R. Graf*[3]*, K. Tang*[2]*, G. M. Preston*[4] *and T. Hanania*[5]*, (1)Axial Biotherapeutics, Inc., Waltham, MA, (2)Axial Biotherapeutics, inc., Waltham, MA, (3)Axial Biotherapeutics, Inc., Boston, MA, (4)Axial Biotherapeutics, Waltham, MA, (5)Behavioral Pharamcology, PsychoGenics, Inc., Paramus, NJ*

Background: Rett syndrome (RTT) is a neurodevelopmental disorder primarily caused by spontaneous mutations in the methyl-CpG binding protein (*MECP2*) gene on the X-chromosome and occurs in ~1:10,000 live female births. Approximately 50% of RTT individuals have behaviors that meet criteria for an autism spectrum disorder (ASD) diagnosis at some point in their development (Wulffaert, J *et* al. Autism 2009). As in ASD, gastrointestinal (GI) complications are common in RTT individuals (>80%). In preclinical studies, Hsiao *et* al. (Cell 2013) demonstrated a relationship between gut dysbiosis and ASD symptoms that specifically implicated bacterial metabolites from the metabolism of tyrosine and tryptophan. Furthermore, that study established that *Bacteroides fragilis* (i.e. a live biotherapeutic product like AB-1224) was able to correct gut dysbiosis, aberrant metabolite levels, and ASD-like behaviors in a well-established mouse model of ASD. RTT individuals have been shown to have both dysbiosis and aberrant metabolite levels, and thus may benefit from treatment with AB-1224.

Objectives: The purpose of this study was to assess the therapeutic potential for AB-1224 to mitigate the RTT-like phenotypes found in *Mecp2*$^{tm1.1Bird}$ mice.

Methods: Study groups included AB-1224 dosed in applesauce 3 times during the 6th week of life to female heterozygous *Mecp2*$^{tm1.1Bird}$ mice (n=15), applesauce vehicle only in female heterozygous *Mecp2*$^{tm1.1Bird}$ mice (n=15), and an untreated female C57BL/6J (WT) control cohort (n=16). Mice were assessed at 8 and 12 weeks of age for hindlimb clasping (HLC), rotarod performance, startle response, and gait analysis. To measure intestinal permeability FITC-dextran was administered orally to all groups at 12 weeks of age and plasma concentrations were measured via fluorescence in 4-hour post-dose samples. Microbial metabolites measured in urine using LC-MS/MS. Inflammation and immune system regulation in these mice were characterized in plasma using a V-Plex Mouse Cytokine 29-plex kit from Meso Scale Discovery.

Results: Consistent with the expected phenotype in this model, *Mecp2*$^{tm1.1Bird}$ mice showed significant deficits in the rotarod performance, startle response, and gait, and significantly more HLC relative to the WT cohort. The AB-1224 treated cohort showed improvements in rotarod performance and HLC. Intestinal permeability was significantly increased in control *Mecp2*$^{tm1.1Bird}$ mice relative to the WT and the AB-1224 treated cohorts, suggesting that AB-1224 was able to prevent the development of increased intestinal permeability. A variety of microbial metabolites and immune regulatory markers were altered in these mice.

Conclusions: For the first time, to the best of our knowledge, female heterozygous *Mecp2*$^{tm1.1Bird}$ mice were found to have a robust leaky gut phenotype. Interestingly, treatment with AB-1224 restored GI integrity, and improved motor deficits (rotarod and HLC) in these mice. Taken together, these findings suggest that AB-1224 may warrant further investigation as therapeutic for the treatment of GI and motor dysfunctions in RTT.

441.002 *(Poster)* Can “Red Flags” for Autism Spectrum Disorder be Reliably Assessed Via Remote Parent Administration?

T. Halligan*, L. R. Hamrick, R. Felicicchia and B. Kelleher, Psychological Sciences, Purdue University, West Lafayette, IN*

Background: It is unclear whether autism-related "red flags" derived for idiopathic autism exist at similar base rates in genetically-associated autism risk groups, such as children with neurogenetic syndromes (NGS). Addressing this gap may inform more accurate early screening protocols and etiological models of autism, however studying NGS is challenged by the high cost and travel burden associated with geographically-dispersed samples. Here, we assess the feasibility and validity of using Parent-Administered Neurodevelopmental Assessment (PANDABox), a remotely-administered, caregiver-facilitated platform we developed for assessing autism risk via telehealth, to measure behavioral red flags in a national sample of children with NGS.

Objectives: Our goals were to assess (1) the feasibility of PANDABox for assessing autism-related red flags in NGS, and (2) consistency between observed behaviors and caregiver reports. We also (3) preliminarily examined whether base rates of red flags were higher in NGS.

Methods: Participants were 4- to 25-months-olds at low risk for autism (LR; n=20) and with NGS (n=33; Down, fragile X, and Angelman syndromes) and their caregivers. Discrete autism-presses (DAP) tasks were informed by well-validated screening tools and literature on early features of autism (Bryson, et al., 2008; Lord et al., 2012; Table 1). Tasks were coded offline by three coders who assigned codes based on typical versus atypical responses and usability of data. To assess validity, parents also completed the Modified Checklist for Autism in Toddlers (M-CHAT-R) and Vineland Adaptive Behavior Scales (VL-3). We hypothesized (1) similar feasibility across LR and NGS, as measured by coder reliability and rates of usable data, (2) valid measurement of red flags, as demonstrated by consistency between observed behavior and reports on parallel M-CHAT-R/VL-3 items, and (3) higher base rates of atypical behavior in NGS. We used nonparametric Fisher's exact tests to compare rates of feasibility, consistency, and atypical behavior.

Results: Average coding agreement across paired raters reached 81% (GAC Kappa=.80). LR and NGS groups did not differ by rates of unusable data codes across DAP tasks (insufficient behavior and out-of-view), with the exception of greater out-of-view presses in the LRC group during Joint Attention (30%; NGS=6%; p=.042). Most DAP task responses did not correspond to M-CHAT-R/VL-3 skills, with the exception that Peekaboo related to VL-3 (84% with typical DAP and VL-3; 50% with atypical DAP and VL-3; p=.065). In this preliminary sample, groups did not differ in their behavioral responses on DAP tasks (Figure 1).

Conclusions: Our results suggest PANDABox is a feasible method for examining "red flags" for autism in geographically-dispersed cohorts; work is needed to inform the validity relative to gold-standard protocols. Both groups demonstrated similar proportions of usable data across DAP tasks; however, behaviors did not demonstrate expected associations with caregiver-reported skills. This is consistent with reports that caregiver-reported symptoms contain valuable input for diagnostic evaluations but frequently differ from behavioral data (Sikora et al., 2007). We also did not find differences in atypical behavior across groups. Next steps will examine group differences in DAP responses and associations with clinical diagnoses in larger, representative samples.

441.003 *(Poster)* Characterizing Repetitive Behaviors in Fragile X Syndrome across the Lifespan: The Impact of Age, IQ, Gender, and Comorbid Autism Spectrum Disorder

D. L. Reisinger[1], *R. Shaffer*[1], *N. Tartaglia*[2], *E. Berry-Kravis*[3] *and C. A. Erickson*[4], *(1)Division of Developmental and Behavioral Pediatrics, Cincinnati Children's Hospital Medical Center, Cincinnati, OH, (2)Pediatrics, University of Colorado School of Medicine, Aurora, CO, (3)Pediatrics, Neurological Sciences, & Biochemistry, Rush University Medical Center, Chicago, IL, (4)Cincinnati Children's Hospital Medical Center, Cincinnati, OH*

Background: Fragile X syndrome (FXS) is the leading heritable cause of intellectual disability that presents with a variable clinical phenotype, typically affecting males with the full mutation more than females. FXS is characterized by mild to severe ID with a series of other deficits including social communication deficits and restricted, repetitive behaviors (RRBs) resulting in high comorbid rates of autism spectrum disorder (ASD). Literature is limited on the specific RRB profile found in FXS across the lifespan. Verbal perseverations in boys with FXS is a hallmark feature of the FXS behavioral phenotype[1,2,3]. Increased rates of restricted interests, stereotyped, self-injurious, sensory motor, and sameness behaviors have been reported in FXS[4,5,6]. Characterizing the RRB profile specific to FXS is important for understanding the neurological underpinnings and behavioral mechanisms of RRBs that can affect behavioral and pharmacological treatments.

Objectives: This study utilizes a large, chronologically diverse sample of FXS participants to characterize the effects of age, IQ, gender, and comorbid ASD on RRBs and RRB subtypes.

Methods: Participants included 119 individuals with FXS (74% male) ranging from 3 to 50 years of age (M=17.26, SD=11.02). Caregiver report of participants' RRBs was obtained using the Repetitive Behavior Scale – Revised (RBS-R)[7]. The RBS-R consists of six subscales that combine to create a total score. Participants' IQ was obtained using the Stanford-Binet Intelligence Scales, Fifth Edition (SB-5)[8]. Participants' current ASD diagnostic status was obtained via clinician report (42% with a clinical ASD diagnosis). Current data come from two collection sites. A third site will be included at the time of the presentation.

Results: A regression revealed a significant relationship between RBS-R total score and age, F(1, 117)=11.44, p=0.001. Participant's RBS-R total score decreased 0.48 for each year of age. Pearson correlations revealed significant negative associations between age and the following subscales: Stereotyped Behavior, Routine Behavior, Sameness Behavior, and Restricted Behavior. A regression revealed a significant relationship between RBS-R total score and IQ, F(1, 100)=12.53, p=0.001. Participant's RBS-R total score decreased 0.39 for each IQ point. Pearson correlations revealed significant negative associations between age and all of the RBS-R subscales. Controlling for IQ, an ANCOVA revealed no significant group differences on RBS-R total score based on gender, F(1, 93)=0.13, p=0.719. An ANOVA revealed significant group differences on RBS-R total score based on current ASD diagnostic status F(1, 84)=29.18, p=0.000. Participants with a comorbid ASD diagnosis (M=36.86, SD=2.60) had higher RBS-R total scores in comparison to participants without a comorbid ASD diagnosis (M=18.46, SD=2.20). These findings remain across each subscale on the RBS-R (ps<0.01).

Conclusions: Findings suggest RRBs tend to decline with age and are more severe with lower IQ. Unexpectedly, rates of RRBs did not differ by gender, even when controlling for IQ, despite common gender differences found in FXS. Lastly, despite majority of the sample not having a comorbid clinical diagnosis of ASD, those with ASD experience more severe RRBs. Results build on the evidence that RRBs are specific to the FXS behavioral phenotype, with more severe RRBs potentially differentiating those with and without ASD.

441.004 *(Poster)* Differences in Resting State Alpha Power between LGD Mutations, Idiopathic ASD, and Typically Developing Individuals

W. R. Ganz[1], *L. T. Hall*[1], *C. L. Sargent*[1], *K. Wadhwani*[1], *R. K. Earl*[1], *E. E. Eichler*[2], *R. Bernier*[1], *S. J. Webb*[1] *and C. M. Hudac*[3], *(1)Psychiatry and Behavioral Sciences, University of Washington, Seattle, WA, (2)Department of Genome Sciences, University of Washington, Seattle, WA, (3)Psychiatry and Behavioral Sciences, University of Washington, Seattle, AL*

Background: Electroencephalography (EEG) oscillations have been used as a biomarker to assess cognitive processes and functioning. Specifically, alpha rhythms (oscillations ranging from 8-12 Hz) are associated with attention and sensation (Bernard & Gage, 2013; Garcia-Rill, 2015; Kropotov, 2009). These correlates of alpha make it a possible biomarker for Autism Spectrum Disorder, as ASD is associated with atypical sensory processing (Linke et al., 2017). Differences in alpha power occur during resting state (Wang et al., 2013) and imitation tasks (Bernier, Aaronson, & McPartland, 2013) between typically developing (TD) and ASD populations. Additionally, advances in genomics highlight the importance of taking a 'genetics-first' approach for research in subgroups of the ASD population, such as *Likely* Gene Disrupting (LGD) mutations, hindered protein function resulting from single allele damage (Iossifov et al., 2014). Phenotypic heterogeneity (Stessman, Bernier, & Eichler, 2014; Iossifov et al., 2014; Goin-Kochel, Trinh, Barber, & Bernier, 2017) and unique neurophysiological differences exist among those with LGD mutations (Hudac et al., 2017), thus warranting further investigation on individual differences among LGD mutation carriers.

Objectives: We sought to characterize alpha rhythm differences related to various genetic etiologies of ASD.

Methods: Data from 204 children (see Table 1) were included in analyses in three groups: 66 children with ASD but no known genetic etiology (ASD No Event group), 57 children with an ASD diagnosis and a likely-gene disruptive mutation to an ASD-risk gene (LGD mutation group), and 81 typically-developing children (TD group). A resting state EEG paradigm, displaying randomly selected screensaver-like videos of various shapes and colors were presented for two and a half minutes (16 trials per block) to participants as they were instructed to attend to the presentation monitor with their eyes open. Each child's peak alpha rhythm within the 8-12 Hz range was extracted from 8 different bilateral regions (see Figure 1) and included in linear mixed-effects analyses. A full factorial model included genetic group, region, and sex as predictors of alpha rhythm.

Results: Results indicated a significant group x region interaction, $F(1,14) = 9.08$, $p <. 0001$, that highlighted group differences at medial central (MC) electrode locations. Specifically, the LGD mutation group exhibited more alpha rhythm than the ASD No Event group, $p = .042$, and the TD group, $p = .033$. There were no differences between ASD No Event and TD group in this region, $p = .99$. However, this pattern was observed for females, p's < .0007, but males with an LGD mutation exhibited comparable levels of MC alpha rhythm to ASD No Event and TD groups , p's > .70 (Figure1).

Conclusions: Our results introduce sex differences in alpha power among those who carry an LGD mutation, but contradicts previous evidence of differing neural expression between males and females with ASD (Werling & Geschwind, 2013). Current findings suggest further research on sex-differential genetic and neurophysiological factors among the LGD mutation population with ASD. Future studies should focus on differences in alpha power between sex and various LGD mutations associated with ASD.

441.005 *(Poster)* Does a Dietary Intervention Affect Metabolic and Behavioral Phenotypes of the Autism-Associated 3q29 Deletion?

R. M. Pollak[1], *R. Purcell*[2], *T. Rutkowski*[1], *T. Malone*[1], *K. Pachura*[3], *G. J. Bassell*[2], *M. P. Epstein*[1], *T. Caspary*[1], *P. A. Dawson*[3], *D. P. Jones*[4], *S. T. Warren*[1], *D. Weinshenker*[1], *M. E. Zwick*[1] *and J. G. Mulle*[1], *(1)Department of Human Genetics, Emory University School of Medicine, Atlanta, GA, (2)Department of Cell Biology, Emory University School of Medicine, Atlanta, GA, (3)Department of Pediatrics, Emory University School of Medicine, Atlanta, GA, (4)Division of Pulmonary, Allergy, and Critical Care Medicine, Emory University School of Medicine, Atlanta, GA*

Background: 3q29 deletion syndrome (3q29Del) is caused by a rare (~1:30,000) 1.6 Mb heterozygous deletion on chromosome 3 and is associated with a wide range of neurodevelopmental and neuropsychiatric phenotypes, diminished growth, and other physical features. Individuals with 3q29Del have significantly reduced birth weight compared to matched controls (15.04oz difference, p=1.5E-6); in Emory University's 3q29Del mouse model, a growth deficit persists throughout development (1.81g difference, 8% of body weight, p=8.8E-12). The consistency of this phenotype, and the presence of four mitochondria- or metabolism-associated genes within the 3q29 interval, suggests there may be an unidentified metabolic defect in 3q29Del.

Objectives: This study utilizes our mouse model of the 3q29 deletion to characterize the 3q29 deletion-associated growth defect mechanism and implements a postnatal dietary manipulation to determine whether metabolic or behavioral phenotypes are affected.

Methods: We used a mouse model of the 3q29 deletion created by Emory 3q29 Project investigators using CRISPR/Cas-9 technology. Adult C57Bl/6 wild type (WT) and 3q29 mice on standard chow (13% calories from fat) were subjected to indirect calorimetry and liver samples were collected for untargeted metabolomics ($n^3$8/group). These experiments were repeated in mice on a high-fat diet (HFD; 42% calories from fat); growth curves were also constructed for HFD mice and a behavioral battery was performed on a subset of HFD mice. All experiments included males and females.

Results: Via untargeted metabolomics, palmitoylcarnitine was significantly increased in liver of 3q29 animals on standard chow after adjusting for sex (p<0.05, FC=0.314). In stratified analyses, phosphatidate was significantly increased in female mutants versus WT (p=0.02, FC=1.997), with males showing a similar trend (p>0.05). Pathway enrichment analysis identified fatty acid metabolism pathways as enriched for significant metabolites (p<0.05). In metabolic cages, there were no differences between 3q29 and WT mice on standard chow for food and water consumption, activity, and energy expenditure ($n^3$8/group). Preliminary results indicate feeding mice a HFD reduces the 3q29 deletion-associated weight deficit (1.67g difference, 4.8% of body weight, p=0.0005), and metabolic cage data shows that HFD female 3q29 mice have significantly reduced respiratory exchange ratio (RER) peaks (p<0.006, n=10/genotype). Untargeted metabolomics on HFD liver will assess altered metabolic pathways, dietary fat absorption will be quantified for WT and 3q29 mice, and behavioral testing will identify behavioral changes resulting from the HFD intervention.

Conclusions: Metabolic cage data from mice fed standard chow confirm that the 3q29Del-associated weight deficit is not due to decreased feeding or increased energy expenditure, and instead likely results from altered metabolism. Metabolomics data indicates that the 3q29 deletion-associated weight deficit may be due to an alteration in fatty acid metabolism. Growth curves from the HFD mice suggest that increasing dietary fat calories can partially ameliorate the weight deficit in 3q29 deletion mice. Reduced RER peaks in HFD female 3q29 mice indicate that 3q29 mice are preferentially utilizing lipids as a primary energy source. Taken together, these data shed light on the nature of metabolic phenotypes in 3q29Del, and may highlight metabolic pathways relevant to autism, intellectual disability, and other neurodevelopmental and neuropsychiatric phenotypes.

441.006 *(Poster)* Nonverbal Communication in Children with FOXP1 Syndrome

H. Walker[1]*, I. Giserman-Kiss*[2]*, L. Tang*[1]*, M. P. Trelles*[1]*, D. Halpern*[1]*, J. Zweifach*[1]*, A. Kolevzon*[1]*, P. M. Siper*[1] *and J. Buxbaum*[3]*, (1)Seaver Autism Center, Department of Psychiatry, Icahn School of Medicine at Mount Sinai Hospital, New York, NY, (2)University of Massachusetts Boston, Brookline, MA, (3)Department of Psychiatry, Icahn School of Medicine at Mount Sinai, New York, NY*

Background: FOXP1 syndrome is a rare neurodevelopmental disorder caused by mutations and deletions in the Forkhead-Box P1 (FOXP1) gene. Previous studies identified FOXP1 as a common single-gene cause of autism spectrum disorder (ASD). In addition to ASD traits, language deficits are reported in all documented cases and include delayed acquisition of speech, varying levels of speech complexity (nonverbal to fluent speech), and significant articulation problems. Intellectual disability, motor delays, hypotonia, and externalizing psychiatric symptoms are also commonly reported. Given known expressive language deficits, understanding nonverbal communication in this population may offer critical insight into the influence of FOXP1 mutations on communication skills more broadly.

Objectives: To examine clinician-rated nonverbal communication skills in children with FOXP1 syndrome.

Methods: Sixteen children with mutations in FOXP1 (12 female; ages 3-11; 25% ASD) received autism-focused evaluations using gold-standard diagnostic tools including the Autism Diagnostic Observation Schedule, 2nd Edition (ADOS-2). The ADOS-2 was administered to all participants by research reliable clinical psychologists. Five children received a Module 1, eight children received a Module 2, and three children received a Module 3. Nonverbal ADOS-2 items that overlapped across modules were selected for analyses: (1) use of gestures, (2) eye contact, and (3) facial expressions. Given differences across modules in scoring criteria for these items, all scores were dichotomized to reflect intact (score=0) or impaired (score³1) skills. A nonverbal communication composite score was also calculated. Relationships between nonverbal communication skills and DSM-5 consensus diagnosis based on psychiatric evaluation, ADOS-2, and the Autism Diagnostic Interview-Revised (ADI-R) were explored

Results: Participants' use of nonverbal communication skills varied across skills measured (see Figure 1). During the ADOS-2, 66.7% of participants demonstrated appropriate use of modulated eye contact. The majority of the sample (80.0%) presented with reduced use of gestures and approximately half (46.7%) exhibited a limited range and/or poorly directed facial expressions. Chi-square tests revealed that participants' use of eye contact (χ^2 (1, N= 16) = 4.26, p=.04) and facial expressions (χ^2 (1, N= 16) = 4.78, p=.03) significantly correlated with ASD consensus diagnosis. There was no significant relationship between use of gestures and ASD consensus diagnosis (χ^2 (1, N=16) = 1.36, p=.24). A composite score based on all three measures of nonverbal communication was moderately correlated to ASD consensus diagnosis (r=.640, p=.01).

Conclusions: Children with FOXP1 syndrome presented with a range of nonverbal communication skills during the ADOS-2. Eye contact was preserved in the majority of participants, although use of facial expressions and, to a greater degree, gestures, was notably limited. While children with limited use of facial expression were more likely to meet DSM-5 diagnostic criteria for ASD, use of gestures was not significantly correlated with ASD consensus diagnosis. Limited use of gestures may be related to high rates of motor delays and hypotonia, rather than an underlying social communication deficit. These findings have meaningful implications for the evaluation and treatment of social communication deficits in children with FOXP1 syndrome. Future studies should include additional assessments to assess the impact of FOXP1 on nonverbal communication skills.

441.007 *(Poster)* Predicting Change in Autism Symptomatology in Young Males with Fragile X Syndrome

K. E. Caravella[1] *and J. E. Roberts*[2]*, (1)Carolina Institute for Developmental Disabilities, University of North Carolina, Chapel Hill, NC, (2)Department of Psychology, University of South Carolina, Columbia, SC*

Background: Fragile X syndrome (FXS) has the highest penetrance of any single gene disorder implicated in ASD, with 60-75% of individuals meeting criteria for ASD and upwards of 90% exhibiting at least one symptom. Little is known about the stability of ASD diagnoses in young children with FXS, and how symptom trajectories are related to diagnostic stability.

Objectives: The present study aims to utilize the Brief Observation of Social Communication Change (*BOSCC*) to measure change in autism symptomatology in young males with FXS. Two research questions were proposed, 1) What are the stability patterns of ASD in young males with FXS?, 2) Do patterns of change in autism symptomatology differ in young males with FXS dependent on their clinical best estimate diagnosis of ASD, and the stability of that diagnosis?

Methods: Participants included 28 males with FXS between 2-8 years. Participants are a subset of a parent study that conducted diagnostic assessments using the *ADOS-2*, at 2, 3, 4 and 5 years of age, with some variability at the age of enrollment. Clinical best estimate diagnoses of ASD were determined at each visit to track stability. For inclusion in the present study, participants were required to have at least 2 video recorded diagnostic assessments with the *ADOS-2* (range 2-4). Select video clips from the *ADOS-2,* designated by the authors of the *BOSCC*, were combined to create video segments that were coded and scored using the *BOSCC* codes. Participants were grouped based on the stability of their ASD diagnoses. Multilevel models were used to examine longitudinal trajectories of *BOSCC* total scores.

Results: Regarding diagnostic stability, 75% of the participants demonstrated stable positive or negative ASD diagnoses (Stable ASD; n =15 and Stable noASD; n=6), and 25% demonstrated unstable diagnoses (i.e., Unstable ASD (i.e., false negative, n=4) and Unstable noASD (i.e., false positive, n=3)). On average, participants in the Stable ASD group had initial BOSCC scores at 24 months of 31.64 (t = 14.40, p = 0.00) which were higher than the Stable NoASD group (b = -16.49, p = 0.00), and Unstable ASD group (b = -9.86, p = .034), but not different from the Unstable NoASD group (b = 0.68, p = .924). Slopes did not differ between the Stable ASD group and the Stable NoASD or Unstable ASD groups. However, Unstable NoASD participants evidenced a negative slope (b = 0.42, p = .065).

Conclusions: Results suggest that 75% of young males with FXS display a high degree of stability in ASD diagnostic categorization for both the presence and absence of ASD. Young males with FXS and stable ASD display the most severe symptomatology, with symptom levels remaining high across time. In a parallel pattern, participants with a stable diagnosis of FXS noASD, evidence much lower levels of autism symptomatology at 24 months with symptoms remaining low and stable over time. In contrast, the Unstable noASD participants display similar levels of ASD symptoms to the Stable ASD group at 24 months, however show a significant improvement in symptoms over time.

441.008 *(Poster)* Psychiatric Features of Children and Adolescents with Phelan-McDermid, ADNP, FOXP1, and DDX3X Syndromes

L. Tang[1]*, I. Giserman-Kiss*[2]*, H. Walker*[1]*, D. Grice*[3]*, M. P. Trelles*[1]*, R. Lozano*[3]*, J. H. Foss-Feig*[1]*, J. Buxbaum*[4]*, A. Kolevzon*[1] *and P. M. Siper*[1]*, (1)Seaver Autism Center, Department of Psychiatry, Icahn School of Medicine at Mount Sinai Hospital, New York, NY, (2)University of Massachusetts Boston, Brookline, MA, (3)Icahn School of Medicine at Mount Sinai, New York, NY, (4)Department of Psychiatry, Icahn School of Medicine at Mount Sinai, New York, NY*

Background: Deletions and mutations in the SHANK3, ADNP, FOXP1, and DDX3X genes represent four common single-gene causes of autism spectrum disorder (ASD) and/or intellectual disability (ID). All four syndromes are characterized by significant impairments in cognitive, language, and motor functioning. Comorbid psychiatric features are also present, although poorly characterized in existing literature.

Objectives: To examine the psychiatric profiles of individuals with Phelan-McDermid (SHANK3), ADNP, FOXP1, and DDX3X syndromes.

Methods: Caregivers of 34 participants with Phelan-McDermid syndrome (PMS; 16 females; ages 3-17, 73.5% ASD), 19 participants with ADNP syndrome (8 females; ages 2–17; 57.9% ASD), 17 participants with FOXP1 syndrome (11 females; ages 2–17; 23.5% ASD), and seven participants with DDX3X syndrome (7 females; ages 4–16; 57.1% ASD) completed an age-appropriate version of the Child Behavior Checklist (CBCL). Overlapping scales between the two versions were included in analyses. The CBCL is a standardized caregiver-report questionnaire used to obtain information about the behavioral, social, and emotional functioning. The CBCL produces empirically-based syndrome scales (e.g., Attention Problems, Anxious/Depressed, Aggressive Behavior) and DSM-oriented scales (e.g., Attention Deficit/Hyperactivity Disorder, Anxiety, Oppositional Defiant Problems). *T*-scores≥65 represent clinically significant symptomatology.

Results: Within the PMS group, all participants scored within normal limits on the overall externalizing symptoms domain, although clinically significant Attention Problems (55.9%) and ADHD symptoms (29.4%) were reported. In the area of internalizing symptoms, 9.7% of participants scored in the clinically significant range overall. The most prominent internalizing symptoms included Withdrawn/Depressed (32.4%) and Depressive Problems (35.3%).

In the ADNP syndrome group, 47.4% reported clinically significant externalizing symptoms and 15.8% reported clinically significant internalizing symptoms. Externalizing symptoms included Attention Problems (68.4%), ADHD (52.6%), Aggressive Behavior (47.4%), and Oppositional Defiant Problems (21.1%). Internalizing symptoms included Depressive Problems (31.6%), Somatic Complaints (26.3%), Withdrawn/Depressed (21.1%), and Anxiety (15.8%).

Within the FOXP1 syndrome group, 35.3% of participants scored within the clinically significant range on the externalizing symptoms scale and <1% on the internalizing symptoms scale. Clinically significant externalizing scores included Attention Problems (82.4%), ADHD (64.7%), Aggressive Behavior (29.4%), and Oppositional Defiant Problems (23.5%).

In the DDX3X syndrome group, both externalizing and internalizing symptoms were reported by 28.6% of caregivers. Externalizing symptoms included Attention Problems (57.1%), ADHD (71.4%), and Aggressive Behavior (28.6%). Internalizing symptoms included Withdrawn/Depressed (42.9%) and Depressive Problems (42.9%). No participants fell in the clinically significant range on the Anxiety scale.

Conclusions: With regard to externalizing symptoms, caregiver-reports across the four syndromes revealed clinically significant attention problems in over half of the participants in each group. Aggressive behavior was prominent in the ADNP group, although present in a subset of individuals with FOXP1 and DDX3X syndromes. Clinically significant internalizing symptoms, such as withdrawal and depression, were reported in a substantial proportion of participants with ADNP, DDX3X, and Phelan-McDermid syndromes. Results suggest that proper evaluation and management of psychiatric comorbidities in children and adolescents with genetic conditions associated with ASD and ID is critical. Further research in this area is necessary to better understand the behavioral health needs of these understudied populations.

441.009 *(Poster)* Psychopathological Profiles across Individuals with PTEN Mutation

M. Steele[1]*, M. Uljarevic*[2]*, G. Rached*[3]*, J. M. Phillips*[4]*, R. Libove*[5]*, T. W. Frazier*[6,7]*, R. M. Busch*[8]*, P. Klaas*[9]*, J. A. Martinez-Agosto*[10]*, C. Eng*[11]*, M. Sahin*[12] *and A. Y. Hardan*[4]*, (1)Department of Psychiatry and Behavioral Sciences, Stanford University, Stanford, CA, (2)The School of Psychological Sciences, University of Melbourne, Melbourne, VIC, Australia, (3)Faculty of Medicine, Saint Joseph University, Beirut, Lebanon, (4)Psychiatry & Behavioral Sciences, Stanford University, Stanford, CA, (5)Psychiatry and Behavioral Sciences, Stanford University, Stanford, CA, (6)Autism Speaks, New York, NY, (7)Psychology, John Carroll University, University Heights, OH, (8)Neurology, Cleveland Clinic, Cleveland, OH, (9)Cleveland Clinic, Cleveland, OH, (10)Departments of Human Genetics, Pediatrics and Psychiatry, University of California, Los Angeles, Los Angeles, CA, (11)Genomic Medicine, Cleveland Clinic, Cleveland, OH, (12)Boston Children's Hospital/Harvard Medical School, Boston, MA*

Background: Autism spectrum disorder (ASD) is an etiologically and phenotypically heterogeneous disorder. It has been suggested that focusing on individuals who share a common genetic etiology holds promise for improving our understanding of symptom etiology, and informing the development of targeted treatments. Although evidence of a relationship between germline heterozygous *PTEN* mutations and ASD is well established, a significant knowledge gap exists in terms of the impact on the expression and fine-grained profile of psychopathology symptoms and disruptive behaviors. Importantly, limited progress has been made towards understanding whether *PTEN* mutation with or without ASD is associated with specific co-morbidity profiles when compared to idiopathic ASD.

Objectives: To compare: (1) concurrent psychopathology profiles across individuals with *PTEN* mutation with no ASD (PTEN-No ASD), *PTEN* mutation with ASD (*PTEN*-ASD) and ASD with macrocephaly but no *PTEN* mutation (macro-ASD) groups using the Child Behavior Checklist (CBCL) and the Aberrant Behavior Checklist (ABC); and (2) the trajectory of psychopathology symptoms and disruptive behaviors across the patient groups.

Methods: Sample included 28 individuals with *PTEN* no ASD (10 females; M_{age}= 9.19 years, *SD*= 4.91), 43 with *PTEN*-ASD (9 females; M_{age}= 11.79 years, *SD*= 5.34), and 33 with macro-ASD (5 females; M_{age}= 9.21 years, *SD*= 4.72). The CBCL and the ABC were completed by parents at 6 month intervals to explore outcome variable trajectories.

Results: There were significant group effects for both CBCL (Internalizing: *F*= 4.67, *p*= .012; Externalizing: *F*= 8.64, *p*< .001) and ABC (Irritability: *F*= 3.29, *p*= .042; Lethargy: *F*= 7.80, *p*= .001; Stereotypy: *F*= 7.48, *p*= .001; Hyperactivity: *F*= 3.74, *p*= .028; Inappropriate Speech: *F*= 3.55, *p*= .033) subdomain scores. Post-hoc comparisons indicated that for CBCL, *PTEN* no ASD group had significantly lower Externalizing and Internalizing scores than *PTEN*-ASD group (*p*= .01 and .003 respectively) and significantly lower Externalizing scores than macro-ASD group (*p*= .001). For the ABC subscales, *PTEN* no ASD group had significantly lower scores for Lethargy (*p*= .001), Stereotypy (*p*= .002), and Inappropriate Speech (*p*= .04) than *PTEN*-ASD group and significantly lower Irritability (*p*= .037), Lethargy (*p*= .004), Stereotypy (*p*= .003) and Hyperactivity (*p*= .028) than macro-ASD group. CBCL or ABC subscale scores did not differ for *PTEN*-ASD and macro-ASD groups. Generalized Linear Modelling showed that CBCL scores were largely stable, with the exception of a significant increase in Internalizing scores for *PTEN*-ASD (*F*= 29.92, *p*< .001) and *PTEN* no ASD (*F*= 18.80, *p*= .001) groups from baseline-6 months. Similar observations were observed in Externalizing scores for macro-ASD (*F*= 4.66, *p*= .044) and *PTEN* no ASD (*F*= 9.25, *p*= .008) groups. ABC subscale scores were mostly stable with the exception of baseline-6 months increase in the Irritability (*F*= 7.44, *p*= .013) and Hyperactivity (*F*= 8.95, *p*= .007) subscales in macro-ASD group.

Conclusions: Our findings provide evidence of specific behavior profiles across *PTEN* no ASD, *PTEN*-ASD, and macro-ASD groups, and shed light on symptom trajectories and disruptive behavior patterns. These findings are important for informing assessment and treatment approaches across these groups.

441.010 *(Poster)* Relationship between Ethnicity, SES, and the Time between First Developmental Concern and Diagnosis of an ASD-Linked Genetic Event

B. M. Boyd[1]*, E. Kurtz-Nelson*[1]*, R. K. Earl*[1]*, C. M. Hudac*[2,3]*, E. E. Eichler*[4] *and R. Bernier*[1]*, (1)Psychiatry and Behavioral Sciences, University of Washington, Seattle, WA, (2)Psychiatry and Behavioral Sciences, University of Washington, Seattle, AL, (3)Department of Psychology; Center for Youth Development and Intervention, The University of Alabama, Tuscaloosa, AL, (4)Department of Genome Sciences, University of Washington, Seattle, WA*

Background: Individuals with Autism Spectrum Disorder (ASD) & related genetic disorders may experience disparities in accessing various medical services due to their ethnicity and socio-economic status (SES), including access to genetic testing and research (Sankar et al., 2004; Shaw, 2014), genetic counseling (McGrath et al., 2009), and diagnostic treatment services for ASD (Begeer et al., 2009; Broder-Fingert et al., 2013). Concerns about atypical development are often raised within the first year of life for children with ASD (Baio et al., 2018), but diagnosis is consistently delayed for lower-SES and non-White families (Fountain, King, & Bearman, 2011; Mazurek et. al, 2014). Disparities in access to genetic testing have been documented for genetic disorders including ASD (Case et al., 2007), yet it is currently unknown whether individuals with single-gene events associated with ASD experience similar disparities.

Objectives: Investigate the impact of ethnicity and income on time between age of first parental concern to age of genetic diagnosis among individuals with an identified genetic event causally linked to ASD.

Methods: Ninety-five participants with a known ASD-associated single gene disruption were included in analyses. Self-reported ethnicity and household income were derived from a background history assessment. Participants endorsing ethnicity other than White/Caucasian (n = 15) were coded as “Non-White.” Age of parents’ first developmental concern was derived from the ADI-R (Rutter, LeCouteur, & Lord, 2008) and age of genetic diagnosis was derived from the genetic report. Elapsed time between age of first parental concern and age of genetic diagnosis was calculated and compared between ethnic groups using a *t*-test. Chi-square analyses were used to investigate relationships between income & ethnicity, and linear regression was used to determine whether ethnicity predicted time between first concern and diagnosis after controlling for IQ.

Results: White and non-White participants did not differ significantly in time between first concern and genetic diagnosis, t (92)= .33, p =0.65 (see Table 1), even after controlling for IQ , $R^2 = 0.06$, $F(2,69) = 0.22$, $p = .81$. Ethnic groups did not differ by SES , $X^2(7) = 11.17$, $p = 0.13$. Importantly, the analyzed cohort was predominantly White (n = 83) and positively skewed (s = 1.09) as compared to the non-White group (n = 15, s = 0.16).

Conclusions: Time between first parental concern and genetic diagnosis did not significantly differ between White & non-White individuals with disruptive events in high confidence ASD-associated genes. Notably, the sample includes over five times as many White participants as compared to non-White participants. Given that risk of de novo genetic variants related to ASD is influenced by biological factors rather than ethnicity or SES (Cuna-Hidalgo, Veltman, & Hoischen, 2016), findings likely reflect differences in access to and participation in genetic research. SES is a powerful driver of disparities in care (LaClair et al., 2019), and no differences in household income were found in this sample. Future research must address differential access to clinical research before conclusions can be drawn regarding disparities in time from concern to diagnosis for individuals with ASD-associated genetic events.

441.011 *(Poster)* Seizure Onset, Intractability, and Developmental Outcomes Among Individuals with SCN2A or DYRK1A Mutations

A. C. Petriceks[1]*, C. P. Haensli*[1]*, E. Kurtz-Nelson*[2]*, R. K. Earl*[2]*, E. E. Eichler*[3,4] *and R. Bernier*[2]*, (1)University of Washington, Seattle, WA, (2)Psychiatry and Behavioral Sciences, University of Washington, Seattle, WA, (3)Department of Genome Sciences, University of Washington, Seattle, WA, (4)Howard Hughes Medical Institute, Seattle, WA*

Background: Mutations to *SCN2A* or *DYRK1A* are associated with autism spectrum disorder (ASD), intellectual disability (ID), and seizures, but the mechanisms by which these mutations contribute to neurodevelopmental disabilities and seizures differ notably (Earl et al., 2017; Sanders et al., 2018). *SCN2A* encodes the neuronal sodium channel NaV1.2, and mutations to *SCN2A* can lead to infant or childhood onset seizures according to their impact on NaV1.2 activity (Sanders et al., 2018; Wolff et al., 2017). In contrast, *DYRK1A* encodes for a kinase involved in phosphorylation and mutations to *DYRK1A* impact multiple aspects of neuronal development (Dang et al., 2018). Among individuals with *DYRK1A* mutations, febrile seizures in infancy often progress to generalized tonic-clonic seizures (Ji et al., 2015). Early seizure onset and seizure intractability generally contribute to poorer developmental outcomes (Thompson & Duncan, 2005; Vasconcellos et al., 2001), but these associations have not yet been examined in individuals with mutations to *SCN2A* or *DYRK1A*.

Objectives: To determine if associations between age of seizure onset, intractability, and cognitive and adaptive outcomes vary between *SCN2A* and *DYRK1A* mutation groups.

Methods: Participants are individuals with a pathogenic or likely pathogenic mutation to *SCN2A (n* = 19, *M* age = 7.18 years) or *DYRK1A (n* = 26, *M* age = 9.77 years). Caregivers reported on seizure history, age of seizure onset, and whether seizures had been described as intractable (occurring at high frequency or medication resistant). IQ was measured using the Differential Abilities Scale-II (Elliott, 2007) or the Mullen (Mullen, 1995), and adaptive behavior was measured using the Vineland-II (Sparrow, Balla, and Cicchetti, 2005) or Vineland-III (Sparrow, Cicchetti, & Saulnier, 2016). Chi-square and t-tests were conducted to assess whether seizure prevalence, onset, and intractability differed across mutation groups, while bivariate correlations and t-tests were conducted to determine whether age of onset and intractability were associated with cognitive and adaptive skills within each group.

Results: 69% of participants with a *DYRK1A* mutation and 89% of participants with a *SCN2A* mutation had a history of seizures; seizure prevalence did not differ between groups. Age of non-febrile seizure onset ($t(44) = 4.47$, $p = .02$) and intractability ($X^2(2) = 8.09$, $p = .004$) differed between groups, with the *SCN2A* group demonstrating earlier seizure onset and higher intractability. Age of onset was not associated with verbal IQ, nonverbal IQ, or adaptive behavior among individuals with *SCN2A* or *DYRK1A* mutations. Intractability was not related to cognitive or adaptive skills for individuals with *SCN2A* mutations; intractability analyses for *DYRK1A* were not completed as only one participant's seizures were described as intractable.

Conclusions: Seizures in individuals with *SCN2A* mutations have earlier onset and greater intractability than in those with *DYRK1A* mutations, which likely reflects the impact of *SCN2A* mutations on sodium channel functioning, which has a strongly established connection to seizure activity. No significant associations between seizure onset or severity and cognitive or adaptive skills were identified across groups, suggesting that alternate mechanisms might be contributing to variability in developmental outcomes for individuals with mutations in *SCN2A* or *DYRK1A*.

441.012 *(Poster)* Social Activity Monitoring Among Carriers of Disruptive Mutations to DYRK1A

T. DesChamps[1], *M. M. Mahony*[2], *F. Shic*[3], *R. K. Earl*[4], *T. M. Rutter*[5], *J. Gerdts*[4], *S. Trinh*[4], *E. E. Eichler*[6], *R. Bernier*[4] *and C. M. Hudac*[7,8], *(1)Psychology, University of Washington, Seattle, WA, (2)Bernier Lab, Psychiatry and Behavioral Sciences, University of Washington, Seattle, WA, (3)Center for Child Health, Behavior and Development, Seattle Children's Research Institute, Seattle, WA, (4)Psychiatry and Behavioral Sciences, University of Washington, Seattle, WA, (5)Seattle Pacific University, Seattle, WA, (6)Department of Genome Sciences, University of Washington, Seattle, WA, (7)Psychiatry and Behavioral Sciences, University of Washington, Seattle, AL, (8)Department of Psychology; Center for Youth Development and Intervention, The University of Alabama, Tuscaloosa, AL*

Background: Disruptive mutations to *DYRK1A* are associated with ASD (O ' Roak et al., 2012) and samples of *DYRK1A* mutation carriers show ASD diagnostic rates as high as 88% (Van Bon et al., 2016). *DYRK1A* haploinsufficiency results in a unique clinical phenotype marked by microcephaly, dysmorphic features, medical conditions, intellectual disability, and language delays (Ji et al., 2015), a profile which may represent a genetically-defined subtype of ASD (Earl et al., 2017). Although previous work demonstrates a categorical association between disruptive *DYRK1A* mutations and ASD diagnosis, work is needed to quantify behavioral symptoms shared with the canonical ASD phenotype, such as atypical patterns of attention to social agents during activities (Shic et al., submitted). However, the clinical profile of *DYRK1A* poses a challenge for traditional behavioral assessment. Eye-tracking technology provides a sensitive, noninvasive, and low-demand measurement of attention to social interactions and activities.

Objectives: We sought to quantify social activity monitoring among carriers of disruptive mutations to *DYRK1A* compared to carriers of likely gene-disrupting mutations to other known ASD-risk genes and individuals with idiopathic ASD.

Methods: Data from individuals with disruptive mutations to *DYRK1A* (DYRK1A, $n = 10$), likely gene-disrupting mutations to other known ASD-risk genes (LGDM, $n = 11$), and idiopathic ASD (iASD, $n = 12$) were included in these analyses. An eye-tracking paradigm measured patterns of visual attention to social scenes depicting two social agents engaged in a shared activity. Proportion scores of time visually fixating on specific areas of interest (AOIs: Head, Body, Shared Activity, and Background) were calculated for conditions in which the agents were looking at each other (i.e., mutual gaze) and both looking to the shared activity (i.e., activity-directed gaze). Linear mixed-effects analyses with random effects tested group differences in condition for each AOI.

Results: A main effect of group revealed that DYRK1A looked significantly less to the agents' heads compared to iASD, $F(2, 30) = 3.87$, $p = .032$. Group and interaction effects (p's $< .037$) revealed that iASD looked more at the shared activity compared to LGDM, $p = .0034$. Unlike other groups, DYRK1A looked more at the shared activity during the mutual gaze condition than the activity-directed gaze condition, $p = .0078$. The iASD group looked more to the shared activity during the activity-directed gaze condition compared to the LGDM group, $p = .031$. A main effect of condition revealed that all groups looked more at the body in the activity-directed gaze (vs mutual gaze) condition, $F(1, 138) = 4.17$, $p = .043$. There were no effects of proportion looking to the background, p's $> .091$.

Conclusions: Preliminary analyses revealed that carriers of disruptive mutations to *DYRK1A* showed markedly reduced patterns of visual attention to the heads of social agents while viewing an interactive social activity, particularly compared to individuals with idiopathic ASD. These preliminary results suggest that disruptive mutations to *DYRK1A* are associated with atypical patterns of social activity monitoring characteristic of the ASD phenotype, but may represent a uniquely diminished attentional pattern.

441.013 *(Poster)* Using EEG to Examine Brain Activity and Functional Connectivity in Phelan Mcdermid Syndrome (PMS) and Autism.

J. Cooke[1], *C. Terzo*[1], *A. San Jose Caceres*[1], *P. Garces*[2], *L. Mason*[3], *E. J. Jones*[3], *J. Ahmad*[1], *H. L. Hayward*[1], *D. V. Crawley*[1], *B. Oakley*[1], *C. L. Ellis*[1], *R. Haartsen*[3], *L. Gallagher*[4], *C. Molloy*[4], *R. O'Conaill*[5], *D. G. Murphy*[1] *and E. Loth*[6], *(1)Forensic and Neurodevelopmental Sciences, Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, United Kingdom, (2)Neuroscience, Ophthalmology, and Rare Diseases (NORD) Roche Pharma Research and Early Development. Roche Innovation Center Basel, Hoffmann-La Roche, Basel, Switzerland, (3)Centre for Brain and Cognitive Development, Birkbeck, University of London, London, United Kingdom, (4)Trinity College Dublin, Dublin, Ireland, (5)Psychiatry, Trinity College Dublin, Dublin, Ireland, (6)Department of Forensic and Neurodevelopmental Sciences, Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, United Kingdom*

Background: Phelan McDermid Syndrome (PMS) is caused by haploinsufficiency of the SHANK3 gene. Around 70-80% of PMS individuals have Autism Spectrum Disorder (ASD). EEG studies have highlighted differences in brain activity and functional connectivity associated with social (theta activity) and attentional (alpha activity) processing in ASD, but little is known about PMS.

Objectives:

- To investigate EEG power in theta (4-6hz) and alpha (7-10hz) bands within children with PMS, ASD, and typically developing (TD) controls whilst viewing social and/or object videos.
- To examine differences in functional brain connectivity between groups whilst viewing videos.

Methods: EEG was recorded from 12 PMS ($\bar{x}$ age = 10 years), 12 ASD ($\bar{x}$ age = 9 years), and 10 TD ($\bar{x}$ age = 4 years) children as they watched social and object videos (session = 4mins). Fast Fourier Transforms (FFTs) were computed using a Hanning window. Power values were logged and averaged. Mixed model ANOVAs of stimulus type (social and object) x Region of Interest (ROI) were conducted for theta and alpha bands seperately. Functional brain connectivity was computed on all trials (social + object) using debiased weighted phase lag indexes (dbwPLIs) averaged across all possible electrode combinations.

Results: Group differences in power were observed for both theta ($F_{(2,31)} = 9.558$, $p < .01$, $\eta_p^2 = .381$) and alpha ($F_{(2,31)} = 11.178$, $p < .001$, $\eta_p^2 = .419$). Post hoc tests for theta revealed reduced power in PMS and ASD vs. TD respectively at $p < .05$ (MD = -1.24, SE = .28; MD = -.6057, SE = .23). For alpha, PMS individuals elicited reduced power compared with ASD and TD groups respectively at $p < .05$ (MD = -.648, SE = .23; MD = -1.118, SE =.24). Interactions between ROI*stimulus type were found in both theta ($F_{(3,93)} = 3.196$, $p < .05$, $\eta_p^2 = .093$) and alpha ($F_{(3, 93)} = 4.154$, $p < .05$, $\eta_p^2 = .118$), although simple effects were ns.

Functional connectivity differed between groups within theta ($\chi^2_{(2)} = 8.169$, $p < .05$, $\eta^2 = 0.206$), with reduced connectivity in PMS ($\bar{x}$ = .0048, SD = .0050) versus TD ($\bar{x}$ = .0118, SD = .0114, $p < .01$), and marginally reduced connectivity in PMS versus ASD ($\bar{x}$ = .0142, SD = .0100, p = .058).

Functional connectivity also differed between groups within alpha ($\chi^2_{(2)} = 9.923$, $p < .05$, $\eta^2 = 0.264$), with reduced connectivity in PMS ($\bar{x}$ = .0064, SD = .0024) versus TD ($\bar{x}$ = .0164, SD = .0077, $p < .01$), and marginally reduced connectivity in PMS versus ASD ($\bar{x}$ = .0236, SD = .0234, p = .052).

Inspection of functional connectivity as a function of frequency (1-20hz) revealed no peak for the PMS children. Meanwhile, peaks within theta (10hz) and alpha (6hz) were observed for TD and ASD groups respectively.

Conclusions: On average, both PMS and ASD individuals showed reduced activity associated with social processing. However, PMS was characterized by reduced functional connectivity during social and attentional processing.

441.014 *(Poster)* Variability in Externalizing Behavior Problems Among Individuals with ASD-Associated Disruptive Mutations

E. Kurtz-Nelson[1], *R. K. Earl*[1], *A. S. Wallace*[1], *E. E. Eichler*[2,3] *and R. Bernier*[1], *(1)Psychiatry and Behavioral Sciences, University of Washington, Seattle, WA, (2)Department of Genome Sciences, University of Washington, Seattle, WA, (3)Howard Hughes Medical Institute, Seattle, WA*

Background: Externalizing behavior problems are elevated among individuals with autism spectrum disorder (ASD; Bauminger, Solomon, & Rogers, 2010), but the biological and genetic mechanisms that influence externalizing behavior severity in ASD are not well understood (Ibrahim et al., 2019). Phenotyping individuals with disruptive single gene mutations associated with ASD may increase understanding of how genetic mechanisms influence externalizing behavior in ASD. Case series have noted elevated externalizing problems among individuals with mutations in specific ASD-associated genes (e.g., Siper et al., 2017), but rates and predictors of externalizing behavior have not been systematically reported or compared across gene groups. Individuals with mutations in ASD-associated genes also may exhibit factors associated with externalizing behavior severity in ASD, such as elevated ASD symptoms, adaptive behavior deficits, and gastrointestinal problems (Beighley et al., 2019; Hartley, Sikora, & McCoy, 2008; Jang, Dixon, Tarbox, & Granpeesheh, 2011; Neuhaus, Bernier, Tham, & Webb, 2018); variability in these factors could also influence externalizing behavior severity among individuals with ASD-associated mutations.

Objectives: To examine if externalizing behavior severity differs across ASD-associated mutation groups and whether differences persist after controlling for demographic, clinical, and medical factors.

Methods: 196 individuals (mean age = 7.25 years, 51% female) with a disruptive mutation to one of 14 ASD-associated genes were drawn from an ongoing genetics-first study and the Simons Variation in Individuals Project (Simons VIP Consortium, 2012). Caregivers completed assessments including the Child Behavior Checklist (CBCL; Achenbach & Rescorla, 2001), the Vineland-II (Sparrow, Balla, and Cicchetti, 2005) or Vineland-III (Sparrow, Cicchetti, & Saulnier, 2016), the Social Responsiveness Scale-II (Constantino & Gruber, 2012), and a medical history interview. The Externalizing Problems CBCL T-score was used to measure externalizing severity. A one-way ANOVA was conducted to compare externalizing severity across gene groups, and a one-way ANCOVA was conducted to determine whether cross-gene differences remained significant after controlling for age, adaptive behavior, ASD symptom severity, and GI problems (severe constipation or diarrhea).

Results: Externalizing severity significantly differed across gene groups, $F(13, 182) = 4.20$, $p < .001$. 23% of participants had externalizing behavior problems in the clinically significant range; however, rates of clinically significant externalizing problems ranged from 0% to 100% across groups. Cross-gene differences in externalizing severity remained significant after controlling for ASD symptom severity, adaptive behavior, age, and GI problems, $F(13, 113) = 2.68$, $p = .003$. ASD symptom severity was significantly associated with externalizing severity, $F(1, 113) = 26.27$, $p < .001$; age, adaptive behavior, and GI problems were not associated with externalizing severity. Post-hoc pairwise comparisons (Bonferroni correction applied) indicated that after controlling for the above factors, cross-gene differences were driven by high externalizing in the *ADNP* and *FOXP1* groups and low externalizing in the *PACS1* group.

Conclusions: Externalizing behavior problems vary across ASD-associated mutation groups, with individuals with *ADNP* and *FOXP1* mutations displaying elevated externalizing severity as compared to individuals with mutations in other ASD-associated genes. Future research should examine genetic and environmental mechanisms that contribute to significant externalizing problems in these specific groups and across individuals with ASD-associated mutations.

Sensory Physiology

PANEL SESSION — **SENSORY PHYSIOLOGY**

219 - Brain Dynamics from Synapses to Systems: Bridging Rodents to Humans to Examine Brain Sensory Reactivity/Responsivity and How It Is Altered in Neurodevelopmental Conditions

Panel Chair: Grainne M. McAlonan, *NIHR-Biomedical Research Centre for Mental Health at the Institute of Psychiatry, Psychology and Neuroscience, South London and Maudsley Foundation NHS Trust, London, United Kingdom*

The panel will build from rodent studies of experience dependent plasticity to examine brain dynamics (including 'habituation') in response to ‘lower-order’ sensory and ‘higher-order’ social stimuli in individuals with and without autism spectrum condition (ASC). Dr Samuel Cooke will present preclinical work from his lab (King’s College London; KCL) interrogating the neuroscience of cortical plasticity and its relevance to neurodevelopmental conditions. Dr Jannath Begum Ali (Birbeck) will then report how infants with Neurofibromatosis Type 1, who have an elevated likelihood of developing ASC, process repeated low level auditory stimuli. Next, Dr Nicolaas Puts (Johns Hopkins) will describe how neuroimaging methods (edited MRS of GABA) and transcranial magnetic stimulation can be used to examine the relationship between neurotransmitter concentration, GABA-receptor function, quantifiable aspects of altered sensory perception, and clinical manifestations of ASD in ASC. Finally, Dr Nichol Wong (KCL) will present evidence for differences in the (5HT) neurochemical control of the temporal dynamics of limbic responses to facial emotions in adults with and without ASC. We suggest that these insights into brain dynamics of plasticity and stability and their relationship to sensory and social-cognitive function in ASC will both inform causal mechanisms and identify novel treatment targets in neurodevelopmental conditions.

219.001 *(Panel)* Biomarkers of Synaptic Plasticity, Cortical Inhibition and Neural Feedback Accompanying Habituation and Novelty Detection

*F. A. Chaloner[1], C. Gelegen Van Eijl[2], R. W. Komorowski[3], P. S. Finnie[3], E. S. Kaplan[3], M. F. Bear[3] and **S. F. Cooke**[2], (1)Centre for Developmental Neurobiology, Institute of Psychology, Psychiatry and Neuroscience, King's College London, London, United Kingdom, (2)Department of Basic and Clinical Neuroscience, Institute of Psychology, Psychiatry and Neuroscience, King's College London, London, United Kingdom, (3)Picower Institute for Learning and Memory, Massachusetts Institute of Technology, Cambridge, MA*

Background: Habituation enables organisms to suppress behavioural response to neutral stimuli and devote attention to elements of the environment that reward, punish or are novel and therefore have the potential to bring either. It is a fundamental form of cognition that is often disrupted in neurodevelopmental psychiatric disorders such as intellectual disability, autism and schizophrenia. Habituation is equally critical to mice and we have developed new assays to measure this foundational form of learning in mice, which afford a wide range of experimental approaches to deeply understand underlying processes.

Objectives: Here we describe our observations of response dynamics in primary visual cortex (V1) across different timescales of visual habituation, what we understand about the cellular and circuit origins of those dynamics and the results of interventions to disrupt them and observe the consequences for habituation.

Methods: We have used behavioural analysis in head-fixed mice, single unit recordings, local field potential recordings, electroencephalogram (EEG), optogenetics, chemogenetics and genetic knockdown.

Results: We have found that, during short-term visual habituation, thalamo-cortical synapses in primary visual cortex (V1) undergo depression, consistent with previous work. By contrast, long-term habituation is accompanied by paradoxical synaptic potentiation. Blockade within V1 of the NMDA receptor, and other canonical mechanisms of Hebbian synaptic plasticity, prevents learning and plasticity alike. Using local field potential (LFP) recordings and surface electroencephalogram (EEG) recordings in awake viewing mice (n = 27), we have now also identified a striking switching over the course of a few seconds between two cortical processing modes: The first of these modes is characterised by high voltage slow oscillations, which reflect neuronal bursting activity, and this emerges with stimulus familiarity. The second is characterised by high gamma oscillations, which require the activity of parvalbumin-expressing inhibitory neurons (PV+) and is driven by presentation of novel stimuli. Only during these gamma oscillations do animals distinguish novel and familiar stimuli, either physiologically or behaviourally. We now have multiple lines of evidence demonstrating a critical role for both PV+ neurons and feedback from cortex to thalamus in this gating of the detection of novelty. Finally, we present recent observations of disruptions of this visual cortical plasticity in a mouse model of Tuberous Sclerosis Complex (n = 12 per genotype), which is a neurodevelopmental disorder of defined genetic origin that often includes features of intellectual disability and autism.

Conclusions: Thus, a simple but fundamental form of cognition drives a variety of signals that are often aberrant in neurodevelopmental psychiatric disorders, and the mouse provides a system to deeply understand their origins and dysfunction. Based on our results, we also believe that the potential exists in the future to record these signals non-invasively using EEG from human populations for patient stratification and assessment of response to treatment.

219.002 *(Panel)* Early Differences in Auditory Processing in Infants with Neurofibromatosis Type 1

J. Begum Ali[1], *A. Kolesnik*[2], *T. Del Bianco*[3], *S. Garg*[4], *J. Green*[4], *E. J. Jones*[1] *and M. H. Johnson*[1], *(1)Centre for Brain and Cognitive Development, Birkbeck, University of London, London, United Kingdom, (2)Centre for Brain and Cognitive Development, Birkbeck University of London, London, United Kingdom of Great Britain and Northern Ireland, (3)Centre of Brain and Cognitive Development, Birkbeck College, University of London, London, United Kingdom, (4)University of Manchester, Manchester, United Kingdom of Great Britain and Northern Ireland*

Background: Neurofibromatosis Type 1 is a genetic disorder that results from a mutation of the NF1 gene on chromosome 17. The NF1 gene produces the neurofibromin protein that is responsible for regulating cell growth. Whilst NF1 presents with a number of physical symptoms, the condition has also been associated with neurodevelopmental disorders. For example, individuals with NF1 are five times more likely to receive an Autism Spectrum Disorder (ASD) diagnosis (Bilder et al., 2016) than the general population. Thus, prospective longitudinal studies of infants with NF1 may provide translational insights into the mechanisms that underpin symptom emergence.

Objectives: Here, we assessed neural habituation to repeated auditory stimulation in a group of infants with NF1 tested at 5 and 10 months. Habituation is a particularly important function as it is necessary to determine the level of processing that occurs for incoming sensory information. Research has demonstrated atypical habituation patterns in neurodevelopmental disorders such as Fragile X Syndrome and ASD (Ethridge et al., 2016; Guiraud et al., 2011; Gomot et al., 2006) and more recently in infants with later ASD (Kolesnik et al., 2018). If individuals cannot reduce the sensory response to repeated incoming stimuli (i.e., habituate), this may underpin core symptoms of ASD such as sensory hypersensitivity.

Methods: 30 infants with NF1 and 46 age-matched typically developing infants were assessed longitudinally at 5- and 10 months of age. Infants listened to 150 repetitions of trains of tones; a single 'train' was made up of three consecutive 'Standards', a /u/ vowel sound administered at 500Hz before a final 'deviant' sound. As we are particularly interested in the habituation process, current analysis focused on the 'Standards'. Each tone was presented for 100ms, with a 5ms rise and fall time and the inter-stimulus interval was jittered around 500ms. Neural activity was recorded over the whole scalp using a high density EEG array, with analysis focused on fronto-central regions of interest.

Results: Examining the mean amplitude of the auditory evoked potential in the first 200ms after stimulus onset, preliminary analysis showed that that the TL group demonstrated a reduction in amplitude between the first and second repetition of each stimulus at both 5 [$F(2,177)=17.79$, $p<.001$, $\eta_p^2=.23$] and 10 months of age [$F(2,231)=25.55$, $p<.001$, $\eta_p^2=.18$]. In comparison, infants with NF1 demonstrated this pattern of habituation only at 10 months [$F(179)=17.79$, $p<.001$, $\eta_p^2=.12$] of age; at 5 months, this group showed no evidence of habituation [$F(2,93)=6.58$, $p=.002$, $\eta_p^2=.12$] (see Figure 1).

Conclusions: Our findings show that infants with NF1 demonstrate developmental delays in the emergence of neural habituation to auditory stimuli. Further analysis will examine how individual differences relate to later diagnostic outcome. We discuss the potential cascading effects of these early differences with respect to how infants process, and engage with, the world around them.

219.003 *(Panel)* Using Multimodal Approaches to Study Altered Gabaergic Inhibition in Children with Autism Spectrum Disorder

N. A. Puts[1,2], *J. L. He*[3,4], *G. Oeltzschner*[2], *M. Mikkelsen*[2,4], *E. L. Wodka*[5], *M. Tommerdahl*[6], *P. A. Celnik*[7], *R. A. Edden*[2] *and S. H. Mostofsky*[5], *(1)F. M. Kirby Research Center for Functional Brain Imaging, Kennedy Krieger Institute, Baltimore, MD, (2)Russell H. Morgan Department of Radiology and Radiological Science, The Johns Hopkins University School of Medicine, Baltimore, MD, (3)Russell H. Morgan Department of Radiology and Radiological Science, The Johns Hopkins University School of Medicine, The Johns Hopkins University School of Medicine, Baltimore, MD, (4)F.M. Kirby Research Center for Functional Brain Imaging, Kennedy Krieger Institute, Kennedy Krieger Institute, Baltimore, MD, (5)Center for Autism and Related Disorder, Kennedy Krieger Institute, Baltimore, MD, (6)Biomedical Enginering, University of North Caroline at Chapel Hill, Chapel Hill, NC, (7)Department of Physical Medicine and Rehabilitation, The Johns Hopkins University School of Medicine, Baltimore, MD*

Background: Despite decades of study, the neurophysiological basis of ASD remains poorly understood. Multiple lines of evidence (e.g. mouse models, expression of GABA receptor genes, reduced interneuron density) suggest that γ-aminobutyric acid (GABA), the main inhibitory neurotransmitter in the brain, plays a role in the pathophysiology of ASD. However, it remains unclear how the GABA system is altered and how inhibitory dysfunction relates to the behavioral phenotypes in humans with ASD. Over the past years we have used edited Magnetic Resonance Spectroscopy (MRS) of GABA to measure brain GABA levels in vivo, Transcranial Magnetic Stimulation (TMS) to measure $GABA_A$ and $GABA_B$-receptor function, and behavioral psychophysics - linked to inhibitory function - to study inhibitory dysfunction in children with ASD.

Objectives: Here, we investigate the relationship between brain GABA levels, GABA-receptor function, sensory perception, and clinical ratings in children with ASD. We hypothesize that altered GABA function associates with psychophysical and clinical sensory abnormalities and comorbid ADHD.

Methods: In total, we included 103 children with ASD, 52 children with ASD + comorbid ADHD, 108 children with ADHD, and 210 typically developing children (TDC); 8-12 years old. *MRS*. GABA levels were measured over sensorimotor cortex (SM1) and thalamus using spectral editing (MEGA-PRESS and HERMES; TE/TR 68 & 80/2000 ms; 320 averages). *TMS.* Data were acquired using short- (SICI; 2.5 ms ISI, probing $GABA_A$) and long-interval intracortical inhibition (LICI; 100 ms ISI, probing $GABA_B$) paired-pulse TMS approaches. *Psychophysics* We measured static and dynamic detection threshold (probing feed-forward inhibition), amplitude discrimination (probing lateral inhibition) and temporal order judgement.

Results: We will give an overview of our data up to date including measures of GABA+, MM-suppressed GABA, and glutathione (preliminary) in children ASD. Our prior work shows children with ASD have reduced sensorimotor GABA levels, which predicts tactile abnormalities ($R = 0.54$, $p < 0.05$). Children with ASD show normal SICI (inhibition of motor evoked potentials, $p = 0.5$), but abnormal *modulation* of SICI ($p < 0.001$). Children with ASD show reduced LICI compared to TDC ($p > 0.05$) and LICI in ASD is not significantly different from 1 (no inhibition, $p < 0.01$). Tactile psychophysical measures show different patterns of abnormal perception between ASD and ADHD, which relate to disorder-specific (e.g. autism severity in ASD and ADHD severity in ADHD) and disorder-general (hyperresponsivity) dimensional ratings.

Conclusions: We show that GABA is affected at both the presynaptic and postsynaptic level in children with ASD. Reduced cortical GABA levels associate with altered behavioral performance. Children with ASD appear to show an absence of $GABA_B$-receptor driven inhibition (LICI), consistent with abnormal tactile detection threshold (linked to $GABA_B$ feedforward inhibition) and prior work linking altered $GABA_B$ receptor subunits to ASD. Children with ASD also show abnormal modulation of $GABA_A$ receptor function which may relate to inflexibility in neuronal processing. Tactile behavioral findings correlate with disorder-general and specific clinical measures. Imaging and psychophysics can provide important neurochemical and behavioral biomarkers for ASD, linking cortical function to behavioral outcome - key in developing biologically and potential patient-specific treatments.

219.004 *(Panel)* Citalopram Differentially Modulates the Temporal Dynamics of Negative Facial Emotion Activation in Adults with and without ASC

Background: Facial emotion processing is often altered in autism spectrum conditions (ASC), but its biological basis remains poorly understood[1] and may include neurochemically mediated differences in the responsivity of key 'limbic' regions. Serotonin (5-HT) has been shown to be a key regulator of both facial emotion processing[2] and brain temporal dynamics[3], and 5-HT abnormalities have been consistently implicated in ASD[4]. However, to our knowledge, no-one has examined how 5-HT influences the temporal dynamics of facial emotion processing in ASC.

Objectives: Therefore, we compared the influence of an acute dose of the selective 5-HT reuptake inhibitor (SSRI) citalopram on the responsivity of the temporal dynamics during facial emotion processing in adults with and without ASC in a pharmacological-fMRI study.

Methods: 18 male adults with ASC and 21 age and IQ matched neurotypical male adults were included in the current randomised double-blind crossover study. Participants with ASC were diagnosed by consultant psychiatrists according to ICD-10 and all participants completed two MRI scanning sessions. They were given either 20 mg citalopram or placebo before scanning, during which an emotional face-matching task[5] was administered. The task asked the participants to respond to blocks of trials of angry/fearful faces and geometric shapes (**Figure 1A**). The preprocessed task-based fMRI data were analysed with a general linear model approach using FSL and block-wise beta of the limbic regions were retrieved for subsequent analyses.

Results: We found significant group×drug interaction effects in the temporal dynamics in amygdala, ventromedial prefrontal cortex and nucleus accumbens during processing of negative facial emotion in adults with and without ASC ($p_{corrected}<0.001$), where sustained activation after citalopram was only observed in adults with ASC (**Figure 1B**).

Conclusions: Serotonergic homeostatic control of the temporal dynamics in limbic regions is distinct in ASC.

ORAL SESSION — SENSORY PHYSIOLOGY
325 - Sensory Responsiveness: Physiology and Behaviour

325.001 *(Oral)* Attenuated Pupillary Response Mediates Slower Reaction Time in Autism Spectrum Disorder

N. Bast[1], *C. M. Freitag*[2] *and S. Boxhoorn*[3], *(1)Department of Child and Adolescent Psychiatry and Psychotherapy, University Hospital Frankfurt, Frankfurt, Germany, (2)Autism Research and Intervention Center of Excellence Frankfurt, University Hospital Frankfurt, Frankfurt am Main, Germany, (3)Department of Child and Adolescent Psychiatry, Goethe University Frankfurt, Frankfurt, Germany*

Background: Attention is a central cognitive ability of selective information processing that is often measured as reaction time (RT) in behavioral tasks. Studies reported slower RT in Autism Spectrum Disorder (ASD) and Attention Deficit Hyperactivity Disorder (ADHD), which has been interpreted in both cases as altered attention by atypical arousal regulation. Phasic activity of the Locus Coeruleus – Norepinephrine (LC-NE) system is a promising underlying mechanism of arousal regulation, which has never been compared between ASD and ADHD. Phasic activity of the LC-NE system can be assessed by stimulus-evoked pupillary responses (SEPR).

Objectives: We compare attention performance between ASD and ADHD in an established reaction time task with concurrent assessment of pupillometry. We hypothesize attenuated SEPR to predict slower RT across groups and explore SEPR between groups. This would indicate atypical arousal regulation to contribute to atypical attention, which might be specific to ASD or ADHD.

Methods: We assessed 90 adolescents with either ASD (n=18, age=13.8/2.6[1], IQ=108/12, gender=2/16 [m/f]), ADHD (n=28, age=13.5/2.4, IQ=104/14, gender=3/25 [m/f]), ASD and comorbid ADHD (ASD+ADHD, n=13, age=12.2/2.8, IQ=103/15, gender=1/12 [m/f]), and neurotypical controls (NTC, n=31, age=14.4/2.7, IQ=111/14, gender=16/15 [m/f]). Participants completed a cued reaction time task ('fast task') while pupillometry was assessed by infrared remote eye-tracking. The task manipulates arousal regulation by two conditions: A baseline condition with a long foreperiod (8s) that is associated with lower arousal and a fast condition with a short foreperiod (1s) *and* rewards for fast reaction times that is associated with higher arousal. We applied three linear mixed models with (1) RT or (2) SEPR as dependent variable, ASD and ADHD as dummy-coded fixed effects, task condition as fixed effect, and fixed-effect interactions. We further included sex, age, and IQ as covariates. In a third model (3), SEPR was included as fixed effect with RT as dependent variable to investigate the mediation of RT differences between groups.

[1] Mean / SD.

Results: (1) We found RT differences between groups specific to conditions (βs < -0.14; *p*s < .002). Post-hoc contrasts indicated that all clinical groups showed slower RT in the baseline condition (baseline-fast contrast: ASD=216ms [203-229][2]; ADHD=217ms [206-228]; ASD+ADHD= 250ms [234-266]) compared to NTC (192ms [181-202]). (2) Only in ASD, we observed a lack of SEPR change between conditions (baseline-fast; -0.08 [-0.19 – 0.03]) compared to ADHD (-0.12 [-0.21- -0.02]), ASD+ADHD (-0.25 [-0.39 - -0.11], and NTC (-0.18 [-0.26 - -0.09]). (3) Inclusion of SEPR delivered a strong effect on RT across groups (β= -0.52 [-0.64 - -0.41] that mediated reaction time differences between groups in the baseline condition (*p*s > .07).

[2] 95% confidence intervals.

Conclusions: Full mediation (see figure 1) is only observed for ASD. A lack of SEPR change indicated atypical arousal regulation in ASD, but not in ADHD or ASD+ADHD. This supported atypical LC-NE phasic activity as underlying mechanism of slower RT specific to ASD without comorbid ADHD. We outlined that different mechanisms probably underly slower reaction times in ASD and ADHD. LC-NE phasic activity could represent a promising biomarker in future ASD research.

325.002 *(Oral)* Exploring Heterogeneity in Auditory Electrophysiological Responses of Young Autistic and Typically-Developing Children Using Hierarchical Clustering

P. Dwyer[1], *X. Wang*[2], *F. Hsieh*[3], *C. D. Saron*[4,5] *and S. M. Rivera*[1], *(1)Department of Psychology, University of California, Davis, Davis, CA, (2)Department of Statistics, University of California, Davis, Davis, CA, (3)Statistics, University of California, Davis, Davis, CA, (4)MIND Institute, UC Davis Medical Center, Sacramento, CA, (5)Center for Mind and Brain, Clifford Saron, Davis, CA*

Background: Atypical autistic (AUT) sensory processing is related to quality of life (Lin & Huang, 2019), but attempts to investigate atypical sensory processing are complicated by the heterogeneity of AUT sensory features (Uljarević et al., 2017). Prior studies exploring AUT sensory heterogeneity have relied largely on caregiver-report questionnaires (DeBoth & Reynolds, 2017), which leave variability at the neural level unclear.

Objectives: The present study aims to explore clusters of AUT and typically-developing (TYP) participants defined on the basis of auditory ERP responses. AUT and TYP participants were clustered together to situate the diagnostic groups in relation to one another. While it is not clear that these data are strictly categorical rather than dimensional, imposing categories permits data exploration.

Methods: ERPs were examined in 130 AUT participants (110 male, M_{Age} = 38.50 months, SD_{Age} = 6.02; $M_{DQ\ (MSEL)}$ = 65.25, SD_{DQ} = 20.91) and 81 TYP controls (52 male, M_{Age} = 37.09 months, SD_{Age} = 6.46; M_{DQ} = 106.37, SD_{DQ} = 11.58). While watching a quiet video, participants heard, via headphones, brief complex tones randomly varying in loudness (50, 60, 70, or 80 dB SPL). 200-300 trials were collected in each loudness condition at an ISI randomly varying between 1-2s. 61-channel EEG was sampled at 1000 Hz and average-referenced. Second-Order Blind source Identification (SOBI; Belouchrani et al., 1997) was used to remove artefacts. To minimize variability from biophysical factors such as skull thickness, averaged ERP amplitudes were rescaled, separately for each participant and time point, such that each participant's highest amplitude in any channel or condition became 1 and the lowest became 0. Participants' rescaled data were then averaged, separately by condition, within seven topographical regions in consecutive 25ms windows between 51-350ms, and hierarchically clustered using Ward's method.

Results: Three clusters (C1-3) were defined. A late negativity, referred to in previous literature as the N2, had shorter latencies in C2 and seemed more delayed in C1; in C3, a positivity was observed in the N2 latency range. N2 responses were not always evoked by softer sounds. Though overlap of diagnostic groups was extensive, proportions of AUT and TYP participants varied across clusters, $\chi^2 = 6.84$, $p = .03$; there were more AUT participants than expected in C3, corrected $p < .05$. Among AUT participants, age also varied across clusters, Kruskal-Wallis $\chi^2 = 11.22$, $p = .004$; age was younger in C3 than C2, Wilcoxon corrected $p = .007$, or C1, Wilcoxon corrected $p = .02$. Among TYP participants, clusters varied in Noise Distress on the Short Sensory Profile (McIntosh, Miller, & Shyu, 1999; Williams et al., 2018), Kruskal-Wallis $\chi^2 = 6.35$, $p = .04$; post-hoc effects were nonsignificant after correction but scores appeared more typical in C2.

Conclusions: Disproportionately more and younger AUT participants displayed an unusual pattern of positive voltages fronto-centrally in lieu of the N2. TYP participants with clear, early N2 responses may be protected against experiencing noise distress. These inter-individual differences may caution against over-reliance on simple group comparisons in research.

325.003 *(Oral)* Heart Rate Responses to Aversive Sensory Stimulation and Their Relationship to Brain and Behavioral Markers of Sensory over-Responsivity

J. Jung[1]*, T. Zbozinek*[2]*, K. K. Cummings*[1]*, F. H. Wilhelm*[3]*, M. Dapretto*[1]*, M. Craske*[4]*, S. Y. Bookheimer*[1] *and S. A. Green*[1]*, (1)Dept of Psychiatry and Biobehavioral Sciences, University of California, Los Angeles, Los Angeles, CA, (2)Div of the Humanities and Social Sciences, California Institute of Technology, Pasadena, CA, (3)Dept of Psychology, University of Salzburg, Salzburg, Austria, (4)Dept of Psychology, University of California, Los Angeles, Los Angeles, CA*

Background: Individuals with autism spectrum disorder (ASD) commonly display sensory over-responsivity (SOR), which is associated with physiological and attention abnormalities (Leekam et al., 2007; Chang et al., 2012; Baranek et al., 2007) and atypical brain responses to aversive sensory stimuli (Green et al., 2015). Since most MRI studies include older, verbal participants, the neural mechanisms underlying SOR are not well understood among other ASD populations. Peripheral physiological measurements such as heart rate (HR) could provide a proxy of brain response for individuals unable to complete MRI scans. However, little is known about the relationship between physiological and neural responses to sensory stimulation in autism. We investigated both HR response (arousal) to sensory stimulation and orienting response, an initial decrease in HR following aversive stimulation, which allows processing of information prior to responding (Bradley, 2009).

Objectives: To investigate how HR responses (mean HR and orienting) during aversive sensory stimulation relate to 1) behavioral SOR severity and 2) fMRI response to the same stimulation.

Methods: Participants were 50 ASD (38M) and 31 TD (21M) youth aged 8-18. SOR severity was measured using tactile and auditory SOR subscales from the Short Sensory Profile and Sensory Over-Responsivity Inventory (Dunn, 1999; Schoen et al., 2008) to divide ASD participants into high or low SOR groups. Participants experienced six 15-sec blocks each of mildly aversive tactile, auditory, and joint (tactile+auditory) stimuli first during fMRI then outside of the scanner during HR measurement. Orienting response was calculated as the slope of the inter-beat interval (IBI) from 0-2 seconds of stimulation. Mean HR and orienting responses were averaged across stimuli then used to predict brain responses in whole-brain analyses (thresholded/corrected at $z>2.3/p<0.05$).

Results: There were no diagnostic group differences in mean HR controlling for HR baseline, but the ASD-high-SOR group had higher mean HR responses Higher mean HR was correlated with greater brain activation to sensory stimuli in primary visual cortex, lingual gyrus, and left frontal regions including middle frontal gyrus (MFG; Fig.1). ASD participants, particularly those with high SOR, showed less HR deceleration than TD participants, followed by increased HR acceleration, indicating high SOR is associated with reduced orienting response to aversive sensory stimulation. Reduced orienting response was associated with greater activation in lateral occipital cortex, lingual gyrus, left temporal regions, and left MFG (Fig.2).

Conclusions: Results suggest that higher mean HR and reduced HR deceleration (orienting) were related to SOR severity in youth with ASD. Both HR measures were also associated with fMRI response to aversive sensory stimulation in sensory cortical regions unrelated to the sensory stimulation, a pattern associated with SOR (Green et al., 2019), as well as regions implicated in reorienting to internal cues (MFG; Thiel et al., 2003). Deficits in initial regulated processing of sensory stimuli may increase subsequent arousal and reduce the ability to produce planned responses in individuals with SOR. Results have implications for using HR metrics to identify SOR and predict brain responses in individuals with ASD who cannot undergo MRI.

325.004 *(Oral)* Examining Gamma Oscillatory Response As a Marker of Disrupted Excitatory/Inhibitory Balance in Autism Spectrum Disorder and Phelan-Mcdermid Syndrome

H. Grosman[1]*, S. B. Guillory*[1]*, C. McLaughlin*[1]*, B. Britvan*[1]*, E. Isenstein*[2]*, K. Keller*[3]*, O. Jones*[4]*, P. M. Siper*[1]*, A. Kolevzon*[1] *and J. H. Foss-Feig*[1]*, (1)Seaver Autism Center, Department of Psychiatry, Icahn School of Medicine at Mount Sinai Hospital, New York, NY, (2)University of Rochester, Rochester, NY, (3)Department of Psychiatry, Icahn School of Medicine, Seaver Autism Center, New York, NY, (4)Fordham University, Bronx, NY*

Background: Autism spectrum disorder (ASD) is a neurodevelopmental disorder behaviorally defined by a core set of features, including social communication deficits and restricted and repetitive behaviors. Sensory abnormalities are present in up to 90% of affected individuals. Phelan-McDermid syndrome (PMS) is a rare disorder caused by deletion or mutation of the *SHANK3* gene on chromosome 22. Over 80% of individuals with PMS meet diagnostic criteria for ASD. Neural oscillations are a key mechanism by which communication and synchronization occur within the brain, in turn driving coordinated cognition and behavior. Gamma band oscillations reflect GABAergic synaptic function, and alterations in the balance between inhibitory GABAergic and excitatory glutamatergic activity have been identified in ASD. *SHANK3* codes for a scaffolding protein localized to excitatory synapses, such as the glutamate receptor complex, resulting in disrupted glutamatergic function in individuals with PMS. Auditory steady-state response (ASSR) is a neurological response that occurs when the brain entrains to rapid auditory stimuli presented at a given frequency. ASSR in the gamma frequency range (30-50 Hz) has been identified as a robust measure of abnormal neural oscillations in other disorders where excitatory/inhibitory balance is disrupted. Measurement of gamma oscillations may offer a valuable biological tool to reveal mechanisms underlying cognitive dysfunction and behavioral symptomatology. We hypothesized ASSR would be diminished in individuals with ASD as well as in PMS compared to typically-developing (TD) controls.

Objectives: 1) Use electroencephalography (EEG) to test for alterations in gamma band response during auditory entrainment using an ASSR paradigm. 2) Explore differences in gamma band response among PMS, idiopathic ASD and TD populations.

Methods: Twenty-two individuals participated in the study: 8 with ASD (63% male), 5 with PMS (40% male), and 9 TD controls (67% male). EEGs were recorded using 128-channel Hydrocel Geodesic Sensor Nets and Philips/EGI NetStation software. The auditory stimulus was a 500ms click train with a stimulation rate of 40Hz, presented 150 times (inter-trial interval: 50ms). We calculated inter-trial phase coherence (ITC), a value between 0 and 1, where 0 represents a random distribution of phase angles and 1 reflects absolute neural synchrony. Group differences were computed using a one-way ANOVA with post-hoc t-tests.

Results: Results revealed significant differences in 40Hz gamma-band ASSR among groups, $F(2,19) = 8.60$, $p = .002$. Both ASD (0.25 ± 0.09; $t(15) = -3.99$, $p = 0.001$) and PMS (0.27 ± 0.11; $t(12) = -2.85$, $p = 0.015$) groups had significantly weaker ITC than controls (0.43 ± 0.10). ASD and PMS groups did not differ significantly ($p = 0.68$).

Conclusions: These results reinforce prior findings of diminished ASSR response in individuals with an ASD and extend them to PMS, a syndromic form of ASD with known excitatory dysfunction. ASSR is collected through a passive, non-invasive task, making it a promising potential biomarker for screening and stratification, particularly in lower-functioning populations. ASSR may also be useful to assess change in clinical trials, particularly for medications targeting the GABAergic system or in rare diseases with known excitatory/inhibitory balance disruption.

POSTER SESSION — SENSORY PHYSIOLOGY
442 - Sensory physiology Posters

442.001 *(Poster)* Altered Sensorimotor Postural Control of ASD Subjects: Findings from the Physiological Profile Approach

*C. Perin[1], G. Valagussa[1,2], M. Mazzucchelli[1], V. Gariboldi[1,3], D. Piscitelli[4,5], R. Meroni[4], **E. Grossi**[2], C. Cornaggia[6], J. Menant[7] and C. G. Cerri[1], (1)School of Medicine and Surgery, University of Milan-Bicocca, Milano, Italy, (2)Autism Research Unit, Villa Santa Maria Foundation, Tavernerio, Italy, (3)Ospedale "G. Salvini" - Garbagnate MIlanese, ASST Rhodense, Garbagnate MIlanese, Italy, (4)School of Medicine and Surgery, University of Milan-Bicocca, MIlano, Italy, (5)School of Physical and Occupational Therapy, McGill University, Montreal, QC, Canada, (6)School of Medicine and Surgery, University of Milan–Bicocca, Milano, Italy, (7)Neuroscience Research Australia and School of Public Health and Community Medicine, University of New South Wales, Sydney, NSW, Australia*

Background: Effective sensorimotor postural control to maintain an upright stance is a crucial component for daily functional activity. A sound postural control system underlines a spatiotemporal integration of sensory and motor and systems. Evidence suggests that Autism Spectrum Disorder (ASD) population present postural control disruption.

Objectives: A cross-sectional study was carried out aimed at investigating sensorimotor contributions to postural control and behavior in children and adolescents with ASD compared to typically developing (TP) peers through the Physiological Profile Assessment – long form (PPA).

Methods: ASD and TD age-matched TD subjects were consecutively recruited in a northern metropolitan city in Italy. Participants were assessed with the PPA by residents in physical medicine and rehabilitation clinician. PPA includes 17 tests: Visual acuity with high- and low-contrast, Edge contrast sensitivity, Depth perception, Touch sensitivity, Tactile lower limb Proprioception, Simple reaction time of hand and foot, Isometric knee extensor and flexor muscle strength, Ankle isometric dorsiflexion strength, Postural sway with eyes open and closed, first on a firm surface, then on a medium density foam rubber mattress, Maximum balance range and Coordinated stability. Percentiles of each PPA subset were computed from the TD peers. PPA performances of ASD participants were compared to the TD percentiles.

Results: Eighteen ASD individuals' (16/2 male/female), mean age (SD) 12.4 (3.7) years, were included. Their intellectual disability ranged from mild (n=5), moderate (n=11) to severe (n=2). In the TD age-matched group, 135 subjects (100/35 male/female) were enrolled of the following ages: 6 years (n=11), 8 years (n=16), 11 years (n=21), 12 years (n=12), 13 years (n=14), 14 years (n=24), 16 years (n=18) and 18 years (n=19). ASD individuals' scores were above the 90th percentile, i.e., poor performance, in most motor, sensory, and balance subtests. In particular: half of our sample of children and adolescents with ASD performed poorly in the tests of visual acuity, particularly when the lighting conditions were poor (low contrast). Tactile sensitivity was inferior in our ASD population, with three-quarters of participants scoring above the 90th percentile and one performing below the 10th percentile. One-quarter of ASD participants performed poorly in the test of proprioception. More than half of our participants performed above the 90^{th} percentile in the tests of simple reaction time at the finger and the foot. Over a quarter of the children and adolescents with ASD presented muscle weakness in at least one of the three lower limb muscle groups we investigated. Performance in the majority of PPA significantly improved with older age in the TD group but not in the ASD group.

Conclusions: These findings suggest how poor balance performance may be due to sensorimotor deficiencies integration in ASD children and adolescents. The investigation of the mechanisms underlying impaired age-related maturation of sensorimotor systems should drive the research agenda of the scientific community.

442.002 *(Poster)* Effective Postural Control Complexity As a Biomarker for Autism Spectrum Disorder

***E. Grossi**[1] and G. Valagussa[1,2], (1)Autism Research Unit, Villa Santa Maria Foundation, Tavernerio, Italy, (2)School of Medicine and Surgery, University of Milan-Bicocca, Milano, Italy*

Background: Complex neurodevelopmental disorders like ASD may be characterized by subtle brain function signatures which can be measured using advanced machine learning tools. Sound postural control system requires the interaction of sensory, motor and integration systems. There is evidence that individuals with Autism Spectrum Disorder (ASD) present postural control deficits but is not known if the complexity of sensorimotor contribution can play a role.

Objectives: The aim of the study is to compare the degree of complexity of sensory and motor functions in a group of subjects with autism with a matched group of Typically developing children and adolescents.

Methods: The study sample included 18 children and adolescents with ASD and 18 age-matched typically-developing (TD) individuals, (age range 6-18 years; 16 males for both groups). Participants completed a Physiological Profile Assessment, which includes 17 tests : Visual acuity with high- and low-contrast, Edge contrast sensitivity, Depth perception, Touch sensitivity, Tactile lower limb Proprioception, Simple reaction time of hand and foot, Isometric knee extensor and flexor muscle strength, Ankle isometric dorsiflexion strength, Postural sway with eyes open and closed, first on a firm surface, then on a medium density foam rubber mattress, Maximum balance range and Coordinated stability. The complexity of interaction among these physiological functions has been explored with Maximally Regular Graph (MRG) theory applied to the Semantic Connectivity map produced by a fourth-generation artificial neural network (Auto-CM system; Semeion, Rome, Italy). MRG is the graph whose hubness function attains the highest value among all the graphs generated by adding back to the original Minimum Spanning Tree (MST), one by one, the connections previously skipped during the computation of the MST itself. In other words, starting from the MST, the MRG, presenting the highest number of regular microstructures, highlight the most important connections of the dataset. The resulting “diamond” volume expresses the complexity core of the system and in our specific case, the core of the physiological system.

Results: The map relative to TD group showed a coordinating role of Maximal Balance Range with respect to physiological functions on study. The MRG was generated by the addition of twelve links to MST involving eight Nodes. At variance, the map relative to ASD group showed a coordinating role of touch sensitivity. The MRG was characterized by only six additional links involving five nodes (Figure 1).

Conclusions: This proof-of-principle study suggests that ASD postural physiology is characterized by a loss of complexity in its component interaction which in the future might become a useful biomarker for early detection of risk for ASD.

442.003 *(Poster)* Electroencephalography (EEG) during Auditory Perception in Children with Autism Spectrum Disorder: An Investigation of the Predictive Coding Hypothesis

E. J. Knight[1]*, L. A. Oakes*[2]*, D. Mitchell*[3]*, S. Hyman*[1]*, E. Freedman*[2] *and J. J. Foxe*[2]*, (1)Developmental and Behavioral Pediatrics, University of Rochester Medical Center, Rochester, NY, (2)The Ernest J. Del Monte Institute for Neuroscience, University of Rochester Medical Center, Rochester, NY, (3)University of Rochester, Rochester, NY*

Background: The brain's ability to encode temporal patterns and to predict upcoming events is critical for speech perception as well as other aspects of social communication. Deficits in predictive coding may contribute to difficulties with language function and social communication as well as overreliance on repetitive predictable environments in individuals with ASD. We explored this hypothesis in individuals with ASD associated with variable levels of verbal ability using electroencephalography (EEG) during an auditory mismatch negativity (MMN) task using rhythmic tone sequences of varying complexity.

Objectives: We tested the hypotheses that 1) individuals with ASD have reduced neural MMN response to auditory stimuli that deviate in presentation timing from expected patterns, particularly as pattern complexity increases, and that this reduction will be most pronounced in individuals with lower language abilities and 2) amplitude and/or latency of MMN signal is inversely correlated with level of impairment in the domains of social communication and restrictive interests/repetitive behaviors in individuals with ASD.

Methods: During an unattended task, EEG was continuously acquired as individuals (age 8-21 years) listened to repeated five rhythm tones that varied in the baseline complexity of the rhythm across three separate conditions. Conditions included an isochronous condition in which the tones were evenly spaced in time, and conditions with medium (1 bit) entropy and high (2 bit) entropy (Shannon entropy: $H(X)=-\sum P(xi)\log_2 P(xi)$). Within each condition, the majority of the tones conformed to the established rhythm (standard tones); occasionally the 4th tone was presented 300ms early (deviant tones). In typical adults, this paradigm has revealed that high-entropy stimuli are more difficult to model for the brain, resulting in less confident predictions and yielding smaller MMN signals for deviant sounds. Social communication and repetitive behaviors were measured in all subjects using the Social Responsiveness Scale (SRS-2) and Repetitive Behavior Scale (RBS-R).

Results: The mismatch negativity response to deviant tones in each of the conditions was compared between experimental groups (1-nonverbal/minimally verbal individuals with ASD; n=1, 2-fluent individuals with ASD; n=10, 3-age and IQ-matched controls; n=10). Consistent with previously described findings in typically-developing adults, both typically developing children and children with ASD who are fluent speakers show a stepwise decrease in MMN as a function of entropy. Mixed design ANOVA reveals no statistically significant difference between these two groups. Data collection in all groups with emphasis on nonverbal/minimally verbal individuals with ASD is ongoing.

Conclusions: Children with high functioning ASD do not differ from typically developing controls in neural mechanisms of prediction error when presented auditory rhythms of varied temporal complexity. However, given the particular importance of temporal modelling of patterns for language development, we predict that individuals with ASD who have lower verbal ability may be differentially affected.

442.004 *(Poster)* Extremely Wide Temporal Binding Windows in a Subgroup of Individuals with Autism

P. Webster[1]*, K. Jonathan*[1]*, J. W. Lewis*[2] *and S. Wang*[1]*, (1)West Virginia University, Morgantown, WV, (2)Neuroscience, West Virginia University, Morgantown, WV*

Background: A critical aspect of sensory processing in autism spectrum disorder (ASD) is the ability to integrate what we see and hear in order to make sense of the world. Previous research shows that individuals with autism may not integrate auditory and visual information in the same timeframe as those without autism and this wider temporal binding window (TBW) may contribute to core deficits in autism. Standard testing of audio-visual integration often excludes some individuals with autism since their data did not fit a normal distribution and thus a TBW was unable to be calculated. Our prior study found 8 ASD participants whose TBWs were not able to be calculated using the standard 500msec testing.

Objectives: We **hypothesized** that some individuals with ASD have extremely wide TBWs beyond what is typically tested and may constitute a subgroup within the broader autism spectrum disorder phenotype. Therefore, the goal of the present study was to bring back participants from our prior study to retest their TBW using the same with a much wider timeframe (up to 1,500msec) to determine whether these individuals have extremely wide TBWs or whether they may not be complying with task demands.

Methods: We recruited 27 age-matched participants (typically developed [TD] n=17(9F) Mean age=25.4±6.1 years; ASD n=10(3F) Mean age=22.5±4.6 years; two-tailed *t*-test p=0.15). A simultaneity judgment task was used to measure each person's audio-visual TBW. Participants were seated approximately 60cm from a 100Hz refresh rate monitor in an isolation booth and presented with a white circle on a black background that was accompanied by a tone. The tone was either presented synchronously with the circle or asynchronously (offset by 10msec to 1,500msec). During the asynchronous presentations the tone either occurred prior to the appearance of the circle, constituting the Left TBW, or occurred after the circle was presented, constituting the Right TBW. A sigmoid curve was fit to the data points to calculate the Left and Right TBWs with the zero (synchronous) timepoint included for both. Task compliance was monitored via a video camera mounted in the isolation booth. Behavioral measures included the Autism Quotient and Social Responsiveness Scale (SRS)for all participants and the Autism Diagnostic Observation Scale (ADOS-2) Module 4 for ASD participants.

Results: The ASD group included 3 participants whose TBWs were previously unable to be calculated. Retesting showed that one participant had a TBW that fell within the range of the ASD group (Left=162; Right=393), but the other 2 participants had Right TBWs that exceeded 500msec with one participant having a total TBW>1,000msec. The groups differed significantly in the Left TBW (TD Mean=168±63.3; ASD Mean=275±97.8; Kruskal-Wallis p=0.005) and in the Right TBW (TD Mean=266±108; ASD Mean=397±128.3; Kruskal-Wallis p=0.016). The ASD group had significantly higher SRS scores compared to controls (TD Mean=29±19.6; ASD Mean=77±28.0; Kruskal-Wallis p<0.001).

Conclusions: While this data suggests that a small subgroup of ASD participants may have extremely wide TBWs, this data is exploratory and we are continuing to recruit the remaining 5 participants whose TBWs were previously unable to be calculated.

442.005 *(Poster)* Lived Experiences of Interoceptive Challenges in ASD

D. A. Trevisan *and J. McPartland, Child Study Center, Yale University School of Medicine, New Haven, CT*

Background: "Interoception," is a process by which the brain detects, discriminates, and regulates internal bodily signals to maintain healthy bodily functioning (Khalsa et al. 2018). Atypical interoception may contribute to co-occurring social cognitive and health challenges in ASD, such as impaired face processing, alexithymia, anxiety, depression, and atypical eating patterns (Murphy et al. 2017). To date, there has been no qualitative study of interoception in ASD, which is needed to better understand atypical interoception in this population.

Objectives: The purpose of this study is to understand the self-reported nature of interoceptive difficulties in ASD.

Methods: Data were collected from Wrongplanet.net, a publicly accessible online resource for the ASD community. Data were collected from keyword searches on forum pages of Wrongplanet.net that included various combinations of the following terms: "interoception," "interoceptive," "internal signals," "body signals," "introspection," "internal sensory," "bodily feelings," "body sensations," "mind body," "hunger," "thirst," "nausea," "heartbeat," and "alexithymia." Data were transcribed into NVivo and subsequently analyzed using qualitative content analysis (Babbie & Benaquisto, 2009) to identify themes.

Results: (Preliminary Themes)

1) ***Difficulty reading body cues of emotion.*** Participants (22 posts) expressed difficulties recognizing physiological indicators of affect—For example, failing to recognize that certain gut sensations or increases in heart rate may be associated with feelings of anxiety or anger.

2) ***Difficulty recognizing hunger, thirst or satiation.*** Many (56 posts) described rarely feeling thirsty or hungry, in some cases leading to dehydration or fainting. Conversely, others described not knowing when they are completely full, contributing to weight gain, binge-eating, or other atypical eating behavior.

3) ***Hyposensitivity to nausea and sickness.*** Some participants (10 posts) described rarely knowing when they are sick. For example, some said they are surprised when they vomit without warning beforehand or that others tell them they look sick before they feel sick themselves.

4) ***Incontinence.*** Some (9 posts) described not knowing when they needed to go to the bathroom, sometimes resulting in toileting accidents.

5) ***Hypersensitivity/hypochondria.*** While most data concerned a failure to detect interoceptive cues (hyposensitivity), a smaller proportion of data (13 posts) concerned *hypersensitivity* to internal sensations. Some likened this constant awareness and sensitivity to internal cues to "sensory overload," in which they constantly process internal sensory information without accurately identifying the meaning or significance of those cues. Others expressed constant worry about minor or benign bodily sensations, consistent with hypochondriasis.

6) ***Strategies.*** Some (8 posts) described the utility of schedules to remind them when to eat or when to go to the bathroom. One person lined up several water bottles on their desk daily to make sure they drank enough. Others (3 posts) noted the utility of mind-body meditation practices—exercises that focus one's attention on internal bodily processes, which over time, improved awareness and correct classification of internal signals.

Conclusions: The findings offer the first nuanced account of first-person perspectives on interoception in ASD. Findings reveal categories of concerns and strategies that can inform future research on interoception and its relationship to other features of ASD and on novel intervention strategies.

442.006 *(Poster)* Otoacoustic Emissions in a Critical Frequency Band Do Not Improve with Age in Children with ASD

L. Bennetto[1]*, P. Allen*[2]*, J. M. Keith*[1] *and A. E. Luebke*[2]*, (1)Clinical and Social Sciences in Psychology, University of Rochester, Rochester, NY, (2)University of Rochester Medical Center, Rochester, NY*

Background: Autism spectrum disorder (ASD) is a behaviorally diagnosed disorder characterized by impairment in social communication, and restricted/repetitive behavior and sensory atypicalities. Some of the earliest signs of ASD involve auditory processing, and a recent study found that hearing thresholds in children with ASD in mid-range frequencies were significantly related to receptive and expressive language measures. In addition, otoacoustic emissions, an objective measure of auditory function, has been used to detect reduced cochlear function in the presence of normal audiometric thresholds. We previously determined that older children and adolescents with ASD showed robust differences in otoacoustic emissions in mid-frequency ranges compared to typically developing (TD) controls, but this has not been tested at younger ages.

Objectives: Our objective was to determine if group differences we found in older children—in critical band (1-2 kHz) but not other (4-8 kHz) frequencies —extend to younger children with ASD. Our objective was to specifically measure baseline otoacoustic emissions (distortion-product otoacoustic emissions [DPOAEs], and transient-evoked otoacoustic emissions [TEOAEs]) in children with ASD compared with aged-matched TD controls, both inside and outside this critical frequency band.

Methods: Participants were children and adolescents ages 4-17 years with ASD (n=48) and typically developing controls (n=67). Participants were rigorously characterized via ADOS-2, plus ADI-R and/or SRS-2, and matched on age and gender. All children had normal audiometry. Exclusion criteria included neurological or genetic disorders or other conditions/illnesses that could affect hearing. Cochlear function was tested in a sound attenuated room, using baseline DPOAE and TEOAE in the right and left ears, over frequencies spanning 1 kHz to 8 kHz. To measure age differences cross-sectionally, groups were further divided via a median split into younger (<10 years) and older (≥10 years) subgroups.

Results: OAEs were examined via mixed-model MANOVAs with 2 groups (ASD, TD) x 2 ages (younger, older) x 2 frequencies (lower [1-2 kHz], higher [4-8 kHz]) x 2 ears (right, left). The DPOAE analysis yielded a significant group x age x frequency interaction (p=.001). Follow-up analyses yielded a significant group x age interaction only at lower frequencies (p=.01), reflecting an age-related improvement in the TD group in this critical band but no developmental change in the ASD group. In particular, ASD and TD groups were similar at younger ages (p=.93) but differed significantly at older ages (p=.001). In contrast, the groups had comparable DPOAE function across both younger and older age groups for higher frequencies. Analyses of the spectral features of TEOAEs yielded a similar patterns of results, including group differences in the 1-2 kHz band for older but not younger subgroups. No significant differences were noted in DPOAE or TEOAE noise floors between ASD and TD groups.

Conclusions: While older children with ASD demonstrated impairments in both DPOAEs and TEOAEs in the critical 1-2 kHz region, younger children with ASD did not show impairments. This robust pattern may reflect differences in auditory maturation; attention to specific-frequency deficits using measures of cochlear function is important for understanding auditory processing impairments found in ASD throughout the lifespan.

442.007 *(Poster)* Physiological Synchrony in Parent-Child Dyads with and without Autism Spectrum Disorder and Sensory Processing Dysfunction

I. C. Chen[1] *and E. A. Larson*[2]*, (1)University of Wisconsin-Madison, Madison, WI, (2)Kinesiology, University of Wisconsin-Madison, Madison, WI*

Background: Parent-child dyadic synchrony is believed to capture reciprocity and mutuality in the relationship. This synchrony supports the child's overall development, and emotional regulation. Dyads including children with autism spectrum disorder (ASD) and co-occuring sensory processing dysfunction may have disrupted synchrony that impacts the quality of parent-child interactions as they support their child in everyday tasks. Poorly processing sensory input during self-care activities may induce emotional and physiological responses that interfere with children with ASD and SPD's ability to complete self-care routines.

Objectives: To assess levels and synchrony of physiological responses of parent-child dyads during the child's toothbrushing and viewing of a muted video of parent-child dyads with ASD and SPD compared to parent-child dyads with typical development (TD) and without SPD.

Methods: In Taiwan, seven mother-child dyads with ASD and SPD (5-9 years, mean = 6.80) were compared with seven age-, gender-, and IQ-matched dyads with TD and without SPD (5-9 years, mean = 6.81). Electrodermal activity (EDA), a sympathetic nervous system (SNS) measure of the intensity of emotional arousal, was continuously measured by a Q Sensor during five weekday morning toothbrushing routines and while watching a muted video together once (only visual input). Both the parent and child wore Q sensors on their wrists during the child's toothbrushing and video-watching. *T*-tests were used to compare EDA between two groups, and multiple linear regression analyses were used to examine physiological synchrony in mother-child dyads.

Results: During toothbrushing and video-watching together, the child EDA in ASD group was significantly lower than child EDA in the TD group. The mother EDA in ASD group was significantly higher than mother EDA in TD group during toothbrushing, but was significantly lower than in TD group during video-watching together. During toothbrushing, some mother-child dyads were always or sometimes in the same space, and some were always in different spaces. During toothbrushing, mother and child staying in the same space or not was a significant predictor for child EDA for both groups, and child EDA was lower when dyads were in the same space. The group moderated the association between child and mother EDA. In TD group, child EDA and mother EDA fluctuated together in the same direction; however, in ASD group, when mother EDA increased, child EDA decreased. During video watching together, child EDA and mother EDA fluctuated together in the same direction in both groups. Again, the group moderated the association between dyadic EDA and the influence of mother EDA on child EDA was larger in TD group than in ASD group.

Conclusions: Children in the ASD group appeared to demonstrate hypoarousal in SNS, and atypical mother-child synchrony patterns compared to the control group in some conditions. In low-demand, low-challenge sensory conditions (video watching) and dyads in the same space, ASD dyads demonstrated synchrony in EDA. When in the same space allowing mothers to support the child's self-care performance, mothers EDA increased while children's EDA diminished. This suggested that mothers were experiencing greater arousal whereas children may be hypoaroused or suppressing their responses.

442.008 *(Poster)* Sensory and Emotional Responses to Smell and Taste Cues in Autism Spectrum Disorder.

A. Singh *and H. S. Seo, Food Science, University of Arkansas, Fayetteville, AR*

Background: Autism spectrum disorder (ASD) is associated with significant sensory challenges that influence feeding behavior, leading to inadequate nutritional balance. Additionally, food evoked emotions have been shown to affect food acceptability and choice. While previous studies in this field have been done with autistic children, this study focused on adults, due to the lack of research and dissimilarities in child and adult eating behavior.

Objectives: The objectives of this study were to better understand the sensory experiences of adults with ASD and their responses toward food and beverages, and to determine whether ASD influences sensory and emotional responses to smell and taste stimuli.

Methods: In Study 1 (*smell*), 20 adults with ASD (12 males; mean age ± SD = 30 ±13) and 20 well-matched adults in the control group (12 males; mean age ± SD = 30 ±12) participated. Participants were given odor discrimination and odor identification test from an odor kit containing food and non-food odors. They were also asked to rate the intensity, liking, pleasantness, arousal, familiarity, and edibility of the odor samples on categorical scales. In Study 2 (*taste*), 20 adults with ASD (13 males; mean age ± SD = 29 ± 12) and 20 well-matched adults in the control group (12 males; mean age ± SD = 27 ±12) participated. Five basic taste solutions at low and high concentrations were used: salty, sweet, sour, bitter, and umami. Intensity and liking ratings for taste solutions were measured using line scales. Food evoked emotional responses toward the taste solutions were measured using self-report and facial expression analysis.

Results: In Study 1, the ASD group showed impaired odor identification and odor discrimination ability. Odors with trigeminal sensation (e.g., peppermint and lemon) were more arousing and intense for the ASD group than the control group. In Study 2, the ASD group showed increased sensitivity to sweet taste and decreased liking of sour taste for high concentrations when compared to the control group. The control group reported a higher number of emotions evoked by taste solutions. For sweet taste at high concentration, the ASD group reported feeling more aggressive and more disgusted. Facial expression analysis showed higher "sadness" for the ASD group for sweet and sour tastes at high concentrations.

Conclusions: This study was able to identify sensory challenges that potentially cause unusual feeding behavior. This study also found that similar emotions to tastes are not elicited by the ASD group and control group, indicating differences in food appreciation. The results from this study can be useful in developing interventions directed toward feeding habits to improve nutritional adequacy and ultimately the quality of life.

Sensory, Motor, and Repetitive Behaviors and Interests

ORAL SESSION — SENSORY, MOTOR, AND REPETITIVE BEHAVIORS AND INTERESTS
326 - Sensorimotor Subtyping

326.001 *(Oral)* Dissecting the Phenotypic Heterogeneity in Sensory Behaviours in Autism Spectrum Disorder: A Factor Mixture Modelling Approach

J. Tillmann[1], *M. Uljarevic*[2], *D. V. Crawley*[3], *G. Dumas*[4], *E. Loth*[5], *D. G. Murphy*[3], *J. K. Buitelaar*[6], *T. Charman*[7] *and L. G. EU-AIMS*[8], *(1)Institute of Psychiatry Psychology & Neuroscience, London, United Kingdom, (2)Department of Psychiatry and Behavioral Sciences, School of Medicine, Stanford University, Stanford, CA, (3)Forensic and Neurodevelopmental Sciences, Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, United Kingdom, (4)Human Genetics and Cognitive Functions Unit, Institut Pasteur, Paris, France, (5)Department of Forensic and Neurodevelopmental Sciences, Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, United Kingdom, (6)Karakter Child and Adolescent Psychiatry University Centre, Nijmegen, Netherlands, (7)Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, United Kingdom, (8)EU-AIMS Organization, London, United Kingdom*

Background: Heterogeneity in the phenotypic presentation of Autism Spectrum Disorder (ASD) is apparent in the profile and the severity of sensory symptoms, which has hampered progress towards understanding etiological mechanisms, developing effective treatments, and predicting outcomes. A number of studies have utilised both variable-centered approaches such as confirmatory or exploratory factor analysis (CFA/EFA) and person-centered approaches such as different types of cluster analyses and latent class/profile analysis in an attempt to characterise noted heterogeneity yielding mixed and inconclusive findings. However, no studies to date have attempted to simultaneously model categorical and dimensional structures of sensory behaviours in ASD. This approach, psychometrically represented by the Factor Mixture Modelling, has the potential to enable a more fine-grained understanding of heterogeneity in sensory behaviours in ASD.

Objectives: This is the first study to utilise Factor Mixture Modelling (FMM) to test a multidimensional factor model of sensory processing in ASD by identifying more homogenous sensory subgroups/classes in ASD that differ in both their severity within and across classes along continuous factor scores. We also investigated class membership in relation to different clinical variables of interest: sex, age, full-scale IQ, ASD core symptoms, and symptoms of anxiety and ADHD.

Methods: 332 children and adults with ASD as part of the EU-AIMS LEAP cohort between the ages of 6 and 30 years with IQs varying between 40 and 148 were included. First, three different CFAs were fit to the 38 items of the Short Sensory Profile (SSP) to test a 7-factor, 6-factor and a novel 5-factor solution. Then, four different LCA models (with two-to-five classes) were evaluated. The best performing CFA, the 7-factor structure, was subsequently used in two FMMs that varied in the number of classes: a two-class, seven-factor model and a three-class, seven-factor model.

Results: A direct comparison of all competing models demonstrated that the 'three-class/seven-factor' FMM provided the best fit to the data and was superior to all other models based on different goodness-of-fit criteria (AIC=34,902; BIC=35,473). Class 1 ("sensory severe", *N*=24) endorsed more frequently severe sensory behaviours across all seven SSP domain scores compared to class 2 ("sensory moderate", *N*=51) and class 3 ("sensory low/mild, *N*=257). Participants in the severe sensory group were more likely to have more severe social-communicative symptoms compared to the mild sensory group (p=.003, d=1.24). Difference in social-communicative symptoms was approaching significance for the moderate vs. mild sensory group (p=.056, d=.52). Symptoms of anxiety also differentiated sensory classes overall (p=.024), and particularly the sensory moderate vs. mild sensory group, with the former presenting with more severe symptoms (p=.006, d=.37).

Conclusions: Modelling simultaneously categorical and dimensional structures of sensory behaviours in ASD allowed a more fine-grained understanding of heterogeneity in sensory behaviours in ASD. Our results suggest that sensory behaviours can be best described by three more homogeneous sensory subgroups that differ in sensory severity gradients within and between classes along seven continuous factor scores. Current social-communicative symptoms and symptoms of anxiety differentiated sensory classes, providing novel evidence on the associated clinical correlates of sensory subgroups.

326.002 *(Oral)* Felt but Not Seen: Observed Restricted Repetitive Behaviors Are Associated with Self-Report - but Not Parent-Report - OCD Symptoms in Youth with ASD

A. H. Gerber[1]*, L. A. Santore*[1]*, A. N. Gioia*[2]*, R. Bianchi*[1]*, F. Talledo*[1]*, T. S. Peris*[3] *and M. D. Lerner*[1]*, (1)Department of Psychology, Stony Brook University, Stony Brook, NY, (2)Psychology, Stony Brook University, Albertson, NY, (3)Semel Institute for Neuroscience and Human Behavior, Los Angeles, CA*

Background: Restricted and repetitive behaviors (RRBs) are a core diagnostic feature of autism spectrum disorder (ASD). However, they also can appear similar to compulsive behaviors that are hallmark symptoms of obsessive-compulsive disorder (OCD; Jiujias et al., 2017). While the subjective distress caused by OCD obsessions may drive behavior meant to diminish unpleasant affect, RRBs are theorized to be reward- or sensory-driven, and may be stress-relieving. Phenotypic overlap between RRBs and OCD rituals may be due in part to a reliance on parent- and clinician-based assessments to classify observable behaviors, without fully considering what motivates them or how they are experienced (Leekam et al, 2011). Integrating information from multiple informants on both observable and subjective experiences of OCD symptoms and RRBs is vital for disentangling the overlap between these symptoms and informing intervention efforts.

Objectives: To determine the relationship between OCD symptoms (observable and subjective) with both clinician-observed and parent-reported RRBs, while controlling for current ASD-related social-communication symptoms.

Methods: Participants were 92 youth ages 7-17 (Table 1) with ADOS-2-confirmed (Lord et al., 2012) ASD and IQ>70 (per KBIT-2 ; Kaufman & Kaufman, 2004) Parents completed measures of their child's current ASD symptoms (SRS-2; Constantino, 2012) and general psychopathology (CASI-5; Gadow & Sprafkin, 2012). In addition, youth and their parents completed a measure of the child's OCD symptoms (MASC-2; March, 2012). Clinician-observed RRBs were indexed by the RRB subscale of the ADOS-2, while parent-reported RRBs were indexed by the RRB subscale of the CASI-5. First, we examined the bivariate correlations among all variables. Next, we ran hierarchical multiple regressions between parent- and self-reported OCD symptoms and clinician-observed and parent-reported RRBs. Finally, we utilized a novel technique (commonality analysis; Rowell, 1996) to better tease apart the unique contributions of each predictor on each dependent variable including both parent-and child-report of OCD symptoms as predictors.

Results: All parent-report measures correlated with each other, while clinician-observed RRBs and self-report OCD symptoms only correlated with each other (all *p*s<.05). While controlling for parent-reported current ASD social-communication symptoms, parent-report of OCD symptoms significantly predicted parent-reported, but not clinician-observed, RRBs (Table 2). In a comparable model, child-report of OCD symptoms significantly predicted both parent-reported and clinician-observed RRBs. Commonality analyses indicated that child self-reported OCD symptoms were the largest predictor of clinician-observed RRBs, uniquely explaining 67.04% of the variance; meanwhile, parent-reported current ASD symptoms were the best predictor of parent-reported RRBs, uniquely explaining 45.39% of the variance.

Conclusions: Results indicated that greater child self-reported, but not parent-reported, symptoms of OCD were associated with greater clinician-observed RRBs. Although both parent- and child self-reported OCD symptoms were associated with parent-reported RRBs, links between parents' reports of OCD and their reports of RRBs were likely explained by common method variance. This study suggests that children exhibiting objectively-observed RRBs may be experiencing relatively greater levels of subjective distress associated with restricted behavior patterns. These results provide guidance for better distinguishing and treating OCD behavior in youth with ASD, and open the door to new conceptualizations of the phenotypic overlap between these two conditions.

326.003 *(Oral)* Differential Presentations of Restricted Repetitive Behaviors in Individuals with Tuberous Sclerosis Complex and Autism Spectrum Disorder

H. K. Root[1]*, S. E. O'Kelley*[1]*, M. Bebin*[1]*, H. Northrup*[2]*, J. Wu*[3]*, D. A. Krueger*[4] *and M. Sahin*[5]*, (1)University of Alabama at Birmingham, Birmingham, AL, (2)McGovern Medical School, Univ. TX Health Sci Cntr-Houston, Houston, TX, (3)University of California Los Angeles, Los Angeles, CA, (4)Cincinnati Children's Hospital Medical Center, Cincinnati, OH, (5)Boston Children's Hospital/Harvard Medical School, Boston, MA*

Background: Despite a breadth of research focused on the social communication profile of individuals with tuberous sclerosis complex (TSC; Jeste et al.,2016; McDonald et al.,2017), a common population for examining the emergence of autism spectrum disorder (ASD) symptoms, few studies have examined restricted repetitive behaviors (RRBs). It has been noted that despite the presence of ASD-specific behaviors, both caregivers and clinicians do not immediately recognize the proper diagnosis as being ASD (Capal et al.,2017). As such, increased understanding of RRBs seen in individuals with ASD within the TSC population may aid early detection, diagnosis, and treatment of affected individuals.

Objectives: To define the presence and profile of RRBs in individuals with TSC, particularly those with comorbid ASD.

Methods: Participants included 196 individuals with TSC participating in a multisite longitudinal study through the TSC Autism Center of Excellence Network (TACERN) or Rare Diseases Clinical Research Network (RDCRN). 111 individuals participated in the TACERN study (M_{age}=3.05 years,*SD*=0.14) and 85 individuals participated in RDCRN (M_{age}=8.90 years,*SD*=4.8). Within TACERN, 19.8% of individuals received an ASD diagnosis, as opposed to 45% in the RDCRN sample. Of note are the differential recruitment parameters between the two studies, barring direct study-to-study comparisons. Cognitive ability was assessed via the Mullen Scales of Early Learning or the Stanford-Binet-5, adaptive functioning via the Vineland Adaptive Behavior Scales-2, and RRBs via the Autism Diagnostic Interview-Revised (ADI-R). RRBs were further examined in RDCRN via the Repetitive Behavior Scale-Revised (RBS-R).

Results: Mann-Whitney U tests with Bonferroni-adjusted alpha levels of .007 per test were run to compare RRBs on the ADI-R between ASD and non-ASD groups. The ASD group had significantly higher scores for Total Number of Endorsed Items, Severity of Endorsed Items, and Total Number of Items Scored a 1 and 2 on the ADI-R in both studies (p's<.001). The ASD group from the RDCRN study showed significantly more stereotypic, self-injurious, compulsive, and ritualistic behaviors (p's<.001) on the RBS-R, but not sameness behavior (p>.05). Endorsement of each RRB item on the ADI-R was compared between diagnosis groups using chi-square tests of independence (Table 1). The RDCRN ASD group showed significantly higher endorsement on all variables except compulsions/rituals, while only repetitive use of objects, unusual sensory interests, and hand/finger mannerisms were significant for TACERN ASD (p's<.001).

Conclusions: Individuals with ASD in both studies exhibited a greater total number and severity of RRBs endorsed in comparison to individuals without ASD. However, when considered at the item level, there were differences in the patterns of significance between TACERN and RDCRN. In the older and more impaired participants (RDCRN), the ASD group had significantly higher scores on almost all ASD-specific behaviors, while younger and higher functioning groups (TACERN) differed only on repetitive use of objects, unusual sensory interests, and hand/finger mannerisms. Although less than the ASD group overall, the non-ASD group did not exhibit an absence of RRBs, rather they demonstrated elevated levels of many types of RRBs. There is potential for screening measures to be developed based on the unique profile of RRBs exhibited.

326.004 *(Oral)* Utilizing Quantitative Motor Measures to Improve Identification of Motor Differences in Infants at High Familial Risk for Autism

R. B. Wilson[1]*, S. Vangala*[1]*, D. Elashoff*[1]*, D. Sim*[1]*, T. Safari*[1] *and B. Smith*[2]*, (1)UCLA Medical Center, Los Angeles, CA, (2)University of Southern California, Los Angeles, CA*

Background: Motor development is an early observable benchmark of developmental progress and is crucial in driving multiple cognitive processes. During the first year of life, infants acquire a set of motor skills that fundamentally transform their experiences with the environment and people and support advances in cognition, language, and social interaction (Piaget, 1952). Impairments in motor development are ubiquitous in autism spectrum disorder (ASD), and studies in infants at high risk (HR) for ASD have posited that these impairments might be the first sign of atypical development (Piven et al., 2017). However, these studies have produced varying results. One reason for this is that current standardized measures of infant motor function use subjective categorical ratings of a limited range of infant motor milestones and do not objectively identify subtle and specific motor impairments. Quantitative analysis of infant motor skills can provide objective results and may improve early detection of motor impairments that are associated with clinical risk for ASD.

Objectives: Utilize a quantitative wearable sensor to identify distinct motor differences in HR infants compared to low risk (LR) infants in the first year of life, and to identify motor differences in HR infants associated with ASD behaviors.

Methods: Participants included 12 LR infants and 15 HR infants (5 HR infants with behavioral outcomes). HR infants had one older sibling with ASD. LR infants had no elevated concern for ASD. Full day quantitative measurement of spontaneous leg movements was obtained utilizing the opal wearable sensor at 4 time points across the first 12 months of life. Two novel quantitative features of the movement data were developed to measure amount of leg movement and variability in leg movement patterns. Standardized motor assessment using the Alberta Infant Motor Scale (AIMS) was conducted at these time points. ASD symptoms were measured at 18 months with the Autism Diagnostic Observation Schedule toddler module.

Results: HR infants showed significantly lower leg movement rates compared to LR infants [p=0.032, Figure 1]. All HR infants scored within the norms on the AIMS, despite showing lower leg movement rates compared to LR infants. Lower leg movement rates were associated with greater concern for ASD. HR infants with severe concern for ASD showed significantly lower variability in leg movement patterns compared to HR infants with no concern for ASD (p=0.017, Figure 2).

Conclusions: Specific quantitative motor measures can differentiate HR and LR infants, while the standardized motor assessment did not. Furthermore, HR infants showed lower leg movements rates which could be a potential marker of fewer volitional movements. Moving forward, this metric could be applied in different environmental and caregiver interactions to evaluate whether infants move less in specific social situations. HR infants also showed less variability in leg movement patterns. Lower variability suggests more repetitive movements, and this metric could serve as a measure of repetitive behaviors, a core diagnostic feature of ASD. These results support the use of quantitative motor measures to aid in early identification of motor impairments that could be associated with risk for ASD.

POSTER SESSION — SENSORY, MOTOR, AND REPETITIVE BEHAVIORS AND INTERESTS
443 - Sensory, Motor, and Repetitive Behaviors and Interests Posters

443.001 *(Poster)* A Conversation on Twitter: Autistic Adults Perceptions of Physical Activity

A. M. Colombo-Dougovito[1]*, S. McNamara*[2]*, J. Blagrave*[3] *and H. Kupferstein*[4]*, (1)Kinesiology, Health Promotion, & Recreation, University of North Texas, Denton, TX, (2)University of Northern Iowa, Cedar Falls, IA, (3)Kinesiology, California State University, Chico, Chico, CA, (4)HennyK.com, San Diego, CA*

Background: Recent evidence (Garcia-Pastor et al., 2019) suggests that autistic adults are less likely to be physically active than children and adolescents on the spectrum. Suggesting that physical inactivity is either maintained or increases as individuals age. Given the myriad of potential benefits from physical activity engagement (Bremer & Lloyd, 2016; Healy et al., 2018; Saunders et al., 2016; Schuch & Stubbs, 2019), the rate of physical inactivity among autistic adults is discouraging. Yet, little focus has been given to the experiences of autistic adults regarding physical activity, nor on how to utilize affinities and increase access; more-so-even in populations often missed by traditional recruitment techniques.

Objectives: Therefore, through a phenomenological inquiry, the purpose of this study was to gather information from autistic adults about their experiences with physical activities and the role it has in their daily lives utilizing the social media platform, Twitter.

Methods: Through Twitter, a total of 21 participants recruited that had a diagnosis of autism or identified as autistic; though only 11 participants engaged for the duration of the study. Of those that consented, a majority self-identified as “female” (n = 14); two individuals self-identified as “male”, one as a “transgender male”, one as “female/Agender”, one as “female/Demigirl”, and one as “female with masculine tendencies”. Over half of those consented self-reported a motor-related issue such as dyspraxia, low muscle tone, hypermobility, motor planning, or arthritis. A total of 6 “Twitter chats” were used as open, focus groups using the hashtag #AutStudy. A total of 35 questions were posed across the 6 chats; the first 5 chats had 5 questions each and the 6th chat had 10 questions. The primary author tweeted each question during a predesignated day and time; all authors followed up with each “reply”. Data were aggregated and thematically analyzed (Braun & Clarke, 2006) for common themes among the responses.

Results: Overall, several themes emerged from the data. Participants, each, recognized the importance of physical activity in their daily lives and connected participation in physical activity to improvements in mental health. However, most participants stressed the difficulty with access to physical activity spaces, a lack of knowledge about what to do, increased physical issues (e.g., joint pain, dizziness) due to physical activity engagement, the necessity for executive function capacity to plan for physical activity, and a need to balance current mental health with physical activity engagement.

Conclusions: Through the use of Twitter, this study was able to gather data from a broader sample than through a traditional method of recruitment. Findings suggest that autistic adults understand the importance of physical activity, but may not have the knowledge base to know what to do or may not have access to accommodating spaces for physical activity. Further, while most participants participated semi-regularly (i.e., at least once per week) in physical activity, this was often counterbalanced an individual's mental health status. Despite acknowledged benefits, if an individual was having difficulty coping, they would forego physical activity.

443.003 *(Poster)* A Pilot Evaluation of the Ignite Challenge, an Advanced Gross Motor Skills Assessment for Children with ASD to Help Get Them "into the Game."

I. D. Naiman[1,2]*, K. P. Arbour-Nicitopoulos*[3] *and V. Wright*[2]*, (1)Rehabilitation Sciences Institute, University of Toronto, Toronto, ON, Canada, (2)Bloorview Research Institute, Holland Bloorview Kids Rehabilitation Hospital, Toronto, ON, Canada, (3)Faculty of Kinesiology and Physical Education, University of Toronto, Toronto, ON, Canada*

Background: Children with ASD participate in less physical activity (PA) than their typically developing peers due to communication/social interaction challenges, environmental and societal barriers. Gross motor deficits related to balance, fine and gross motor skills may further contribute to reduced motivation, confidence, positive affect, physical competence, and knowledge to participate in PA (key components of physical literacy). Search for an advanced motor skills measure that tapped into co-ordination, balance, speed motor planning and associated listening skills and focus revealed a measurement gap. Thus, our research team created the *Ignite Challenge* (*I-Challenge*), derived from the advanced motor skills measure known as the *Challenge-CP,* developed and validated by the senior author's CP research team for children with cerebral palsy to address similar motor areas and offer a positive and engaging assessment process. The *I-Challenge* is shorter than the *Challenge-CP* (13 versus 25 items) with more stringent time cut-points to make it a better fit for children with ASD and amenable for use by instructors within a busy community setting. Each item is scored on an item-individualized 5-point (0 to 4) accuracy/time-based scale.

Objectives: The purpose of this study is to investigate the *I-Challenge*'s discriminant validity, individual item profiles and reported item enjoyment in a convenience sample of children with ASD undertaking the *I-Challenge* as part of a larger body language evaluation study. This study is the first research evaluation of the *I-Challenge* in North America, and is running in parallel with a two-year reliability study (2018–2020) in Adelaide, Australia with our research partners there.

Methods: Thirty participants are being recruited. Inclusion criteria are: diagnosis of ASD, age 6 to 12 years, no medical contradictions to physical activity, and ability to follow complex 3-step instructions. Participants completed the *I-Challenge* and then rated enjoyment of item performance. For these ratings, each participant first created a personalized scale (10-cm line) by drawing in anchor boxes of their favourite activity (10/10), least favourite activity (1/10) and an activity that they neither like nor dislike (5/10). Photos of the researcher completing each *I-Challenge* item were viewed after the testing, and the participant rated enjoyment of each task on their personalized scale.

Results: Seventeen participants (1 female) with mean age 9.1 years (SD 1.9) have completed the *I-Challenge* thus far. The *I-Challenge* mean score (based on n=17) was 42.6/60 (SD 7.9, minimum=25, maximum=56). Item mean scores varied from 1.2 (SD 0.8) for the standing long jump and 3.4 (SD 0.7) for the stopping on a line after a 10m pathway run. Overall mean enjoyment was 7.6/10 (SD 0.7). The least enjoyed item was 'jumping jacks' (mean score 6.1 [SD 2.3]), while most enjoyed was 'step ups' (mean score 8.5 [SD 2.1]).

Conclusions: There was a wide range of item/total scores demonstrating the *I-Challenge's* ability to detect performance skill differences among children with ASD. The interactive and positive nature of the *I-Challenge* appeared to support children's engagement and enjoyment. Future research will compare the psychometric properties of the *I-Challenge* to current motor skills assessments being used clinically.

443.003 *(Poster)* A Longitudinal Study on Autism, Hyperlexia, and the Acquisition of Language in Monozygotic Twins

A. Ostrolenk[1,2]*, V. Courchesne*[3,4] *and L. Mottron, M.D.*[3,5]*, (1)Department of Psychiatry, Université de Montréal, Montreal, QC, Canada, (2)Autism Research Group, CIUSSS du Nord-de-l 'Île-de-Montréal, Montreal, QC, Canada, (3)Autism Research Group, CIUSSS du Nord-de-l 'Île-de-Montréal, Montréal, QC, Canada, (4)Department of Neurology and Neurosurgery, McGill University, Montréal, QC, Canada, (5)Université de Montréal, Montréal, QC, Canada*

Background: Hyperlexia is defined by a strong orientation towards written materials along with a discrepancy between the precocious acquisition of decoding skills and weaker comprehension abilities. Although the hyperlexic profile might characterize over 20% of autistic children, there are few accounts of how this skill develops prior to becoming obvious, and how it evolves as the child grows up and enters school. While some articles suggest that hyperlexia is an obstacle to oral language acquisition, others hypothesize that it is a strength that grounds future language skill, providing a potential bridge between no speech at all and fluent speech. Consequently, strategies guiding how precocious decoding skills should be approached in intervention have not been detailed.

Objectives:

- Provide an in-depth description of hyperlexia in two prototypical cases;
- Document the longitudinal development of oral language and hyperlexia in parallel;
- Document natural strategies established by the parents in the face of hyperlexia.

Methods: We followed the cognitive and language development from ages 4 to 7 of two monozygotic twin brothers who presented with unambiguous autism and hyperlexia, with 16 data points between 2016 and 2019. Five sessions provided an initial cognitive evaluation and in-depth assessment of their expressive and receptive language. Three sessions consisted of questionnaires targeting aspects of their interests, strengths, and family environment. Four sessions were dedicated to additional language assessments, four sessions to the observation and evaluation of reading and writing skills, and the intervention strategies employed and how they related to the children's interest in written material.

Results: At 4y, both children could not complete most of the sub-tests on the WPPSI-IV and scored under the 5th percentile on the few they completed. In contrast, their scores on the Raven Color Progressive Matrices placed both above the 90th percentile. Their results on the Vineland Adaptive Behavior Scales were similarly uneven, with above-average motor and written skills and delayed communication and socialization aptitudes. Their language was minimal and challenging to assess. At 5y6m, the CELF, consistently with other assessments, revealed receptive and expressive language skills under the 1st percentile. Both children could spell the alphabet forward and backward at 12m and write complex words at 2y. One of them also had a strong interest in drawing, while the other built elaborate structures with Lego. The parents developed strategies to use the children's interests in daily activities to foster the development of other skills. Between 5y and 7y, their language developed quickly towards the use of full sentences in mutual interactions. Most new words were first pronounced after being read, and their interest in letters merged with their other interests (*e.g.* drawing and writing names of *Angry Birds* characters), thus becoming more complex.

Conclusions: These results provide a proof of concept that hyperlexic skills can be harnessed to favour oral language development and allow us to more clearly define the specificities of autistic hyperlexia as opposed to precocious reading in typical children, hence contributing to a more precise definition of hyperlexia and the development of individualized intervention strategies.

443.004 *(Poster)* A Transdiagnostic Assessment of Restricted and Repetitive Behaviors in School-Age Children with ASD and ADHD

B. Vibert[1], *P. Segura*[1], *J. Bellamy*[1], *F. X. Castellanos*[2], *S. Bishop*[3], *S. H. Kim*[4], *C. Lord*[5] *and A. Di Martino*[6], *(1)Autism Center, Child Mind Institute, New York, NY, (2)Department of Child and Adolescent Psychiatry, NYU Langone Health, New York, NY, (3)University of California San Francisco, San Francisco, CA, (4)Psychiatry, Center for Autism and the Developing Brain, White Plains, NY, (5)University of California, Los Angeles, Los Angeles, CA, (6)The Child Mind Institute, New York, NY*

Background: There is overwhelming evidence that symptoms of autism spectrum disorder (ASD) and attention deficit hyperactivity disorder (ADHD) often co-occur in the same children. However, the specific role and the extent of overlap in restricted repetitive behaviors/interests (RRB) has been understudied.

Objectives: Accordingly, we aimed to 1) quantify the prevalence and severity of RRB in a sample of school-age children with ADHD relative to age-matched ASD children; 2) examine RRB type, ADHD-related symptoms, as well as general psychopathology as a function of RRB severity within and across diagnostic groups.

Methods: We analyzed data from a well-characterized sample of children (N=168, M=8.7±1.7, range=5.6-11.9 years; n=33 females) with DSM-5 ADHD-only or ASD (N=101, N=67, respectively). Presence of RRB was indexed by computing a meta-z-score derived by averaging across all subjects z-scores obtained from parent and clinician RRB ratings (Restricted and Repetitive Behavior Scale-Revised [RBS-R] and Autism Diagnostic Observation Schedule-2ndEdition [ADOS-2], respectively). Children with meta-z-scores above average ($z \geq 0$) were identified as High-RRB, those below average as Low-RRB. After identifying the diagnostic composition of Low- and High-RRB groups, univariate ANOVAs were used to explore RRB type, sensory, ADHD, and general psychopathology symptoms based on the RBS-R subscales, sensory experience questionnaire (SEQ), Strengths and Weaknesses of Attention (SWAN), and Child Behavioral Checklist (CBCL), respectively. Main effects of DSM-5 diagnosis, RRB group, and their interaction were determined significant at $p<0.05$.

Results: High- and Low-RRB groups (N=82, n_{ASD}=51, ADHD n_{ADHD}=31; N=86, n_{ASD}=16, n_{ADHD}=70, respectively) were not significantly different in age, sex, nor IQ. Analyses of the SEQ and RBS-R subscale revealed a significant effect of RRB group only for hyposensitivity, stereotype and compulsive behavior subscales. A main effect of diagnostic group was observed only for hypersensitivity. In contrast a main effect of group and diagnosis were observed for ritualistic, sameness and restricted interest subscales, their interaction was significant for the sensory seeking subscale. Results from analyses on the SWAN and CBCL ratings showed significant main effects of RRB-group, irrespective of diagnosis.

Conclusions: Our preliminary findings suggest that a subset of school-age children with ADHD (30%) show RRB severity similar to those observed in ASD exists. A closer look revealed that one set of RRB is similar across ASD and ADHD (e.g., stereotypic behavior), some RRB are ASD-specific, regardless to their severity (e.g., sensory hypersensitivity), and another set of RRB is ASD-specific as a function of their severity (e.g., sensory seeking) – i.e. differences between high and low-RRB groups are specific to diagnosis. Further, consistent with prior findings, children with high RRB have more severe ADHD and psychopathology symptoms, regardless of their DSM-5 diagnosis. Further transdiagnostic investigations of RRB using multimodal behavioral and biological assessments are necessary for improved characterization and understanding of underlying mechanisms in order to develop more individualized treatment.

443.005 *(Poster)* Achilles Tendon Shortening Is Related to TIP-TOE Behavior Severity in ASD Subjects: A CROSS-Sectional Study

G. Valagussa[1,2], *V. Balatti*[1], *A. Grassi*[1], *M. Azzaretto*[1] *and E. Grossi*[1], *(1)Autism Research Unit, Villa Santa Maria Foundation, Tavernerio, Italy, (2)School of Medicine and Surgery, University of Milan-Bicocca, Milano, Italy*

Background: Toe-walking is a phenomenon present in 20-30% of ASD subjects. Persistent tip-toe behavior (TTB) can produce a shortening of the Achilles's tendon (made up by the soleus muscle – SM, and gastrocnemius muscle - GM) in ASD subjects. It is currently unclear why some ASD subjects develop this tendon shortening while others do not. One possible contributing factor could be the amount of time subjects spend in TTB during the day. In a previous study, we described three mutually exclusive clinical functional TTB classes of increasing severity: TTB present only in running (TTBclass1), in walking and running (TTBclass2), in standing, walking and running (TTBclass3). We also found the existence of a positive correlation between the severity of TTB presence and the Achilles's tendon shortening using a qualitative testing approach.

Objectives: The aim of this cross-sectional study is to evaluate the relationship between the quantity of TTB expressed during both static and dynamic tests and the Achilles tendon shortening in a cohort of TTB and NON-TTB ASD subjects.

Methods: The cross-sectional study included 51 consecutive ASD subjects (44 males, 7 females, mean age = 13.9 years – 3.67 SD) diagnosed according to the DSM V criteria and under observation at our Institute. The ASD severity was established through ADOS (2nd version). A therapist assessed the amount of TTB during both standardized static and dynamic tests previously described. The intensity of TTB expression during the static and dynamic tests was quantified as percentage of time spent on the tip-toes and as the percentage of toe steps, respectively. Two therapists, blind to the TTB quantitative testing, assessed both the soleus and gastrocnemius muscle lengths using a manual goniometer.

Results: The overall ADOS calibrated severity score (CSS) of all the subjects was 7.61 (1.65 SD). Overall 21/51 subjects presented TTB. Two subjects were in TTBclass1, 10 in TTBclass2 and 9 in TTBclass3.The mean percentage of time spent in TTB during the static test was 5.96% (15.68 SD) (range: 0%-96%). The mean percentage of toe steps during the dynamic test was 15.39% (26.51 SD) (range: 0%-100%). The mean length of the left and right GM of the sample were 6.84° (6.2 SD) and 7.9° (6.07 SD) respectively. The mean length of the left and right SM of the sample were 16.1° (6.89 SD) and 15.96° (6.36 SD) respectively. Using a Pearson's correlation test we found a significant inverse correlation between the percentage of time spent on the tip-toes and both the GM and SM lengths (left GM: $r=-0.703$, $p<0.001$; right GM: $r=-0.678$, $p<0.001$; left SM: $r=-0.541$, $p<0.001$; right SM: $r=-0.518$, $p<0.001$ respectively). We also found an inverse correlation between the percentage toe steps and both the GM and SM lengths (left GM: $r=-0.484$, $p<0.001$; right GM: $r=-0.425$, $p=0.002$; left SM: $r=-0.386$, $p=0.005$; right SM: $r=-0.363$, $p=0.009$ respectively).

Conclusions: The quantitative data show the existence of an inverse relationship between TTB intensity during both the static and the dynamic tests and the Achilles's tendon shortening in ASD subjects. Further research is required to confirm the results.

443.006 *(Poster)* Activity Participation Predictors in Children with Disabilities

C. L. Hilton[1], *K. Ratcliff*[2] *and I. Hong*[3], *(1)University of Texas Medical Branch, Galveston, TX, (2)Occupational Therapy, University of Texas Medical Branch, Galveston, TX, (3)Rehabilitation Science, University of Texas Medical Branch, Galveston, TX*

Background: Participation in meaningful activities or occupations is the essence of a healthy, happy, thriving person. Research indicates that those individuals who engage in meaningful occupations have higher quality of life, more satisfaction with life, and are healthier physically and mentally. Many with autism spectrum disorders (ASD) and intellectual disability (ID) are negatively impacted by difficulty participating in occupations, which contribute to adult problems with living independently, employment, secondary education, and getting married. It is important to better understand the predictors of difficulty participating in meaningful occupations across all participation areas.

Objectives:

1. Examine the differences in participation difficulties of children with ASD without ID, ASD + ID, ID alone, and controls in the areas of home life, friendships, classroom learning, and leisure activities by controlling for selection bias (e.g., sex, age).
2. Identify and compare the magnitude of various predictors of activity participation difficulties in children with ASD without ID, ASD + ID, and ID alone and controls.

Methods: The 2011 Survey of Pathways to Diagnosis and Services is a national dataset of a survey of caregivers of children in the US with special needs developed to better understand their pathway to services and the difficulties experienced (Child and Adolescent Health Measurement Initiative, 2015). Approximately 4,000 interviews and 3,000 written questionnaires were administered to parents of children aged 6-17 years who were ever diagnosed with ASD, developmental disorder, or ID across the United States.

We used chi-square tests and ANOVA to compare the factors among the groups of children with ASD without ID, ASD + ID, and ID alone. Next, we plan to use multivariate regression models to examine the relationship and predictive capacity of strengths and difficulties, skills, and participation in occupational therapy and sensory integration intervention on activity participation from the Pathways survey. We will use multivariate regression models to examine the predictive capacity of environmental, personal, body structures and function, and activity level variables on participation.

Results: We found that the greatest mean difficulty levels were seen in friendships and classroom learning for all groups. The children with both ASD and ID had the most difficulty in all areas, followed by the group with ASD alone, followed by the group with ID alone. For classroom learning, the groups with ASD alone and ID alone had equal difficulty.

Next, we will analyze potential predictors of difficulty with participation in those areas. Our findings will increase our knowledge of what areas we should address earlier in life for children with autism and intellectual disability to improve the trajectory of their activity participation outcomes.

Conclusions: The knowledge gained from this study will help to determine the impact of a group of factors that can be addressed by therapy services for individuals with ASD and ID to increase their activity participation. It will also reveal the possibility of inadequate therapy services for children with ASD without ID.

443.007 *(Poster)* Adults with Autism Who Achieve Different Functional Outcomes Show Distinctive Trajectories of Rrbs from Age 2 to 18

E. Clark-Whitney[1], *A. Zweifach*[2], *J. B. McCauley*[3], *C. Lord*[3] *and S. H. Kim*[1], *(1)Psychiatry, Center for Autism and the Developing Brain, White Plains, NY, (2)Dartmouth College, Hanover, NH, (3)University of California, Los Angeles, Los Angeles, CA*

Background: Restricted and repetitive behaviors (RRBs) are a core diagnostic feature of ASD, and can cause substantial functional impairment. Higher-order RRBs (e.g., circumscribed interests, unusual preoccupations) increase with age, while lower-order RRBs (e.g., mannerisms, sensory interests) are more prevalent in those with lower IQ and decrease with age. However, longitudinal studies of RRBs are limited, and research has not identified how trajectories of RRBs from early childhood to young adulthood are related to adult outcomes.

Objectives: Examine differences in RRB trajectories from ages 2-18 for groups of individuals with ASD who show different functional outcomes at age 25.

Methods: Eighty-nine individuals with ASD (78 male) for whom functional outcome data at age 25 was available were drawn from a sample of 192 children followed longitudinally from age 2-25. Participants were classified into More Cognitively-Able (MA; age 25 verbal IQ ≥ 70) and Less Cognitively-Able (LA; verbal IQ < 70); within each group, participants were further classified into three groups based on the number of functional outcomes achieved at age 25 (**Table 1**). RRBs were assessed at age 2, 3, 9 and 18 using the Autism Diagnostic Interview-Revised. General linear mixed models were used to investigate how RRBs developed across time, and whether adult functional groups showed distinct trajectories, for individual behaviors and higher-/lower-order clusters, while controlling for non-verbal IQ and language level at age 2 or 3.

Results: For the LA group, a main effect of age emerged such that higher-order RRBs increased and lower-order decreased from 2-18; for MA individuals, lower-order RRBs also decreased significantly with age. For the LA group, a main effect of group emerged for both lower-order and higher-order RRBs, with those meeting no functional outcomes demonstrating significantly more RRBs than the other two groups. In the MA group, there was a main effect of group for one lower-order RRB (complex mannerisms), with the group who met no functional outcomes showing a more severe presentation across ages. For LA and MA groups, there was an interaction between group and age for lower-order RRB (**Figure 1**). Lower-order RRBs in LA individuals who met all three functional outcomes decreased from age 2 to 9 whereas the lower-order RRBs in those who met fewer outcomes increased until 9. MA individuals who did not achieve any functional outcomes showed an early decrease in lower-order RRBs from age 2 to 9 then remained constant, whereas lower-order RRBs in those who met all three functional outcomes decreased continuously from 2 to 18 years.

Conclusions: Trajectories of lower-order RRBs from 2 to 18 years could serve as a potential indicator of positive adult outcomes among individuals with comparable cognitive functioning. For the LA group, the group who achieved the most optimal outcomes showed a decrease in lower-order RRBs in early childhood, whereas those who met fewer positive outcomes as adults showed stability. For the MA group, those who achieved the most positive outcomes in adulthood were differentiated by a sharp decrease in lower-order RRBs between 9 and 18 years.

443.008 *(Poster)* Altered Multisensory Facilitation in Younger and Older Autistic Individuals

K. Ainsworth[1]*, A. Ostrolenk*[2]*, C. Irion*[3] *and A. Bertone*[1]*, (1)McGill University, Montreal, QC, Canada, (2)Department of Psychiatry, Université de Montréal, Montreal, QC, Canada, (3)Université Paul Sabatier, Toulouse, France*

Background: Atypical sensory processing is an important aspect of the current autism diagnosis (APA, 2013). The *integration* of multiple sensory inputs (multi-sensory integration (MSI)) is thought to be idiosyncratic in autistic individuals (Wallace and Stevenson, 2014) and may have cascading effects on the development of higher-level processing such as speech perception (Stevenson et al., 2017). Thus far, there is mixed evidence as to whether altered MSI in autistic individuals is related purely to the social context employed in many MSI tasks (Feldman, 2019), and exactly how this process develops with age remains unclear.

Objectives: Our aims were twofold: (1) explore MSI in autistic and neurotypical individuals using a task void of social context and (2) assess performance differences in younger and older participants.

Methods: Multisensory facilitation was assessed using a target detection paradigm in 45 autistic and 111 neurotypical individuals. Participants were divided into younger and older age groups at a cut-off age of 15 (as reflected in the Sensory Profile (Dunn, 2014)). Participants were matched on age and performance IQ using the WASI-II. Three different types of stimuli were presented as targets: auditory (A; beep), visual (V; flash) or simultaneous audiovisual (AV; beep and flash). A, V and AV trials were presented in a randomized order with varying stimulus onset delays. Participants were required to respond to the stimulus (A, V or AV) as fast as possible via button press and reaction time (RT) was recorded.

Results: Redundancy gain (RG) was calculated for each participant ((mean bimodal RT - fastest mean unimodal RT)/ fastest mean unimodal RT). Overall, RG was greater in both typical groups compared to autistic groups [autistic young group mean RG: 12.33% (SD 9.34%), autistic older group: 11.22% (9.88%), typical young group: 16.34% (7.33%) and typical older group: RG of 17.76% (7.60%)]. Variance in RG was assessed using a 2-way ANOVA (2 groups x 2 ages), revealing a significant main effect of group: $F(1,152) = 13.67$, $p < 0.001$. No significant effect of age or significant interactions were found. Next, we applied a race model analysis which computes a bound value that represents the facilitation effect provided by MSI. If the mean RT on the audiovisual trials is shorter than this bound at any percentile, the race model is "violated", indicating multisensory integration. Our results revealed MSI facilitation occurred (violation of the race model) in neurotypical individuals, and with more efficient MSI in older participants. In both the younger and older autistic groups, we found reduced MSI facilitation (no or limited violation of the race model), with increased variability in both autistic groups.

Conclusions: Autistic participants showed reduced multisensory facilitation compared to typical participants in a simple target detection task, void of social context. This remained consistent for younger and older autistic individuals. Our results support evidence that autistic individuals integrate low-level, non-social information in an atypical fashion, possibly leading to higher-level, core difficulties such as sensory processing and speech perception in autism.

443.009 *(Poster)* An Evaluation of Autism Symptomatology and Toe Walking Severity in Children with and without Autism Spectrum Disorder (ASD)

E. Hong*, J. L. Matson and A. Issarraras, Department of Psychology, Louisiana State University, Baton Rouge, LA*

Background: The prevalence of toe walking is significantly higher among individuals with ASD than individuals with intellectual disability (ID), developmental disabilities (DD), or typical development (TD; Barrow, Jaworski, & Accardo, 2011; Sala et al., 1999). Despite the fact that toe walking is the most frequently studied gait abnormality in individuals with ASD (Weber, 1978), there are mixed findings on the factors that are associated with higher frequency of toe walking (Engström, Van't Hooft, & Tedroff, 2012). Among children with ASD, a positive relationship between autism symptomatology and toe walking has been found (Kantzer, Fernell, Gillberg, & Miniscalco, 2013; Shetreat-Klein, Shinnar, & Rapin, 2012).

Objectives: The purpose of this study was to evaluate toe walking severity in children with ASD, ID, atypical development (AD), and typical development. Additionally, the study evaluated if ASD symptom severity predicted the presence and severity of toe walking in children with ASD.

Methods: A Kruskal-Wallis H test was conducted to determine if there were differences in toe walking severity between four diagnostic groups: ASD, ID, AD, and TD. Toe walking severity was assessed using an item rating score on the Autism Spectrum Disorder- Diagnostic Child Version (ASD-DC; Matson & Gonzalez, 2007). Participants included 401 children between the ages of 2 and 8 years (M = 5.59, SD = 1.71). Subsequent analyses were conducted to evaluate if total ASD severity and body use severity, assessed using the Childhood Autism Rating Scale, Second Edition (CARS-2-ST; Schopler, Van Bourgondien, Wellman, & Love, 2010), predicted the presence and severity of toe walking. A binomial logistic regression was conducted to determine if ASD symptomatology predicted the presence of toe walking, and an ordinal regression was conducted to determine if ASD symptomatology predicted toe walking severity. Participants included 110 children between the ages of 2 and 8 years (M = 5.23, SD = 1.73).

Results: There were significant differences in in toe walking severity ratings between groups $\chi^2(3) = 43.05$, $p = .000$. A Bonferroni correction for multiple comparisons was performed, and statistical significance was accepted at the $p < .0083$ level. Post hoc analyses revealed statistically significant differences in toe walking severity between the ASD (Mdn = .00) and AD groups (Mdn = .00; $p = .001$) and ASD and TD groups (Mdn = .00; $p = .000$), but not between the ASD and ID groups. The logistic regression model was not statistically significant ($\chi^2(8) = 9.550$, $p = .298$). The model explained 11.3% of the variance in the presence of toe walking and correctly classified 65.5% of cases. The ordinal logistic regression was not statistically significant $\chi^2(3) = .097$, $p = .755$.

Conclusions: The current findings indicate that children with ASD exhibit higher severity of toe walking than children with AD and TD, but not children with ID. Higher total ASD severity and body use severity were not found to be significant predictors of the presence and severity of toe walking. Further research on ASD symptomatology and toe walking is needed for effective assessment and treatment of toe walking.

443.010 *(Poster)* Are Early Emerging Individual Differences in Repetitive Behaviour Subtypes Predictive of Subsequent Emotional and Behavioural Problems?

S. J. Carrington[1]*, M. Uljarevic*[2]*, E. Meins*[3]*, A. LeCouteur*[4] *and S. R. Leekam*[5]*, (1)Department of Psychology, School of Life and Health Sciences, Aston University, Birmingham, United Kingdom, (2)Department of Psychiatry and Behavioral Sciences, School of Medicine, Stanford University, Stanford, CA, (3)University of York, York, United Kingdom, (4)Institute of Health and Society, Newcastle University, Newcastle upon Tyne, United Kingdom, (5)School of Psychology, Cardiff University, Cardiff, NSW, United Kingdom*

Background: Repetitive sensory motor behaviours (RSM) and Insistence on Sameness (IS) are two subtypes of restricted and repetitive behaviour (RRB) that have consistently emerged in a range of factor analyses across both ASD and normative samples (e.g. Evans et al., 2017; Leekam et al., 2007; Richler et al., 2010). Although a typical feature of early development, the persistence of RRBs into later childhood has been associated with poorer developmental outcomes (e.g. Evans et al., 2014; Ghanizadeh & Moeini, 2011; Thelen, 1981), and linked to RRBs in neurodevelopmental disorders including autism spectrum disorder (ASD; Leekam et al., 2011). However, the limited research to date on the association between RRB and different cognitive, language and emotion (anxiety) outcomes, suggests that outcome depends on the type of RRB being measured (Evans et al., 1999; Larkin et al., 2017; Lidstone et al., 2014; Rogers et al., 2012). Another consideration is that RSM and IS RRBs also show different developmental trajectories (Arnott et al., 2010; Çevikaslan et al., 2014; Evans et al., 1997; Uljarević et al., 2017). Therefore timing is also important. The current study examined the selective association between RRB subtypes at different ages and later emotional and behavioural developmental outcome assessed as internalising and externalising behaviours. This is an important area to address in order to understand whether the persistence of either RSM or IS RRBs beyond their typical trajectory has a negative impact on subsequent outcomes.

Objectives: To examine the differential association between early and late RSM and IS behaviours and emotional and behavioural difficulties in children.

Methods: Parents of 485 children were recruited as part of the Gateshead Millennium Study and Tees Valley Baby Study, an opportunity-sampled cohort studied prospectively from 8 months. RRBs were measured using the Repetitive Behaviour Questionnaire-2 (RBQ-2; Leekam et al., 2007) at 24 (Time 1) and 77 (Time 2) months. Emotional and behavioural difficulties were measured at Time 2 using the Strengths and Difficulties Questionnaire (SDQ; Goodman et al., 1997). Hierarchical linear regression analyses were conducted to investigate predictors in internalising and externalising scales of the SDQ (step 1=socio-economic status; step 2=Time 1 RSM and IS mean scores; step 3=Time 2 RSM and IS mean scores).

Results: Elevated rates of Externalising behaviour outcome at 77 months were significantly predicted by RSM RRBs at both Time 1 (t=-2.173, p=.016, β=-.110) and Time 2 (t=6.899, p<.001, β=.325). However, only the final model (step 3) accounted for a significant proportion of the variance (12.5%; $F_{(5,479)}$=14.873, p<.001). Internalising behaviours were significantly predicted by Time 2 IS RRBs only (t=4.894, p=.001, β=.237), with the final model accounting for 8.2% of the variance ($F_{(5,479)}$=9.607, p<.001).

Conclusions: Elevated RRBs beyond early childhood were significantly associated with emotional and behavioural difficulties, with selective association between IS RRBs and internalising behaviours, and between RSM RRBs and externalising behaviours. These findings are an important first step towards better understanding how RSMB and IS affect subsequent development and thus have the potential to inform both the future assessment and treatment efforts.

443.011 *(Poster)* Auditory Hyper-Reactivity, Anxiety and Social Avoidance in Autism

T. Carson*, S. Rodriguez, L. Weatherwax and B. Montgomery, Occupational Therapy, Florida International University, Miami, FL*

Background: Children with autism spectrum disorders (ASD) suffer from a variety of comorbidities, such as auditory hyper-reactivity and anxiety, that have the potential to exacerbate the inherent social skills deficits associated with ASD. Although auditory hyper-reactivity is suggested to be the most common sensory-perceptual abnormality seen in children with ASD (Gomes, Pedroso, and Wagner, 2008), little is known about how auditory hyper-reactivity, specifically, relates to anxiety and social participation. The present study was conducted to further investigate whether relationships exist between auditory sensory hyper-reactivity features of ASD, anxiety, and social skills.

Objectives: Although anxiety and auditory hyper-reactivity are common among children with autism spectrum disorders (ASD), little is known about the functional impact of auditory hyper-reactivity. It is reasonable to suspect that social avoidance occurs concomitantly with auditory hyper-reactivity due to avoidance of noisy crowded environments and that anxiety would also be elevated. This study aims to evaluate the possible relationships between hyper-acusis, anxiety and social avoidance through parent report measures.

Methods: Twenty-seven parents/legal guardians of children with ASD were recruited through the Center for Autism and Related Disabilities (CARD) across the State of Florida. Participants were asked to complete a 15-minute online survey. Criteria for participating in this study required that parents/guardians were over the age of 18 and had children diagnosed with ASD between the ages of 7 and 13 and who also have difficulties tolerating some sounds. The online survey consisted of three caregiver questionnaires including: (1) a pediatric version of the Modified Khalfa Hyperacusis Questionnaire (Khalfa et al., 2002), to assess the child's level of auditory hyper-reactivity (20 items); (2) the Spence Children's Anxiety Scale – Parent Report (Spence, 1999) to assess the severity of anxiety symptoms (38 items); and (3) the Social Worries Questionnaire (Spence, 1995) to assess social avoidance behaviors. Spearman's correlations were conducted to evaluate potential relationships between hyper-acusis, anxiety and social participation.

Results: Results suggest a significant correlation between auditory hyper-reactivity and anxiety ($p = .028$) and a weaker relationship between auditory hyper-reactivity and social avoidance ($p = .059$).

Conclusions: These findings highlight the need for effective sensory interventions to address auditory hyper-reactivity as well as any symptoms of anxiety. Additionally, the impact on social function and avoidance of social situations should be considered and addressed. It remains reasonable to assume that social avoidance may occur concomitantly with auditory hyper-reactivity. Particularly in patients who demonstrate avoidance of noisy, crowded social settings. Future studies with a larger sample size may be able to better identify potential relationships or other connections between social avoidance and auditory hyper-reactivity. Additionally, it may be beneficial to consider additional limiting social skills/behaviors rather than avoidance/worry alone. Patients with ASD and auditory hyper-reactivity may demonstrate improvements with social engagement following treatment for auditory hyper-reactivity symptoms. Further research is warranted regarding the connection between these symptoms and behaviors.

443.012 *(Poster)* Behavioral Inflexibility and Anxiety in Autism Spectrum Disorder

C. Harrop[1]*, A. R. Dallman*[1]*, L. Lecavalier*[2]*, J. W. Bodfish*[3] *and B. A. Boyd*[4]*, (1)Department of Allied Health Sciences, University of North Carolina at Chapel Hill, Chapel Hill, NC, (2)Ohio State University, Columbus, OH, (3)Vanderbilt Kennedy Center, Vanderbilt University, Nashville, TN, (4)Juniper Gardens Children's Project, University of Kansas, Kansas City, KS*

Background: Behavioral inflexibility (BI) has been defined as the inability of the individual to tolerate change to his/her surrounding even when the situation calls for it. Both BI and anxiety are frequently reported as elevated to clinically significant levels in ASD. Anxiety prevalence rates in ASD range between 11 to 84%. Restricted and repetitive behaviors and cognitive inflexibility have been found to predict anxiety in ASD (Lawson et al., 2016; Rodgers et al., 2012), however it is unclear how BI specifically contributes to anxiety compared to other variables known to increase the likelihood of co-occurring, such as ASD diagnosis, IQ and biological sex.

Objectives: To understand how BI is associated with anxiety in a large sample of children and adolescents (3 – 17 years) with a diagnosis of ASD.

Methods: 237 individuals (3-17 years) and their caregivers were recruited from three sites into one of two groups; ASD (N=145) or typical development (TD; N=92). Parents completed the Behavioral Inflexibility Scale (BIS; Boyd et al., 2018); a 38-item parent report measure of behavioral inflexibility of children with ASD rated on a scale from 0 to 5. Parents also completed the Parent-Rated Anxiety Scale for ASD (PRAS-ASD; Scahill et al., 2019); a 25-item parent report measure of anxiety for youth with ASD rated on a scale from 0 to 3. Children completed the abbreviated Stanford-Binet 5. We ran a stepwise linear regression to investigate the relative contributions of diagnosis, sex, chronological age, IQ, and BI on anxiety.

Results: BI and anxiety were highly correlated in ASD ($r=.68$, $p<.001$) and TD ($r=.70$, $p<.001$). Diagnosis was a significant predictor in steps 1, 2 and 3, accounting for 38% of the variance in anxiety scores. This was driven by individuals with ASD having higher anxiety scores ($F=114.84$, $p<.001$). Biological sex and chronological age were not significant predictors in steps 2 or 3. The inclusion of IQ in model 3 increased the variance explained, with both diagnosis ($p<.001$) and IQ significantly predicting anxiety ($p=.001$). Higher IQ scores associated with higher anxiety scores in the ASD group only ($r=.26$, $p=.008$). In step 4, the inclusion of BI scores was highly significant ($R2 =.74$). In a subsequent model which included BI, both chronological age ($p =.01$) and biological sex ($p =.008$) became significant. Older children in our ASD group had marginally higher anxiety scores ($r=.14$, $p=.08$). Females had higher anxiety scores ($F=4.61$, $p=.03$), particularly in the ASD group ($F=5.04$, $p=.02$).

Conclusions: Anxiety appears to be strongly associated with ASD, independent of other characteristics that often mediate changes in ASD phenotype such as age, biological sex, and IQ. BI appears to be strongly associated with anxiety, at least when jointly measured by parent report; however by modeling the combined effects of diagnosis, age, biological sex, IQ and BI we found that the relation between BI and anxiety was strongest in individuals with ASD, with higher cognitive ability, and in females. Future work is warranted to examine the distinct and overlapping underlying neural mechanisms that contribute to BI and anxiety.

443.013 *(Poster)* Blurring Speaker's Eyes Enhances Audiovisual Speech Integration in Children with Autism Spectrum Disorder

W. Ni[1]*, S. Feng*[1]*, L. Chen*[1] *and L. Yi*[2]*, (1)School of Psychological and Cognitive Sciences, Peking University, Beijing, China, (2)School of Psychological and Cognitive Sciences and Beijing Key Laboratory of Behavior and Mental Health, Peking University, Beijing, China*

Background: Children with autism spectrum disorder (ASD) have deficits in audiovisual speech integration (e.g., Feldman, et al., 2018). Audiovisual speech integration is often measured by "McGurk effect" (e.g., Bebko, et al., 2014; Stevenson et al., 2014). McGurk effect is the fused perception when an auditory phoneme is dubbed onto a different visual phoneme (McGurk & McDonald, 1976). Eye region is socially threatening to children with ASD according to "eye avoidance hypothesis" (Tanaka & Sung, 2013). It remains unknown whether the socially threatening information conveyed by eye region would influence the audiovisual speech integration in children with ASD.

Objectives: The current study aimed to examine whether reducing socially threatening information of the speaker's eye region by blurring speaker's eyes could improve the audiovisual speech integration in children with ASD. We also explored whether this effect was mediated by eye-looking time in children with ASD. Similar to previous studies, we measured audiovisual integration using "McGurk effect" (e.g., Bebko, et al., 2014; Stevenson et al., 2014).

Methods: Participants included 30 children with ASD and 30 typically-developing (TD) children. The two groups were matched on both age and IQ. Participants watched videos of a female speaker articulating syllables. Syllables contained audiovisual congruent phonemes (/ba/ and /ga/) and audiovisual incongruent phoneme (/AbVg/; auditory /ba/ was dubbed onto visual /ga/). The audiovisual incongruent /AbVg/ was designed to elicit the McGurk effect, which occurred when it was perceived as /da/ (McGurk & McDonald, 1976). The speaker's eyes were either clear or blurred, which was defined as clear-eyes condition and blurred-eyes condition separately. Participants were asked to report what the speaker said.

Results: Children with ASD showed stronger McGurk effect in blurred-eyes condition than in clear-eyes condition, but TD children showed equal McGurk effect in both conditions (Figure 1). That is, blurring speaker's eye region improved the audiovisual speech integration in children with ASD but not in TD children. Eye movement analysis displayed that both groups showed less eye-looking time in blurred-eyes condition than in clear-eyes condition. Mediation analysis showed that blurring speaker's eye region could enhance the audiovisual speech integration in children with ASD through shortening their eye-looking time (Figure 2). No mediation effect was found in TD children.

Conclusions: The present study found that reducing socially threatening information of speaker's eye region improved the audiovisual speech integration in children with ASD. This improvement was mediated by their eye-looking time. It indicated that the socially threatening information conveyed by eyes was one mechanism of the weaker audiovisual speech integration in children with ASD. It also implicated that future intervention for audiovisual speech integration in children with ASD could be achieved by reducing socially threatening information of speaker's eye region.

443.014 *(Poster)* Characterizing Intense Personal Interests in Young Children with Autism Spectrum Disorder

K. J. Godfrey[1,2,3,4]*, S. Espenhahn*[1,2,3,4]*, C. A. McMorris*[4,5]*, D. Dewey*[1,3,4]*, K. Murias*[3,6]*, A. D. Harris*[3] *and S. Bray*[1,2,3,4]*, (1)Cumming School of Medicine, University of Calgary, Calgary, AB, Canada, (2)Child and Adolescent Imaging Research (CAIR) Program, University of Calgary, Calgary, AB, Canada, (3)Hotchkiss Brain Institute, University of Calgary, Calgary, AB, Canada, (4)Alberta Children's Hospital Research Institute, University of Calgary, Calgary, AB, Canada, (5)Werklund School of Education, University of Calgary, Calgary, AB, Canada, (6)Department of Pediatrics, University of Calgary, Calgary, AB, Canada*

Background: Intense personal interests are present in ~75-95% of individuals with autism spectrum disorder (ASD; Turner-Brown et al., 2011; South et al., 2005). Interests provide joy and therapeutic utility as rewards (Harrop C., et al. 2019) but interest intensity may interfere with other areas of life including educational opportunities or relationship formation. We know little about what leads to intense interests in ASD, and less is known about this symptom in young children. Hypotheses proposed to explain this symptom in ASD include: increased interest engagement due to reduced responsiveness to social or other reward stimuli (Zeeland et al., 2010), difficulty disengaging from interests due to executive functioning deficits in ASD (Granader et al., 2014), or that the hedonic value of personal interests mediates elevated levels of anxiety (Kim et al., 2000). Despite several theories, the mechanisms underlying this symptom are still unclear and different hypotheses have yet to be examined in the context of a single study.

Objectives: Our overarching goal is to characterizing intense interests in young children with ASD and examine relationships between intense interests and other cognitive and behavioral traits. We first aimed to characterize personal interests in 3 – 6-year-old children with ASD by comparing interest intensity and diversity to typically developing controls. We then aimed to investigate associations between interest intensity and reward sensitivity, attention shifting, and anxiety to uncover shared variability.

Methods: Preliminary data reported here was collected from parents of 3 – 6-year-old children with ASD (N=29) and parents of typically developing controls (N=40). Parents completed the Interests Scale (Bodfish, 2003) to quantify their child's interest diversity and intensity. To evaluate reward sensitivity, executive functioning, and anxiety, parents respectfully completed: The Behavioral Approach and Behavioral Inhibition System (BISBAS; Vervoort et al., 2015), Behavior Rating Inventory of Executive Functioning Preschool Version (BRIEF-P; Gioia et al., 2003), and Behavior Assessment System for Children (BASC-3; Reynolds & Kamphaus, 2015).

Results: Two sample t tests showed higher interest intensity in the ASD group ($p < 0.001$) but similar interest diversity between groups ($p = 0.9$). Pearson's correlations on data from the ASD group show interest intensity is associated with deficits in attention shifting (BRIEF-P Shift Subscale, $r = 0.5$, $p = 0.01$), but not reward responsiveness (BISBAS Reward Responsiveness Subscale; $r = -0.1$, $p = 0.5$) or anxiety (BASC-3 Anxiety Subscale; $r = 0.09$ $p = 0.6$). Recruitment will continue into 2020. A larger sample will be used to examine associations and interactions in a multivariate model and explore the potential that subgroups exist in our population. This data will be included in the final conference presentation.

Conclusions: This study supports the early presence of intense interests in ASD and describes relationships with other traits. The relationship between executive functioning and interests in this sample indicates that interventions targeted at improving attention shifting may also be beneficial for managing the interference of intense interests in other aspects of life.

443.015 *(Poster)* Characterizing Peripheral and Central Olfactory Processing in Children with Autism Spectrum Disorder, Sensory Processing Dysfunction, and Typical Development

J. R. Sweigert*, T. St. John and N. M. Kleinhans, University of Washington, Seattle, WA*

Background:

Sensory dysfunction is a commonly reported symptom of autism spectrum disorder (ASD), affecting multiple sensory modalities. Much attention has been devoted to visual and auditory modalities but research into olfactory processing remains inconclusive.

Objectives:

To assess olfactory processing, specifically odor detection, identification, and perceived pleasantness, in children with ASD, sensory processing dysfunction (SPD), and typically developing children (TYP), determine whether olfactory performance varies by target odorant or perceived pleasantness, and consider whether olfactory performance is associated with autism-related behaviors.

Methods:

43 children with high-functioning ASD (Age=10.21±1.63), 44 children with SPD (Age=9.98±1.62), and 46 TYP children (Age=10.32±1.44) participated in this study. Group inclusion was determined by the Autism Diagnostic Observation Schedule (ADOS2), Autism Diagnostic Interview (ADI-R), and Child Sensory Profile-2 (CSP-2).

Three measures of olfactory processing were assessed. Odor detection threshold was measured for two separate odorants (phenylethyl alcohol/PEA, vanillin) using Sniffin' Sticks Threshold Test. Perceived pleasantness of these odorants was assessed with a 7-point Likert scale (0=Very Unpleasant, 6=Very Pleasant). Smell identification was measured using the University of Pennsylvania Smell Identification Test (UPSIT). Autism severity was assessed using ADOS-2 calibrated scores. All statistical analyses were completed with SPSS Version 18.0.

Results:

Children with ASD showed no significant difference in Sniffin' Sticks scores for either odorant, compared to SPD and TYP children. The ASD group showed reduced UPSIT scores (M_{ASD}= 25.73, SD_{ASD}= 6.35) relative to the TYP group (M_{TYP}= 30.76, SD_{TYP}=3.36, t(84)=4.68, p<.001).

In contrast, both PEA and vanillin Sniffin' Sticks scores were reduced among children with SPD, relative to TYP children (for PEA, M_{SPD}=7.23, SD_{SPD}=4.39, M_{TYP}=9.03, SD_{TYP}=3.78, t(86)=2.10, p_{PEA}=.039; for vanillin, M_{SPD}=6.04, SD_{SPD}=2.72, M_{TYP}=7.28, SD_{TYP}=2.78,t(88)=2.15, p_{vanil}=.035). The SPD group also showed reduced UPSIT scores (M_{SPD}=27.17, SD_{SPD}=5.91) relative to the TYP group (M_{TYP}=30.76, SD_{TYP}=3.36, t(85)=3.53, p=.001). UPSIT scores did not differ between the ASD and SPD groups.

No significant difference in pleasantness rating was observed between the groups (for PEA, M_{ASD}=4.31, SD_{ASD}=1.52, M_{SPD}=3.58, SD_{SPD}=1.96, M_{TYP}=4.39, SD_{TYP}=1.30; for vanillin, M_{ASD}=5.08, SD_{ASD}=1.55, M_{SPD}=4.81, SD_{SPD}=1.58, M_{TYP}=5.00, SD_{TYP}=1.16).

Pleasantness rating for PEA was corelated with UPSIT scores in the ASD group (r(23)= -.422, p=.036) and the TYP group (r(31)= -.361, p=.039), but no such correlation was observed in the SPD group. Pleasantness ratings for vanillin were correlated with UPSIT scores only in the ASD group (r(22)= -.425, p=.038).

Within the ASD group, UPSIT scores demonstrated a negative correlation with the ADOS Total Score (r(38)= -.431, p=.005) and Social Affect Score (r(38)= -.424, p=.006). This relationship was not observed in the SPD group. No correlation was observed between UPSIT scores and ADOS Restricted Repetitive Behaviors.

Conclusions:

Children with ASD show impaired odor identification, reflecting possible central processing deficits in secondary olfactory cortices, while children with SPD show deficits in peripheral odor detection and identification, reflecting dysfunction along the entire olfactory pathway.

Our results indicate that odor-averse children have better odor identification skills, suggesting involvement of multiple secondary olfactory regions. Additionally, the relationship between odor identification and autism-related social behaviors points to a shared neural substrate underlying central processing of both secondary olfactory and social information.

443.016 *(Poster)* Deficits in Feedback and Feedforward Processes Are Distinct in Individuals with Autism Spectrum Disorder

K. E. Unruh[1], *S. Gunter*[1], *L. M. Schmitt*[2], *D. E. Vaillancourt*[3], *J. A. Sweeney*[4] *and M. W. Mosconi*[5], *(1)Kansas Center for Autism Research and Training (K-CART), University of Kansas, Lawrence, KS, (2)Cincinnati Children's Hospital Medical Center, Cincinnati, OH, (3)Applied Physiology and Kinesiology, University of Florida, Gainesville, FL, (4)Psychiatry and Behavioral Neuroscience, University of Cincinnati College of Medicine, Cincinnati, OH, (5)Clinical Child Psychology Program, Schiefelbusch Institute for Life Span Studies, University of Kansas, Lawrence, KS*

Background: Motor abnormalities are among the most common comorbid features of ASD, are related to core social and cognitive impairments, and predictive of worse functional outcomes. Reported deficits implicate dysfunction of both rapid feedforward processes executed prior to availability of sensory feedback, and continuous movements requiring dynamic adjustment of motor commands based on sensory feedback.

Objectives: The current study characterized rapid (saccade) and continuous (precision grip) motor behaviors in individuals with ASD and healthy controls to determine individual differences in feedforward and feedback processes and whether these behaviors differ as a function of age.

Methods: Individuals with ASD (N=72, age = 4-38) and healthy controls (N = 78, age = 4-38) completed two precision grip tests and one visually-guided saccade test (VGS). During the grip tests, participants viewed two parallel, horizontal bars (FORCE and TARGET) and pressed to raise the FORCE bar to the level of the TARGET bar across multiple force levels (Force test) and visual gain levels (Gain test). Force variability (force SD) and regularity (ApEn) were examined. During the VGS test, targets were presented at 12 degrees to the left or right of center. The mean and trial-to-trial variability of saccade accuracy and latency were examined.

Results: During grip tests, individuals with ASD showed increased force SD across all force levels and at the highest gain level. They also showed reduced ApEn compared to controls across all force and gain levels. During the VGS test, mean saccade amplitude and latency did not differ between groups, but trial-to-trial variability of both saccade amplitude and latency were greater in ASD than in controls. Force SD was associated with age in controls showing a quadratic relationship characterized by age-associated decreases until age 25 in healthy controls and then age-associated increases into middle adulthood. Force SD did not show any age-related differences in ASD. Similarly, increased ApEn was associated with increased age in healthy controls, but not in ASD. Increased age was associated with reduced variability of saccade latencies in both groups, but not saccade amplitude. Neither force SD nor force ApEn were associated with variability of saccade amplitude or latency in either group.

Conclusions: We report deficits in feedback and feedforward processes that are independently affected within individuals with ASD and therefore likely represent distinct neurophysiological processes. Increased force variability and regularity in ASD likely reflects dysfunction of parietal-cerebellar circuits involved in dynamic adjustment of motor commands based on sensory feedback error. Increased variability of saccade accuracy across trials implicates dysfunction of premotor-cerebellar networks that guide movement via internal action representations, while latency variability suggests deficits in cortical-striatal-cerebellar systems involved in regulating timed motor responses. Together, these results document dysfunction of multiple sensorimotor processes that are differentially affected in individuals with ASD and implicate distinct neurophysiological mechanisms.

443.017 *(Poster)* Developmental Trajectories in Coordinated Joint Action and Their Link to Motor Functioning in ASD: Preliminary Results

N. Bauminger-Zviely[1]*, Y. Estrugo*[2]*, E. Karin*[3] *and S. Bar Yehuda*[3]*, (1)Bar-Ilan University, Ramat Gan, Israel, (2)School of Education, Bar - Ilan University, Ramat-Gan, Israel, (3)School of Education, Bar - Ilan University, Ramat - Gan, Israel*

Background: Coordinated Joint Action (CJA) takes place when two confederates accomplish a shared goal by coordinating their social-motoric movement in time and space. The ability to mirror, complement and predict other's actions during CJA, requires the successful operation of social-motor capabilities. Though the manifestation of motor deficits in cognitively able (IQ>70) children and adolescents with autism spectrum disorder (ASD) is relatively explored, the development of CJA and the contribution of cognitive and motor functioning to CJA in ASD is yet underexplored.

Objectives: Our study examined developmental trajectories in CJA and their link with ASD severity, cognitive and motor functioning in cognitively able children and adolescents with ASD. Findings regarding the role motor functioning play in the development and performance of CJA in ASD may open a new path for social-motor intervention in the future.

Methods: Study included fifty-six cognitive-able participants with ASD (IQ=95.04, CA=11.8) in two developmental age groups - school-aged children (6-12-years) and adolescents (12-16-years) (*n*=28, each). Background measures included the Autism Diagnostic Observation Schedule (ADOS) and the Wechsler Intelligence Scale for Children - Fifth Edition (WISC-IV). Peer dyads were paired based on IQ and Chronological Age (CA).

Study measures included an observation (the Individual Motor Observation Scale - IMOS) and a parent-report (the Developmental Coordination Disorder Questionnaire - DCDQ) to evaluate motor functioning. In addition, we executed two dyadic CJA tasks - a side-by-side mirroring-walking and a prediction-football task in which participants were instructed to kick and catch a virtual football. The motor measures provided total motor functioning score that was mainly based on gross and fine motor behaviors. CJA performance was measured with total dyadic joint steps and proximity duration in the walking-mirroring task and a total dyadic coordinated movements direction and average reaction time in the football-prediction task.

Results: Results yielded significant group difference between school-aged children and adolescents with ASD in dyadic joint steps and proximity duration during the walking CJA task; and in coordinated movements direction during the football CJA task. In all measures older outperformed younger. Group difference in reaction time during the football-CJA-task was not significant (see Figure1).

A positive correlation was found between three of the CJA categories, CA, and IQ. Motor functioning was correlated positively only with the walking CJA task. This highlight, the developmental improvement in CJA among ASD, and the important contribution of cognitive and motor functioning to social tasks that involve motor coordination (CJA). As expected, negative correlation was found between proximity duration in CJA-walking task and ASD severity, meaning that children with less severe disorder were better in coordinating their movement. Unexpectedly, significant negative correlation was found between ASD severity and football-reaction time, indicating faster reaction in more severely affected children (see table 1).

Conclusions: Findings indicate the maturation of CJA abilities in ASD during the transition from childhood to adolescence and the important contribution of cognitive and motor functioning to CJA performance in ASD. Findings regarding the link between the participants' ASD severity and their reaction time requires further comparison with same-age typically developing sample.

443.018 *(Poster)* Developmental Trajectory of Sensorimotor Integration for Postural Stability in Autism Spectrum Disorder

N. E. Fears[1]*, G. M. Sherrod*[2]*, T. Templin*[1]*, N. L. Bugnariu*[1]*, R. M. Patterson*[1] *and H. L. Miller*[1]*, (1)University of North Texas Health Science Center, Fort Worth, TX, (2)University of Alabama at Birmingham, Birmingham, AL*

Background: Although Autism Spectrum Disorder (ASD) is primarily associated with social communication differences and restricted interests/repetitive behaviors, individuals with ASD also exhibit significant sensorimotor differences. Postural stability is a foundational motor skill that requires integration of input from multiple sensory systems (visual, somatosensory, vestibular) into motor plans. Individuals with ASD show more postural instability during quiet standing compared to typically developing (TD) individuals. When lacking a sensory modality (i.e., eyes closed) or receiving distorted sensory input (e.g., vision without environmental spatial cues), individuals with ASD experience increased postural instability. Despite substantial differences in sensorimotor integration for postural stability in ASD, there has been relatively little work on how these differences change across development from childhood into adulthood.

Objectives: We examined the development of sensorimotor integration and postural stability from middle childhood to early adulthood using the Clinical Test of Sensory Integration in Balance. We examined differences in postural stability between children and adults with ASD and TD and how they change across development. We also examined how postural stability was influenced by changes in visual input. Finally, we used cluster analyses to determine potential developmental stages in postural stability.

Methods: We tested the postural stability of children and young adults with ASD (n=27, M_{age}=12.44, SD_{age}=3.18) or TD (n=41, M_{age}=10.89, SD_{age}=3.50). Participants assumed a comfortable stance on the hard surface of a Biodex BioSway force plate and remained still for 30-second intervals in each of the following conditions: eyes open, eyes closed, and eyes open in a translucent paper sphere (dome) placed on the participant's head. The eyes open condition provides a measure of quiet standing postural stability with all relevant sensory inputs. Eyes closed measures postural stability when participants do not have visual input for maintaining balance and must rely more heavily on proprioceptive (a modality of the somatosensory system) and vestibular input. In the dome condition, participants have visual input, but the input does not include visuospatial cues from the environment that would typically be used to aid in maintaining balance.

Results: A linear mixed-effects model for postural stability (Figure 1) indicated significant main effects of group (F(1,67.90)=10.60, p=.002), age (F(1,68.10)=28.59, p<.001), and condition (F(2,134.60)=44.83, p<.001). Participants with ASD (M=1.33) showed increased postural instability compared to TD participants (M=1.11). Participants showed more instability in the eyes closed (M=1.32) and dome (M=1.35) conditions than the eyes open condition (M=0.91). Postural instability decreased as age increased (b=-0.03). K-means clustering indicated 3 distinct developmental stages of postural stability across group and condition: 7-10 (M=8.83),11-15 (M=12.44), and 16-20 (M=18.00) years with between cluster sum of squares explaining 82.1% of the total variance (Figure 2).

Conclusions: These results indicate that individuals with ASD follow a similar trajectory for the development of postural stability as TD individuals, but exhibit more instability overall. These results also demonstrate that for individuals with ASD, differences in postural stability persist across childhood and into adulthood. These clinically-significant findings can be used for the development of targeted interventions for the unique pattern of sensorimotor problems observed in individuals with ASD.

443.019 *(Poster)* Establishing Measurement Invariance and Modeling Change in Restricted and Repetitive Motor Behaviors from 8-36 Months

R. D. Sifre[1]*, D. Berry*[2]*, J. Wolff*[3] *and J. T. Elison*[3]*, (1)Education and Human Development, University of Minnesota, Twin Cities, Minneapolis, MN, (2)Institute of Child Development, University of Minnesota, Twin Cities, Minneapolis, MN, (3)University of Minnesota, Minneapolis, MN*

Background: Restrictive and Repetitive Behaviors (RRBs) are a key component of autism spectrum disorder (ASD) symptomology and are detectable in high risk ASD toddlers from an early age. However, RRBs are not unique to ASD. In addition to their association with anxiety and other neurodevelopmental disorders, RRBs have also been observed in typically developing infants (Thelen 1979, 1981) and preschool children (Hoch et al, 2015). Studying the early development of RRBs in both typical and atypical populations may therefore be critical for distinguishing between behaviors that may be typical in early childhood, and those that are predictive of emerging psychopathology.

The ability to examine longitudinal change in RRBs is incumbent upon the assumption that our measure of RRBs captures the same latent construct over time. This refers to longitudinal Measurement Invariance (MI). When non-invariance occurs, items mean something different for different groups and/or ages. For example, parents of very young children may endorse "mouthing objects" more frequently when that behavior is developmentally normative; without accounting for the non-invariance of this item, RRBs would be overestimated in this age group. Thus, accounting for non-invariance is critical when comparing assessment scores across different ages, and diagnostic groups.

Objectives: 1) Test measurement invariance – and adjust for potential non-invariance – in the RBS-EC in a longitudinal sample of low-risk toddlers. 2) Examine longitudinal change in RRBs across toddlerhood.

Methods: RRBs were measured using the RBS-EC, a 34-item parent-report questionnaire that is a downward-extension of the Repetitive Behavior Scale–Revised. The RBS-EC is psychometrically validated on a sample of 17-27-month-old toddlers (Wolff, Boyd, & Elison, 2016), and is intended to capture normative variation in young children. The final sample included responses from parents of 606 low-risk 8- to 36-month-old toddlers. Moderated Nonlinear Factor Analysis (MNLFA, Bauer et al., 2019) was used to generate factor score estimates for RBS-EC subscales while adjusting for non-invariance. Multi-level linear mixed-effects models were used to estimate change in latent subscale scores across development.

Results: Seven items demonstrated differential item functioning (DIF) as a function of age (**Table 1).** Factor score estimates adjusted for DIF were highly correlated with the raw mean estimates from each subscale. However, factor score estimates provided more individual variability for growth curve modelling than raw scores. Longitudinal change varied across subscales (**Figure 1**). While both Repetitive motor and Self-directed behaviors decreased across time, Repetitive motor scores decreased more rapidly ($B_{\text{Repetitive motor}}$ = -0.11, $B_{\text{Self-directed}}$ = -0.06, p's <.001). There was a significant linear and quadratic effect of age on higher-order behaviors, such that behaviors began to decline around 21 months.

Conclusions: MNLFA results suggested that the assumption of MI does not hold for all subscales of the RBS-EC, and that factor score estimates must be adjusted for when comparing RRB scores across different ages. Growth curve analysis of adjusted factor score estimates suggested different trajectories for each subscales of the RBS-EC, suggesting that these reflect separable constructs. Future work examining differences in RRBs across age and/or diagnostic groups should establish MI before comparing trajectories.

443.020 *(Poster)* Evaluating Methods for Assessing Circumscribed Interests in Children with Autism Spectrum Disorder

Y. Bean[1]*, M. Kumareswaran*[2] *and A. J. Harrison*[3]*, (1)School Psychology, University of Georgia, Athens, GA, (2)Marcus Autism Center, Children's Healthcare of Atlanta, and Emory University School of Medicine, Atlanta, GA, (3)Educational Psychology, University of Georgia, Athens, GA*

Background: Circumscribed Interests (CI), a narrow and intense interest in specific and unique subjects, are a core feature of autism spectrum disorder (ASD; American Psychiatric Association, 2013). The characterization of CIs is important for making diagnostic decisions and intervention development for children with ASD (Boyd et al., 2011). The heterogenous nature of CIs and reliance on parent report of intensity (Li, Fan, Jin, 2018) both introduce challenges in reliably assessing these behaviors (Turner-Brown, Lam, Holtzclaw, Dichter, Bodfish, 2011).

Objectives: This study aims to evaluate existing methods for characterizing CIs. First, to help increase the consistency of how CIs are represented in research, we sought to identify the most efficient yet comprehensive approach for classifying CI into categories. Second, we evaluated the validity of parent ratings of CI intensity, through a comparison to direct attentional allocation.

Methods: Parents of children with ASD and of typically developing (TD) children were asked to submit six examples of their child's highly preferred objects. 221 total CI pictures were coded by two independent coders for alignment with three different published CI categorization schemes (See figure 1; Baron-Cohen & Wheelwright, 1999; Sasson, Turner-Brown, Holtzclaw, Lam, & Bodfish, 2008; South, Ozonoff, & McMahon, 2005). To determine if any of these approaches represented a comprehensive categorization scheme, images that did not align with any of the categories were coded into an "other" category. Next, we examined the convergent validity between parent report of CI object preference and children's gaze allocation to these objects, measured with eye tracking. Parents completed three visual analog scales that evaluated their perception of the intensity/functional impact of the CI. Children in both diagnostic groups were then allotted five seconds to view a series of randomly presented, personalized CI objects presented with a familiar/unfamiliar facial stimulus. Parent ratings and the average amount of time viewing each CI were compared.

Results: Coding results, with an average percent agreement of 93.5%, provided validity for the more comprehensive CI coding scheme published by Baron-Cohen & Wheelwright (1999). Only 13.5% of coded objects did not align with one of the existing categories for this coding scheme; however, both the Sasson (2008) and South (2005) categories, resulted in much higher rates of objects falling into the "other" category (86% and 71.2%; see Figure 1). For aim two, no significant correlations were found between parent ratings and the total time viewing CIs for either diagnostic groups (see Table 1).

Conclusions: This identified the category scheme developed by Sasson & Wheelwright (1999) as the more comprehensive; therefore, it may be the most useful for research using exemplars that are maximally representative of a broad collection of objects. The lack of alignment between attention allocation and parent report of preference indicates that additional research is required to determine the best way to assess the magnitude of CI preference. Additional analyses will examine if an alternative metric of proportion of time viewing the CI to total time might be more conclusive.

443.021 *(Poster)* Examining Specific Aversions and Aggressive Behaviors in Children with Autism Spectrum Disorder

D. L. Limon[1]*, A. C. Ramirez*[1]*, K. Ahmed*[1]*, J. Dempsey*[1]*, Z. Liu*[1]*, T. N. Takahashi*[2]*, S. M. Kanne*[3] *and R. P. Goin-Kochel*[1]*, (1)Baylor College of Medicine, Houston, TX, (2)Thompson Center for Autism & Neurodevelopmental Disorders, University of Missouri, Columbia, MO, (3)Thompson Center for Autism & Neurodevelopmental Disorders, Columbia, MO*

Background: Sensory aversions in children with autism spectrum disorder (ASD) are prevalent, impairing, and often difficult to address with traditional therapies because of executive-functioning challenges. Similarly, aggressive behaviors are often observed in youth with ASD. Prior studies have shown that sensory profiles—key components of ASD symptom severity—have been associated with poor social-emotional functioning and behavioral problems; however, less is known about potential associations between sensory aversions and self-regulation difficulties, such as aggressive behavior.

Objectives: To examine the prevalence, severity, quality of sensory aversions, as well as the relationship between sensory aversions and aggressive behavior, in a subset of youth from the Simons Simplex Collection (SSC) cohort. The SSC is a national repository of 2,600 families with one child affected by ASD and their unaffected parents and siblings.

Methods: Participants included 407 families from the Simons Simplex Collection at Baylor College of Medicine (n=203, male = 86.2%; mean proband age = 8.7 years [SD = 3.3], range = 4.2-17.8) and the University of Missouri (n= 208; male = 86.7%; mean proband age =9.6 years [SD=3.7], range = 4.0-17.9). Information about recruitment, measures, and procedures related to the SSC can be found in Fischbachand Lord (2010). Sensory sensitivity/aversions were measured using the Autism Diagnosis Interview-Revised (ADI-R) sensory items #72 and #73. The Child Behavior Checklist (CBCL) for ages 6-18 aggression subscale score was used as an index of aggressive behaviors. Descriptive statistics were used to characterize the prevalence and severity of sensory aversions (items #72 and #73). Qualitative analysis was used to categorize different types of aversions. Point-biserial correlations and Spearman correlations were used to assess potential relationships between group status for each aversion (present or absent) and (a) child characteristics (age, ratio IQ scores, CBCL- aggression scores) and (b) severity codings for items #72 and #73, respectively.

Results: At least one type of sensory aversion was reported for 398 participants (97.9%), with an average of between 3 and 4 different categories of aversions noted per participant. The most commonly reported aversions across the full sample were *appliances* (43.2%), *loud sounds* (42.8%), *background sounds* (41.8%), and *foods* (40.1%). Severity codings for ADI-R item #72 (undue general sensitivity to noise) indicated that the largest proportions of children showed definite aversion to noises (44% current, 49% ever). Similar results were observed for item #73 (abnormal, idiosyncratic, negative response to specific sensory stimuli) with 34% exhibiting mild/controllable aversions currently, and 39% having tantrums/exposure avoidance at some point. Results from analyses of associations between sensory aversions and the CBCL aggression subscale are forthcoming.

Conclusions: Sensory aversions affected the vast majority of participants, and severity codings indicated that sizeable portions of children were moderately to significantly impaired by their aversions (codes of 2 or 3 items #72 and #73). An understanding of sensory profiles and how they relate to aggressive presentations may help tailor future behavioral interventions that target maladaptive behavior in individuals with ASD.

443.022 *(Poster)* Exploring Retrospective Sensory School Experiences in Late-Diagnosed Autistic Women.

E. Jones[1]*, M. Hanley*[2] *and D. M. Riby*[3]*, (1)Durham University, Durham, United Kingdom, (2)South Road, Durham University, Durham, United Kingdom of Great Britain and Northern Ireland, (3)Department of Psychology, Durham University, Durham, United Kingdom*

Background: Many autistic individuals experience sensory atypicalities that impact daily functioning. In particular, self-report has indicated that sensory differences can have a profound impact at school by inducing anxiety, reducing concentration and causing physical discomfort (Humphrey & Lewis, 2008; Howe & Stagg, 2016). The focus thus far however has been on males. This represents a gap in the literature because the presentation of ASD may differ across sex and gender. For instance, higher levels of social motivation, internalizing behaviours and lifetime sensory scores have been observed in autistic females (Sedgewick et al., 2017; Mandy et al., 2012). School experiences of autistic females may therefore be qualitatively different to that of autistic males. Furthermore, many autistic females remain undiagnosed at school (Mandy et al., 2012). It is these later-diagnosed women who may be most representative of the autism female phenotype- often flying under radar by not conforming to the male model of ASD (Bargiela et al., 2016)

Objectives: The current study therefore explored the school experiences of late-diagnosed autistic females, focusing specifically on the impact of sensory processing differences.

Methods: Sixty females (Mean Age=33.49, SD=9.85) who had received a diagnosis of Autism Spectrum Disorder after finishing school (Mean Age of Diagnosis =27.69, SD=13.85) completed an online questionnaire. Sixty percent of participants had been taught in the UK and a further 26% had been taught in North America. Participants were highly educated with 66% achieving at least a bachelor's degree. An online questionnaire was designed that focused on the type of sensory experiences encountered at school, the potential impacts of these experiences, and strategies used to manage sensory differences. Data were analysed using data-driven thematic analysis.

Results: We found that sensory differences interacted and exacerbated many of the social challenges faced by autistic females at school. Friendships and 'fitting in' were key difficulties for several participants, with 46% reporting bullying at school. Sensory differences could limit the opportunities for socializing, as the stimulating nature of the school hall and playground, often made these spaces inaccessible for participants. Instead, environments such as the library (N=17) were sought as this allowed for a reduction in sensory stimulation. The majority of sensory experiences were negative however and could result in "meltdowns" (N=12) and physical discomfort (N=10). Such responses were reported to result in further teasing by peers (N=8). Finally, sensory differences were associated with heightened anxiety at school (N=26), yet several participants reported masking these experiences until they arrived home (N=5).

Conclusions: Sensory processing differences can have a profound impact on school life. These differences were found to interact with, and exacerbate, several of the difficulties already faced by autistic females at school. Findings suggest that adapting the environment to meet the sensory needs of pupils, or helping individuals manage their sensory differences, may too improve social experiences and mental health at school. Critically, understanding the presentation and impact of sensory differences may also aid in the identification of undiagnosed autistic females at school and further challenge the male conceptualization of ASD

443.023 *(Poster)* Exploring Sensory Reactivity, Mental Health and Behaviour in Autistic Preschoolers

T. Rossow[1] *and T. Tavassoli*[2]*, (1)University or Reading, Reading, United Kingdom, (2)Centre for Autism, School of Psychology & Clinical Language Sciences, University of Reading, Reading, United Kingdom*

Background: Research shows that sensory reactivity symptoms are often present in individuals with a diagnosis of autism spectrum disorder (ASD), irrespective of level of functioning. The literature also asserts that autistic individuals are at a significantly higher risk of developing mental health conditions than their neurotypical peers. Whilst some research has investigated individual sensory reactivity constructs within specific diagnoses, particularly with hyper-reactivity/sensory sensitivity and anxiety, little research has been conducted more broadly into the relationship between other sensory reactivity constructs (poor registration/hypo-reactivity and sensation seeking) and the development of other mental health disorders. The current study explores the correlational relationship between sensory reactivity, behaviour and mental health constructs across sample of autistic preschoolers.

Objectives: To examine whether there are relationships between emerging sensory reactivity, behaviour and mental health in autistic preschoolers.

Methods: In total 55 children diagnosed with ASD (ages 3 to 5) took part, clinical diagnosis was confirmed using an ADOS assessment. Sensory measures included the Sensory Profile Second Edition - Parent (SP2), the Sensory Processing Scale Inventory (SPSI) and Sensory Assessment of Neurodevelopmental Disorders (SAND). Mental health was measured using the Behavioural Assessment System for Children Third Edition (BASC3). The SP2, SPSI and SAND provided symptom scores for auditory, visual and tactile, and total scores for sensory seeking, hypo-reactivity and hyper-reactivity. The BASC3 provided symptom scores for hyperactivity, aggression, anxiety, depression, somatization, anger control, bullying, emotional self-control, executive functioning and negative emotionality, and index scores for executive functioning, attention control, behaviour control, emotion control, externalising problems and internalising problems. Bivariate correlational analyses were used to assess the relationship between sensory reactivity, behaviour and mental health.

Results: Significant correlations were found between sensory sensitivity constructs and mental health symptoms, with consensus significance found across all three sensory measures for hyper-reactivity and internalizing problems ($p < .05$), hypo-reactivity and executive functioning ($p < .05$) and sensation seeking and externalizing problems ($p < .05$). Significance was also found between the BASC3 and individual sensory measures across sensory constructs and sensory domains.

Conclusions: Our results provide further support to emerging research suggesting there is a relationship between sensory reactivity and mental health, both at a total construct level and at an individual domain level. Future directions include understanding the causal relationship between sensory reactivity and mental health

443.024 *(Poster)* Identifying Auditory Subtypes of Children with Autism Spectrum Disorder Based on Pitch Processing: A Machine Learning Approach

K. Lai[1]*, B. Wang*[2]*, L. Yu*[1]*, D. Huang*[1,3]*, Y. Zhang*[4] *and S. Wang*[1]*, (1)School of Psychology, South China Normal University, Guangzhou, China, (2)Department of Statistics and Actuarial Science, University of Iowa, Iowa city, IA, (3)Guangzhou Rehabilitation & Research Center for Children with Autism, Guangzhou Cana School, Guangzhou, China, (4)Department of Speech-Language-Hearing Sciences, University of Minnesota, Minneapolis, MN*

Background: Abnormal auditory processing is commonly reported in autism spectrum disorder (ASD) (Tomcheck et al., 2007). Children with ASD have been found to show enhanced neural sensitivity to pitch changes in pure tones compared to typically developing children at the group level (e.g., Ferri et al., 2003; Yu et al., 2015). These evidences have prompted the notion of auditory hyper-sensitivity. However, it is still unclear that whether such enhanced pitch sensitivity reflects behavioral manifestations of auditory sensitivity. Given the considerable heterogeneity of sensory-perception in ASD (Uljarević et al., 2017), it is also necessary to examine the individual variability existing in the observed neurobehavioral abnormality and how it is implicated in sensory symptoms.

Objectives: This study aimed to examine whether abnormal pure tone pitch-related mismatch negativity (MMN) can identify autistic children with hyper- or hypo-sensitivity in the auditory modality with a machine learning approach.

Methods: Sensory Profile (SP; Dunn, 1994) scores and neural sensitivity measure in terms of MMN to pure tone pitch changes were collected from 38 autistic children (mean age = 10 yrs, *SD* = 1 yrs). First, using K-means clustering, behavioral classification of children was obtained along the hyper-sensitivity dimension based on the low-threshold subscale of the SP, as well as along the hypo-sensitivity dimension using the high-threshold subscale. Second, logistic regression with adaptive lasso penalty was applied with the MMN amplitude at nine classic electrode sites as predictors to determine whether neural measures align with the behavioral classification along the hyper- or hypo-sensitivity dimension.

Results: The F3 and C4 electrodes significantly predicted behavioral classification of children along the hypo-sensitivity dimension. Specifically, MMN amplitude reduction at F3 and increment at C4 were associated with the presence of auditory hypo-sensitivity, with a classification accuracy of 71%, sensitivity of 70% and specificity of 72%. No electrode contributed to the classification of children along the hyper-sensitivity dimension.

Conclusions: The neural measures of pitch processing predicted the behavioral manifestation of auditory atypicality to some extent. However, the results also indicated that the alignment between the Sensory Profile and neural measures of sensory abnormality was questionable. Further research is needed with larger sample sizes to examine the validity of the parent-reported assessment for sensory hyper- and hypo-sensitivity. Multi-dimensional evaluations would provide important insights for the subtyping of sensory abnormality in ASD.

Keywords: ASD, Sensory Profile, pitch processing, machine learning

443.025 *(Poster)* Identifying Strengths in Preschool Autistic Children: Using the New Autism Toddler Strengths and Interests Questionnaire-Atsiq

V. Larose[1], *K. Sotelo*[1], *V. Courchesne*[2], *L. Mottron, M.D.*[2] *and C. Jacques*[1,3], *(1)University of Quebec in Outaouais, Gatineau, QC, Canada, (2)Autism Research Group, CIUSSS du Nord-de-l 'Île-de-Montréal, Montréal, QC, Canada, (3)Autism Research Group, CIUSSS du Nord-de-l 'Île-de-Montréal, Montreal, QC, Canada*

Background: The enhanced perceptual functioning model proposes a unique profile of perceptual strengths and an association between interests and strengths (Mottron et al. 2006; Samson et al. 2012). This relation is well established in the adolescent and adult autistic population (Jones et al. 2018; Mercier et al. 2000). Recent data suggest that early interests in autistic children could be correlated with perceptive cognitive peaks later in the life trajectory (Mottron, 2017; Ostrolenk et al. 2017). However, perceptual strengths in preschool autistic children are sparsely documented and how they are associated to their interests at that particular stage of development is unknown.

Objectives: 1-To document preschool autistic children's strengths by comparing them to those of typical children using the *Autism Toddler Strengths and Interests Questionnaire* (ATSIQ). 2-To document, according to parents, how interests are associated to strengths in preschool autistic children using the ATSIQ.

Methods: The ATSIQ, a parent-reported questionnaire documenting interests and strengths of preschool autistic children, was completed during a phone interview with 27 parents of autistic children (Mean age = 59.89 months *SD*= 8.21) and 28 parents of age-matched typically developing children (Mean age = 54.86 months *SD*= 16.26; *p*=.156). Two quantitative sections composed of 27 and 12 items are respectively designed to document the nature and frequency of 1-interests and 2-strengths. Most frequent interests (electronics, logos, numbers, letters and plumbing) were reported in a previous publication (Larose et al. 2018). Non-parametric tests (U Mann-Whitney) were performed to compare the frequency of each reported strength between autistic and typical children. The qualitative section of the ATSIQ is composed of 5 open questions allowing the parent to comment on the evolution of his child's most prominent interest. A content analysis was used to evaluate the trajectory of the above-mentioned more frequent interests.

Results: Parents identified three strengths that were significantly more frequent in autistic children in comparison to typical children: Forms, Construction and Manipulation of screens (all *p*'s<.01). No strengths were identified as more frequent in typical children. Four major themes were extracted from the thematic analysis, all of which indicated a positive impact of the use of letters, numbers and electronics (3 of the 5 previously identified frequent interests): 1-skills enhancement, 2-use of varied materials, 3-development of autonomy and 4-development of parallel skills.

Conclusions: The present study is among the first attempt to document specific strengths in preschool autistic children. It also provided information on the evolution of strengths early on in autism development. The use of the ATSIQ, specifically designed to document interests and strengths in preschool autistic children, could improve our understanding of autistic characteristics and how they contribute to learning, skill acquisition and development of expertise in autism.

443.026 *(Poster)* Impaired Spontaneous Mimicry and Elicited Motor Imitation in Autism: Interactions and Associations with Clinical Presentation

R. Santra[1], *B. Tuncgenc*[2], *C. Pacheco*[3], *R. Vidal*[3], *D. Crocetti*[4], *S. H. Mostofsky*[5] *and R. N. Rochowiak*[4], *(1)Center for Neurodevelopmental and Imaging Research; Kennedy Krieger Institute, Baltimore, MD, (2)Psychology, University of Nottingham, Nottingham, MD, United Kingdom, (3)Johns Hopkins University, Baltimore, MD, (4)Center for Neurodevelopmental and Imaging Research, Kennedy Krieger Institute, Baltimore, MD, (5)Center for Autism and Related Disorder, Kennedy Krieger Institute, Baltimore, MD*

Background: Impaired motor imitation is commonly reported in individuals with autism spectrum disorder (ASD). Given the importance of imitation for facilitating social interactions and learning, imitation impairments in ASD may be associated with decreased social-communicativefunctioning. Motor imitation may occur spontaneously insocialcontexts (e.g., yawning after seeing others yawn) or instructuredcontextsthatprompt, orelicit, imitation (e.g., copying an expert during a training). There is evidence that both spontaneous (Helt et al., 2010) and elicited (Mostofsky et al., 2006) imitation are impaired in ASD. However, no research to date has examined how these two forms of imitation are related to each other and may uniquely inform autism-associated social-communicative deficits within the same cohort of children with ASD.

Objectives: This study aims to: (1) examine, in the same cohort of children with ASD, performance on both spontaneous and elicited motor imitation tasks as compared to typically-developing (TD) children, and (2) examine associations of elicited and spontaneous imitation performance with ASD diagnosis, clinical severity and core clinical features of ASD.

Methods: Forty children, aged 8-12 years, participated (20 ASD, 20 TD). The measure of spontaneousimitationwas the frequency of specific gestures copied (i.e., face-rubbing, arm-scratching, and yawning) during a storytelling taskin which a narrator inconspicuously performed those actions. Elicited imitation was assessed using a one-minute, engaging videogame-like task during which the children were instructed to imitate the dance-like movements of an avatar. Motion tracking data collected with Kinect Xbox cameras was analyzed using a novel Computerized Assessment of Motor Imitation (CAMI) algorithm to assess imitation performance.

ASD severity was assessed using the Autism Diagnostic Observation Schedule (ADOS-2) administered on-site; core clinical features of ASD was assessed using the Social Responsiveness Scale (SRS-2) questionnaire which was collected from parents.

Results: There was no significant association between elicited and spontaneous imitation (R=0.04; p=0.81). A multiple linear regression examining effects of imitation measures on diagnosis (ASD vs TD) revealed that poorer performance in the elicited imitation task (b=-0.70, p=0.001) was a better predictor of ASD diagnosis than spontaneous imitation task performance (b=-0.04, p=0.71).

A multiple linear regression test with ADOS-2 score as the dependent variable revealed that neither elicited (b=0.26, p=0.30) nor spontaneous imitation (b=0.08, p=0.74) were predictive of ASD clinical severity.

A final multiple linear regression test with SRS-2 total score as the dependent variable also showed that elicited imitation (b=-0.55, p<0.001) was a better predictor of social responsiveness than spontaneous imitation (b=-0.09, p=0.53). Follow-up Pearson correlation analyses indicated that, within the sub-scales of SRS-2, elicited imitation performance was associated with both restricted and repetitive behaviors (R=-0.59, p<0.001) and social-communication and interaction impairments (R=-0.53, p<0.001).

Conclusions: Our findings suggest that ASD-associated impairments in spontaneous and elicited imitation are not correlated. Elicited imitation deficits appear more indicative of autism diagnosis and greater symptom severity, although this may be related to the increased precision of assessment with the CAMI algorithm rather than the underlying constructs. The findings warrant further investigation of the comparative and inter-related associations of spontaneous and elicited imitation with aspects of autism presentation.

443.027 *(Poster)* Insistence-on-Sameness Repetitive Behaviors in Young Children with ASD: Age of Emergence, Relationship to Cognitive Level, and Expression in the Daily Routine and Play

P. Towle[1]*, B. Vibert*[2]*, D. Swain*[3] *and S. H. Kim*[3]*, (1)Westchester Institute for Human Development, Valhalla, NY, (2)Autism Center, Child Mind Institute, New York, NY, (3)Psychiatry, Center for Autism and the Developing Brain, White Plains, NY*

Background: Recent research has shown that restricted and repetitive behaviors (RRBs) reliably occur in young children with ASD, and that different subtypes ("higher order" --Insistence on Sameness (IS) and Restricted Interests--and "lower order" --Motor Stereotypies and Sensory Abnormalities) are fairly distinct in neural substrate, genetics, and developmental course (Lam, Bodfish, and Piven, 2008). Richler et al. (2010) demonstrated that IS behaviors were present in two-year olds at low levels and increased up to four years of age. However, no detailed information currently exists regarding their presence in children under two years of age, or their development and specific manifestations. This study used a younger group (from 17 months) and a more comprehensive list of behaviors than typically sampled.

Objectives: 1) Document ages IS behaviors first appeared in the sample, 2) Examine the relationship between cognitive level and IS, and 3) Provide functional examples, and relative frequency, of IS behaviors in infants, toddlers, and young preschoolers.

Methods: This archival, cross-sectional study used diagnostic evaluation reports/test protocols for 58 children with ASD, ages 17 to 48 months (M_{age}= 2.4 years, SD=1.2, 82% male, 84% White/Non-Hispanic). Instruments.*RRBs*. A new RRB instrument for young children with ASD, the Infant-Toddler Restricted and Repetitive Behavior Inventory (IRRBI), was used. The IRRBI has six scales: Motor Stereotypies, Visual Stereotypies, Repetitive Play, IS (two subscales: Daily Routines and Ritualized Play), Restricted Interests, and Sensory Reactions. Each scale has clusters (of items) based on functional categories. *Cognitive.*The Diagnostic Assessment Scale and the Mullen Scales of Early Development provided VIQ, NVIQ, and FSIQ. Procedure. Two raters coded the evaluation materials for 28 charts using the IRRBI. Mean Cohen's kappa across scales was .58, and .62 for IS. Analyses.Pearson correlations were conducted to examine the association between IS and age and cognitive skills. ANOVAs were conducted to examine the differences in RRBs among five age groups of six-month intervals.

Results: Relationship with Chronologic Age. Age was significantly correlated with both IS subscales (r=.327, p=.014 for Daily Routines; r=.362, p=.006 for Ritualized Play). ANOVAs for mean item endorsement over five increasing age groups showed significant group differences for Daily Routines (F=3.265, p=.019) and Play Routines (F=3.164, p=.021). Relationship with Cognitive Scores. VIQ significantly correlated with Ritualized Play (r=.415, p =.002) but not Daily Routines (r=-.058, p=.674); NVIQ significantly correlated with Total Sameness (r=.413, p =.002) but neither subscale individually. Age of Emergence. Although most types of IS behaviors were more frequent as age increased, Daily Routines first emerged at 21 months. The specific IS behavior identified at this age was related to wanting morning and/or evening care routines the same. Developing one's own idiosyncratic routine with toy or game, a behavior in the Ritualized Play subscale, first emerged at 17 months.

Conclusions: Consistent with previous studies, IS behaviors increased from toddlerhood to preschool age. The relationship with cognitive level is discussed in light of the mixed findings of previous studies. This study contributes novel, detailed information about early IS behaviors, age of emergence, and association with cognitive level.

443.028 *(Poster)* Integration of Visual and Proprioceptive Information in Children with Autism Spectrum Disorder

E. Isenstein[1], *E. J. Knight*[2], *V. Alleluia Shenge*[3], *D. Johnson*[1], *S. Iyer*[1] *and D. Tadin*[3], *(1)University of Rochester, Rochester, NY, (2)Developmental and Behavioral Pediatrics, University of Rochester Medical Center, Rochester, NY, (3)Brain and Cognitive Science, University of Rochester, Rochester, NY*

Background: Variations in sensory reactivity were recently added to the diagnostic criteria for autism spectrum disorder (ASD), yet limited studies have investigated the role of proprioception and its integration with other sensory modalities in the autism phenotype. The proprioceptive sense plays a critical role in early motor planning and coordination, designating this type of perception as an important facet of typical development. As such, innate alterations in proprioception may implicate downstream developmental variability and contribute to features of ASD involving repetitive behaviors and social communication. Investigation of simultaneous perception of proprioceptive and visual information may provide insight into proprioceptive functioning and multisensory integration in this population.

Objectives: To investigate whether children with ASD utilize and integrate proprioceptive and visual information differently as compared to children with typical development (TD) by exploring weighting of and reliance on visual and proprioceptive cues in a virtual reality (VR) task.

Methods: We evaluated proprioceptive-visual integration with a stimulus that paired movement of the participant's physical hand with the visual presentation of a virtual sheet of dots that moved in the same plane as the hand. While viewing the visual stimulus, participants held a VR controller attached to a sliding rail and moved their hand along the rail. Virtual dot speed was matched to the hand motion speed, and dot direction was either mapped exactly onto the hand movement (congruent condition), or at an angle slightly horizontally offset to the hand motion (incongruent condition). After each trial, the participants reported the perceived direction of the visual motion by adjusting a dial. Four children with ASD aged 9-17 and five IQ and age-matched TD controls have each completed 512 total trials, with six offset angles as well as no-offset trials. We expected that the hand motion would influence the perceived direction of the visual stimulus. We quantified this visual perception change by measuring the difference between the perceived angle (reported by the dial) and the true visual angle.

Results: In both groups, the perceived visual stimulus direction was repulsed away from the hand motion. Mixed design ANOVA reveals a significant main effect of angle on level of repulsion ($F(1,3)=3.35$, $p=0.029$). The magnitude of repulsion correlates positively with the degree of incongruence, with marginally stronger correlation in TD (TD:r=.791; ASD:r=.327). The differences in repulsion between the ASD and TD groups at various incongruent conditions do not reach statistical significance, but appear to trend toward weaker repulsion in ASD when the incongruence brings the visual stimulus toward the central field of vision.

Conclusions: These early results demonstrate that TD and ASD groups may utilize visual and proprioceptive information differently when making perceptual judgments that employs both modalities. Results suggest decreased coupling of visual and proprioceptive information as incongruence increases, an effect that appears marginally stronger in the TD group. Children with ASD may perceive visual and proprioceptive information as more tightly coupled in central visual fields and may integrate competing information differently.

443.029 *(Poster)* Intense Interests in Relation to Later Autism Symptoms and Internalizing Problems in Typically Developing Toddlers and Toddlers Who Develop ASD

C. A. Burrows[1], *M. R. Altschuler*[2], *J. Wolff*[3], *K. Botteron*[4], *S. R. Dager*[5], *A. Estes*[6], *H. C. Hazlett*[7], *J. Pruett*[8], *R. T. Schultz*[9], *L. Zwaigenbaum*[10], *J. Piven*[11] *and J. T. Elison*[3], *(1)Pediatrics, University of Minnesota, Minneapolis, MN, (2)Institute of Child Development, University of Minnesota, Minneapolis, MN, (3)University of Minnesota, Minneapolis, MN, (4)Washington University School of Medicine, St. Louis, MO, (5)Radiology, University of Washington, Seattle, WA, (6)Speech and Hearing Sciences, University of Washington, Seattle, WA, (7)University of North Carolina, Chapel Hill, NC, (8)*Co-senior author, **For the IBIS Network, Washington University School of Medicine, St. Louis, MO, (9)Center for Autism Research, Children's Hospital of Philadelphia, Philadelphia, PA, (10)University of Alberta, Edmonton, AB, Canada, (11)*Co-senior author, University of North Carolina, Chapel Hill, NC*

Background: Circumscribed and unusually intense interests represent a core characteristic of autism spectrum disorder (ASD). However, intense interests have historically been omitted from autism assessments early in childhood. There is evidence that young children, both those with and without autism, do show extremely intense interests. Understanding intense interests early in childhood may augment early identification and may have prognostic value.

Objectives:

1. Examine whether interest intensity and peculiarity at 18- and 24-months is associated with autism diagnosis.
2. Investigate longitudinal correlates of early intense interests for children not diagnosed with ASD.

Methods: This study prospectively examined infants at high-familial-risk (HR) and low-familial-risk (LR) for ASD. Participants included HR younger siblings who were diagnosed with ASD at 24 months (HR-ASD, n=43), HR siblings who did not receive an ASD diagnosis (HR-Neg, n=127) and an LR comparison group (LR, n=62). We collected the Intense Interests Inventory (I-3; Elison & Bodfish, 2009), a semi-structured interview that measures intensity and peculiarity of interests (each measured on a 1-5 point scale) at 18- and 24-months of age. We also collected measures of autism symptoms (i.e., SRS) and socio-emotional problems (i.e., CBCL) at 36 months of age.

Results: There was a difference in 24-month interest intensity and peculiarity by diagnostic group, $F_{intensity}(2,228)=7.46$, $p=.001$, $F_{peculiarity}(2,227)=11.68$, $p<.001$ (Table 1). The LR group showed lower intensity interests than HR-Neg and HR-ASD groups (p's<.02), though the HR-Neg and HR-ASD were not significantly different from each other ($p>.05$). For 24-month peculiarity, the HR-ASD group differed from both the HR-Neg and LR groups (p's<.001), but the HR-Neg and LR group did not differ from each other ($p>.05$). At 18 months, there was a diagnostic group difference in interest peculiarity only, $F_{intensity}(2,228)=4.44$, $p=.01$, such that the HR-ASD group showed higher peculiarity scores than the LR group ($p=.01$), but not the HR-Neg group ($p>.05$). We then examined whether differences in interest intensity correlated with later autism and emotional symptoms in the non-diagnosed (i.e., LR and HR-Neg) groups. Intensity of interests at 18 and 24 months were both positively related to social impairments on the SRS at 36 months (p's<.05). Intensity of interests at 24 months was also related to total problems on the CBCL at 36 months ($p=.03$).

Conclusions: Young children, both those with and without ASD, show great variability in intensity and peculiarity of interests. Peculiarity of interests appears to be especially informative for later ASD outcomes. For children who do not go on to develop ASD, early intensity of interests appears to be related to later social difficulties and behavioral problems. It may be that those who show early intense interests are less flexible in their attention, which might be an early marker for psychopathology generally, as well as subclinical autism characteristics.

443.030 *(Poster)* Interventions Using Neurotypical Peers and Siblings to Influence Motor Skills, Physical Activity, and Play in Individuals with Autism Spectrum Disorder: A Review of Literature

Y. Lu[1]*, I. Felzer-Kim*[1]*, L. Qu*[2] *and J. L. Hauck*[1]*, (1)Department of Kinesiology, College of Education, Michigan State University, East Lansing, MI, (2)School of Kinesiology, University of Michigan, Ann Arbor, MI*

Background: Many individuals with Autism Spectrum Disorder (ASD) experience motor skill development delays or deficits (Fournier et al. 2010). Inadequate motor skills can lead to lower participation in physical activity and more sedentary behavior which can increase the risk of being overweight or obese (Curtin, Jojic, & Bandini, 2014). Research also indicates motor skill development is associated with social skills (MacDonald et al. 2013), language development (McCleery et al, 2013), and cognitive skills (Bedford et al. 2016). Siblings are the most significant members of families after parents. Accordingly, the involvement of neurotypical siblings in the upbringing of individuals with disabilities could have long term positive consequences (Banda, 2015). Peers also play an important role by fostering inclusion in the school setting and creating opportunities for individuals with ASD to practice skills with multiple people. However, few interventions on motor skills, physical activity, and play for children with ASD have been investigated, and our knowledge is even more limited on the effect of peer and sibling involvement.

Objectives: To summarize the existing interventions using neurotypical siblings or peers to influence motor skills, physical activity, and play in individuals with ASD.

Methods: Databases including PubMed, Web of Science, Education Resources Information Center (ERIC), Sports Medicine and Education Index (Previous known as Physical Education Index), and PsycINFO (on ProQuest) were searched for relevant studies published prior to August 2019. Studies that met the following criteria were included: (a) Participants of the studies included neurotypical siblings/peers and participants with ASD; (b) There is interaction between neurotypical siblings/peers and individuals with ASD; (c) Desired outcomes of the studies related to motor, physical activity or play behaviors.

Results: The full search process produced a total of 2671 studies. Of those, 19 studies met the inclusion criteria. Participants were aged between means of 4 to 13 years. Sample size of included studies ranged from 3 to 44, and the ratios of individuals with ASD to their neurotypical siblings or peers ranged from 1:1 to 3:41. 10 out of 19 studies were conducted in a school setting, while the other 9 studies were conducted at home, summer camp, university-based early childhood center, or hospital and health center, etc. 12 out of 19 studies provided pre-training for neurotypical siblings or peers only, both children with ASD and their neurotypical siblings or peers, or parents. Intervention activities included physical education lessons, hide-and-seek, free play, catching, and balance beam, etc. The duration of the included studies varied from 2 to 16 weeks, and each study used varied measures of outcomes. Overall, included studies showed improvements in motor skills, physical activity, and play of participants with ASD.

Conclusions: This review summarized the existing interventions using neurotypical siblings or peers to influence motor skills, physical activity, and play in individuals with ASD. In the future, more sibling- and peer-mediated or guided interventions are needed with motor skills, physical activity, or play behavior as main targeted outcomes.

443.031 *(Poster)* Investigating the Factor Structure of the Childhood Routines Inventory-Revised in the EU-AIMS LEAP Cohort

D. V. Crawley[1]*, E. Loth*[2]*, J. Tillmann*[3]*, T. Charman*[4]*, J. F. Hipp*[5]*, T. Ciobanu*[5]*, E. Eule*[5]*, D. W. Evans*[6] *and E. U. AIMS LEAP*[7]*, (1)Forensic and Neurodevelopmental Sciences, Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, United Kingdom, (2)Department of Forensic and Neurodevelopmental Sciences, Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, United Kingdom, (3)Institute of Psychiatry Psychology & Neuroscience, London, United Kingdom, (4)Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, United Kingdom, (5)Neuroscience and Rare Diseases (NRD), Roche Pharma Research and Early Development, Roche Innovation Center, Basel, Switzerland, (6)Department of Psychology, Bucknell University, Lewisburg, PA, (7)EU-AIMS Consortium, London, United Kingdom*

Background: The Childhood Routines Inventory-Revised (CRI-R) is a standardised measure of repetitive and ritualistic behaviours. In a large representative sample of over 3000 individuals aged 2-17 years, the CRI-R yielded two factors: Rigidity/insistence on sameness (RIS) and Repetitive sensory and motor behaviours/compulsions (RSMBC). It is not known whether the same factor structure applies to individuals with clinical diagnoses of autism spectrum disorder (ASD).

Objectives: 1) Investigate the factor structure of the CRI-R in children/adolescents with ASD from EU-AIMS LEAP; 2) Examine associations among factors and with clinical correlates.

Methods: Parents of 137 individuals with ASD and 87 comparison individuals (N=78 TD; N=9 ID) aged 6-17 years completed the CRI-R. Principal axis exploratory factor analysis (EFA) was conducted for the ASD sample. The resultant 5-factor solution was then tested with confirmatory factor analysis and compared to the published 2-factor structure, for the ASD group and total sample. Internal consistency was examined. Convergent and discriminant validity were established; the former by comparing factors with the Repetitive Behaviour Scale-Revised (RBS-R) subscales (ASD only), and the latter by comparing cases and controls. In the ASD group, associations with demographic (age, IQ, sex) and clinical variables (Social Responsiveness Scale (SRS), Sensory Experience Questionnaire (SEQ), Strengths and Difficulties Questionnaire (SDQ), DSM-5 ADHD rating scales) were investigated using Spearman's correlation.

Results: EFA yielded a 5-factor solution, which then showed a superior model fit to the 2-factor solution (CFI=0.667, RMSEA=0.086 vs. CFI=0.568, RMSEA=0.095). The factors were interpretable as: “Compulsive/Sameness”, “Food rigidities”, “Restricted/Repetitions”, “Self-directed motor behaviours” (SDMB) and “Aversion to sensory/novelty”, accounting for 47% of the variance. The first two factors comprise the original RIS factor, the last two factors represent the RSMBC factor and Restricted/Repetitions items were split between the two. Internal consistency was demonstrated in the ASD group (alphas ranging 0.83-0.95) and in the TD/ID sample (0.63-0.92). The ASD group scored significantly higher than the TD/ID group on all factors (*d*’s ranging 1.03 (Food rigidities) to 1.40 (Compulsive-Sameness), *p*s<5.69e-12). In the ASD group, correlations with RBS-R subscales ranged from r_s=0.15 (CRI-R Food rigidities–RBS-R Stereotyped behaviour, *p*=.1; Fig1) to r_s=0.73 (CRI-R Compulsive/Sameness–RBS-R Ritualistic-Sameness, *p*<2.2e-16). ASD females scored significantly higher than ASD males on SDMB (*p*=.046, *d*=0.33, other *p*s>.2). In the ASD group, age correlated negatively with Restricted/Repetitions (r_s=-0.30, *p*=.0005) and SDMB (r_s=-0.19, *p*=.031). IQ was not associated with any factors (*p*s>.1). Social communication difficulties (SRS) related to higher scores on all factors (r_s=0.18-0.45, *p*s<.04). Aversion to sensory/novelty and Compulsive/Sameness correlated most highly with sensory sensitivities on the SEQ (r_s=0.71, *p*s<2.2e-16), though all factors were significantly related (r_s=0.37-0.63, *p*s<1.21e-05). Anxiety was most strongly associated with Compulsive/Sameness (r_s=0.55, *p*=9.54e-11), whilst ADHD-hyperactivity-impulsivity was most strongly associated with SDMB (r_s=0.57, p=7.98e-13) and ADHD-inattention with Restricted/Repetitions (r_s=0.30, p=.0006). See Fig1.

Conclusions: Evidence supports a 5-factor structure on the CRI-R in a clinical ASD cohort and shows differing strengths of associations with key clinical correlates, including core ASD and associated symptoms. These factors may facilitate a better understanding of RRB subtypes, both in terms of their clinical profiles and possible neural and genetic substrates.

443.032 *(Poster)* Levels of Physical Activity Among Children with and without Autism Spectrum Disorder between the Ages of 2 and 9 Years

K. L. Staples[1] *and L. R. Ketcheson*[2]*, (1)University of Michigan, Ann Arbor, MI, (2)Department of Kinesiology, Health and Sport Studies, Wayne State University, Detroit, MI*

Background: One of the most widely researched components of health are weight status and physical activity (PA). To date, the majority of PA results have been based on parental report data from the National Survey of Children’s Health. While this provides a national estimate of PA for children with and without ASD, there remains very little objective data examining levels of PA among young children with ASD. The latest PA Guidelines for Americans recommend that preschool aged children (2 to 5 years) engage in active play throughout the day and school aged children (6 to 17 years) engage in at least 60 minutes of moderate to vigorous physical activity (MVPA) each day.

Objectives: The purpose of this study is to examine weight status and levels of PA among children with and without ASD, between the ages of 2 and 9 years.

Methods: 54 children with ASD and 47 neurotypical children were divided by age into 2 groups: preschool (2 to 5 years) and school (6 to 9 years). Height (cm) and weight (kg) were measured and body mass index (BMI) was calculated. BMI percentiles were used to determine weight classification relative to children of the same age and sex. PA was measured objectively for 7 days using Actigraph GT3X+ accelerometers. Wear time was validated manually using parental logs and Actilife 6 data analysis software. Intensities of PA were determined using the Butte (2011) and Evenson (2008) activity cut points for preschool- and school-aged children, respectively. Independent samples t-tests were used for all analyses.

Results: 40.9% and 42.9% of preschool- and school-aged children with ASD were classified as overweight or obese. These estimates are significantly higher compared to 9.1% and 8% of neurotypical children in the same age groups [t(1,95) = 2.580, p = .011, d = .52]. Overall, the mean of all groups exceeded the recommended 60 minutes of MVPA. There were no significant differences in MVPA between children with and without ASD [t(1, 98) = -.174, p = .862]. However, only 37.5% of children with ASD compared to 41.7% of neurotypical children participated in at least 60 minutes of MVPA on most days of the week. Among children with ASD, there were no significant differences in MVPA when comparing children who were of healthy weight and those who were overweight or obese [t(1, 47) = -.543, p = .590].

Conclusions: Despite having significantly higher levels of overweight and obesity, children with ASD engage in similar amounts of objectively measured PA. Accelerometers do not differentiate between purposeful and stereotypical movements, meaning that for children with ASD not all PA has health benefits. Current PA recommendations do not seem sufficient, given the estimated number of young children with ASD who are already overweight or obese. In order to improve and promote positive trajectories of health, PA recommendations may need to be more robust and more specific to age related cohorts as many children with ASD already seem to be meeting the current recommendations.

443.033 *(Poster)* Manual Motor Deficits in Individuals with Autism Spectrum Disorder and Their Unaffected Biological Parents

E. Bojanek[1]*, L. M. Schmitt*[2]*, S. P. White*[3]*, J. A. Sweeney*[4] *and M. W. Mosconi*[5]*, (1)University of Kansas, Lawrence, KS, (2)Cincinnati Children's Hospital Medical Center, Cincinnati, OH, (3)Department of Pediatrics, Emory University, Atlanta, GA, (4)Psychiatry and Behavioral Neuroscience, University of Cincinnati College of Medicine, Cincinnati, OH, (5)Clinical Child Psychology Program, Schiefelbusch Institute for Life Span Studies, University of Kansas, Lawrence, KS*

Background: Sensorimotor impairments, including feedforward and feedback deficits of manual motor control, are prevalent in individuals with autism spectrum disorder (ASD). Oculomotor impairments also have been documented in unaffected relatives of individuals with ASD. The degrees to which skeletomotor systems are affected in unaffected parents and are familial have not yet been determined.

Objectives: 1) To examine precision manual motor control in individuals with ASD and their biological parents, and 2) to determine whether manual motor impairments are familial.

Methods: We studied 53 probands with ASD and 100 parents of individuals with ASD (ASD parents). Thirty three typically developing (TD) controls were matched with probands on age (5-17 years), and nonverbal IQ. An additional 42 controls were matched with ASD parents on age (29-54 years), sex, and IQ. All participants completed the sustained task across varying force conditions (force task) and a subgroup of these participants (20 probands, 18 TD controls; 49 parents, 31 parent controls) completed the sustained task across varying visual feedback conditions (gain task) to assess motor and visuomotor feedback mechanisms. During the tasks, participants pressed opposing load cells with their thumb and index finger while they viewed a static red/green target bar and a white force bar that moved upwards with increased force. They were instructed to press when the target bar turned green so that the white bar reached the level of the target bar and hold it there as steadily as possible for 8 seconds. We measured the variability of the sustained force and the complexity of the force time series.

Results: During the sustained force task, ASD participants showed greater variability (p=0.03) and reduced complexity (p=0.01) compared to TD controls. Similarly, parents showed increased variability compared to controls during the highest force condition (group x MVC interaction, p=0.05). During the sustained gain task, ASD participants showed increased variability at the highest gain level (p<0.001) and reduced complexity (p<0.001) across conditions compared to TD controls. ASD parents also showed reduced complexity compared to controls when using their nondominant hand (p=0.02). Data collection is complete and analysis of the familiality of sensorimotor issues in ASD is ongoing.

Conclusions: We found that individuals with ASD and their unaffected biological parents show reduced precision manual motor control suggesting that these impairments may be familial. Specifically, individuals with ASD and their parents show a reduced ability to integrate sensory feedback to make corrective motor adjustments to decrease variability. These studies implicate cortico-cerebellar circuits involved in sensory feedback control of precision motor behaviors in the pathophysiology of ASD, and highlight new motor physiological targets useful for characterizing genotype-phenotype relationships in family genetic studies.

443.034 *(Poster)* PTEN Mutation As a Model for Understanding of Restricted and Repetitive Behaviors in Children and Adolescents

M. Uljarevic[1], *G. Rached*[2], *T. W. Frazier*[3], *J. A. Martinez-Agosto*[4], *M. Steele*[5], *R. Libove*[6], *J. M. Phillips*[7], *R. M. Busch*[8], *P. Klaas*[9], *R. Filip-Dhima*[10], *C. Eng*[11], *M. Sahin*[12] *and A. Y. Hardan*[7], *(1)Department of Psychiatry and Behavioral Sciences, School of Medicine, Stanford University, Stanford, CA, (2)Faculty of Medicine, Saint Joseph University, Beirut, Lebanon, (3)Autism Speaks, New York, NY, (4)Departments of Human Genetics, Pediatrics and Psychiatry, University of California, Los Angeles, Los Angeles, CA, (5)Department of Psychiatry and Behavioral Sciences, Stanford University, Stanford, CA, (6)Psychiatry and Behavioral Sciences, Stanford University, Stanford, CA, (7)Psychiatry & Behavioral Sciences, Stanford University, Stanford, CA, (8)Neurology, Cleveland Clinic, Cleveland, OH, (9)Cleveland Clinic, Cleveland, OH, (10)Boston Children's Hospital, Boston, MA, (11)Genomic Medicine, Cleveland Clinic, Cleveland, OH, (12)Boston Children's Hospital/Harvard Medical School, Boston, MA*

Background: Germline mutations in *PTEN* are associated with abnormalities in white-matter and impaired cognitive abilities among individuals with autism spectrum disorder (ASD), as well as expression of both social impairments and restricted and repetitive pattern of behaviors and interests (RRB) in animal models. However, limited progress has been made in understanding whether *PTEN* mutations are associated with specific phenotypic profiles when compared to idiopathic ASD. This knowledge gap is particularly pronounced in terms of RRB domain. The impairments in specific aspects of executive functioning, heightened rates of anxiety and motor abnormalities have been associated with PTEN loss in both animal models and clinical studies. Given that these processes have been suggested to serve as transdiagnostic mechanisms underpinning Insistence on Sameness (IS), Circumscribed Interests (CI) and Repetitive Motor Behaviors (RMB) RRB domains, *PTEN* mutation offers a unique model for furthering our understanding of the mechanisms involved in the development and maintenance of RRB and therefore has the potential to inform the development of targeted treatments.

Objectives: To (i) characterize RRB profiles in children and adolescents with *PTEN* mutation with no ASD (PTEN-No ASD), *PTEN* mutation with ASD (PTEN-ASD) and idiopathic ASD with macrocephaly but no *PTEN* mutation (macro-ASD) groups and (ii) explore continuities and discontinuities in predictors of distinct RRB domains across these groups.

Methods: Sample included 28 individuals with *PTEN* no ASD (M_{age}= 9.19years, *SD*= 4.91), 43 with *PTEN*-ASD (M_{age}= 11.79 years, *SD*= 5.34) and 33 with macro-ASD (M_{age}= 9.21 years, *SD*= 4.72). The Repetitive Behavior Scale-Revised (RBS-R), the Child Behavior Checklist (CBCL), Behavior Rating Inventory of Executive Function (BRIEF), and the Developmental Coordination Disorder Questionnaire (DCDQ) were completed by parents as measures of RMB, IS and CI (RBS-R), negative valence (CBCL internalizing score), response inhibition and set-shifting (BRIEF) and motor problems (DCDQ). Full Scale IQ (FSIQ) data was also available.

Results: There were significant group effects for RBS-R RMB (*F*= 5.01, *p*= .009) and Circumscribed Interests (*F*= 8.48, *p*< .001) but not for IS (*F*= 1.02, *p*= .37) scores. Post-hoc comparisons showed that *PTEN*-no ASD group had significantly lower RMB and CI scores than both *PTEN*-ASD and Macro-ASD groups, which, in turn, did not significantly differ. Across all three groups higher IS severity was associated with higher CBCL internalizing scores (*r* range: .44-.77) and greater difficulties with set shifting (*r* range: .60-.88). Problems with response inhibition were associated with greater CI severity (*r* range: .35-.78). Motor problems were significantly associated with RMB only in Macro-ASD group (*r*= -.54, *p*< .001) but not in the other two groups. The FSIQ score was significantly associated with RMB across *PTEN*-ASD (*r*= -.57, *p*= .002) and macro-ASD groups (*r*= -.44, *p*= .03) but not in PTEN-No ASD group.

Conclusions: This investigation provides the first preliminary evidence for common and distinct mechanisms influencing RRB domains across *PTEN*-ASD, *PTEN*-no ASD and Macro-ASD groups. These findings have important implications for the design of targeted treatment strategies.

443.035 *(Poster)* Participation in Physical Activity, Sport, and Physical Education Among Canadian Children and Youth on the Autism Spectrum

E. Bremer[1], *K. A. Martin Ginis*[2,3], *R. L. Bassett-Gunter*[4] *and K. P. Arbour-Nicitopoulos*[1], *(1)Faculty of Kinesiology and Physical Education, Mental Health and Physical Activity Research Centre, University of Toronto, Toronto, ON, Canada, (2)Department of Medicine, University of British Columbia, Kelowna, BC, Canada, (3)School of Health & Exercise Sciences, University of British Columbia, Kelowna, BC, Canada, (4)School of Kinesiology and Health Science, York University, Toronto, ON, Canada*

Background: A growing body of literature suggests that children and youth on the autism spectrum are less physically active than their neurotypical peers. Insufficient physical activity may have detrimental effects on the physical, mental, and cognitive well-being of this population. However, we still have a limited understanding of the types of physical activity in which children and youth on the autism spectrum participate (e.g., active play, sports, physical education). Further, no large-scale studies have examined physical activity participation in a Canadian sample of children and youth on the autism spectrum.

Objectives: The National Physical Activity Measurement (NPAM) study aims to address the lack of population-level data on physical activity participation among Canadian children and youth with disabilities. The aim of the current sub-analysis was to examine the rate of participation in overall physical activity, as well as two sub-types of physical activity (sport and physical education) among Canadian children and youth on the autism spectrum.

Methods: School-aged children and youth (4-17 years) on the autism spectrum were recruited across Canada through various community and sport/recreation organizations. Parents reported their child's demographic characteristics, along with their rates of participation in physical activity via an online questionnaire. Participants were then mailed a Fitbit Charge HR and instructed to wear it for 28 consecutive days. Descriptive analyses were used to describe participants' level of participation in overall physical activity and the subtypes of sports and physical education. Fitbit analyses are on-going and will provide a direct measure of physical activity.

Results: Data on 255 participants (78% male, 9.4±3.3yrs) on the autism spectrum has been provided thus far. Results demonstrate that the majority (86%) of participants are not engaging in the recommended 60 minutes of moderate-to-vigorous physical activity (MVPA) each day, with the average participant only meeting the recommended dose of MVPA on three days per week. Moreover, overall participation in leisure-time physical activity was generally low, averaging 34±39 minutes per day. In regard to sport participation, fewer than half (48%) of the participants engaged in unorganized sports (i.e., without a coach) in school, while two-thirds (66%) of participants engaged in unorganized sports outside of school. In contrast, higher rates of engagement in organized sports (i.e., with a coach) were reported, with 63% and 85% of participants engaging in and outside of school, respectively. Lastly, time spent in physical education ranged from 0 to 570 minutes per week, with participants engaging in physical education classes for an average of 108±90 minutes per week.

Conclusions: Preliminary findings from this sub-analysis of NPAM data indicate that Canadian children and youth on the autism spectrum are not meeting physical activity guidelines. Participation in unorganized physical activities and sports appear to be particularly low in this population. Next steps include further analyses of this data including an examination of individual (e.g., level of functioning), familial (e.g., SES), and environmental (e.g., neighbourhood amenities) factors that may help to further explain and contextualize the participation levels of children and youth on the autism spectrum.

443.036 *(Poster)* Physical Activity and Screen-Time Among Children with Autism; A Longitudinal Analysis from 9 to 18 Years.

M. I. MacDonald[1], *J. Dahlgren*[1], *S. Healy*[2], *J. Geldhof*[1] *and J. A. Haegele*[3], *(1)Oregon State University, Corvallis, OR, (2)Behavioral Health and Nutrition, University of Deleware, Newark, DE, (3)Old Dominion University, Norfolk, VA*

Background: Children with autism spectrum disorder are at an increased risk of poor health outcomes when compared to neurotypical children (Scharoun, 2017). For example, children with ASD have a higher prevalence of obesity compared to their neurotypical peers (23.05% versus 15.91%) (Healy, 2018). In an effort to understand and ultimately reduce these health disparities, researchers have examined modifiable health behaviors, including physical activity (PA) and screen-time (ST). However, our current understandings of PA and SB are derived primarily from cross sectional studies. There are no known longitudinal studies which have examined these health behaviors in children with ASD across time.

Objectives: The purpose of this study was to examine how time spent in physical activity and screen-time changed over time among children with and without ASD.

Methods: Data were utilized from three different time points (age 9, 13 and 17/18)of a nationally representative longitudinal dataset 'Growing up in Ireland'. Parents and youth reported on demographic variables (e.g., sex, socio-economic status, and support services received), time in PA (days with at least 20 minutes of vigorous PA and days with at least 20 minutes of light PA over the last ten days) and time in ST (hours per weekday spent watching television and hours spent playing videogames). T-tests and robust regression analyses were used to understand the relationship between the matched sample and the variables of interest.

Results: The study included 88 children with ASD and a propensity-score matched sample of 88 neurotypical children, matched based on sex and income at waves 1, 2, and 3. The full sample included 138 males and 38 females. At all time-points (i.e. 9, 13, and 17/18 years of age), children with ASD were significantly less likely to engage in VPA compared to neurotypical children (all p's < .05). From age 9 to age 17/18, VPA decreased for both groups, with a steeper decline among children with ASD (p = .002). More specifically children with ASD most commonly participated in 9+ days of VPA at age 9, 1-2 days at age 13, and 0 days at age 17/18. This compared to neurotypical children who most commonly participated in 9+ days of VPA at age 9 and 13, and 6-8 days of VPA at age 17/18. Regarding light PA, children with ASD and neurotypical children participated in similar levels at aged 9 and 17/18 but were significantly less active at age 13 (p = .0013). Time spent watching TV or playing video-games did not differ between groups at each of the three time-points.

Conclusions: This study, for the first time, examined PA and ST levels from childhood to late adolescence revealing steep declines in VPA among children with ASD. Interventions to reduce the decline in VPA that occurs from childhood to adolescents are urgently needed among this at-risk population.

443.037 *(Poster)* Preferences of Autistic Children for Multi-Sensory Environment Equipment: Patterns of Use and Individual Differences

K. L. Unwin*, G. Powell and C. R. Jones, Wales Autism Research Centre, Cardiff University, Cardiff, United Kingdom*

Background: Multi-Sensory Environments (MSEs; also called sensory or Snoezelen rooms) are rooms that contain equipment that modifies the sensory environment. They are common in special needs schools and are widely used with autistic children. However, there is no empirical guidance on how to use MSEs with autistic children. Our qualitative research has shown that practitioners believe the benefits of MSEs occur through autistic users being motivated, which can be fostered by using preferred MSE equipment. However, there have been no investigations to date into the equipment preferences of autistic users, including how preference may vary by relevant characteristics such as sensory profile, autistic symptoms, IQ or age.

Objectives: To investigate autistic children's preferences for MSE equipment, and whether equipment preferences vary according to sensory profile, autistic symptoms, IQ or age.

Methods: Forty-one autistic children (8 female) aged 4-12 years (*M*=8 years, *SD*=2.05 years) were each given free use of an MSE for five-minutes. Four key pieces of equipment were available: a bubble tube; touch, sound and light board; fibre optic cabling; and a tactile board. The frequency and duration (seconds) of visits to each piece of equipment was recorded, as well as where each participant chose to visit first. Sensory behaviours performed during the session were coded from videos. IQ and Autism Diagnostic Observation Schedule-2 (Lord et al. 2012) assessments were also completed. Parents completed the Social Communication Questionnaire (Berument et al., 1999) and the Sensory Profile (Dunn, 1999) questionnaire.

Results: Choice of first visit and frequency and duration of visits produced a rank order preference of equipment: (1) bubble tube; (2) touch, sound and light board; (3) fibre optics; (4) tactile board. Greater hypersensitivity and less time spent performing sensory seeking behaviours correlated with more engagement at the tactile board, which requires interaction for stimulation, and less engagement at the bubble tube, which is highly stimulating without active interaction. Higher IQ was associated with more time spent at equipment requiring active interaction for stimulation (i.e. tactile board, and touch, sound and light board) and less time at equipment requiring no interaction (i.e. bubble tube). Age and degree of autistic symptoms did not associate with patterns of use.

Conclusions: This study is the first to investigate the preferences of autistic children for different types of MSE equipment. The strongest preference was for the bubble tube, which offers auditory, visual and tactile stimulation and is commonly used in MSEs (Unwin et al., in prep). The preferences of autistic children were significantly associated with both their sensory and intellectual profiles. It can be suggested that children's sensory needs are influencing patterns of engagement, while greater intellectual ability seems to draw children to equipment that provides greater capacity for intellectual stimulation. The data imply that practitioner consideration of users' sensory and intellectual profiles can help inform how best to use an MSE with autistic children. Further research should directly measure the impact of equipment preference on motivation and capacity to learn.

443.038 *(Poster)* Presence of Symptoms of Attention Deficit/Hyperactivity Disorder Is Correlated with Increases in Restrictive and Repetitive Behaviors in Children Diagnosed with Autism Spectrum Disorder

S. Mussarrat[1]*, D. Aygun*[2]*, P. Hickey*[3] *and E. Hanson*[4]*, (1)Boston Children's Hospital, Boston, MA, (2)Tufts University, Medford, MA, (3)Psychology, Tufts University, Boston, MA, (4)Boston Children's Hospital/Harvard Medical School, Boston, MA*

Background: Restrictive and Repetitive Behaviors (RRBs) are a core feature of Autism Spectrum Disorder (ASD) and can be extremely impairing for individuals and their families (Richler, Huerta, Bishop, & Lord, 2010). RRBs are also present in other psychiatric, genetic and developmental disorders (Harrop et al., 2015). They have also been shown to predict symptoms of Attention Deficit/Hyperactivity Disorder (ADHD) (Stratis & Lecavalier, 2013). In Fragile X syndrome, over-activity, impulsivity and repetitive behaviors were found to be higher in participants diagnosed with ASD (Crawford et al., 2018). The effect of ADHD symptoms on the type and severity of RRBs in children with ASD has not yet been researched.

Objectives: To determine, whether overactive symptoms of ADHD are correlated with greater severity of RRBs in children with ASD.

Methods: We completed preliminary analysis on previously gathered data from the Simons Simplex Collection and the Boston cohort of the Autism Consortium by analyzing 87 children 3-15 years with ASD. ASD diagnosis was confirmed using the "gold standard" of Autism Diagnostic Observation Schedule-Second Edition (ADOS-2) and Autism Diagnostic Interview-Revised.

ADOS-2 E1 code for Overactivity was used as a proxy for ADHD. Participants in the analysis were put into two groups. Individuals with a code of "2" on E1 were placed into the "More Activity" group (n=43) and those with a code of "0" on E1 were placed in the "Typical Activity" group (n=44).

The ADOS-2 D codes were used to measure RRBs: D1=Unusual sensory interests, (D-sens); D2=Hand/finger mannerisms (D-man) and D3=Unusually repetitive interests/stereotyped behaviors (D-stereo). In addition, the average of the three D codes (D-avg) and the ADOS RRB total score (RRB-tot) were used.

Since the data was not normally distributed, non-parametric statistics were used in the analysis. First, Mann-Whitney-U tests were used to compare if there was a difference in the RRB-tot and D-Avg. Next, we performed chi-squared test to assess the relationship between the coding of overactivity and the rating distribution of the different types the RRBs (D-sens, D-man and D-stereo).

Results: Preliminary analysis found that individuals in the More Activity group had significantly higher RRB-tot scores than those in the Typical Activity group ($p < 0.01$). D-avg was also higher in the More activity group but did not reach significance (P=0.41).

Children in the More Activity group were significantly more likely than those in the Typical Activity group to have elevated D-stereo codes ($p < 0.01$). There were no significant differences for D-sens ($p = 0.11$) or D-man ($p = 0.97$).

Conclusions: This preliminary analysis supports the hypothesis that individuals with ASD with overactive symptoms of ADHD may have greater severity of certain types of RRBs. In our subsequent analysis, we will control for age, IQ and ADOS comparison score and include additional items from the ADOS-2, Child Behavior Checklist and the Behavior and Sensory Interest Questionnaire (BSIQ) to better understand the impact of symptoms of ADHD on individual RRBs. We predict that our original hypothesis will stand in this more specifically directed analysis.

443.039 *(Poster)* Professional Bias in View of Restricted and Focused Interests: Implications for Educational Settings

K. P. Koenig[1], *L. Hough Williams*[2], *M. Schneider*[3] *and K. Kirkman*[4], *(1)Occupational Therapy, New York University, New York, NY, (2)Metrocenter for Urban Education, New York Univeristy, New York, NY, (3)Applied Psychology, New York University, New York, NY, (4)Metrocenter for Urban Education, New York University, New York, NY*

Background: In a 2017 study, Koenig & Williams surveyed adults with autism (n = 85) about the personal significance of their restricted or preferred interests. Participants overwhelmingly indicated that they felt teachers should incorporate preferred interests into the classroom, but pointed out a lack of awareness on teachersâ€™ part of the existence, importance, and power of utilizing studentsâ€™ preferred interests. This follow up study explored the relationship between practitionerâ€™s characterization of studentsâ€™ special interests and the positive, negative or neutral utilization of said interests in actual classroom practice. This survey of professional educators (teachers and related service providers) of students with autism (K-8 grade) sought to capture and characterize how their view of preferred interests is associated with their ability or inability to leverage the motivation that studentsâ€™ special interests can potentially provide in classrooms.

Objectives: To determine professional educators attitudes towards restricted or preferred interests that students on the autism spectrum display in the classroom setting.

Methods: A online survey was sent to general and special educators as well as related service providers in a larger urban school district (n= 80). Survey questions included likert scale items as well as open ended responses to two case scenarios of a young (kindergarten) and older (5th grade) student. Each of these scenarios described a focused interest that a child would typically have and descriptors of behaviors that the child exhibited. Descriptive data was collected on the likert responses. The open ended questions were coded by the research team which included a graduate student on the autism spectrum. A priori codes were set that included such items as "not age appropriate", use of interest for "coercion or control", "respect for intrinsic value" of the interest, etc. These codes were classified as positive, or negative codes and a taxonomy of responses was developed. For example, if a teacher described utilizing the interest for social or learning goals, it was a positive rating. Inter-rater reliability of all coded descriptions was established at 85% agreement on the first round of coding.

Results: Only 5% of the educational professionals surveyed found that interests are very helpful when learning content in the classroom as compared to 70% that used interests to soothe or calm the student. When describing interests in given scenarios, negative ratings predominanted regardless of age, years experience, type of professional or gender. Related service providers had higher frequency ratings of positive descriptions for focused interests than classroom teachers.

Conclusions: There is a dissonance between the benefit that the self advocacy community places on focused interests that could be utilized to enhance learning in classrooms and educational professionals view and use of these interests. These attitudes have the potential to negatively impact not only learning but career pathways and enhanced opportunities for socialization. A taxonomy of attitudes was developed based on the results of this survey that can be used for self rating and review of educational practices. These results can assist in guiding educators to examine their own view and alter practices.

443.040 *(Poster)* Prosodic Changes in Noisy Environments: Sensory Sensitivity Scores Predict Interference of Prosodic Control in Autistic and Non-Autistic Adults

V. Ly[1], *N. E. Scheerer*[1,2], *T. Q. Boucher*[1], *J. A. Jones*[3] *and G. Iarocci*[1], *(1)Psychology, Simon Fraser University, Burnaby, BC, Canada, (2)Psychology, Western University, London, ON, Canada, (3)Psychology, Wilfrid Laurier University, Waterloo, ON, Canada*

Background: Autism is associated with sensory differences, including hyper- or hypo-sensitivities, and social communication challenges (APA, 2013). Prosodic changes in speech (changes in pitch, stress, rhythm, etc.), play important roles in social communication, as they express the speaker's emotionality and intent (Bryant & Barrett, 2007). Since one's own auditory feedback helps regulate speech prosody (Donath et al., 2002), exposure to ambient noise may disrupt this process (Foxe et al., 2015). As autistic people report difficulties communicating in noisy environments, it is of interest to investigate whether their auditory sensitivities lead to poorer prosodic control in noisy environments.

Objectives: The objectives of this study were to determine whether increased sensory sensitivity is linked to poorer prosodic control in noisy environments, and whether autistic and non-autistic individuals differ in their vocal pitch control in high noise conditions.

Methods: 13 autistic (M_{age}=29.1, *SD*=12.5; M_{IQ}=114.1, *SD*=12.5; M_{AQ}=33.5, *SD*=7.9) and 25 non-autistic adults (M_{age}=21.4, *SD*=8.4; M_{IQ}=97.8, *SD*=11.4; M_{AQ}=15.9, *SD*=5.8) were recruited. Autistic participants provided documentation of an ASD diagnosis. Participants produced vocalizations while exposed to frequency altered feedback (FAF), +/- 100 cent perturbations of their own vocalizations. During half the trials, a multi-speaker babble track was played. The size of the participants' compensatory responses to the FAF was measured. Difference scores were calculated to quantify interference by the babble by subtracting the median response in the babble condition from the median response in the no babble condition for both +100 and -100 perturbation conditions. The Adolescent/Adult Sensory Profile (SP) was used to assess sensory processing patterns across four domains: low registration, sensation seeking, sensory sensitivity, and sensation avoiding.

Results: Interference scores were entered into an ANOVA with group (autistic, non-autistic) and perturbation direction (+/-100) as factors. A direction by group interaction, $F(1,37)=6.446$, $p=.015$, $\eta p^2=.148$, was found as autistic participants experienced greater interference for -100 cents perturbations, while non-autistic participants experienced greater interference for +100 cent perturbations. A hierarchical linear regression was conducted to determine whether group and/or SP scores could predict interference by the babble. Group alone could not account for significant variance. However, when SP scores were added to the model, significant variance in interference scores was accounted for, $F(5,32)=2.625$, $p=.042$, $R^2=.291$. Specifically, the sensory sensitivity sub-scale of the SP was a significant predictor of interference, $t(1)=2.944$, $p=.006$.

Conclusions: Higher sensory sensitivity predicted greater interference by babble noise on auditory feedback control of speech for both autistic and non-autistic participants. One possible explanation is that in noisy environments, the babble captures more of the hypersensitive individual's attention, leaving fewer cognitive resources available to respond to the perturbation. Hypersensitivities to noise are more common in autistic people, which makes interference in noisy environments more problematic for these individuals. Elevated sympathetic responses to noise in autistic people (Chang et al., 2012) may also contribute to the babble's effects on attention. However, autistic people can also be hyposensitive to noise and this heterogeneity in responses to sound may explain the lack of main effect. Future research will explore how Sensory Profile scores are related to perturbation effects.

443.041 *(Poster)* Quantitative Assessment of Motor Movement in Autism during a Functional Dressing Task

A. Ardalan[1] *and B. G. Travers*[2]*, (1)Computer Sciences, University of Wisconsin-Madison, Madison, WI, (2)University of Wisconsin - Madison, Madison, WI*

Background: Sensorimotor challenges have been shown to relate to poorer daily living skills in individuals with autism spectrum disorder (ASD) (Jasmin et al., 2009; Travers et al., 2017), even after controlling for key variables like age and IQ (Travers et al., 2017). However, to our knowledge no study has quantitatively and systematically measured motor skills during functional tasks in youth with ASD. This type of information would inform what aspects of movement may be different in ASD and how movement patterns in ASD may affect performance of everyday tasks.

Objectives: 1) To identify group differences in movement kinematics and postural sway during a dynamic dressing task that mimics real-world dressing, and 2) To examine whether whole-body movement during dressing can reliably distinguish youth with ASD from youth with typical development.

Methods: 54 participants with ASD and 34 age-matched participants with typical development (TD) underwent diagnostic testing and completed our Motor Rainsuit Assessment During Dressing (M-RADD) task. In this task, we asked participants to put a clear rain suit (pants and a jacket) over their clothes, and we recorded whole-body kinematics using a Kinect camera. We then calculated various angles of each participants articulated figure segments and used discrete Wavelet transform to clean the time series of each angle. Next, we used dynamic time warping to measure the dissimilarity between various sessions' time series and used these dissimilarities to train and test support vector classifiers using a leave-one-out cross-validation scheme. We compared classification accuracy, to assess the generalizability of the classification paradigm, along two main dimensions, namely (1) all the sessions vs. pre-balance training sessions, and (2) younger participants vs. older participants (<= vs > participants' median age).

Results: Initial analyses found that the dressing task was completed more slowly in the ASD group than the TD group, $t(158) = 6.81$, $p < 0.01$. Classification positive predictive values (PPV=0.81) and true positive rates (TPR=0.81) were significantly higher in younger participants.

Conclusions: The present findings suggest that the group with ASD tended to complete the dressing task significantly more slowly than the group with typical development. Moreover, the classification analyses, suggested that the motor kinematics during the dressing task were able to distinguish between the two groups with high predictive validity, particularly in the younger participants. Future analyses will examine which movements during dressing were the most distinguishable between the two groups, which will help inform how movement differences may impact those with ASD during daily living tasks.

443.042 *(Poster)* Reduced Lateralization of Precision Motor Behavior in Individuals with Autism Spectrum Disorder

M. H. Campbell[1]*, K. E. Unruh*[1]*, E. Bojanek*[2] *and M. W. Mosconi*[3]*, (1)Kansas Center for Autism Research and Training (K-CART), University of Kansas, Lawrence, KS, (2)University of Kansas, Lawrence, KS, (3)Clinical Child Psychology Program, Schiefelbusch Institute for Life Span Studies, University of Kansas, Lawrence, KS*

Background: Sensorimotor abnormalities in autism spectrum disorder (ASD) are highly prevalent, associated with core social and communication impairments, and predictive of worse functional outcomes. Despite frequent reports of increased mixed handedness and atypical lateralization of motor brain networks, few studies have compared precision sensorimotor behavior across dominant and nondominant hands or determined how lateralization of precision motor behavior relates to more complex motor coordination and behavior.

Objectives: 1) Characterize dominant and nondominant precision motor behavior in ASD and healthy controls and 2) Determine associations between sensorimotor behavior and performance on standardized tests of motor abilities.

Methods: A precision grip test was administered to individuals with ASD (N = 63, range = 10-34) and age-matched controls (N = 34). Participants viewed two parallel, horizontal bars (FORCE and TARGET) and were instructed to use their thumb and index finger to press opposing load cells to raise the FORCE bar to the level of the TARGET bar at 15% of maximum voluntary contraction (MVC). Force variability (force SD), and regularity (ApEn) were examined. Clinical measures of fine and gross motor behaviors were evaluated using the Bruininks-Oseretsky Test of Motor Proficiency Ed. 2 (BOT). The Annett Hand Preference Questionnaire was administered to quantify the degree of each individual's lateralized dominance.

Results: Individuals with ASD showed reduced grip strength (MVC) compared to controls when using their dominant hand, but not their nondominant hand. Force SD was increased in ASD compared to controls, but did not differ between hand for either group. Across both groups, ApEn was higher for the dominant compared to the non-dominant hand. Individuals with ASD scored lower on all BOT subscales than healthy controls, including Fine Motor Precision, Fine Motor Integration and Manual Dexterity. Annett rated manual laterality did not differ between groups. Greater ApEn and lower force SD were associated with better performance on the BOT Fine Motor Precision subtest for controls but not for individuals with ASD.

Conclusions: Our finding that grip strength is greater for the dominant relative to the nondominant hand in controls but not in ASD suggests reduced cortical lateralization in patients. These results could reflect perturbations of developmental processes affecting peripheral strength, but lateralized effects more likely reflect neurodevelopmental processes involving specialization of left hemisphere motor cortices. We also find that precision visuomotor behavior is strongly related to everyday tests of fine motor control in healthy controls but not individuals with ASD suggesting that distinct motor issues develop relatively independently in patients. Consistent with previous studies, these findings indicate that deficits in motor skill in ASD cannot be explained by deficits in basic motor behavior alone, but point to dysfunction in left hemisphere parietal-premotor networks that support skilled movements.

443.043 *(Poster)* Relations of Restricted & Repetitive Behaviors to Social Skills in Toddlers with Autism

P. Chaxiong[1], *K. Botteron*[2], *S. R. Dager*[3], *A. Estes*[4], *H. C. Hazlett*[5], *R. T. Schultz*[6], *L. Zwaigenbaum*[7], *J. Piven*[8], *J. Wolff*[9] *and .. The IBIS Network*[5], *(1)Educational Psychology, University of Minnesota, Minneapolis, MN, (2)Washington University School of Medicine, St. Louis, MO, (3)Radiology, University of Washington, Seattle, WA, (4)Speech and Hearing Sciences, University of Washington, Seattle, WA, (5)University of North Carolina, Chapel Hill, NC, (6)Center for Autism Research, Children's Hospital of Philadelphia, Philadelphia, PA, (7)University of Alberta, Edmonton, AB, Canada, (8)*Co-senior author, University of North Carolina, Chapel Hill, NC, (9)University of Minnesota, Minneapolis, MN*

Background: Adaptive behavior refers to the skills an individual needs in order to operate independently in their daily environments and is often assessed in four domains using the Vineland. Previous work suggests that individuals with autism tend to have the highest deficits in the socialization domain (Sparrow et al., 2005). Studies have also found that deficits in adaptive behavior tend be higher than general intelligence would predict for individuals with autism (e.g., Perry et al., 2009; Yang et al., 2016), and this discrepancy is also most consistently seen with socialization (Liss et al., 2001). Wolff et al. (2014) found that restrictive repetitive behavior (RRB) was strongly negatively correlated with socialization, but not other domains of adaptive behavior, during toddlerhood, suggesting interplay between RRB and social skills early in development. What is yet unclear is whether specific forms of RRB differentially impact aspects of early social function.

Objectives: To further elucidate relations between RRB and socialization ability, we sought to address the following research questions:

1. Are RRB subtypes (insistence on sameness [IS], repetitive sensory motor [RSM], self-injurious behavior [SIB]) differentially associated with socialization scores among children with ASD at 24 and 36 months?
2. What are the specific relations between each RRB subtype and each aspect of socialization (coping skills, play-leisure, interpersonal relationships)?

Methods: We analyzed longitudinal RBS-R (Bodfish et al. 2000) and Vineland II data from 24 (n = 63) and 36-month olds (n = 35) with a diagnosis of ASD from an ongoing study. For RQ1, a two-step hierarchical multiple linear regression was conducted with standard socialization score as the dependent variable. Sex and Mullen Early Learning Composite were entered at step 1 as control variables, followed by RRB subtypes in step 2. To examine RQ2, multiple linear regressions were conducted with RRB subtypes predicting three aspects of socialization.

Results: Hierarchical multiple regression for 24-month olds revealed that sex and IQ did not contribute significantly to the regression model. Each subtype of RRB (IS, RSM, and SIB) uniquely explained a significant amount of variation in average socialization score. For 36-month olds, IQ contributed significantly to the regression model at step 1, but not sex. When IS, RSM, and SIB were introduced in step 2, IQ remained a significant predictor and sex became significant only for SIB. Each subtype uniquely explained a significant amount of variation in average socialization score (Table 1). For our second research question, analyses revealed that all three RRB subtypes were significant predictors of all three socialization aspects, with the exception of SIB with interpersonal relationships at 36 months (Table 2).

Conclusions: Our findings provide evidence that all three RRB subtypes are negatively associated with multiple aspects of socialization, with RSM showing the strongest effect. These relations were evident even when accounting for general cognitive ability. It is plausible that early RRB interferes with the acquisition of social skills, though experimental work is necessary to investigate this possibility.

443.044 *(Poster)* Saccade Adaptation and Autism Spectrum Disorder

K. Tarrit[1], *S. Nuvvula*[1], *A. Alves Francisco*[2], *D. J. Horsthuis*[2], *S. Molholm*[1,2], *E. Freedman*[1] *and J. J. Foxe*[1,2], *(1)The Ernest J. Del Monte Institute for Neuroscience, University of Rochester Medical Center, Rochester, NY, (2)Albert Einstein College of Medicine, Bronx, NY*

Background: According to the Center for Disease Control and Prevention, 1 in 59 children is affected by Autism Spectrum Disorder (ASD) which is 4 times more common among boys than among girls. ASD is a neuro-developmental disorder, characterized by social interaction difficulties, communication challenges and a tendency to engage in repetitive behavior. In the literature, there is some evidence that eye movement performances in a saccadic adaptation task are reduced in a subgroup of individual with ASD. However, results are not consistent and more research is necessary to show that this could be used as a potential indicator of ASD.

Objectives: In this paper, we will examine the hypothesis that saccadic adaptation performances are reduced in individuals with ASD compared to typically developing. We will also investigate the impact of individuals' age on those performances.

Methods: In this experiment, individuals between the age of 7 and 45 years old served as participants during a saccadic adaptation task. Thirty were diagnosed with Autism Spectrum Disorder (ASD) while sixty-six were typically developing (TD). Pre-adaptation and post-adaptation trials were similar and started with the presentation of a central fixation cross (T0) that participants were instructed to fixate within ± 1.25° between 600 and 1200 ms. After this interval, T0 was turned off and a new target (T1) was presented 20° to either the left or right or 10° to either the top or bottom of the T0 location. Participants were then asked to look at the T1 target as fast as they could. Initiation of the saccade was detected and the T1 target was turned off before the saccade was complete. After 68 pre-adaptation trials, adaptation trials started. They were similar to pre- and post-adaptation trials, but after the initial saccade ended a new target T2 was illuminated 5° closer to the right of the T0 location. The mean amplitude of the first 10 adaptation trials was also compared to the mean amplitude of the last 10 pre-adaptation trials using a t test (single tailed, p = 0.05). A moving average for each age group was computed to determine the differences in amplitude of the eye movement between TD and individuals with ASD.

Results: In a first analysis, we observed that there were no statistically significant differences in adaptation between ASD and TD populations. However, more subjects adapted in the TD population than the ASD population. A secondary analysis show that there may be some differences in the amplitude of the eye movement depending on the subject's age. TD adults adapt faster than ASD, while children and teenager in both groups have difficulty adapting.

Conclusions: Saccadic adaptation may be reduced in individual with ASD. The data presented in this paper clearly show that there is no significant differences in adaptation between individual with ASD and TD in general. However, the data also show that there is a difference in saccadic adaptation performances between the two groups depending on age.

443.045 *(Poster)* Saccadic Eye Movement Abnormalities in ASD and First-Degree Family Members

S. E. Kelly[1]*, L. M. Schmitt*[2]*, S. P. White*[3]*, J. A. Sweeney*[4] *and M. W. Mosconi*[5]*, (1)Clinical Child Psychology Program, Schiefelbusch Institute for Life Span Studies, Kansas Center for Autism Research and Training (KCART), University of Kansas, Lawrence, KS, (2)Cincinnati Children's Hospital Medical Center, Cincinnati, OH, (3)Department of Pediatrics, Emory University, Atlanta, GA, (4)Psychiatry and Behavioral Neuroscience, University of Cincinnati College of Medicine, Cincinnati, OH, (5)Clinical Child Psychology Program, Schiefelbusch Institute for Life Span Studies, University of Kansas, Lawrence, KS*

Background: Previous studies have identified abnormalities in the accuracy of rapid eye movements (i.e., saccades) in individuals with autism spectrum disorder (ASD) and in first degree relatives of individuals with ASD. Together these findings suggest that impairments in oculomotor control in ASD may be heritable. While previous familiality studies have examined parents separately from their children with ASD, our examination of oculomotor control in family trios (child and biological mother and father) allows for the investigation of parent of origin effects. As the discrete neurophysiological processes that support eye movements have been well defined through single cell recording studies in monkeys and neuroimaging in humans, further investigation into these abnormalities presents an opportunity to gain insight into heritable neurological features associated with ASD.

Objectives: To characterize oculomotor impairments in individuals with ASD and their unaffected biological mothers and fathers.

Methods: Forty-four individuals with ASD (aged 5-22 years), 105 unaffected biological parents, and 73 age-, sex-, and nonverbal IQ-matched typically developing controls (27 matched to ASD participants, 46 matched to parents) completed two oculomotor tasks. During the visually guided saccade task, peripheral stimuli (i.e., white circles) appeared pseudorandomly at $\pm$ 12 or 24 degrees, and participants were instructed to look toward the stimuli as quickly as possible. The latency and accuracy of saccades were measured. During the antisaccade task, targets again were presented at $\pm$ 12 or 24 degrees, and participants were tasked with inhibiting saccades toward the stimuli and making saccades in the opposite direction. The latency and rate of correct antisaccades (i.e., saccades directed away from stimuli) were examined.

Results: Compared to control participants, individuals with ASD exhibited less accurate saccades to 24 degree targets during the visually guided saccade test. Comparisons of ASD parents and controls identified a group x sex x distance interaction in which mothers, but not fathers, of individuals with ASD demonstrated reduced saccade accuracy compared to controls, especially for 24 degree targets. Latencies of visually guided saccades did not differ between individuals with ASD and controls, but parents of individuals with ASD showed reduced latencies relative to controls. Participants with ASD made fewer correct antisaccades than controls, but parents and controls did not differ. No differences in antisaccade latency were seen for probands with ASD or their parents relative to controls.

Conclusions: Reduced saccade accuracy in mothers and their children with ASD implicate alterations in cerebellar mechanisms involved in feedforward movement planning processes in the pathophysiology of ASD. Identification of saccade dysmetria in mothers but not fathers of individuals with ASD suggests that the familiality of this trait may follow a maternal lineage. Our finding that individuals with ASD show a reduced ability to inhibit reactive saccades, but inhibitory control processes were unaffected in parents suggests that higher level cognitive control deficits involving frontostriatal brain circuits may covary with disease state and be specific to individuals with ASD.

443.046 *(Poster)* Self-Rated Executive Function Impairments Among Young Adults with Autism Are Associated with Sensory Processing Experiences.

A. Job Said[1]*, J. Crutcher*[2]*, K. D. Csumitta*[2]*, L. Kenworthy*[3]*, A. Martin*[2] *and G. L. Wallace*[1]*, (1)The George Washington University, Washington, DC, (2)NIMH, Bethesda, MD, (3)Center for Autism Spectrum Disorders, Children's National Hospital, Washington, DC*

Background: Executive functioning (EF) challenges in real world settings are well-documented among children with autism spectrum disorder (ASD). Emerging evidence suggests adults with ASD experience similar difficulties; however, many existing studies have relied upon primarily parent/caregiver report. Therefore, this study examined self-ratings of real-world EF problems among young adults with ASD without intellectual disability and age-matched neurotypical adults. EF challenges, like inflexibility, have been correlated with sensory sensitivity in children with ASD in prior studies, yet these associations have not been evaluated in adults. Thus, we also examined correlations between self-report of both EF difficulties and sensory experiences among adults with ASD.

Objectives: Characterize self-rated real-world EF difficulties experienced by young adults with ASD and their associations with sensory processing.

Methods: Participants consisted of young adults with ASD (n=41; M age=25.60+/-10.28; M IQ=113.49+/-13.86; 32 males) and young neurotypical adults (n=73; M age=24.27+/-7.06; M IQ=117.04+/-11.11; 61 males) who completed psychometrically sound and well-established questionnaires assessing EF (Behavior Rating Inventory of Executive Function-Adult, BRIEF-A) and sensory processing (the Adolescent/Adult Sensory Profile). Analysis of variance was utilized to examine diagnostic group differences in BRIEF-A ratings and interactions between diagnostic group and BRIEF-A scale. Correlational analyses were used to identify associations between BRIEF-A scale ratings and sensory processing domains on the AASP. Where significant associations were identified, these variables were submitted to multiple linear regression analyses with step 1 including control variables of age, sex, and IQ, while step 2 included the additions of the BRIEF-A scales in predicting variance in AASP scores.

Results: Adults with ASD rated themselves as experiencing more EF problems overall than did neurotypical adults (F=58.32, p<.001). When examining the profile of EF difficulties, there was an interaction between BRIEF-A scale and diagnostic group. More specifically, the adults with ASD rated themselves as experiencing particular challenges in shifting/flexibility (M=61.59+/-14.64) and working memory (M=62.93+/-11.88; F=3.78, p=.001). Based on correlational analyses, only two of the BRIEF-A scales were associated with sensory processing in ASD. Follow-up linear regressions demonstrated that after accounting for the effects of age, sex, and IQ, shifting/flexibility challenges were predictive of sensory sensitivity (R^2 change=.28; t=3.25, p=.003) and self-monitoring difficulties were associated with low registration of sensory information (R^2 change=.15; t=2.08, p<.05).

Conclusions: Utilizing self-ratings of EF challenges, we demonstrate comparable EF profiles to those previously documented in autistic adults using parent report. People with ASD rated themselves as having particular difficulties with shifting/flexibility and working memory. Additionally, flexibility problems were correlated with sensory sensitivity while self-monitoring difficulties were associated with low registration of sensory information. These findings strongly support utilizing self-ratings of EF to provide insight into the lived experiences of people with ASD, and establish links between EF and sensory processing in ASD during adulthood for the first time. The shared cognitive and/or neural mechanisms underpinning this relationship should be probed further. EF problems remain an important target for intervention among young adults with ASD.

443.047 *(Poster)* Sensory Processing Patterns in Adults with Autism Spectrum Disorder and Intellectual Disability

N. Bagatell[1]*, Y. C. Syu*[1]*, E. M. Lamarche*[2]*, M. R. Klinger*[3] *and L. G. Klinger*[4]*, (1)University of North Carolina at Chapel H, Chapel Hill, NC, (2)TEACCH Autism Program, University of North Carolina, Chapel Hill, NC, (3)UNC TEACCH Autism Program, Chapel Hill, NC, (4)TEACCH Autism Program; Psychiatry, University of North Carolina, Chapel Hill, NC*

Background: Individuals with ASD often have differences in sensory experience, with some studies reporting atypical sensory behavior in as many as 90% of individuals (Green et al., 2015). While sensory differences are reported to occur across the life span, most of the research has focused on children with few studies addressing sensory processing in adults. The studies on adults typically focus on those without intellectual disabilities (ID) leaving a gap in our understanding of how sensory processing affects daily life in adults with ASD with ID (ASD/ID). Understanding the sensory processing patterns of this group may offer insights regarding strategies to improve participation in daily activities.

Objectives: The objective of this study was to identify patterns of sensory processing in adults with ASD/ID.

Methods: Caregivers of 20 adults with ASD/ID completed the Adolescent/Adult Sensory Profile (AASP) (Brown & Dunn, 2002) as part of a longitudinal study of adults with ASD. The adults with ASD/ID (15 male, 5 female) ranged in age from 30-55 (M = 39.7); all had a full range IQ score < 70 (M = 46; SD = 8.5). The AASP contains 60 items about everyday sensory experiences. Caregivers rated each item based on how frequently behaviors occur. Each item relates to one of four quadrants: low registration, sensory seeking, sensory sensitivity, and sensory avoiding.

Results: Each participant received a raw score for each quadrant in three categories: less than most people, similar to most people, and more than most people. Table 1 shows the number of participants who received a raw score in each quadrant. Participants were similar to most people or more than most people in all quadrants except for sensation seeking. In this quadrant 80% were less than most people. In the low registration and sensation avoiding quadrants, 50% of participants were rated more than most people. Table 2 also shows the mean scores from the AASP standardization study compared with the ASD/ID sample. The ASD/ID sample differed significantly from the AASP standardization group in the sensation seeking quadrant (t=7.65, p<.001).

Conclusions: The results of the study suggest adults with ASD/ID continue to have sensory processing differences and that they may be less sensitive to sensory events and seek out and register less sensory input than most people. According to Dunn's Model of Sensory Processing (1997), this pattern of processing may result in difficulty detecting and responding to sensory stimuli in the environment and less initiation of sensory experiences. This pattern is different than what has been most frequently reported in adults with ASD without ID, where high sensory sensitivity is common (e.g., Clince, Connolly, & Nolan, 2016). The findings of this study highlight the need to understand the distinct sensory needs of adults with ASD/ID and to identify the types of strategies necessary to support participation in daily activities. Given the small sample size and individual variation, further investigation of sensory patterns in adults with ASD/ID is warranted.

443.048 *(Poster)* Sensory Profiles Among Individuals with ASD and ASD+ADHD

C. M. Harkins *and M. O. Mazurek, University of Virginia, Charlottesville, VA*

Background: Sensory problems are a hallmark feature of ASD, but have also been found in individuals with ADHD. It is unclear how ADHD symptoms contribute to sensory dysfunction in individuals with ASD. With the possibility of a comorbid diagnosis of ASD and ADHD recognized by the DSM-5, there is a growing need for research in this domain. The present study explored sensory profiles among individuals with ASD without ADHD (ASD group) and individuals with ASD with clinically-significant ADHD symptoms (ASD+ADHD group).

Objectives: To investigate differences in type and severity of sensory problems reported by individuals with ASD and ASD+ADHD.

Methods: Participants included 473 individuals with ASD ages 2-16 (M=6.10, SD=3.22) participating a larger research study. ADHD symptoms were assessed using the CBCL DSM-oriented subscale for ADHD. Participants with clinically-significantly ADHD symptoms were included in the ASD + ADHD group. The ASD group consisted of 370 individuals (80.81% male) and the ASD + ADHD group consisted of 103 individuals (77.67% male). Parents completed the Short Sensory Profile (SSP) and IQ was assessed using various measures. Lower scores on the SSP indicate greater dysfunction while higher scores indicate less sensory dysfunction. A one-way ANCOVA was performed to evaluate group differences on the SSP total score, controlling for age, gender, and IQ. A one-way MANCOVA was conducted to examine group differences on the seven subscales of the SSP, while controlling for age, gender, and IQ. A Bonferroni correction was performed to account for multiple comparisons (a=.0071) and pairwise contrasts were evaluated.

Results: Bivariate Pearson correlations were calculated between the SSP total score and age (r=.129, p=.005) and IQ (r=-.024, p=.610), and a t-test was conducted to evaluate the relationship between gender and SSP total score, t(471)=-2.99, p<.001. The ANCOVA revealed that the ASD and ASD+ADHD groups differed significantly on the SSP total score, $F(1, 472)=53.85$, $p<.001$, with the ASD group obtaining higher total scores on the SSP (M=136.16, SD=24.16), indicating less impairment, than the ASD+ADHD group (M=116.83, SD=22.34). The MANCOVA revealed a statistically significant difference between the groups on the combined dependent variables after accounting for all covariates, $F(7, 462) = 19.72$, $p < .001$, Wilks' $\Lambda = .77$, partial $\eta 2 = .23$. The ASD+ADHD group demonstrated greater sensory dysfunction, on average, than did the ASD group for all subscales. The ASD+ADHD group scored significantly lower, indicating greater impairment, on the underrepsonsivity subscale, $F(1, 468)=120.44$, p<.0001, $h^2=.21$, the auditory filtering subscale, $F(1, 468)=64.38$, p<.0001, $h^2=.12$, and the visual/auditory sensitivity, $F(1, 468)=32.69$, p<.0001, $h^2=.07$.

Conclusions: Greater sensory impairment was reported for the ASD+ADHD group compared to the ASD group across all subscales. ADHD symptoms may exacerbate impairment in individuals with ASD. ADHD symptoms were associated with increased sensation seeking, greater auditory filtering difficulties, and hyper-sensitivity to visual and auditory stimuli. It is possible that the diminished inhibitory control, hyperactivity, and attention difficulties characteristic of ADHD may drive these increased sensory problems.

443.049 *(Poster)* Sensory Profiles As Predictors of Adaptive Behavior in Toddlers with Autism

E. Worthley[1], *R. L. Grzadzinski*[2], *K. Botteron*[3], *S. R. Dager*[4], *A. Estes*[5], *H. C. Hazlett*[6], *R. T. Schultz*[7], *L. Zwaigenbaum*[8], *J. Piven*[9], *J. Wolff*[1] *and .. The IBIS Network*[6], *(1)University of Minnesota, Minneapolis, MN, (2)University of North Carolina Chapel Hill, Chapel Hill, NC, (3)Washington University School of Medicine, St. Louis, MO, (4)Radiology, University of Washington, Seattle, WA, (5)Speech and Hearing Sciences, University of Washington, Seattle, WA, (6)University of North Carolina, Chapel Hill, NC, (7)Center for Autism Research, Children's Hospital of Philadelphia, Philadelphia, PA, (8)University of Alberta, Edmonton, AB, Canada, (9)*Co-senior author, University of North Carolina, Chapel Hill, NC*

Background: Individuals with autism spectrum disorder (ASD) have, on average, atypical responsivity to sensory stimuli that includes hypo- and hyper-responsivity as well as sensory seeking behaviors (Baranek, David, Poe, Stone, & Watson, 2006; Ben-Sasson et al., 2009). Previous work has shown that elevated sensory profiles (i.e. hypo, hyper, and seeking) have been shown to predict later adaptive behavior skills in elementary school aged children with ASD (Williams et al., 2018; doi:10.1016/j.ridd.2018.07.002). What is not yet known is whether these findings generalize to infants and toddlers with ASD.

Objectives: The objective of the current study was to determine whether or not sensory profiles predict adaptive behaviors among high-risk infants and toddlers who are later diagnosed with ASD. We achieve this through a replication and downward extension of methods and procedures described by Williams et al. (2018).

Methods: Data were collected as part of an ongoing longitudinal study of high risk infant siblings. Of the high-risk sibling group (n=391), 90 toddlers went on to receive an ASD diagnosis based on clinical best estimate (HR-ASD). This study analyzed parent report data on sensory responsivity, collected at 12 months of age (Sensory Experiences Questionnaire; SEQ 2.1) and a semi-structured assessment of adaptive behavior collected at 36 months of age (Vineland Adaptive Behavior Scales; Vineland-II) in the HR-ASD group specifically. A series of hierarchical multiple linear regressions were computed using sensory profiles (hyperresponsivity, hyporesponsivity, and sensory seeking) to predict adaptive behaviors (communication, socialization, daily living skills, and motor skills). Other model variables included sex, age at the first point of data collection, household income, maternal education, elapsed time between the first point of data collection and the second point of data collection, and an IQ proxy (Mullen Early Learning Composite; MSEL-ELC).

Results: For toddlers with ASD, the inclusion of hyperresponsivity scores at age 12 months to the base model predicted deficits in communication at age 36 months (. Hyperresponsivity scores on the SEQ () and the MSEL-ELC () were significant predictors in the model. Hyperresponsivity did not predict other domains of adaptive behavior. While Williams et al., (2018) found that a hyporesponsivity model predicted socialization scores, results for our sample did not indicate a significant predictive relation with for the addition of hyporesponsivity scores (total $R^2 = 0.26$). Overall, hyporesponsivity and seeking behaviors at 12 months did not significantly predict adaptive behavior domain scores at 36 months.

Conclusions: Results suggest that the predictive relation of sensory profiles with later adaptive function seen reported in school-age children with ASD partially extend to familial high-risk infants later diagnosed with ASD. In particular, sensory hyperresponsivity in late infancy was strongly related to communication ability at preschool age. These results suggest that early differences in sensory responsivity could have downstream developmental consequences related to language function, though further research is necessary to explore this possibility (Baranek et al., 2018). If a causal link between early sensory responsivity and language acquisition is found, it would have potentially important implications for early intervention.

443.050 *(Poster)* Sleep Problems and Externalizing Behavior in Children with ASD: The Effect of Restricted and Repetitive Behavior

L. A. Alba[1], *M. R. Ledoux*[2], *K. K. Stavropoulos*[1] *and J. Blacher*[1], *(1)Graduate School of Education, University of California Riverside, Riverside, CA, (2)Graduate School of Education, University of California, Riverside, Riverside, CA*

Background: Restricted and repetitive behavior (RRB) is a core characteristic of autism spectrum disorder (ASD), along with social communication difficulties[1]. Children with ASD often experience co-occurring mental and physical health issues[2]. Studies report that 50-80% of children with ASD[2,3] experience sleep problems (e.g., night-waking, insomnia)[4,5], compared to 20-30% of neurotypical children[6]. Additionally, children with ASD (i.e., between 25-70% [2,7]) often demonstrate behavioral difficulties (e.g., aggression, inattention). There is evidence that sleep problems and behavior problems exacerbate each other; however, the direction of this relationship remains unclear[8-10]. The relationship between RRBs, sleep problems, and externalizing behavior is not well understood. This study measured the relationship between sleep problems, externalizing behaviors, and RRBs in children with ASD.

Objectives:

1. What is the association between sleep problems, externalizing behavior, and RRBs in children with ASD?
2. Do RRBs mediate the relationship between sleep problems and externalizing behavior?
3. When mediated by RRBs, is there a bidirectional relationship between sleep problems and externalizing behavior?

Methods: Seventy children with ASD (mean age (*SD*)= 4.14 years (.92); *range*=2.10-5.70); 46% Latinx) and their parents from a screening clinic sample participated. Parents completed a demographic intake form, the Child Behavior Checklist (CBCL), and Social Responsiveness Scale (SRS). Children were screened for ASD using the Autism Diagnostic Observation Schedule-Second Edition (ADOS-2). Sleep problems and externalizing behavior were derived from the CBCL subscale *T*-scores; RRBs were derived from the mannerisms/RRB subscale *T*-score of the SRS.

Results: Externalizing behavior was negatively correlated with maternal education (p=.007), while age was positively correlated with externalizing behavior (p=.02); partial correlations were conducted controlling for maternal education and age. RRB was positively correlated with sleep problems (p= .005) and externalizing behaviors (p< .001). Sleep problems were positively correlated with externalizing behavior (p<.001). Maternal education and age were covariates in the mediation analyses.

Using PROCESS[11] model 4, mediation analyses were conducted. The overall model was significant, $F(4, 57)= 19.62$, p <.001, R^2= .58. RRBs (M_1) significantly mediated the relationship between sleep problems (X) and externalizing behavior (Y) (b= .10, SE= .04, 95% CI = [.02, .20]). The direct effect between sleep problems and externalizing behaviors was significant (b=.48, SE=.09, $t(62)= 5.14$, p< .001, 95% CI [.29 - .67]).

To explore whether the relationship between sleep problems, externalizing behavior, and RRB is bidirectional, another mediation was conducted, with externalizing behavior as (X), sleep problems as (Y) and RRB as (M_1). The overall model was significant, ($F(4,57)= 10.54$, p <.001, R^2= .43). However, the indirect effect was not significant, (b= .04, SE= .06, 95% CI = [-.08, .14]) suggesting that RRBs did not mediate the relationship between externalizing behavior and sleep problems. The direct effect between sleep problems and externalizing behaviors was significant (b=.65, SE=.12, $t(67)= 5.46$, p< .001, 95% CI [.41 - .89]).

Conclusions: Findings contribute to the growing literature implicating RRBs as a mediator of the relationship between sleep problems and externalizing behavior. This line of research is critical for increasing awareness of sleep problems and externalizing behavior in children with ASD and to develop effective treatment strategies.

443.051 *(Poster)* Sound Sensitivity: How Auditory Hypersensitivty Is Expereinced By Individuals with ASD

J. Yang[1], *B. Bahmei*[2], *R. Fisher*[3], *A. Herdman*[4], *G. Iarocci*[3], *S. Arzanpour*[2] *and E. Birmingham*[1], *(1)Faculty of Education, Simon Fraser University, Burnaby, BC, Canada, (2)Mechatronic Systems Engineering, Simon Fraser University, Surrey, BC, Canada, (3)Psychology, Simon Fraser University, Burnaby, BC, Canada, (4)University of British Columbia, Vancouver, BC, Canada*

Background:

Auditory hypersensitivity to specific stimuli is demonstrated in children with ASD, and interferes with participation in social, educational and recreational activities. However, more research is needed on the nature of children's responses to sounds in their environments.

Objectives:

Many children with Autism Spectrum Disorders (ASD) experience auditory hypersensitivity. The goal of the current study was to 1) determine how auditory hypersensitivity influences the everyday lives and behaviors of individuals with ASD, and 2) explore the nature of responses to specific sounds including loudness comfort levels.

Methods:

Adolescents with ASD (aged 13-18 years) and their parents were recruited to complete 3 sessions in the lab. Inclusion in the full study required full-scale IQ>85 (Weschler Abbreviated Scale of Intelligence) and normal hearing thresholds (<=25db) confirmed by pure-tone audiometry for each ear. Session 1 included interviews, questionnaires (e.g., the Child Sensory Profile 2 [CSP2], Adolescent/Adult Sensory Profile [ASP], and the Auditory Sensitivity and Child Safety Questionnaire [ASCSQ]). In Sessions 2 and 3, youth were presented with sounds that they reported to be pleasant (Session 2) or aversive (Session 3). Participants were asked to manually adjust the volume and/or pitch of sounds to a comfortable listening level while wearing a wristband measuring physiological signals (e.g., Empatica E4), and to rate the sounds on loudness comfort level using a 4-point Likert scale.

Results:

Preliminary results from Session 1 (n = 5 families, mean age of child 15.4 years) confirmed that all children experienced negative reactions to sound in the last 6 months. Frequency of negative reactions: every day (1/5), a few times/month (2/5), once/month (2/5). The number of specific sounds that trigger the participants ranged from 2-3 sounds to more than 10 sounds. Among sounds that trigger participants' negative reactions, they are described to be loud (4/5), sudden (4/5), shrill (3/5), high-pitched (2/5), and repetitive (2/5). Specific reactions to aversive sounds included being anxious (4/5), irritable (3/5), not responding to name (3/5), yelling and screaming at other children/adult (2/5), and being unaware of surroundings (2/5). Various strategies that were used by parents included blocking or staying away from the source of noises (e.g., earbuds, leaving the environment; 3/5), gradual exposure to aversive sounds (1/5), and no specific strategies (1/5). Despite various strategies, frequency of participant experiencing limited participation in school activities: always (2/5), sometimes (2/5), rarely (1/5); in family activities: always (1/5), frequently (2/5), rarely (1/5), and never (1/5); in community activities: always (1/5), sometimes (2/5), rarely (1/5), never (1/5). When sound hypersensitivity issues compared with other ASD related behaviors, parents described them as one of the most concerning behaviors (1/5), concerning but not the most concerning behaviors (2/5), and not that concerning compared to other behaviors (2/5).

Data collection for Session 2 and 3 is in progress and will be available for the poster.

Conclusions:

Auditory hypersensitivity is an important challenge in ASD. The results of this study will shed new light on the nature of this issue and how it affects families.

443.052 *(Poster)* Swipe Kinematics Differ in Different Aged Children with Autism Spectrum Disorders during Smart-Tablet Gameplay

S. C. Lu[1], *P. Rowe*[2], *C. Tachtatzis*[3], *I. Andonovic*[3], *A. Anzulewicz*[4,5], *K. Sobota*[4] *and J. Delafield-Butt*[1], *(1)Laboratory for Innovation in Autism, University of Strathclyde, Glasgow, United Kingdom, (2)Department of Biomedical Engineering, University of Strathclyde, Glasgow, United Kingdom, (3)Department of Electronic and Electrical Engineering, University of Strathclyde, Glasgow, United Kingdom, (4)Harimata Sp. z.o.o., Kraków, Poland, (5)Faculty of Psychology, University of Warsaw, Warsaw, Poland*

Background: Atypical movement patterns in people with autism spectrum disorders (ASD) have been reported (Dowd et al., 2012; Trevarthen and Delafield-Butt, 2013; Cook, 2016). In our previous observation, children with ASD moved slower than typical developing (TD) children in a goal-oriented food-sharing task during smart-tablet gameplay (Lu et al., 2019). However, contradictory results have been noticed in another cohort. Further, it is well known that visual-motor integration skills change dynamically in early childhood, improving remarkably at 4-5 years old (von Hofsten and Rösblad, 1988; Fang et al., 2017). Consequently, this study re-examines the swipe kinematics in different age groups.

Objectives: This study compares the goal-oriented swipe kinematics of ASD and TD children in different age groups, and determines the feasibility of using smart-tablet devices to identify movement signatures in children with ASD.

Methods: Gameplay data from two cohorts were analysed: Cohort 1, a previous study (Anzulewicz et al., 2016), in which 45 TD and 37 ASD children aged 25-79 months took part; in Cohort 2, 316 TD and 202 ASD children aged 30-90 months participated as part of a multi-site trial (Millar et al., 2019). The participants played a food-sharing game on a smart-tablet (iPad mini, Apple Inc.) and their on-screen touch trajectories were recorded. The data were analysed using customised MATLAB scripts. The food-to-target swipes data were mined to yield the duration, travelled distance, minimal distance (distance between the start and end points), distance difference (the difference between the travelled and minimal distances), and average speed (travelled distance divided by duration) of each swipe. The data were then categorised into two age groups: <60 months and ≥60 months, and Mann-Whitney U tests were used to determine kinematic differences between TD and ASD in each age group.

Results: In Cohort 1, ASD moved significantly faster than TD at the younger age (median of 52.65 mm/s vs. 49.70 mm/s) while they moved significantly slower than TD at the older age (median of 46.82 mm/s vs. 81.72 mm/s). The same pattern was observed in Cohort 2, the median value of average speed being 57.81 mm/s in ASD vs. 49.65 mm/s in TD at the younger age, and 65.81 mm/s in ASD vs. 67.00 mm/s in TD at the older age. An analysis on the combined data from the two cohorts yielded the same patterns in the average speed (see details in the attached image).

Conclusions: The kinematic differences between TD and ASD during goal-oriented swipe movements follow different profiles in different age groups; ASD moved faster than TD at the younger age (<60 months) while they moved slower than TD at the older age (≥60 months), suggesting different strategies should be used for different aged children with ASD to compensate the disruption to their sensorimotor control. This study also demonstrates the feasibility of using smart-tablet devices to support the early identification of ASD in the gameplay paradigms.

443.053 *(Poster)* The Body Movement When Persons with ASD Walk through the Narrow Space.

S. Imura[1] *and J. Adachi*[2]*, (1)Hokkaido University, Sapporo, Japan, (2)Graduate School of Education, Hokkaido University, Sapporo, Japan*

Background: It is said that persons with Autism Spectrum Disorders (ASD) have awkwardness in walking. Takahashi (2011) reported that persons with ASD diagnosis encounter problems when walking. In his questionnaire survey, many persons with ASD gave an answer like that they sometimes bump into someone when passing by one another. Based on his survey, Takahashi suggested the possibility that people with ASD have difficulty recognizing the positional relation between their body and surrounding objects.

Objectives: This study focuses on the differences of body movement of people between those with and those without ASD when they walk through a narrow walkway. The measurements of this study are as follows: (1) the angle of the trunk rotation and (2) the time taken for each step to go through the walkways of different widths.

Methods: There were 18 participants in this study, and they were divided in to two groups, “control (Non-ASD) group” (N=11, mean age=22.36 years) and “ASD group” (N=7, mean age=29.14 years). This study consisted of three phases; Pre-test, Instruction video, and Post-test. In Pre-test and Post-test, we let participants walk through the narrow walkway (7meters long) with their ordinary speed. There were three walkway conditions with differing widths of narrowness. (1)narrow condition (which is 10% narrower than the width of participants’ back), (2) equivalent condition (which is as wide as the width of participants’ back), and (3) wide condition (which is 10% wider than the width of participants’ back). We recorded video throughout this study.

Results: The ASD group tend to rotate trunk more than necessary when they walk through the narrow space(Figure 1). The rate of change of the time taken for each step was significantly different between control group and ASD group (U=9.0 *p=.27)(Figure 2).

Conclusions: We can say that the pattern of the transition in angle of trunk rotation is irregular in the ASD group, but on the other hand, the pattern of it for the control group is constant. We concluded that typically developed persons require less amount of labor to walk. Moreover, the participants in the ASD group took a longer time than the control group when they walked for each step when they went through the narrow walkway. In the experiment, we instructed the participants to be careful not to touch the obstructions which formed the narrow space when they walked. We thought that persons with ASD tended to focus on not touching the obstructs more than the persons in the control group. So that, in conclusion, we thought that persons with ASD feel difficulty in moving their body correctly in demanding situations, such as when walking in narrow spaces.

443.054 *(Poster)* The Effect of Sensory Processing on Emotion Regulation in Autism Spectrum Disorder and Typical Development

J. Ziolkowski[1]*, M. Malihi*[2]*, R. Cardy*[1]*, J. Nguyen*[1]*, B. Andrade*[3]*, A. Dupuis*[4]*, S. Monga*[5]*, J. A. Brian*[1]*, E. Anagnostou*[1] *and A. Kushki*[6]*, (1)Holland Bloorview Kids Rehabilitation Hospital, Toronto, ON, Canada, (2)University of Toronto, Toronto, ON, Canada, (3)Centre for Addiction and Mental Health, Toronto, ON, Canada, (4)Biostatistics, University of Toronto, Dalla Lana School of Public Health, Toronto, ON, Canada, (5)The Hospital for Sick Children, Toronto, ON, Canada, (6)Bloorview Research Institute, Toronto, ON, Canada*

Background: Emotion regulation is broadly defined as a collection of processes that enable emotion modulation alongside a host of goal-directed behaviours. Difficulties with emotion regulation are prevalent in autism spectrum disorder (ASD) and have been identified as a risk factor for a variety of psychopathologies. Although the underpinnings of emotion dysregulation remain largely unknown in ASD, sensory processing sensitivity is posited to be among the many contributing factors due to feelings of discomfort and distress that are experienced.

Objectives: The primary objective of this study was to investigate the association between sensory processing and emotion regulation abilities in children with ASD and to examine whether this association differs between ASD and typical development (TD).

Methods: Participants (age range 8 to 12 years) consisted of 14 ASD (mean age = 10.35 years; 2 females) and 15 TD individuals (mean age = 9.13 years; 7 females) from an ongoing study. All subjects had IQ scores of $\geq$ 85. Caregivers completed the Short Sensory Profile (SSP) to assess participants' ability to process sensory information and respond to sensory experiences. Emotion regulation was measured with the Emotion Dysregulation Inventory (EDI), a 30-item parent questionnaire validated in ASD samples. Subscales of this questionnaire include Reactivity Short Form (EDI-RS) and Full Reactivity (EDI-FR) indices which assess the degree of intense, poorly regulated negative emotional reactions, as well as the EDI Dysphoria Index (EDI-DI) which evaluates anhedonia and nervousness. T-scores from each subscale were used for analyses.

Results: There was no effect of age, diagnosis, or sex on emotion regulation scores. Linear regression revealed significant associations between total SSP score and the EDI-RS ($F(3, 24) = 13.949$, $p < 0.001$, $R^2 = 0.63$), EDI-FR ($F(3, 24) = 4.767$, $p = 0.018$, $R^2 = 0.37$), and EDI-DI ($F(3, 24) = 2.470$, $p = 0.043$, $R^2 = 0.23$). This pattern of results was largely consistent across SSP sensory modalities. Visual/Auditory Sensitivity significantly predicted scores on the EDI-RS ($p = 0.001$) and EDI-FR ($p = 0.040$). Similarly, Tactile Sensitivity significantly predicted performance on the EDI-RS ($p < 0.001$) and EDI-FR ($p = 0.004$). Underresponsive/Seeks Sensation values were significantly correlated with EDI-RS ($p = 0.002$), EDI-FR ($p = 0.007$), and EDI-DI ($p = 0.009$) subscales. Finally, Taste/Smell Sensitivity ($p = 0.013$), Movement Sensitivity ($p = 0.020$), Low Energy/Weak ($p = 0.009$), and Auditory Filtering ($p = 0.018$) domains were significantly associated with the EDI-RS subscale.

Conclusions: Taken together, the results suggest that greater levels of sensory sensitivity enhance susceptibility to emotion dysregulation irrespective of diagnosis. When replicated in larger samples, these findings may improve the current conceptualization of factors contributing to emotion dysregulation in ASD.

443.055 *(Poster)* The Impact of Sensory Processing Differences on Academic Achievement and Classroom Behaviour for Autistic and Neurotypical Pupils

E. Jones[1]*, M. Hanley*[2] *and D. M. Riby*[3]*, (1)Durham University, Durham, United Kingdom, (2)South Road, Durham University, Durham, United Kingdom of Great Britain and Northern Ireland, (3)Department of Psychology, Durham University, Durham, United Kingdom*

Background: In 2017, 70.4% of pupils in the UK achieved a grade C or above in GCSE English or Maths. In contrast, only a third of autistic pupils achieved this 'high pass' grade. Identifying the factors that contribute to variability in academic attainment is vital as it is associated with a range of future outcomes. For neurotypical pupils, intellectual functioning (IQ) has been identified as a powerful predictor of academic success (Deary et al., 2007). However, this association is not consistently found in autism, with many pupils displaying achievement profiles that are not commensurate with IQ (Estes et al., 2011). We hypothesize that sensory atypiclaities may be one factor that impacts upon autistic pupil's academic achievement. Indeed, the typical classroom contains rich sensory inputs that may not be compatible with the sensory needs of pupils, which in turn could impact upon learning (Barrett et al., 2015).

Objectives: The first aim of the current study was to apply hierarchical linear regression to examine if sensory processing differences related to academic achievement and classroom behaviour for autistic and neurotypical pupils. Using model-based cluster analysis, our second aim was to also explore if sensory subtypes could be identified, before examining if these subtypes differed on academic achievement (Aim 3).

Methods: Thirty-six autistic (Mean Age =8.87, SD=1.39) and 28 (Mean Age= 8.36, SD =1.51) neurotypical children between the ages of six and eleven participated in the current study. All autistic pupils attended special education provision whereas all neurotypical children attended mainstream primary schools. The neurotypical group (M= 110.35, SD=14.5) had a significantly greater mean IQ compared to the ASD group (M=83.53, SD=12.60) and therefore analysis was undertaken for each group separately. Children completed the reading and mathematics subscales of the Wechsler Individual Achievement Task, in addition to the Wechsler Abbreviated Scale of Intelligence. Teachers completed the School Companion Sensory Profile (SCSP) and the Connors Teachers Questionnaire.

Results: IQ and SCSP Behaviour Scores, which provide an overall rating of a persons way of acting relating to sensory experiences, accounted for 57.2% of the variance in autistic pupils reading scores. IQ however was found to be the only significant predictor of academic achievement for neurotypical pupils (17% variance explained). Significant positive correlations were also found between sensory differences and classroom behaviour, such that greater sensory differences were related to greater behavioural challenges in the classroom. Using model-based cluster analysis we established the presence of two sensory subtypes within the autistic group, which differed on the severity of differences (Figure 1). Although groups did not differ on academic outcomes, the subtype characterized by greater severity of sensory differences was found to have significantly greater levels of hyperactivity and aggression in the classroom.

Conclusions: Sensory processing differences can significantly impact academic achievement and classroom behaviour for autistic pupils. However, there is considerable heterogeneity in terms of academic achievement and sensory processing differences. A direct link between sensory differences and poor academic achievement is unlikely. Rather variables, such as attention, multisensory integration and anxiety may moderate this relationship.

443.056 *(Poster)* The Interaction of Fine Motor and Structural Language Skills in ASD

E. Taverna[1]*, I. M. Eigsti*[2] *and D. A. Fein*[2]*, (1)Department of Psychological Sciences, University of Connecticut, Storrs, CT, (2)Psychological Sciences, University of Connecticut, Storrs, CT*

Background: Motor skills are related to language skills in typical development (Iverson, 2019); they may contribute to the development of language skills by, e.g., facilitating opportunities for labelling (Smith & Yu, 2012). Individuals with ASD consistently show impairments in both basic and complex motor skills (Jansiewicz et al., 2006; Dzuik et al., 2007; Bhat et al., 2011; Whyatt & Craig, 2013). Moreover, motor skills predict ASD symptom severity (Bal et al., 2019); motor skills at two years were the best predictor of losing the ASD diagnosis at age four (Sutera et al., 2007). Our team has studied children with documented ASD, who no longer have symptoms in adolescence (Loss of ASD Diagnosis, or LAD; Fein et al 2013). We test whether language development mediates the relationship between motor skill deficits and ASD outcomes and severity.

Objectives: This study assessed group differences in fine motor imitation skills, and tested relationships among *fine motor* skills, *language* skills, and *autism symptomatology* in youth with ASD, LAD. or a history of typical development (TD).

Methods: Participants were children, adolescents, and young adults with ASD (*n*=14), LAD (*n*=14), and TD (*n*=12), ages 8-16, all with FSIQ scores in the typical range; details in Table 1. Measures included assessments of ASD symptomatology, IQ, and language abilities, as well as the NEPSY-II Imitating Hand Positions subtest, a reliable measure of motor imitation.

Results: All scores were in the average range (aside from participants as follows: *n*=2 LAD, *n*=5 ASD, *n*=1 TD) suggesting generally intact motor imitation. ANOVA revealed a significant group difference in fine motor imitation, F=4.58, p=0.01; this group difference was driven by lower scores in the ASD relative to the LAD groups, t=2.48, p=0.02. The LAD/TD and ASD/TD groups did not differ, p's>.05.

Multiple regression analyses revealed that, controlling for IQ, both fine motor imitation (β=-0.30, p<0.05) and core language (β=-0.63, p<0.001) independently predicted total ADOS score. NEPSY fine motor imitation did not predict CELF core language (r=0.21, p=0.22). Contrary to predictions, fine motor skills did not predict core language skills (p=0.51).

Conclusions: Results suggest that individuals who lost the ASD diagnosis by adolescence show significantly better motor imitation skills, compared to their peers with current ASD. Further, those fine motor imitation skills, along with structural language abilities, were associated with ASD symptoms, over and above FSIQ. There was no mediation of motor abilities and language vis a vis ASD symptoms; the two domains were relatively independent. The results of the present study are consistent with the hypothesis that individuals with stronger praxis skills are better at gesture and other nonverbal aspects of communication such as mirroring, contributing to more "typical" scores on the ADOS. Results are also consistent with a less-specific model in which individuals with stronger skills in Domain A are more likely to have stronger skills in Domain B (e.g., the "Matthew effect"). These findings highlight the importance of motor deficits in contributing to core symptoms of ASD. Results need to be extended using a task probing non-social (non-imitative) motor skills.

443.057 *(Poster)* The Relationship between Perceptual Ability and Cognition Changes from the School-Age to Adolescence in Autism.

D. Silvestre[1]*, L. Mottron, M.D.*[2] *and A. Bertone*[1]*, (1)Perceptual Neuroscience Lab (PNLab) for Autism and Development, McGill University, Montreal, QC, Canada, (2)Autism Research Group, CIUSSS du Nord-de-l 'Île-de-Montréal, Montréal, QC, Canada*

Background: Autistic individuals often demonstrate faster and more accurate performance on the Block Design Task (BDT) subtest of the Wechsler Intelligence Scale. Such cognitive peaks have been explained by an optional use of "top-down" flow of information (Caron et al, 2006), resulting in a more local-level analysis, or a "bottom-up" effect of enhanced low-level perceptual information (Muth et al, 2014). Meta-analyses suggest that the autistic local bias leading to superior performance on visuo-spatial tasks is unequally replicated in hierarchical tasks, may vary according to the way *local* and *global* processes are operationalized across tasks, and may originate from perceptual processes in autism (van de Hallen, 2015). Accordingly, although autistic individuals demonstrate a unique lower-level perceptual phenotype, with more efficient processing of luminance-defined stimuli compared to stimuli defined by more complex physical attributes such as texture (Bertone et al., 2005), this perceptual influence is most often never considered when assessing cognitive peaks in autism.

Objectives: This study aimed to assessed visuo-spatial perception in autism while manipulating both the cohesiveness (biasing top-down local and global analysis) and perceptual attributes (biasing bottom-up analysis) of the patterns of a computerized BDT completed by school-aged and adolescent participants.

Methods: Thirty autistic and 30 neurotypical (NT) children and adolescents (7-18 years of age) completed a reversed match-to-sample BDT (Caron et al, 2006) on a touchscreen where they were asked to match a centrally presented target block design with one of four segmented surrounding probes (see Figure 1). Top-down processes were assessed by manipulating the pattern cohesiveness of the block patterns (low-cohesiveness (LC) = block-by block, local-level analysis; high-cohesiveness (HC) = pattern-first, global-level analysis). Bottom-up influences were assessed by manipulating low-level, perceptual attributes of the component block surfaces comprising the block patterns across three conditions: traditional (red/white), high-contrast luminance, (black/white), and texture information (high- vs low-contrast noise) (see Figure 2). Both cognitive (cohesiveness) and perceptual (block attribute) manipulations were assessed for target-probe combinations defined by three matrix sizes: 4 (2 x 2) blocks, 9 (3 x 3) blocks, and 16 (4 x 4) blocks.

Results: While the autism group had significantly faster RTs compared to the NT group at young ages in the 4-block matrix, the NT group improved across age at a faster rate compared to the autism group. In the 16- block condition, the autism group had significantly slower RTs for the LC texture-defined pattern condition (compared to HC patterns) compared to the NT group with increasing age.

Conclusions: For most conditions assessed, manipulating the physical block attributes did not differentially affect performance across age. However, when the reverse-BDT biased a local processing style (LC) and was defined by a large matrix size (16 blocks), the autism and NT groups performance changed with age in a different manner, but only when blocks were texture defined. This suggest that under under high task demands (texture-defined information and 16 blocks), the development of visuo-spatial abilities in autism across age is contingent on the physical attributes defining its local components.

443.058 *(Poster)* The Relationship between Sensory Reactivity Differences, Intolerance of Uncertainty and Anxiety Symptomology in Young Autistic Children

K. MacLennan *and T. Tavassoli, Centre for Autism, School of Psychology & Clinical Language Sciences, University of Reading, Reading, United Kingdom*

Background: 60-90% of autistic individuals experience sensory reactivity differences, such as being hyperreactive (e.g. over-sensitive to sounds), hyporeactive (e.g. under-responsive to touch), or seeking (e.g. fascinated by lights). Additionally, over half of autistic children experience co-morbid anxiety. Sensory hyperreactivity has previously been linked to anxiety in autistic children and intolerance of uncertainty (IU) and has been suggested to mediate the relationship. However, little is understood about how sensory reactivity differences relate to IU and specific anxiety symptomology, such as generalised anxiety disorder (GAD). Additionally, research has not yet explored this relationship in young autistic children.

Objectives: This study aimed to elucidate the relationships between sensory reactivity differences, IU and specific anxiety symptomology in autistic children aged 3-5 years.

Methods: Sensory reactivity differences, anxiety and IU were assessed for 54 autistic children (age 3 – 5 years, 13 females, 41 males).

Caregiver reported and observed sensory reactivity differences was measured by the Sensory Processing Scale Inventory (SPSI). Caregiver-reported total anxiety, separation anxiety (SAD), physical injury fears (PIF), social phobia (SOC), obsessive-compulsive disorder (OCD), and GAD was measured by the Preschool Anxiety Scale (PAS). Caregiver reported IU was measured using the Responses to Uncertainty and Low Environmental Structure (RULES) questionnaire. In addition, broader autism traits were assessed using the Autism Spectrum Quotient (AQ).

The relationship between sensory reactivity differences, IU and anxiety was analysed using partial correlation analysis controlling for autism traits. Mediation analysis was then conducted to explore the total, direct and indirect effects between sensory hyperreactivity and anxiety through IU.

Results: Partial correlation analysis (table 1) revealed significant correlations between SPSI sensory hyperreactivity and total anxiety ($r_s = .57$, $p < .001$), SOC ($r_s = .45$, $p = .001$), PIF ($r_s = .44$, $p = .002$), SAD ($r_s = .49$, $p < .001$), OCD ($r_s = .40$, $p = .004$) and GAD ($r_s = .49$, $p < .001$). There were no significant correlations between sensory hyporeactivity or seeking and anxiety ($p > .05$).

Significant correlations were also found between IU and SPSI sensory hyperreactivity ($r_s = .61$, $p < .001$), total anxiety, ($r_s = .70$, $p < .001$), SOC ($r_s = .56$, $p < .001$), PIF ($r_s = .41$, $p < .001$), SAD ($r_s = .65$, $p < .001$), OCD ($r_s = .60$, $p < .001$) and GAD ($r_s = .64$, $p < .001$).

Mediation analysis controlling for AQ (figure 1) indicated that the relationship between sensory hyperreactivity and anxiety is mediated by IU, as the indirect coefficient was significant, (B = .356, SE = .10, LLCI = .1733, ULCI = .5804).

Conclusions: Our results suggest sensory hyperreactivity is related to IU and anxiety in young autistic children, and that the relationship is mediated by IU. Future directions should explore this relationship longitudinally. Understanding the relationship between sensory reactivity, IU and anxiety is important for developing early clinical interventions to improve outcomes for autistic children.

443.059 *(Poster)* The Relationship between Stereotyped Behaviors and Oral Sensitivity in Autism: An Exploration in the ACE Gendaar Cohort

E. L. Richard *and A. Jack, The George Washington University, Washington, DC*

Background: Autism Spectrum Disorder (ASD) is typified by impaired social communication and restricted, repetitive patterns of behavior and interests (RRBIs; APA, 2013). Disrupted eating patterns (e.g., 'picky' eating, overeating) have also been documented in ASD (Ledford & Gast, 2006; Zheng et al 2017). Because eating offers both gustatory and tactile feedback, the act of eating may serve a self-stimulatory function. Self-stimulation is a common explanation for stereotyped behaviors in ASD, but stereotyped behaviors are often discouraged. This may make a socially-acceptable self-stimulatory behavior especially favorable to autistic individuals. We hypothesize that eating can provide socially-acceptable self-stimulation. Although there is some evidence that RRBIs predict eating disturbances in young autistic females (Bitsika & Sharpley, 2017), this relationship has been under-explored, and to our knowledge remains untested in male-inclusive samples.

Objectives: To explore the possible link between stereotyped behaviors , we test the fit of several models predicting oral sensitivity from stereotyped behaviors in a sex-balanced sample of autistic youth to determine a best-fitting model for this relationship. We theorize that because Oral Sensitivity includes not only avoidance, but also preference, for specific tastes and textures in food, then if there is an association between eating and stimming, heightened oral sensitivity can serve as a measure of sensory-specific eating behavior. We expect that youth who exhibit heightened stereotyped behavior may also exhibit heightened sensitivity to oral taste and texture.

Methods: We examine a sample of 55 (31 male; 8-17y; FSIQ > 70) youth with ASD from Wave 1 of the NIMH ACE Network GENDAAR project. For our analyses, we consider the Stereotypy subscale of the Repetitive Behavior Scale – Revised (RBS-R; Lam & Aman, 2007), and the Oral Sensitivity subscale of the Sensory Profile Caregiver Questionnaire (Dunn, 1999). Higher Stereotypy scores indicate increased stereotyped behaviors; higher Oral Sensitivity scores indicate lower oral sensitivity. We explored the fit of several linear regression models predicting Oral Sensitivity from Stereotypy, including a simple linear regression without covariates, and linear regressions accounting for age, sex, and FSIQ.

Results: In a simple linear regression without covariates, Stereotypy predicts Oral Sensitivity (p=.005, F=8.454, adjusted R^2=.12). A linear regression accounting for Stereotypy, age, gender, and FSIQ maintained significance (p=.02, F=3.205, adjusted R^2=.14), but age and FSIQ were not significant contributors. A final model consisting only of Stereotypy and gender , adjusted R^2=.18). Figure 1 depicts the association between Stereotypy and Oral Sensitivity by sex, in which both sexes demonstrate similar slopes, but girls exhibit greater Oral Sensitivity (indicated by lower scores).

Conclusions: This study suggests that stereotyped behaviors are related to oral sensitivity in both sexes. This lends some support to the theory that eating behaviors in ASD may be related to RRBIs. Given the exploratory nature of our results, additional research in an independent sample should be conducted to further test whether eating can serve a self-stimulatory function in ASD. Such work could help explain the heightened incidence of overeating in ASD, and inform interventions for disordered eating in autistic individuals.

443.060 *(Poster)* Understanding Levels of Motor Skill Competence Among Children with ASD

K. L. Staples[1]*, L. R. Ketcheson*[2] *and D. A. Ulrich*[3]*, (1)School of Kinesiology, University of Michigan, Ann Arbor, MI, (2)Department of Kinesiology, Health and Sport Studies, Wayne State University, Detroit, MI, (3)University of Michigan, Ann Arbor, MI*

Background: Children with ASD experience a host of health disparities, including higher rates of obesity and lower levels of physical activity (PA). Participation in PA plays an integral role in the prevention of obesity and maintenance of a healthy weight. However, for a child to participate meaningfully in PA they must first have the requisite motor skills to do so. To develop interventions that will promote positive trajectories of PA and health for children with ASD, we first must determine their current levels of motor skill competence.

Objectives: Therefore, purpose of this research was to examine levels of motor skill competence among 6 to 9 year old children with ASD using the Test of Gross Motor Development (TGMD-3).

Methods: The primary group of 28 children with ASD (23 boys; 7.95 ± 1.22 years) were individually-matched to 2 comparison groups of neurotypical children on different aspects of development. The first comparison group was matched on sex (21 boys) and age (7.97 ± 1.29), while the second group was matched on sex (22 boys) and level of locomotor skill competence. All children were assessed on the TGMD-3, a criterion referenced assessment that examines the performance of locomotor and ball skills. Multiple performance criteria for each skill allow children to receive credit for any aspect of the movement they are able to perform; scoring is based on 46 and 54 possible performance criteria for the locomotor and ball skills subtests, respectively.

Results: Children with ASD demonstrated significantly lower levels of motor skill competence on both the locomotor [$t(1,52) = -4.879$, $p = .000$, $d = 1.34$] and ball skills [$t(1,52) = -7.845$, $p = .000$, $d = 2.15$] subtests of the TGMD-3 compared to neurotypical children of the same age. To match the second comparison group on the raw score of the locomotor skill subtest of the TGMD-3 [$t(1, 52) = -.558$, $p = .580$, $d = .15$], the children were between the age of 3 and 7 years. Despite being significantly older, children with ASD and the developmentally matched comparison group had similar levels of competence on the ball skills subtest [$t(1,52) = -1.370$, $p = .177$, $d = .37$].

Conclusions: By the age of 10, the majority of neurotypical children perform the fundamental motor skills included in the TGMD-3 with competence and confidence. Having a greater repertoire of motor skills affords children additional opportunities for PA participation across a greater variety of activities. Regardless of disability motor skill competency in young children does not naturally develop, it must be taught, practiced, and reinforced. The results of this research suggest children with ASD are not acquiring the same level of motor skill competence and may not have the same access to opportunities for learning as neurotypical children. It is during these formative years when it is developmentally and age-appropriate for children with ASD to be learning these skills. Without intervention, children with ASD will not acquire sufficient levels of motor skill competence that will afford them an opportunity for lifelong participation.

443.061 *(Poster)* Usefulness of the Sensory Profile As a Biomarker for Autism Spectrum Disorder

C. Kamiya[1], *K. Kagitani-Shimono*[1,2,3], *M. Nakanishi*[2,3], *M. Tachibana*[1,2,3], *I. Mohri*[1,2,3] *and M. Taniike*[1,2,3], *(1)Division of Developmental Neuroscience, United Graduate School of Child Development, Osaka University, Suita, Osaka, Japan, (2)Molecular Research Center for Children's Mental Development, United Graduate School of Child Development, Osaka University, Suita, Osaka, Japan, (3)Department of Pediatrics, Osaka University Graduate School of Medicine, Suita, Osaka, Japan*

Background: Sensory abnormalities are common symptoms in patients with autism spectrum disorder (ASD) and can cause various behavioral problems in daily life. Sensory abnormalities have been evaluated in several studies using the Sensory Profile (SP), a commonly used questionnaire. However, few studies have focused on the relationships among sensory abnormalities and the difference in age-dependent prevalence, intellectual quotient (IQ) or characteristics of ASD, such as social communication.

Objectives: The aim of this study was to evaluate the prevalence of sensory abnormalities in children with ASD using the SP and compare them with those in typically developing (TD) children. We analyzed the relationship depending on age, IQ, and characteristics of ASD. We further examined whether the SP could be used as a biomarker for ASD.

Methods: A total of 252 children with ASD aged 4 to 17 years and 94 TD children aged 4 to 17 years were recruited for this study. ASD diagnosis was made according to the Diagnostic and Statistical Manual of Mental Disorders Fifth Edition criteria and confirmed using the Autism Diagnostic Observation Schedule Second Edition (ADOS-2) in 138 participants. The severities of autistic characteristics were divided into mild (autism spectrum) and moderate to severe (autism) according to ADOS-2 scores. IQ were divided into normal, border, moderate delay, and severe delay. The Japanese version of the SP, which was evaluated by the guardians and consists of six sensory processing subdomains (i.e., auditory, visual), and four quadrant scores (i.e., avoidance, sensitivity), was used to evaluate sensory abnormalities using the age appropriate cut-off values. Behavioral problems were measured using the Child Behavior Checklist (CBCL). The relationship between sensory abnormalities and behavioral problems was analyzed using linear regression analysis. To test the specificity and sensitivity of the measured SP as a biomarker of ASD, receiver-operating characteristic curve analysis was performed. Statistical analysis was performed using SPSS version 23.0 (IBM Corp., Tokyo, Japan). This study was approved by the Internal Review Board in Osaka University Hospital.

Results: Children with ASD had a remarkably higher prevalence of sensory abnormalities in short SP total score (ASD: 43.8%, TD: 9.8%; $p<0.05$) and higher CBCL total scores compared to that in TD children (ASD: 66.19±9.4, TD: 49.9±7.8; $p<0.05$). Furthermore, children with ASD with low IQ and severe characteristics of ASD showed a higher prevalence of sensory abnormalities ($p<0.05$). The prevalence of sensory abnormalities showed no differences regarding age in children with ASD. The sensitivity and avoiding quadrant scores and boys exhibited higher CBCL total scores ($p<0.01$, $p=0.02$, and $p<0.01$, respectively). The three or more abnormal sensory modalities can predict for ASD with high area under the curve (0.88, 95% CI = 0.84-0.92, sensitivity = 69%, specificity = 95%).

Conclusions: The number of abnormal sensory modalities could be used as a predictive biomarker for ASD. This suggests that sensory abnormalities in children with ASD may not arise from a single sensory pathway, but may involve multiple sensory processing pathways. Evaluating sensory abnormalities and managing them adequately may improve their social adaptation in patients with ASD.

Service Delivery/Systems of Care

PANEL SESSION — **SERVICE DELIVERY/SYSTEMS OF CARE**

220 - Take a Seat at the Table: Engaging Community Stakeholders to Guide Intervention Adaptation for Youth with Autism

Panel Chair: Jill Locke, *Speech & Hearing Sciences, University of Washington, Seattle, WA*

Discussant: David Mandell, *Center for Mental Health, University of Pennsylvania, Philadelphia, PA*

Conducting research in community settings creates opportunities to build capacity in existing service systems to ensure intervention supports are readily accessible, relatively low-cost, and sustainable. However, interventions for children with autism often are not successfully implemented in real-world contexts, in part because they often are not adapted in the context of implementation, which results in poor intervention-setting fit, defined as the interactions among the context, intervention characteristics, and intended end-users or practitioners. Collaboration and partnership with community stakeholders in the adaptation process is a methodological paradigm shift in the ways in which interventions are typically designed and has the potential to improve intervention usability and implementation. We will present data from four studies that use established methods from the fields of user-centered design and implementation science to offer end-users an active role in intervention and implementation strategy adaptation to ensure practical relevance and contextual appropriateness. The four studies engage multiple stakeholders (e.g., parents, providers, agency leaders) to adapt a: 1) pediatric integrated mental health care model for youth with autism; 2) disruptive behavior intervention for school-aged children with autism; 3) parent-coaching implementation strategy for young children with autism; and 4) leader-level implementation strategy to support schools use autism interventions.

220.001 *(Panel)* Caregiver Insights to Inform Co-Creation of Integrated Mental Health Care for Children with Autism

N. A. Stadnick[1], *K. Martinez*[2], *G. A. Aarons*[1] *and L. Brookman-Frazee*[3,4,5], *(1)University of California, San Diego, La Jolla, CA, (2)Clinical Psychology, San Diego State University / University of California, San Diego Joint Doctoral Program in Clinical Psychology, San Diego, CA, (3)Psychiatry, University of California, San Diego, La Jolla, CA, (4)Child and Adolescent Services Research Center, San Diego, CA, (5)Autism Discovery Institute, Rady Children's Hospital-San Diego, San Diego, CA*

Background: Children with autism spectrum disorder (ASD) have a variety of unmet healthcare needs including access to needed specialty care. Access to and successful linkage to mental health care is particularly important for children with ASD to address the high rates of co-occurring psychiatric conditions that they may experience (Leyfer et al., 2006; Simonoff et al., 2008). Leveraging integrated care approaches, such as primary care providers collaborating with families to identify concerns and facilitate connection to specialty services, hold promise to address this healthcare need. Strategic and community-partnered methods are needed to tailor service coordination and delivery models to enhance linkage to mental health services for children with ASD. One such method is co-creation, defined as the collaborative mobilization and exchange of knowledge by and between stakeholders to improve health service delivery and experiences (Greenhalgh et al., 2016; Osborne et al., 2016). As part of a larger program of ASD implementation research (Stadnick et al., 2019), this study highlights one example of the co-creation process undertaken with caregivers of children with ASD.

Objectives: The purpose of this exploratory qualitative study was to understand the experiences of caregivers accessing mental health services for their child with ASD. The objective of gathering caregiver insights is to guide co-creation targets of tailored integrated mental health care for children with ASD.

Methods: Participants were eight mothers of children with a documented ASD diagnosis who received primary care at one of three health care organizations in Southern California. Caregivers were invited to participate in a focus group or individual interview. The semi-structured interview guide inquired about the following: 1) the mental health needs of children with ASD, 2) comfort discussing mental health in primary care appointments, 3) current primary care procedures for mental health screening and linkage and 4) needed adaptations to current procedures for children with ASD. A deductive approach to data analysis using rapid qualitative analytic methods was employed (Hamilton, 2018).

Results: Qualitative results highlighted three primary themes based on caregiver perspectives: 1) limited discussion about mental health and largely initiated by caregivers, 2) uncertainty about mental health referral options, which is complicated by the child's ASD diagnosis and 3) limited follow up with the family or mental health providers after referral. Caregivers provided several recommendations to guide co-creation of tailored integrated care practices for ASD. Recommendations included: routine mental health screening in primary care; encouraging primary care providers to initiate discussions about mental health, informational brochures about mental health and mental health services; follow-up contact with the family after mental health needs identified.

Conclusions: Caregiver insights provide targeted guidance towards tailoring integrated mental health care practices for children with ASD. Many of the recommendations shared by caregivers are actionable and feasible to implement. Next steps will be to align caregiver perspectives with the perspectives of primary care providers that were concurrently collected to produce an integrated mental health care model for ASD and test it in an upcoming pilot feasibility study.

220.002 *(Panel)* Iterative Redesign of a Behavioral Skills Training Program for Use in Educational Settings

J. Locke[1] *and K. Bearss*[2]*, (1)Speech & Hearing Sciences, University of Washington, Seattle, WA, (2)Psychiatry and Behavioral Sciences, University of Washington, Seattle, WA*

Background: Children with autism engage in disruptive behavior at a rate higher than their typically-developing peers in schools.Teachers endorse disruptive behavior as a considerable concern for students with autism, which is compounded by the lack of adequate resources for behavior management in the classroom. Considering schools are the most accessed service system for children with autism, there is a dire need to improve community-viable, empirically supported interventions targeting disruptive behavior for children with autism in schools. RUBI is a proven-efficacious intervention that addresses disruptive behavior in children with autism. Over the past decade, the RUBI Autism Network developed and systematically tested a low-intensity (11-session) manualized intervention for children ages 3 to 14 with autism and co-occurring disruptive behavior. RUBI is a weekly, one-hour outpatient treatment based on principles of applied behavior analysis, where therapists train parents to assess the function of their child's behavior (e.g., to get attention, gain access to a tangible items, escape demands) and use a range of behavioral strategies, which leads to reductions in child disruptive behavior. Although RUBI is an empirically supported intervention for children with autism and co-occurring disruptive behavior, adaptations are needed for its use in schools.

Objectives: The goal of this presentation is to introduce a novel methodological approach to redesign a proven-efficacious intervention, RUBI, for use in community settings. We use the Discover, Design/Build, Test (DDBT), a user-centered design and implementation science framework to enhance the usability, contextual fit, uptake, and effective implementation of an intervention, to guide assessment of the implementation context (elementary schools) and iteratively redesign the RUBI intervention to improve usability and implementation (feasibility, acceptability, appropriateness).

Methods: Forty school staff (general and special education teachers, paraprofessionals, school counselors, administrators, etc.) that support children with autism in general and special education classrooms from 20 partner elementary schools were included in this study. In the first stage, we use a day-long observation and retrospective think-aloud interview protocol to identify the contextual constraints and work processes relevant to the management of disruptive behavior in the classroom. In the second stage, we use an in-depth intervention demonstration of RUBI paired with behavioral rehearsal, a prospective think-aloud interview protocol, and structured assessment methods to identify targets for RUBI redesign (adaptation or pruning needs related to RUBI content and structure). In the third phase, we engage in collaborative redesign feedback sessions to iteratively adapt RUBI content and procedures, and we measure the usability, feasibility, acceptability, and appropriateness of the redesigned RUBI intervention.

Results: Data collection is ongoing and will be completed in January 2020. Conventional content analysis, in which meaning is derived from the content of verbal communications, but no a priori codes are identified prior to reviewing transcripts, will be used to code qualitative data. Quantitative ratings (usability, feasibility, acceptability, appropriateness) of RUBI will be interpreted using measures of central tendency to identify targets for RUBI redesign.

Conclusions: The use of a user-centered design and implementation science approach to redesign a proven-efficacious intervention may provide greater usefulness and usability in community contexts.

220.003 *(Panel)* Engaging Multiple Stakeholder Groups to Develop Strategies to Support the Implementation of Parent Coaching in Early Intervention.

M. Pellecchia[1]*, R. Beidas*[1]*, C. Cannuscio*[1] *and A. C. Stahmer*[2]*, (1)University of Pennsylvania, Philadelphia, PA, (2)Psychiatry and Behavioral Sciences, University of California at Davis MIND Institute, Sacramento, CA*

Background: Parent-mediated early intervention (EI) for young children with autism spectrum disorder (ASD) improves child and family outcomes. Parent coaching is a critical component of parent-mediated interventions. However, recent evaluations of community-based EI providers' use of evidence-based intervention techniques indicate that they infrequently implement parent-coaching strategies during usual practice, especially in under-resourced settings. The reasons for this implementation gap are unclear, but are likely multi-layered and complex. An in-depth understanding of the challenges to using parent coaching is necessary to inform the development of strategies to improve their implementation in publicly-funded early intervention settings.

Objectives: This study sought to learn about experiences with and perspectives toward using parent coaching from stakeholders across multiple levels of involvement (i.e., parents, providers, and agency leaders) within a publicly funded early intervention system to inform the development of strategies to improve parent coaching implementation.

Methods: Semi-structured interviews were conducted with 20 stakeholders (5 parents, 10 providers, and 5 agency leaders) which probed for information about respondents' experiences using evidence-based parent coaching strategies, and barriers and facilitators to using each strategy. Transcripts were analyzed iteratively based upon an integrated approach incorporating both inductive and deductive features.

Results: Common themes are consistent with constructs described in the Consolidated Framework for Implementation Research (CFIR: Damschroder et al., 2009) including: 1) providers' preferences (e.g., prefer a child-directed approach), beliefs (e.g., perception that some parents are not ready for coaching), and self-efficacy (e.g., lack of confidence in their ability to coach parents); 2) family characteristics (e.g., parent expectations for treatment); 3) intervention setting (e.g., chaotic homes), and 4) organizational factors (e.g., inconsistent approach across providers within agencies).

Conclusions: This study is one of the first to provide first-hand perspectives regarding community providers' use of parent coaching across multiple groups of stakeholders. Findings highlight the unique challenges to implementing parent coaching within publicly funded service systems and the complexity of these implementation challenges as they relate to different stakeholder groups. These findings will inform the development of implementation strategies tailored to meet the needs of each stakeholder group including developing easy-to-use educational materials for parents, creating a learning collaborative among providers to foster collaboration and improve consistency in treatment approach, and working with agency leaders to develop a formal implementation blueprint to guide the implementation of parent coaching. Implications and recommendations for strategies to improve the implementation of parent coaching within similar publicly-funded service systems will be discussed.

220.004 *(Panel)* Special Education Leaders' Feedback to Inform Adaptation of the Leadership and Organizational Change for Implementation Intervention

J. Suhrheinrich[1]*, M. Melgarejo*[1]*, B. Ventenilla*[2] *and G. A. Aarons*[3]*, (1)San Diego State University, San Diego, CA, (2)Special Education, San Diego State Universtiy, San Diego, CA, (3)University of California, San Diego, La Jolla, CA*

Background: Although evidence-based practices (EBP) for children with autism spectrum disorder (ASD) exist, current methods for selecting, implementing and sustaining these practices in school settings are not effective.Implementation leadership has been identified as a critical factor supporting use and sustainment of EBP across service sectors, including services for students with ASD (Aarons, Ehrhart, Farahnak, & Sklar, 2014; Lyon et al., 2018). The Leadership and Organizational Change for Implementation (LOCI) intervention provides targeted training to first-level leaders, those who supervise and support direct service providers, in leadership development, while building alignment and support for organizational change across all levels of leadership (Aarons, Ehrhart, Farahnak, & Hurlburt, 2015). Although school principals have been the primary focus of leadership in educational research, school-based services for children with ASD involve a team of individuals involved in leading and managing providers. Specialized staff (i.e Autism Specialist, Behavior Specialist) are first-level leaders (Priestland & Hanig, 2005) providing clinical guidance to direct service providers and are well-poised to influence adoption of new programs.

Objectives: The purpose of this exploratory mixed-methods study was to identify which leaders and what leader actions were key in the implementation process of school-based interventions for students with ASD. A second objective was to use these data to inform adaptations to the LOCI intervention to fit the special education service context.

Methods: Participants were recruited in partnership with the California Autism Professional Training and Information Network. Data were collected from survey participants (n=340) across organizational levels of special education services, including high-level administrators (n=19) (Special Education Director, District-level Administrator), specialized staff/first-level leaders (Autism Specialist, Behavior Specialist, Program Specialist, Mentor Teacher), principals (n=15), teachers and other direct service providers (n=153), and mental health providers (n=33; school psychologist, MFT). A subset of 12 survey questions regarding identification, selection, resource allocation, and training of educational programs for students with ASD were selected from a larger survey. Focus group participants (n=30) were specialized staff/first-level leaders in school-based services for students with ASD. Coded data from one set of questions focused on gathering feedback on the LOCI protocol were selected from the full focus group transcripts.

Results: Survey results indicated specialized staff/first-level leaders are critical in implementation of interventions for students with ASD as compared to high-level administrators, school site principals, teachers, and mental health providers. First-level leaders were most frequently identified as having the most impact on "identifying new educational programs for ASD for possible implementation" (56.8%) and "choosing which new educational intervention(s) for children with ASD will be implemented" (48.3%). Qualitative results highlighted three themes: 1) reduction in initial LOCI training time; 2) inclusion of leaders at multiple levels, but job titles of participants may vary by district size; 3) clear goals supported by all team members and accompanying timelines.

Conclusions: Findings will advance our understanding of the complex leadership structure within special education services and influence the adaptation of a leadership intervention to support the implementation and sustainment of EBP for ASD in schools.

PANEL SESSION — **SERVICE DELIVERY/SYSTEMS OF CARE**

221 - Understanding Stakeholder Perspectives Towards Evidence-Based Practices for ASD in Publicly-Funded Systems of Care

Panel Chair: Brooke Ingersoll, *Psychology, Michigan State University, East Lansing, MI*

Discussant: Melanie Pellecchia, *University of Pennsylvania, Philadelphia, PA*

Implementation science highlights the importance of stakeholder perspectives in the successful implementation of evidence-based practices (EBPs) in community settings. This panel describes research examining key stakeholder perspectives regarding the use of EBPs for youth with ASD in publicly-funded intervention systems, with a focus on barriers and facilitators that influence their implementation. The first two studies present data from two stakeholder groups on the use of family training practices within the same Medicaid-funded community mental health system: (1) ABA providers' perceptions of barriers and facilitators to the use of family training with their clients with ASD and (2) parent perspectives of engagement in current family training practices and attitudes toward evidence-based parent-mediated intervention (PMI) models. The third study examines the concordance between therapist and caregiver ratings of therapist use of EBPs in publicly-funded mental health programs. Finally, the fourth study examines agency trainer and therapist perspectives on a staff training model to support the use of an evidence-based PMI for toddlers in the Part C early intervention system. Dr. Melanie Pellecchia (discussant) will draw on her expertise on the implementation of EBPs in publicly-funded systems and make recommendations for strategies that can inform dissemination and implementation efforts, particularly for diverse families.

221.001 *(Panel)* A Mixed Methods Investigation of Barriers and Facilitators to Providers' Use of Parent Training with Medicaid-Enrolled Families of Individuals with Autism

D. Straiton *and B. R. Ingersoll, Psychology, Michigan State University, East Lansing, MI*

Background: Recommendations for best practice in the treatment of children with autism spectrum disorder (ASD) stress the importance of interventions such as parent training, in which caregivers are involved in implementing intervention strategies to teach their child skills. Many traditionally underserved (e.g., racial or ethnic minority, language minority, low socioeconomic status) families of children with ASD experience barriers that obstruct their access to and participation in autism-related services. Parent training has the potential to mitigate many of these barriers.

Objectives: This project examined barriers and facilitators endorsed by community providers who work with Medicaid-enrolled families of individuals with ASD under age 21. We sought to examine the relationship between parent training extensiveness (a measure of frequency and quality) and barriers and facilitators at the family-, provider-, and organization-levels.

Methods: This study utilized a convergent QUAN + qual mixed-method design. Ninety-seven applied behavior analysis (ABA) providers completed a survey regarding their parent training practices with Medicaid-enrolled clients with ASD. The relationship between parent training extensiveness (calculated by z-scoring the values for parent training frequency and quality and then summing both z-scores) and a number of provider demographic, training, and caseload variables were examined. Hierarchical linear regression was used to examine to what extent providers' perceptions of barriers and facilitators to their use of parent training predicted parent training extensiveness, after controlling for significantly associated provider demographic and training variables. Thematic analysis was used to analyze follow-up interviews from 13 providers.

Results: Results indicated that a) the number of providers' training experiences regarding parent training (r = .33, p = .001) and years of experience in working with children with ASD (r_s = .24, p = .02) were associated with parent training extensiveness; b) the final hierarchical linear regression model in which barriers predicted parent training extensiveness was significant [$F(5,86) = 7.32$, $p < .001$)] and explained 30% of variance, with family-level barriers explaining unique variance, β = -.23, t = -2.29, p = .03 (see Table 2); c) thematic analysis yielded the following themes for barriers: limited family engagement and interest, family stressors and/or cultural differences from the provider, logistical barriers (e.g., transportation in rural areas), lack of agency support or agency norms regarding parent training, and limited provider training about parent training (pre-service and in-service); d) no facilitators uniquely predicted parent training extensiveness; and e) thematic analysis yielded the following themes for facilitators: high family engagement and interest, logistical facilitators, agency support and norms regarding parent training, and training providers about parent training.

Conclusions: Taken together, these results indicate that providers perceive family-level barriers to be particularly challenging, over and above provider- and organization-level barriers. Providers perceived Medicaid-enrolled families as difficult to engage and/or uninterested in participating in parent training. Providers also noted having few pre-service and in-service training experiences that adequately prepared them to use parent training. Results suggest that implementation efforts to increase the use of parent training in community settings should address providers' perceptions of family-level barriers and foster high-quality training opportunities regarding parent training.

221.002 *(Panel)* Family Training Under the Medicaid Autism Benefit: Understanding Caregiver Perspectives on Engagement

K. Casagrande *and B. R. Ingersoll, Psychology, Michigan State University, East Lansing, MI*

Background: Parent-mediated intervention (PMI), in which providers coach parents to use intervention strategies with their child, is considered best practice in family training for children with ASD. Parents value PMI and view it as an unmet need, but families receiving services through Medicaid are significantly underrepresented in this research. These families have much to gain from PMI, as it can increase the accessibility, intensity, and effectiveness of evidence-based services in a system with limited resources. However, previous research on family training in a Medicaid setting suggests providers' perceptions of high family-level barriers limit their use of PMI strategies.

Objectives: In the context of a larger community-engaged project on family training during Medicaid-funded Applied Behavior Analysis (ABA), our goal is to better understand: 1) caregivers' perceptions of PMI as part of their child's current ABA; 2) caregivers' motivation to participate in PMI; and 3) the influence of barriers and facilitators on their motivation to participate.

Methods: Caregivers (N=203; 63% White; 82% Mothers; 32% ≤ High school education) of children with ASD (Age in years: M=8.86, SD=4.16; 52% White) receiving Medicaid-funded ABA services (Years of ABA: M=1.97, SD=1.39; Hours per week: M=14.60, SD=9.11; 53% Center-based) completed a survey. Caregivers were shown a one-page flyer describing evidence-based PMI and asked how similar this was to their current ABA family training support, as well as their motivation to participate in PMI using a validated measure. Caregivers also reported factors that could affect motivation to participate using validated measures of family-centered care, daily stress, external barriers to treatment, therapeutic alliance, and beliefs about the relevance and effectiveness of PMI. Semi-structured follow-up interviews (N=16) provided additional context for quantitative findings.

Results: Families reported high motivation to participate in PMI (M=4.26/5, SD=0.83); this was unrelated to parent, child, or service characteristics (r_{pb} p's≥.195), but was related to satisfaction with current involvement in ABA (r_{pb}=0.216, p=0.005) and perceived similarity of PMI with current ABA family support services (r_{pb}=0.169, p=0.033). After controlling for those factors, family-centered care explained a significant amount of variance in motivation to participate in PMI (ΔR^2=0.041, p=0.010). Furthermore, while therapeutic alliance (ΔR^2=0.063, p=0.001) and attitudes about PMI (ΔR^2=0.382, p=<0.001) explained additional variance in the model, daily stress and external barriers to treatment did not (ΔR^2=0.025, p=0.124; see Table 1). Interviews found that most caregivers valued the coaching and feedback components of PMI, but shared that current ABA family support services, which were primarily progress monitoring, were not worth the burden of participation. However, caregivers were willing to prioritize involvement in PMI specifically despite the burden.

Conclusions: Previous research on provider perspectives within this Medicaid system found high perceived family-level barriers to engagement. However, parents themselves reported relatively few barriers and high motivation to participate in PMI. Parents also reported that their current ABA family training experiences were not consistent with evidence-based PMI. The difference in perspective between parents and providers within this system may be related to caregivers' limited perceived value in current family training services, rather than a lack of motivation to participate overall.

221.003 *(Panel)* Comparing Therapist and Caregiver Perceptions of Therapists' Evidence Based Strategy Use in Children's Mental Health Services

C. Chlebowski[1,2], *T. Lind*[3], *W. Ganger*[2] *and L. Brookman-Frazee*[2,4,5], *(1)University of California San Diego, La Jolla, CA, (2)Child and Adolescent Services Research Center, San Diego, CA, (3)University of California, San Diego, La Jolla, CA, (4)Psychiatry, University of California, San Diego, La Jolla, CA, (5)Autism Discovery Institute, Rady Children's Hospital-San Diego, San Diego, CA*

Background: There are increased calls for therapists to implement evidence based practices (EBP) in children's publicly-funded mental health (MH) services. For children with autism spectrum disorder (ASD), caregiver participation plays an important role in effective delivery of EBPs. Limited work has examined concordance between therapist and caregivers in perceptions of therapist in-session EBP strategy delivery in children's MH treatment.

Objectives: The current study 1) compares therapist and caregiver ratings of therapist EBP strategy delivery in publicly-funded psychotherapy sessions, 2) examines the impact of therapist EBP training on therapist-caregiver rating concordance, and 3) examines child, therapist, and treatment factors impacting therapist-caregiver agreement.

Methods: Participants included a subset of 146 therapists and 158 caregivers of children with ASD aged 5-13 years drawn from a community effectiveness trial of AIM HI ("An Individualized Mental Health Intervention for ASD") conducted in publicly-funded outpatient and school-based MH programs. Ratings of therapist in-session EBP strategy delivery were collected from therapists and caregivers using the ASD EBP Therapist Strategies Questionnaire following 6 months of either AIM HI training or delivery of usual care. Agreement of therapist and caregiver perceptions of therapist EBP strategy use was examined using standardized difference scores and q-correlations. Linear mixed models were used to assess the impact of AIM HI therapist training and predictors of therapist-caregiver agreement.

Results: Therapist self-ratings of Caregiver-Directed ($t(41.44)=-5.85$ $p<.001$) and Child-Directed ($t(156)=-2.21$, $p<.05$) strategies differed by training condition with trained therapists reporting significantly higher EBP strategy use. Caregiver ratings followed the same pattern with higher rated EBP strategy use for both Caregiver-Directed ($t(38.22)=-5.06$ $p<.001$) and Child-Directed ($t(34.69)=-2.844$, $p<.01$) strategies for therapists who received AIM HI training.

The mean q-correlation between therapist and caregiver ratings for all intervention strategies was 0.31 (SD = 0.31), indicating that ratings covaried in a predictable, linear fashion. The mean standardized difference score was .00 (SD = 2.42), indicating that therapists and caregivers did not disagree on the overall rating of in-session EBP strategy use.

In multivariate models examining training group, child, caregiver, therapist or treatment characteristics predicting agreement, children who had at least one co-occurring mental health disorder had lower therapist-caregiver agreement (q-correlation: B = -.20, SE = .10, $p < .05$) and higher disagreement (standardized difference: B = -.20, SE = .10, $p < .05$), with therapists reporting lower strategy use than caregivers. Therapist with a self-identified ASD specialty reported more in-session strategy use than caregivers, with higher rates of disagreement (standardized difference: B = .97, SE = .26, $p < .01$). Other child characteristics (ethnicity, cognitive level, baseline behavior problems), caregiver characteristics (education, preferred language); and session treatment characteristics (session structure, treatment continuity, pursuit of skills in session) were not significantly associated with agreement.

Conclusions: Therapist EBP training was associated with higher ratings of therapist EBP strategy use from both therapists and caregivers suggesting that EBP training may impact therapist in-session behaviors. Ratings between therapists and caregivers suggested low levels of disagreement of overall therapist in-session EBP strategy use. Future study will explore the relationship between rating concordance and client outcomes.

221.004 *(Panel)* Community Provider Perspectives on Project Impact for Toddlers Training and Implementation in Early Intervention Settings

J. A. Ko[1], *S. R. Rieth*[2], *K. S. Dickson*[1], *R. Haine-Schlagel*[1], *A. C. Stahmer*[3] *and L. Brookman-Frazee*[1,4,5], *(1)Child and Adolescent Services Research Center, San Diego, CA, (2)San Diego State University, San Diego, CA, (3)Psychiatry and Behavioral Sciences, University of California at Davis MIND Institute, Sacramento, CA, (4)Psychiatry, University of California, San Diego, La Jolla, CA, (5)Autism Discovery Institute, Rady Children's Hospital-San Diego, San Diego, CA*

Background: Community provider perceptions of evidence-based interventions (EBIs) are critical to the utility, feasibility, and adoption of these interventions in community settings (Borntrager et al., 2009). However, there has been limited examination of EBIs in community settings and the perspectives of therapists being trained to deliver EBIs have largely not been examined. Project ImPACT for Toddlers (PI for T; Stahmer et al., 2016; Ingersoll & Dvortscak, 2019) is a parent-mediated EBI for very young children with social communication challenges. A community trial of PI for T demonstrates preliminary evidence of gains in positive parent-child interaction and children's social and communication skills (Stahmer et al., 2019); however, more information is needed regarding provider perspectives on the intervention and training process to promote sustainment of the practice over time in the community.

Objectives: This study utilized qualitative interviews and quantitative survey results to examine agency trainer and therapist perspectives on training in PI for T and their experiences delivering the program to families in the community.

Methods: Participants were recruited from 12 community agencies providing early intervention services. A train-the-trainer training model was utilized, where leaders (designated as agency trainers) were first trained in the PI for T intervention, and then trained therapists at their agencies. Agency trainers (n = 14) were 21% Hispanic/Latinx; Therapists (n = 24) were 29% Hispanic/Latinx. A total of 29% of agency trainers and 33% of therapists had a special education credential. Training in PI for T took place over approximately six months and consisted of didactic teaching of PI for T curriculum, in-person practice and feedback, and ongoing coaching and fidelity monitoring. Three months following training, agency trainers and therapists completed a feedback survey (1=strongly disagree to 5=strongly agree) and were invited to participate in an interview about their experiences with the training process and delivering the PI for T intervention. Qualitative data were coded using an iterative grounded theory approach (Glaser & Strauss, 1967) and transcripts from interviews were coded and analyzed using QSR-NVivo 2.0.

Results: Quantitative results indicated high acceptability and appropriateness of training (M=3.84, SD=.61 and M=3.45, SD=.97, respectively), as well as moderate intervention feasibility (M=3.14, SD=.92) and sustainment (M=3.01; SD=.87). Interview results indicated both agency trainers and therapists reported the acceptability and appropriateness of the training model, and indicated the group-based model of training, comprehensive materials, and agency support served as primary facilitators of these outcomes. Agency policies and time were key barriers. Interview data also supported the feasibility, acceptability, and utility of the intervention approach in community settings, particularly the focus on parents. Family characteristics/fit with the family was identified as both a barrier and facilitator to feasibility.

Conclusions: Results indicate that community providers support the training and use of the PI for T intervention in their practice. Continued efforts to disseminate EBIs for children with autism in the community will be improved by particular attention to key barriers and facilitators identified here.

POSTER SESSION — SERVICE DELIVERY/SYSTEMS OF CARE
444 - Service Delivery/Systems of Care Posters

444.001 *(Poster)* A Pilot Study Examining Implementation Strategies for the Autism Support Checklist

B. O'Hagan[1]*, C. Bays-Muchmore*[2]*, P. Sonikar*[1]*, A. Friedman*[1]*, L. Bartolotti*[1]*, S. King*[1] *and M. Augustyn*[1]*, (1)Developmental and Behavioral Pediatrics, Boston Medical Center, Boston, MA, (2)The Autism Program, Boston Medical Center, Boston, MA*

Background: Individuals with Autism Spectrum Disorder (ASD) have higher rates of various medical conditions and are higher utilizers of the healthcare system[1–4]. Despite higher usage, patients with ASD and their families report lower satisfaction with care recieved[5–8]. This may be partly due to the unique unmet needs in the typical hospital environment[9–11]. In an effort to address this, the Autism Friendly Initiative (AFI) at Boston Medical Center (BMC) implemented the Autism Support Checklist (ASC), a questionnaire derived from the Autism-Specific Care Plans[12] that summarizes a patient's communication, sensory, and safety/behavioral needs. This information is then entered into the patient's Electronic Health Record (EHR) for clinicians and staff to access.

Objectives: The goal of this study is to (1) evaluate two implementation strategies (i.e., high-intensity and low-intensity trainings), (2) determine the acceptability of the ASC, and (3) collect patients' caregivers' feedback.

Methods: We looked for upcoming appointments in February-August 2019 for patients who had ASCs in their EHR and randomly assigned their clinicians (n = 23) to one of two groups; (1) low intensity group (received an email about ASC) and (2) high intensity group (received an email and in-person training about ASC). After the appointment, clinicians completed a brief online survey. We also collected data from 17 patient caregivers through a phone survey after their appointments. Both clinician and caregiver surveys included quantitative and qualitative items. Responses were analyzed using Fisher's exact tests.

Results: 71% of clinicians reported reading the ASC in full and among these clinicians, 70% reported finding it useful. In terms of potential barriers to ASC, 43% of clinicians reported "lack of time", 14% reported "information is irrelevant", 14% reported "information is too long", and 17% reported "unsure where to locate". 18% of clinicians reported changing their behavior because of the ASC. There is a trend in which high-intensity group clinicians were more likely than low-intensity group clinicians to report reading the ASC in full ($p = 0.068$) and lack of time as a potential barrier for using the ASC ($p = 0.10$). There was no significant difference between the responses of the clinicians in the high-intensity group and the low-intensity group. Patient caregivers reported similarly positive outcomes across both clinician groups regarding clinicians' ability to communicate with the patient and address their sensory needs.

Conclusions: In this pilot study, the ASC was generally well-received by clinicians, and there is preliminary evidence suggesting that an active training component may be helpful in increasing clinician engagement. However, the active training component does not translate to an increased likelihood that the clinician will rate the ASC as more helpful or report behavior change. Further research is needed to explore other potential implementation strategies for the ASC and its longitudinal impact and effectiveness on improving care delivery and patient/family-related outcomes.

444.002 *(Poster)* A Spatial Analysis of Service Lag to Early Intensive Behavioral Intervention

A. F. Dimian*, J. Wolff, F. J. Symons and J. Simacek, University of Minnesota, Minneapolis, MN*

Background: Early intensive behavioral intervention (EIBI) is one of the most common evidence based early intervention approaches to increase adaptive behavior among children with autism spectrum disorder (ASD). Despite emphasis on intervening early following identification and diagnosis, significant barriers can interfere with timely service access. Among the most common barriers (e.g., waitlists, service provider shortages), geography has been relatively unexamined. More specifically, geographic location is a known but not widely investigated barrier to both receiving a timely diagnosis and starting or sustaining ASD treatment efforts. Previous research suggests that there is limited access to care for autism-related services in non-metropolitan/ rural areas (Mandell et al., 2005; Thomas, Ellis, McLaurin, Daniels, & Morrissey, 2007).

Objectives: The purpose of this study was to assess the relation between geographical distribution and starting EIBI services.

Methods: A cohort of children ages 3-5 years old (n=667) with ASD residing in Minnesota between 2008 and 2010 were identified through Minnesota's Medicaid Management Information System. We compared metro and non-metro residence using Kaplan- Meier product limit estimates of survival and Chi- square analyses. The distribution of service providers and the average time lag to EIBI was also assessed utilizing geographical information system (GIS).

Results: Approximately 70% of children in this study experienced a time lag to EIBI services, with an average lag of approximately 9 months (range= 0-45 months). Average time lag ranged from 0 to 28 months. The average age to start EIBI services was 4.70 years (SD=1.24 years). In the metro area, the average start age was 4.79 years. In the non-metro area, children started EIBI at a younger age, 4.50 years, on average. The Kaplan-Meier median time to starting EIBI per the survival functions for the whole sample was 5 months. The children who resided in the metro area, median time lag was 6 months and for the children who resided in the non-metro areas, median time lag was 4 months. At 12 months, the probability of 'survival' (i.e., starting EIBI) was approximately 18% for the non- metro children and 35% for the metro children. Overall, the survival curves showed that non-metro children experienced less time lag to starting EIBI over time.

Conclusions: Overall, sample sizes and number of service providers varied by county with most of the children residing in the metropolitan/urban areas. There was a statistically significant mean difference between metro and non-metro time lag to service estimates with the non-metro areas having overall shorter time lags. Notably, we also found that the average age at start of EIBI was 5 years regardless of urban or rural residency. This represents a systematic time lag that runs counter to the theoretical basis of early intervention for ASD. With the increase in ASD prevalence, resources and service provision are critical for meeting the needs of children and families early on and throughout the lifespan. Research focusing on socio-cultural factors – including where one happens to live –has the potential to significantly inform both clinical practice and public health policy.

444.003 *(Poster)* An Exploration of a Community-Based Autism Intervention Implemented within Part-C Services

***S. T. Stronach**, Communication Sciences and Disorders, University of Wisconsin - River Falls, River Falls, WI*

Background: While fidelity is often held to high standards for research projects, procedural fidelity in community and educational settings is variable (e.g., Stahmer et al., 2015) if measured at all. There is a pressing need to bridge research and practice in systematic ways. In 2015, the Minnesota Department of Education (MDE) received a State Personnel Development Grant (SPDG) from the Office of Special Education Programs (Grant number: H323A150010) with the goals of improving early ASD identification, enhancing intervention, and preparing for transitions out of Part C services. The Early Social Interaction (ESI) intervention (Wetherby et al., 2014) is being conducted through the Autism Navigator, a collection of web-based courses and tools developed by the Florida State University Autism Institute to bridge the gap between science and community practice using a highly interactive web platform with extensive video footage to illustrate effective evidence-based practice for both early identification and intervention.

Objectives: The goal of this exploratory study was to determine the feasibility of implementing ESI in a community setting using the Autism Navigator online training.

Methods: Five Minnesota districts are implementing this project, three in the Twin Cities metro area and two greater Minnesota districts added in 2017. Early intervention providers in these districts have completed the 30-hour Autism Navigator training and participate in monthly webinars and annual training events. Data has been collected through year four of five for the SPDG project, with the final data collection deadline scheduled for March 1, 2020. A sample of 19 Part C providers have completed self-ratings of fidelity completed across sessions with 31 children identified with ASD and their families and 76 providers have completed an annual survey asking about their use of the intervention strategies.

Results: Average self-ratings of fidelity for the first four years have been 30.2% (n = 34), 61.6% (n = 63), 71.6% (n = 73), and 71.0% (n = 63). External observations of fidelity were completed for a minimum of 20% of providers in years two through four. The mean year three external fidelity rating was 48% (range of 20% to 75%), compared to a mean self-rating of 51% for the same visits (range of 0% to 75%), while the mean year four external fidelity rating was 65% (range of 30% to 85%), compared to a mean self-rating of 69% for the same visits (range of 55% to 85%) with an overall inter-rater agreement of 85%. Quantitative and qualitative survey data across all five years of the project will be presented as well.

Conclusions: Results of this exploratory professional development project provide preliminary evidence to support the use of online training, supplemented with in-person and web-based follow-up, to implement community evidence-based early autism intervention. The use of systematic self-ratings of fidelity may be an important and feasible tool for improving community practices and outcomes for young children with ASD receiving Part-C services.

444.004 *(Poster)* Assessing the Ability of the Infant-Toddler Checklist to Identify Developmental Concerns in a Low-Income, Ethnically Diverse Population

***J. Levinson**[1], P. Fuchu[1], A. Chu[1], S. broder-Fingert[2,3] and E. Feinberg[1,3], (1)Boston University School of Public Health, Boston, MA, (2)Boston Medical Center, Boston, MA, (3)Boston University School of Medicine, Boston, MA*

Background: While screening tools exist to identify communication delays prior to 18 months, there is a need to better understand whether these tools can accurately identify developmental concerns in younger, ethnically diverse children. One such tool is the Communication and Symbolic Behavior Scales Developmental Profile Infant-Toddler Checklist (ITC), a broadband communication screening tool that has successfully identified autism spectrum disorder (ASD), language delay, and developmental delay among children ages 9 to 24 months.

Objectives: This study aims to answer the following question: in a low-income, ethnically diverse population, can the ITC predict developmental and communication concerns earlier than more commonly used screeners?

Methods: The setting for this study is an urban primary pediatric care clinic that serves a culturally and linguistically diverse population. Children were screened per clinic standard of care with the Parents' Evaluation of Developmental Status (PEDS) at 12 and 15 month well child visits and the Modified Checklist for Autism in Toddlers, Revised with Follow Up (M-CHAT-R/F) at 18 and 24 month well child visits. As part of this study, parents and guardians of children between the ages of 11 and 20 months received additional screening with the ITC. Results on the ITC were compared to subsequent results on the PEDS and the M-CHAT-R/F. Of those who screened positive, research staff performed chart reviews through 24 months of age. The following data were abstracted from the child's medical record: screening results from the PEDS and the M-CHAT-R/F; developmental diagnoses; referrals for developmental services; and notation of parental and provider concerns. Preliminary data were analyzed descriptively. Once all participants have reached 24 months and charts can be fully abstracted, the kappa statistic will be used to measure agreement between the ITC and the PEDS, the M-CHAT-R/F, and parental concern.

Results: 300 children were screened using the ITC; 56% were Black or African American, 23% were Hispanic, 49% were male, and 16% of parents/guardians preferred a language other than English. 98 children (33%) scored above the cut off for developmental concern on the ITC. Of these 98, we obtained permission to access the charts of 92 children. Of these 92, 66 (73%) were screened with either the PEDS or the M-CHAT-R/F at the closest proximal well child visit; 15 screened positive and 51 screened negative. 26 had no documentation of routine screening. ITC positive screening results were discordant with M-CHAT-R/F and PEDS results in 77% of proximal screens.

Conclusions: Preliminary results show a higher positive screen rate on the ITC than previous studies. This finding is likely due to the higher risk and younger age of participants in this study. The ITC appeared to identify new concerns, not revealed by the clinic's standard screening tools. Findings suggest that broadband screening may lead to earlier diagnosis of ASD and other communication delays. However, it is also possible that the tool over-identifies developmental concerns among typically developing very young, low-income children. Ongoing chart review and analysis will assess the potential advantage of this screener for identifying ASD.

444.005 *(Poster)* Autism Alertness in Dutch Physicians Screening in the Child General Population: Effects of an Online Course

M. van 't Hof[1,2]*, A. van Nieuwenhuyzen*[3]*, I. A. van Berckelaer-Onnes*[3,4]*, M. Deen*[5,6]*, H. W. Hoek*[7,8,9] *and W. A. Ester*[2,10,11]*, (1)Sarr Expert Centre for Autism, Lucertis Child- & Adolecent Psychiatry, Rotterdam, Netherlands, (2)Parnassia Psychiatric Institute, The Hague, Netherlands, (3)Sarr Expert Centre for Autism, Lucertis Child and Adolescence Psychiatry, Rotterdam, Netherlands, (4)Faculty of Social Sciences, Clinical Child and Adolescent Studies, Leiden University, Leiden, Netherlands, (5)Faculty of Social and Behavioural Sciences, Institute of Psychology, Methodology and Statistics Unit, Leiden University, Leiden, Netherlands, (6)Parnassia Psychiatric Institute, The hague, Netherlands, (7)Parnassia Academy, Parnassia Psychiatric Institute, Den Haag, Netherlands, (8)Department of Psychiatry, University of Groningen - University Medical Center Groningen, Groningen, Netherlands, (9)Department of Epidemiology, Columbia University - Mailman School of Public Health, New York, NY, (10)Department of Child and Adolescent Psychiatry, Curium-LUMC, Leiden University Medical Center, Oegstgeest, Netherlands, (11)Sarr Expert Centre for Autism, Lucertis Child- & Adolecent Psychiatry, Rotterdam, Netherlands, Rotterdam, Netherlands*

Background: Signalling autism is a significant task of Youth and Family Centre (YFC) physicians performing preventative health care in the Netherlands by screening the child general population from birth to adolescence. Knowledge about screening for Autism Spectrum Disorder (ASD) in preventative health care practitioners is limited and little is known about the lasting effect of ASD education.

Objectives: To evaluate the effect of an online course on the level of ASD knowledge, psychiatric stigma, perceived competence and referrals in YFC physicians.

Methods: Physicians followed the online course 'Detection of Autism Spectrum Disorders in Children aged 4-6 Years by Youth and Family Center Physicians' consisting of three Live Online Learning (LOL) sessions. We assessed ASD knowledge and competence signalling ASD before, directly after and at six months follow up using questionnaires. Psychiatric stigma was measured using the Community Attitudes towards the Mentally Ill (CAMI) questionnaire, before the course and at six months follow up. Participants were asked to register referrals two months before the course and at follow up.

Results: Results showed an increase in general ($F(2, 154) = 8.93$, $p < .001$) and specific ($F(2, 154) = 23.92$, $p < .001$) ASD knowledge after the course. Physician specific ASD knowledge mean scores remained higher ($p = .01$) at follow up ($M = 6.46$, $SD = 1.65$) compared to pre-course means ($M = 5.87$, $SD = 1.65$). Psychiatric stigma amongst YFC physicians did not change as a result of the course. Perceived competence related to the detection of ASD ($F(1.56, 120.27) = 141.41$, $p < .001$) was higher after the course than at the start, and mean scores remained higher ($p < .001$) at follow up ($M = 36.95$, $SD = 4.08$) than before the course ($M = 29.05$, $SD = 5.56$). We found no effect of the course on the number of potential ASD referrals.

Conclusions: This study shows that an educational online course has long-term effects on autism knowledge and especially perceived competence of Youth and Family Centre physicians. Education on the early signs of ASD, communication and municipal referral options should have adequate attention in primary care settings.

444.006 *(Poster)* Autism Parent Training in a Developing Country: A Public/Non-Governmental Organization (NGO) Partnership.

P. Bahadursingh*, South West Regional Health Authority, Couva, Trinidad And Tobago*

Background: Multidisciplinary support services for autism spectrum disorder are minimal in the public service and often inaccessible due to the high cost privately. Repeated advocacy efforts have also failed to impact significantly the public service provisions. The stark reality is that many families do not access basic services like speech therapy and occupational therapy. Many children do not receive adequate access to school placements.

Early detection and intervention is the way forward but in a developing country, impacting service provision is limited by resource challenges regarding funding, management, political will, infrastructure limitations, and limited human resources.

This project accessed funding from a NGO to train professionals within the public health system to provide parent training modules to parents in their service regions.

Objectives: We studied the impact of a NGO sponsored training in providing training to parents of children with ASD.

Methods: In March 2016, December 2016 and November 2017, a local Rotary Club, a Child Health Department of a tertiary institution, a Community Paediatric team in a Regional Health Authority (RHA) and a foreign university autism research and treatment centre came together to host autism parent training modules. Selected professionals from all five Regional Health Authorities in the country were invited to be trained. Parents from various public clinics were invited to attend. Eight modules were completed. Professionals trained then offered training to parents in their respective regions.

Results: Within twenty four months subsequent to the initial training, sixty percent of the RHAs held some form of parent training for local families.

In one RHA, a child psychiatry team and a community paediatric team collaborated to provide parent training during afternoon sessions within working hours in a local health centre. Materials were provided through the RHA print centre. Light refreshments were sponsored by a drug company. Eight training sessions were carried out during the twenty four month period. On average thirty parents were invited for the training but the average attendance rate was 60% of parents invited. Initial feedback indicated that parents found the training beneficial. Data regarding the outcome after training is to be collected.

In another RHA, training was carried out in a local health centre for small groups of parents. A medical officer teamed up with nurses in the health centre to provide the training.

In another RHA, an initial large group parent training session was carried out. A further six parent training sessions were carried out over the next two years.

Training was also provided in the context of clinical consultations in paediatric follow up clinics.

Conclusions: In keeping with the United Nations mandate for upgrading services for Autism this Public/NGO partnership has improved capacity by training parents. Given the constraints, financial and otherwise, this type of partnership is a way forward in developing countries. While the partnership has bolstered capacity, further supports and strategies beyond provision of initial training is necessary to achieve sustainable improvements in care.

444.007 *(Poster)* Autism Services Research Funding: Trends across a Decade

P. E. Cervantes[1]*, M. Matheis*[2]*, J. A. Estabillo*[3]*, D. Seag*[1]*, R. M. Peth-Pierce*[4] *and S. Horwitz*[1]*, (1)Department of Child and Adolescent Psychiatry, NYU Langone Health, New York, NY, (2)Psychiatry and Behavioral Sciences, University of California at Davis MIND Institute, Sacramento, CA, (3)Psychiatry, UCLA Semel Institute for Neuroscience & Human Behavior, Los Angeles, CA, (4)Public Health Communications Consulting, LLC, North Royalton, OH*

Background: The autism field's substantial, prolonged emphasis on biology and putative risk factors, as well as the subsequent NIH funding targeted to these issues, has come at the expense of areas such as treatment and services that have the capacity to more rapidly improve the lives of many individuals with autism spectrum disorder (ASD) and their families. Recently, a shift has occurred highlighting this issue both in the media and by funding agencies. In fact, the NIH has identified the development and delivery of evidence-based services as an area in need of resource growth. However, with the exception of knowing the broad fact that, since 2008 service research funding averaged <10% of total autism-related funds, little is known about the patterns of services funding, the issues addressed by the services specific funding or the products from that funding.

Objectives: Therefore, the objective of this study was to conduct a detailed analysis of trends in services research funding for ASD using data on NIH-funded projects to understand funding patterns and issues addressed by funded projects and to identify future areas of research.

Methods: Given that NIH funds the majority of ASD research, we examined data on federal funding for ASD services research via NIH RePORTER from 2008-2018; 135 projects met criteria for review. Data collected included, but was not limited to, administering institute/center, cost per year, services category of focus, population of interest, symptom focus, setting and intervention agents, linked publications, and US state.

Results: The number of services projects funded was highest in 2018 (*N*=26); however, the 10-year trend was inconsistent and did not show a linear increase across time. Spending has increased from $4.43 to 22.99 million, though this may be proportionate to funding overall. Most projects focused on treatment development/efficacy/evaluation (~51%), with policy research (~8%) least prevalent. Trends in total spending mirrored these results, with few resources going to policy (~6% of overall funds). Notably, ~50% of projects came out of just three states, and there was no funding for services research in 21 states. Research most often took place in universities/medical centers. Encouraging results were found in regard to intervention agent, symptom targets, and age range studied. Analyses of trends across time and services categories, as well as a detailed review of linked publications are in process.

Conclusions: Few services projects related to ASD were funded in the last decade and most were treatment studies in university/medical center settings, which often fail to address important factors relevant to providing services in community settings. Thus, more attention to implementation and dissemination is needed. Further, the limited representation of states holds important implications for generalization of results, as each state service system is unique. This is further complicated by the lack of attention to policy in ASD services research, which has recently received attention as a potential, powerful mediator between research and practice.

444.008 *(Poster)* Autism, Poverty and Family Financial Hardship

K. Anderson[1]*, J. Rast*[2]*, A. Roux*[2] *and P. Shattuck*[2]*, (1)Life Course Outcomes Research Program, Drexel University A.J. Drexel Autism Institute, Philadelphia, PA, (2)A.J. Drexel Autism Institute, Drexel University, Philadelphia, PA*

Background: Families of children with ASD face several financial challenges due to complex service needs and high out of pocket expenditures. Families living in poverty are especially vulnerable due to high demands on family resources, reduced earnings and disconnection from services and supports. As of 2016, an estimated one-third of children with ASD are living in poverty. Despite this, we know little about the characteristics, financial hardships and use of financial supports among households of children with ASD. Gaining such an information can help to inform policies aimed at promoting economic well-being of children with ASD and their families.

Objectives: This report explored family financial hardship among families of children with ASD (ages 3-17 years) and their participation in safety net programs. We addressed the following three aims: 1) to present levels of family financial hardship among households of children with autism, 2) to describe the types of safety-net programs low-income households of children with autism report using, and 3) to report levels of family financial hardship among low-income households of children with autism that do and do not receive safety-net benefits.

Methods: We analyzed data from the combined 2016 and 2017 National Survey of Children's Health (NSCH). Our sample included 1,679 children, ages 3-17 years, whose parents reported a current diagnosis of autism. We compared findings to households of children with other special healthcare needs (SHCN), but no autism (N=13,959) and to all other households of children (N=61,940). We used descriptive analysis to generate national point estimates across several domains of family financial hardship including household poverty, family out-of-pocket expenses, and material hardship (which included: difficulty paying for basics like food or housing; unable to afford adequate food; difficulty paying a child's medical bills; and reducing work hours to care for their child). We also assessed household receipt of the following four safety net programs: Temporary Assistance to Needy Families (TANF), Supplemental Nutrition Assistance Program (SNAP), Special Supplemental Nutrition Program for Women, Infants, and Children (WIC), and the National School Lunch Program (NSLP).

Results: Over half (56%) of children with ASD lived in low-income households. Children with ASD from low-income households tended to have poorer health and higher levels of autism severity than their peers from higher-income households. Two-thirds of parents of children with ASD reported experiencing at least one type of material hardship. Material hardship was higher among parents of black and Hispanic children with autism and younger children (ages 3-5 years). Out-of-pocket expenses were lower among children with ASD from lower-income households and those that received Medicaid. Over one-fourth (30%) of children from households under 200% of the FPL were disconnected from all safety net programs.

Conclusions: The high proportion of households of TAY with ASD that participate in safety-net programs, coupled with high rates of material hardship among this population, warrants the further investigation of antipoverty programs and ASD.

444.009 *(Poster)* Autism-Friendly Language and Literacy Library Program: Development and Evaluation of an Online Package for Librarians

J. M. Paynter[1,2]*, K. Simpson*[2,3]*, K. O'Leary*[2,4]*, R. T. Wicks*[2,5] *and M. F. Westerveld*[2,5]*, (1)School of Applied Psychology, Griffith University, Gold Coast, QLD, Australia, (2)Autism CRC, Brisbane, QLD, Australia, (3)Messines Rd, Griffith Univeristy, Brisbane, QLD, Australia, (4)Griffith University, Gold Coast, QLD, Australia, (5)School of Allied Health Sciences, Griffith University, Gold Coast, QLD, Australia*

Background: Learning to read with understanding is essential for participation in education, the workforce, and society. Concerningly, up to 65% of students on the autism spectrum show impairments in reading (e.g., Johnels et al., 2019). Literacy development commences before children begin school providing an opportunity for early supports prior to the onset of challenges. Public libraries provide a free avenue for many families during this time to support children's skill development through access to multimedia, reading materials, and early language and literacy sessions. However, families of children on the spectrum report accessing these resources less often than families of children without autism (e.g., Simpson et al., 2019). They also report barriers to access including challenging sensory environments, difficulties engaging their child, and concerns about their children's challenging behaviours (Prendergast, 2016; Simpson et al., 2019).

Objectives: We aimed to develop an online training package for librarians to support implementation of autism friendly library sessions. This included evaluation of the effectiveness of training in increasing autism knowledge and self-efficacy to include children on the autism spectrum in library activities as well as social validation.

Methods: A mixed methods approach was used across three phases. Phase 1 included development and evaluation of face-to-face delivery of training with 22 (20 females, 2 males) librarians including quantitative evaluation of changes in autism knowledge and confidence in including children on the spectrum (adapted from the Autism Inclusion Questionnaire, Segall & Campbell, 2007), and social validity of the training (adapted from the Intervention Rating Profile, Martens et al., 1985). Phase 2 included implementation in libraries and qualitative evaluation of the utility and implementation of training through interviews conducted with five female librarians. Phase 3 included translation to an online module which was completed by 22 female librarians and evaluation of autism knowledge, confidence, and social validity of the training in response to the online delivery of content.

Results: In Phase 1 statistically significant changes in knowledge and confidence were found following training. Phase 2 provided insight into implementation in practice including increased confidence in providing a more supportive environment and valuing library sessions as literacy learning experiences. Phase 3 showed the initial feasibility and effectiveness of the online translation of training including increases in knowledge and confidence. Across phases the training was rated as socially valid by participants with feedback for fine-tuning such as including example scripts incorporated from Phases 1-2 into the Phase 3 online translation.

Conclusions: The use of a mixed methods approach to the development and refinement of training provides a model for future development of knowledge translation tools to disseminate research into community practice. Our research provides the first proof-of-concept of the online training package to support participation of children on the spectrum through changes in librarian practice. The next stage is to evaluate the implementation of learned strategies by librarians and the impact on child access and outcomes including development of emergent literacy skills relative to comparison groups not accessing library services to ultimately support better literacy outcomes for this population.

444.010 *(Poster)* Autistic Adult Services Availability and User Experiences in the EU: Results from the Autism Spectrum Disorder in the European Union (ASDEU) Survey on Residential, Employment, Education, Financial and Social Services

Background: The research base for autism in adulthood is underdeveloped and there is very little knowledge regarding autistic adult services practices and delivery.

Objectives: The overall objective was to improve understanding of current services practices for autistic adults and opportunities for improvement as part of the Autism Spectrum Disorder in the European Union (ASDEU) project comprised of 20 partners in 14 European Union (EU) states. This study's specific objective was to examine autistic adult services availability and user experiences based on an ASDEU survey of residential, employment, education, financial and social services.

Methods: ASDEU survey questions included services availability, user preferences, waiting times and alignment of user experiences with published guidelines regarding residential, employment, education, financial and social services provision for autistic adults. Separate survey versions were created for autistic adults, carers of autistic adults and professionals in adult services. The survey was translated into 11 languages and distributed in 2017 by ASDEU partners via electronic media hosted by ASD organizations and in-country adult services facilities. For this study, distributions of responses from all three respondent groups regarding features of each type of service were analyzed separately; responses from the carer group for analysis were stratified on level of independence of the autistic adult under care.

Results: 1,842 persons responded to the survey: 631 autistic adults (66% female; 52% 26-35 years old), 526 carers of autistic adults (autistic adults were 27% female; 54% 18-25 years old), 685 professionals in adult services (80% female; 52% in non-medical services). There were from 100 to 590 responders per country from Denmark, Finland, France, Iceland, Italy, Poland, Spain and UK; and 50-60% of responders were in communities of 20,000-1 million inhabitants. The top choices by autistic adults or carers (10%-42% of responders) for services best suiting their current needs were: residential - 'help in own home', 'full time residential facility'; employment - 'job mentors'; education - 'support in regular education setting'; financial - 'supplementary income if not fully employed', 'supported employment', 'full pension (if cannot work)'; social - 'behavior training for individual', 'peer-to-peer matching', 'peer-to-non-peer matching', 'life skills training'. The top choices of professionals (29-75% of responders) for services most needed were: residential - 'day center', 'help at college'; employment - 'job mentors', 'employer programs'; education - 'support in regular education setting', 'day school'; financial - 'supported employment'; social - 'life skills training'. Median waiting times for specific services were generally <1 month or 1-3 months, except for residential services which could be up to 6 months. Most professionals were uninformed of waiting times ($\geq$ 50%: 'don't know'). Seven of the 9 recommended residential services features were experienced by <50% of carers or adults.

Conclusions: Variation in services experiences and perceptions reported by autistic adults, carers of high or low independence autistic adults, or adult services professionals underscores the need to query all groups for a complete picture of community services availability and needs. The results reveal areas for improvement in autistic adult services delivery in the EU to achieve recommended standards.

444.011 *(Poster)* Capturing the Autistic Experience: Self-Advocates Develop Self-Assessment Tools to Inform Autism Diagnosis across the Gender Spectrum

J. Bascom[1], *S. daVanport*[2], *L. Anthony*[3], *A. B. Ratto*[4], *J. F. Strang*[4,5], *G. L. Wallace*[6], *S. Bishop*[7], *A. Verbalis*[4], *C. Jeppsen*[4], *L. Saldana*[8], *M. Troxel*[3], *C. E. Pugliese*[4], *K. A. Pelphrey*[9] *and L. Kenworthy*[4], *(1)Autistic Self Advocacy Network, Washington, DC, (2)Autistic Women & Nonbinary Network, Lincoln, NE, (3)University of Colorado, Denver, Aurora, CO, (4)Center for Autism Spectrum Disorders, Children's National Hospital, Washington, DC, (5)Children's National Health System, Washington, DC, (6)The George Washington University, Washington, DC, (7)University of California San Francisco, San Francisco, CA, (8)Children's National Health System, Rockville, MD, (9)University of Virginia, Charlottesville, VA*

Background: Current gold standard tools for identifying and studying autism are critiqued for their lack of specificity and sensitivity, especially in autistic people who are older, have higher IQs, and are not cisgender boys (e.g., Lai, Lombardo, Auyeung, Chakrabarti, & Baron-Cohen, 2015). For example, evidence from an epidemiological study indicates that girls are diagnosed later than boys, particularly girls without intellectual disability (Shattuck et al., 2009). Information from autistic people about their own experience of autism represents an untapped resource for enhancing clinical and research tools for diagnosis and phenotyping. To fully capture the inner experience of autism, however, autistic people need to define the questions asked, as well as the answers given.

Objectives: Leverage a collaborative team of autistic self-advocates, clinicians and researchers to develop an ADOS-2, Module 4 participant feedback questionnaire and a self-report autism trait questionnaire to capture the inner experiences of autistic people.

Methods: As part of an NIMH Autism Center of Excellence Network study of gender in autism, and using participatory research techniques, autistic self-advocates partnered with autism researchers and clinicians to develop and collect self-report measures on two autism evaluation tools. These are:

- A participant feedback questionnaire to capture the inner experience of people receiving the ADOS-2, Module 4, in order to inform ADOS findings. Feedback will also be collected after the research appointment about participants' experience in the study overall.
- A self-report autism trait questionnaire constructed with items identified by an iterative process consisting of: environmental scanning of writings by autistic people validated by the autistic community as touchstones; condensing those descriptions into themes; generating an item list from those themes; and revising the items through a two-stage Delphi procedure, adapted for the diverse Delphi panel of autistic experts (e.g., speaking and non-speaking, full gender spectrum).

Results: The development of the ADOS feedback questionnaire has identified important issues such as the level of effort expended to participate in the ADOS interview and whether any of the participant's comments had been previously rehearsed or practiced. The questionnaire has also expanded to assess both the positive and negative experiences autistic people encounter in assessment and research. The self-report autism trait questionnaire, based on the environmental scan, addresses aspects of the autistic experience that are not captured with current diagnostic tools, such as "autistic inertia" and experiences of "camouflaging." The involvement of the autistic Delphi experts and autistic lead researchers was crucial in revealing the challenge of developing self-report questionnaires of autistic traits that are non-stigmatizing and truly assess autism without making comparisons to an implicit neurotypical standard. The process further revealed the challenge of disentangling autistic traits from trauma and bias.

Conclusions: Participatory research techniques with autistic researchers as co-investigators leading researchers and clinicians in the development of new assessment tools yields measures which introduce previously unrecognized components of the autistic experience. The development of these promising new tools illustrates the necessity of enabling autistic experts to lead research efforts in order to drive meaningful lines of inquiry and obtain valid, important, and exciting findings that arise from that work.

444.012 *(Poster)* Comparing Social Capital Among Parents of Low-Resource Children on the Autism Spectrum during Key Life Stages

E. McGhee Hassrick[1]*, E. Morgan*[2]*, C. Friedman*[3]*, R. E. King*[4]*, D. E. Linares*[5]*, S. Iadarola*[4]*, A. C. Stahmer*[6]*, D. S. Mandell*[7]*, C. Kasari*[8] *and H. J. Nuske*[7]*, (1)A..J. Drexel Autism Institute, Drexel University, Philadelphia, PA, (2)UC Davis, Sacramento, CA, (3)Drexel University A.J. Drexel Autism Institute, Philadelphia, PA, (4)University of Rochester Medical Center, Rochester, NY, (5)Maternal and Child Health Bureau, Office of Epidemiology and Research, Health Resources and Services Administration, Rockville, MD, (6)Psychiatry and Behavioral Sciences, University of California at Davis MIND Institute, Sacramento, CA, (7)Center for Mental Health, University of Pennsylvania, Philadelphia, PA, (8)University of California, Los Angeles, Los Angeles, CA*

Background: Low resource caregivers with children with autism spectrum disorder (ASD) experience difficulties accessing services post-diagnosis and during key life events (e.g., school transitions; Nuske,et al 2018). Disparities may relate to levels of social and cultural capital, i.e., resources within social networks that provide advantages (Lin 2001). Family and community supporters can provide additional resources and professionals can provide access to services. Cultural capital is the dominant social assets that one possesses (e.g., education) that promote social mobility. It also includes non-dominant cultural resources and social assets found in communities of color, e.g., aspirational capital (ability to maintain dreams for the future; Yosso 2005).

Objectives: Describe community cultural capital, network density, network size and role in a sample of low-resource caregivers with children with ASD and explore cross sectional variation in community cultural and social capital across key life stages.

Methods: Participants were recruited for two behavioral intervention RCTs across four Autism Intervention Research Network on Behavioral Health (AIR-B) sites: Los Angeles, CA; Sacramento, CA; Philadelphia, PA; and Rochester, NY. Participants included primary caregivers of children (2-14 years) with ASD (n=249) who were largely female (90%), and ethnically diverse (41% Hispanic; 23% Black; 5% Asian; 29% other non-white), with mean age of 36.8 years. Families fell below the federal poverty level standards, with 83% of caregivers at an average household income of under $50,000. Families identified up to ten supporters of their child and their connections with one another. We used a multi-dimensional community capital survey to capture Cultural Wealth (Yosso, 2005), Motherhood Capital (Lo, 2016), and Black Cultural Capital (Carter, 2003). Caregivers were grouped into four different categories by child's age/grade, including "infant/toddler" (n=17; age 0-3); "pre-school/kindergarten" (n=146); "elementary" (n=49; 1-5 grade); and "middle school" (n=37; 6-8 grade).

Results: Caregivers reported high levels of non-dominant community cultural capital, excepting social capital. Caregivers of color reported higher levels of all non-dominant forms of community capital, except navigational and familial forms. Few network members had weekly or more contact with one another. White caregivers had greater professional density that caregivers of color (24% vs. 14%) Contact density was lowest during the early childhood stage (5%) and highest during elementary stage (10%). Mean network size was lowest during middle school (5.03) and highest during early childhood (5.53). Weekly connections bridging family/community supporters and professionals were sparse across all life stages (overall 2%).

Conclusions: Low resource caregivers identified cultural resources (e.g., aspirations for the future). This study provided confirmation that caregivers of color rely on nondominant forms of cultural capital while parenting their child with autism. However, access to key social capital is lacking, creating a systemic barrier. The disparity in professional densities between caregivers of color and white caregivers suggest key barriers that require further investigation. Future interventions should use asset-based tactics to build on the community capital strengths of caregivers. Strategies to build connections that bridge home, community and professional contexts will allow for increased access to key resources to better support children with ASD across all life stages.

444.013 *(Poster)* Critical Time Points When Accessing Diagnosis and Early Treatment Among Children with ASD: A Comparison between Immigrant Children and Children of US-Born Parents

Y. Xu[1]*, L. A. Bilaver*[2]*, K. Acharya*[3]*, R. L. Dodds*[4] *and S. Magaña*[5]*, (1)Disability and Human Development, University of Illinois at Chicago, Chicago, IL, (2)Pediatrics, Northwestern University, Chicago, IL, (3)University of Illinois at Chicago, Chicago, IL, (4)Special Education & Counseling, California State University Los Angeles, Los Angeles, CA, (5)Steve Hicks School of Social Work, University of Texas at Austin, Austin, TX*

Background: The number of children diagnosed with Autism Spectrum Disorder (ASD) has grown at a striking rate. Numerous researches have shown that early detection, treatment and services are crucial in advancing outcomes and reducing symptoms. Center for Disease Control's report on ASD was based on 11 states, which does not include the State of Illinois (Biao et al., 2018). As one of the top immigrants receiving states, Illinois hosts approximately 1.8 million immigrants (US Census Bureau. 2017). Little is known about the timeline or critical time points of their experiences as they seek diagnosis and therapy compared to children with ASD of non-immigrant parents.

Objectives: This paper sought to compare the timeline of diagnosis and early therapy access between immigrant families and US born families of children with ASD in the state of Illinois.

Methods: A survey was developed based on previous studies on access to diagnosis and treatment. 213 parents of children with ASD who were under the age of 18 at the time of data collection completed the survey. Among them, 21 were immigrant parents. Using immigrant vs US-born as the grouping variable, we conducted independent sample t-test comparing children's age (in months) when parents first noticed something different in their child, when parents first talked to a doctor or clinician about their concerns, when child gets their diagnosis, and when child first received any kinds of therapy services.

Results: Comparing immigrant children with ASD's timeline for diagnosis and treatment with children with ASD of US born parents, we found no significant differences in all critical time points except marginally significant differences in children's first access to any kinds of therapy (t=1.148, *p*=0.058). Children of US born parents' first access to therapy earlier (M=37.7, SD=28.1) than children of immigrant parents (M=46,1 SD=41.6). When only children who requires substantial support were included (N=74), children of immigrant parents (N=12) were significantly older for all four critical time points compared to children of US born parents (N=52). Specifically, immigrant parents first notice something different when their children were significantly older (M=29.3, SD=25.4) compared to the other group (M=16.5, SD=10.3, t=1.63, *p*=0.000). Immigrant parents also brought up their concern to a doctor or clinician when their children were much older (M=34.6, SD=33.9) compared to US born counterparts (M=18.9, SD=13.2, t=1.58, *p*=0.001). Children of immigrant families also had later diagnosis (M=52.9, SD=42) compared to children of US born parents (M=40.1, SD=22, t=0.944, *p*=0.005). Similarly, children of immigrant families also accessed any kinds of therapy at an older age (M=54.2, SD=51.3) compared to children of US born parents (M=26.7, SD=15, t=1.84, *p*=0.000).

Conclusions: It is alarming that children of immigrant families who requires substantial support had a significantly delayed timeline at every single critical time points as their parents seek diagnosis and therapy. Our findings underscore the importance of targeting immigrant families of children with ASD with more profound functional limitations to facilitate early detection and access to treatment. Awareness campaigns and screening events should take measures to improve outreach to immigrant families.

444.014 *(Poster)* Developing the Autistic Satisfaction with Care Holistic Interview Using the Delphi Method.

C. J. Crompton[1]*, C. Michael*[2] *and S. Fletcher-Watson*[3]*, (1)University of Edinburgh, Edinburgh, United Kingdom of Great Britain and Northern Ireland, (2)Independent Autistic Consultant, Norwich, United Kingdom, (3)Division of Psychiatry, University of Edinburgh, Edinburgh, United Kingdom*

Background: Autistic adults may need residential care as they transition into old age, as in the non-autistic population. Very little is known about the needs of older autistic adults in residential care, and how to support them within residential care services. Care homes for older people play a central role in their social, physical and psychological quality of life, and it is important to identify and understand what factors can contribute to wellbeing for autistic adults, who may have specific and unidentified needs. One obstacle to research in this field is a lack of appropriate tools to capture the experience of older autistic adults in residential care settings.

Objectives: To create a new research tool to investigate the experiences of autistic adults living in residential care services. We aimed to incorporate community derived priorities and questions, using a Delphi method to design the interview-based research tool.

Methods: Twenty-six UK-based experts in autism, ageing, and residential care including autistic adults, their family members, service providers, clinicians, and academics were recruited as expert panellists for the Delphi study. All participants completed the two-round Delphi process, which involved identifying and prioritising key areas of interest, generating and providing feedback on interview content.

Results: Four areas of interest and high priority for older adults living in residential care were identified and rated as important by > 70% of respondents, and used to design the research tool: (1) Daily life, including daily routine, spending time with others, hobbies and interests; (2) The home environment, including comfort of the surroundings, safety and privacy, and the sensory environment; (3) Independence and advocacy, including supporting autonomy, flexibility, and advocacy; and (4) Health and wellbeing, including physical health, food, fitness and hygiene. To allow for inclusion of all priority topics, four linked interviews were designed, each covering one topic. Subsequent interview questions were generated by expert panellists, and refined to create the final interview schedule. This co-creation process gave rise to the Autistic Satisfaction with Care Holistic Interview (ASCHI), an open-access interview schedule designed to be used with autistic adults in residential care homes.

Conclusions: To identify and support the needs of older autistic adults in residential care, it is essential to first understand their experiences. Co-creating this research tool to facilitate future research is an essential step in the process. A participatory research paradigm was used to ensure areas of enquiry were defined by the autism community. The ASCHI is an open-access tool that can be used in future studies to explore the experiences of older autistic adults in residential care, and help shape future research, practice and policy. With appropriate validation, it could also be developed for use in service evaluations. More broadly, our Delphi method could be replicated by teams developing new measures for use with under-researched populations.

444.015 *(Poster)* Early Intervention Effects on Gesture Use in Children with ASD: A National Query of SLPs

J. R. Miller *and A. B. Barber, Communicative Disorders, University of Alabama, Tuscaloosa, AL*

Background: Gesture development, use, and repertoire differ in young children with ASD than in those with typical development (Manwaring et al., 2018 and Watson et al., 2013). Gestures play a fundamental role in social interaction and are an important intervention outcome in early ASD interventions. However, which interventions are most effective at improving gestures for the purpose of social interaction remains unclear. Naturalistic Developmental Behavioral Interventions (NDBI's, Schreibman et al., 2015) frequently incorporate gestures into their teaching targets and outcomes. For example, Ingersoll (2010) studied the impact of object and gesture imitation on language use in children with ASD and found that teaching gestural imitation alongside object imitation lead to higher rates of language use than object imitation alone. Even within the scope of NDBIs, techniques used to teach gestures, measurement, and how gestures are prioritized within the intervention context vary. Further, Speech Language Pathologists (SLP) are often the first professionals to intervene with children with ASD and prioritize communication objects. However, very little is understood regarding how SLPs address gestures in early interventions. Therefore, the purpose of this study is to survey practicing SLPs to determine which methods are most frequently used to teach gestures to young children with ASD and if those methods are considered NDBIs.

Objectives: To survey practicing SLPs to determine which intervention methods are most frequently used to teach deictic gestures to young children with ASD.

Methods: First, a comprehensive literature review was completed to determine intervention strategies that result in increased gesture production. Next, a survey was distributed nationwide through ASHA, SLP message boards, and social media sites to ask SLPs about their training and experiences with deictic gestures. Specifically, the survey asks how often SLPs teach gestures, in what contexts gestures are taught, which methods are used (i.e. NDBIs, direct strategies, caregiver coaching), and how effectively SLPs feel their intervention improves gestures.

Results: Preliminary analyses were conducted with 85 participants. Participants were provided with a comprehensive list of 25 intervention techniques and packages, some of which are considered effective according to the National Autism Center (NAC) Standards Report, and others are not. They were asked to identify all strategies they use to target deictic gestures. Twenty-five percent of the sample reported they had specific training in deictic gestures. Seventy-two percent reported they received specific training on social communication in ASD. Regarding intervention strategies, descriptive analyses revealed modeling as the most frequently implemented strategy, followed by prompting, following child's lead, naturalistic teaching, and PECS. Twelve percent of the sample reported they do not target gestures in interventions. All 25 intervention strategies were endorsed by at least two respondents.

Conclusions: Results indicated that SLPs are implementing a wide range of intervention strategies to teach deictic gestures. Among the top five endorsed categories, prompting and naturalistic teaching are deemed established treatments according to the NAC. All but PECS are captured within the NDBI framework. The large variance in findings emphasizes the need for targeted pre-professional and inservice training experiences targeting knowledge and interventions for deictic gestures.

444.016 *(Poster)* Employment Policy for Working Age Youth and Adults with ASD

A. Roux[1]*, J. Rast*[1]*, K. Anderson*[2]*, T. Garfield*[1] *and P. Shattuck*[1]*, (1)A.J. Drexel Autism Institute, Drexel University, Philadelphia, PA, (2)Life Course Outcomes Research Program, Drexel University A.J. Drexel Autism Institute, Philadelphia, PA*

Background: Over half of transition-age youth with autism (TAY-ASD) are disconnected from employment in the first two years after high school. The 2014 Workforce Innovation and Opportunity Act (WIOA) encourages earlier provision of Vocational Rehabilitation (VR) services to support youth with disabilities during the school-to-work transition. Approximately half of TAY-ASD who use VR services are secondary students at VR application. However, no published research examines prevalence and correlates of the VR services students with autism may receive during high school and their association with successful employment outcomes. Understanding VR service utilization and associated outcomes during the critical period of transition to adulthood is important for informing effective policies.

Objectives: Determine prevalence and correlates of VR service utilization and employment outcomes for TAY-ASD who entered VR as students, compared to non-student TAY-ASD and adults with ASD.

Methods: We analyzed the federal Rehabilitation Services Administration database for VR cases closed in FFY 2015-2017. Analysis included 18,773 TAY-ASD (ages 16-21) who entered VR as students; 12,710 TAY-ASD Non-students; and 12,611 Adult ASD Non-students (ages 22-39), who received VR services. We used binary analyses and logistic regression to examine the types of services utilized, association of demographic and impairment characteristics with services received, and the relationship between employment outcomes and receipt of key VR services (VR counseling and guidance, job search, job placement, short-term on-the-job supports).

Results: TAY-ASD Students received similar patterns of VR services as TAY-ASD and Adult Non-students; although TAY-ASD Students less frequently received key job-related services (job search, job placement, on-the-job supports) than TAY-ASD or Adult Non-students ($p<.001$). One-fourth of TAY-ASD Students received no key services. Approximately 26% of TAY-ASD Students who received no key VR services achieved employment at VR exit, compared to 87% of those who received all four key services. Adults with ASD had higher odds of receiving on-the job supports (OR=1.09), job placement (OR=1.1) and job search (OR=1.35), compared to TAY-ASD Students. The odds of TAY-ASD Students being employed at VR exit increased as the cost of services increased (OR=1.59). TAY-ASD Students who received job placement (OR=2.25) or on-the-job supports (OR=2.95) had the highest odds of achieving employment. Odds of employment were lower for TAY-ASD Students who were female (OR=.77), Hispanic (OR=.81), received SSI or SSDI at the time of exit (OR=.75), with less than high school education or a special education certificate at exit (OR=.88) or a "most significant disability" (OR=.76). TAY-ASD Students were less likely to be employed with every three-month increase in receipt of VR services (OR=.97).

Conclusions: TAY-ASD Students were less likely to receive key VR services or to exit VR with a job, than TAY-ASD or Adult Non-students. However, receiving key VR services was influential for increasing employment of TAY-ASD Students. States should focus on providing key VR services that support employment outcomes for TAY-ASD Students and optimize their transition into adulthood. Future research should continue to delineate the effectiveness of specific VR services for students and youth on the spectrum and determine how their service needs change across the lifespan.

444.017 *(Poster)* Enhancing Community Participation through Better Understanding of Families, Recreation Providers and Therapists.

L. Lowery[1] *and B. Stevenson*[2]*, (1)Occupational Therapy, University of Missouri, Columbia, MO, (2)Health Professions, Thompson Center for Autism and Neurodevelopmental Disorders, Columbia, MO*

Background: Although programming related to education and therapeutic gains is a central focus on ASD care, integration into community activities is an essential for reducing potential safety risks such as drowning and to increase community acceptance. This study examines the similarities and difference from 3 perspectives and provides strategies for successful implementation of community-based programming to reduce risk of drowning and to increase engagement of families in typical recreational activities.

Objectives: The purpose of this study was to identify perceived barriers to community-based recreation and to provide strategies for improving access to community-based programming; specifically swimming instruction.

Methods: Combination of descriptive research design through electronic survey to identify naturally occurring perceptions. Structured interviews with a constant comparative analysis to explore family perspectives on community participation were also used.

Participants included community recreation providers (n=25), therapists with a caseload of at least 75% children (n=85) and parents (n=12). Participants were recruited through various listservs via email and personal contacts as a convenience sample.

Online Qualtrics survey was created by researchers to administer to participants via email and Facebook. Questions were developed based on researcher's past knowledge on community participation and analysis of previous research. Structured interview for families was developed review of content experts and families.

Researchers used SPSS for analysis of data and identified commonly perceived barriers as well as the level of importance of community participation. Thematic analysis of an open-ended question from the survey and interviews was also conducted.

Results:

Community recreation providers identify lack of training/preparation and constraints such as lack of staff and limited space/time results in barriers to inclusion. Forty-six percent of providers indicate a preference for hands-on training and 50% indicate preference for training by someone with “expertise”. Furthermore, respondents also indicated they would like more training through educational resources (23.08%) as well as additional staff or volunteers on site (23.08%).

Therapy providers identified financial burden and transportation as perceived barriers. Less than 10% of all providers indicate they “always” (1-5 Likert scale) refer, provide information on community activities, provide information on transportation options or provide a list of funding options.

Families consistently report concerns regarding the training of recreation providers and access to services that are receptive to their child’s needs. Availability of programming that supports the unique needs of children is not regularly available. Family well-being is enhanced when offered opportunities to participate in community activities.

Conclusions: Community participation is an essential component of care for children and youth with ASD and their families. For programming to be successful and for families to feel comfortable and accepted, training by experts is needed to increase competence and comfort of providers. Community participation can potentially lead to reduced safety risks and increased feelings of acceptance and social opportunity for both children and families.

444.018 *(Poster)* Enhancing Providers’ Delivery of Feedback about an Autism Spectrum Disorder Diagnostic Evaluation

R. Haine-Schlagel[1,2]*, T. Carr*[3,4]*, K. Chau*[2]*, C. Corsello Orahovats*[5]*, G. Gyurjyan*[6] *and L. Brookman-Frazee*[1,7,8]*, (1)Child and Adolescent Services Research Center, San Diego, CA, (2)San Diego State University, San Diego, CA, (3)Autism Discovery Institute, Rady Children's Hospital San Diego, San Diego, CA, (4)UCLA Center for Autism Research and Treatment, Los Angeles, CA, (5)Division TEACCH, University of North Carolina, Chapel Hill; Chapel Hill, NC, Raleigh, NC, (6)San Diego Regional Center, San Diego, CA, (7)Psychiatry, University of California, San Diego, La Jolla, CA, (8)Autism Discovery Institute, Rady Children's Hospital-San Diego, San Diego, CA*

Background: Serving children with ASD is a significant public health concern (CDC, 2014). Up to 25% of children with ASD do not receive any services (Karp et al., 2018), and time to initiate recommended services is often lengthy. The manner in which clinicians deliver an ASD diagnosis after an evaluation may impact caregiver’s subsequent implementation of services. To date, only one study has examined a training on delivering an ASD diagnosis and found it increased trainees’ flexibility, attentiveness, and responsivity (Kawamura et al., 2016). To address this gap, the SPIRIT toolkit was recently developed for and piloted with psychologists at a regional children’s hospital to help them individualize communication with families during an ASD diagnostic evaluation (DX; Haine-Schlagel et al., 2019).

Objectives: To pilot SPIRIT for different provider types within a community agency, including examining: (1) providers’ perceptions of acceptability, appropriateness, usefulness, and utilization using mixed-method data; and (2) whether toolkit perceptions differed by provider characteristics.

Methods: 80 attendees at one of two trainings at the San Diego Regional Center for the Developmentally Disabled included: 1) psychologists who provide DXs; 2) service coordinators (SCs) who meet with families following a diagnostic evaluation; and 3) managers. Approximately 1-2 months later, attendees were sent a mixed-method feedback survey; 49 attendees (61.3%) responded. Respondents were 55.1% SCs, 24.5% psychologists, 4.1% managers, and 16.3% unknown. All respondents who reported gender were female. Average age was 40.2 (SD=11.4) and years in current position averaged 7.3 (SD=10.1). Close-ended responses (1-strongly disagree to 5-strongly agree) were analyzed descriptively using SPSS; open-ended responses were coded using an open-coding process (Haine-Schlagel et al., 2013). Bivariate correlations and independent t-tests were conducted to compare toolkit perceptions by provider characteristics.

Results: For objective 1, the training was considered acceptable (M=4.27; SD=.90; 87.8% agree-or-strongly-agree) and useful (M=4.05; SD=.80; 74.4% agree-or-strongly-agree). Open-ended responses were consistent; the training served as a useful reminder to tailor communication with families. The toolkit was considered an appropriate fit for agency mission and population served (M=4.29; SD=.70; 89.7% agree-or-strongly-agree). Many respondents reported using at least one tool in the last month (M=3.63; SD=1.15; 68.4% agree-or-strongly-agree) and planning to use at least one tool in the next month (M=3.90; SD=.87; 72.5% agree-or-strongly-agree). Some respondents reported improvements in communication with other providers and families due to the toolkit. For objective 2, provider age was significantly correlated with toolkit appropriateness (r=.345; *p*=.039) and marginally correlated with training acceptability (r=.300; *p*=.072). Psychologists reported significantly higher perceptions of toolkit appropriateness than SCs (psychologist M=4.63; SC M=4.12; *p*=.042). Time in position was not associated with any perceptions.
Conclusions: Mixed-method data indicate a toolkit designed to improve and individualize providers' communication to families following an ASD DX is acceptable, appropriate, and useful across provider types. Given SPIRIT was initially designed for psychologists, it is not surprising that they considered it more appropriate than SCs. Future efforts will be focused on increasing the intensity of the training and enhancing its appropriateness for service coordinators and other providers who help families process DX feedback and recommendations.

444.019 *(Poster)* Establishment of Operating Standards for Support Services for Children with Autism Spectrum Disorders in LMIC: Vietnam As a Case Example

C. V. Tran[1] *and B. Weiss*[2]*, (1)Department of Educational Sciences, VNU University of Education, Hanoi, Viet Nam, (2)Vanderbilt University, Nashville, TN*

Background:
Evidence-based intervention (EBI) as well as evidence-based assessments for ASD can be complex, both within a particular method but also in regards to the coordination across methods and providers for a particular child. To guide agencies and their services towards use and appropriate implementation of services such as these, "operating standards" are essential. Operating standards are guidelines that structure service provision to focus on and implement accepted standards of care believed to be most effective (Manghani, 2011).
Objectives:
The purpose of the present study was to develop a set of operating standards for ASD services for the Southeast Asian LMIC Vietnam, and to conduct a preliminary evaluation of the standards. In addition, the study can provide a model that may help guide development of ASD operating standards in other LMIC.
Methods:
This project involved three phases, each with separate research procedures. The first phase involved drafting an initial set of operating standards. The second phase of this project involved evaluation and modification of these initial standards by professionals (e.g., teachers; psychologists) and experts (university faculty) in Vietnam involved in ASD service provision, research and training. The third phase involved evaluation and finalization of the revised standards by a different set of experts in the ASD field.
Results:
A set of 9 standards was established including: (1) Legality indicates that an agency must be registered under some governmental authority, which can include sanctioned professional associations, or national, provincial, or district departments of education; (2) Ethics focus on agency ethics such as putting the benefit and well-being of family and children as the highest priority; (3) Human Resources structures the qualifications for each position with the agency; (4) Intervention Approach emphasizes that practice activities should be "empirically-based" practice, and that agencies should only use approaches recommended by the scientific community; (5) Intervention Process focuses on the sequence of procedures that a child would go through at the agency; (6) Intervention Plan describes what targets and activities to achieve the targets should be included in intervention plans; (7) Periodic Training describes the regular trainings that both the agency staff as well as the child's caregivers should receive; (8) Facilities recommends the minimum space for each child, and types of functional rooms that a center should have; (9) Recommended Standards has several components that are recommended but not required.
Conclusions:
After a long study with the application of a variety of research methods on the appropriate target population, a set of standards was developed for tested, disseminated widely, and incorporated into the policies of related governmental organizations and units. Almost every professional agreed that the standards were necessary, appropriate and scientific, suggesting that the standards are feasible, but there are still concerns about the application in practice.

444.020 *(Poster)* Evaluating Possible Disparities in School-Provided Services for Students with ASD: A Systematic Review

M. Melgarejo[1]*, B. Ventenilla*[1]*, S. F. Vejnoska*[2]*, K. S. Dickson*[3]*, S. R. Rieth*[1] *and J. Suhrheinrich*[1]*, (1)San Diego State University, San Diego, CA, (2)University of California, Davis, Sacramento, CA, (3)Child and Adolescent Services Research Center, San Diego, CA*

Background: School districts are required to provide for students' educational and associated needs (United States, Congress, & Senate, 2003) and schools are the primary service provider for children with ASD (Brookman-Frazee et al., 2009). However, there are equity concerns regarding possible differences in the amount or type of school-provided services across subgroups of children with ASD. For example, Hispanic children with ASD are less likely than White children to receive in-school behavioral health services (Locke, et al., 2017) and children diagnosed with ASD at older (versus younger) ages have lower school-based therapy use (Zuckerman, Lindly, & Chavez, 2017). This highlights a need for systematic examination of differences and potential disparities in school-provided services received by students with ASD.
Objectives: To characterize differences and potential disparities in amount or type of school-provided services received by students with ASD and to identify related factors.

Methods: Selected keywords and inclusion criteria were used to identify relevant articles through two electronic databases, ERIC and PsycINFO (1990-2019), resulting in 540 articles. Articles were screened based on the following study criteria: 1) Conducted in U.S. or Canada, 2) Published in a peer-reviewed journal, 3) Included participants diagnosed with ASD from preschool to transition-age, 4) Examined school-based services, and 5) Included sub-groups within ASD participants. Articles were screened by two reviewers and discrepancies were resolved through discussion, resulting in 36 eligible articles. A codebook was collaboratively developed and iteratively refined by all six reviewers. Articles were independently coded by three reviewers, with discrepancies resolved through consensus discussions.

Results: Preliminary evaluation indicates several key findings. Articles used quantitative (n=36) and mixed (n=1) methodology. Studies involved youth ages 3-6 (n=20), 6-11 (n=27), 12-14 (n=20), 15-18 (n=20), 19-22 (n=6), and 3 studies did not specify age. Aspects of school services examined included type of service (e.g., behavior supports and mental health services; n=28), service characteristics (e.g., intensity and parental involvement; n=15), quality of service (e.g., satisfaction and staff knowledge; n=6), and other (n=1). Factors examined as related to school services included child clinical characteristics (e.g., ASD severity level and adaptive functioning; n=26), family demographics (e.g., education level and SES; n=16), child demographics (e.g., ethnicity/race and age; n=13), family characteristics (e.g., parental stress; n=8), program characteristics (e.g., program fidelity and cost of services; n=6), and other (n=1). Differences in services received by related factors were coded and analyzed for frequency of service differences by associated factors. For example, one study linked higher ASD severity with receipt of more occupational, physical, social skills, and speech therapy, and another study indicated students with ASD in families with incomes under $50,000 had greater odds of receiving services at school. A summary of relationships between specific service categories and related factor categories will be presented.

Conclusions: Outcomes will advance our understanding of factors related to access, scope and intensity of school-provided services for youth with ASD and may inform critical areas for program evaluation to ensure service equity.

444.021 *(Poster)* Evaluating Registration Location on Sample Quality and Survey Completion of Participants in the SPARK Study

L. M. Herbert[1]*, N. Decius*[2]*, G. David*[2]*, D. Correa*[2]*, M. N. Hale*[1]*, A. Gutierrez*[3]*, M. Alessandri*[1] *and M. K. Rayos*[1]*, (1)University of Miami, Coral Gables, FL, (2)Center for Autism and Related Disabilities, University of Miami, Coral Gables, FL, (3)University of Miami, Miami, FL*

Background: Simons Powering Autism Research for Knowledge (SPARK) is a research study developed by the Simons Foundation, aimed at advancing the understanding of how genetics contribute to autism. The UM-NSU Center for Autism (UM-NSU CARD) is one of the 31-sites participating in the recruitment of individuals into SPARK. Participant registration includes providing a sample of saliva for genetic analysis. The UM-NSU CARD SPARK-site offers registration opportunities across 3 locations including (1) registering offsite via a web-based registration and saliva collection kit sent by mail; (2) onsite at a UM-NSU CARD hosted registration event; and (3) home-based consultation whereby a UM research visits a participant at home to assist in completing registration process. Following registration, participants are prompted via email, to provide more detailed information clinical history via questionnaires on a web-portal.

Objectives: The purpose of this study is to examine the quality of genetic samples and subsequent survey completion rates across three location options that UM-NSU CARD utilizes for SPARK participant registration.

Methods: We reviewed the registration location, genetic sample quality, and subsequent survey completion among 624 affiliated UM-NSU CARD SPARK registrants who completed the study from 3/2018 and 2/2019. The sample consisted of 222 (37%) individuals with ASD, and 402 (33%) biological parents. The categorization of the three registration locations as follows: offsite, onsite, and home-consultation. For this sample, 248 (39.7%) registrations occurred offsite, 311 (49.8%) onsite, and 65 (10.4%) via home-consultation. Sample quality was evaluated as pass or fail, based upon laboratory analysis of its utility for genetic analysis. For this sample, 558 (90.1%) passed quality analysis. The survey completion was deemed completed if subsequent questionnaires were completed entirely. Not-completed and partially-completed surveys were categorized as not-completed. For this sample, 306 (49%) completed surveys.

Results: Regarding the sample quality, pass rates for registrations occurring via home-consultation (98.5%) was significantly better than pass rates for offsite (87.7%) or onsite (90%). There was no difference in the quality pass rate by participant status (i.e., ASD or biological parent). In terms of the survey completion rates, offsite registrants had significantly higher completion (64.5%) then both onsite (42.8%), and home consultation (20%).

Conclusions: Based on this sample, the location of registration has implications for both the quality of the obtained genetic sample and the subsequent completion of surveys. Providing one on one support via home consultation may foster a better quality of the sample collected. However, home-consultation and onsite registration do not result in optimal levels of subsequent survey completion. It will be important for future researchers to examine ways to improve survey completion following home-consultation and onsite registrations, as well as ways to foster improved sample quality of those participants registering offsite.

444.022 *(Poster)* Evaluating the Efficacy of Home Visits on Participant Enrollment in SPARK

V. Ranganathan[1], *M. Alessandri*[2], *C. Bradley*[3], *A. Brown*[4], *C. Buescher*[5], *L. Carpenter*[6], *K. Coleman*[7], *S. Consortium*[8], *S. Conyers*[9], *D. Correa*[10], *H. Cottrell*[11], *A. Daniels*[12], *G. David*[10], *N. Decius*[10], *K. Diehl*[12], *R. A. Gordon*[13], *A. Gutierrez*[14], *M. N. Hale*[2], *L. M. Herbert*[2], *S. Hunter*[15], *T. C. Kalmus*[16], *S. Kanne*[17], *R. Landa*[18], *H. Lechniak*[19], *A. McKenzie*[4], *M. McTaggart*[4], *J. Michaelson*[20], *N. Nagpal*[12], *S. Palmer*[21], *J. Pandey*[22], *K. Pierce*[23], *R. Shikov*[4], *M. Shir*[24], *A. Shocklee*[11], *V. Singh*[18], *R. T. Schultz*[22], *C. J. Smith*[25], *B. Van Metre*[26] *and E. L. Wodka*[27], *(1)CHOP, Philadelphia, PA, (2)University of Miami, Coral Gables, FL, (3)Developmental-Behavioral Pediatrics, Medical University of South Carolina, Charleston, SC, (4)Kennedy Krieger Institute, Baltimore, MD, (5)Psychiatry, University of Iowa, Iowa City, IA, (6)Medical University of South Carolina, Charleston, SC, (7)Southwest Autism Research and Resource Center, Phoenix, AZ, (8)SPARKForAutism.org, New York, NY, (9)MUSC, Charleston, SC, (10)Center for Autism and Related Disabilities, University of Miami, Coral Gables, FL, (11)University of Missouri Thompson Center, Columbia, MO, (12)Simons Foundation, New York, NY, (13)Psychiatry, Rush University Medical Center, Chicago, IL, (14)University of Miami, Miami, FL, (15)Thompson Center, University of Missouri, Columbia, MO, (16)Psychiatry, The University of Iowa, Iowa City, IA, (17)Thompson Center for Autism and Neurodevelopmental Disorders, Columbia, MO, (18)Center for Autism and Related Disorders, Kennedy Krieger Institute, Baltimore, MD, (19)Child and adolescent psychiatry, Rush University Medical Center, Chicago, IL, (20)Division of Computational and Molecular Psychiatry, Iowa City, IA, (21)CHOP Center for Autism Research, Philadelphia, PA, (22)Center for Autism Research, Children's Hospital of Philadelphia, Philadelphia, PA, (23)Autism Center of Excellence, Neurosciences, University of California, San Diego, La Jolla, CA, (24)UCSD, San Diego, CA, (25)Southwest Autism Research & Resource Center, Phoenix, AZ, (26)Kennedy Krieger Institute CARD, Baltimore, MD, (27)Center for Autism and Related Disorder, Kennedy Krieger Institute, Baltimore, MD*

Background: Simons Powering Autism Research for Knowledge (SPARK) is a research initiative designed to accelerate our understanding of the causes of autism. SPARK enrolls any individual with an autism diagnosis, their biological parents, and siblings. SPARK aims to identify ASD genetic risk factors and has sequenced DNA from 39,981 individuals with ASD. 25,691 of the sequenced samples were collected through the 31 clinical sites. Although saliva collection can be completed autonomously from home, 8 sites offered home visits, wherein study team members visit families' homes to complete registration, consent and saliva collection.

Objectives: Assess the impact of home visits on SPARK recruitment and enrollment; evaluate the most common and successful home visit strategies; share effective home visit practices with sites who offer home visits, and those who seek to implement them.

Methods: CHOP surveyed the SPARK Network to identify sites employing home visits. Eight sites conduct home visits: CHOP, MU Thompson, MUSC, UM-CARD, Rush, UIOWAKKI and UCSD/ SARRC. Sites were asked to describe successful visit strategies, data regarding frequency, duration and number of visits performed. SPARK Central provided data regarding saliva kit failure rates for each site. Saliva kit data was analyzed to determine failure rate differences in capture method.

Results: Of the 8 sites, 3 primarily used phone calls to schedule visits. Four used phone calls and emails, and 6 sites scheduled home visits during in-person interactions. All sites indicated that home visits required 2-3 hours of staff time, including scheduling, driving, visit completion and follow-up. The number of home visits completed since March 1, 2019 varied per site, with a minimum of 8 and a maximum of 98. Six sites offered visits during evenings/weekends, while all 8 sites set their own limitations on allowable distance. Feedback from families was positive, with participants referring others for these visits, highlighting the additional support for saliva collection, opportunity to ask questions and convenience of completing the kits at home.

SPARK Central data revealed that 29 of 31 sites perform "onsite" collection (study team assisted saliva sample collection). Of these 29 sites, 23 (and all 8 home visit sites) experienced lower saliva kit failure rates for samples collected onsite as compared with kits completed without.

Conclusions: Regardless of home visit volume, all sites surveyed observed a decrease in saliva kit failure rate with assistance, as compared with kits completed by families independently. This suggests that sites already performing home visits should increase home visits, while sites not using home visits should strongly consider their use. Two sites indicated that their rural surrounding communities limit their number of home visits, while 2 sites cited staff availability as a limiting factor. Sites who frequently perform home visits should consider collaborating in order to produce home visit SOPs for the network. Increasing awareness of home visits amongst families may also lead to an increase in overall SPARK participation. A questionnaire assessing families' thoughts on home visits may support a concerted effort to increase resources needed to make home visits a regular component of SPARK enrollment.

444.023 *(Poster)* Evaluation of an Information Support Program for Parents Accessing Services within an Individualized Funding Model: The Autism Ontario Service Navigation Program

S. J. Gentles[1], *C. Sawyer*[2], *N. Bardikoff*[2], *S. Shaw*[2] *and M. Spoelstra*[2], *(1)McMaster University, Hamilton, ON, Canada, (2)Autism Ontario, Toronto, ON, Canada*

Background: Ontario is Canada's most populous province (population 14 million) with approximately 135,000 people on the spectrum. In April 2019, Ontario's provincial Ministry of Child Community and Social Services (MCCSS) began transitioning from an autism centre-based funding model to an individualized funding model (or, direct funding model) for providing autism services to children and youth. Individualized funding models are promoted as a means to increase choice within publicly funded systems by providing families with self-directed budgets to purchase eligible services according to their preference. Other jurisdictions previously implementing such models for autism service delivery have provided examples to learn from, including Australia and the Canadian provinces of Alberta and British Columbia. Among the greatest concerns with this model has been providing adequate information to families to enable equitable access to budgets and support informed choices. To support families' informational needs within the individualized funding-based Ontario Autism Program (OAP), the MCCSS funded Autism Ontario to develop and implement the OAP Service Navigation Program (SNP).

Objectives: To describe early experience implementing the SNP by reporting results of an ongoing program evaluation.

Methods: Development of the SNP, including training of regional service navigators, was informed by a jurisdictional scan and a framework for providing information in individualized funding programs. Among other responsibilities (e.g., direct parent support, outreach activities), service navigators provided Childhood Budget Workshops to promote access and use of funds. Results below include second quarter (Q2) program evaluation highlights, and a survey of 133 parents who attended 34 Childhood Budget Workshops in September 2019. Further results (to Q4) will be available by the conference.

Results: In its first 6 months, the program's reach was actively extended through: connections made by the program's 18 regional service navigators with over 300 community agencies, online campaigns (e.g., Facebook ads, newsletters), and translation of promotional materials to 14 languages (beyond standard French language services). In Q2, service navigators had 1165 unique family contacts, and number of service navigation requests (1392) increased 245% from Q1. In the Childhood Budget Workshop survey, participants generally found workshops useful (98%; n=51), although not everyone necessarily felt better equipped to complete paperwork to access the program and manage funds (88%; n=49). Regarding barriers to managing funds, 50% felt they did not know what services their child needs, 33% did not know where to access services, and 34% did not know how to begin accessing services (n=42). Future program elements to be evaluated include a goal setting process, and peer-to-peer mentorship.

Conclusions: Childhood Budget Workshop survey findings are consistent with findings from other jurisdictions regarding the significant knowledge gaps within many families, which represent barriers to equitable access and informed use of self-directed budgets to purchase services. This highlights the importance and need for a robust informational service like the SNP in Ontario. The Q4 program evaluation results, including future Childhood Budget Workshop surveys, will be useful to policy makers in jurisdictions that provide or are considering providing informational services for families within an individualized funding model.

444.024 *(Poster)* Examining Access to Teacch Services across North Carolina

M. E. Villalobos[1]*, N. Ginn*[2]*, J. Scercy*[3]*, L. Scott*[4]*, R. Thomson*[4]*, J. Delisle*[4] *and L. G. Klinger*[5]*, (1)Psychiatry, UNC Chapel Hill, Asheville, NC, (2)TEACCH, University of North Carolina Chapel Hill, Chapel Hill, NC, (3)UNC TEACCH Autism Program, Greenville, NC, (4)UNC Chapel Hill, Chapel Hill, NC, (5)TEACCH Autism Program; Psychiatry, University of North Carolina, Chapel Hill, NC*

Background: The UNC TEACCH Autism Program was established in 1972 with approximately 7 regional centers allocated across the state of North Carolina in order to provide access to services for families with autism. North Carolina is comprised of 100 counties, 80 of which are considered rural and ~40 underserved. Recently, the state was ranked 44/51 for access to mental health services (MHA, 2019). Further, in comparison to other children with special health care needs, families of children with autism are more likely to report unmet need for care and financial difficulties (Thomas et al, 2012; Parish, Thomas et al, 2012a&b). As such, it is unknown how well families from rural or underserved demographics access autism services. Additional barriers to care such as language have also been noted in the literature (Zuckerman, et. al., 2014).

Objectives: Our primary aim was to examine access to TEACCH services across the state. Our objectives were: First, to determine the proportion of counties served through regional TEACCH centers across the state. Second, to examine the impact of underserved county status on accessing services. Lastly, to identify additional previously documented demographic barriers to accessing TEACCH services including race and language spoken.

Methods: Data included 4080 families accessing TEACCH services from 2016-2018 through all seven regional clinics for treatment, evaluation or consultation. Counties were classified as underserved based the definition of Health Professional Shortage Areas (HPSAs) which are designations that indicate health care provider shortages in primary care, dental health; or mental health. Proportion of counties accessing TEACCH services was calculated followed by proportion of underserved counties. Next, proportion of language spoken in the home, race and ethnicity were calculated based on underserved county status. Further analyses will further explore percentage of cases in underserved counties accessing services by modality (e.g. treatment, evaluation).

Results: In terms of counties served, 99/100 counties were reached from 2016-2018. 41 counties were determined to be underserved based on the HPSA definition; 40/41 underserved counties accessed TEACCH services. 799 (19.6 %) families from an underserved county accessed TEACCH services. Language reported was 75.3% English N= 3059; 5.6% Spanish N= 228. Other notable languages included 7 Arabic speaking families; 4 Russian; 2 French. Families from underserved counties were 92% English and 3.6% Spanish speaking. Distribution of race and ethnicity from underserved counties was 70% white, 16% Black/AA, and 8.5% indicated Hispanic ethnicity.

Conclusions: Our results indicated that families from almost every county (including underserved counties) in NC access TEACCH services. Distribution of language spoken and ethnicity is comparable to state-wide demographics suggesting that North Carolinians are accessing TEACCH services equally regardless of ethnicity or language barriers. This suggests that families with ASD in North Carolina may experience less disparate access to care than previously reported. Further analyses will explore differences based on type of service accessed and trends over time.

444.025 *(Poster)* Expanding Autism Knowledge and Access in Early Childhood Community-Based Settings

S. I. Habayeb[1]*, A. Inge*[2]*, Y. Myrick*[1]*, R. Williams*[3]*, M. Long*[4]*, L. Kenworthy*[5] *and L. Godoy*[4]*, (1)Children's National Health System, Washington, DC, (2)Center for Autism Spectrum Disorder, Children's National Hospital, Rockville, MD, (3)Child Health Advocacy Institute, Children's National Hospital, Washington, DC, (4)Children's National Hospital, Washington, DC, (5)Center for Autism Spectrum Disorders, Children's National Hospital, Washington, DC*

Background: Early childhood care providers ("care providers"; e.g., teachers, mental health consultants) play a critical role in the process of identifying children with Autism Spectrum Disorder (ASD) and connecting families to resources. While children are increasingly being routinely screened for developmental concerns in early childhood education (ECE) settings, care providers continue to report limited knowledge about ASD, including diagnostic considerations and resource navigation. Moreover, care providers report interest in better engaging parents in the referral process.

Objectives: To determine the feasibility of ASD-focused trainings for care providers in community-based settings and to evaluate changes in care provider knowledge about ASD. An additional objective is to strengthen and synergize partnerships between a large pediatric hospital and community agencies that work with young children to ensure that efforts to increase timely ASD identification and connections to care are co-created and sustainable.

Methods: Project activities include developing and piloting a standardized, replicable set of ASD trainings for care providers to increase knowledge about ASD, engage parents in care, and navigate local services. Informal training development was conducted with stakeholders including staff at ECE organizations across Washington, DC. A day-long community leader in-person training was then conducted. Baseline and post-training data were collected. Measurements included attendance, satisfaction, impressions of the training, suggestions for improvement, knowledge of ASD (Maternal Autism Knowledge Questionnaire; MAKQ, Kuhn & Carter, 2006), and impressions of impact on knowledge and confidence. Fifty-six community providers attended the day long training including family/community engagement specialists (N=13), mental health clinicians (N=10), early childhood educators/special educators (N=8), care coordinators (N=8) and others.

Results: Most participants felt that the training was well-organized (95.7% Agree/Strongly Agree), the trainers were effective (95.7% Agree/Strongly Agree), topics covered were relevant to their work with children and families (93.6% Agree/Strongly Agree), materials provided were useful (87.0% Agree/Strongly Agree), and they were satisfied with the knowledge gained from the training (93.3% Agree/Strongly Agree). Qualitative analyses of open-ended responses indicated that participants most enjoyed learning about resources and hearing from a parent panel. Participants expressed discontent with the length of the training and noted that there was too much information provided at once. All participants felt Somewhat (51.1%) or Very Prepared (48.9%) to share the information learned with others at their community sites. There was a significant increase in ASD knowledge (MAKQ; $t(42)=-4.22$, $p<0.001$). Further, participants rated increased confidence in engaging parents in conversations about their child's development and ASD concerns ($t(40)=-5.55$, $p<0.001$) and in supporting parents in navigating ASD concerns ($t(40)=-6.99$, $p<0.001$). Participants also rated increased knowledge and skills in recognizing atypical development ($t(40)=-2.56$, $p=0.014$) and in helping families connect with ASD resources ($t(40)=-4.74$, $p<0.001$).

Conclusions: This project contributes to efforts to increase engagement in ASD services for families of young children served in community settings. Participants are currently co-leading trainings within their community sites with a trainer from this study team and continued data collection is in process. Findings from this pilot will be used to inform larger scale community implementation programs to better support ECE providers.

444.026 *(Poster)* Facilitating EBP Implementation in Community-Based ASD Agencies: Clinical Effectiveness of the ACT SMART Implementation Toolkit

A. Sridhar[1] *and A. Drahota*[2]*, (1)Michigan State University, East Lansing, MI, (2)Psychology Department, Michigan State University, East Lansing, MI*

Background:

Autism spectrum disorder (ASD)—the pervasive, lifelong neuro-developmental disorder, characterized by impaired social communication and repetitive behavior and/or restricted interests—affects 1.5% of the population in the U.S. (Xu et al., 2018). Evidence-based practices (EBPs) for ASD lead to improvements in the core deficits of ASD, as well as social, behavioral and adaptive functioning (Wong et al., 2015). Unfortunately though, the utilization of EBPs is varied in ASD community-based organizations (ASD-CBOs). The ACT SMART Toolkit (Drahota, Meza, & Martinez, 2014), is a comprehensive, web-based interface developed to guide implementation teams through phases of EBP implementation (e.g. needs assessment, adoption, planning). A pilot study was conducted testing the feasibility, acceptability, utility, and fidelity of the toolkit, with the overall aim of facilitating the implementation of EBPs in ASD-CBOs.

Objectives: Assess preliminary effectiveness of the ACT SMART Toolkit within ASD-CBOs to increase use of video-modeling.

Methods: Six Southern California ASD-CBOs meeting eligibility criteria (social and/or research collaborations with other agencies/researchers/collaborative groups; efforts to receive additional staff training; interest in implementing new EBPs) participated in the pilot study. ASD-CBOs provided: Applied Behavior Analysis (ABA; *n*=4), ABA and mental health (*n*=1), and Speech and Language Pathology services (*n*=1). All six agencies reported a need for one of the three EBPs selected for the ACT SMART Toolkit pilot study (i.e. social narratives, video modeling, self-management) during agency recruitment. Once the pilot study began, all six agencies selected video modeling to be implemented at their agency, with five completing all phases of the ACT SMART Toolkit, and one agency selecting not to adopt an EBP. Supervisors and direct providers at each participating agency completed an agency assessment, including the ASD-SIS (Pickard et al., 2018), at pre- and post-pilot to report the utilization of various interventions, including video modeling.

Results: Effect sizes (Hedges g) were calculated for the agencies that completed the pilot, in order to examine clinically meaningful changes in reported utilization of video-modeling from pre- to post-pilot. Results indicate a medium effect size (0.52) for supervisor-reported use of video-modeling and a large effect size (0.88) for supervisor-report of direct provider's use of video modeling. Results indicate a large effect size (0.94) for direct provider-reported use of video modeling.

Conclusions: Due to the low number of participating agencies in this study, the researchers did not expect to find statistically significant differences in reported use of video modeling from pre- and post-pilot. Effect sizes were used to calculate a more accurate estimate of the magnitude of the effect of the ACT SMART Implementation Toolkit (Ferguson, 2009) on use of video-modeling.

Overall, effect sizes indicate clinical significance between pre- and post-pilot in the reported utilization of video-modeling. These findings signal that the ACT SMART Toolkit yields behavioral changes in provision of EBPs as reported by supervisors and direct providers. Importantly, this is the first implementation toolkit designed specifically for ASD-CBOs; as a result, these findings indicate the ACT SMART Toolkit may be an effective strategy to facilitate the uptake of EBPs in ASD-CBOs.

444.027 *(Poster)* Factors Associated with Service Utilization Among Low-Resourced Families of Children with ASD

A. Gulsrud[1], *J. R. Williams*[2], *S. Iadarola*[3], *H. S. Lee*[4], *L. Hauptman*[4], *D. S. Mandell*[5], *A. C. Stahmer*[6] *and C. Kasari*[4], *(1)UCLA Semel Institute for Neuroscience & Human Behavior, Los Angeles, CA, (2)Biostatistics, UCLA, Los Angeles, CA, (3)University of Rochester Medical Center, Rochester, NY, (4)University of California, Los Angeles, Los Angeles, CA, (5)Center for Mental Health, University of Pennsylvania, Philadelphia, PA, (6)Psychiatry and Behavioral Sciences, University of California at Davis MIND Institute, Sacramento, CA*

Background: Engaging children with autism spectrum disorder (ASD) in early intervention improves child and family outcomes. Family involvement and engagement in service access is critical; however, families face many challenges navigating the complex ASD service systems. These challenges are exacerbated among low-resource families. Psychoeducation and supportive interventions can assist them in accessing services, although barriers to participation still exist (e.g., childcare, transportation, buy-in). Service utilization and barriers were studied within the context of Mind the Gap (MTG), a flexible, caregiver-focused intervention for families of young children with ASD, designed to increase service access for young children with a new ASD diagnosis. This study reports initial level of service access for low income families of children with ASD.

Objectives: The goals of this study are to describe service use and potential barriers to service use in a sample of underrepresented families recruited for participation in the Mind the Gap RCT at the point of recruitment.

Methods: Participants were recruited across four Autism Intervention Research Network on Behavioral Health (AIR-B) sites: Los Angeles, CA; Sacramento, CA; Philadelphia, PA; and Rochester, NY. Participants included primary caregivers of children ages 2-7 years who were diagnosed with ASD within the last year (n=121). Inclusion criteria were: 1) child not receiving any autism-specific services; 2) family's annual household income at or below 185% of the federal poverty level; and 3) participating caregiver speaking English, Spanish or Korean. Participating caregivers were largely female (90%), and ethnically diverse (37% Hispanic or Latinx; 30% African American or Black), with an average age of 34.4 years. The mean age of the children was 4.2 years; most were male (75%). Most caregivers (81%) had an average income of less than $50,000 a year. Families completed a Service Access form, aimed at quantifying the type, frequency and length of early intervention services at intake.

Results: At baseline, 112 caregivers completed the Service Access form. 24% reported no services, with the average number of services being 1.89, primarily delivered in schools (1.29). The most commonly received service was speech and language therapy (65%), followed by occupational therapy (50%). Most services were child-directed services, with few, if any parent-directed services reported. Only 5% of families reported ever having attended a parent support group, 1% reported receiving any form of parent training, and none reported receiving any parent advocacy or counseling support. Number of services received was examined by primary language, race/ethnicity, and family income. A Wilcoxson Rank sum test revealed that only primary language was significant ($p<.05$), with non-English speaking families receiving fewer services (1.4) than English speaking families (2.1).

Conclusions: Low income, racially diverse families access fewer early intervention services for their children outside the school setting. Even with a focus on the importance of parent-implemented intervention for all children with developmental delays, fewer than 5% of families report any type of support services. Primary language limits service access even further.

444.028 *(Poster)* Factors Inhibiting the Detection of Toddlers with ASD Among the Bedouin Population in Southern Israel

O. Kerub[1], *A. Rosenthal*[2], *I. Menashe*[3], *G. Meiri*[4], *E. J. Haas*[5] *and N. Davidovitch*[6], *(1)Ben-Gurion University, Ministry of Health, Be'er Sheva,, Israel, (2)Ben-Gurion University in the Negev, Ministry of he, Be'er Sheva,, Israel, (3)Public Health, Ben-Gurion University of the Negev, Beer Sheva, Israel, (4)Preschool Psychiatric Unit, Soroka University Medical Center, Beer Sheva, Israel, (5)Ministry of Health, Beer Sheva, Israel, (6)Ben Gurion University in the Negev, Beer Sheva, Israel*

Background: One of the main challenges of ASD is the difficulty in achieving early diagnosis. Early detection and diagnosis are a precondition for early and efficient intervention. The Bedouin population in Israel is distinct in terms of religion, culture, and language. These characteristics influence their perception of health and illness and their patterns of using health services. The number of Bedouin children who are diagnosed with ASD is estimated at 1/1000. Apparently, this rate is an underestimation of the true situation.

Objectives: This research examines the stakeholders, processes, and forces, both overt and hidden, which influence the process of detection and diagnosis of children with ASD among the Bedouin population in the Negev.

Methods: A Qualitative Research: In-depth interviews were conducted with eighteen health policymakers and managers of health institutions that engage in diagnosis and treatment of ASD, as well as three focus groups including nurses from the Maternal and Child Health Centers (MCHC) and pediatricians in primary care clinics that provide services to the Bedouin population.

The environmental-ecological-social system model of Bronfenbrenner (1979) served as a theoretical framework for mapping factors delaying the detection of ASD in children that emerged from interviews and focus groups. Factors were grouped into themes that served for the creation of ecological maps that describe the factors delaying the detection of ASD in Bedouin children. These maps show the influential connections between the themes, the ecological environment levels, and the content.

Results: The delaying factors in the Macro-environment (policymakers), were found to be the lack of a clear policy, lack of a budget policy, lack of tools and standards and lack of a policy for professional training.

The delaying factors in the Mezo-environment (service providers), were found to be lack of professional qualifications of service providers, problematic inter-institutional communication, lack of available appointments, lack of cultural and language accessibility, and fear of lawsuits.

The delaying factors in the Micro-environment (Bedouin population), as described by the interviewees, were fear of exposure and stigma, lack of awareness to developmental problems.

The lack of policy theme was found to have central influence on other themes. Other correlations were found between all levels of the ecological environment, e.g. between the following themes of the Macro-environment: lack of clear policy, lack of tools and standards, and lack of training policy. Correlations were found with the Mezo-environment, influencing the professional qualifications of the service providers and the inter-institutional communication that was found to be tied to the lack of available appointments. The lack of professional qualification theme at the Mezo-environment was found to be correlated with the theme of lack of knowledge and parental awareness of developmental delays at the Micro-environment.

Conclusions: To decrease ASD diagnosis gaps among Bedouin toddlers, it is necessary to determine a clear policy of detection and diagnosis procedures for all service providers engaged in prevention, detection and diagnosis of autism in toddlers. This will force service providers to specialize and create a more professional environment for ASD detection.

444.029 *(Poster)* Family Outcomes Using a Culturally Grounded Model of ASD Intervention with Latinx Families

M. Carrasco[1] *and K. Lopez*[2]*, (1)School of Social Work, Arizona State University, Phoenix, AZ, (2)Arizona State University, Phoenix, AZ*

Background: Despite improvement in early identification of autism spectrum disorder (ASD), differences in ASD rates among racial and ethnic minority children have persisted (Baio et al., 2018). Research shows that Latinx children are diagnosed later than their white counterparts and receive fewer intervention services. Several factors influence the access to services and the diagnosis of ASD for Latinx children (Lopez, 2014). These factors include socio-cultural individual, family, healthcare systems, educational systems, and community systems (Lopez, 2014). Numerous studies have explored the importance of early diagnosis and early intervention. However, there is a significant gap of research focused on culture in early intervention. Parents Taking Action (PTA), is a culturally informed psychoeducation program for Latinx families of children with ASD. PTA utilizes a promotora de salud model, whereby Latina mothers of children with ASD deliver information about ASD, child development, advocacy, evidenced-based practices, and teach parents skills to enhance their children's social communication to Latina mothers of children with recent ASD diagnoses.

Objectives: 1) Increase the understanding of ASD among Latinx families. 2) Address the need for culturally informed interventions. Present a promotora model of ASD intervention delivery combined with bicultural/bilingual pivotal response training.

Methods: Ten Latina mothers were recruited for this pilot study. Recruitment criteria was: Latin American descent, mother of a child with ASD or at-risk for ASD between 1 and 8 years of age. All mothers were offered the Parents Taking Action (PTA) program from two trained *promotoras* community health workers. PTA included 14 sessions of 2 hour in-home didactic psychoeducation. Mothers also received 4 one-hour sessions of pivotal response training (PRT) from bilingual/bicultural coaches in their homes. Children were present for the PRT sessions. The attrition rate was 30%, thus the data represented here are from the seven mothers who completed pre and posttests (See Table 1 for sample demographics). A questionnaire regarding child, parent, and family outcomes was provided before and after the intervention program. We focus on the Family Outcome Survey, which addresses five family outcomes that are prioritized in early intervention programming. Lastly, focus groups (English and Spanish) to assess experience in the intervention were conducted after all participants completed assessments.

Results: Paired samples t-tests showed significant increases in three family outcomes (understanding child's rights and needs, know your rights and advocate for your child, have a support system) and the overall total score on the Family Outcome Survey (Table 2) from pre to post test. Qualitative analysis of focus group transcripts, available for 4 mothers, illuminated positive influence of promotoras who shared the experience of being Latina and raising a child with ASD.

Conclusions: The promotora model of ASD intervention delivery combined with bicultural/bilingual pivotal response training addresses the factors that influence Latinx families of children with ASD. Family outcomes were positively influenced with this culturally informed model of intervention. Further, mothers felt a sense of support that was unique to the shared experience with promotoras. Further implications and limitations will be discussed.

444.030 *(Poster)* Functional Outcome in a Highly Specialized Unit in Autism Spectrum Disorders (URTEA)

R. Calvo Escalona[1,2]*,* ***A. Blazquez Hinojosa***[1]*, O. Puig Navarro*[1,2]*, R. Nicolau*[1]*, A. Hagemeijer*[1]*, M. Garcia*[1]*, M. Salmeron*[1]*, L. Real*[1]*, B. Cejas*[1]*, M. Gimenez*[1]*, A. Bretones*[1] *and M. L. Lazaro*[1,2]*, (1)Hospital Clinic, Barcelona, Spain, (2)CIBERSAM, Barcelona, Spain*

Background: URTEA provides comprehensive care tailored individually to children and adolescents with Autism Spectrum Disorder (ASD) who also have comorbid psychiatric disorders or severe behavioural problems which impact severely on their functioning despite previous interventions in communitarian mental health facilities. The multidisciplinary team provides treatment in close collaboration with all communitarian resources involved.A recurrent finding in those individuals is the pronounced discrepancy in cognitive ability and impairment in functioning. Factors related to functioning are receiving recent attention in research[1] but it is still unclear which individual characteristics or components of the intervention predict better functional outcomes.

Objectives: The main aim of the study is to examine the characteristics of those children and adolescent with ASD associated to more improvement in functioning as measured with the DD-CGAS after intervention in URTEA.

Methods: All children and adolescents seen in the URTEA between January 2018 and August 2019 were included. The local IRB approved the use of their retrospective clinical and sociodemographical data. All participants (n=58) fulfilled DSM-5 criteria for ASD. The assessment of basal and post-discharge functioning was obtained with the Spanish version of the Developmental Disability Children's Global Assessment Scale in Autism (DD-CGAS).

All tests were 2-tailed, and all statistical analyses were carried out with SPSS 18.0. Continuous variables were normally distributed. Differences between groups were examined with the Student's t-test. The level of statistical significance was set at <0.05

Results: 58 participants were included, 84.5% male, mean age 12.78 (SD 3.01), IQ=80.33 (15.55). They were referred to our unit from outpatient care (63.7%), inpatient units (20.6%) and day hospitals (15.5%). Most of the sample (46.6%) attended mainstream schools with support and 32.7% special educational centers or educational health units. 20.7% were not attending to any school. 37.8% associated intellectual disability and psychiatric comorbidity was the rule (77.6%).

After one year treatment in URTEA, all participants improved their functioning significatively (t= -8.34, p=0,000), specially ASD individuals without associated intellectual disability (t=-3.45, p=0.001) and older than 12 years of age (t= -2.05, p=0,045).

A trend towards greater improvement was found in those with psychiatric comorbidities compared to those without any comorbid disorder, but this difference was not statically significant (t=1.62, p=0.090). No differences were found attending to sex (t=-3.99, p=0.779)

Regarding intervention factors, better functioning outcomes were present in those who participate in psychotherapeutic groups (t=1.78, p=0.04) and those who were advised to attend schools specifically for children with learning disabilities (t= -2.69, p=0.01). No significative differences were found taking into account psychopharmacological interventions.

Conclusions: Our findings show improvements in all children and adolescents seen in URTEA, after they have failed to improve in previous communitarian interventions. Those with high functioning ASD seem to benefit more, as there is a narrow margin for improvement in those severely affected. Comorbid psychiatric disorders associated to ASD pose a challenge to regular services and the specialized approach seems to contribute to better outcomes. Our results suggest that reduced or adapted demands in special needs schools could ameliorate functioning in those populations.

444.031 *(Poster)* Healthcare Experiences of Autistic Adults at a Specialized Primary Care Center

B. N. Hand[1]*, A. Darragh*[2]*, S. White*[3]*, D. Coury*[4]*, S. Moffatt-Bruce*[5] *and J. Garvin*[6]*, (1)Health and Rehabilitation Sciences, The Ohio State University, Columbus, OH, (2)Division of Occupational Therapy, The Ohio State University, Columbus, OH, (3)Comprehensive Cancer Center, The Ohio State University, Columbus, OH, (4)Nationwide Children's Hospital, Columbus, OH, (5)Department of Surgery, The Ohio State University, Columbus, OH, (6)Health Information and Management Systems, The Ohio State University, Columbus, OH*

Background: Transitioning from pediatric to adult healthcare systems is challenging for many autistic individuals due to a variety of interpersonal and systematic barriers. These barriers to care often result in poor satisfaction with healthcare among autistic adults, relative to the general population. The Center for Autism Services and Transition (CAST) at The Ohio State University is a patient-centered primary care model aiming to remove many barriers to care for autistic adults. For example, CAST patients may receive modifications to the standard patient workflow (e.g., bypass the waiting room due to sensory sensitivity) and are seen by physicians with extensive experience working with the autistic adult population.

Objectives: The objective of this study is to compare the self-reported satisfaction with healthcare of CAST patients to autistic and non-autistic adult population comparison groups.

Methods: We compared results from a cross-sectional online survey of adult CAST patients to published self-report data from United States-based samples of autistic and non-autistic adults (Nicolaidis et al., 2013). Approximately 53% of the non-autistic adult population comparison group had at least one other self-reported disability. Satisfaction with healthcare provision was quantified using 8 items validated by Nicolaidis et al. (2013), where respondents rate the extent to which their healthcare provider: (1) gave them time ask all of their questions; (2) addressed their feelings/emotions; (3) involved them in healthcare decisions; (4) ensured understanding of needed steps for health management; (5) helped them deal with feelings of uncertainty; (6) understood what they were trying to communicate; (7) communicated in a way they understood; and (8) could be trusted to take care of their needs. All items were rated on a 5-point Likert scale, where higher scores indicated greater satisfaction. We performed preliminary independent samples t-tests to compare the satisfaction of N=16 CAST patients (50% female) to the autistic adult (N=209; 59% female) and non-autistic adult (N=228; 66% female) comparison groups at the item-level.

Results: On average, CAST patients reported levels of satisfaction 0.91 points (SD=0.14) higher than the autistic adult comparison group and 0.58 points (SD=0.20) higher than the non-autistic adult population comparison group. CAST patients' satisfaction with care was significantly higher than the autistic adult comparison group for all items (all $p<0.001$). CAST patients also rated their satisfaction with care significantly higher (all $p<0.01$) than the non-autistic adult comparison group, except for one item; CAST patients and non-autistic adults reported similar perceptions about the extent to which healthcare professionals understood what they were trying to communicate ($p=0.11$).

Conclusions: Preliminary findings reveal CAST patients have higher satisfaction with healthcare than a comparison group of autistic adults and similar or higher satisfaction with healthcare than a non-autistic adult comparison group. These early findings provide robust support for patient satisfaction with CAST, which will be important for disseminating this model of care delivery beyond the local level.

444.032 *(Poster)* Healthcare Utilization Patterns of Patients with Autism Spectrum Disorders (ASD)

B. O'Hagan[1]*, C. Bays-Muchmore*[2]*, P. Sonikar*[1]*, C. Huang*[3]*, S. Qin*[3]*, A. Friedman*[1]*, L. Bartolotti*[1]*, S. King*[1] *and M. Augustyn*[1]*, (1)Developmental and Behavioral Pediatrics, Boston Medical Center, Boston, MA, (2)The Autism Program, Boston Medical Center, Boston, MA, (3)Boston Medical Center, Boston, MA*

Background: Individuals with Autism Spectrum Disorder (ASD) have reported higher rates of various medical conditions, care utilization, and costs[2–6]. However, despite higher usage rates, patients with ASD and their families reported lower satisfaction due to unmet communication, sensory, and behavioral needs that were incompatible with a typical hospital enviroment[7–11].

Objectives: This study aims to examine utilization patterns of pediatric and adult patients with ASD at Boston Medical Center (BMC).

Methods: Data were retrieved from the clinical data warehouse of Boston Medical Center (BMC). Our sample data included BMC patients who were (1) coded to have relevant ICD-9 or ICD-10 codes at least once within the past ten years, and (2) seen in 2017. The ICD-9 and ICD-10 codes deemed relevant to include for identifying our sample are listed in Table 1 and Table 2. The final sample included 1,787 unique pediatric (≤22 years old) and 304 unique adult (≥23 years old) patients. Descriptive statistics were used to analyze utilization patterns by department.

Results: 1,787 unique pediatric patients generated 8,000 encounters (92% outpatient, 6% emergency, 1% inpatient, 2% other) and 304 unique adult patients generated 1,953 encounters (86% outpatient, 10% emergency, 2% inpatient, 2% other) in 2017. "Other" includes: observation, pre-admit, pre-clinic, recurring, and same day care visits. For these pediatric patients, the top five most frequently visited departments are: (1) Pediatrics Specialties Clinic (e.g., Developmental Behavioral Pediatrics, Pediatric Neurology), (2) Pediatric Primary Care Clinic, (3) Child Psychiatry, (4) Pediatric Emergency Department (ED), and (5) Otolaryngology. For these adult patients, the top five most frequently visited departments are: (1) Psychiatric Clinic, (2) Adult ED, (3) Primary Care, (4) Social Service Office, and (5) Family Medicine.

The ED was one of the most visited departments for all patients (#4 for pediatric and #2 for adult patients). In 2017, 317 pediatric patients (507 encounters) and 74 adult patients (185 encounters) were seen in the BMC ED. The most common reason for pediatric ED encounters was reported behavioral crises, comprising 70 (24.5%) of cases. For adult patients, this number is 18 (17%), making it the second most common reason after body aches/heart problems.

Conclusions: Patients with ASD are regularly seen across departments throughout BMC, suggesting that strategies to improve their experiences should be implemented on a hospital-wide level. The number of adult patients is disproportionately low, which may be due to underdiagnosis or underreporting of ASD in adults. Alternatively, it is possible that autism diagnoses are not always accurately reported in the Electronic Health Record (EHR). Lastly, behavioral crises were among the most common reasons for ED encounters, suggesting a need for additional staff training to address behavioral health needs within the ASD community.

444.033 *(Poster)* Implementing a Nation-Wide Continuous Support System for People with ASD and Their Relatives in Russia: Current Problems and Perceived Barriers

I. L. Shpitsberg[1]*, I. V. Skorokhodov*[1] *and A. A. Varlamov*[1,2]*, (1)Our Sunny World, Moscow, Russian Federation, (2)Center for Neurocommunicative Research, Pushkin State Russian Language Institute, Moscow, Russian Federation*

Background: Improved understanding of needs of individuals with autism in Russia has led to development at a federal level of the nation-wide continuous support system (CSS) for people with ASD and their relatives. This cross-sectoral system is meant to provide continuous support to autistic individuals and their families throughout their whole lives and covers the aspects of early care and diagnostics, education, medical care, psychological and social support. One of the most vital problems of Russian regions is low transport accessibility and in-person service availability in remote areas, and, at the same time, low availability of digital solutions (distant learning, remote diagnostics, telemedicine etc.), and it seems vital to evaluate possible barriers to the roll-out of such digital solutions for remote areas.

Objectives: A survey covering central and distant regions of Russia was needed to assess the opinion of autism professionals and parents of children with ASD on the current state of different aspects of the CSS and to evaluate the barriers perceived as most important.

Methods: A 52-item survey in Russian (approximately 20-25 min to complete) was arranged by a joint research team (Pushkin State Russian Language Institute, Rehabilitation Center for Children With Autistic Spectrum Disorders OUR SUNNY WORLD, Federal Resource Center for Organization of Comprehensive Support to Children with Autism Spectrum Disorders, and NGO “Project Office for the Development of the Arctic”). The data collection was performed online via a link shared across several professional and parental communities. Region of Russia, place of work (governmental vs non-governmental), and autism related work experience in years were assessed to get a clear demographic picture.

Results: 126 respondents from 11 regions of Russia (50 from Moscow and Moscow region, 76 from other regions) and more than 40 organizations completed the survey. 75 respondents had professional and/or volunteering experience (40 from non-governmental, 35 from governmental organizations), 53 were family members of people with ASD. The data analysis reveals that respondents from metropolitan areas assess the current situation significantly more positively in all the general aspects of the CSS (general efficiency of governmental, non-governmental and parental organizations) than respondents from remote regions (p_s ranging from <.015 to <.0001). In general, the efficiency of non-governmental agents was rated significantly higher than for governmental agents (p <.0001; this was true even for the respondents working in governmental structures). The attitude to distant learning and remote diagnostics for children with ASD was generally optimistic but the readiness of the existing structures, particularly governmental, to implement digital technologies is viewed as very low.

Conclusions: The quality of support for people with ASD and their families is perceived as lower in remote regions of Russia compared to metropolitan regions, particularly due to low availability of in-person services. Measures should be taken to eliminate this disparity but implementation of distant technologies and online education is hindered by very low readiness of different institutions to these changes. The results of the survey can be helpful not just for Russia but for other countries with areas of low transport accessibility.

444.034 *(Poster)* Increasing Access to Autism Diagnostic Consultation in Rural and Underserved Communities: Streamlined Evaluation within Primary Care

J. F. Hine[1]*, Z. Warren*[1]*, A. S. Weitlauf*[2]*, L. Wagner*[1]*, R. Goode*[3] *and W. B. Allen*[4]*, (1)Vanderbilt University Medical Center, Nashville, TN, (2)Vanderbilt Kennedy Center, Vanderbilt University Medical Center, Nashville, TN, (3)Developmental Medicine, Vanderbilt University Medical Center, Nashville, TN, (4)Cherokee Health, Talbott, TN*

Background: Embedding processes for effective triage and diagnosis of children at risk for ASD within the medical home may be a viable mechanism for reducing age at detection and initiation of services. In recent work, many young children with ASD (and those without) were identified using a streamlined diagnostic model embedded within our medical center’s primary care clinics. These findings supported preliminary feasibility, accuracy, and clinical utility of this model and resulted in dramatically reduced waits for diagnostic consultation, accurate diagnostic decision making, high levels of family/provider satisfaction, and reductions in referrals to an overtaxed tertiary diagnostic center. To combat growing disparities within rural and underserved communities, this model was then implemented across a diverse range of primary care clinics and through remote telemedicine clinics that provide healthcare to rural and underserved communities within our state. Success of this model also spurred implementation of a training program for pediatric residents designed to improve upon previously passive shadowing experiences by integrating procedural, physician-tailored training in within-practice diagnostic identification and care coordination

Objectives: To extend previous work by providing data pre- and post-implementation of the streamlined model across a diverse range of primary care clinics that provide healthcare to rural and underserved communities. Use and results of model through state-wide telehealth project and resident training initiatives will also be discussed.

Methods: Data about referral types, show rates, and latency to consultation and diagnosis were used to assess feasibility and impact and were collected via the medical record. Specifics of this model will be discussed. Using a streamlined diagnostic model, 400 children within the medical center’s primary care clinics were seen over 24 months. We will also report on data for the 80 children seen through clinics with a more rural/underserved catchment, and children seen through our resident training clinic.

Results: Implementation of the streamlined model resulted in a significant decrease in latency to diagnostic conclusion (mean of 144.7 days to 49.9 days). Median age at diagnosis was 32 months: considerably lower than national averages or comparable data from tertiary specialized clinics. Provider feedback indicated significant improvements related to quality and continuity of care and decreased waits for service. Updated feasibility and sustainability data will be provided in detail. Of the first 90 residents to complete the enhanced rotation activities, 94% completed new training requirements. Participants reported increased comfort differentiating ASD from other concerns, making a formal diagnosis, providing feedback about diagnostic decisions, and effectively connecting families with services.

Conclusions: By reducing waits and identifying concerns more efficiently, we may increase the ability of families to access early intervention and support services. Also, without giving pediatricians competence and ownership over diagnosing ASD within practice, wide-scale screening—and reliance upon specialty tertiary care diagnostic centers—will continue to create long waits for diagnostic evaluation. If we do not provide support/resources in the basics of ASD recognition, diagnostic triage, and post-diagnostic care coordination in the medical home, then "screen-and-refer" will continue to lead to lengthy waits for diagnostic confirmation, continuing to postpone access to early intervention services.

444.035 *(Poster)* Integrating Input from Service Providers and Service Recipients Relative to Autism Spectrum Disorder and Mental Health Issues: Toward Knowledge for Action.

W. Mitchell[1]*, D. B. Nicholas*[2] *and R. Zulla*[3]*, (1)Social Work, University of Calgary, Calgary, AB, Canada, (2)University of Calgary, Edmonton, AB, Canada, (3)School of Public Health, University of Alberta, Edmonton, AB, Canada*

Background: The prevalence of autism spectrum disorder (ASD) in Canada according to the 2018 National Autism Spectrum Disorder Surveillance System (NASS) Report is 1 in 66. Parents raising children with ASD require an array of services across sectors such as health, social services and education. Unfortunately, the system of care is often fragmented, suboptimal, and difficult to navigate. Particularly concerning are the 30-70% of individuals who present with ASD and a co-existing mental health problem (dual diagnosis) (Moseley et al., 2011). These individuals and their families face additional challenges accessing appropriate and unified care, often encountering multiple barriers within and between systems of care.

Objectives: As part of a larger study, the objective is to identify navigation processes that are working well, and barriers or challenges, as perceived by stakeholders.

Methods: A Community Based Participatory Research orientation guided the interviews and focus groups that were conducted with 57 service providers and service recipients in relation to navigational services for children with a dual diagnosis in urban, rural and remote communities in Alberta. Interviews were based on a semi-structured interview guide. NVivo data management and analysis software was used. Analysis was comprised of 1) line-by-line coding, 2) review of codes for textual linkages both within and across transcripts and 3) examination of the emerging categorization of codes in yielding themes. Interrater review of data by leaders in the ASD and MH field verified themes.

Results: Based on families experiences a multi-level model emerged consisting of four care levels (universal support, specialized services, complex care and crisis care). Crisis was often identified as a service catalyst for families. At every level, service providers and families indicated that there was a need to make information more assessible to families, that more coordinated services were needed, especially in rural areas, and that parents play a key role, although parental care, preparation for the long haul, and training are sorely lacking. Peer support for families was highly valued and recommended as it addresses parent isolation, is non-judgemental, and offers hope to families.

Conclusions: Navigational support programming requires coordinated service network across sectors (health, social services, and education), particularly in rural and remote communities. There is also a need to involve people impacted by and /or with lived experience in service planning and policy development.

444.036 *(Poster)* Introduction of the Screening Tool for Autism in Toddlers and Young Children (STAT) in Ukraine and Vietnam

R. E. Nickel[1] *and A. R. Swanson*[2]*, (1)Oregon Health and Sciences University, Portland, OR, (2)Vanderbilt University Medical Center, Nashville, TN*

Background: In both Ukraine and Vietnam, the diagnosis of autism in young children is made by child neurologists and child psychiatrists. These professionals have limited access to formal diagnostic assessments such as the ADOS-2, and the diagnosis is often delayed and made solely by clinical judgement.

Objectives: Introduce the Screening Tool for Autism in Toddlers (STAT), a relatively brief interactive level 2 screen, in 3 sites in both Ukraine and Vietnam to improve the identification of young children with autism.

Methods: We selected the STAT as it is a relatively brief interactive, observational tool, contains many key social communication items, and is relatively easy to learn and administer. We conducted 3 formal training workshops in Ukraine (Fall 2018); and 3 workshops in Vietnam (Spring 2019). Following the workshops, participants needed to score an online video of STAT administration (Helen video) and submit 2 separate videos of their own STAT administration for certification. We provided 2 STAT kits for use by participants in each of the 6 sites and 1 additional kit for Vietnam and 2 for Ukraine. We conducted follow-up online webinars by Zoom approximately 3 and 6 months after the initial workshops. The process we are following to introduce and validate the use of the STAT is as follows: translation, back translation (to improve clarity and identify wording errors), review and pilot use by 2 or more selected individuals in each site (to identify any items/activities that may need to be modified), and finally formal normative and validity studies.

Results: A total of 55 professionals attended STAT workshops in 3 sites in Ukraine in Fall 2018, and 101 in 3 sites in Vietnam in Spring 2019 (limited information on the Ukraine workshops was reported at INSAR 2019). Participants included psychologists, child psychiatrists, child neurologists and pediatricians. They rated the workshops highly, most planned to pursue STAT certification and use it in their practice. To date, 20 Ukrainian professionals have scored the Helen video; 8 submitted 1 video of their own STAT administration; and 6 submitted a second video. 26 Vietnamese professionals have scored the Helen video; 7 submitted 1 video of their own STAT administration; and none as of yet have submitted a second video. A total of 91 professionals from both Ukraine and Vietnam participated in the online webinars. We have completed translation and back translation of both the Ukrainian and Vietnamese versions of the STAT. We will initiate the pilot review process in Ukraine this Winter and in Vietnam this Spring. Following this review in each site, we will plan to begin normative and validity studies. Our work has been supported in part by 2 NGO's, the Samaritan Ministries in Ukraine and Project Vietnam.

Conclusions: The STAT, a level 2 screen for autism developed in the USA, can be successfully implemented in countries with limited resources. Barriers to and factors that support its use will be discussed.

444.037 *(Poster)* Investigating Variation in Pre-Employment Program Features for Transition-Aged Youth on the Autism Spectrum

E. McGhee Hassrick[1]*, M. Potros*[2]*, C. Friedman*[3]*, A. Roux*[4] *and P. Shattuck*[4]*, (1)A..J. Drexel Autism Institute, Drexel University, Philadelphia, PA, (2)Drexel University, Philadelphia, PA, (3)Drexel University A.J. Drexel Autism Institute, Philadelphia, PA, (4)A.J. Drexel Autism Institute, Drexel University, Philadelphia, PA*

Background: Over 66% of young adults on the autism spectrum are disconnected from opportunities for work or schooling in the first few years after high school, especially low-income young adults on the spectrum[1]. They experience a "service cliff" ,[1] which often includes disruptions in access to needed supports as they age out of eligibility for school-based and pediatric care. Pre-employment programs offered to youth on the autism spectrum during transition could help them secure employment or connect with post-secondary training and educational opportunities. Recent federal policies mandate at least 15% of federal vocational rehabilitation (VR) state funds be used for pre-employment transition services for high school students with disabilities. However, little research has been done to identify if the recent VR policy has impacted pre-employment programming for youth on the autism spectrum. Also lacking is knowledge about possible differences in the types of pre-employment training and support that transition-aged youth on the autism spectrum.

Objectives: To identify the components of differently funded pre-employment programs for autistic youth and investigate differences in pre-employment program delivery.

Methods: This exploratory study examines differences in preemployment supports for a purposeful sample of transition-aged autistic youth, drawn from a multi-state area, including southeastern Pennsylvania, New Jersey, southern New York and the DC metropolitan area. Publicly available data was systematically collected using databases from the Department of Higher Education, Google Maps, and U.S. Census Bureau, as well as program descriptions found on program, school, district or state websites, to preliminarily survey pre-employment programming components and to determine program variation across SES.

Results: Three types of pre-employment programing for youth on the autism spectrum were identified. Programs exemplifying each type were selected. Types included 1) Combination VR & Other (i.e. district, non-profit and state) pre-employment support (n=9 sites); 2) Combination District and other (non-profit, private pay) pre-employment programing (n=9 sites) and 3) State Only (i.e. BOCES, IU) pre-employment programs (12 sites). Type 1 sites offered more advanced and basic features than Type 2 and Type 3. Type 1 sites served many low resources students. However, Type 2 programs were more common in higher income districts, while Type 3 programs were concentrated in low resource districts.

Conclusions: Federal policy to support pre-employment transition services is in section 113 of the Rehabilitation Act. Preliminary analysis suggests that combined VR funded programming allows for more fully developed pre-employment programs for young adults on the autism spectrum. Further investigation is needed to confirm findings.

444.038 *(Poster)* Investigating the Need for Autism Training for Custody Staff in England and Wales

C. A. Holloway[1]*, N. Munro*[1]*, J. Jackson*[1] *and D. Ropar*[2]*, (1)School of Law, University of Nottingham, Nottingham, United Kingdom, (2)University of Nottingham, Nottingham, United Kingdom of Great Britain and Northern Ireland*

Background: Police custody can be a challenging environment for vulnerable individuals who have been arrested and detained as suspects of a criminal offence which can lead to significant adverse outcomes. Previous studies have suggested that autistic individuals may be more likely to come into contact with police officers and report negative experiences in the criminal justice system due to a lack of appropriate support (Crane et al., 2016; Helverschou et al., 2018). Importantly, research has also highlighted the need for effective and *role specific autism training* for police forces (Crane et al., 2016). Currently, there is no research that has examined the difficulties (e.g. communication, sensory) autistic individuals experience during the custody process (e.g. booking in, personal search) or the specific changes which may be required to improve support in police custody.

Objectives: Study 1 was conducted to explore the difficulties autistic individuals experience during the custody process and how to improve support. A training programme for custody staff was co-developed with autistic individuals and police officers based on these findings. Study 2 was conducted to investigate the effectiveness of this training programme for custody staff.

Methods: *Study 1* - semi-structured interviews were conducted with 12 autistic individuals (male=8; female= 4) about their experiences in police custody in England and Wales (age range 18-64). Data was analysed using a constructed grounded theory approach to explore where autistic individuals experienced difficulties during the custody process and whether changes were needed to improve support.

Study 2 - Fourteen training sessions for custody staff were delivered across four regions in England and Wales. Training was carried out in three formats: i) presentation only i) presentation and training video iii) presentation, training video and toolkit demonstration. Quantitative and qualitative data were collected through questionnaires.

Results: *Study 1* - All participants reported having negative experiences in police custody due to difficulties coping with the demands of detention such as: i) not knowing what was going to happen in police custody because of a lack of adequate (n = 10) and/or accessible information (n = 4) and/or ii) the sensory demands i.e. light (n = 9), noise (n = 9), space (n = 10) and touch (n = 7). Participants also reported difficulties participating in the custody process such as waiving their legal rights (n = 4) and/or being able to understand (n = 9) and/or answer (n = 6) questions.

Study 2 - Data collection from the training sessions is ongoing but data has so far shown positive feedback from custody staff in terms of their understanding of the needs and support of autistic individuals in custody. In particular, custody staff have reported greater awareness of communication and/or sensory needs and the adjustments they can make in their role to address these areas.

Conclusions: Autistic individuals report negative experiences in police custody which can lead to significant personal and legal outcomes when appropriate support is not provided. Context-specific autism training may be an effective way of improving the support of autistic individuals in police custody.

444.039 *(Poster)* Medicaid 1915(c) Home and Community-Based Services Waivers Are Associated with Lower Emergency Department Utilization Among Youth with Autism Spectrum Disorder

G. Liu[1], *D. Velott*[2], *L. Kong*[1], *A. Dick*[3], *D. S. Mandell*[4], *B. Stein*[5], *M. Murray*[6], *D. Ba*[7], *E. Agbese*[8], *M. LaClair*[9], *Z. Cidav*[10], *M. Sorbero*[5] *and D. Leslie*[11], *(1)Penn State College of Medicine, Hershey, PA, (2)Penn State Hershey, Hershey, PA, (3)The RAND Corporation, Boston, MA, (4)Center for Mental Health, University of Pennsylvania, Philadelphia, PA, (5)RAND, Pittsburgh, PA, (6)Department of Psychiatry/Division of Autism Services, Penn State Hershey/Penn State College of Medicine, Hershey, PA, (7)Penn State University College of Medicine, Hershey, PA, (8)Penn State Hershey College of Medicine, Hershey, PA, (9)Public Health Sciences, Penn State University College of Medicine, Hershey, PA, (10)University of Pennsylvania, Philadelphia, PA, (11)Penn State Milton S. Hershey Medical Center, Penn State College of Medicine, Hershey, PA*

Background: Youth with autism spectrum disorder (ASD) are more likely to experience exacerbation of physical illnesses or acute psychiatric episodes that require visits to the emergency department (ED) than those without ASD. Many states have enacted Medicaid home and community-based services (HCBS) waivers to improve access to services for individuals with ASD. However, little is known on the impact of these waivers on reducing the utilization of ED services.

Objectives: This study used the Medicaid claims data to investigate the effects of HCBS waivers on ED visits among youth with ASD.

Methods: We conducted a retrospective cohort study using the Medicaid Analytic eXtract (MAX) files from all 50 states to analyze the odds of ED visits by youth (aged ≤21) with ASD from 2008 through 2013. We identified ASD subjects as those having ≥2 outpatient visits or 1 inpatient/long-term care claim with a diagnosis of ASD (ICD-9 codes 299.xx) during the study period. A dichotomous variable (Yes/No) was created for each calendar year to indicate whether a subject had any ED visits. We categorized HCBS waiver status as: ASD waiver, IDD waiver (intellectual disabilities, developmental disabilities, or autism), other waiver types, and no waiver. Descriptive analyses and multivariable logistic regression were performed to estimate the effect of the waiver types on ED utilization.

Results: Our longitudinal cohort consisted of 574,337 subjects with ASD (Table 1), contributing 2,663,460 annual observations from 2008 to 2013. On annual average, 0.4% of youth were enrolled in an ASD waiver, 11.2% in an IDD waiver, 1.4% in a waiver in another category, and 87.0% had no waiver. Subjects on ASD waivers had the lowest rate of ED visits (13.5%), followed by those on an IDD waiver (18.8%), other waiver types (23.9%), and 28.5% for those not on a waiver. Lower ED utilization associated with ASD or IDD waiver was observed across race and age subgroups (Figure 1). Multivariable logistic regression with repeated measures of ED visit status at each year confirmed the findings from the descriptive analysis that HCBS waivers were consistently associated with a reduced risk of ED visits. The variables adjusted in the model included age, sex, race/ethnic group, calendar year at cohort entry, state and Medicaid eligibility type. There was a significant association between being enrolled in an ASD or IDD waiver and a reduced risk of ED visits (adjusted odds ratio [aOR]: 0.62; 95% Confidence Interval (CI): [0.58-0.66] and 0.65; [0.64-0.66], respectively; reference: no waiver). Risk of ED visit was not linearly associated with age, with higher risk for youth under age 6 and between the ages of 18 and 21 compared to those aged 9-11 (aOR:1.58 [1.56-1.60] and 1.45 [1.42-1.48], respectively).

Conclusions: Our study shows that 1915(c) waivers, particularly autism specific waivers and IDD waivers, are strongly associated with reduced risk of ED visits. These findings suggest that Medicaid 1915(c) waivers are effective at improving access to routine, evidenced-based services, thereby reducing the onset of acute adverse events leading to ED visits among children and adolescents with autism spectrum disorder.

444.040 *(Poster)* Mental Health Service Utilization and Early Work in Youth on the Autism Spectrum

T. Garfield*, J. Rast, A. Roux and P. Shattuck, A.J. Drexel Autism Institute, Drexel University, Philadelphia, PA*

Background: Transition-age youth on the autism spectrum (TAY-ASD) experience high rates of both unemployment and mental health conditions. Over half of TAY-ASD are reported to have two or more mental health conditions and over half of TAY-ASD did not participate in postsecondary education or employment in the two years following their exit from high school. While unemployment for youth has been linked to poorer mental health in mid-life, untreated mental health conditions can also present challenges for early work experiences. TAY-ASD and their families may experience barriers to accessing mental health services due to a lack of mental health professionals competent to serve people on the spectrum, costs associated with services, or a lack of service providers in close proximity. However, the relationship between work and access to mental health services has not been thoroughly explored in TAY-ASD.

Objectives: Determine whether unmet needs for mental health services significantly impact participation in early paid work experience for TAY-ASD. Assess the correlates, including demographic factors and impairment characteristics, of participation in paid work for TAY-ASD.

Methods: We analyzed data from the 2016 and 2017 National Survey of Child Health (NSCH). Analysis included 894 TAY-ASD, ages 12-17, whose caregivers reported that they had a current ASD diagnosis. Caregivers were asked if their children had participated in paid work during the previous twelve months. We used logistic regression to assess whether unmet mental health service needs, demographic factors, and impairments associated with communication or intellectual disability (ID) were significantly associated with participation in paid work.

Results: Approximately 54.9% of TAY-ASD needed and received mental health services, while 12.7% of TAY-ASD needed mental health services but did not receive them, and 31.2% of TAY-ASD did not need or receive mental health services. TAY-ASD whose caregivers reported unmet needs for professional mental health services within the past year were significantly less likely to participate in paid work during that period compared to TAY-ASD who received mental health services and TAY-ASD who did not need mental health services (OR: 0.22; 95% CI: 0.07, 0.74). Odds of paid employment increased with age for TAY-ASD (OR: 1.40; 95% CI: 1.17, 1.67). Race, ethnicity, and poverty level were not significantly associated with participation in paid work in this sample of TAY-ASD. Odds of participating in paid work were significantly lower for TAY-ASD with ID (OR: 0.16; 95% CI: 0.06, 0.42) and TAY-ASD with communication impairments (OR: 0.62; 95% CI: 0.41, 0.96).

Conclusions: TAY-ASD with unmet mental health service needs were significantly less likely to have participated in paid work within the past year compared to TAY-ASD without unmet mental health service needs. Early paid work experience in TAY-ASD is associated with better adult employment outcomes, so unmet mental health service needs could have lasting, deleterious effects for this population. This research suggests that promoting access to mental health services for TAY-ASD could reduce disparities in early paid work participation for this population. Additional research should further explore the potential relationship between untreated mental health conditions and employment in TAY-ASD.

444.041 *(Poster)* Novel Approach to Reducing Variability in Diagnostic and Longitudinal Care Delivery through Echo Autism: Center Development & Support

K. Sohl[1], *A. Bennett*[2], *E. Butter*[3], *J. G. Farmer*[4], *A. Kelly*[5], *D. S. Murray*[6], *L. Nowinski*[7], *L. Zwaigenbaum*[8] *and S. Hyman*[9], *(1)Child Health, University of Missouri - School of Medicine, Columbia, MO, (2)The Children's Hospital of Philadelphia, Philadelphia, PA, (3)Nationwide Children's Hospital, Columbus, OH, (4)General Academic Pediatrics, Massachusetts General Hospital for Children, Harvard Medical School, Boston, MA, (5)Devereaux Advanced Behavioral Health, Malvern, PA, (6)Autism Speaks, Boston, MA, (7)Massachusetts General Hospital - Lurie Center, Lexington, MA, (8)University of Alberta, Edmonton, AB, Canada, (9)Developmental and Behavioral Pediatrics, University of Rochester Medical Center, Rochester, NY*

Background: As the reported prevalence of autism spectrum disorder (ASD) increases, so do demands for specialty services. ASD specialty centers report varying infrastructure and service delivery processes creating large variations in care. The Autism Treatment Network (ATN), consisting of 12 specialty centers throughout North America has a focus on developing and disseminating best practices for the core and associated medical and behavioral health conditions in ASD. ATN centers disseminate these findings directly to community providers using the Extension for Community Healthcare Outcomes (ECHO) model. The ECHO Model typically connects specialists and primary care providers (PCP) to improve medical care for individual patients. This project expands the use of the ECHO model by bringing together ASD specialty care teams with the goal of sharing common challenges, learnings and successes within practice protocols, unique business management ideas, and standardized and novel treatment and prescribing procedures. To our knowledge, this is the first time the ECHO framework has been applied to build capacity, share best practices, and support center development in ASD specialty centers.

Objectives: 1) Use the ECHO Autism model to engage interdisciplinary leaders from autism centers as they integrate clinical, research and family support practices

2) Assess the feasibility and participant experience related to a pilot implementation of the ECHO Autism: Center Development & Support model

3.) To develop a platform for developing and sharing best practices across the autism field, benefiting both the clinical and research field, and patients and families alike.

Methods: The ECHO framework uses multi-point video conferencing to share case-based learning in an “All Teach, All Learn” format, providing an 'in-person meeting' feel and team dynamic. 11 autism centers and 1 emerging autism center participated in this pilot. The specialist "hub" team included developmental-behavioral pediatricians, psychologists, administrators, family navigators, parent advocates, researchers, and an outreach/dissemination specialist. The ECHO Autism sessions were held for 75 minutes twice-per month and consisted of a "spoke" case/process-presentation, discussion and brief didactic. Didactic topics including diagnostic best practice, waitlist triage, incorporating the family voice, and integrating research into clinical practice.

Results: Key participant learning topics included family advisory councils (58%; n=7), quality improvement (50%; n=6), PCP trainings (42%; n=5) and standardized diagnostic batteries (42%; n=5). Overall, the individual participants reported high satisfaction with the ECHO Autism program, 94% (n=16) reporting being extremely or very satisfied, and 88% (N=16) reporting that participating in this project resulted in practice change. One participant described their experience as "Learning about other clinics and program has been amazingly helpful. I feel like I am building connections with other organizations, which will benefit long after this ECHO experience."

Conclusions: ECHO Autism: Center Development & Support offers a consistent, virtual opportunity for interdisciplinary teams from specialty centers to engage in shared learning. It appears to be feasible and participants report high satisfaction with the model and a high degree of practice change as a result of engaging with other centers.

444.042 *(Poster)* Parent Engagement in a Self-Directed Vs. Therapist-Assisted Telehealth Program for Families of Young Children with Autism Spectrum Disorder (ASD)

A. Wainer[1], *Z. Arnold*[1,2], *C. Leonczyk*[3], *S. Licona*[4], *E. V. Ocampo*[1], *M. Printen*[5] *and L. Soorya*[1], *(1)Department of Psychiatry, Rush University Medical Center, Chicago, IL, (2)Psychology, University of Alabama at Birmingham, Birmingham, AL, (3)AARTS Center, Rush University Medical Center, Chicago, IL, (4)Rush University Medical Center, Chicago, IL, (5)Child and Adolescent Psychiatry; Autism Assessment Research and Treatment Center, Rush University Medical Center, Chicago, IL*

Background: There is strong support for parent-mediated early interventions (PMI) for autism spectrum disorder (ASD) and related neurodevelopmental disorders. However, such programs are highly under-utilized in community settings, due in large part to a lack of trained professionals, lengthy waitlists, transportation, and reimbursement issues. These barriers compel examination of alternative service delivery methods, such as telehealth, to increase access to care. Indeed, telehealth is well-suited to deliver interventions with different levels of support depending on the specific needs of an individual and family. While self-directed programs have strong potential for dissemination and a large public health impact, the extent to which therapist-assistance or “coaching” influences program engagement and outcomes remains largely unknown.

Objectives: Our group developed a telehealth program, Mirror Me, to teach families of young children with ASD an evidence-based naturalistic developmental behavioral intervention called reciprocal imitation training (RIT). Mirror Me uses video modules to introduce intervention strategies and was designed to be used in either a self-directed or therapist- assisted format. A goal of this pilot randomized control trial was to determine differences in parent engagement between the self-directed and therapist-assisted formats of Mirror Me.

Methods: This 10-week pilot RCT compares two different formats of Mirror Me: self-directed to therapist-assisted. Participants include 21 families of young children, ages 16 to 49 months, with a diagnosis of ASD and deficits in social imitation skills. All families used the self-directed website for five weeks and then were randomized to continue on their own or receive remote therapist-assistance in the form of "coaching" once per week over the subsequent five weeks. Participants attended in person study assessment visits at baseline (pre-intervention), 10-weeks (post-intervention), and 15-weeks (follow up). Parent engagement with the website, intervention and study assessments was tracked across the active treatment and follow up phases.

Results: One hundred and thirty young children were screened over the phone for interest and eligibility. Twenty-eight enrolled in the study, with 21 (75%) meeting eligibility criteria. Of those 21, four families withdrew during the initial five weeks of the trial, while another three withdrew during the second five weeks of the trial. None of the nine families who withdrew had been randomized to the coaching condition. On average, parents rated Mirror Me as highly acceptable, relatively easy to use, and easy to "see" and "explain to others" the benefits of the program. However, the seven families who withdrew reported "feeling uncertain," having difficulties finding the time to use the website, and challenges determining how to prioritize Mirror Me with respect other concurrent services and interventions.

Conclusions: Results from this pilot study suggest that integration of support, in the form of remote therapist-assistance, may be beneficial for increasing sustained parental engagement with telehealth interventions. Identifying optimal timing and format of remote therapist assistance will be an important next step, along with understanding characteristics that might indicate which families are most likely to require that support. These lines of research will help build a foundation for the development of more adaptive and personalized approaches to telehealth.

444.043 *(Poster)* Patterns of Service Acquisition in Infant-Toddlers with ASD

K. Sterrett[1]*, A. Gulsrud*[2] *and C. Kasari*[3]*, (1)University of California Los Angeles, Los Angeles, CA, (2)UCLA Semel Institute for Neuroscience & Human Behavior, Los Angeles, CA, (3)University of California, Los Angeles, Los Angeles, CA*

Background: Recognition of early behavioral indicators of children who are at risk for a later diagnosis of autism spectrum disorder (ASD) has improved greatly over the past few years. Largely, this is due to increased awareness of these factors (Landa et al., 2012; Sacrey et al., 2013) and understanding of genetic risk and heritability of ASD (Sandin et al., 2017). One of the main goals of early identification is to provide access to intervention for younger children. While there have been attempts to understand service use patterns in older children (Mire, Raff, Brewton & Kochel, 2015) less is known about the type and frequency of early intervention that infant-toddlers at risk for ASD are receiving.

Objectives: To describe patterns of service use of infant-toddlers who are at risk for ASD and whether factors such as children's cognitive abilities and sibling ASD status were related to likelihood of service acquisition.

Methods: This analysis includes baseline data from 80 infants with ASD who met for mild to moderate concern on the ADOS Toddler Module (MAge= 17.66 months, 54% non-white, 80% Male) enrolled in a clinical trial for children at risk for ASD (NCT01874327). Children's developmental age was assessed using the Mullen Scales of Early Learning and current intervention services were recorded via a parent report survey at baseline, post intervention (8 weeks), and at two, four and 12 months after baseline. Demographic information including sibling status was also collected at baseline.

Results: The two most common services that children received at each of the timepoints were Speech Therapy and Occupational Therapy. Patterns of service acquisition across time are noted in table 1. Of note, only one family was receiving intensive behavioral therapy at entry, 10% at exit, 34% at the two and four-month follow-up timepoints and 27% at the 12 month follow up. The median number of services at entry was 0 (max 3), 1 at exit (max-3), 2 (max- 6) at the 2 and 4 month follow-ups and 3 (max-7) at the 12-month follow-up. At baseline, having an older sibling with a diagnosis of ASD (n=16) did not increase the likelihood that children would be receiving services, ($X^2(1)= .17$, p=.68). Children who were receiving services had lower visual receptive t-scores (t(61) = 1.98, p=.04) at baseline, but did not differ across the other domains. Chronological age was also not a factor (all p>.05).

Conclusions: Overall, children's enrollment in each category of services increased over the course of the study. Consistent with research in older children, the most common types of services were speech and occupational therapy (Carlon, Stephenson & Carter, 2014). Children with older siblings with ASD were not more likely to receive services, which may be an artifact of the overall low number of services received at entry. Understanding which services children at risk for autism are likely to receive is the first step in evaluating the effectiveness of those services on their later outcomes.

444.044 *(Poster)* People with Autism Spectrum Disorder in the Criminal Justice System: Improving Recognition in Criminal Justice Mental Health Services, Identifying Views of the ASD Community and Developing Preliminary Guidelines for Support.

C. M. Murphy[1,2]*, J. Harvey*[3]*, E. L. Woodhouse*[4]*, D. Robertson*[2]*, S. Whitwell*[3]*, A. Carrier*[3]*, A. Forrester*[3]*, D. G. Murphy*[5] *and G. M. McAlonan*[6]*, (1)Department of Forensic and Neurodevelopmental Sciences, and the Sackler Institute for Translational Neurodevelopment, Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, United Kingdom, (2)Behavioural Genetics Clinic, Adult Autism Service, Behavioural and Developmental Psychiatry Clinical Academic Group, South London and Maudsley Foundation NHS Trust, London, United Kingdom, (3)Forensic and Neurodevelopmental Science, Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, United Kingdom, (4)Forensic & Neurodevelopmental Sciences, Institute of Psychiatry, Psychology & Neuroscience, London, United Kingdom, (5)Forensic and Neurodevelopmental Sciences, Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, United Kingdom, (6)NIHR-Biomedical Research Centre for Mental Health at the Institute of Psychiatry, Psychology and Neuroscience, South London and Maudsley Foundation NHS Trust, London, United Kingdom*

Background: People with autism spectrum disorder (ASD) may have contact with the criminal justice system (CJS) as victims of crime, offenders, or from misunderstandings. The number of ASD people who offend is unknown. However, it has been suggested that ASD is over-represented and under-recognised in the CJS. Despite this, neither ASD training for criminal justice mental health services (CJMHS), nor clear ASD care-pathways or guidelines linking the CJS and health/social services are available. Furthermore, ASD community and CJMHS staff views regarding this are unknown.

Hence, interactions between the CJS and ASD people may be unnecessarily distressing, unsuccessful and costly. Lack of ASD awareness and absent ASD CJS care-pathways/guidelines may adversely impact on everyday police, court and prison processes and contribute to increased costs.

Objectives: To improve ASD recognition in a local CJMHS, determine ASD community and CJMHS staff views and, with the ASD community, draft first available UK CJS ASD guidelines.

Methods:

1. Local CJMHS staff received 1 day's ASD awareness training from ASD experts, including a) mental health/behaviour/communication/sex/risk/de-escalation, management of anxiety/distress, liason with local/national ASD services, local/national care pathways, b) Assessment (Observed-Structured-Clinical-Examination), c) 55-item ASD questionnaire (pre/post training), d) on-going supervision.
2. Two focus groups gathered views of 6 ASD adults with CJS experience and their families and of 5 CJMHS staff about ASD in the CJS.
3. A one day ASD CJS workshop invited expert speakers and multidisciplinary ASD/CJS professionals (including health/education/social care/CJS, and the National Autistic Society) to identify problems, solutions and develop ASD CJS guidelines.

Results:

1. CJMHS ASD knowledge significantly improved post-training ($p < .05$)
2. CJMHS staff felt significantly more able to a) identify ASD people in the CJS, b) communicate with, and safely manage, ASD people, c) understand ASD mental health/behaviour/communication possibly contributing to CJS difficulties/misunderstandings, and d) identify and access local and national ASD clinical-care pathways
3. Both focus groups expressed concerns; the ASD community regarding their CJS experiences and CJMHS staff regarding ASD awareness/management in the CJS. Both suggested possible improvements; these contributed to guidelines development.
4. Local ASD CJS guidelines and an ASD CJS film have been made and will be a) freely accessible educational materials for all staff/students across the study site, so enabling widespread and cost-effective dissemination (36,000 university/hospital staff and 25,000 students, with over 4.2 million patient contacts each year), b) available to local and national CJS teams, c)included in local health/social care pathways.

Conclusions: Brief training can raise awareness of ASD in CJMHS staff and may improve management of ASD people in the CJS. This supports statutory requirements for needs-led local services (UK 2009 Autism Act, 2010/2014 Autism Strategies) and responds to the UK 2009 Bradley report, tasking CJS liaison/diversion services to identify, assess and refer vulnerable people from their first police contact. The ASD community and CJMHS expressed ASD CJS concerns. The development of local and national ASD CJS training, guidelines, services and care pathways may enable ASD people to be better understood and to have their needs met, and may contribute to reduced individual and societal costs.

444.045 *(Poster)* Process Improvement Initiative to Increase Frequency of Genetic Testing in Autism Spectrum Disorders

M. Chiujdea[1]*, S. J. Spence*[1] *and N. Abreu*[2]*, (1)Autism Spectrum Center, Boston Children's Hospital, Boston, MA, (2)Center for Gene Therapy, Nationwide Children's Hospital, Columbus, OH*

Background: Genetic testing including a chromosomal microarray (CMA) should be offered to all patients with non-syndromic autism spectrum disorders (ASD), however there are many barriers to CMA completion. Boston Children's Hospital (BCH) data from February 2015 through January 2016 demonstrated that only 40% of patients with a new ASD diagnosis underwent CMA testing. We conducted an anonymous mixed methods survey of providers in the BCH Autism Spectrum Center, which demonstrated that navigating insurance authorization was a major barrier to recommending genetic testing. 52.0% reported being uncomfortable with the prior authorization (PA) process. In response to the survey results, the BCH Autism Spectrum Center designed an intervention with the aim to improve recommendation rates and ultimately genetic testing completion.

Objectives: To describe the initial implementation of a process improvement project to increase adherence to genetic testing guidelines for patients newly diagnosed with Autism Spectrum Disorder in the BCH Autism Spectrum Center.

Methods: In response to the initial survey results key stakeholders from the Autism Spectrum Center, Genetics, Lab Medicine, and Patient Financial Services (PFS) at BCH convened to develop a standardized process to obtain insurance authorizations for CMA and Fragile X testing for patients newly diagnosed with ASD. Survey results and the proposed intervention plan were presented at departmental meetings in Spring 2019. Using the Plan-Do-Study-Act (PDSA) method, a process improvement pilot was launched in August 2019 with two Autism Spectrum Center providers. Actions taken to standardize the process included the development of a template Letter of Medical Necessity (LOMN), identification of specific roles for staff members in PFS and clinic administration, a tracking template, a communication algorithm, use of DNA Extract and Freeze blood samples, and an Autism Spectrum Center patient-family education sheet.

Results: Overall, the Autism Spectrum Center genetic testing recommendation rates increased from 85.7% to 90.3% between November 1, 2017 and October 31, 2019. For PDSA 1 of the pilot, twelve patients newly diagnosed with autism initially agreed to genetic testing. 75.0% of patients received insurance authorization for genetic testing since the pilot start in August 2019, 41.7% underwent phlebotomy with DNA extract and freeze, and 25.0% have genetic testing processed. 16.7% of patients had insurance that required a visit with a board-certified geneticist or genetic counselor for PA approval. Despite insurance authorization approval, 8.3% of families chose to forgo genetic testing.

Conclusions: Identifying provider barriers and presenting a multidisciplinary intervention plan can improve recommendation rates and completion for the standard-of-care genetic testing for patients with newly diagnosed ASD. With the support of key stakeholders, it is possible to create a standardized process to address the ever-changing complexities of genetic testing insurance. This pilot effort demonstrated high PA approval rates, though with low testing completion rates as a result of data collection limited to 3 months. Next steps include increasing the number of included Autism Spectrum Center providers, cost-analysis, ongoing data review, and a follow-up survey to evaluate the perceived benefits and potential flaws of this initiative.

444.046 *(Poster)* Project Echo Autism for Mental Health: Empowering Community Practitioners to Treat ASD Comorbidities

M. L. Cook[1]*, L. G. Klinger*[2]*, E. M. Lamarche*[3] *and N. Dreiling*[2]*, (1)TEACCH Autism Program; Psychology & Neuroscience, University of North Carolina, Chapel Hill, NC, (2)TEACCH Autism Program; Psychiatry, University of North Carolina, Chapel Hill, NC, (3)TEACCH Autism Program, University of North Carolina, Chapel Hill, NC*

Background: Despite recent comorbidity rates as high as 92%, there is little information available to empower mental health practitioners to meet the unique needs of patients diagnosed with both autism (ASD) and co-occurring mental health (MH) conditions (Brookmann-Frazee et al., 2017). The combination of ASD/MH conditions has shown to be predictive of significantly poorer health outcomes as well as greater parental dissatisfaction in providers. Still, these families utilize MH services with high frequency (Ahmedani & Hock, 2012). MH practitioners, however, often perceive working with children with ASD as a challenge for which they have not been trained (Brookmann-Frazee et al., 2012). Consequentially, there are far more families seeking MH services than there are practitioners prepared to provide appropriately adapted care, particularly in rural areas. Project ECHO Autism, a tele-mentoring platform which connects physicians to interdisciplinary ASD experts, has demonstrated improvement in primary care providers' ASD related knowledge, self-efficacy, and practice (Mazurek et al. 2017, 2019a, 2019b) and shows high potential to effect similar meaningful change for MH providers.

Objectives: Given the growing prevalence of ASD and need for autism-specific competencies in MH care, this study aimed to develop and implement a new adaptation of ECHO Autism to impact provider knowledge, self-efficacy, and knowledge application in community MH practitioners.

Methods: We developed and implemented a new MH focused curriculum in a 6-month (10 session) ECHO Autism pilot program for MH providers (N=24) across 11 counties (mostly rural) in North Carolina. Biweekly sessions were 90 minutes and consisted of a brief didactic (focused on MH treatments for anxiety, ADHD, and behavior management for clients with ASD) followed by provider case presentations. Each provider completed pre/post assessments; change in ASD knowledge was observed via an Autism Knowledge test and provider self-efficacy was measured via an adapted version of the Primary Care Autism Self-Efficacy (PCASE) survey (Mazurek et al., 2017). Participants also provided written case conceptualizations in response to applied vignettes as a measure of provider knowledge application. Satisfaction surveys were collected at posttest.

Results: At baseline, MH providers reported perceived barriers in treating children with ASD which included a lack of access to ASD specialists (n=15, 62.5%), knowledge about ASD resources (n=11, 45.8%), and prior training in ASD (n=11, 45.8%). At posttest, providers collectively demonstrated significant improvement in their knowledge of ASD ($t(24)=5.5$, $p<.0001$) and self-efficacy ($t(23)=9.3$, $p<.0001$). Additionally, participants reported high satisfaction with their experience (M=1.33, SD=.54) on a 5-point scale with "1" indicating the highest degree of satisfaction.

Conclusions: This study demonstrates the feasibility and impact of adapting the ECHO Autism model for a community mental health provider population. Significant improvements in provider competence related to comorbid treatment considerations suggests that this may be an effective way to build capacity among rural community mental health providers. We are engaged in qualitative analyses of vignettes to examine whether changes in knowledge lead to increased provider knowledge application as well as conducting follow up assessments to observe the stability of these gains.

444.047 *(Poster)* Provider Report on Part C Early Intervention Service Use: Who Is Engaging in EI, How Much and Why?

M. Troxel[1]*, S. M. Brunt*[2]*, A. Eisenhower*[3] *and A. S. Carter*[4]*, (1)Clinical Psychology, University of Massachusetts Boston, Boston, MA, (2)Psychology Department, University of Massachusetts Boston, Boston, MA, (3)University of Massachusetts Boston, Boston, MA, (4)Department of Psychology, University of Massachusetts Boston, Boston, MA*

Background: Early intervention (EI) providers work in community and home settings with young children (ages 0-3), and their families, to help identify developmental delays and build skills related to development. While rates of family engagement and retention in mental health treatment are variable (Ingoldsby, 2010), amount, in hours, of EI services received is linked to magnitude of positive functional impacts (McManus et al., 2019). Little is known about EI service use, intensity and barriers to engagement.

Objectives: To understand the utilization of EI services by families and to evaluate if EI provider or family characteristics, such as race, socioeconomic status, or primary language, lead to disparities in service engagement.

Methods: Participants include a subset of 100 EI providers from a larger study that evaluated implementation of an evidence-based autism screening intervention at three EI sites in Massachusetts. The present sample includes EI providers that attended a university-based diagnostic evaluation with a child and family and completed a survey about providing services to the family.

Results: EI providers (N=100) were primarily white, non-Hispanic (75.0%), females (98.0%) with an average of 3.4 years (SD=5.2) of experience working in EI. Eighty-nine percent of providers' first language was English, however 64.0% reported bilingualism or multilingualism. Families were diverse with respect to race/ethnicity (78.0% non-White or White Hispanic), poverty status (56.7%) and language (43.8% primary language not English). Eighty-three percent of children received an ASD diagnosis. Providers reported that 45.0% of families had at least one other EI provider previously. Children received a median of 3 sessions (range: 0-12) with the reporting EI provider in the month prior to completing the survey, and 54.0% of providers indicated that at least one session "did not happen or was shorter than planned in the last month." Providers endorsed "Parent does not have enough time or forgets" (16.0%) and "I have had to cancel sessions due to conflicts..." (13.0%) as primary reasons for why EI sessions did not happen or were shortened. Notably, no providers endorsed "Parent feels child does not need as many sessions" or "Parent does not believe it helps the child." The majority (70.4%) of providers indicated the child should receive additional services that he/she is not currently getting. Neither provider race nor child race was related to number of sessions the child received (χ^2=5.01, p>.05; χ^2=12.10, p>.05, respectively) or missed (χ^2=0.33, p>.05; χ^2=4.84, p>.05, respectively). Similarly, child primary language, poverty status or diagnostic status did not relate to number of sessions the child received (χ^2=15.10, p>.05; χ^2=0.723, p>.05; χ^2=5.28, p>.05) or missed (χ^2=1.99, p>.05; χ^2=0.69, p>.05; χ^2 =4.88, p>.05).

Conclusions: Surprisingly, level of engagement was not related to demographic factors of the provider or child. As treatment engagement is commonly moderated by sociodemographic factors, reflecting treatment disparities for low-income and minority populations, EI services may hold promise in reducing barriers to engagement in treatment for all children with developmental disabilities. Despite this, most providers reported that children needed more support, suggesting that access barriers to other forms of services may persist in EI.

444.048 *(Poster)* Psychotropic Medication Use By Children with ASD in Publicly-Funded Mental Health Services

B. Caplan[1,2]*, L. Brookman-Frazee*[3,4,5]*, C. Chlebowski*[4,6] *and G. May*[7]*, (1)Psychology, UCLA, Los Angeles, CA, (2)UC San Diego Department of Psychiatry, Child and Adolescent Services Research Center, San Diego, CA, (3)Psychiatry, University of California, San Diego, La Jolla, CA, (4)Child and Adolescent Services Research Center, San Diego, CA, (5)Autism Discovery Institute, Rady Children's Hospital-San Diego, San Diego, CA, (6)University of California San Diego, La Jolla, CA, (7)Psychiatry, UC San Diego, San Diego, CA*

Background: Use of psychotropic medications for children is common in publicly-funded mental health (MH) services (Garland et al 2013). These services play an important role in caring for with children with autism spectrum disorder (ASD) for their co-occurring psychiatric conditions (Brookman-Frazee, Stadnick, Chlebowski, Baker-Ericzén, & Ganger, 2017). Understanding patterns and predictors of psychotropic medication use is imperative for children with ASD to guide care improvement.

Objectives: The present study seeks to: (1) characterize patterns of parent-reported psychotropic medication use for children with ASD in publicly-funded MH services (2) assess child, family and program-level factors associated with any psychotropic medication use and (3) examine predictors of specific medication classes (i.e., ADHD-targeted/stimulants, antipsychotics, antidepressants/SSRIs).

Methods: Data on medication use patterns were extracted from the baseline assessments of 202 children with ASD drawn from a community effectiveness trial of AIM HI ("An Individualized Mental Health Intervention for ASD") conduced in 29 publicly-funded outpatient and school-based MH programs in Southern California. Children were ages 5 to 14 years (M= 9.3 years; SD = 2.4), 60% Latinx and were receiving ongoing psychotherapy services at the time of the baseline assessment. Children were assessed for ASD (ADOS-2), cognitive ability (WASI-II or DAS-II), and psychiatric diagnoses (MINI Kid) at baseline. Parents reported child psychotropic medication use, family demographics, caregiver strain (CGSQ) and parent sense of competence (PSOC), as well as child autism severity (SRS-2) and behavior problems (ECBI).

Results: At study entry, 49.5% of participant children were reported to use one or more psychotropic medications. The average number of medications used was 0.72 (SD = 0.90, range = 0 to 4), with 37.8% of those who used medication using more than one. Rates varied by medication class, with the most prevalent classes endorsed including: ADHD-targeted medications (primarily stimulants; 31.2%), antipsychotics (14.9%), antidepressants (primarily SSRIs; 12.9%), and other (16.4%). Multiple logistic regressions including variables with significant bivariate associations with medication use suggest that children with white race/ethnicity (B= 1.22, p=.001), lower cognitive ability (B= - 0.03, p =.02), and whom meet criteria for ADHD (any subtype; B = 1.30, p<.01) were significantly more likely to use psychotropic medications. Children with higher autism severity were less likely to use ADHD medications and more likely to use antidepressants. There were no significant predictors of antipsychotic use.

Conclusions: Rates of any psychotropic medication use are comparable to epidemiological samples of children with ASD (Madden et al., 2017). Results of the study suggest that sociodemographic (race/ethnicity) and clinical factors (cognitive level, co-occurring psychiatric conditions, autism severity) play a role in patterns of psychotropic medication use in community MH settings, which may help to inform targeted care improvement interventions for this population.

444.049 *(Poster)* Relationships between Late Cancellations and Demographic Features in a High-Throughput Metropolitan Autism Center

N. Ono*, Seattle Children's Autism Center, Seattle, WA*

Background: Inequities in access to developmental services for ASD for under-resourced communities and for minorities are well-documented. It is not clear, however, how these inequities come to be, and whether challenges are manifest even at the first-line of contact in just making it to a scheduled appointment. This study examines particularly difficult cancellations, i.e. those cancellations that occur within 24 hours of the appointment time, or no shows. These cancellations result in tremendous strain in clinical resources and infrastructure. However, from the family perspective, they represent last-minute burdens and likely continuing challenges for obtaining services for their children.

Objectives: To examine how patient diagnosis, visit type, payment types, race, language, age, and sex relate to the likelihood of late cancellations (i.e. cancellations within 24 hours of the appointment time or no shows).

Methods: Data were obtained from 18,360 scheduled appointments involving 3,673 patients (M age = 9.74 years, SD = 4.97; 77.4% male, 72.6% ASD) involving a randomly sampled subset of scheduling and payer information extracted over the period 9/1/2018 to 8/30/2019. We used a generalized linear model with logistic link to model the probability of late cancellation as linear sum of group (ASD, non-ASD), visit type (new visit, return visit, or telemedicine), payment type (Medicaid/Medicare, commercial insurance, self-pay, or other), race (American Indian, Asian, Black, White, or unknown/unspecified), language spoken (English or non-English), age group (approximate age quartiles of 0-6, 6-9, 9-13, 13+ years), and sex. Significance of terms was assessed using Chi-square tests and odds ratios with 95% confidence intervals not overlapping reference categories (1.0) reported.

Results: Chi-square tests revealed significant effects of group (p<.001), visit type (p<.001), payment type (p<.001), race (p<.001), and age group (p=.013). The following factors were associated with greater likelihood of late cancellations: having an ASD diagnosis (Odds ratio (OR): 1.29; 95% CI: 1.13-1.47); visit types of return (OR: 2.58; 2.12-3.18) or telemedicine (OR: 2.24; 1.53-3.22); Medicaid payment type (OR: 1.44; 1.27-1.63); race of American Indian (OR: 1.64; 1.21-2.18) or African-American/Black (OR: 1.70; 1.45-2.00); age group 9-13 years of age (OR: 1.22; 1.06-1.41).

Conclusions: This work describes additional challenges faced in the effort to provide equitable services to minorities and families of under-resourced communities. While late cancellations result in strain on clinical infrastructure, it also reflects difficulty by families to acquire timely attainment of services for their children. This work suggests that additional support should be considered for families of children with a diagnosis of autism at the middle school/Junior-high age, who may lack resources for completing scheduled appointments. A focus on understanding the factors leading to difficulties in meeting scheduled appointments will help the design and development of such support with the ultimate goal of providing the greatest equity of access to developmental services for children and families in need.

444.050 *(Poster)* Staff Trainings to Improve Care for Youth with Autism Spectrum Disorder

L. Donnelly[1], *P. E. Cervantes*[2], *E. Okparaeke*[1], *F. Guo*[1], *C. R. Stein*[1], *S. Kuriakose*[3,4], *B. Filton*[1,5] *and S. Horwitz*[2], *(1)Department of Child and Adolescent Psychiatry, NYU Langone, New York, NY, (2)Department of Child and Adolescent Psychiatry, NYU Langone Health, New York, NY, (3)New York State Office of Mental Health, Albany, NY, (4)Child and Adolescent Psychiatry, NYU School of Medicine, New York City, NY, (5)Department of Child and Adolescent Psychiatry, Bellevue Hospital Center, New York, NY*

Background: Youth with autism spectrum disorder (ASD) access emergency services and are psychiatrically hospitalized at high rates. In the absence of specialized inpatient services for these youth, they are served in general inpatient psychiatric settings. However, this environment is challenging for youth with communication and social vulnerabilities. Plus, most providers are not trained in evidence-based practices (EBPs) for ASD. To improve outcomes for these patients, an ASD Care Pathway (ASD-CP) was developed and implemented within a general inpatient psychiatric service at a public hospital. Prior to implementation, clinic staff received a three-hour training on ASD symptoms and evidence-informed strategies for preventing and reducing challenging behaviors for youth with ASD. The ASD-CP was associated with significant reductions in crisis interventions (i.e., intramuscular medication, holds/restraints). The ASD-CP training has since been modified for dissemination to other sites providing care for youth with ASD.

Objectives: To improve care for patients with ASD and provide necessary specialized training for professionals, we created and modified the ASD-CP training for dissemination at five additional sites providing care, treatment, and housing for youth with ASD. The purpose of this study was to examine the effectiveness of trainings regarding knowledge of ASD and comfort providing ASD care.

Methods: Staff at five sites who participated in a modified version of the ASD-CP training (approximately 75 minutes in length) completed pre- and post-training assessments (n=233). Assessments included the Challenging Behaviour Attributions scale (CHABA) short form and a modified version of the Confidence in Coping with Patient Aggression Instrument. Additionally, staff selected evidence-based strategies for youth with ASD from a list containing both valid strategies and common misperceptions. The anonymous surveys also collected trainee age, gender, race/ethnicity, and education level. To examine associations between demographic characteristic and pre-training assessment scores, we used linear regression or Spearman correlation for continuous or ordinal characteristics and one-way ANOVA or Kruskal-Wallis tests for categorical characteristics. Paired sample t-tests examined differences between pre- and post-training responses.

Results: Pre-training responses on the CHABA short form differed by training location (p=.01). Education level predicted pre-training knowledge (p<.05). Significant differences were observed between all pre- and post-assessment scales. There was a significant increase in CHABA short form total scores from pre to post training (p<.001), indicating changes in perceptions about challenging behaviors. Significant mean differences in pre and post responses were also found on Confidence in Coping with Patient Aggression Instrument (p<.001), indicating higher comfort levels working with the ASD population following training. Staff also demonstrated more knowledge of EBPs for ASD following training (p<.001).

Conclusions: Through a short, focused training on strategies for reducing challenging behaviors of patients with ASD, significant improvements were observed between pre- and post-training assessments. Following the modified ASD-CP training, staff reported higher levels of comfort for working with the ASD population and greater knowledge of EBPs for ASD. Perceptions of challenging behaviors also changed. Limitations include potential differences between trainees who did and did not complete the surveys and lack of follow-up assessments to examine retention of knowledge and changes in clinical practice.

444.051 *(Poster)* Summary of Qualified Service Providers By the 'ABA in PA Initiative'

A. Kwegyir-Aggrey[1], *G. Vece*[1], *A. Moroco*[1], *T. Gorshe*[2], *A. Shaffer*[3], *G. Everette*[4] *and C. D. Tierney-Aves*[5], *(1)Penn State Hershey Medical Center, Hershey, PA, (2)Penn State Hershey Medical Center, 17033, PA, (3)Expressive Pathways LLC, Harrisburg, PA, (4)Behavior Therapy International, Dillsburg, PA, (5)Penn State Health Children's Hospital, Hershey, PA*

Background: Despite the fact that Pennsylvania has had an autism insurance law on the books since 2008, Pennsylvania's Department of Human Services was not ensuring appropriate availability or quality of Applied Behavior Analysis (ABA) for children with Autism Spectrum Disorder (ASD). This deprived individuals in Pennsylvania access to this medically necessary intervention. The ABA in PA Initiative, a 501(c)(3) advocacy organization, supported the Disability Rights Network of Pennsylvania in a class action lawsuit (Sonny O. v. Dallas) filed in 2014 to hold the Department of Human Services accountable. As a result of the lawsuit, ABA must meet the evidence-based standards of the Behavior Analyst Certification Board ®. Furthermore, the ABA in PA Initiative supports PA HB1900, (Better Access to Treatment (BAT) Act), to set minimum training and experience standards to license behavior analysts. However, data is limited about the availability and quality of care delivered by provider agencies.

Objectives: To evaluate changes in the landscape of ABA provider agencies between 2016 and 2020, a time period of several key advocacy accomplishments in Pennsylvania.

Methods: The ABA in PA Initiative has curated a voluntary directory of ABA providers for Pennsylvania since 2014. Agencies are added if they contact us, or by internal outreach efforts. Only agencies that provide ABA services to children in PA using board certified behavior analysts qualify for inclusion. To learn about provider qualifications and availability, agency data was collected at several time-points and will continue into the future. Time-points were chosen to correlate with certain key advocacy accomplishments such as the Sonny O settlement, public awareness campaigns (BCBA® Appreciation Day) and BCBA licensure.

Results: We have collected simple demographics and compared data from June 2016 through September 2019. Of the 48 agencies identified in June 2016, 23% took Medicaid, 8% employed BCaBA's® and 21% employed registered behavior technicians (RBT's®). Of the 123 agencies identified in September 2019, 56% take Medicaid, 18% employ BCaBA's® and 51% employ registered behavior technicians (RBT's®), a significant improvement from 2016. An 11-item survey was developed to collect additional information including 1) agency size, 2) number of providers that hold the BCBA®, BCaBA® or BCBA-D® certification and RBT® credential, 3) The percentage of autism cases staffed with certified and credentialed providers, 4) payer mix to include medicaid, 5) hiring and staffing strengths and barriers and 6) opinions regarding licensure. Figure 1 demonstrates barriers agencies cite as to why they currently do not accept Medicaid.

Conclusions: The ABA in PA Initiative's convenient directory provides a comprehensive listing of these businesses in Pennsylvania. While autism insurance laws are important, additional advocacy is necessary to ensure that medically necessary, quality ABA reaches the public. Preliminary analysis of agency metrics indicates promising changes in the landscape of ABA following the efforts of initiatives undertaken by this Advocacy organization.

444.052 *(Poster)* Telehealth Diagnoses of Autism in Toddlers

***M. Butsch**, Madigan Army Medical Center, Tacoma, WA*

Background: Autism Spectrum Disorder (ASD) is a neurodevelopmental disorder characterized by impairments in social interaction and communication, as well as repetitive behaviors and restricted interests. ASD is screened for at the 18- and 24-month well child visits as recommended by the American Academy of Pediatrics. Symptomology and impairments of ASD will continue throughout the child's lifespan, however they may be decreased with early interventions. Early recognition and identification is encouraged by health care professionals but there remains a significant amount of time difference between initial parental concern and the diagnosis of ASD. The average age for a diagnosis of ASD in the United States is above 4 years old. Telehealth (TH) models have been found to be successful across a variety of medical and psychiatric conditions, demonstrating improved service delivery, clinical impact, financial reimbursement, and applied behavioral analysis service delivery. Within the Department of Defense, families often may be located in areas that lack the capabilities to timely diagnose and treat ASD. Military Family stress, impacting soldier readiness, has been associated with reductions and difficulty in accessing diagnostic and therapeutic services for a young child with ASD. TH would provide a model capable of early evaluation of children without relying as much on community service or travel, potentially decreasing family stress, increasing soldier readiness, and improving long-term outcomes associated with ASD.

Objectives: Determine TH accuracy in diagnosing ASD in children aged 21 to 48 months.

Methods: Children receiving care at a military hospital in Alaska received comprehensive TH evaluations by two Developmental Pediatricians (DBP) located at an Army Medical Center in the Northwest. Following parent interview, two of the physicians independently observed the child while directing the parent to engage their child in the Selective Play Observation via Telehealth (SPOT), a brief structured observation adapted from the Screening Tool for Autism in Toddlers (STAT). Each item presented (ball, bubbles, balloon and car) was scored in accordance with the scoring standards of the STAT. The DBP providers then independently rendered a determination of the presence or absence of autism using a DSM-structured framework, completed a confidence scale (very confident, somewhat confident, and uncertain) regarding their diagnosis, and discussed their determination with the family. Parents completed satisfaction surveys and scheduled a confirmatory in-person evaluation with an independent DBP. Results of the TH and confirmation evaluation were then compared.

Results: Of the 15 children enrolled, 7 received ASD diagnoses after the TH evaluation. In-person evaluation diagnoses matched telehealth diagnoses in 15/15 children. 14/15 of the children completed the confirmatory evaluation with an independent DBP. DBP providers were more frequently 'very confident' (78%) using TH to evaluate a child for autism compared to Fellows (48%); and were similarly 'very confident' (100%) rendering a diagnosis of autism via TH compared to Fellows (40%). Caregiver satisfaction data will also be discussed.

Conclusions: This is the first study to report utilizing TH to diagnose ASD using a parent-led play observation. This study supports the concept of conducting ASD evaluations remotely without the need for an in-person provider**.**

444.053 *(Poster)* The Implementation of Reciprocal Imitation Training (RIT) within Part C Early Intervention

***L. V. Ibanez**[1] and W. L. Stone[2], (1)UW READi Lab, Seattle, WA, (2)Psychology, University of Washington, Seattle, WA*

Background: Despite the existence of several evidence-based Naturalistic Developmental Behavioral Interventions (NDBIs; Schreibman et al., 2015), few have been adapted for use in community-based settings, such as Part C IDEA Early Intervention (EI), where they may increase early access to ASD-specialized treatment for a broader segment of the population. Furthermore, little is known about how providers in the "real world" decide with whom to initiate treatment and what type of adaptations they make to meet the demands of the context/setting. This study examines the implementation of an NDBI--Reciprocal Imitation Training (RIT)--by community EI providers serving toddlers from birth to 3 years.

Objectives: To examine: (1) the effectiveness of a training workshop for EI providers for increasing their self-efficacy when providing intervention to toddlers with possible ASD; (2) toddler characteristics that lead providers to initiate RIT; (3) types of RIT adaptations implemented; and (4) EI providers' perceptions about the effectiveness of RIT for improving toddler outcomes.

Methods: 80 EI providers from 9 agencies in 4 counties across Washington State were enrolled. A stepped-wedge design was used to randomly assign counties to the timing of the training workshops. Survey data were collected at baseline (T1) and 12-months post-training (T2); 64 providers (80%) had T1 and T2 data. The 1-day interactive, training workshop focused on imitation impairments in ASD, the RIT cycle steps, and parent coaching. RIT (Ingersoll, 2008; 2010; 2012) is a manualized ASD-specialized treatment that is low intensity, easy to use, and applies an NDBI approach to teach object and gesture imitation within a play-based context. Self-report measures of practices and self-efficacy regarding ASD care were collected at T1 and T2. At T2, providers also: (1) indicated which child characteristics led them to use RIT and what adaptations they had implemented; and (2) rated how effective they perceived RIT to be.

Results: From T1 to T2, there were significant increases in providers' self-efficacy in discussing treatment goals and progress and in providing coaching to families of children with ASD, *ps*=.04. 52 providers (81%) reported using RIT with 490 children and coaching 358 parents. The top three most endorsed child characteristics that prompted providers to initiate RIT included: the presence of social communication delays (75%), motor imitation delays (66%), and/or a formal ASD diagnosis (55%). 20 providers (38%) indicated making adaptations due to their own clinical style (90%), child characteristics (70%), and/or parent/family characteristics (60%). The majority of providers using RIT perceived it to be effective at improving motor imitation (90%), social interactions (79%), and communication (75%).

Conclusions: A relatively brief training for EI providers' led to increases in their sense of efficacy and subsequent widespread use of an evidence-based ASD treatment over the course of a year. RIT seems promising as an accessible treatment that can help families get an early start on specialized services within an established infrastructure available across the U.S. Additional research is needed to *directly assess* child moderators of treatment response, RIT adaptations that may impact treatment fidelity, and RIT's effectiveness at improving child outcomes.

444.054 *(Poster)* The Relationship between Age of Diagnosis and Core Deficits in Autism Spectrum Disorder (ASD)

L. R. Ketcheson[1]*, E. A. Pitchford*[2] *and C. Wentz*[3]*, (1)Department of Kinesiology, Health and Sport Studies, Wayne State University, Detroit, MI, (2)Department of Kinesiology, Iowa State, Ames, IA, (3)Department of Kinesiology, Wayne State University, Detroit, MI*

Background: Autism Spectrum Disorder (ASD) is the fastest growing developmental disability in the United States. While the American Academy of Pediatrics (AAP) recommends screening for ASD at 18 and 24 months of age, the average age of diagnosis in the United States is approximately 4 years of age. One of the most widely disseminated messages regarding treatment practices for children with ASD is that early intervention results in the most optimal outcomes. As such, the majority of research to date has focused on the evaluation and intervention on the core deficits in ASD. While growing attention on the early services in children with ASD is warranted, what is not well understood is the relationship between the core deficits of ASD and age of diagnosis.

Objectives: The objective of this study was to determine if there is a relationship between the core deficits of ASD and the age of diagnosis, using a large and representative dataset.

Methods: The current study is a secondary data analysis from the Simons Foundation Powering Autism Research for Knowledge (SPARK) cohort. 4,388 children with ASD, ages 1 to 18 years (M=8.23, SD = 3.88 years), were selected for analysis based on complete data. The sample was 80.4% male and all children had a formal diagnosis. The principle caregiver of the child completed the Autism Impact Measure (AIM); a 41-item survey on a 5-point Likert-scale to measure the frequency and impact of core ASD deficits. The AIM includes five subdomains including Repetitive Behavior, Communication, Atypical Behavior, Social Reciprocity, and Peer Interaction. Caregivers also reported the specific ASD diagnosis, date, and method. Linear regression was used to examine the relationship between AIM subdomains at present and the age of ASD diagnosis.

Results: On average, children with ASD in the sample were diagnosed at approximately 4.5 years (M=53.68, SD = 32.96 months). The R2 for the linear regression model was 0.26 ($F(7,4380) = 221$, $p < .001$). The age at diagnosis was significantly associated with current age ($\beta = 0.32$, $p < .001$), sex ($\beta = -.05$, $p < .001$), AIM Repetitive Behaviors subscale ($\beta = -.05$, $p < .01$), AIM Communication subscale ($\beta = -.30$, $p < .001$), and AIM Atypical Behavior subscale ($\beta = 0.20$, $p < .001$). The additional AIM subscales were not significant predictors in the model, including Social Reciprocity ($\beta = -.02$, $p = .39$) and Peer Interaction ($\beta = .01$, $p = .61$).

Conclusions: Among core deficits, current findings suggest subscales on the AIM including repetitive behavior, atypical behaviors as well as communication are significantly related to age of diagnosis. Outcomes from this study should underscore the importance of accurate measures evaluating core delays and deficits in children early on in development. This may lead to an earlier ASD diagnosis and more impactful intervention. Next, further investigation is warranted into the gender differences in age of diagnosis, the current study suggests males are diagnosed significantly earlier than females.

444.055 *(Poster)* Unpacking the Mechanisms of High-Quality Therapist Training on Parent Attendance in Mental Health Treatment for Children with ASD

R. Haine-Schlagel[1]*, K. S. Dickson*[1]*, C. Chlebowski*[1,2]*, W. Ganger*[1,3] *and L. Brookman-Frazee*[1,4,5]*, (1)Child and Adolescent Services Research Center, San Diego, CA, (2)University of California San Diego, La Jolla, CA, (3)San Diego State University, San Diego, CA, (4)Psychiatry, University of California, San Diego, La Jolla, CA, (5)Autism Discovery Institute, Rady Children's Hospital-San Diego, San Diego, CA*

Background: Parent or caregiver (hereafter referred to as parent) engagement is widely documented as an important component and key quality indicator in evidence-based interventions for children, and specifically for children with autism spectrum disorder (ASD) (Becker et al., 2018; Haine-Schlagel & Walsh, 2015; Nock & Kazdin, 2005; Wright et al., 2019), Community mental health (MH) services are particularly important for children with ASD in caring for their common co-occurring psychiatric conditions (Brookman-Frazee et al., 2009). Previous research shows sub-optimal parent engagement in MH services for this population; however, there is limited research on determinants of parent engagement and the impact of therapist training in evidence-based, parent-mediated interventions.

Objectives: The current project examines: 1) the effect of training community-based therapists in "An Individualized MH intervention for ASD (AIM HI)" Brookman-Frazee et al., 2016 on parent attendance at children's therapy sessions; and 2) key moderators and mediators of therapist training on parent attendance.

Methods: Data for the current study are drawn from the AIM HI community effectiveness trial conducted in outpatient and school-based MH services in Southern California.

Participants included a subset of trial participants including 189 children with ASD aged 5-14 years (M age=9.15 years; SD=2.46; 84.1% male) and their parents (M age=40.24 years; SD=8.35; 93.1% female; 51.3% Hispanic/Latinx) corresponding to 168 therapists (M age=34.13 years; SD-8.18; 86.3% female; 34.5% Hispanic/Latinx) from the trial with available session attendance data. 145 families from 127 therapists were in the AIM HI condition; 44 families with 41 therapists were in the usual care (UC) condition.

The outcome measure was percent of sessions with parent attendance over the 6-month study period. Moderator variables included baseline caregiver strain, parenting sense of competence, caregiver race/ethnicity, therapist licensure status, therapist previous training in parent-mediated interventions, and primary treatment setting (school versus other community setting). Mediator variables included observationally coded therapist fidelity.

Results: Multilevel regression models in Stata were used to account for the clustered of nature of the data (i.e. therapist-client dyads [level 1] nested within enrolled MH programs [level 2]). Parents working with therapists trained in AIM HI attending a higher percentage of their child's treatment sessions ($EMM_{AIM\ HI}$=73.44, SE=4.95) compared to usual care (EMM_{UC}=42.62, SE=5.60), *Estimate*=30.82, p<.01). No parent-level or therapist- level factors were significant moderators. Service setting was a significant moderator (*Estimate=-25.78,* Wald $X^2(5)$=156.99, p<.01), such that higher parent attendance was observed in non-school (i.e. outpatient, home) settings compared to school settings but in the AIM HI condition, the difference between school and non-school settings was significantly smaller compared to UC. The percentage of parent attendance in schools for families in the AIM HI condition approximated that seen in other settings (e.g., clinics, home) among the UC condition. Treatment fidelity significantly mediated the relationship between therapist training condition and parent attendance.

Conclusions: The results suggest that AIM HI may be an effective way to increase parent participation in MH treatment for children with ASD served in school settings, which may further contribute to improved child outcomes.

444.056 *(Poster)* Using Measurement-Based Care to Inform Course of Treatment in Autism Spectrum Disorder: Evidence from a Community Clinic

T. McFayden[1]*, A. V. Dahiya-Singh*[2]*, L. Antezana*[1]*, A. J. Gatto*[3]*, Y. Miyazaki*[4] *and L. Cooper*[1]*, (1)Virginia Polytechnic Institute and State University, Blacksburg, VA, (2)Virginia Tech, Blacksburg, VA, (3)Virginia Polytechnic Institute & State University, Blacksburg, VA, (4)Education Research and Evaluation, Virginia Tech, Blacksburg, VA*

Background: Measurement-Based Care (MBC), or the use of repeated measurement of patient progress, is an evidence-based practice in research, community, and university clinic settings with adults. MCB has been used to evaluate course of treatment and to indicate appropriate treatment termination across a variety of disorders and populations. However, no current work has used MBC to evaluate course of treatment in individuals with Autism Spectrum Disorder (ASD). ASD is a neurodevelopmental disorder with a manifestation of symptoms that makes it difficult to monitor the effectiveness of treatment progress and to select appropriate treatment goals.

Objectives: The current study aimed to evaluate the course of treatment for youth with ASD, compared to clinical controls without ASD, using MBC in a community clinic. A supplementary objective was to use a novel statistical method to analyze MBC data and to evaluate course of treatment over time.

Methods: Participants (n = 40, 15 females) seeking treatment at a community, cognitive-behavioral clinic completed brief, symptom-specific questionnaires at each treatment session. Twenty ASD participants were sex-, age- and primary presenting problem-matched with 20 clinical controls (M_{age} = 13.9, SD = 4.89). Individual session scores were z-scored based on the outcome measure's global means and standard deviations to compare across participants. T-tests were conducted to evaluate group differences in overall symptom changes and number of sessions. Multilevel growth modeling was used as a novel methodology to evaluate individual patterns and change over course of treatment.

Results: Results of t-tests indicated differences in number of treatment sessions, $t(38) = -2.23$, $p = .03$, where ASD clients (M = 31.7; SD = 20.43) were seen significantly longer than non-ASD clients (M = 20; SD = 11.06). Further, ASD clients had significantly smaller change scores than non-ASD clients, regardless of treatment duration, $t(38) = 2.42$, $p = .02$. Results from multilevel growth model analyses indicated no significant group difference on the severity of the symptoms at intake, $t(36) = .38$, $p = .71$ or the rate of change over time, $t(36) = 1.39$, $p = .17$. However, model-based trajectories suggested that the subclinical cutoff differed by group: non-ASD group reached subclinical levels after 23 weeks, but ASD only after 37 weeks.

Conclusions: These results yield an important practical implication: clients with ASD require significantly longer courses of treatment (on average 50% more sessions) to make the same amount of progress as non-ASD clients. This is the first examination of MBC in ASD using novel methodologies to address challenges in treatment progress. These results demonstrate the ability of MBC to provide valuable information regarding the treatment trajectories of effective intervention in a challenging clinical group and for significant public policy impact.

444.057 *(Poster)* Using Participatory Process to Bridge the Research to Practice Gap in Intervention Development: Flexible Futures, a Novel, School-Based Executive Function Treatment for Transition-Age Autistic Youth

C. E. Pugliese[1]*, M. A. Werner*[2]*, J. Bascom*[3]*, M. F. Skapek*[4]*, L. Saldana*[5]*, L. Kenworthy*[1] *and L. Anthony*[6]*, (1)Center for Autism Spectrum Disorders, Children's National Hospital, Washington, DC, (2)Program Development and Training, Ivymount School, Rockville, MD, (3)Autistic Self Advocacy Network, Washington, DC, (4)Psychological Sciences, University of Connecticut, Storrs, CT, (5)Children's National Health System, Rockville, MD, (6)University of Colorado, Denver, Aurora, CO*

Background: Large numbers of autistic and their families report "falling over a services cliff" as they transition to adulthood due to the loss of school and social supports after high school graduation. Autistic people have much to contribute to society, including unique perspectives, knowledge and skills, but are often prevented from sharing their gifts because executive function (EF) weaknesses get in the way. EF problems are pivotal targets for intervention because they are common, linked to independence, and responsive to treatment in younger children. However, there are no evidence-based EF treatments for transition-age youth and youth have difficulty generalizing skills learned in the clinic to real-world settings. In response to these needs, we utilized community-based participatory research methods to develop a novel EF intervention, designed to be implemented by school personnel to maximize accessibility, intervention dosage and generalizability.

Objectives: To 1) develop and iteratively refine intervention content using input from stakeholders (autistic individuals; parents and teachers of autistic youth), and 2) assess intervention feasibility and acceptability (retention, fidelity, consumer satisfaction) in a RCT across 8 high schools.

Methods: In the course of development we conducted focus groups with autistic high school and college students (*n*=5), their parents (*n*=9), and high school/college personnel (*n*=7) to develop curriculum content. Iterative refinement of content was based on 1) youth feedback during clinic-based groups (*n*=22), 2) teacher feedback during pilot testing in two schools, 3) review by the Autistic Self Advocacy Network, 4) and parent, youth, teacher program satisfaction from the RCT. Barriers and facilitators to implementation were examined during focus groups (*n*=7) conducted with RCT interventionists.

Results: Feedback from stakeholders highlighted the importance of curriculum content focusing on: flexible problem-solving, time management, motivation, independent goal setting, planning, and social flexibility skills. Curriculum changes based on feedback included: lessons focusing on neurodiversity and self-advocacy (from autistic youth), inclusion of more activities (autistic youth/interventionists), skills practice connected to real-world situations (i.e., registering for disabilities services in college; sending e-mail, navigating a college-roommate agreement; college/high school teachers).

- **Retention**: 100% of the schools completed Flexible Futures and 92% of students completed the post-testing.
- **Fidelity:** Observations of interventionists indicated strong procedural implementation fidelity and competence (*M*=7.6 out of 10, *SD*=1.16)
- **Acceptability**:
    - Interventionists (*n*=9): 100% reported that each lesson could be conducted easily and 95% indicated each lesson was helpful in acquiring new skills
    - Parents (*n*=25): 95% reported Flexible Futures helped their child; 100% learned something new; and 70% indicated their child's flexibility and planning skills improved.
    - Teens (*n*=26): 88% would recommend the intervention to other teens; 100% were more flexible afterwards and 72% were better at planning; They used skills at home (92%), school (92%), with parents (76%), and friends (68%).

Conclusions: The incorporation of stakeholder feedback in the development of a novel intervention led to an intervention that could be implemented with minimal training (3 hours) by school staff with fidelity and high consumer satisfaction. FF holds promise as an accessible, low-cost intervention targeting skills needed for successful transition to adulthood.

444.058 *(Poster)* Utilization of the Medical Homes As Developmental Extenders to Provide Level 2 Autism Screening for Children < 5 Years Old

E. Flake*, Madigan Army Medical Center, Tacoma, WA*

Background: Prevalence of Autism Spectrum Disorder (ASD) in young children has been steadily rising over the last 20 years. Efficient screening within the medical home leading to timely identification of children less than 5 years old at risk for ASD is necessary especially for military facilities that are in remote and overseas locations. Primary care clinics in the military currently refer, on average, 25 children annually for every 1000 empaneled to a sub-specialty clinic to rule out ASD. The time from initial MCHAT screening to evaluation is often longer than 9 months. Recent studies suggest that the use of supported specialty-trained community primary care providers as part of a spoke-and-hub model ("STAT-MIL") that are connected to ASD evaluation centers of excellence can serve as a significant force multiplier. In the military, additional benefits of strategically placed providers with targeted extender capabilities include improved readiness and access to resources in environments where these were previously unavailable.

Objectives: Determine the feasibility of utilizing a tier 2 screening tool (Screening Tool for Autism in Toddlers & Young Children-STAT), in a medical home supported by a hub site tertiary autism center to improve access and decrease age of diagnosis while maintaining high fidelity of diagnostic accuracy.

Methods: Within a remote military medical home, a trained primary care provider with the assistance of a nurse coordinator identified children at-risk for ASD using the MCHAT-R + F/U, or the Autism Spectrum Quotient – 10. These children then received a tier 2 screening evaluation utilizing the STAT and received a provisional diagnosis of ASD, when appropriate. Metrics measured included number of referrals, age of diagnosis, time from referral to diagnostic evaluation, and validity of diagnosis when compared with sub-specialty evaluation. Data was then compared both with national community averages as well as pre-implementation data from the local treatment facility.

Results: Over 6 months, the developmental extender trained in the STAT-MIL performed 22 evaluations for ASD, with 13 receiving a provisional diagnosis of ASD. Note review and a follow up visit with a Board Certified Developmental Pediatrician determined validity between sub-specialist and primary care diagnosis to be 100%. To date, the program has a conservative cost savings of $27,000 with anticipated cost savings of $245,000 in FY2019. Since STAT-MIL inception the average age of diagnosis has been 32.5 months of age which is 15.5 months earlier than the national average. Time to diagnosis from referral has also been reduced from 28.8 weeks to 12.1 weeks in first 3 months (Oct-Dec 2018) and further reduced to 3.9 weeks during the subsequent 3 months (Jan-Apr 2019).

Conclusions: This Developmental Extender model (STAT-MIL) appears to be a promising force multiplier in remote environments by enhancing diagnosis capabilities, improving access to resources which augments military family readiness. This high reliability model empowers primary care to utilize additional tools which provide comprehensive coordinated care through an integrated relationship between primary medical homes and specialty care services.

444.059 *(Poster)* Validation of a Statewide System of Early ASD Diagnosis: A Preliminary Report on Diagnostic Accuracy

R. McNally Keehn[1]*, G. Kadlaskar*[2]*, A. Paxton*[3]*, B. Keehn*[2]*, M. Ciccarelli*[1] *and N. Swigonski*[3]*, (1)Indiana University School of Medicine, Indianapolis, IN, (2)Speech, Language, and Hearing Sciences, Purdue University, West Lafayette, IN, (3)Pediatrics, Indiana University School of Medicine, Indianapolis, IN*

Background: Autism spectrum disorder (ASD) can be reliably diagnosed during the second year of life. However, the average age of diagnosis across the United States is 4 to 5 years, with diagnosis of lower income, minority, and rural children lagging further behind. The significant delay between the emergence of ASD symptoms and diagnosis means that young children are missing critical opportunities for evidence-based interventions at the time of optimal impact. As such, developing and testing streamlined community-based methods of ASD diagnosis has been identified as a priority.

Objectives: To determine the diagnostic accuracy of a statewide system for early ASD diagnosis in the primary care setting. Specifically, we sought to 1) determine ASD diagnostic agreement between primary care providers (PCP) trained to conduct standardized ASD evaluations and an expert ASD specialist, and 2) identify child characteristics associated with diagnostic accuracy.

Methods: Fourteen Early Autism Evaluation (EAE) Hubs have been established in primary care practices across Indiana. PCPs in the EAE Hubs participated in standardized didactic and practicum training on early ASD diagnosis. Over 2000 children, ages 18-42 months, have been evaluated by PCPs in the EAE Hubs using a standard assessment protocol (including the Screening Tool for Autism in Toddlers). In the current study, one EAE Hub was selected to refer consecutive children for follow-up comprehensive evaluation (within 8 weeks) by an expert neurodevelopmental team, including a clinical psychologist specializing in early ASD diagnosis. During this evaluation, the Mullen Scales of Early Learning (MSEL), Vineland Adaptive Behavior Scales (VABS-3), Autism Diagnostic Observation Schedule (ADOS-2), and caregiver DSM-5 ASD interview is conducted. Data collection and analysis is ongoing (projected N=25-30).

Results: To date, 12 children (8 male) have been evaluated (age: M: 2.5 years; SD: 0.6). For 9 of 12 (75%) children, there was diagnostic agreement between the EAE Hub PCP and ASD specialist (k: 0.53; $p < 0.05$) indicating a moderate level of agreement. Four cases were true positives (TP; diagnosed by both EAE Hub PCP and ASD expert with ASD) and 5 cases were true negatives (TN; diagnosed by both EAE Hub PCP and ASD expert with non-ASD). The 3 diagnostic disagreements were false negatives (FN; EAE Hub PCP diagnosed non-ASD, ASD expert diagnosed ASD). Compared to TP cases, FN cases tended to be older (TP: age: 2.4 years; FP: age: 3.3 years) and have higher non-verbal (TP: MSEL Visual Reception T: 23; FN: MSEL Visual Reception T: 35), language (TP: MSEL Receptive T: 23; MSEL Expressive T: 25, VABS-3 Communication SS: 50; FN: MSEL Receptive T: 24, MSEL Expressive T: 28, VABS-3 Communication SS: 67), and adaptive abilities (TP: VABS-3 ABC SS: 58; FN: VABS-3 ABC SS: 71).

Conclusions: Preliminary findings suggest that community-based PCPs trained as part of a statewide EAE Hub system make ASD diagnoses in young children with moderate accuracy. Diagnostic misses were associated with older age and higher cognitive, language, and adaptive functioning. These results have implications for how ASD diagnostic training for community clinicians may be improved to facilitate more accurate diagnosis.

444.060 *(Poster)* Vulnerabilities Associated with Physical Health Concerns for Emergency Department Utilization in Adolescents with Autism Spectrum Disorder

G. Liu[1]*, A. Pearl*[2]*, L. Kong*[1]*, S. L. Brown*[3]*, D. Ba*[4]*, D. Leslie*[5] *and M. Murray*[2]*, (1)Penn State College of Medicine, Hershey, PA, (2)Department of Psychiatry/Division of Autism Services, Penn State Hershey/Penn State College of Medicine, Hershey, PA, (3)Psychiatry, Penn State University College of Medicine, Hershey, PA, (4)Penn State University College of Medicine, Hershey, PA, (5)Penn State Milton S. Hershey Medical Center, Penn State College of Medicine, Hershey, PA*

Background: Utilization of the Emergency Department (ED) for urgent and/or higher levels of care can be a strong indicator of poor overall physical health and well-being. Given the frequent occurrence of both physical and mental health comorbidities, adolescents with Autism Spectrum Disorder (ASD) have been found to have higher ED utilization compared to adolescents without ASD. Little attention has been given to identification of physical health risk factors specifically associated with ED utilization in this population.

Objectives: This study uses a large, national healthcare claims database of a privately insured population in the United States to profile physical health concerns for adolescents with ASD and evaluates their potential associations with elevated ED utilization.

Methods: Using the 2005-2014 MarketScan® database, we design a retrospective, longitudinal study to examine the physical health profile among adolescents with ASD (aged 12-21) in association with risk of ED visits. This database contains billing claims from commercial insurers of large employers across the US. We identify ASD subjects as those with ≥2 documentations of ASD (ICD-9 codes 299.0x, 299.8x). Causes of ED visits were established by the billed primary/second diagnoses. Descriptive analyses and multivariable logistic regression were performed to examine the effects of prior physical health problems in conjunction with, mental health comorbidities and prescribed medications on ED utilization.

Results: Our longitudinal cohort consisted of 185,076 observations from 63,886 subjects with ASD from 2006 to 2014. Some subjects had multiple ED visits during the same calendar year. A total of 11,115 ED visits were examined. Overall, 85.4% of all the ED visits were at least partially due to one or more urgent physical health concerns and 26.5% were particularly due to acute injuries. 20.8% of the ED visits documented a mental health concern other than ASD as primary or secondary diagnosis (Figure 1a). Adolescents who presented to the ED frequently had co-occurring physical and/or mental health concerns aside from ASD. We also observed high incidence of ED visits among top comorbid illnesses including: epilepsy (15.8%), GI problems (16.4%), asthma (13.6%), pneumonia (15.1%), injures (15.9%) and eating disorders (24.3%) (Figure 1b). The adjusted regression analysis (Table 1) showed that prior physical health conditions, mental health conditions and polypharmacy of psychotropic medication were significantly associated with elevated ED utilization. In particular, epilepsy was found to be strongly associated with the increased ED utilization (adjusted Odds Ratio [aOR]: 2.33; 95% confidence interval [CI]: 2.10-2.59). So were GI problems (2.14; 1.95-2.35), asthma (2.19; 1.91-2.52) and pneumonia (1.82; 1.43-2.31). Prior injuries posted the highest risk of ED visit (2.54; 2.34-2.74) among all physical and mental health risk factors.

Conclusions: This study documents high ED utilization for physical health concerns by adolescents with ASD. Individuals with co-occurring physical health concerns, particularly respiratory illness, GI illness, epilepsy and prior injuries, appear to be at high risk.

444.061 *(Poster)* Youth with ASD and the Criminal Justice System

Y. Yu[1]*, A. D. Boan*[1]*, L. Carpenter*[1] *and C. Bradley*[2]*, (1)Medical University of South Carolina, Charleston, SC, (2)Developmental-Behavioral Pediatrics, Medical University of South Carolina, Charleston, SC*

Background: Few studies have examined the involvement of individuals with autism spectrum disorder (ASD) and intellectual disability (ID) with the criminal justice system, and the results are still mixed as to whether individuals with ASD are more likely to be involved in the criminal justice system than the general population. No studies have examined recidivism in individuals with ASD.

Objectives: The goal of this study is to describe the lifetime involvement of transition-age youth and young adults (ages 17– 23) with ASD with the criminal justice system and to examine rates of recidivism.

Methods: Data for this study come from a large epidemiological autism dataset [i.e., South Carolina Autism and Developmental Disabilities Monitoring (SC ADDM) Network], which was linked with datasets from multiple state agencies [i.e., Department of Juvenile Justice (DJJ); SC Law Enforcement Division (SLED)]. Four participant groups were included in the study: individuals with ASD without intellectual disability (ASD-only; n=316), individuals with ASD and ID (ASD+ID; n=291), individuals with ID without ASD (ID-only; n=1277), and a population control (PC; n=2980) group, identified via birth records and 5:1 frequency matched to ASD participants by gender and birth year.

Results: The ASD+ID group (1.37%) was less likely to be charged through the DJJ than the PC group (4.70%) [OR (95%CI) 0.28 (0.10-0.77)]; whereas the ID-only group (6.81%) was more likely to be charged compared to the PC group [OR (95%CI) 1.48 (1.13-1.95)]. The ID-only group (5.09%) was more likely than the PC group (2.72%) to be charged with crimes against person in DJJ [OR (95%CI) 1.92 (1.38-2.68)]. The ID-only group had the highest DJJ recidivism rate (5.17%) compared to PC (3.62%), ASD-only (3.48%), and ASD+ID (1.03%) groups. Similarly, the ASD+ID (3.09%) and ASD-only (6.65%) groups were less likely to be involved in the adult legal system (SLED) than the PC group (11.04%) [OR (95%CI), ASD+ID: 0.26 (0.13-0.50); ASD-only: 0.57 (0.36-0.91)]. The PC group had the highest recidivism rate (5.50%) compared to ID-only (4.86 %), ASD-only (4.11 %), and ASD+ID (1.72%) groups.

Conclusions: Individuals with ASD had lower charge rates compared to youth with ID-only or PC in both the juvenile and adult justice systems. There are also important differences in rates of recidivism across groups, such that individuals in the ASD-only and ASD+ID groups had the lowest rates of recidivism in both the juvenile and adult justice systems.

Social Cognition and Social Behavior

PANEL SESSION — SOCIAL COGNITION AND SOCIAL BEHAVIOR
222 - Novel Approaches to Understand the Cognitive and Neural Bases of Social Interaction in Autism

Panel Chair: Elizabeth Redcay, *Department of Psychology, University of Maryland, College Park, MD, Neuroscience and Cognitive Science Program, University of Maryland, College Park, MD, Department of Psychology, University of Maryland, College Park, MD, Neuroscience and Cognitive Science Program, University of Maryland, College Park, MD*

Difficulties with reciprocal social interaction are core to the diagnosis of autism. These social difficulties affect cognitive and social development and quality of life. However, much of our understanding of cognitive and neural underpinnings of social interaction comes from an “observer” approach in which participants are not directly engaged in interaction. Further, relatively few studies examine interpersonal or dyadic measures of interactions. The current panel discusses novel social-interactive approaches spanning eye-tracking, motion-tracking, EEG, and fMRI to investigate mechanisms of social interaction in autism. Papers highlight the feasibility of novel dyadic measures in autism such as nonintrusive motion tracking, dual head-mounted eye tracking, and dual-brain EEG measures. Novel findings demonstrate that the presence of an interactive partner changes patterns of gaze to objects and modulates oscillatory brain activity. Further, interpersonal measures of gaze can predict diagnostic group. Finally, the neural response to social-interactive reward (i.e., a reciprocal response from a peer) predicts interaction enjoyment in peer interactions in both typically developing and autistic children. Overall, this panel highlights the cutting-edge approaches and findings to identify the mechanisms contributing to real-world challenges with social interaction in autism.

222.001 *(Panel)* Autistic Traits Influence Oscillatory Cortical Dynamics during Dual Brain EEG Recording

***M. J. Rolison**, A. Naples, H. Rutherford and J. McPartland, Child Study Center, Yale University School of Medicine, New Haven, CT*

Background: Humans are innately social creatures, and the social environment strongly influences brain development. Autism spectrum disorder is hallmarked by interpersonal difficulties emerging early in development. Neuroimaging studies consistently implicate atypical resting activity across multiple modalities in ASD. However, the association between resting-state activity and social function is incompletely understood. Despite strong evidence for associations between at-rest brain activity and social function, the majority of research has measured brain activity when participants are in isolation; we know little about brain activity during in vivo social interactions. In this study we examined how the presence of another person modulated resting state brain activity by recording EEG simultaneously from pairs of participants during varying levels of interpersonal proximity. We expected that variation in oscillatory activity between contexts, as a marker of sensitivity to social context, would be associated with autistic traits, as measured through self-report measures of autistic traits.

Objectives: Examine the influence of different levels of interpersonal proximity on resting state brain activity and its association with autistic traits.

Methods: EEG was recorded simultaneously from 20 typically-developing participants (10 pairs) during 3 social contexts: in separate rooms, together facing away from one another (back-to-back), and together face-to-face (facing). Additionally, heart rate variability was recorded from all participants. Participants completed a series of self-report questionnaires designed to measure variation across sub-clinical to clinical levels of autistic traits including the Social Responsiveness Scale 2nd Edition (SRS) and the Broad Autism Phenotype Questionnaire (BAPQ).

Results: Theta activity was greater when separate compared to back-to-back, p=0.01, or facing, p=0.04. Additionally, alpha activity was greater when separate compared to back-to-back, p=0.03, or facing, p=0.02. Further, gamma was greater when separate compared to back-to-back, p=0.01, or facing, p=0.01. Correlations with behavioral measures revealed that a greater difference in beta power when back-to-back versus facing was associated with lower scores on the BAPQ, r=0.60, p=0.03. Further, higher total score on the BAPQ was associated with greater difference in gamma activity between separate and back-to-back, ρ=0.61, p=0.03. Additionally, this difference score between separate and back-to-back was associated with higher total score on the SRS, ρ=0.70, p<0.01.

Conclusions: Interpersonal proximity modulated broadband EEG power from 4-55hz and individual differences in self-reported autistic traits modulated these effects in the beta and gamma frequency bands. These results suggest that the social presence of another human, regardless of interpersonal orientation, modulates brain activity. These findings provide novel insight into the influence of social environment on brain activity and its association with autistic traits through dual-brain EEG recording and demonstrate the importance of using interactive methods to study the human brain, with particular importance for understanding ASD.

222.002 *(Panel)* Neural Correlates of Social Interaction Enjoyment in Children with Typical Development and Autism Spectrum Disorder

***K. A. McNaughton**[1], D. Alkire[1], L. A. Kirby[2], K. R. Warnell[3], H. A. Yarger[4], D. Moraczewski[4] and E. Redcay[4], (1)Neuroscience and Cognitive Science Program, University of Maryland, College Park, MD, (2)Yale Child Study Center, New Haven, CT, (3)Department of Psychology, Texas State University, San Marcos, TX, (4)Department of Psychology, University of Maryland, College Park, MD*

Background: Although social reward processing during everyday interactions is proposed to be atypical in autism spectrum disorder (ASD), its underlying mechanisms are predominantly studied in static, non-interactive contexts. Yet there are significant differences between the cognitive and neural processes engaged in these non-interactive contexts and those engaged in reciprocal social interactions, highlighting the importance of characterizing neural and self-reported reward during naturalistic social interaction in ASD.

Objectives: To examine the neural and behavioral predictors of self-reported enjoyment of a face-to-face peer interaction in children with typical development (TD) and ASD.

Methods: 40 children 8-14 years old (14 ASD, 2 female, mean IQ=118; 26 TD, 4 female, mean IQ=122) participated in two visits to examine relations between neural response to perceived peer interaction and self-reported enjoyment of a face-to-face peer interaction. In the first visit, children participated in a text-based, real-time peer interaction while undergoing a functional magnetic resonance imaging (fMRI) scan. Briefly, children sent text messages to a perceived peer or computer (e.g. “I like cookies”) and received engaged (e.g. “Me too!”) or disengaged (e.g. “I’m away”) responses. Following the scan, children reported their enjoyment of interacting with the perceived peer. Neural response in the bilateral nucleus accumbens, a key region in the reward network, was examined for the differential response to the receipt of the engaged compared to disengaged peer messages controlling for response to engagement in computer messages. In a follow-up visit, children were invited back in pairs to participate in a 25-minute face-to-face interaction with a real peer that consisted of both structured tasks and free conversation. Children rated their enjoyment of this interaction using an interaction success measure, and parents completed the Social Responsiveness Scale to quantify autistic traits.

Results: Increased self-reported enjoyment of interacting with the perceived peer in the fMRI task significantly predicted increased self-reported enjoyment of the face-to-face interaction (beta=2.04, standardized beta=0.36, p<0.05). Furthermore, increased nucleus accumbens response significantly predicted increased enjoyment of the face-to-face interaction (beta=8.08, standardized beta = 0.34, p<0.05). These predictions remained after controlling for age, time between scan and face-to-face interaction, the mean level of autistic traits in the dyad, and the discrepancy on autistic traits in the dyad, none of which significantly predicted enjoyment of the face-to-face interaction. ASD diagnosis was not a significant predictor of enjoyment of the face-to-face interaction, nor did diagnosis significantly interact with the neural response to or self-reported enjoyment of the perceived peer to predict enjoyment of the face-to-face interaction.

Conclusions: In this preliminary sample, we identify relationships between self-reported enjoyment of interacting with a perceived peer, neural selectivity to engaged messages from a perceived peer, and self-reported enjoyment of a live face-to-face interaction with a real peer. Importantly, these relationships were seen in both children with TD and ASD, providing novel evidence of nucleus accumbens selectivity to a reciprocal response from a peer as a transdiagnostic neural correlate of enjoyment of live social interactions.

222.003 *(Panel)* Using Dual Head-Mounted Eye Tracking to Study Visual Attention in Socially Interactive Contexts in Young Children with ASD

D. P. Kennedy[1,2,3], *J. R. Yurkovic*[1,2], *R. Shaffer*[4], *E. Pedapati*[5], *C. A. Erickson*[5,6] *and C. Yu*[1,2], *(1)Psychological and Brain Sciences, Indiana University, Bloomington, IN, (2)Cognitive Science Program, Indiana University, Bloomington, IN, (3)Program in Neuroscience, Indiana University, Bloomington, IN, (4)Division of Developmental and Behavioral Pediatrics, Cincinnati Children's Hospital Medical Center, Cincinnati, OH, (5)Cincinnati Children's Hospital Medical Center, Cincinnati, OH, (6)Department of Psychiatry and Behavioral Neuroscience, University of Cincinnati College of Medicine, Cincinnati, OH*

Background:

The vast majority of eye tracking research on visual attention in ASD is acquired during highly controlled and non-interactive conditions, typically with a participant passively seated in front of a 2-dimensional screen and presented with various stimuli. However, visual experiences in the real world are actively constructed, and choosing when and where to look involves the complex coordination between one's own movements (e.g., of heads, bodies, hands), behaviors of their social partner, and their environment. Here, we adapt a recently developed technology — dual head-mounted eye tracking — to study visual attention in young children with ASD while freely interacting with their parents in an unconstrained toy play context.

Objectives: Our goals were to (1) examine the feasibility of using this dual head-mounted eye tracking technology with young children with ASD (24-48 months), (2) examine whether patterns of visual attention differ as a function of interactive vs. non-interactive toy play (joint vs. solo conditions), and (3) examine whether individuals with ASD are sensitive to the coordinated visual attention of their parent.

Methods: Young children with ASD and their parents both wore light-weight head-mounted eye trackers (SR research) while freely playing with 24 toys, thus providing first-person egocentric video acquired simultaneously with gaze. During the joint play condition, parents were instructed to simply play with their child as they would at home. During the solo play condition, parents were asked to fill out a questionnaire and respond appropriately to their children but not engage further. Gaze was calibrated offline and targets of gaze were defined.

Results:

We successfully acquired dual eye tracking data from 21 dyads (i.e., children with ASD together with their parents). Cases of unsuccessful data acquisition were primarily due to children refusing to wear or repeatedly removing the eye tracker, or difficulty with subsequent calibration. Preliminary analyses on a subset of dyads revealed that children shifted their gaze between objects more often in the joint play vs. solo play conditions ($p < 0.01$, Cohen's $d = 1.36$). We also found that during joint play, when parents and children simultaneously looked to the same object, child gaze to an object was extended in time relative to gaze at objects not jointly gaze at ($p < 0.01$, Cohen's $d = 0.89$). Both of these findings suggest that gaze in dynamic, real world environments in young children with ASD is modulated by the joint interaction of a social partner.

Conclusions:

We demonstrate that dual head-mounted eye tracking is a feasible method for examining visual attention in complex environments in ASD. We also show that young children with ASD are sensitive to the interactive responding by a parent and modulate their gaze accordingly. These findings suggest that dual head-mounted eye tracking can serve as a new method to explore visual attentional differences in ASD, and may provide novel insight into the real-world mechanisms underlying altered social, communicative, and cognitive development in ASD.

222.004 *(Panel)* Interaction-Based Phenotyping to Characterize the Autism Spectrum

L. Schilbach *and J. M. Lahnakoski, Max Planck Institute of Psychiatry, Munich, Germany*

Background: Autism is characterized by profound impairments of social interaction, but currently no observer-independent, quantitative measure of disorders of social interaction is available in clinical or research practice.

Objectives: To implement a novel tool that can be used to provide interaction-based phenotyping in autism (and other disorders), we constructed an unintrusive, infrared-based motion tracking system that enables detailed analysis of behavior at the individual and dyadic interpersonal level.

Methods: We conducted a suite of behavioral studies to validate the new setup in comparison to conventional, wearable motion tracking sensors and to use the new setup as part of ADOS interviews that were conducted in adult individuals that presented to the outpatient clinic for disorders of social interaction at the Max Planck Institute of Psychiatry. In terms of data analysis, we evaluated dyadic measures of joint orienting and distancing, synchrony and gaze behaviors to summarize data collected during natural conversation and joint action tasks as well as ADOS interviews.

Results: Our results demonstrate that patterns of proxemic behaviors, rather than more widely used measures of interpersonal synchrony, best predicted the subjective quality of the interactions. Furthermore, we tested the utility of the novel motion tracking technique by using it during ADOS interviews that were conducted in adult individuals as part of a diagnostic procedure for autism. Here, results of preliminary analyses demonstrate that interpersonal gaze plots derived from motion tracking can be used to predict the diagnostic group with good accuracy, particularly in cases when ADOS scores alone are not informative.

Conclusions: Taken together, this set of findings demonstrates that observer-independent measures of social behavior can be obtained in an unobtrusive manner in clinical interview and other everday life situations. These measures are particularly sensitive to the subjective quality of social interactions and appear to be useful as part of clinical autism assessments.

PANEL SESSION — **SOCIAL COGNITION AND SOCIAL BEHAVIOR**

223 - Personality Traits in Autism Spectrum Disorder

Panel Chair: Jennifer Lodi-Smith, *Psychology, Institute for Autism Research, Canisius College, Buffalo, NY*

Understanding the relationship between personality trait variability and symptom variability in the context of autism spectrum disorder (ASD) is critical as personality traits are important indicators of adaptive outcomes in clinical and non-clinical samples across the lifespan. The first talk reviews a meta-analysis and secondary data analysis of personality traits in ASD. The second talk explores the personality trait differences between the typically-developing and ASD population in both youth and adult subsamples as well as how these differences may translate to variability in clinical characteristics. The third talk presents a latent profile analysis which identifies personality subgroups in an ASD youth sample from a cognitive-behavioral therapy randomized, controlled trial and examines its concurrent validity across various clinical measures. The final talk presents evidence for the potential value of extending emerging personality-based interventions to individuals with ASD. The speakers will close the panel with a discussion of best practices in and future directions for research in personality and ASD.

223.001 *(Panel)* Meta-Analysis and Secondary Data Analysis of Big Five Personality Traits in Autism Spectrum Disorder

J. D. Rodgers[1], *J. Lodi-Smith*[2], *S. Cunningham*[3], *C. Lopata*[1], *M. Thomeer*[1], *S. L. Brennan*[1] *and H. J. Virginia*[4], *(1)Institute for Autism Research, Canisius College, Buffalo, NY, (2)Psychology, Institute for Autism Research, Canisius College, Buffalo, NY, (3)Fordham University, New York, NY, (4)Clinical Psychology, Clark University, Worcester, MA*

Background: Understanding personality in the context of ASD is critical as personality traits are important indicators of adaptive outcomes in clinical and non-clinical samples (Soto, 2019).

Objectives: This talk presents a meta-analysis of the relationship of Big Five personality traits to ASD. It then provides evidence from a preregistered analysis of archival data from the National Database for Autism Research (NDAR) addressing the most notable gap in the published literature on personality traits and ASD - how core diagnostic symptoms relate to personality traits.

Methods:

- Study 1. Meta-analysis: Studies were included if they (1) either (a) measured ASD characteristics using a metric that yielded a single score quantification of the magnitude of ASD characteristics and/or (b) studied individuals with an ASD diagnosis compared to individuals without an ASD diagnosis and (2) measured Big Five traits in the same sample or samples. Fourteen reviewed studies include both correlational analyses and group comparisons. Eighteen effect sizes per Big Five trait were used to calculate two overall effect sizes per trait. Meta-analytic effects were calculated using random effects models.
- Study 2. NDAR data: The relationship of personality traits to ASD symptoms was tested in two independent samples from the NDAR. Sample 1 is a sample of 98 children from NIMH/NIH #R01MH094391-01 (Wood, 2012) who completed the Big Five Questionnaire-Children version (BFQ-C; Caprara et al., 1993). Participants were 9.84 years (SD = 1.94, range = 6.17 – 13.92), primarily male (n = 84, 85.7%) and White (n = 51, 52.0%). Sample 2 is a sample of 32 adults from NICHD/NIH #P50HD055748-01 (Minshew et al., 2007) who completed the NEO Five Factor Inventory (NEO-FFI; Costa and McCrae, 1992). Participants were 23.89 years (SD = 7.92, range = 14.00 – 44.17), primarily male (n = 28, 87.5%), and White (n = 29, 90.6%). In both samples, ASD symptoms were measured by the Autism Diagnostic Observation Schedule (ADOS; Lord et al., 2000) and the Autism Diagnostic Interview-Revised (ADI-R; Rutter et al., 2003).
- All analyses were conducted in R.

Results:

- Study 1. Meta-analysis: Correlational findings yielded a negative association between each Big Five personality trait and ASD characteristics (Fisher's *z* ranged from -.21 [conscientiousness] to -.50 [extraversion]). Effects from comparisons of individuals diagnosed with ASD to neurotypical individuals were also substantial (Hedges' *g* ranged from -.88 [conscientiousness] to -1.42 [extraversion]).
- Study 2. NDAR data: Conscientiousness, agreeableness, and openness were negatively related to Autism Diagnostic Observation Schedule scores (Lord et al., 2000). Effects were not as robust as in the meta-analytic findings and varied across samples and symptoms.

Conclusions: Meta-analytic findings indicate that individuals with ASD and elevated ASD characteristics have personality trait profiles that may put them at heightened risk for poor outcomes. However, the relationship of ASD symptoms to personality traits appears to be less robust within individuals with ASD, replicating the one prior published report of the relationship of personality trait variability to ASD symptom variability within ASD (Schriber et al., 2014). These patterns suggest a relative independence of ASD diagnostic characteristics and personality traits.

223.002 *(Panel)* Exploring Multiple Autisms through the Lens of Personality: Differences in ASD Phenotypes

A. C. Cho[1], *J. J. Wood*[1], *K. A. Rosenau*[2] *and A. R. Johnson*[1], *(1)Human Development & Psychology, University of California, Los Angeles, Los Angeles, CA, (2)GSE&IS, University of California, Los Angeles, Los Angeles, CA*

Background: Within the autism spectrum disorder (ASD) population, there is considerable variability in individuals' symptom expression, verbal/intellectual ability, and comorbid symptoms. This heterogeneity can also be observed in the ASD genetics and neuroscience literature, which presents ASD as a neurodevelopmental syndrome that consists of multiple separable phenotypes with different etiological causes (Tordjman et al., 2017). Thus, a recent goal in ASD research has been to identify the possible subtypes that are represented under this broad clinical diagnosis. Although the relationship between personality traits and ASD symptomatology has been explored (Lodi-Smith et al., 2018), personality research has yet to be utilized in identifying underlying subtypes and etiological pathways, something which has been effective in other mental health fields. Comprehensive descriptions of personality such as the five-factor model incorporate most areas of human behavioral variability into their taxonomies, providing a unique lens for identifying meaningful subgroup differences with a frame that goes considerably beyond clinical symptoms and theoretical constructs such as social motivation. As such, the intersection between personality research methods and the "multiple autisms" model provides a promising direction in understanding the heterogeneity within the ASD population.

Objectives: To identify meaningful, homogeneous personality subgroups that may be representative of autism subtypes in the ASD population.

Methods: The current study utilized data from a randomized, controlled trial comparing personalized cognitive-behavioral therapy (CBT) to group CBT for school-aged youth with ASD (N=105). A latent profile analysis was conducted using the participants' baseline personality measure scores (i.e., Hierarchical Personality Inventory for Children). A best-fitting model was determined by relative fit indices, including the Bayesian Information Criterion (BIC) and sample size-adjusted Bayesian Information Criterion (SS-BIC), as well as considerations for parsimony and interpretability. Concurrent validity was assessed by comparing the identified personality subgroups (i.e., classes) on measures of ASD symptomatology and comorbidities (SRS, CASI, CBCL) and measures of cognitive performance (WISC-IV, D-KEFS).

Results: A 4-class solution emerged as the best-fitting model with significant reductions in fit indices through four classes, while the 5-class solution presented an increase in BIC value. The additional class in the 5-class solution was deemed spurious given its similarity to another class and small class membership (representing less than 5% of the sample). The class with the largest membership (n=55) was characterized by low scores across all five personality factors, while another (n=9) exhibited the highest scores across all factors. A third class (n=27) presented uniquely low scores in Agreeableness and Emotional Stability, while the fourth class (n=14) presented very low Extraversion with high Agreeableness. The four classes were significantly different in SRS-2 and WISC-IV scores, as well as CASI, CBCL, and D-KEFS subscale scores.

Conclusions: Results suggest that subgroups of children with ASD (IQ>70) seeking behavioral treatment may possess distinct personality profiles which may affect the autism symptom expression, severity level, cognitive features, and comorbid symptomatology which characterize them. Future research should determine the clinical significance of identified personality subgroups and whether or not they are identifiable on a neurobiological level as well.

223.003 *(Panel)* Beyond the Lorna Wing Typologies: Personality Profiles in Autism Spectrum Disorder Reconsidered

M. Solomon[1]*, A. C. Cho*[2]*, M. K. Krug*[3]*, A. J. Gordon*[4] *and J. J. Wood*[2]*, (1)Department of Psychiatry and Behavioral Sciences, The Medical Investigation of Neurodevelopmental Disorders (MIND) Institute, UC Davis School of Medicine, University of California Davis, Sacramento, CA, (2)Human Development & Psychology, University of California, Los Angeles, Los Angeles, CA, (3)Department of Psychiatry & Behavioral Sciences, UC Davis MIND Institute, Sacramento, CA, (4)Psychiatry & Behavioral Sciences, University of California, Davis, M.I.N.D. Institute, Sacramento, CA*

Background: Recent research has highlighted the substantial association between personality traits (as assessed by the Five-Factor Model [FFM]) and autism spectrum disorder (ASD) characteristics (Lodi-Smith et al., 2018). Notably, FFM personality domain scores appear to differ across typically-developing and ASD populations and are moderately correlated with ASD symptom expression. However, there is a great deal of variability in personality profiles of individuals with ASD (Vuijk et al., 2018), reflecting the notion of "multiple autisms" found in the ASD genetics and neuroscience literatures (Tordjman et al., 2017). Additionally, few studies have evaluated how the relationship between ASD symptomatology and personality traits varies as a function of age within the ASD population (Schriber et al., 2014). By observing ASD symptomatology through a personality lens and across age groups, it may be possible to better understand variability in symptom profiles and identify potential ASD subtypes.

Objectives: The present study aimed to (1) replicate previous findings on differences in personality traits between typically-developing and ASD populations, (2) determine the extent to which personality traits predict autism symptom expression in both youth and young adults, and (3) identify common personality profiles that may be representative of autism subtypes in the ASD population.

Methods: Personality and ASD symptom expression data were collected in a sample consisting of both typically-developing individuals and individuals with ASD ages 12 to 22 (N=176). Youth with ASD (cASD; n=47; M_{age}=14.49 years) were compared with typically-developing youth (cTYP; n=49; M_{age}=14.47 years) and young adults with ASD (aASD; n=41; M_{age}=19.88 years) were compared with typically-developing adults (aTYP; n=39; M_{age}=19.95 years) on each Big Five Inventory (BFI) domain (Extraversion, Agreeableness, Conscientiousness, Negative Emotionality, Open-Mindedness) and secondary personality facets. Regression models were used to calculate the variance accounted for by BFI domains and facets in Social Responsive Scale (SRS-2) scores. A K-means cluster analysis was used to examine BFI score patterns to identify common profiles within the ASD subsample (n=81), and clusters were validated by various clinical measures.

Results: T-tests revealed significant differences (p<.05) across three domains (Extraversion, Conscientiousness, Negative Emotionality) between the cTYP and cASD groups and across all five domains between the aTYP and aASD groups. Personality facets accounted for 30% and 37% of variance in autism core symptom expression in youth and adult subsamples, respectively. Three personality profiles were identified in the ASD subsample (37%, 35%, and 28% of the sample, respectively). The clusters differed markedly on Extraversion, Agreeableness, Conscientiousness, and Negative Emotionality, and presented differential scores on various clinical measures (e.g., SRS-2, Personality Inventory for DSM-V).

Conclusions: The present results converge with previous findings, suggesting a significant association between personality traits and ASD characteristics. Consistent with past literature, this relationship is more pronounced in the adult subsample. Three identified cluster subgroups presented distinct personality profiles that are indicative of notably heterogeneous ASD phenotypes. In accordance with the NIMH's Research Domain Criteria project (Insel et al., 2010), the present study's findings may be leveraged to better understand the etiology and symptomatology of autism and the associated neurobiological mechanisms that underlie them.

223.004 *(Panel)* Potential for Personality-Based Interventions in the Context of Autism Spectrum Disorder

J. Lodi-Smith[1] *and J. D. Rodgers*[2]*, (1)Psychology, Institute for Autism Research, Canisius College, Buffalo, NY, (2)Institute for Autism Research, Canisius College, Buffalo, NY*

Background: Meta-analytic work (Lodi-Smith et al., 2018) indicates that individuals with autism spectrum disorder (ASD) and elevated ASD characteristics have personality trait profiles that may put them at heightened risk for poor outcomes (Soto, 2019). Personality-based interventions are, therefore, a potential future resource for this community. However, before personality-based interventions can be initiated, a number of additional assumptions must be tested through basic research.

Objectives: This talk provides evidence that important assumptions underlying personality-based interventions replicate in the context of ASD. Specifically, we summarize findings from an ongoing preregistered three sample study (current n = 718) testing the hypothesis that individuals with ASD and elevated ASD characteristics desire to change their personality traits, an important component of successful personality-based interventions (Hudson & Fraley, 2015).

Methods: The relationship of personality traits to desired trait change is tested in three independent samples. Participants in all three samples completed an ASD diagnostic history form, the Autism Quotient Scale (AQ, Baron-Cohen et al., 2001) and a measure of desired personality trait change developed for the project combining features of the C-BFI (Hudson & Roberts, 2014) and the Ten Item Personality Inventory (Gosling et al., 2003). Sample 1 is a sample of 395 adults who completed the surveys via MTurk. MTurk participants were 33.76 years (SD = 11.07), primarily female (62%) and White (70%). Sample 2 is a sample of 86 students who completed the surveys for course credit. Student participants were 22.03 years (SD = 7.28), primarily female (74%), and White (78%). Sample 3 is a sample of 237 adults who completed the surveys as part of the Canisius Aging in Autism Study (NIA/NIH #1R21AG059051-01). Sample 3 participants were 66.77 years (SD = 13.78), primarily female (58%), and White (92%). All analyses were conducted in R and collapsed across samples for a combined sample size of 718 participants, 61 of whom self-reported an ASD diagnosis.

Results: Findings indicate that ASD characteristics were modestly related to desired change in personality traits (correlation coefficients ranged from .13 - .20, $p < .05$). Individuals who self-reported having an ASD diagnosis also self-reported a desire to become less neurotic relative to individuals who did not self-report an ASD diagnosis ($t = 2.37$, $p < .05$).

Conclusions: Findings indicate that individuals with self-reported ASD and elevated ASD characteristics desire personality trait changes in ways that closely replicate desired personality trait change in general community samples. Combined with existing evidence that personality is adaptive in the context of ASD in ways that are parallel to those seen in non-clinical samples and other clinical populations, these findings give added support for the potential value of extending emerging personality-based interventions to individuals with ASD.

PANEL SESSION — SOCIAL COGNITION AND SOCIAL BEHAVIOR
224 - Translational Perspectives on Social Motivation in Autism Spectrum Disorder

Panel Chair: Emily Neuhaus, *Seattle Children's Hospital, Seattle, WA*

Discussant: Alexandra P.F. Key, *Vanderbilt Kennedy Center; Dept. of Hearing and Speech Sciences, Dept, of Psychiatry and Biological Science, Vanderbilt University Medical Center, Nashville, TN*

Social motivation lies at the foundation of social functioning, promoting specialized neural development as early as infancy and setting the stage for sophisticated social cognition and skill throughout development. Prominent etiological theories of autism spectrum disorder (ASD) propose deficits in social motivation as a core feature of ASD, shifting developmental trajectories, altering brain development, and underlying social difficulties across the lifespan. In this panel, we will present innovative research on distinct facets of social motivation in ASD, spanning neuroscience to intervention. Speakers will present novel research exploring (1) conceptualization of social motivation as a construct with respect to neural and behavioral correlates, (2) relations between social motivation and emotional difficulties as they contribute to social success and challenges, (3) social motivation as a target of naturalistic behavioral intervention, and (4) effects of social skills intervention on ERP correlates of social motivation among teens with ASD. As a whole, this panel presents a translational perspective on social motivation that bridges neural mechanisms to clinical outcomes.

224.001 *(Panel)* Assessing the Construct Validity of Social Motivation

M. D. Lerner[1]*, C. M. Keifer*[2]*, P. Felsman*[2]*, J. P. Giacomantonio*[2] *and E. Kang*[1]*, (1)Department of Psychology, Stony Brook University, Stony Brook, NY, (2)Stony Brook University, Stony Brook, NY*

Background: The notion of social motivation deficits as a core construct of autism spectrum disorder (ASD) has been a source of great interest in recent years (Dawson et al., 2005; Chevallier et al., 2012). While recent meta-analyses support the role of social motivation in ASD (Clements et al., 2018), other theoretical (Jaswal & Akhtar, 2019) and empirical (Garman et al., 2016) work suggest its role to be inconsistent at best, and perhaps even contradictory. One source of these conflicting findings is the lack of consistent and clear construct specification of social motivation (Keifer, Dichter, McPartland, & Lerner, 2019). To date, no known study has psychometrically evaluated the validity of measures of social motivation in ASD.

Objectives: We sought to test the convergent and divergent validity of a measure of social motivation in ASD.

Methods: 56 youth with ASD (M_{age}=12.06, SD_{age}=2.95; 73% male) completed social skills ratings (SSIS; Gresham & Elliott, 2008) and a facial recognition task (Nowicki et al., 2004) with concurrent EEG measurement (specifically the N170, an event-related potential often associated with ASD symptoms; Kang et al. 2018). Their parents completed a measure of social motivation (the social motivation subscale of the Dimensions of Mastery Questionnaire [DMQ], representing social persistence; Morgan et al., 2014), as well as other social-emotional and behavioral measures (SSIS, SRS-2 [Constantino et al., 2012], CASI-5 [Gadow & Sprafkin, 2013], MASC-2 [March, 2013]). To test convergent validity, we examined associations of DMQ with social-emotional and EEG measures hypothesized to be related to social motivation (SRS-2, SSIS, and the N170 latency). To test divergent validity, we examined associations between DMQ and demographic and behavioral variables hypothesized *not* to be related to it (Age, gender, IQ, ADHD and anxiety symptoms).

Results: The DMQ subscale correlated with SRS-2 total score and both parent- and self-reported social skills on the SSIS, and the N170 latency to faces (Table 1). The association between the DMQ and SRS-2 was driven by relations with social motivation (convergence on the same construct), social awareness, communication, restricted interests & repetitive behaviors (all r<-.292; all p<.05), but not social cognition (p=.20). The DMQ's association with the parent-report SSIS was driven by empathy and engagement (r>.290, p<.05), and self-report SSIS by cooperation, assertion, responsibility, empathy, and engagement (r>.292, p<.05). The association with N170 latency was driven by high intensity faces (r=.291, p=.034). As hypothesized, the DMQ was not associated with most demographic and clinical variables (parental age, ADHD or anxiety symptomatology, parent- or self-reported problem behaviors, composite, verbal, or nonverbal IQ scores, or sex) except for child age (Table 1).

Conclusions: Overall, these results largely support the convergent and divergent validity of the DMQ as a measure of parent-reported social motivation in youth with ASD. Notably, even more distal hypothesized convergent variables (child self-report social skills; N170 ERP) correlated with the DMQ, supporting the utility of social motivation as an observable construct. Future investigations should examine the reliability and other forms of validity of the DMQ to systematically evaluate this instrument as an index of social motivation.

224.002 *(Panel)* Contributions of Social Motivation and Emotion Dysregulation to Social Outcomes Among Children and Adolescents with Autism Spectrum Disorder

E. Neuhaus[1]*, S. J. Webb*[2] *and R. Bernier*[2]*, (1)Seattle Children's Hospital, Seattle, WA, (2)Psychiatry and Behavioral Sciences, University of Washington, Seattle, WA*

Background: Prominent hypotheses suggest that early-emerging alterations to social motivation underlie social difficulties in autism spectrum disorder (ASD), and neurophysiological and behavioral studies support social motivation as a contributor to social cognition and behavior. However, links between social *motivation* and social *outcomes* are not straightforward, with influence from any number of individual differences. In particular, recent work from our group suggests that emotional difficulties may blunt the facilitative effects of social motivation on social functioning, and that these relations may be further moderated by sex.

Objectives: In a large sample recruited intentionally for balanced sex ratios, we sought to explore (1) contributions of social motivation to social skills and social problems among youth with and without ASD, (2) possible moderating effects of emotional difficulties across a number of symptom areas, and (3) possible moderation of social-emotional associations by diagnostic group and participant sex.

Methods: Data were collected within a large, multisite study spanning four U.S. sites, yielding a total of 309 children and adolescents (47% female; mean age=12.6 years, SD=2.95, range=8-18 years) with ASD (n=147) or with typical development (n=162). All participants were verbally fluent, without intellectual disability, and well-characterized clinically. Social motivation, social skills, and social problems were assessed via the Social Reciprocity Scale, 2nd edition, Vineland Adaptive Behavior Scales, 2nd edition, and Child Behavior Checklist, respectively. Emotion dysregulation was assessed via the Child Behavior Checklist (internalizing, aggression, attention concerns) and the Repetitive Behavior Scale, Revised (self-injurious behavior). Direct effects of emotion dysregulation and interactions between social-emotional variables were tested with a series of regression models.

Results: For participants with and without ASD, stronger social motivation was associated with stronger social skills (rs>.3, ps<.001) and fewer social problems (rs>.21, ps<.01) but sizeable variation in social outcomes remained unexplained. Among those with ASD, models including emotional difficulties accounted for significant variance in social problems, with internalizing (r^2_{adj}=.33, p<.001), aggression (r^2_{adj}=.40, p<.001), attentional concerns (r^2_{adj}=.39, p<.001) and self-injurious behaviors (r^2_{adj}=.11, p<.001) emerging as more robust predictors of social outcomes than social motivation. This pattern was largely consistent across sexes. Among typically developing individuals, sizeable interactive effects emerged as well, such that associations between social motivation and broader social outcomes were moderated by internalizing symptoms (r^2_{adj}=.52, p<.001), aggression (r^2_{adj}=.31, p<.001), and attentional difficulties (r^2_{adj}=.30, p=.009). Effects varied according to sex, but models for some forms of emotion dysregulation accounted for over half of the variance in broader social outcomes (e.g., among males, aggression: r^2_{adj}=.83, p<.001).

Conclusions: Although social motivation does appear to promote social skills and attenuate social difficulties among verbal youth with ASD, it is not sufficient for understanding broader social outcomes. Instead, difficulties with emotion regulation appear to overshadow social motivation as a predictor of outcomes. Clinically, these results highlight the need to assess and treat emotion dysregulation in the service of social functioning. Theoretically, findings reinforce both the value and the nuance of social motivation as a construct for understanding social outcomes, and underscore the need to consider social motivation in relation to other individual differences.

224.003 *(Panel)* Social Success: Using a Naturalistic Behavioral Intervention Approach with Parent Training to Enhance Child Motivation to Initiate Peer Interactions

J. Shkel[1]*, J. M. Schwartzman*[2]*, E. Gagnon*[3]*, M. E. Millan*[1]*, R. K. Schuck*[4]*, D. White*[1]*, A. Y. Hardan*[5]*, J. M. Phillips*[5] *and* ***G. W. Gengoux***[1]*, (1)Psychiatry and Behavioral Sciences, Stanford University School of Medicine, Stanford, CA, (2)Palo Alto University, Palo Alto, CA, (3)PGSP-Stanford Psy.D. Consortium, Palo Alto, CA, (4)Psychiatry and Behavioral Sciences, San Jose State University, Palo Alto, CA, (5)Psychiatry & Behavioral Sciences, Stanford University, Stanford, CA*

Background: Social deficits in children with Autism Spectrum Disorder (ASD) are difficult to remediate and can have long-term negative consequences (e.g., loneliness, lower self-worth, impaired ability to function in the community, and weaker academic performance). As social functioning requires child social motivation, there is a critical need for treatment models that directly enhance motivation to initiate and interact with peers. Naturalistic developmental behavioral intervention strategies applied in inclusive settings have particular promise given their emphasis on natural contingencies and enhancing child social motivation.

Objectives: This presentation reviews child outcome data from a randomized controlled trial of Systematic Use of Cooperative Contingencies to Enhance Social Success (i.e., the Social SUCCESS program). Social SUCCESS is a novel social intervention using naturalistic behavioral treatment strategies which includes both child social groups and parent training which specifically target child motivation to initiate to peers.

Methods: Children with ASD (4-6 years old) were randomly assigned to the Social SUCCESS intervention or a delayed treatment control group (DTG). SUCCESS participants received 12 weekly social group sessions with typically-developing peers, during which therapists arranged cooperative activities to teach and reinforce initiations to peers. Parents also participated in a weekly parent training group to learn naturalistic behavioral strategies for facilitating positive peer interactions during play dates at home, in addition to receiving coaching during social group sessions. Participants in DTG continued stable community-based services. To date, data from multimethod, multi-informant assessments are available for 23 children with ASD (SUCCESS=11; DTG=12).

Results: Following the 12-week treatment, an independent clinician blinded to group assignment rated children in the SUCCESS group as more improved following treatment on the Clinical Global Impressions Improvement Scale (CGI-I; p=0.006). Specifically, the majority of participants in the SUCCESS group (64%) were rated as “Much Improved”, while all the participants in DTG were rated as either “No Change” (45%) or “Minimally Improved” (55%). A new measure of social motivation (Stanford Social Motivation Scale) was also collected as a potential predictor of treatment response. For participants in the SUCCESS treatment, low baseline social motivation was associated with greater improvement in frequency of initiations following intervention based on parent ratings on a Visual Analog Scale (r=-0.815; p=0.002). Standardized measures of social functioning (Vineland-3, SRS-2) and parent use of effective facilitation strategies (i.e., setting up cooperative arrangements, prompting initiations to peers and coaching peers to provide contingent reinforcement) as measured by behavioral coding of videos at baseline and post-treatment will also be discussed.

Conclusions: Findings suggest that naturalistic behavioral treatment and parent training focused on teaching children to successfully initiate to peers shows promise for enhancing social motivation and aspects of social functioning in children with ASD. Implications for design of effective inclusive social skills programming and remediation of core social deficits in ASD will be discussed.

224.004 *(Panel)* Impact of PEERS Social Skills Intervention on Social Motivation and Reward

K. K. Stavropoulos[1]*, E. Baker*[2]*, L. A. Alba*[1] *and E. Veytsman*[1]*, (1)Graduate School of Education, University of California Riverside, Riverside, CA, (2)University of California Riverside, Riverside, CA*

Background: Individuals with ASD have social-communication difficulties that impede their ability to form friendships. Social skills interventions for adolescents that target conversational skills and perspective taking (PEERS©) are effective in ameliorating these challenges (Laugeson et al., 2012). However, neural mechanisms of behavioral improvements remain unclear. Event-related potentials (ERPs) can objectively measure differences in brain activity pre- and post- intervention and identify potential underlying mechanisms of change.

Objectives: We measured two ERPs related to social motivation and reward: the stimulus preceding negativity (SPN) measuring reward anticipation, and the reward positivity (RewP) measuring reward processing. Children were presented with rewards accompanied by incidental face or non-face stimuli.

Methods: Brain activity was measured in teens with ASD before (T1) and after (T2) the 16-week intervention, and 16-weeks later (T3) in an immediate treatment (IT) group. Individuals on a waitlist control (WLC) are currently completing the intervention. Neurotypical (TD) teens, age and gender-matched to teens with ASD, had brain activity measured identically but did not participate in the intervention. We report T1 and T2 data for the IT group (N = 7, M = 13.3 yrs) and T1 data for the WLC (N = 8, M = 14.06 yrs) and TD groups (N = 11, M = 13.3 yrs).

Results: *SPN.* Age and SPN amplitude were significantly correlated across groups such that younger children evidenced larger reward anticipation for faces (p = .022). Age was used as a covariate in all analyses.

T1 and T2: Children with ASD evidenced increased reward anticipation from pre- to post-intervention across stimulus types (p = .03). Post intervention, a correlation was observed (p = .016) between SPN amplitude to faces and scores on the social skills improvement system (SSIS). Adolescents with *better social* skills evidenced *smaller* SPN magnitude to faces.

T1: A significant interaction between group and condition was observed (p = .02) —TD adolescents evidenced larger SPN amplitude to non-faces vs. faces; those with ASD evidenced the opposite pattern. Across groups, a correlation was observed (p = .047) between SSIS score and the SPN to faces—teens with *better social* skills evidenced *smaller* SPN amplitude to faces.

Results: *RewP.*

T1 and T2: A marginal correlation was observed (p = .076) between change in the SSIS and the RewP to faces—children with a larger RewP to faces at T1 had greater improvement in social skills from T1 to T2.

Conclusions: This is the first study to compare reward anticipation and processing in both adolescents with ASD before and after PEERS© and well-matched controls. At T1, adolescents with and without ASD differ—neurotypical teens anticipate non-social rewards *more* than social rewards; teens with ASD show the opposite. SPN results suggest that for adolescents with ASD, reward anticipation significantly increases after participation in PEERS©. Brain and behavioral correlations indicate that all teens with better social skills have *less* robust SPNs to faces. Reward processing data suggest that as social skills improve in adolescents with ASD, reward processing of faces increases. The results have important implications for the social motivation theory of autism.

ORAL SESSION — **SOCIAL COGNITION AND SOCIAL BEHAVIOR**

327 - Cognitive and Social-Cognitive Functioning Across Domains

327.001 *(Oral)* Better Cognitive Level, Communicative Gestures and Joint Engagement Behaviors in Toddlers with Autism Spectrum Disorder Predict Better Outcome in Adolescence

D. A. Zachor[1] *and E. Ben-Itzchak*[2]*, (1)The Autism Center/ALUT, Pediatrics, Tel Aviv University /Shamir (Assaf Harofeh) Medical Center, Zerifin, Israel, (2)Bruckner Center for Research in Autism, Communication Disorder, Ariel University, Ariel, Israel*

Background: Long-term outcomes for individuals with autism spectrum disorder (ASD) can range from having continuous severe social-communication and functional impairments to nearly typical functioning in adolescence. Very few prospective long-term studies searched for baseline predictors for favorable outcomes. Previous research found that optimal outcome was associated with improved restricted and repetitive behaviors during the first year after ASD diagnosis, less severe parental reports on social interaction symptoms, and early intensive intervention. This is a long-term prospective study that followed toddlers who were diagnosed with ASD until adolescence.

Objectives: -To compare characteristics in toddlerhood (cognitive ability, adaptive functioning and autism severity), birth risk factors, and neurological conditions of three groups in adolescence, one with 'best outcome' (BO) - not meeting cut-off points for ASD and IQ scores ≥85; the second with high functioning HF-ASD, and the third with lower functioning LF-ASD.

-To compare the aforementioned three outcome groups for: the severity of comorbidities that are considered inherited conditions, attention deficit hyperactivity disorder (ADHD), and anxiety symptoms

-To search for characteristics in toddlerhood that may predict future membership in one of the outcome groups

Methods: The study included 69 adolescents, 64 males and 5 females, with a mean age of 13:10 years (SD=1:11), diagnosed with ASD at toddlerhood. Participants (BO-16%; HF-ASD-20%; LF-ASD-62%) underwent a comprehensive assessment of cognitive ability, adaptive skills and autism severity at toddlerhood (T1) and adolescence (T2). In addition, the severity of ADHD and anxiety symptoms was assessed using standardized questionnaires.

Information on birth risk factors, micro/macrocephaly. and developmental regression at toddlerhood were obtained from the baseline medical charts.

Results: Among the behavioral characteristics at T1, less severe autism symptoms - mostly in the social affect domain of the Autism Diagnostic Observation Schedule (ADOS -) were documented for the BO and HF-ASD groups as compared to the LF-ASD group. Of the examined ADOS pro-social behaviors at T1, less severe impairments in ‘frequency of vocalizations directed toward others', 'pointing', 'facial expression directed toward others', 'showing' and 'response to joint attention', were associated with membership in the BO group. BO had also the lowest prevalence of significant T2 inattention symptoms (11.1% vs. 30.8% and 59.5% for the HF-ASD and LF-ASD groups respectively). In addition, the BO group had the lowest percentage of participants with significant symptoms in at least one anxiety subdomain (27.3% vs. 69.2%, 57.1 for the HF-ASD and LF-ASD groups respectively). No significant differences between the three outcome groups were noted in the prevalence of developmental regression, low birth weight, prematurity, assisted reproductive technology, or macro/microcephaly, although their prevalence in the entire group was higher than in the general population.

A linear regression model revealed that higher cognitive ability and better showing and pointing behaviors at toddlerhood predicted belonging to the best outcome group, and in total explained 27% of the variance.

Conclusions: Better cognition and social communication skills, specifically better communicative gestures and joint engagement behaviors in toddlers with ASD, and later lower prevalence of ADHD and anxiety are associated with better outcome in adolescence.

327.002 *(Oral)* Interactive Psychometrics for Autism with the Human Dynamic Clamp: Measuring Interpersonal Synchrony from Sensory-Motor to Socio-Cognitive Domains

F. Baillin[1]*, A. Lefebvre*[2]*, A. Pedoux*[3]*, Y. Beauxis*[1]*, D. A. Engemann*[4]*, A. Maruani*[5]*, F. Amsellem*[6]*, T. Bourgeron*[7]*, R. Delorme*[8,9] *and* ***G. Dumas***[10]*, (1)Neurosciences, Institut Pasteur, Paris, France, (2)Institut Pasteur, Paris, France, (3)Institut de psychologie, Université Paris Descartes - Sorbonne Paris Cité, Paris, France, (4)Parietal Team, INRIA, Gif-sur-Yvette, France, (5)hopital robert debre, paris, FRANCE, (6)Pasteur, Paris, France, (7)Human Genetics and Cognitive Functions, Institut Pasteur, Paris, France, (8)Excellence centre for Autism and Neurodevelopmental disorders, Paris, France, (9)Pasteur Institute, Human Genetic and cognitive function, Paris, France, (10)Human Genetics and Cognitive Functions Unit, Institut Pasteur, Paris, France*

Background: The Human Dynamic Clamp (HDC) is a human-machine interface for studying dynamic bidirectional interaction in real time between a human and a virtual avatar. Interpersonal Synchrony (IS) comprises multiple components, such as socio-cognitive, sensory-motor, and motor skills, as well as adaptive capacities. HDC thus allows to probe IS under controlled and reproducible conditions.

Objectives: Here, we propose to probe the validity of the HDC as psychometric instrument for quantifying social aptitude in neurotypical and Autism Spectrum Disorders (ASDs) children. This condition is frequently found to be associated with difficulties in the ability to attribute mental states to oneself and to others. In addition to these primary deficits in social communication skills, about 80% of children diagnosed with ASDs also show impairments in motor skills and 50% to 80% deficits in perceptual motor performance. Furthermore, ASDs children tend to have more difficulties in IS.

Methods: To study behavioral synchrony, based on the interaction with the HDC avatar, we derived five standardized scores following a gradient from sensory-motor to higher socio-cognitive skills. Our sample comprised 155 individuals (113 with ASDs, 42 typically developing participants; aged 5 to 25 years; IQ>70) who received extensive cognitive assessments. We used normative modeling to normalize the scores across developmental trajectories.

Results: Regression analyses were conducted to predict normalized HDC scores from avatar behavior (cooperative/competitive), human task (in-phase/anti-phase), diagnosis (Controls/ASDs), and age. We observed that children with ASDs tend to have significant lower scores than control participants for motor skills. Sensory-motor skills, task comprehension and socio-cognitive skills significantly improved as age increased. Socio-cognitive skills were also strongly modulated by the difficulty of the ongoing task and the cooperativeness of the avatar.

Conclusions: The weaker performance in ASDs participants for motor skills suggest convergent validity and support motor skills as a developmental marker of children and adolescents at risk with ASDs. Results provide additional evidence of a relationship between sensory-motor and socio-cognitive skills. As we found a significant main effect of age, HDC may be useful to decipher the developmental trajectories of sensory-motor and socio-cognitive skills during real-time social interaction. Through its standardized and objective evaluation, the HDC not only represents a valid paradigm for the study of interpersonal synchrony but also a clinically relevant psychometric instrument for the evaluation and stratification of disorders with a social dimension such as ASDs.

327.003 *(Oral)* Overall Cognitive Functioning Partially Mediates the Relationship between Facial Emotion Recognition Accuracy and Social Impairment Related to Autism Spectrum Disorder Among Adolescents

K. M. Hauschild[1] *and M. D. Lerner*[2]*, (1)Psychology, Stony Brook University, Stony Brook, NY, (2)Department of Psychology, Stony Brook University, Stony Brook, NY*

Background: Facial emotion recognition (FER) ability is often associated with levels of social impairment for individuals with autism spectrum disorder (ASD; Trevisan & Birmingham, 2016). This finding is frequently interpreted as evidence for the importance of FER in promoting effective social communication and interaction. However, successful FER relies on domain-general cognitive abilities such as sensitivity to spatial relations (Bombari et al., 2013) and verbal ability (Barrett et al., 2007). Moreover, both FER ability and impairments in social communication vary by overall cognitive functioning, as indexed by an intelligence quotient (IQ; Harms, Martin, & Wallace, 2010; Skuse et al., 2009). Therefore, it may be that, in its association with ASD-related social impairment, FER performance accuracy acts as a proxy for overall cognitive functioning. Yet, this relationship has not been directly tested in a large sample of individuals with varying degrees of social impairment. Given the importance of domain-general cognitive abilities to successful FER, we hypothesized that overall cognitive ability would mediate the relationship between FER and ASD related social impairment.

Objectives: To determine if the relationship between FER behavioral accuracy and ASD-related social impairment is mediated by IQ among adolescents with and without ASD.

Methods: One hundred and forty-one adolescents with and without ASD completed a standardized FER task (Table 1). IQ was assessed by the Kaufman Brief Intelligence Test-2 (KBIT-2; Kaufman & Kaufman, 2004). ASD related social impairment was measured using the Social Responsiveness Scale, second edition (SRS-2; Constantino et al., 2012). A model whereby the relationship between FER accuracy and ASD related social impairment is mediated by IQ was tested.

Results: FER accuracy was indirectly related to social impairment through its relationship with overall cognitive ability (Figure 1). Higher FER accuracy was associate with higher FSIQ, and higher FSIQ was subsequently related to lower SRS-2 t-scores. The indirect effect of FER accuracy on SRS-2 T score through FSIQ was significant. Additionally, FER accuracy remained associated with SRS-2 t-score after taking into account FSIQ, although this effect was attenuated.

Conclusions: As predicted, findings indicated that the relationship between FER performance accuracy and ASD-related social impairment was partially mediated by overall cognitive functioning in a large sample of adolescents. Consistent with previous interpretations (Trevisan & Birmingham, 2016), this suggests that the inability to accurately recognize emotional facial expressions of others uniquely predicts impairment in social functioning, and this process is potentiated via differences in cognitive ability. While higher overall cognitive functioning may represent increased use of compensatory processing mechanisms (Rutherford & Troje, 2012), even small aberrations in the ability to recognize facial cues of emotion likely hinders appropriate and sensitive responding to conversational partners (Izard et al., 2001). Thus, the improvement of FER abilities should remain a primary target of social skills interventions for adolescents with ASD-related social impairment, though consideration of how IQ may impact translation of these abilities to social outcomes (i.e., this translation may be especially facilitated for those with greater cognitive abilities) is important.

327.004 *(Oral)* Cognitive Profiles in Toddlers Identified with Autism Spectrum Disorder

N. M. Hendrix[1]*, C. Aoki*[1]*, B. Brooks*[2]*, S. P. White*[3]*, E. A. Doernberg*[4]*, L. J. Dilly*[5]*, M. Lambha*[6]*, S. Richardson*[5]*, A. Klin*[2] *and C. Klaiman*[2]*, (1)Marcus Autism Center, Emory University School of Medicine, Atlanta, GA, (2)Marcus Autism Center, Children's Healthcare of Atlanta and Emory University School of Medicine, Atlanta, GA, (3)Department of Pediatrics, Emory University, Atlanta, GA, (4)Psychological Sciences, Case Western Reserve University, CLEVELAND, OH, (5)Marcus Autism Center, Atlanta, GA, (6)Marcus Autism Center/Children's Healthcare of Atlanta, Atlanta, GA*

Background: Although prevalence discrepancies in autism spectrum disorder (ASD) across racial and ethnic groups have decreased over time (Baio et al., 2018), disparities remain related to age of diagnosis, access to intervention, and outcomes for children diagnosed with ASD (e.g., Durkin et al., 2017; Zeleke, Hughes, & Drozda, 2019). In the CDC study by Baio and colleagues (2018), the gap in prevalence between Caucasian and African American children has narrowed to a difference of only 1.2 per 1000, yet the rate of intellectual disability remains twice as high in African American (44%) as in Caucasian (22%) 8-year-old children. Parents note developmental concerns by age 36 months for 85% of children with ASD, yet only 42% of children reportedly complete a comprehensive evaluation by this age (Christensen et al., 2019). Recent work by Constantino and colleagues (under review) suggests that African American families experience significant delays in timing of diagnosis relative to first concerns. This work also provides further evidence of a higher burden of intellectual disability found in African American children with ASD.

Objectives: This study contrasted cognitive profiles of African American and Caucasian toddlers within a clinical sample. We hypothesized that African American and Caucasian children who are identified at an earlier time point than the national median may demonstrate less discrepant cross-racial cognitive profiles than children identified later in childhood, possibly due to the progressive effects of health disparities accruing during the period between toddler and school-age years.

Methods: A sample of 285 medically-insured African American (n = 127) and Caucasian children (n = 158) between the ages of 16 and 30 months (M_{age}= 25.22 months, SD = 3.60) were evaluated in an academic medical center clinic and received a diagnosis of ASD. Each child was evaluated using the *Autism Diagnostic Observation Schedule, Second Edition (ADOS-2) Toddler Module*, *Mullen Scales of Early Learning (MSEL)*, and clinician best estimate diagnosis.

Results: When comparing developmental delay as defined by state early intervention eligibility requirements, 95.6% of Caucasian toddlers (n = 151) and 96.9% of African American toddlers (n = 123) met criteria using *MSEL t*-scores within this sample. Focusing on *Visual Reception t*-scores, 48.0% of African American toddlers (n = 61) and 34.2% of Caucasian toddlers (n = 54) fell two standard deviations below the mean. Preliminary analyses controlled for factors such as gestational age, maternal education, and lapse in time between age of first concerns and age of diagnosis. Significant differences (p = .03) in *Visual Reception t*-scores between African American (M = 31.06, SD = 10.44) and Caucasian toddlers (M = 34.32, SD = 10.80) had a small effect size (d = 0.3).

Conclusions: Preliminary exploration within a clinically-referred sample of African American and Caucasian toddlers with ASD indicate less discrepancy in early cognitive skills than those found in school-aged children with ASD. Contrasting the current toddler sample to the CDC sample, a similar percentage of African American children with ASD remains cognitively delayed, whereas there is considerable reduction in developmental delay status in Caucasian children with ASD.

POSTER SESSION — SOCIAL COGNITION AND SOCIAL BEHAVIOR
445 - Social Cognition and Social Behavior Posters

445.001 *(Poster)* A Combinatorial Approach for Determining Social Motivation in Children with and without Autism

B. Thompson[1]*, K. Carlson*[2] *and S. Hulbert George*[2]*, (1)Pediatrics and Human Development, Michigan State University, Grand Rapids, MI, (2)Michigan State University, Grand Rapids, MI*

Background: Determining the neural mechanisms that underlie the heterogeneity of social-affective behaviors is challenging in developing children, especially when social-affective processing is disrupted, leading to difficulty in establishing relationships and effectively regulating emotions. The factors that influence the heterogeneity of these social behaviors in both typically developing (TD) children and children with Autism Spectrum Disorder (ASD), for whom disruptions in social behaviors are among the core deficits, are currently unknown.

Objectives: We aimed to determine whether alterations in social behavior in children with ASD are driven by an aversion to, or lack of reward from, social interactions using a combination of remote eye-tracking techniques and detailed behavioral coding of social play.

Methods: We adapted our previously established associative learning paradigm of conditioned place preference (CPP) in young children for use with a social unconditioned stimulus (US). In this paradigm, during an initial preference test (IPT), TD children (30-60 months) and children with ASD (36-66 months) freely explored two neutral rooms in our child-friendly castle. Then, across training trials (TT), children alternated play between the two rooms while one of the rooms, the conditioned stimulus (CS), was paired with the US, a novel and interactive social experimenter. During the final preference test (FPT), children again freely explored both rooms, in absence of the US. Social CPP (sCPP) scores were calculated as the difference in time spent in the social-paired room during the IPT and FPT. Additionally, these children watched a 6-minute video comprised of social and non-social naturalistic scenes as well as cartoon animations. Eye movements were recorded using a Tobii Pro Spectrum eye-tracker and software. Eye-tracking metrics were then used for a supervised machine learning algorithm to predict performance in the sCPP task.

Results: We found significant heterogeneity in social preference in both typically developing children and in children with ASD, with no differences in sCPP scores between groups. The two groups did demonstrate differences in gaze patterns across the video stimuli, though social scenes produced more frequent fixations in both groups. Preliminary machine learning indicated that eye-tracking metrics accurately predicted sCPP class in these same children.

Conclusions: This work provides a more comprehensive understanding of the mechanisms driving social motivation. The heterogeneity of sCPP scores provides a continuous range of social motivation for both groups and may offer a unique opportunity to distinguish the endophenotypes of social behaviors not defined by ASD diagnosis alone. The high accuracy prediction models suggest that the sCPP task and the eye-tracking paradigm may be measuring a similar social motivation construct.

445.002 *(Poster)* A Follow-up Study of Peer Relationships in Youths with and without Autism Spectrum Disorder: A Mediation Analysis of Autistic and Other Emotional and Behavioral Symptoms

Y. C. Wang[1]*, Y. M. Tai*[2] *and S. S. F. Gau*[1]*, (1)Department of Psychiatry, National Taiwan University Hospital & College of Medicine, Taipei, Taiwan, (2)Department of Psychiatry, Beitou Branch, Tri-Service General Hospital, Taipei, Taiwan*

Background: The core features of autism spectrum disorder (ASD) include impairment of social communication and restricted and repetitive behaviors or interests. In addition to the autistic symptoms, literature documents different levels of emotional and behavioral problems commonly seen in individuals with ASD. With age, individuals with ASD may encounter difficulties in the interactions with peers and problems with peers. However, there is limited information about whether autistic features and other emotional and behavioral problems can mediate the outcome of peer interaction and problems with peers.

Objectives: This longitudinal study aimed to investigate the mediation effects from autistic symptoms, inattention, anxiety/depression, and delinquent behaviors on the link from ASD diagnosis at baseline to peer relationships at follow-up.

Methods: A total of 366 youths with a clinical diagnosis of ASD (mean age: 16.7±4.9 years at follow-up; male, 89.1%) and 134 typically developing controls (TDC) were assessed at baseline and follow-up. The ASD group received Autism Diagnostic Interview-Revised interview at both time points and Autism Diagnostic Observation only at follow-up to confirm the diagnosis. The autistic trait was measured by the Chinese version of Social Responsiveness Scale (SRS), and emotional and behavioral problems were measured by the Child Behavior Checklist (CBCL) at baseline. The peer interactions and problems with peers were assessed by using the Social Adjustment Inventory for Children and Adolescents (SAICA) at follow-up. Multiple mediation models were used.

Results: Youths with ASD scored higher in Social Communication, Unique Mannerism, and Social Emotion Subscores (SRS) than TDC. They also had more severe problems of aggressive behaviors, anxiety/depression, attention problems, delinquent behaviors, social problems, somatic complaints, thought problems, and withdrawal (CBCL). At follow-up, ASD youths had more severe problems with peers and less active interactions with peers than TDC. Simple mediation analyses showed that each subscore of SRS and CBCL had significant mediation effects. Multiple mediation analyses showed that impaired social communication and delinquent behaviors mediated the link from ASD to less active interactions with peers at follow-up after controlling for sex, age, and Full-scale IQ. Moreover, we found that social communication impairment and social, emotional difficulty (SRS), as well as attention problems (CBCL), predict problems with peers after controlling for sex, age, and Full-scale IQ. After considering the mediation effects, ASD still significantly predicted more severe impairment in interactions and problems with peers.

Conclusions: Our findings support that ASD youths suffer from more emotional and behavioral problems and impaired peer relationships. The strong links between ASD and impaired peer relationships can be mediated by social communication and emotion impairments, as well as attention problems and delinquent behaviors. Our other analyses did not find parenting style or family support mediated this link. Hence, our findings suggest to develop specific measures targeting on social communication and emotion, attention problems, and delinquent behaviors may partially offset the interactions difficulty and problematic relationship with peers at their adolescence and young adulthood. Future exploration of potential mediators for the link between ASD and impaired peer relationships is warranted.

445.003 *(Poster)* A Quantitative Content Analysis of Autistic Children's Friendship Conceptualizations: Expectations and Transgressions

J. Cuda[1], *C. Malloy*[2], *S. Y. Kim*[3] *and K. Bottema-Beutel*[3], *(1)Boston College, Chestnut Hill, MA, (2)Lynch School of Education and Human Development, Boston College, Chestnut Hill, MA, (3)Lynch School of Education, Boston College, Chestnut Hill, MA*

Background: It has been argued that autistic and non-autistic people's friendship relationships fundamentally differ (Baron-Cohen, 1991). Yet recent work has demonstrated that autistic and non-autistic children experience some aspects of friendship similarly (Petrina, Carter, Stephenson, & Sweller, 2017). Since friendship can serve as a buffer against adverse social experiences such as bullying (Brendgen et al., 2013) and autistic children can be prone to such acts (Chen & Schwartz, 2010), understanding their friendship conceptualizations is important for practitioners working to support these children's relationships.

Friendship expectations, or attributes and behaviors that children expect their friends to possess and enact (Hall, Larson, & Watts, 2011) and friendship transgressions, or violations of these expectations (MacEvoy & Asher, 2012) can provide a concrete framework for understanding autistic children's friendship conceptualizations (Bottema-Beutel et al., 2019a; 2019b)). However, existing friendship expectation and transgression measures have been designed using the perceptions of non-autistic individuals. Comparing autistic and non-autistic children's perspectives using open-ended interview techniques can provide useful information for the development of instruments that more adequately examine autistic children's friendship.

Objectives: The purpose of this study was to solicit autistic children's friendship expectations and transgressions, and identify differences in the expectations and transgressions described by autistic and non-autistic children.

Methods: 3rd-5th grade autistic (*n*=20) and non-autistic children (*n*=21) matched for mental age were interviewed using a semi-structured protocol probing for friendship expectations and transgressions. We employed quantitative content analysis, which allows researchers to make replicable and valid inferences from qualitative texts to understand social phenomena (White & Marsh, 2006). Units of analysis were statements of friendship expectations and transgressions identified in interview transcripts. A coding scheme was developed by inductively classifying participants' open-ended responses into analytical constructs (Neuendorf, 2017). Researchers blind to group coded interview transcripts for the presence or absence of codes, and, using an intact-group design, $\chi 2$ tests of homogeneity were conducted to identify codes with significant between-group differences.

Results: Tables 1 and 2 provide friendship expectation and transgression codes that emerged from the coding process, and results of $\chi 2$ analyses. No friendship expectations were named by a majority of autistic children. *Social Aggression* was the only transgression identified by a majority of the autistic sample. There were no statistically significant between-group differences for any expectation or transgression categories.

Conclusions: Findings suggest that intra-individual variation in autistic children's friendship conceptualizations may be more critical than variation found between autistic and non-autistic children more generally. Practitioners may need to ask individual children struggling with friendship about their friendship expectations, in order to better support the formation and maintenance of friendships that will conform to their conceptualizations. Researchers may need to present a wide variety of expectations to gain a more comprehensive understanding of children's friendships. Transgressions presented in previous research on autistic children's friendships (*Betrayal, Lack of Validation/Emotional Support, Lack of Instrumental Help, Unreliable Partner)* were identified by less than one-fourth of our autistic sample, suggesting that future work should include other, more salient transgressions (e.g., aggressive acts).

445.004 *(Poster)* ASD Traits Predict Attenuated Social Mimicry in a Subclinical Sample

L. H. Tan[1], *R. M. Ford*[1], *A. Morrison*[2] *and S. D. Stagg*[3], *(1)Psychology, Anglia Ruskin University, Cambridge, United Kingdom, (2)Sports and Exercise Science, Anglia Ruskin University, Cambridge, United Kingdom, (3)Anglia Ruskin University, Cambridge, United Kingdom*

Background: Evidence suggests that some problems exhibited by individuals with autism spectrum disorder (ASD) are present to varying degrees in the general population (Skuse, Mandy & Scourfield, 2005). The concept of a Broad Autism Phenotype (BAP) has been used to describe the mild autism characteristics exhibited by individuals who do not clinically meet the threshold of ASD (Reed et al., 2011). The advantage of studying BAP traits in general samples is that it allows one to take advantage of greater range in the expression of particular ASD traits such as reduced ability in social interactions across individuals. Automatic mimicry and the matching of emotional content in facial expressions are reduced in some individuals with ASD (Rogers et al., 2003). However, research has yet to show whether impairment of the automatic mimicry of facial expressions are present in the BAP.

Objectives: The aim of this study was to determine whether social mimicry is attenuated in individuals without ASD who score high on a measure of autism traits and whether poor social mimicry is associated with lower levels of empathy and higher levels of alexithymia, social responsiveness and facial mimicry.

Methods: A total of 42 participants were recruited with an age range of 18 to 37 years. Participant completed the Autism Quotient, Cambridge Behavioural Questionnaire, Perth Alexithymia Questionnaire, and the Social Responsiveness Scale (SRS). Facial mimicry was recorded using electromyography (EMG). Participants passively viewed facial expressions while the activity of the corrugators and zygomaticus muscle was recorded. Average peak activation for happy and sad expressions in millivolt was included as the dependent variable.

Results: As predicted, higher autistic traits were associated with a reduction in muscle response to happy expressions (r = -.39, p =.01). Reduced levels of mimicry were associated with higher level of alexithymia (r = -.40, p = .01), and higher scores on the SRS (i.e., inferior social responsiveness; r = -.44, p = .01). In contrast, muscle activation was positively associated with empathy scores (r = .46, p = .002). In relation to the expression of sadness, reduced muscle activation was associated with higher level of alexithymia (r = -.33, p = .02), and higher scores on the SRS (r = -.32, p = .02).

Conclusions: Individuals taking part in the study did not have a diagnosis of ASD, but those who scored higher on autistic traits showed reduced automatic facial mimicry when viewing happy and sad expressions. These results have implications for families with children with ASD where a parent shows elements of the BAP (Austin, 2005; Hoekstra et al., 2008; Hurst et al., 2007). Potentially, reduced social mimicry may be reduced across some family members, and more research is needed on how mimicry affects dyadic interactions in families when autism is present.

445.005 *(Poster)* Alexithymia Predicts Poor Social Competence in Youth with and without ASD

B. Thompson[1]*, N. E. Scheerer*[2]*, T. Q. Boucher*[2] *and G. Iarocci*[2]*, (1)School Psychology, University of British Columbia, Vancouver, BC, Canada, (2)Psychology, Simon Fraser University, Burnaby, BC, Canada*

Background: Alexithymia, a condition characterized by difficulties identifying and describing one's own emotions, has high co-occurrence with Autism Spectrum Disorder (ASD) and other disorders (Bird & Cook, 2013). There is a need to understand factors that contribute to different strengths or challenges in social competence in youth with and without ASD. One factor that may play an important role in social competence is alexithymia. Specifically, the compromised understanding of others' emotions in people with alexithymia may give rise to problems in social interaction (Poquérusse, Pastore, Dellantonio & Esposito, 2018). Given that alexithymia frequently co-occurs with ASD, and that both populations have difficulties with social interactions, it is of interest to determine whether alexithymia can help to parse some of the heterogeneity in social competence seen not only in individuals with ASD, but also those without.

Objectives: The aim of the study was to explore the relationship between alexithymia and social competence in youth with and without ASD.

Methods: 241 youth, between the ages of 6 and 14, including 120 with (M=10.20; SD =1.91), and 121 without (M=9.50; SD =1.73) ASD. Caregivers rated their child's social competence on the Multidimensional Social Competence Scale (MSCS; Yager & Iarocci, 2013), and alexithymia traits on the Children's Alexithymia Measure (CAM; Way et al., 2010). Children's IQ scores were assessed using the Wechsler Abbreviated Scale of Intelligence, or Stanford-Binet Intelligence Scales, abbreviated version.

Results: Pearson's correlations indicate that CAM scores were negatively correlated with overall MSCS scores (r (239) = -.73, p<.001). Results of a hierarchical multiple linear regression analyses indicated that age, IQ, sex, diagnosis status, and CAM scores account for 71.2% of the variance in parent-reported social competence. Importantly, after controlling for age, IQ, sex, and diagnosis status, CAM scores accounted for an additional 18% of the variance in social competence (ΔR^2 = .18, ΔF (1,235) = 153.513, $p<.001$). Further investigation of the seven domains of the MSCS [social motivation (ΔR^2 = .15), social inferencing (ΔR^2 = .11), demonstrating empathic concern (ΔR^2 = .11), social knowledge (ΔR^2 = .07), verbal conversation skills (ΔR^2 = .11), nonverbal sending skills (ΔR^2 = .22), and emotion regulation (ΔR^2 = .17)] revealed that alexithymia traits significantly negatively predicted poorer social competence in each individual domain of the MSCS after controlling for age, IQ, sex, and diagnosis status (all p values < .001).

Conclusions: The results indicate that greater alexithymia traits predict lower levels of social competence, suggesting that increased difficulty in identifying and describing one's own emotions is associated with poorer social competence. Additionally, alexithymia predicted overall social competence in all seven individual domains of social competence over and above age, IQ, sex, and diagnosis status. This research contributes to the understanding of the factors associated with the development of social competence in youth with and without ASD and potential targets for the design of interventions to improve social competence.

445.006 *(Poster)* Attention to Emotional Faces and Associations with Emotion Recognition and ASD Traits in College Students

S. Soker Elimaliah[1,2]*, A. Rajpersaud*[2]*, S. Bragerton-Nasert*[2] *and J. B. Wagner*[1,2]*, (1)The Graduate Center, City University of New York, New York, NY, (2)College of Staten Island, City University of New York, Staten Island, NY*

Background: Attention to socially-relevant information, particularly faces, promotes social interactions (Chun et al., 2011). Studies have found that individuals with ASD show less attention to core features of faces and correlations between social attention and adaptive function (e.g., Klin et al., 2002). Work has also found differences in attention to faces when examining non-ASD participants endorsing low vs. high levels of ASD traits (e.g., Chen & Yoon, 2011). Swanson and Siller (2014) studied ASD traits on a continuum in non-ASD adults and found that fewer traits related to better attention to socially-relevant information.

Objectives: The current study expands on past work with a non-ASD sample to look at attention to faces as it relates to emotion recognition and ASD traits. These traits will be examined both continuously and categorically.

Methods: Participants included 80 college students. Gaze data was collected using an SMI RED 120Hz eye-tracker as participants viewed 24 emotional faces (fearful, happy, neutral) from the NimStim database (Tottenham et al., 2009). Each image was displayed for three seconds. Afterwards, participants completed the Social Responsiveness Scale, Second Edition (SRS-2; Constantino & Gruber, 2012), a measure of ASD traits that has been used in ASD and non-ASD samples, and the Reading the Mind in the Eyes test (RMET) of emotion recognition (Baron-Cohen et al., 2001). Eye-tracking variables focused on number of fixations and proportion of looking time to eyes and mouth (proportions divided by time on face).

Results: Two 2 (Region: mouth, eyes) x 3 (Emotion: fearful, happy, neutral) repeated-measures ANOVAs were conducted, with parallel results for number of fixations and proportion of time: main effects of Region (eyes > mouth, *p*s< .001) and Emotion (fearful < happy = neutral, *p*s< .005), and Emotion x Region interactions (*p*s< .001; Figure 1). Correlations between eye-tracking variables (collapsed across emotions), RMET, and SRS-2 Total t-scores were conducted. Significant positive associations were found between both measures of attention to eyes and RMET (*r*s> .29, *p*s< .01), but no relations were found with SRS-2 (*r*s< .14, *p*s> .23). Exploratory analyses then divided the sample based on SRS-2 t-scores based on the cutoff of 59 to create groups high (*n*=19) and low (*n*=61) on ASD traits. Neither group showed relations between eye-tracking and SRS-2. The low traits group showed significant associations between both measures of attention to mouth and RMET (*r*s< -.26, *p*s< .05), and between proportion of time on eyes and RMET (*r*= .31, *p*= .017). For the high traits group, the only association was between number of fixations to eyes and RMET (*r*= .58, *p*= .023; Figure 2).

Conclusions: Overall, we found a positive relationship between attention to eyes and emotion recognition in college students, but no direct associations were found between social attention and ASD traits. When looking separately at groups high and low on ASD traits, differential relations between attention and emotion recognition were found. This work highlights the value of examining ASD traits both continuously and categorically to better understand the associations between ASD-related characteristics and emotion processing.

445.007 *(Poster)* Attention to Faces in Children with Autism Spectrum Disorder

Z. Ambarchi[1], *R. Thapa*[1], *I. Pokorski*[1], *K. A. Boulton*[1], *M. DeMayo*[1], *E. E. Thomas*[2], *Y. J. Song*[3], *I. Hickie*[4] *and A. J. Guastella*[1], *(1)Brain and Mind Centre, Children's Hospital Westmead Clinical School, Faculty of Medicine and Health, University of Sydney, Sydney, NSW, Australia, (2)Brain and Mind Centre, University of Sydney, Camperdown, NSW, Australia, (3)University of Sydney, Camperdown, NSW, Australia, (4)Brain and Mind Centre, Central Clinical School, Sydney Medical School, University of Sydney, Sydney, NSW, Australia*

Background: Research has often pointed to an overall reduction in the attention to social stimuli, such as faces, and has been hypothesised to underlie social difficulties in autistic children. Previous findings have indicated that while significant differences in attention to faces between ASD and TYP cohorts are evident in the presence of objects of high autism interest (HAI, e.g. cars), these differences lose their significance in the presence of objects of low autism interest (LAI, e.g. household items). Furthermore, significant associations with popular measures of social disability have not been replicated (Unruh, 2016). The variability in social attention literature calls for replicability studies to support published findings and facilitate understanding into the nature of social attention impairments in ASD and their relationship with social disability.

Objectives: The aim of this study was to replicate previous findings identifying differences in attention to faces in the presence of high- and low-autism interest objects using an established visual preference paradigm.

Methods: Thirty typically developing children (mean (SD) age: 7.4 (2.63) years) and 34 children with ASD (mean (SD) age: 8.2 (2.58) years) were presented with 20 trials of images containing a face paired with a HAI or LAI object while eye tracking measures were taken. As indices of social orientation and attention, the dependent variables latency to first fixate to face and first fixation duration to face were calculated. Participants were also administered the Leiter-R nonverbal IQ test, and the Social Responsiveness Scale – Second Edition (SRS-2).

Results: Compared to the TYP group, latency to first fixate to face was significantly greater in the ASD group when paired with either HAI or LAI objects (p = .001). When paired with a HAI object, first fixation duration to face was significantly reduced in the ASD group (ASD: Mean (SD) = .26 (.09) TYP: Mean (SD) = .35(.18), p = .009). There was no significant difference between groups when a face was paired with a LAI object (ASD: Mean (SD) = .29 (.09), TYP: Mean (SD) = .34 (.21), p = .50). There were no significant associations between social orientation and attention indices and SRS-2 Total scores across groups.

Conclusions: Contrary previous findings, current results suggest that in ASD, divergence in social orientation was present regardless of interest level of competing non-social stimuli. Influence of object type in ASD was evident when calculating the first fixation duration variable, indicating a reduction in the maintenance of attention to social stimuli, but only in the presence of HAI objects, supporting previous findings. Additional research using larger sample sizes is warranted given the inconsistencies with published literature.

445.008 *(Poster)* Atypical Sense of Agency in Autism: Intentional Un-Binding at the Implicit Level

A. Lafleur[1], *V. Caron*[1], *B. Forgeot d'Arc*[2] *and I. Soulieres*[1], *(1)Département de Psychologie, Université du Québec à Montréal, Montréal, QC, Canada, (2)Département de Psychiatrie, Université de Montréal, Montréal, QC, CANADA*

Background:

Generating an action triggers a subjective experience called 'sense of agency' (SoA), of central importance in social and motor cognition. Cue integration models (Synofzik et al., 2013) suggest that SoA can arise at an implicit, pre-reflective level that can be assessed via Intentional Binding (IB). IB is a *compression* of the perceived time interval between one's movement and its consequences, when compared to two external events (Haggard et al., 2002). Implicit SoA is believed to rely mostly on the integration of sensorimotor prospective (before action) and retrospective (after action) signals, but could also be influenced by social context. In a task where participants had to press a button to create a visual outcome, Sperduti and al. (2014) have found that IB is abolished in autism, offering first evidence of altered implicit SoA in autism. This points to a difference in the underlying integration principles by which sensorimotor and social cues are integrated.

Objectives:

We sought to characterize cue integration in autism by assessing the relative contributions of prospective/retrospective sensorimotor and social cues to implicit SoA, as measured by IB.

Methods:

To date, 10 autistic (M=26.6 years) and 7 neurotypical (M=30.14) participants were recruited. A validated task of movements with ballistic visual outcomes was administered. We manipulated social context and feedback position to alter the relative availability/reliability of sensorimotor and social cues. We investigated IB using a temporal reproduction method (Humphreys & Buehner, 2010) and calculating a relative temporal reproduction error (RTRE). We ran a repeated measures factorial ANOVA using a linear mixed model approach with social context (one, two agent), experimental conditions (observation; no, small, large feedback alteration), and groups (autistic, neurotypical) as independent factors.

Results:

The mixed model for RTRE showed significant main effect of Group ($F(1,17)$=5.757; p<0.05) and significant interaction of Group X Condition ($F(3,3553)$=16.263; p<0.001). Post-hoc pairwise comparisons (Bonferroni corrections) revealed differences in RTRE levels across groups for each feedback alteration conditions (p<0.05), but not for the observation condition. Intragroup differences in RTRE levels across feedback alteration conditions were not significant. However, intragroup differences in RTRE levels between the observation condition and each feedback alteration condition were significant in both autistic (p<0.005) and neurotypical (p<0.001) groups.

Conclusions:

Our preliminary results corroborate previous findings showing atypical functioning of implicit SoA in autism. However, unlike Sperduti and al. (2014) who saw IB as abolished in autism, we detected in the autistic group an effect of intentional *un*-binding, that is, an *expansion* in the perceived time intervals between intentional actions and their consequences, while for the neurotypical group, we found the expected temporal *compression* of perceived time (IB effect).

We also found that implicit SoA was only influenced by prospective sensorimotor cues for both autistic and neurotypical groups, whereas manipulating social context and reliability of retrospective sensorimotor cues (feedback congruency) had no effect on IB strength.

This suggests that implicit SoA is based upon similar cues in autism, but that these prospective sensorimotor cues create an opposite implicit experience of being the author of an action (*un*-binding vs binding).

445.009 *(Poster)* Atypical Social Behavior Is Associated with More Positive Interaction Among Peers with Autism Spectrum Disorder.

***J. E. Granieri**, A. H. Gerber, M. L. McNair and M. D. Lerner, Department of Psychology, Stony Brook University, Stony Brook, NY*

Background: Recent literature has suggested that atypical patterns of social behavior in those with Autism Spectrum Disorder (ASD) may represent unique, not diminished, patterns of social engagement (Heasman & Gillepsie, 2018). Additionally, atypical social communication ability may be associated with increased positive first impressions as rated by peers with ASD (Granieri et al., 2019). Thus, it may be that such impressions arise from differences in the peer interaction elicited by youth presenting with atypical social communication. However, no studies have examined the impact of atypical social communication ability on actual interactions between peers with ASD.

Objectives: This study aimed to explore the effect of atypical communication ability on interactions between peers with ASD. A secondary aim was to examine effects on parent-ratings of these same youth, to better understand the discrepancy between peer interaction among youth with ASD and expectancies of their parents.

Methods: 55 youth with an IQ≥70 and ADOS-2-confirmed diagnoses of ASD participated in 1.5 hours of small group interaction (Table 1). Atypical social behaviors (vocalizations, gestures, eye-contact, facial expressions) were indexed using clinician-report from the ADOS-2 (Lord et al., 2012). Peer interactions were observationally coded from unstructured peer interaction during the session using the social interaction observation scale (SIOS; Bauminger, 2002). Reliability of codes for overall (ICC=.768), positive (ICC=.947), negative (ICC=.924), and low-level (ICC=.775) interactions was excellent. Perceived level of social skills (Gresham & Elliott, 2008) and social motivation (Morgan et al., 2011) were indexed using parent-report. ADOS-2 items were entered into generalized estimating equations (accounting for groupwise nesting) predicting social behavior according to observers and parents.

Results: Those with *moderate amounts* of atypical vocalizations had *more* positive interactions and *more* negative interactions (See Table 2). Those with *more* atypical gestures had *more* negative interactions. However, only those with *large amounts* of atypical gestures had *fewer* positive interactions, *fewer* overall amounts of interaction and were reported by parents as having *lower* social motivation. Those with *less* well-modulated eye contact had *more* overall interaction, despite being reported by parents as having *poorer* social skills. Lastly, those with *more* atypical facial expressions had *more* positive interactions and *fewer* low level interactions, but were also reported by parents as having *less* social motivation. Additionally, only those with *large amounts* of atypical facial expressions also had *more* negative interactions.

Conclusions: Similar to previous literature (Sturm et al., 2017), parents of children with ASD were more likely to report low social skills and motivation when their child presented with more atypical behaviors. However, our findings extend Granieri et al., (2019), suggesting that these same nonverbal behaviors were associated with more interactions (positive and negative) among peers with ASD, reinforcing the presence of unique – but not necessarily ineffective – patterns of communication among individuals with ASD (Heasman & Gillespie, 2018). Findings thus suggest that parental expectations of normative social behavior may not reflect behaviors that lead to successful interactions among peers with ASD, and indicate the potential benefit of reframing assessment and interventions which aim to target these expressive behaviors.

445.010 *(Poster)* Autism Inclusion Training Improves First Impressions of Autistic Adults

***D. R. Jones**, K. M. DeBrabander and N. J. Sasson, University of Texas at Dallas, Richardson, TX*

Background: Stigma towards autistic individuals remains common (Someki et al., 2018), and evidence suggests that peers form negative first impressions of autistic adults and report a reluctance to interact with them (Gillespie-Lynch et al., 2015; Sasson et al., 2017). These judgements and behaviors can negatively affect the social experiences of autistic adults. More optimistically, however, perceptions of autistic adults are more favorable among neurotypicals with increased autism knowledge (Sasson & Morrison, 2019), suggesting that increasing autism knowledge in the general population may improve social outcomes for autistic adults.

Objectives: The current study explores whether a brief inclusion training program designed to increase autism knowledge and sensitivity improves perceptions of autistic adults among college undergraduates.

Methods: Undergraduates (n = 198) were randomly assigned to one of three conditions: general mental health, autism inclusion, or no intervention. For the general mental health and autism inclusion conditions, participants watched a 25-30-minute-long video on either general mental health diagnoses (e.g. depression, anxiety) that did not mention autism, or one adapted from a module developed by Dr. Grace Iarocci that focused on autism and related issues (e.g., social disability, sensory sensitivity, autistic strengths, and neurodiversity). All participants then viewed 10-second videos of twenty autistic adults (stimulus participants; see Sasson et al., 2017), half including an accurate diagnostic label and half with no label, and evaluated each using the First Impressions Scale (Sasson et al., 2017) to assess impressions of six social traits and interest in future interactions.

Results: Multi-level modeling examined the effects of training condition, diagnostic label, and the interaction between them.

Stimulus participants with a diagnostic label were rated significantly more favorably on nine items (p<.001 for eight of them; p=.037 for dominance). Ratings for "I would feel uncomfortable sitting next to" did not improve, and actually decreased when a diagnostic label was included (p =.001).

Undergraduates in the autism inclusion condition rated the stimulus participants more favorably on intelligence (F(197)=18.52, p<.001) and "hanging out with" (F(197)=2.96, p = 0.05) compared to participants in both the general mental health and control conditions, and more favorably on "sitting next to" relative to the control condition F(198)=3.01, p=0.05). No significant interactions were found between condition and diagnostic label for any of the 10 items.

Conclusions: Interventions seeking to reduce social disability in autistic adults have typically focused on improving their social cognition and social skill, with mixed success (Bishop-Fitzpatrick et al., 2014; Gates et al., 2017). Here, we demonstrate that an "intervention" focused on increasing autism knowledge and acceptance within a sample of college students can improve perceptions of autistic people, over and above general mental health training. Most notably, autism inclusion training increased two ratings related to social interest and acceptance of autistic adults. Whether such improvements would extend beyond the immediate testing or translate to real-world environments are open questions warranting future study. Such evidence is needed before extending the preliminary findings reported here to broader educational and professional settings to help improve the social experiences of autistic adults within neurotypical-dominated environments.

445.011 *(Poster)* Baseline Arousal Modulates Face Scanning in Autism Spectrum Disorder

***C. Song**[1], Q. Wang[2,3], J. Xu[4], H. Lu[2,3], S. Qin[4] and L. Yi[1], (1)School of Psychological and Cognitive Sciences and Beijing Key Laboratory of Behavior and Mental Health, Peking University, Beijing, China, (2)Academy for Advanced Interdisciplinary Studies, Peking University, Beijing, China, (3)Peking-Tsinghua Center for Life Sciences, Peking University, Beijing, China, (4)State Key Laboratory of Cognitive Neuroscience and Learning & IDG/McGovern Institute for Brain Research, Beijing Normal University, Beijing, China*

Background: Atypical arousal has been proposed to be the potential mechanisms underlying atypical social behaviors in autism spectrum disorder (ASD). For example, the popular social motivation theory (Chevallier et al., 2012) stated that ASD find social information less rewarding and salience than TD, thus have reduced motivation to look at them. On the contrary, the eye avoidance hypothesis (Tanaka & Sung, 2013) and the intense world theory (Markram & Markram, 2010) proposed that direct eye contact elicits anxiety and discomfort in ASD. Arousal has been hypothesized to play an important role in attention to social stimuli in ASD (Cuve, Gao, & Fuse, 2018), and has attracted much research attention. Many studies have investigated tonic/baseline arousal and arousal level during tasks separately using pupillometry when viewing social and non-social objects (e.g., Martineau et al., 2011). However, few researches focused on the association between baseline arousal and the task performance in ASD.

Objectives: The main purpose of this research is to examine how attention to objects with different levels of social saliency vary during the spontaneous fluctuation of baseline arousal in ASD, reflected by their pupil diameter. We also concern whether baseline arousal influences attention in ASD and TD in different ways.

Methods: Thirty-one children with ASD and 22 TD children participated in the current study. Participants were asked to scan face and house pictures freely and then tell whether they like the picture or not. These two categories of pictures were presented separately in two blocks (see Figure 1). We recorded eye movements and used pupil diameter as a proximate indicator of arousal level. Three areas of interests (AOIs) were defined: the eye region of face, the whole region of face, and the whole region of house. Using these AOIs we established a hierarchy of social saliency from strong to weak.

Results: We tested the effect of baseline arousal (averaging pupil diameters 1000 ms before stimuli onset) on single-trial basis with subjects as the random effect (Figure 2). We observed negative correlations between baseline arousal and eye looking time as well as face looking time in both ASD and TD groups. Importantly, the impact of baseline arousal on eye looking time was more pronounced in ASD than TD, but its impacts on face looking time were approximately the same in ASD and TD groups. As a comparison, no significant association was found between baseline arousal and house looking time in either group. In addition, we found that the variance of baseline pupil diameter was larger in ASD group than TD group, implying that the arousal level of ASD is more unstable.

Conclusions: We found that baseline arousal level was negatively associated with attention to eyes and face, but not house in ASD and TD. Baseline arousal influenced attention to eyes greater in ASD than TD. Our study contributed to a more comprehensive understanding of the arousal atypicality in ASD, and its role in the social attention in ASD.

445.012 *(Poster)* Bidirectional Disconnection between Autistic and Neurotypical Adolescents: A Mixed-Methods Exploration on Autistic and Neurotypical Peer Interaction in Inclusive Context

Y. L. Chen[1]*, K. P. Koenig*[1]*, W. Martin*[2] *and R. Vidiksis*[2]*, (1)Occupational Therapy, New York University, New York, NY, (2)EDC, New York, NY*

Background: An increasing number of autistic adolescents are included in general education, yet their social engagement with neurotypical peers remains challenged. Little research has examined the complex peer interaction among autistic and neurotypical adolescents in inclusive contexts. Further, while peer interaction in adolescence emphasizes peer behaviors and acceptance, research primarily focuses on autistic social behaviors rather than the interplay between autistic and neurotypical behaviors. Investigating bidirectional social behaviors in autistic, neurotypical, and autistic-neurotypical interactions can shed light on the disconnection presented in autistic and neurotypical peer interaction.

Objectives:

1. To investigate bidirectional social behaviors among autistic and neurotypical adolescents in an inclusive school-club, including (a) autistic-to-neurotypical, (b) neurotypical-to-autistic, (c) autistic-to-autistic, and (d) neurotypical-to-neurotypical social behaviors
2. To describe characteristics of disconnected peer interactions among autistic and neurotypical adolescents in comparison to reciprocal interactions

Methods: This sequential explanatory mixed-methods study observed natural peer interaction among six autistic adolescents (grade 6-8, one female, IQ>75) and their six neurotypical peers (grade 6-8, two females) in an inclusive design and making school club.

Part 1 (Quantitative): To quantify participant social behaviors, a structured behavior observation on videotapes of 14 45-minute school-club sections was conducted. Trained observers coded (1) each verbal and non-verbal *social initiation*, including its intended *social partner* (autistic/ neurotypical/ or more than 1 partner), *type* (seeking/ sharing/ attending/ offering/ joking), *purpose* (social/functional), and *outcome* (responded/ not responded), and (2) each *social response,* its *quality* (topic-extending/ topic-relevance/ tangent), and whether the conversation is further *continued* (responded/ not responded). Interrater agreement was above 85%.

Part 2 (Qualitative): Based on the structured behavior coding, we identified disconnected peer interactions defined as (1) not-responded social initiation and (2) not-responded social response, both of which stopped continued interaction. Content analysis of the disconnected interactions over videotapes and transcription was conducted to describe and explain the disconnection.

Results:

While autistic and neurotypical adolescents had comparable rates of social initiation and response, they presented a clear preference for same-group social partners that related to their social initiation type and outcome. Participants of each group tended to choose social partners within the same group. Autistic adolescents interacted more with their autistic peers than neurotypical peers, and vice versa ($p<0.001$, Fig. 1). Further, same-group social initiations were more likely to yield a response than cross-group social initiations in both autistic and neurotypical adolescents ($p<0.001$, Fig. 2). Dominant types of social initiations were contingent upon the group and partner ($p=0.04$, Fig. 3). For both autistic and neurotypical adolescents, same-group social initiations were primarily to share thoughts or experience (43% and 44% of total initiations by autistic and neurotypical adolescents, respectively), while cross-group initiations were to seek help or objects (39% and 38%). Qualitative characteristics of disconnected interaction will be discussed.

Conclusions: By examining bidirectional social behaviors, we found a reciprocal disconnection between autistic and neurotypical adolescents in inclusive interactions. Both autistic and neurotypical adolescents showed more initiation and higher responsiveness in same-group than cross-group peer interactions. These findings emphasize a bidirectional mismatch between autistic and neurotypical interaction.

445.013 *(Poster)* Camouflaging Autistic Traits: Examining the Relationship between Severity of Traits, Timing of Diagnosing, and Educational Support in Adolescents and Young Adults with Autism

D. Simpson-Brown*, Psychology, Everett Community College, Everett, WA*

Background: Through better detection and intervention, adults on the spectrum are now able to report good outcomes (e.g. graduating, finding employment), but still struggle in daily life, including navigating higher education. Young adults have begun reporting a high degree of anxiety, depression, and other social problems due to what is described as “camouflaging” their behaviors (Hull et. al., 2019). These individuals often also seem to be of normal or above average intelligence and find their way to college, yet continue to struggle with social norms and proper integration into the workforce or in holding down a job. Because a student may camouflage their autistic traits in structured environments by mimicking, complying, or obeying, a teacher may not see flags to ask for an evaluation or refer to special education. Parents, however, see their child in every other aspect of their life and have a unique perspective to the daily struggles that no other observer can report.

Objectives: The goal of this study was to identify what relationships exist between severity of autistic traits and possible camouflaging of traits (e.g. masking/compensating) in early (age 0-11) versus late (12+) diagnosis of autism spectrum disorder. The current study surveyed parents of children ages 12-24 with an autism spectrum disorder diagnosis.

Methods: A revised Social Responsiveness Scale-2 (Rutter, 2003), Strengths and Differences Questionnaire (Goodman, 1997), and demographic questions on age of diagnosis, interventions, and co-occurring disorders was created for parents of children currently ages 12-24 with an ASD diagnosis. Online surveys were collected from five online parent support groups in the US, Canada, UK, and Australia.

Results: Early detection and diagnosis correlated with a higher degree of autistic traits and fewer camouflaging behaviors. Children with a diagnosis later than age 12 had a wider variety of autistic traits reported and greater degree of camouflaging.

Conclusions: It is hypothesized that a child will camouflage for as long as their cognitive load can tolerate, and right around puberty this could reach the limit of social understanding and communication, thus leading to an autism diagnosis. Signs for early identifiers of camouflaging traits and coping are suggested.

445.014 *(Poster)* Computerised Assessment of Motor Imitation (CAMI) during a One-Minute Task Distinguishes Children with Autism with High Accuracy

B. Tuncgenc[1,2], *R. N. Rochowiak*[3], *C. Pacheco*[4], *R. Vidal*[4] *and S. H. Mostofsky*[5], *(1)Psychology, University of Nottingham, Nottingham, MD, United Kingdom, (2)Psychology, University of Nottingham, Nottingham, United Kingdom, (3)Center for Neurodevelopmental and Imaging Research, Kennedy Krieger Institute, Baltimore, MD, (4)Johns Hopkins University, Baltimore, MD, (5)Center for Autism and Related Disorder, Kennedy Krieger Institute, Baltimore, MD*

Background: Imitation is an early-emerging and crucial mechanism for social bonding and learning in typically-developing (TD) populations. Mounting research shows motor imitation deficits in autism spectrum conditions (ASC) and imitation-based intervention techniques aim to improve social-communicative functioning in ASC. Although imitation assessments offer promising avenues for early diagnosis and treatment, the scalability of these assessments is poor due to (a) the need to manually identify the important components of the movements being imitated, (b) requiring highly-trained coders to rate imitation performance, (c) subjectivity of imitation performance ratings, and (d) imitation tasks being lengthy. To address these issues, we developed an algorithm that automatically assesses performance from a one-minute imitation task and accurately classifies children into diagnostic groups.

Objectives: To develop a computerised assessment of motor imitation (CAMI) algorithm that objectively assesses imitation performance through automatically detecting the important components of a movement segment.

To examine how well imitation scores obtained from CAMI classifies the children into diagnostic groups (ASC vs TD) and how well they are associated with other known social and motor impairments in ASC.

Methods: Forty-eight children aged 8-12 years (females: 3 ASC, 3 TD) participated in a "dance imitation" game, during which they imitated a video avatar as she performed some unfamiliar dance moves across three one-minute trials. The children's motion data were recorded through two Kinect Xbox depth cameras at 30 frames-per-second, one placed in front of and one behind the children. The children's motion data was compared to the avatar to assess imitation performance.

CAMI algorithm performed dynamic time warping to evaluate the similarity between the child's and the avatar's motion data. Using metric learning, it automatically detected the important joints for each movement segment and returned an imitation performance score that considered not only spatial positions but also timing differences between the child and the avatar.

Results: Children's scores from the three trials were averaged to obtain a single imitation score. We confirmed the validity of CAMI by comparing its results to imitation scores obtained through human coding conducted on the same dataset (r= .917, p<.0001). A support Vector Machine (SVM) classifier trained in a 5-fold cross-validation scheme using CAMI's imitation scores revealed superior classification ability (accuracy= 82.1%) as compared to the human coding method (accuracy= 74.3%; Figure-1). Finally, we found that the lower imitation scores were significantly associated with poorer social-communicative function (parent-report Social Responsiveness Scale: r= -.501, p=.001), poorer motor ability (Movement Assessment Battery for Children-2: r= .608, p<.0001) and more errors in the Florida Apraxia Battery modified for children (r= -.655, p<.0001, Table-1).

Conclusions: This brief (one-minute), highly engaging (videogame format) algorithm can validly assess imitation performance and moreover, is superior at distinguishing ASC from TD than human coding methods. Further, we found robust associations of CAMI performance and both social-communicative and motor impairments in children with ASD. The findings indicate that the CAMI algorithm is a promising, highly scalable tool for assessing children with ASD given it is brief, engaging and does not require special training by clinicians and parents.

445.015 *(Poster)* Contagious Itching Is Heightened in Children with Autism Spectrum Disorders

M. S. Helt[1], *A. de Marchena*[2], *R. Scheub*[3], *M. Schineller*[4] *and T. Sorenson*[5], *(1)Psychology and Neuroscience, Trinity College, Hartford, CT, (2)University of the Sciences, Philadelphia, PA, (3)Neuroscience, Trinity College, Hartford, CT, (4)Beth Israel Deaconess Medical Center, Boston, MA, (5)New England Center for Children, Southborough, MA*

Background: Theories of *embodied cognition* speculate that the means by which we develop empathy is by mentally simulating the experiences of others, as we embody their actions. Sharing motor – and thus, neural – representations with social partners may be especially important early in development, as embodying the actions of others may allow the body to implicitly feel and assign meaning to the actions of others. Therefore, the exploration of emotional contagion in individuals with ASD may shed light on early developmental processes that go awry in autistic development.

Contagious yawning in individuals with ASD appears to be reduced across a variety of contexts (Arnott, Singhal, & Goodale, 2009; Giganti & Esposito Ziello, 2009; Helt et al., 2010, 2019; Senju et al., 2007). Susceptibility to contagious laughter is also reduced in ASD, and both yawning and laughing contagion are inversely correlated with ASD severity (Helt et al., 2010, 2019). Less is known about other contagious behaviors, that may tap different emotional processes or depend less on visual attention to the face and eyes.

Objectives: In the current study, we explore the phenomena of contagious *itching*, yawning, and laughing and their respective relationships to empathy and autism symptoms in typically developing children and children with ASD.

Methods: 55 children with Autism Spectrum Disorder (ASD) and 106 typically developing (TD) children, matched for mental age (n=53) or chronological age (n=53; see Table), watched a series of videos in which an actor would itch, yawn, or laugh, and were coded for contagious behaviors. Children in the control group completed the MDEES, a measure of empathy.

Results: Contagion was significantly different across conditions, p<.001, η^2=.06; itching was the most commonly contagious, followed by laughter, and finally yawning. The main effect of Group was not significant, p=.21, η^2=.02, but the Group by Condition interaction was significant and large, p<.001, η^2=.23, suggesting that the three groups responded to the three target contagious behaviors in different ways. Post-hoc pairwise comparisons demonstrated that children with ASD were less likely to yawn and laugh contagiously relative to controls, but were *more* likely to itch contagiously (see Figure). In the ASD group, ADOS scores were positively correlated with itching (r(52)=.43, p=.001), but unassociated with yawning (r(52)=-.21, p=.12) or laughing (r(52)=-.07, p=.62). In controls, empathy was positively correlated with both contagious yawning (r(103)=.46, p<.001) and laughing (r(103)=.33, p=.001) but unassociated with contagious itching (r(103)=-.03, p=.73).

Conclusions: Consistent with previous literature, children with ASD were less likely to yawn or laugh contagiously compared with their TD peers. However, children with ASD showed *increased* susceptibility to contagious itching compared with their TD peers. Contagious yawning and laughter were positively correlated with emotional empathy in the TD group. In contrast, contagious itching showed no relationship to empathy, and was positively correlated with autism symptom severity in the ASD group, suggesting that contagious itching is associated with distinct social-emotional phenomena from contagious yawning and laughter, and providing novel insight into empathy differences in this population.

445.016 *(Poster)* Discovr-a; Virtual Reality Social Cognition Training for Adults with Autism

B. van Pelt[1,2], *S. Nijman*[3,4], *W. Veling*[3], *A. M. Landlust*[5], *A. Maras*[2], *I. D. van Balkom*[6], *G. H. M. Pijnenborg*[4,7], *E. Horwitz*[8], *N. E. M. van Haren*[1] *and K. Greaves-Lord*[1,6], *(1)Child- and Adolescent Psychiatry/Psychology, Erasmus MC, Rotterdam, Netherlands, (2)Academy, Yulius, Dordrecht, Netherlands, (3)University Center of Psychiatry, UMCG, Groningen, Netherlands, (4)GGZ Drenthe, Drenthe, Netherlands, (5)Autism Team Northern Netherlands, Autism Team Northern Netherlands, Jonx (Lentis), Groningen, Netherlands, (6)Autism Team Northern Netherlands, Jonx (Lentis), Groningen, Netherlands, (7)Rijks Univiersiteit Groningen, Groningen, Netherlands, (8)GGZ Friesland, Leeuwarden, Netherlands*

Background: Deficits in social cognition are among the most challenging aspects of autism spectrum disorder (ASD), impairing individuals throughout their lives. Building relationships or finding a job does not come naturally, when the intention and comprehension of rules and subtle cues of social interaction are poorly understood. This can lead to social exclusion and deteriorating quality of life. Social skills training is usually initiated to handle problems in the emotional- & social perception and poor metalizing skills (Theory of mind) of people with ASD. Some interventions based on Cognitive Behavioural Therapy (CBT) have shown to be effective. However, it is crucial for the effectiveness of the training to achieve transfer of knowledge and skills to situations in everyday life and novel environments. It is therefore important that practicing social skills can happen in a setting that has the same dynamic, complex and interactive nature of true social situations. Advancements in technology, like Virtual Reality (VR), make it possible to offer a more tailored social cognition training. VR provides a safe, dynamic and interactive treatment setting, that could transcend the social cognition training as it is available today. VR offers an 'ecologically valid', immersive environment to experiment with (new) social behavior in a secure, controlled setting that provides direct feedback and learning experiences.

Objectives: In this pilot-study, we explore a VR CBT-based intervention (16, one hour sessions), that aims to enhance the social cognition of adults with ASD. Outcomes of this study are feasibility, tolerance and acceptance of the intervention, and improvements in social cognition.

Methods: A pre-post assessment design (including a 12 week follow-up) is used to assess the outcomes (i.e. feasibility, tolerance/acceptance, and improvements in social cognition). Social cognition was assessed using the Movie for the Assessment of Social Cognition (MASC) and Empathy Quotient (EQ) and social responsiveness with the Social Responsiveness Scale-A (SRS-A). Other relevant measures are also assess focussing on social anxiety and emotion recognition.

Results: Starting in April 2018, the treatment was embedded into multiple mental health organisations in the Netherlands. So far, 13 participants completed the intervention and n= 11 the post assessment (mean age 32.31, mean total IQ 103.42 (SD 14.41), 10 males, 3 females).

Qualitative interviews revealed good f acceptance of the intervention: mean evaluations of the intervention were 7.6 (out of 10), and participants would recommend the training to other people with autism indicating a 7.9.

Preliminary analyses (n=11) showed that MASC scores slightly improved from 30.31 to 33.27 points, yet non-significant ($F(1,22) = 1.514$, $p = .231$).

Conclusions: The preliminary results of 13 participants are clinically relevant and promising. Complete results, including follow-up data will be presented at the conference.

445.017 *(Poster)* Does a Difference in Recursive Embedding Underlie the Varied Features of Autism?

D. Skorich*, University of Queensland, Brisbane, Australia*

Background: Autism is characterized by a number of cognitive-perceptual differences relative to neurotypicals, including differences in theory of mind; local vs. global processing; perceptual flexibility; visual search; imagination; self-categorization; mental time travel; and creativity. It is not immediately clear why these varied features cluster together in the same condition. A deeper analysis of these features, however, reveals that each relies on the cognitive mechanism of recursion – that is, the ability to hierarchically embed concepts within concepts, potentially ad infinitum. Recursion is central to Theory of mind, for example, because understanding the world from another person's point of view requires a perceiver to embed the other's mental representations into their own. Similarly, recursion is central to self-categorization because constructing complex relations between self and other – the main function of self-categorization – requires a perceiver to embed their personal sense of self in higher level self-representations, such as the groups to which they belong. Given the recursive nature of these and every other feature of autism, we argue that a key difference between autistic people and neurotypicals might lie in the tendency of each to recursively embed, and disembed, information.

Objectives: The current project aimed to test the novel proposal that the varied features of autism might emerge from a difference in the tendency to recursively embed information. Specifically, we aimed to test whether the degree of autistic traits would positively predict a measure of recursive disembedding tendencies (i.e., weaker recursive embedding), which in turn would predict theory of mind and self-categorization – both known to function differently in autistic people.

Methods: Across three Experiments with general population samples recruited from Prolific Academic, we measured: participants' autistic traits with the Autism-Quotient (AQ); their recursive disembedding tendencies (RDT) with a number of language-based recursion tasks; their theory of mind abilities (ToM) with an embedded false belief task; and their tendency to self-categorize (SC) with a measure of group-based social identification.

Results: Mediation analyses across all three Experiments revealed negative relationships between AQ and SC, and between AQ and ToM (null in Expt. 1). The relationships between AQ and SC were mediated by RDT, as predicted, such that AQ was positively related to RDT, and RDT was negatively related to SC. The relationships between AQ and ToM were also mediated by RDT, but in contrast to results for SC and to predictions, this indicated a suppression effect, whereby RDT and ToM were positively, rather than negatively, related.

Conclusions: The three Experiments provided reliable support for a weaker recursive embedding tendency at higher levels of autistic traits, and partial support for our broader proposal that the varied features of autism might emerge from a difference in the recursion mechanism. This recursion difference was associated with decreased self-categorization as expected, but, contrary to predictions, it was associated with increased theory of mind. These divergent results will be discussed with reference to the sub-processes underlying theory of mind in autism, and to widely used measures of theory of mind.

445.018 *(Poster)* Dyadic Play in 12-Month-Old Infants at-Risk of Autism Spectrum Disorder

L. A. Sacrey[1]*, L. Zwaigenbaum*[2]*, V. L. Armstrong*[3]*, T. Pham*[4]*, S. Raza*[2]*, J. A. Brian*[5]*, I. M. Smith*[6] *and S. E. Bryson*[7]*, (1)Autism Research Centre, Glenrose Rehabilitation Hospital, Edmonton, AB, CANADA, (2)University of Alberta, Edmonton, AB, Canada, (3)IWK Health Centre, Halifax, NS, Canada, (4)Autism Research Centre, Edmonton, AB, Canada, (5)Holland Bloorview Kids Rehabilitation Hospital, Toronto, ON, Canada, (6)Dalhousie University / IWK Health Centre, Halifax, NS, CANADA, (7)Dalhousie University, Halifax, NS, Canada*

Background: In addition to impaired social communication, children with autism spectrum disorder (ASD) also show unusual play with object. Together, these atypicalities can make it difficult for caregivers to engage their children in reciprocal play. Indeed, infant siblings of children diagnosed with ASD show less engagement during dyadic play (Wai Wan et al., 2012).

Objectives: The purpose of this study was to examine the relationships between the quality of child-and-caregiver play at 12 months of age and ASD symptom presentation at 24 months of age in a high-risk sibling cohort.

Methods: Participants: Dyads of high-risk infants and caregivers (HR; have an older sibling diagnosed with ASD; n = 77) and low-risk infants and caregivers (LR; no family history of ASD; n = 37). *Assessments:* At 12 months, infants and caregivers engaged in a 3-minute session of free play. At 24 months, the Autism Diagnostic Observation Schedule-2 (ADOS) was administered. *Coding*: Free Play sessions were coded using Coding Infant Behaviour (Feldman, 1998), a dyadic rating scheme for infants aged 2 to 36 months that consists of 43 scales: 22 adult, 16 child, and 5 dyadic scales. Composites are calculated: Parent Sensitivity, Parent Intrusiveness, Parent Limit-Setting, Child Involvement, Child Withdrawal, Child Compliance, Dyadic Reciprocity, Dyadic Negative States. *Statistical Analyses*: Free Play composites were compared by Group using Mann-Whitney U analyses. Within the HR group, children were divided and compared based on 24-month ADOS Total score ($\geq$ 8 'moderate- to high-risk'; $\leq$ 7 'low-risk'). The relationship between Free Play composite scores and ADOS Total severity score was explored using Spearman's Correlations.

Results: Mann-Whitney U tests comparing LR and HR dyads showed that (1) caregivers of LR infants were less intrusive and set more limits in play compared to caregivers of HR infants (ps < .05), (2) LR children were more compliant to their caregivers compared to HR children (p <.05), and (3) LR dyads displayed higher levels of reciprocity and lower levels of negative states compared to HR dyads (ps < .05). Mann-Whitney U tests comparing HR infants who were 'low' versus 'moderate-high' risk showed that (1) caregivers of 'low-risk' children had greater levels of sensitivity and limit setting (ps < .003), and (2) children who were 'moderate-high' risk showed less involvement, engaged in less reciprocity with their caregivers, and showed higher levels of negative states (ps < .05). Correlations between Free Play composite scores and ADOS Total severity score showed significant relationships for Parent Sensitivity (r = -.41, p < .001), Parent Limit-Setting (r = -32, p < .01), and Child Involvement (r = -.34, p < .01) in HR dyads but no relationships in LR dyads.

Conclusions: As anticipated, caregiver-child play interactions in HR dyads are less synchronous and reciprocal compared to LR dyads, and these differences are associated with later ASD symptom presentation. Understanding differences in dyadic play can help inform play-based interventions for infants at risk of ASD.

445.019 *(Poster)* EEG Frequency (Beta, Theta & Beta: Theta ratio) during Resting State Eyes Open in Children with ASD and ASD+ADHD: The ACE Gendaar Network

M. McCabe[1]*, M. Santhosh*[2]*, A. Kresse*[1] *and S. J. Webb*[3]*, (1)Seattle Children's Research Institute, Seattle, WA, (2)Center for Child Health, Behavior and Development, Seattle Children's Research Institute, Seattle, WA, (3)Psychiatry and Behavioral Sciences, University of Washington, Seattle, WA*

Background: Autism Spectrum Disorder (ASD) is a neurodevelopmental disorder characterized by social, behavioral, and communication impairments. Attention deficit hyperactivity disorder (ADHD) is a neurodevelopmental disorder characterized by inattention and/or hyperactivity-impulsivity that interferes with functioning and occurs in 14% of children with ASD (CDC, 2013). The Theta-Beta (EEG power) ratio (TBR), which is comprised of increased theta activity and decreased beta activity, has been proposed as a biomarker for a subtype of ADHD (Arns et al., 2013), although this is controversial (Saad et al., 2018). A previous study in male youth with ADHD and ASD+ADHD found increased theta power in the ADHD group compared to the ASD+ADHD group (Bink et al., 2015). To address the hypothesized alterations in beta and theta in these conditions and to expand this work to include female youth, we analyzed data from the GENDAAR study, a multi-site collaboration focused on understanding sex-based differences in youth with ASD.

Objectives: To explore resting-state EEG theta and beta power in youth with ASD, ASD+ADHD, and typically developing (TD) controls, including both male and female participants.

Methods: In 70 youth ages 8 to 18 years; 24 with ASD [7 female], 25 with ASD+ADHD [12 female], and 21 TD controls [11 female] participated in this study. All ASD youth had a community clinical diagnosis, which was confirmed via the ADOS and ADI, and DSM-V criteria. TD youth had no elevated ASD traits. ADHD+ status was determined using the Child Behavior Checklist (CBCL) ADHD DSM scale >63. All participants completed the DAS-II and has an IQ >70. An EEG resting experiment was completed in which children passively observed short, screensaver-like videos. EEG data was collected from a 128 channel EGI system at 4 sites; post acquisition the EEG data was filtered (.1 to 100Hz), segmented in 1 second segments, artifacted detected for values out of range and eye artifacts, re-referenced to an average reference, and then subject to a fast fourier transformation (FFT). Theta was defined as the average power from 6 to 10 Hz; beta was defined as the average power from 12.5 to 30 Hz. We focus on the midline-electrodes at frontal, central and posterior regions.

Results: ANOVAs were conducted to explore differences in group (ASD, ASD+ADHD, TD) and sex (male, female) for beta and theta power. Individual analyses were conducted for each region of interest. Neither of the clinical groups (ASD / ASD+ADHD) differed from the TD group for either theta (all Fs<.45, ps>.50) or beta (all Fs<.17, ps>.68).

Conclusions: In this preliminary analysis, our results do not support a pattern of elevated theta/ decreased beta in children with ASD or ASD+ADHD compared to TD children. Additional analysis will explore qualitative relations between power and ADHD symptoms, as well as the impact of stimulant medication on EEG power in this sample to further understand variability in theta and beta in ASD

445.020 *(Poster)* Elevated Autism Diagnoses and Autistic Traits in Transgender and Gender Diverse Individuals: A Study of over 600,000 Individuals

V. Warrier[1]*, D. M. Greenberg*[1]*, E. Weir*[2]*, C. Buckingham*[1]*, P. Smith*[1]*, M. C. Lai*[3]*, C. Allison*[2] *and S. Baron-Cohen*[2]*, (1)University of Cambridge, Cambridge, United Kingdom, (2)Autism Research Centre, Department of Psychiatry, University of Cambridge, Cambridge, United Kingdom, (3)Autism Research Centre, Department of Psychiatry, University of Cambridge, Cambridge, ON, United Kingdom*

Background: Previous studies in small clinic-based samples have identified an association between gender dysphoria and autism. However, it is unclear whether transgender and gender diverse individuals have elevated rates of autism or autistic traits compared to cisgender individuals in large non-clinic-based datasets.

Objectives: To investigate if transgender and gender diverse individuals have elevated rates of autism/autistic traits compared to cisgender individuals in non-clinic-based datasets.

Methods: We used four independently recruited cross-sectional datasets consisting of 603,885 individuals (N_1=514,100; N_2=85,670; N_3=2,312; and N_4=1,803) who completed information on gender (either classified as male or female [comprising cisgender], or other gender identities [comprising transgender and gender diverse]), neurodevelopmental and psychiatric diagnoses, and measures of traits related to autism (self-report measures of autistic traits, empathy, systemizing, and sensory sensitivity). We also conducted sensitivity analyses to adjust for potential confounders such as educational attainment and age.

Results: Compared to cisgender individuals, transgender and gender diverse individuals had higher rates of autism (ORs: 4.59-6.36). Using subsampling bootstrap testing, we confirmed that the ORs were statistically comparable across the four datasets despite differences in recruitment, ascertainment of gender identity, and autism diagnosis. For both autistic (Cohen's D: 0.55-1.05) and neurotypical individuals (Cohen's D: 0.32-0.96), transgender and gender diverse individuals scored higher on self-report measures of autistic traits, systemizing, sensory perception, and lower on self-report measures of empathy. Transgender and gender diverse individuals also had higher rates of six other neurodevelopmental or psychiatric conditions (ADHD, bipolar disorder, depression, learning disorder, OCD, and schizophrenia) compared to cisgender individuals (1.92 [learning disorders] to 6.39 [schizophrenia]).

Conclusions: Across four independently recruited datasets, transgender and gender diverse individuals have elevated rates of autism and higher autistic traits, compared to cisgender individuals. The results have clinical implications for improving access to care and support for transgender and gender diverse individuals.

445.021 *(Poster)* Emotional Theory of Mind Deficits in Adolescents and Young Adults with ASD

R. A. Wulff[1]*, E. You*[2]*, M. K. Krug*[1]*, D. L. Williams*[3]*, K. E. Bodner*[4] *and M. Solomon*[5]*, (1)Department of Psychiatry & Behavioral Sciences, UC Davis MIND Institute, Sacramento, CA, (2)University of California, Davis, Davis, CA, (3)Communication Sciences and Disorders, Pennsylvania State University, University Park, PA, (4)Thompson Center for Autism & Neurodevelopmental Disorders, Columbia, MO, (5)Department of Psychiatry and Behavioral Sciences, The Medical Investigation of Neurodevelopmental Disorders (MIND) Institute, UC Davis School of Medicine, University of California Davis, Sacramento, CA*

Background:

Theory of Mind can be separated into the ability to infer the mental states (ToM-O) or emotional states (ToM-E) of others, which is distinct from drawing physical inferences. Bodner et. al. (2015) developed the Pittsburgh Inference Task (PIT) to probe whether difficulties in inferencing reported in ASD are due to a general deficit in the ability to make inferences, or to a specific deficit in one type of inferencing. They found ToM-E inferences are especially difficult in those with ASD and identified language ability (verbal IQ) and experience (age) as important factors influencing inferencing ability. Crystallized intelligence, then, which depends on past learning and experiences, should relate to inferencing ability in ASD compared to fluid intelligence, which captures the ability to process new problems (Horn and Cattell, 1967).

Objectives:

1. Replicate previous work showing a deficit in ToM-E but not ToM-O ability in ASD.
2. Using NIH Toolbox to measure fluid and crystallized intelligence, determine their association with different types of inferencing in ASD vs. TYP.

Methods:

42 ASD (Age = 19.64(3.17); VCI = 97.36(15.90)) and 32 TYP participants (Age = 18.56(3.15); VCI = 100.00(12.36)) performed the PIT, consisting of twenty-eight real-life stories read out loud followed by questions requiring participants to verbalize inferences about characters or situations in the stories. Responses are scored correct if appropriate based on the context and according to which type of inference was made (Physical (control), ToM-E, or ToM-O). Participants also completed the NIH Toolbox Cognition Battery, consisting of seven well-validated tasks that produce scores of fluid and crystallized cognition (Akshoomoff et al., 2014).

Results:

A repeated measures ANCOVA was conducted to determine the effect of diagnosis on the number of correct physical, ToM-E, and ToM-O inferences made, controlling for verbal IQ and age (Fig. 1). Results showed a significant main effect of diagnosis ($F(1, 70)=8.46$, $p = .005$) and a significant interaction of diagnosis and inference type ($F(1.98, 138.22)=5.20$, $p = .007$). Post hoc analyses (Bonferroni corrected, $p < .05$) revealed the ASD group provided significantly fewer correct ToM-E answers (M=7.21, SD=2.32) compared to the TYP group (M=9.10, SD=1.65). Within the ASD group, participants provided significantly fewer correct ToM-E answers compared to ToM-O (M=8.71, SD=2.15).

Crystallized cognition scores correlated positively with scores on each type of inference within the ASD group. In the TYP group, the only significant correlation was between ToM-E scores and fluid cognition. Verbal IQ correlated significantly only with ToM-E scores in the ASD group (Fig. 2).

Conclusions: Participants with ASD show a specific deficit in ToM-E inferencing, but no difficulty making ToM-O inferences. Increased crystallized cognition ability in ASD is associated with all three types of inferencing ability, but most strongly with ToM-E. This provides further evidence that those with ASD rely on previous knowledge and verbal ability to make correct inferences, especially in emotional contexts. Conversely, ToM-E in the TYP group relates to the processing of new situations. Data collection is ongoing and future analyses will look at the number and type of words used in responses.

445.022 *(Poster)* Empathy As a Predictor Variable of Bullying, Aggression, and Anger Control: An Analysis of Children with ASD and Children with Conduct Problems

K. Elliott[1]*, M. Hill*[1] *and B. A. Rich*[2]*, (1)Department of Psychology, The Catholic University of America, Washington, DC, (2)Psychology, Catholic University of America, Washington, DC*

Background: Extensive research indicates that children with autism spectrum disorder (ASD) struggle with social understanding and have diminished reaction to others' emotions (i.e., lack of empathy). Research identifies two types of empathy: cognitive and affective. It is theorized that children with ASD have deficits in cognitive empathy, but not affective empathy. Another clinical population that struggles with empathy, theoretically affective empathy, is children with conduct disorder (CD). Despite the theorized difference in the etiology of deficits in empathy between ASD and CD, there is a lack of research examining the role empathy plays in aggression, anger control, and bullying within these populations.

Objectives: We aim to investigate whether empathy is a predictor of bullying, aggression, and anger control in children diagnosed with ASD and children exhibiting significant levels of conduct problems. We hypothesize that in children with ASD, empathy, aggression, and anger control will strongly predict bullying. Conversely, we hypothesize that in children with significant conduct problems, empathy will slightly predict bullying, while aggression and anger control will strongly predict bullying.

Methods: Participants included 140 children ages 7-15 years ($M = 9.56 \pm 1.54$ years; 72.90% male; 73.60% White) who were enrolled in the Resilience Builder Program® (RBP) at a private psychotherapy practice. RBP is a 14-week, transdiagnostic group intervention for children with social deficits and problem behaviors (Alvord, Zucker, & Grados, 2011). Participants were divided into two groups, an ASD group of children diagnosed with ASD, and a CD group with children who presented with no autism diagnosis but “at-risk” or “clinical” levels of conduct problems as measured by the Behavioral Assessment System for Children (BASC-2). Data were collected prior to and at the conclusion of treatment. Measures included the BASC-2 (Reynolds & Kamphaus, 2004), and the Social Skills Improvement System (SSIS; Gresham & Elliot, 2008).

Results: Sequential regression analysis revealed empathy, aggression, and anger control together significantly predicted bullying for both groups, ASD group, $R2 = .10$, $F(3, 22) = .11$, $p = .010$; CD group, $R2 = .72$, $F(3, 63) = 54.88$, $p < .001$. For the ASD group, sequential regression analysis revealed empathy alone did not predict bullying, $\Delta R2 = .00$, $F(1, 24) = .11$, $p = .747$. However, empathy did significantly predict bullying in the CD group, $\Delta R2 = .04$, $F(1, 65) = 2.88$, $p = .094$.

Conclusions: While empathy was found to be predictive of bullying in children with conduct problems, it was not predictive of bullying in children with ASD. One possible interpretation is that children with ASD may lack the higher-level cognitive process required of empathy in the moments before bullying. Another possibility is that the effect of empathy may be smaller in children with ASD than in children with conduct problems, and that would have been identified in a larger, more diverse sample. Since aggression and anger control appear to be strong predictors of bullying in both populations, transdiagnostic treatments should target increasing anger control and decreasing aggression in children as a means of reducing bullying.

445.023 *(Poster)* Evaluating the Relation between ADHD Symptoms and Externalizing Behaviors in Children with Autism Spectrum Disorder

M. S. Feller*, C. E. Quinnett, K. Drafton, T. M. Rutter, B. J. Wilson, A. Shaarda, N. Navarro and I. Hall, Seattle Pacific University, Seattle, WA*

Background: Children with autism spectrum disorder (ASD) are at increased risk for externalizing problems (Bos, Diamantopoulou, Stockman, Begeer, & Reiffe, 2018). This situation is further complicated by the high comorbidity between ASD and attention deficit hyperactivity disorder (ADHD), which has been linked to long-term negative outcomes (Factor, Ryan, Farley, Ollendick, & Scarpa, 2017). A recent study found that 78% of children presenting with ASD and parent-reported challenging behaviors also met criteria for ADHD (Brookman-Frazee, Stadnick, Chlebowski, Backer-Ericzen, & Granger, 2018). Given that early interventions for these disorders are most effective (Turner-Brown, Hume, Boyd, & Kainz, 2019), more research is needed on ASD, ADHD and externalizing symptoms in young children prior to diagnosis.

Objectives: This study investigated whether the relation between ASD status (ASD vs typical development, TD) and externalizing behavior would vary based on differences in ADHD symptoms.

Methods: Participants were 208 children between the ages of 3 years and 6 years and 11 months and their parents. Our sample included 127 TD children (47.7% female) and 81 children with ASD (16.7% female). Child’s diagnostic status was determined by diagnostic reports provided or medically released by parents. Additionally, parents completed the Autism Behavior Checklist (ABC; Krug et al. 1980) to confirm that TD participants did not exhibit symptoms that are commonly associated with ASD. Parent ratings from The Behavioral Assessment System for Children--Second Edition (BASC-2; Reynolds & Kamphaus, 2006) provided an estimate of externalizing problems whereas the ADHD subscale from the Conners estimated ADHD (CBRS, 1990).

Results: We used linear regression to test our moderation model. Continuous variables were centered for ease of interpretation. Our model included the covariate of sex, which explained 4.8% of the variance in externalizing problems. The main effects of developmental status and ADHD symptoms on externalizing were both significant, t(204) = 4.396, p = .0001; t(204) = .6.810, p = .0001, respectively, and jointly accounted for 35.3% unique variance in externalizing problems. The interaction between status and ADHD symptoms was also significant, t(203) = -3.438, p = .001, explaining an additional 3.3% unique variance. The overall model explained 43.3% of the variance in externalizing problems, F(1, 203) = 4.251, p < .0001. Externalizing problems were higher for the ASD and TD groups when ADHD symptoms were also high versus lower but this relations between ADHD and externalizing was stronger for the TD group.

Conclusions: Our findings are consistent with research showing that children with ASD and comorbid ADHD symptoms exhibit higher rates of externalizing behavior than children with low rates (Factor et al., 2017; Sprenger et al., 2013; Tureck et al., 2013). This study extended prior research by examining ADHD and externalizing behavior in a large young sample of children with ASD or TD and varying levels of ADHD symptoms. Our findings are limited by the cross-sectional nature of our study and the use parent report in lieu of observations of externalizing. Future research should verify these findings using a longitudinal design.

445.024 *(Poster)* Evaluating the Relation between Child Adaptability and Engagement in Children with Autism

***E. A. Bisi**, J. M. Myers, M. S. Feller, R. A. Arowolo and B. J. Wilson, Seattle Pacific University, Seattle, WA*

Background: Social engagement refers to the extent individuals involve themselves in interacting with others (Kasari et al., 2011) and is determined by various contextual factors, including familiarity with the setting, strength of relationship, and social-emotional functioning (Teh, Yap, & Liow, 2018). Challenges with social engagement, peer relationships, and social-communicative development are often present in autism spectrum disorder (ASD; Teh, Yap, & Liow, 2018) and have been associated with important outcomes in social development (Kasari et al., 2011). Effective engagement is linked with adaptability, the ability to independently complete tasks from self-care to social coping techniques during transitions (Sparrow, Cicchetti, & Balla, 2005). These skills can influence children's ability to independently initiate and participate in activities (Gardiner & Larocci, 2015). Given that children with ASD often have difficulties with flexibly adapting to unexpected changes in their environments (Mahan & Matson, 2011), this challenge may interfere with appropriate engagement (Kanne et al., 2011).

Objectives: We aimed to determine how child adaptability differentially impacts child engagement in ASD and typically developing (TD) populations. We hypothesized that child adaptability would moderate the relation between child developmental status (ASD vs. TD) and child engagement. We also predicted that decreases in child adaptability would be related to decreased engagement for both ASD and TD groups and that this effect would be greater for our ASD group.

Methods: Participants were 31 children between ages 3 years and 6 years, including 20 TD children (60% female) and 11 children with ASD (18% female). Parent ratings from The Behavioral Assessment System for Children--Second Edition (BASC-2; Reynolds & Kamphaus, 2006) measured child adaptability and the Social Skills Improvement System Rating Scales (SSIS; Gresham & Elliott, 2007) assessed child engagement.

Results: A moderated multiple regression analysis was conducted to investigate the degree to which adaptability moderated the relation between status and engagement. A significant main effect was found for developmental status on engagement (p = .04, B = .29, CI_{95} = .06 to .53), indicating that children with autism demonstrated less engagement behavior than the TD group. There was also a nonsignificant main effect for adaptability on engagement (p = .28, B = .082, CI_{95} = -.07 to .23), which did not support our hypothesis that higher adaptability would yield higher engagement. Finally, there was a significant interaction between developmental status and adaptability on engagement (p = .02, B = .1, CI_{95} = .06 to .53), indicating a significant effect for our overall model.

Conclusions: Results supported our hypothesis that the ASD group would exhibit less engagement than their TD peers. However, results were nonsignificant for adaptability on engagement, which did not support our hypothesis that parent-reported child adaptability overall would predict parent-reported child engagement. Considering these results together in our overall moderation model, the significant interaction suggests that the effect of child adaptability on child engagement is important, but specifically within our ASD sample. More research with larger samples is needed on the role of adaptability in the social engagement of young children with ASD.

445.025 *(Poster)* Examining Gender Differences in Social Interaction between Adults with and without Autism Spectrum Conditions: An Interpersonal Movement Coordination Approach.

***N. Latif**[1], C. Di Francesco[1] and A. Nadig[2], (1)Psychology, McGill University, Montreal, QC, Canada, (2)School of Communication Sciences and Disorders, McGill University, Montreal, QC, Canada*

Background: Autism Spectrum Conditions (ASC) are diagnosed at a higher rate in males than in females (Fombonne, 2009). One possibility for this asymmetry is the female tendency to mask autism-related behaviours by presenting a qualitatively different phenotype than males (Lai et al., 2017). This has been noted in the communication domain, with females reporting fewer difficulties with social interactions than males (Attwood, 2006). Although research efforts characterizing gender differences of socio-communicative abilities are rapidly emerging, most investigations have examined within-group differences in autism without a neurotypical comparison sample (Hull et al., 2017). Here, we investigate whether interpersonal movement coordination, the tendency to move similarly in time, and a hallmark of successful communication, varies between males and females with and without ASC. Further, we examine whether movement coordination relates to autistic traits in both groups.

Objectives: 1) To determine whether interpersonal movement coordination varies between male and female adults with and without ASC and, 2) to examine whether movement coordination relates to autistic traits in both groups.

Methods: Fifty-two neurotypical (NT) adults (26 females; 18-29 years) and thirteen adults with ASC (3 females; 18-24 years) participated. Data collection for adults with ASC is ongoing. Participants were video-recorded while completing a semi-structured interview (sections of the ADOS-2). Using a novel video-based motion analysis method (Barbosa et al., 2012), movement coordination between participant and experimenter was quantified. Autistic traits in the participants with ASC were characterized using the ADOS, while NT participants completed the Broad Autism Phenotype Questionnaire (BAPQ).

Results: Movement coordination with the experimenter was calculated for adults with and without ASC. Results indicated a main effect of group for coordination, with adults with ASC coordinating significantly more than NT controls. Results also suggested a gender difference in coordination in the ASC group; specifically females tend to coordinate more than males, despite having greater symptom severity. This difference was not observed in the NT group. Further, no relationship between coordination and amount of autistic traits was found.

Conclusions: These findings suggest that females with ASC present differently in social interactions with no such gender difference found in our NT sample. Further, autistic traits in either group did not predict how much movement coordination was observed. However, it should be noted that we did not observe the prototypical gender differences in autistic traits where males score higher reflecting more symptoms on both the BAPQ (Ingersoll et al., 2011) and ADOS (Lai et al., 2017) than females. The reverse was true for our NT and ASC samples suggesting that either our samples may not be typical, or that complex nuances of social context (i.e., ADOS interview context for the ASC participants vs. questions asked in a conversational setting for the NT participants) and perception of conversational partners (i.e., potential differences between how the NT interviewer engages with an ASC vs. an NT partner; Morrison et al., 2019) influence nonverbal behaviour during social interactions. Taking consideration of such factors will ensure that future investigations unambiguously reflect socio-communicative gender differences in ASC.

445.026 *(Poster)* Examining the Visual Strategies Underpinning a Self-Processing Bias in Autistic Children: An Eye-Tracking Study Utilising an Ownership Paradigm

*L. M. Jukes[1], K. Gillespie-Smith[2] and **C. Ballantyne**[1], (1)Department of Psychology, University of the West of Scotland, Paisley, United Kingdom, (2)Department of Clinical Psychology, University of Edinburgh, Edinburgh, United Kingdom*

Background: A plethora of research has shown self-awareness to be impaired in Autism Spectrum Disorder (ASD), particularly in regard to psychological rather than physical self-referential information (e.g., the 'absent-self' theory, Frith, 2003; Frith & Happé, 1999; Williams, 2010). Indeed, children with ASD demonstrate impairments in self- and other-referential cognition which may underpin social functioning and communication deficits.

Self-referential cognition is particularly reflected in the *self-reference effect* (SRE) in memory; the phenomenon whereby there is a memory advantage for information encoded in relation to the self than others (Rodgers, Kupier & Kirker, 1977; Symons & Johnson, 1997). Gillespie-Smith and colleagues (2018) showed that through an ownership paradigm, that SRE was superior among autistic children but was dependent upon measures of individual differences; SRE increased in those autistic children with milder ASD symptom severity and greater socio-communicative ability.

Objectives: The current study extends the research exploring SREs through ownership and specifically build upon the work of Gillespie-Smith and colleagues (2018) by examining eye gaze behaviour in autistic and TD children during a computerised version of a non-evaluative ownership task. In doing so, the extant study aimed to provide insight into the visual strategies utilised by autistic children during a self-other processing task. Moreover, this study sought to explore whether the SRE and visual strategies used are related to socio-communicative ability, ASD severity, ToM ability, chronological age (CA), and verbal ability (VA).

Methods: Using a non-evaluative ownership paradigm to assess self-other processing and eye-tracking technology with 12 autistic children (2 Female, 10 Male) and 10 chronological age- and verbal ability-matched typically developing (TD) (4 Female, 6 Male) controls (aged 5 to 12 years). Social communication ability was measured by the Social Communication Questionnaire (SCQ; Rutter, Bailey, Berument, Lord & Pickles, 2003), and autism severity was measured by the Asperger Syndrome Diagnostic Scale (ASDS; Myles, Bock & Simpson, 2001). Finally, Theory of Mind (ToM) was measured using three first-order false-belief litmus tests: two location-change tasks (Baron-Cohen et al., 1985; Wimmer & Perner, 1983), and one unexpected-contents task.

Results: The current study found both groups to accurately recall more self-owned than other-owned toys; a demonstration of the self-reference effect (SRE). Amongst autistic participants, the SRE was slightly superior and its magnitude significantly increased as socio-communicative ability decreased. ASD severity, ToM ability, chronological age and verbal ability did not influence the ASD group's SRE, contradicting some previous findings. Both groups fixated significantly longer on self- and other-owned images than borders and interestingly, the TD group fixated significantly longer on self-owned toy images than the ASD group who fixated slightly longer on self-owned coloured borders in comparison. Finally, only autistic children did not fixate on toys' faces and their fixation on self- and other-owned items significantly increased as socio-communicative ability decreased.

Conclusions: These findings suggest that autistic children can demonstrate a robust SRE despite lower social-communication skills, ASD symptom severity may not influence the SRE, and autistic and TD children select visual attention differently to encode self-referential information which may consequently underpin their SRE ability.

445.027 *(Poster)* Impact of Psychotropic Medication on Resting State EEG Alpha Power and Performance on VEP Task in Children with Autism Spectrum Disorder in the ABC-CT Study

M. Santhosh[1], *H. M. Borland[1], J. T. Benton[1], E. Pompan[2], E. Denluck[3], S. Jeste[4], A. Naples[5], A. R. Levin[6], C. Sugar[4], R. Bernier[7], G. Dawson[8,9], F. Shic[1], J. Dziura[10], C. Brandt[10], S. J. Webb[7] and J. McPartland[5], (1)Center for Child Health, Behavior and Development, Seattle Children's Research Institute, Seattle, WA, (2)University of California Los Angeles, Los Angeles, CA, (3)UCLA Department of Psychiatry, PEERS lab: UCLA PEERS Clinic, Los Angeles, CA, (4)University of California, Los Angeles, Los Angeles, CA, (5)Child Study Center, Yale University School of Medicine, New Haven, CT, (6)Neurology, Boston Children's Hospital, Boston, MA, (7)Psychiatry and Behavioral Sciences, University of Washington, Seattle, WA, (8)Department of Psychiatry and Behavioral Sciences, Duke Center for Autism and Brain Development, Durham, NC, (9)Duke University, Duke Institute for Brain Sciences, Durham, NC, (10)Yale University, New Haven, CT*

Background: It has been estimated that around 56% of children with autism spectrum disorder are taking at least one psychotropic medication, with 22% of these medications being in the stimulant class (Mandell et al., 2008). It is important to understand the implications of medications on EEG responses to better differentiate brain responses due to medication use from responses related to autism or associated conditions. Moreover, as new treatments are tested, many children will already be utilizing a medication and thus treatment effects and their impact on brain functioning will need to be understood above the baseline effects of medication.

Objectives: To investigate the potential impact of medication (broadly defined as acting on the CNS or non-CNS mechanisms) on EEG alpha power and Visual Evoked Potential (VEP) response in participants with and without ASD. Within the ASD group, to examine the effects of different types of psychotropic medication on EEG responses.

Methods: This study used data from the ABC-CT project, a five site, NIH funded project that aims to identify biomarkers that could be used to facilitate understanding of treatment effects in ASD. Participants, ages 6-11yrs completed 3 time points of data collection, each included high density EEG. Tasks were a (calm viewing) resting task that showed screensaver-like videos and a test of basic visual processing, where participants watched images of a checkerboard reversing each 500 msec. A detailed medication history was collected from participants at each time point. Participants were included in the analysis based on having valid derived data on both experiments, and a completed medical history. The preliminary sample includes 88 children with ASD (females=16, male=72) and 14 TD children (females=5, male=9).

Results: There was a significant main effect of CNS medication (ASD+CNSmed, ASD- noCNSmed and TD group) on both the Resting and VEP total number of attended artifact free EEG trials (Resting: $F(2,99)= 4.3$, $p<0.05$; VEP: $F(2,99)=3.8$, $p< 0.05$). No significant results were observed for EEG alpha power ($F(2,99)= 0.3$, p=ns) or VEP P1 amplitude ($F(2,99)= 2.5$, p=ns). As well, no significant effect was observed in the non-CNS medication group for either experiments (Resting alpha power: $F(2,99)= 0.4$, p=ns; VEP P1 amp: $F(2,99)= 2.1$, p=ns).

Within the ASD group, there were no significant differences in IQ in children on CNS medication and children not on CNS medication at T1 ($t[86] =-.59$, p =ns). No significant differences for either experiments were observed between groups (ASD-noMeds, ASD+CNSmeds, ASD+nonCNSmeds and ASD+CNS+nonCNSmeds (Resting alpha power: $F (3,84)= 0.8$, p= ns; VEP P1 amp: $F (3,84) = .57$, p = ns). There were no significant differences based on types of medication (stimulants, SSRIs, antipsychotics, antiepileptics and alpha agonists) as well.

Conclusions: Our preliminary analysis showed that there is an overall impact of CNS medications on the number of good trials obtained during EEG acquisition; however there were no effects of medication on the dependent variables. Additional analysis will examine if medication change or stability from Time-point 1 to Time-point 2 impacts test-retest values.

445.028 *(Poster)* Implicit Empathetic Sensitivity to Others' Pain in Children with Autism Spectrum Disorder: Evidence from Pupil Dilation and Eye Movements

T. Li[1], *J. Decety*[2,3] *and L. Yi*[1], *(1)School of Psychological and Cognitive Sciences and Beijing Key Laboratory of Behavior and Mental Health, Peking University, Beijing, China, (2)Department of Psychiatry and Behavioral Neuroscience, University of Chicago, Chicago, IL, (3)Department of Psychology and Child Neurosuite, University of Chicago, Chicago, IL*

Background: Empathy is a fundamentally adaptive ability that emerges early in life and guilds our social behaviors (Decety, 2015). Deficits in empathy have been widely reported in individuals with Autism Spectrum Disorder (ASD) (Bons et al., 2013; Harmsen, 2019). The underlying mechanisms of their deficient empathy are still under controversy. Individuals with ASD are widely believed to be insensitive to others' pain (Chen et al., 2017; Thaler et al., 2018). However, an alternative explanation is that they could be over-sensitive to others' pain (Blakemore et al., 2006; Gu et al., 2015), so that they actively avoided looking at the scene.

Objectives: The current study investigates the implicit empathetic sensitivity in children with ASD and TD controls when they see other people in pain, using the eye-tracking technique. We aim to provide new evidence for the underlying mechanisms of the inappropriately empathetic reactions to others' pain in children with ASD in terms of their arousal level indicated by pupil dilation. Pupil dilation was found in responses to emotionally salient stimuli in typical developing (TD) people (Bradley et al., 2008), and has been used as an index of arousal level (Eckstein et al., 2016). We hypothesized that an over-sensitivity to others' pain would be reflected by more pupil dilation, while insensitivity to others' pain would be reflected by less pupil dilation.

Methods: We modified the moral reasoning task from that created by Cheng and colleagues (2014). The paradigm included two experimental conditions depicting an individual's limb in painful situations or non-painful control situations. Each condition consisted of 10 trials, and each trial lasted for 5 seconds for eye movements and pupil dilation data collecting.

Twenty-five 5- to 8-year-old children with ASD and twenty-seven TD controls saw static images depicting an individual's limb in pain or control situations. Their pupil diameters and eye-movements were recorded by a Tobii X3-120 eye tracker. Children were also asked to evaluate the pain intensity of the person and to report how sorry they feel about the individual's pain.

We defined the fixation durations on the painful/control situations as areas of interest (AOIs). Children's verbal evaluations, fixation durations, and pupil dilations were compared across group and condition using mixed-design ANOVAs.

Results: We found that (a) compared with TD children, children with ASD's pupils dilated more when they see others in pain; (b) children with ASD looked less to the pain situations than TD children, and the two groups displayed similar looking time in the control condition; and (c) children with ASD expressed less empathetic concern to the individuals in pain, even though they rated the pain intensity of those people in pain similarly to their TD peers.

Conclusions: Our study indicated over-arousal and eye avoidance toward others' pain in children with ASD. They also explicitly expressed less empathetic concern to those people in pain. These findings indicated that the impaired empathetic reactions in children with ASD may be explained by their hyperarousal and active avoidance to the pain stimuli, which interferes further cognitive processing and empathetic responses.

445.029 *(Poster)* Individual Differences in Social Motivation in Autistic Adults: The Role of Alexithymia and Social Anxiety

E. Gurbuz[1], *E. Jones*[2], ***M. Hanley***[3] *and D. M. Riby*[4], *(1)Psychology, Durham University, Durham, United Kingdom, (2)Durham University, Durham, United Kingdom, (3)South Road, Durham University, Durham, United Kingdom of Great Britain and Northern Ireland, (4)Department of Psychology, Durham University, Durham, United Kingdom*

Background: Social motivational factors have been suggested to explain difficulties in social functioning in Autism Spectrum Disorders (ASD) (Chevallier et al., 2012). However, neural and behavioural studies of social motivation in ASD have demonstrated mixed evidence, which might be partially explained by individual differences in other factors that can impact upon sociability and motivation (e.g. social anxiety, depression and alexithymia). Although a few studies have looked at individual differences in social motivation in children with ASD (Neuhaus et al., 2019; Swain et al., 2015), these factors have not been examined together in autistic and neurotypical adults.

Objectives: The objectives are to understand the role of individual differences (autistic traits, alexithymia, social anxiety, depression) in social motivation in both autistic and neurotypical adults (NT) using self-report measures and to examine whether there are subgroups in social motivation within ASD.

Methods: Seventy three adults with ASD (mean age = 29.77, 27 males) and 68 NT adults (mean age = 27.12, 27 males) completed an online study including the following self-report measures: social motivation was measured using the Anticipatory and Consummatory Interpersonal Pleasure Scale (ACIPS; Gooding & Pflum, 2011); Toronto Alexithymia Scale (TAS; Bagbdy et al., 1994) was used to assess alexithymia; social anxiety was measured with the Social Interaction Anxiety Scale (SIAS; Mattick & Clarke, 1998); the Depression Anxiety and Stress Scale (DASS-21; Lovibond & Lovibond 1995) was used to measure depression; participants also completed the Autism Quotient (AQ; Baron-Cohen et al. 2001).

Results: Group comparisons on primary measures demonstrated a significantly lower experience of pleasure in social interactions, heightened alexithymia, social anxiety, and depression in autistic compared to NT participants. However, there was high variability of ACIPS scores within the ASD group and important overlap between the groups (Figure 1). Hierarchical linear regression showed that higher age, autistic traits, and alexithymia, but not social anxiety, were significant predictors of ACIPS scores in the ASD group (38.5% variance explained), while only age and autistic traits significantly predicted reduced social hedonic experience in the NT group (58% variance explained).

Subsequent model-based cluster analyses identified two clusters in the NT and three clusters in the ASD group. NT individuals in the first cluster (n=17) reported significantly less experience of pleasure in social interactions compared to the second cluster, however the clusters did not differ in terms of autistic traits and social anxiety. In the ASD group, the first cluster (n=25) had significantly higher ACIPS and lower AQ scores than the second (n=6) and third cluster (n=42) (Figure 2). The second and third cluster had similar ACIPS scores, however the third cluster had significantly higher alexithymia and social anxiety.

Conclusions: There are individual differences in social motivation among autistic and NT adults. In ASD these are associated with autistic traits and alexithymia. Existence of subgroups within autism based on social motivation, social skills, and social anxiety challenges the idea of social motivational factors as a primary deficit in ASD, and instead suggests that social behaviour is a result of complex interactions with multiple factors.

445.030 *(Poster)* Intermittent Theta Burst Stimulation over the Posterior Superior Temporal Sulcus Modulates Neural Response and Visual Attention to Faces in Autism Spectrum Disorder

M. Zhou[1], *A. Naples*[1], *S. L. Jackson*[1,2], *A. Bagdasarov*[1], *C. Carlos*[1], *S. Kala*[1], *E. Cummings*[1], *M. R. Altschuler*[3], *M. L. McNair*[4], *T. McAllister*[1], *C. C. Cukar-Capizzi*[1], *J. Wolf*[1] *and J. McPartland*[1], *(1)Child Study Center, Yale University School of Medicine, New Haven, CT, (2)Office of Assessment and Analytics, Southern Connecticut State University, New Haven, CT, (3)Institute of Child Development, University of Minnesota, Minneapolis, MN, (4)Department of Psychology, Stony Brook University, Stony Brook, NY*

Background: The superior temporal sulcus (STS) plays an important role in the processing of faces and biological motion. The STS contributes to the generation of a face-sensitive event-related potential (ERP), the N170, the latency of which is a potential biomarker of autism spectrum disorder (ASD). The STS also regulates, in part, visual attention to the face, which is decreased in individuals with ASD. Intermittent theta burst stimulation (iTBS), an excitatory form of noninvasive brain stimulation, over the STS has not been effectively explored in individuals with ASD in conjunction with these recognized neural markers and patterns of visual attention.

Objectives: To investigate changes induced by iTBS over the right posterior STS (rpSTS) in N170 latency to faces and proportion of fixation (POF) to socially relevant facial features in adults with ASD compared to typically developing (TD) adults.

Methods: Preliminary data reflect two adults with ASD (mean age=29.9 years) and ten TD adults (mean age=26.9 years); data collection is ongoing. ASD diagnosis was based on DSM-5, ADOS and ADI-R criteria. All subjects underwent iTBS delivered over the rpSTS [mapped as T6 in the 10-20 electroencephalogram (EEG) coordinate system]. Stimulation was delivered in 2second (s) trains every 10s for a total of 190s (600 pulses) at an intensity of 80% of the active motor threshold. EEG and eye-tracking (ET) data were collected before and after a single iTBS session. Participants were instructed to look naturally at presented static faces and houses after initial fixation on facial regions of interest (left eye, right eye, nose or mouth) and corresponding house regions. The latencies of the N170 were extracted from selected occipitotemporal electrodes and segmented to onset of a face stimulus. POF to eyes on faces was calculated as the number of gaze samples within the eye-region of the face divided by the total number of on-screen gaze samples. Data was analyzed by group before and after iTBS stimulation.

Results: iTBS to the rpSTS decreased N170 latency to faces when eyes were presented at fixation by a mean change in face N170 latency of -2.3milliseconds (ms) [Standard Deviation (SD)=5.2ms] to right eye fixation and 0.5ms [SD=6.6ms] to left eye fixation in TD individuals and by a mean change in face N170 latency of -4.7ms [SD=1.6ms] to right eye fixation and -10.9ms [SD=9.6ms] to left eye fixation in individuals with ASD. After the iTBS session, TD individuals exhibited a mean increase in looking to the eyes of the face of 4.3% [SD=12.6ms] whereas individuals with ASD exhibited an average decrease in looking to the eyes of the face of 1.6% [SD=10.5%]. Results are preliminary, and analysis is ongoing.

Conclusions: This study supports the feasibility and potential utility of an iTBS protocol in participants with ASD. Results of this preliminary study suggest that iTBS over the rpSTS may enhance brain activity in individuals with ASD. A heterogenous response among TD individuals is noted and may reflect the heterogeneity of social perceptual brain systems in the general population.

445.031 *(Poster)* Looking at Me Anxiety: Facial Gaze and Anxiety in Autism

D. J. Milne[1], *A. Saliba*[1] *and N. Sugden*[2], *(1)School Of Psychology, Charles Sturt University, North Wagga Wagga, NSW, Australia, (2)School Of Psychology, Charles Sturt University, Bathurst, NSW, Australia*

Background: Anxiety and differing gaze behaviour are two common characteristics of individuals on the autism spectrum. In the neurotypical population facial gaze can ensure emotional regulation and social learning that may aid in reduced prevalence of anxiety. Many studies can be found for anxiety and autism, and gaze behaviour and autism however, few link the two. Moreover, only two qualitative studies regarding anxiety (Trembath et al., 2012; Robertson et al., 2018) and one regarding eye contact (Trevisan et al., 2017) can be found in the literature. None relating anxiety and eye contact could be found. Investigating how anxiety and gaze behaviour are related in autism may provide insights to this heterogeneous cohort. Consequently, qualitative studies are needed to provide inductive insights into this relationship.

Objectives: To explore the lived experience of those adults on the autism spectrum in relation to anxiety and eye contact.

Methods: A qualitative study was carried out with 16 adults on the spectrum and 7 supporters of adults on the spectrum. Data was collected from semi-structured interviews and analysed using Charmaz's Grounded Theory epistemology.

Results: Themes produced from the analysis show that individuals on the spectrum report having difficulties with gaze behaviour, with related anxiety effects. Themes show that those on the spectrum can change their gaze behaviour to appear “normal”, reduce anxiety in social situations, and allow other sensory modality processing (e.g. avoiding facial gaze to allow verbal language to be processed). Eye contact was found to relate to feelings of anxiety. However, anxiety themes showed that anxiety is caused more by social situations than eye contact alone. Participants reported symptoms of alexithymia and face blindness that affect their everyday social functioning.

Conclusions: Adults on the autism spectrum can be very informative about their gaze behaviours and causes of anxiety. However, data show that while most causes of anxiety are social in nature, specific aetiology and remediation of the anxiety is complex and well communicated by those on the spectrum.

445.032 *(Poster)* Measuring Social and Role Functioning in Adolescents & Young Adults with ASD

N. Dalloul[1]*, A. Davis*[2]*, A. C. Cho*[3]*, R. Botello*[4]*, T. A. Niendam*[5] *and M. Solomon*[6]*, (1)Psychiatry and Behavioral Sciences, UC Davis MIND Institute, Sacramento, CA, (2)UC Davis MIND Institute, Sacramento, CA, (3)Human Development & Psychology, University of California, Los Angeles, Los Angeles, CA, (4)UC Davis, Sacramento, CA, (5)Imaging Research Center, Sacramento, CA, (6)Department of Psychiatry and Behavioral Sciences, The Medical Investigation of Neurodevelopmental Disorders (MIND) Institute, UC Davis School of Medicine, University of California Davis, Sacramento, CA*

Background: Impairments in social and role functioning are central components of autism spectrum disorder (ASD). Understanding intricacies of these impairments is vital for proper treatment; however, it is difficult to obtain a valid measure of functioning in young adults with ASD (Pallathra et al., 2018; Schmidt et al., 2015). Most social functioning scales used in adult research are not sensitive to social issues that occur in adolescence and fail to quantify the complex variability of functioning in ASD (Bolte et al., 2013; Chan et al, 2019). The Global Functioning: Social (GF:S) and Global Functioning: Role (GF: R) are two validated Global Assessment of Functioning (GAF) scales that are rated after administration of a semi-structured interview about daily living. These scales have been validated to assess age-appropriate social and role functioning in adolescents/young adults at clinically high risk for developing psychosis (Cornblatt et al., 2007). Here we report preliminary results of a validation study of these scales which have been updated and adapted for adolescents/young adults with ASD.

Objectives:

1. Examine whether adapted scales of global functioning (GF:S and GF:R) are sensitive to unique deficits of social and role functioning in the ASD adolescent/young adult population.
2. Investigate construct validity of the GF:S and GF:R by examining associations of GF:S and GF:R scores with other validated measures of functioning and clinical traits.

Methods: Participants with ASD (N=88, M_{age}=17 (SD=3.14), 16 female) were administered the modified GF:S/GF:R interview by a trained, reliable rater. These subjects also completed commonly used ASD assessments: Adaptive Behavior Assessment System-3 (ABAS-3) that assesses functional skills through 10 scales within 3 adaptive domains; Social Skills Performance Assessment (SSPA) that entails role-play scenarios to measure social aptitude (Patterson et al., 2001); Social Responsiveness Scale (SRS2) that evaluates autism symptom severity (Constantino et al., 2002); and Autism Diagnostic Observation Schedule-2 (ADOS-2). The original GF:S/GF:R interview and scoring guidelines were modified to further probe the true nature and depth of subjects’ relationships and daily activities. Questions regarding social interactions were adjusted to represent modern-day means of communication (texting, etc.). To assess construct validity, Spearman’s non-parametric correlation (ρ; rho) was used to identify associations between GF:S/GF:R scales and measures listed above.

Results: The GF:S scale is significantly correlated with SSPA, SRS2, ADOS-2-SA and ADOS-2-CSS. The GF:R scale is significantly correlated with ADOS-2-CSS, ADOS-2-SA, and SSPA but is not significantly correlated with SRS-2 score. All 3 ABAS adaptive domains, and total composite score are significantly correlated with the GF:S scale. The GF:R scale is significantly correlated with the ABAS total composite score and 2 adaptive domains (excluding the Practical Composite). The Communication, Community Use, Leisure, and Social sub-scales are significantly correlated with both GF scales.

Conclusions: The modified GF:S/GF:R interview holds promise as a valid indicator of social and role functioning in adolescents/young adults with ASD given its strong association with other commonly used assessments. In order to fully assess whether the modified GF:S/GF:R interview can serve to fill the knowledge gap, further analyses including longitudinal data and regression analyses are being conducted.

445.033 *(Poster)* Measuring Social-Communication Difficulties in School-Age Siblings of Children with ASD: Pragmatic Language Tests Versus Conversational Ratings

D. N. Gangi[1]*, M. M. Hill*[2] *and S. Ozonoff*[3]*, (1)Psychiatry and Behavioral Sciences, University of California, Davis, MIND Institute, Sacramento, CA, (2)UC Davis MIND Institute, Sacramento, CA, (3)Psychiatry and Behavioral Sciences, University of California at Davis, MIND Institute, Sacramento, CA*

Background: Younger siblings of children with ASD (high-risk siblings) who do not develop ASD themselves are at elevated risk for developing the broader autism phenotype (BAP) compared to siblings with no family history of ASD (low-risk siblings). The BAP has been linked to difficulties in social relationships and poor mental health outcomes in adulthood. Prospective studies of high-risk siblings provide an opportunity to characterize aspects of the BAP in childhood, though very few studies have followed children through school-age to evaluate later outcomes.

Objectives: To investigate school-age conversational and language skills in high- and low-risk children with BAP and ASD outcomes, as well as a comparison group.

Methods: Participants were assessed at school-age (*M* age=11.13 years, SD=2.43) and classified into one of three outcome groups: ASD (*n*=13; met *DSM-5* criteria and ADOS-2 cutoff), Broader Autism Phenotype (*n*=18; based on clinical best estimate), or Comparison group (*n*=122; did not meet ASD or BAP criteria). During the study visit, examiners engaged in conversation with participants for 7-10 minutes, beginning with an open-ended question (i.e., "What do you like to do for fun?") and responding naturally to the participant. Participants were then rated using the Conversational Skills Rating Scale (CSRS; Spitzberg, 1995), which contains 25 behaviors rated on a scale of 1 (inadequate) to 5 (excellent); these items were summed to create a total score for analyses. Participants were also administered the Pragmatic Language (PL) and Nonliteral Language (NL) subtests of the Comprehensive Assessment of Spoken Language (CASL-2; Carrow-Woolfolk, 2017).

Results: CSRS Total Score did not differ by risk group, p=.24, therefore analyses were conducted using only outcome group. Analysis of variance showed a significant effect of outcome group on CSRS Total Score, $F(2, 128)=60.36$, $p<.001$ (see Figure 1). Post hoc analyses indicated that the ASD group scored significantly lower than the BAP and Comparison groups. The BAP group scored significantly lower than the Comparison group. There was a significant effect of outcome group on CASL PL, $F(2, 149)=32.40$, $p<.001$, and on CASL NL, $F(2, 150)=33.24$, $p<.001$ (see Figure 1). Post hoc analyses for both CASL subtests indicated that the ASD group scored significantly lower than the BAP and Comparison groups, while the BAP group and Comparison group did not differ. Regression analyses showed that CASL scores did not predict CSRS Total Score when controlling for outcome group, verbal IQ, and age (see Table 1).

Conclusions: School-age children with BAP outcomes exhibited lower conversational skills with an examiner than comparison children, and children with ASD exhibited lower skills than both BAP and comparison groups. Standardized assessment of pragmatic language skills did not predict conversation skills when accounting for effects of outcome group. This suggests that naturalistic conversation—and measures incorporating subtle verbal and nonverbal aspects of communication—may be more sensitive than standardized language assessments in identifying social-communication difficulties in children with the BAP. Despite scoring in the average range on pragmatic tests, children with the BAP struggle implementing such skills moment-to-moment during interaction, making naturalistic settings crucial when assessing social-communication difficulties.

445.034 *(Poster)* Mechanisms of Emotion Understanding in Self and Others and the Role of Autistic Traits

***K. Boegl**, M. Bayer and I. Dziobek, Berlin School of Mind and Brain, Humboldt-Universitaet zu Berlin, Berlin, Germany*

Background: Mindreading is an important prerequisite for successful social interactions. Current research suggests overlapping neural and mental processes for self and other related mindreading which supports so called one-mechanism theories. Investigating autism spectrum condition (ASC), studies on mindreading often propose alterations within this domain. If one-mechanism theories hold true, individuals with ASC should also demonstrate altered inference to their own mental states.

Objectives: We aim to investigate if self and other mindreading is one single, common process in individuals with and without ASC. Specifically, we are interested to which extend internal and external cues are used to infer own and others' mental states and if this varies with degrees of autistic traits. To equally address mindreading in self and others, we established a new paradigm using a gambling task in combination with internal and external cues.

Methods: Twenty-three participants (data collection ongoing) completed an allegedly interactive gambling game in which they rated their own or their partner's affective state in response to positive, neutral and negative outcomes of a wheel of fortune. The different outcome compartments of the wheels varied in size, thus changing the expectancy value of the wheels (external cue). Participants were further listening to an acoustic signal representing their own (or their partner's) realistic heart rate or a 10% accelerated signal (internal cues). We used autism spectrum quotient (AQ) scores to investigate the relation auf autistic traits and mindreading. We hypothesize that mainly individuals with lower autistic traits will use internal cues such as the heart rate to infer their own and their partner's affective states. Further, we expect that individuals with higher autistic traits focus more on external task properties, such as the deviance between expectancy value and actual outcome. Linear mixed-effect models were used to estimate the relations between affective rating and our independent variables feedback, target person (self vs other), AQ, and expectancy value deviance.

Results: As hypothesized, negative outcomes were rated significantly more negative in accelerated feedback trials compared to realistic trials (p = .017). There was no significant effect of AQ on ratings and no relation between AQ and feedback on ratings. However, the data revealed a significant interaction of AQ and expectancy value deviance on rating (p < .001), showing that the predictive value of the external cue was stronger in individuals with higher autistic traits.

Conclusions: Our results suggest that individuals use (alleged) physiological feedback to judge their partner's as well as their own mental states, at least for negative outcomes. These results provide supporting evidence for one-mechanism theories. Further, participants with higher autistic traits focused more on external cues to infer their own as well as their partner's affective mental states. This argues for different mindreading strategies in individuals with high and low autistic traits. The relation between autistic traits and mindreading will be further investigated in individuals with and without autism spectrum disorder diagnosis and the corresponding results presented at the conference.

445.035 *(Poster)* Moral Foundations Theory in Autism Spectrum Disorder: A Qualitative Investigation

***E. E. Dempsey**[1], A. E. Richard[2], I. M. Smith[3] and C. Moore[4], (1)Psychology and Neuroscience, Dalhousie University, Halifax, NS, Canada, (2)Autism Research Centre, IWK, Halifax, NS, Canada, (3)Dalhousie University / IWK Health Centre, Halifax, NS, CANADA, (4)Dalhousie University, Halifax, NS, Canada*

Background: Moral thinking is integral to how humans treat each other and non-human animals. Most research in this area has relied on rationalist accounts of moral psychology that posit hierarchical moral principles derived from taking the perspectives of others, i.e., applying commonsense psychology skills to social interactions. From this perspective, subtle differences in moral reasoning have been found between autistic and neurotypical individuals. Yet even autistic individuals, who sometimes differ in their development of commonsense psychology skills, show moral judgements similar to those by neurotypical individuals. Haidt's moral foundations theory posits a non-hierarchical account of moral psychology wherein moral judgements differ depending on such factors as culture, socioeconomic status, and political orientation.

Objectives: Haidt's theory, which relies less on perspective taking than do rationalist accounts, has not yet been investigated among autistic individuals. The current study was conducted as an initial foray into understanding how moral foundations theory fits with autistic moral thinking.

Methods: In this qualitative study, the first author conducted interviews with 6 autistic adults (female $n = 1$; male $n = 2$; gender non-binary $n = 3$). Participants were recruited via local autism organizations and clinicians. Autistic adults in the study ranged in age from 22 to 50 years. Participants' highest levels of education were: high school certificate ($n = 1$); trade school diploma ($n = 1$); bachelor's degree ($n = 2$); and master's degree ($n = 2$). Participants were relatively homogeneous in terms of political orientation in that all participants identified as either liberal, slightly liberal, or very liberal with regards to social and economic issues, except one participant who reported conservative views on economic issues. Interviews were conducted using Flanagan's (1954) critical incident technique and analyzed with thematic analysis (Braun & Clark, 2006). Analytic auditing was conducted by the second author to strengthen the integrity of themes. Member checking (Tracy, 2010) was completed to ascertain whether participants' views were accurately reflected in the analysis.

Results: All five moral foundations were represented in the interviews. However, emotions posited to be related to moral decision making in neurotypical individuals did not feature prominently in moral justifications offered by these participants.

Conclusions: Moral foundations theory appears to offer a framework that captures some individual variation in decision making, and the qualitative research approach revealed a potential additional source of variation associated with autism spectrum disorder. Responses to morally salient contexts may not be as emotionally driven among autistic compared with neurotypical individuals. In ongoing research, quantitative methods are being used to compare groups of autistic and neurotypical individuals to clarify similarities and differences in moral thinking between the two groups.

445.036 *(Poster)* Multifaceted Empathy Differences in Autism: Negative but Not Positive Emotion Recognition Impairment

J. Quinde[1]*, B. H. Heflin*[2]*, L. E. Mash*[3] *and C. J. Cascio*[4]*, (1)Vanderbilt University, Nashville, TN, (2)Florida International University, Miami, FL, (3)Brain Development Imaging Laboratories, San Diego State University, San Diego, CA, (4)Vanderbilt University School of Medicine, Nashville, TN*

Background: Individuals with autism spectrum disorder (ASD) have historically been described as lacking empathy (Kanner, 1943). Considered a social 'glue', empathy is a multifaceted construct involving both an understanding of self and other's feelings (cognitive empathy, CE) and the experience of shared feelings (emotional empathy, EE) (Shamay *et al.,* 2009). Empathy research in ASD has traditionally used emotionally charged stimuli as a press for empathic responses with a focus on either CE, EE, or both. Notably, there is evidence that suggests differential gaze and neural activity patterns in response to faces depicting negative versus positive emotion. While the cognitive and emotional dichotomy of empathy is beginning to be well understood in ASD, differences related to valence have not been well documented in ASD, nor is it known how valence-specific phenomena relate to behavior.

Objectives: Our study aimed to explore the effects of autism diagnostic status and emotional valence on task-based 1) emotional and 2) cognitive empathy responses, and 3) correlations between empathy and autism symptomatology.

Methods: 62 individuals (ASD = 29, typically developing (TD) = 38) of varied ages ranging from 8-38.30 years performed the multifaceted empathy test (MET) (Dziobek, 2008) consisting of 32 static images depicting people in emotionally charged conditions. Cognitive empathy was assessed by multiple choice emotion recognition and emotional empathy was assessed by self-rating on a 0-9 scale. Group comparisons for empathy scores were calculated using the non-parametric effect size Cliff's delta statistic. Spearman rank correlations were calculated between empathy and Social Responsiveness Scale scores.

Results: There were no significant group differences found in age ($\delta = 0.169$, $p = 0.24$), sex ($= 0$, $p = 1$), verbal IQ ($\delta = 0.233$, $p = 0.12$), performance IQ ($\delta = 0.028$, $p = 0.847$), or full scale IQ $\delta = 0.124$, $p = 0.405$). Groups differed significantly in their cognitive ($\delta = 0.405$, $p = 0.002$) but not emotional empathy ($\delta = 0.046$, $p = 0.761$). Secondary analyses separated by valence revealed that the group difference present in the cognitive empathy comparison was driven by the negative ($\delta = 0.368$, $p = 0.008$) but not the positive images ($\delta = 0.237$, $p = 0.09$). No significant correlations were found between SRS scores and empathy measures.

Conclusions: Findings from this study suggest that there is intact emotional empathy but impaired cognitive empathy in children and adults with autism and corroborated previous findings of emotion recognition deficits in this clinical group (Dziobek, 2008). We also extend previous knowledge by reporting an effect of valence in which cognitive empathy deficits occur for portrayals of negative but not positive facial expressions.

445.037 *(Poster)* Neuropsychological Mechanisms Underlying Deception Detection in Autism Spectrum Disorder

J. A. Trapani[1]*, T. R. Levine*[2]*, M. Martino*[3] *and R. K. Kana*[4]*, (1)University of Alabama at Birmingham, Birmingham, AL, (2)Communication Studies, University of Alabama at Birmingham, Birmingham, AL, (3)Department of Psychology, University of Alabama, Tuscaloosa, AL, (4)University of Alabama, Tuscaloosa, AL*

Background: Despite extensive research on topics of social cognition in autism spectrum disorder (ASD), investigations targeting the vulnerability of this population to deception have received rather limited attention. While a portion of the current literature indicates a deficit in deception detection in ASD, evaluating it has largely been peripheral to lie-detection (e.g., false-belief tests) and/or rely mainly on assessment of Theory of Mind and nonverbal communication[1-5]. The role of executive function (EF) skills in detecting deception is even less understood in both typically developing (TD) and ASD populations. The dearth of current research and the social implications of poor deception detection exemplify the need to better understand the mechanisms that underlie this nuanced form of social interaction.

Objectives: This study investigates the cognitive mechanisms underlying deception detection, an important skill in navigating the interpersonal world, and the extent to which autism symptomology impacts detecting deception.

Methods: Twenty-three adults ages 18-30 (data collection is ongoing; current sample includes 5 ASD, 18 TD, mean FSIQ = 108) completed a previously established deception detection task (Levine et al. 2010) along with a battery of neuropsychological assessment and questionnaires. The deception detection task involved participants watching video-taped interviews of individuals telling a lie or telling the truth and judging each individual's veracity (truth-telling). These tapes spanned across veracity *matched* (sincere truth-tellers and insincere liars) and veracity *mismatched* (insincere truth-tellers and sincere liars) conditions. Hierarchical multiple regressions were conducted to control for age, sex, and IQ, using the Autism Spectrum Quotient (AQ) Total Score and Behavior Rating Inventory of Executive Function (BRIEF) Global Executive Composite T-Score as predictors and percent accuracy across conditions of deception detection (total, matched, and mismatched) as outcome variables. Data collection is ongoing. Final analyses will allow for TD/ASD group comparisons.

Results: The full model predicting total accuracy of deception detection was statistically significant, $F(5,22)=2.89$, $p<0.05$; the addition of AQ and BRIEF scores to the model accounted for 30 percent of variability in deception detection accuracy ($R^2=0.3$). Within the veracity matched condition, BRIEF score was uniquely predictive of accuracy rates such that those with decreased executive dysfunction achieved higher accuracy rates ($\beta=-0.612$, $p<0.05$). Conversely, within the veracity mismatched condition, AQ Total Score was most predictive of accuracy rates such that those with higher self-rated autism symptoms demonstrated higher accuracy ($\beta=0.859$, $p<0.01$).

Conclusions: Preliminary analyses indicate that self-rated autism symptomology and EF skills within ASD and TD uniquely impact deception detection ability across different demeanor-based conditions. Results suggest that EF skills are most important for lie-detection when the accompanying social cues are consistent with the individual's veracity. On the other hand, greater autism symptom severity predicted higher accuracy rates when the individual's social cues are misleading and not indicative of their honesty. These initial findings are inconsistent with research presented by Williams et al. (2018), which suggested that ASD performed similar to TD on mismatched conditions of deception detection. With ongoing data collection, this research will propel the understanding of how individuals with ASD process nonverbal cues in interpersonal domains.

445.038 *(Poster)* No Preference for Direct Versus Averted Gaze in Autistic Adults

*E. Clin, **P. Maes**, F. Stercq and M. Kissine, ACTE — Center of research in Linguistics — ULB Neuroscience Institute, Université libre de Bruxelles, Brussels, Belgium*

Background: Diminished attention to others' faces and eyes is one of the most documented clinical features among the characteristic behaviours encompassed by the deficit in socio-emotional reciprocity that defines autism. However, eye-tracking studies in social attention in autistic adults without intellectual impairment have yield contrasting results.

Objectives: This study aims to assess autistic adults' spontaneous attention to faces, wondering (1) whether a preference for mouths and/or (2) an eye contact avoidance might be observed, and (3) whether patterns of social attention might be influenced by social anxiety, alexithymia and/or gender.

Methods: We have conducted a new reinforced preferential looking paradigm in an autistic group (n = 43, 23 women; age range: 19-55 years, mean: 35,79) paired on age and intellectual quotient to a neurotypical group (n = 43, 21 women; age range: 21-58 years, mean: 35,56). Participants watched two 5 seconds long videos (28 pairs) displayed at the same time on a screen equipped with a remote eye-tracker. The two videos were showing a person uttering a sentence with a neutral expression and only differed from each other in eye gaze direction (direct or averted). The direct gaze videos were reinforced using a brief rewarding animation after a short anticipation window.

Results: Both the neurotypical and the autistic groups fixated significantly less the mouth region than the eye region ($\beta= -0.03$, $se= 0.01$; $t(91.88)= -2.9$, $p=.004$), with no effect of group, gaze direction or gender ($ps>.1$). As shown in Figure 1, neurotypical participants displayed a higher amount of fixations on the stimuli with a direct gaze ($\beta= 0.14$, $se= 0.03$; $z= 5.5$, $p<0.001$), while no such preference emerged in the autistic group ($p=.97$). Accordingly, neurotypical participants fixated more the stimuli with direct gaze than autistic participants ($\beta= 0.1$, $se= 0.03$; $z= 3.3$, $p<0.005$). No group difference emerged relative to the amount of fixation on stimuli with averted gaze ($p=.71$). As suggested by Figure 2, after an initial exploration of both types of stimuli, neurotypical participants quickly focus on the face with a direct gaze, at much greater extent than autistic participants ($\beta= 0.03$, $se= 0.01$; $t(83.03)= 3.35$, $p=.001$). In both groups, a higher alexithymia score correlated with a lower fixation on the stimuli with direct gaze (neurotypical: $\beta= -0.005$, $se= 0.002$; $p=.032$; autistic: $\beta= -0.005$, $se= 0.002$; $p=.012$). The same correlation was found in the neurotypical group for the social anxiety score ($\beta= -0.002$, $se= 0.0008$; $p=.006$), but not in the autistic group.

Conclusions: Those results suggest that, contrary to what is generally assumed, there is no difference in face exploration in autistic adults, compared to neurotypical adults. As expected though, autistic adults fail to display the direct eye gaze preference shown by the neurotypical adults. However, alexithymia seems responsible of the amount of fixation on the stimuli with direct gaze in both groups: alexithymia, and not autism, might predict direct gaze preference.

445.039 *(Poster)* Nonverbal Emotional Expressive Behaviours in Children with Autism: A Meta-Analytic Review

***T. S. Mutusva**[1] and W. Chen[2], (1)Brain & Cognitive Sciences Unit, Visual and Computational Lab, University of Chinese Academy of Sciences, UCAS, Beijing, China, (2)Department of Psychology, Faculty of Science & Technology, Renmin University of China, Beijing, China*

Background: Children with autism spectrum disorders are often faced with difficulty in expressing their emotions, resulting in associated social communication deficit. Children with autism spectrum disorders have impaired use of multiple nonverbal social communication behaviours. Deficits in gestural communication are characteristic of children with autism spectrum disorders. Nonverbal behaviour impairments may include decreased eye contact, restricted affect, limited visual tracking and eye-gaze, and reduced social smiling. This study was a meta-analysis review of emotional expressive behaviour in children with autism spectrum disorders. It evaluated nonverbal social affective cues such as; gestures, gaze behaviour, eye-contact, body posture in emotion expression in children with autism spectrum disorders.

Objectives: The goal of this meta-analysis was to a) summarize what is known about nonverbal social communication behaviour in autism spectrum disorders, b) evaluate how children with autism spectrum disorders make use of nonverbal behavioural cues as part of their emotion expression, and c) identify impairment of nonverbal social behaviour in children with autism spectrum disorders.

Methods: A systematic search was performed in PubMed (MEDLINE), ProQuest (Psychology Database), ScienceDirect (Elsevier) + (Springer-Link; Journal of Autism and Developmental Studies) for papers published between 1998 to 2018. Studies included were those examining social-emotional affective behaviour in the form of any nonverbal action/cues/signals such as; eye-gaze, body posture, gestures and facial affect expression were examined for their effect sizes. All the quantitative data analysis was performed using the Comprehensive Meta-Analysis software program.

Results: 13 studies which tested 331 participants were included. Results show an overall standardized random effects mean effect size grand standard mean deviation of Hedges's *g* 0.357. This medium effect size influence indicates that children with autism have difficulty in the use of nonverbal social communication behavioural cues in their emotion expression. A 95% confidence interval with limits ranging from 0.207 standard deviation to 0.507 standard deviation. The heterogeneity analysis showed that a 95% of the variance in SMD was true and could be attributed to the differences in the ASD group and TD group, Q (13) = 92.847, $I^2 = 87.076$, p = 0.000 means *p-value* < 0.0005 and a T^2 (Tau-squared) value of 0.562. Heterogeneity was $I^2 = 87.076$, indicating considerable greater heterogeneity.

Conclusions: This meta-analysis took a broad review of nonverbal social communicative behaviour. Results show that social communication behaviour; nonverbal cues present challenges to children with autism spectrum disorders. The measures of random effect size show no significance in the relationship between expressed emotion and the use of nonverbal cuessuch as; eye-gaze, body posture, gestures and facial affect expression. Study results and findings support the assertion that children with autism show specific deficits in acquiring convectional social communication or more general deficits that affect cognitive and symbolic functioning especially use of nonverbal emotive cues.

445.040 *(Poster)* On Motor Prediction in Autism Spectrum Disorder

V. Dudarev[1] *and J. T. Enns*[2]*, (1)Psychology, UBC, Vancouver, BC, Canada, (2)Psychology, University of British Columbia, Vancouver, BC, Canada*

Background: There is ongoing debate on whether people with autism spectrum disorder (ASD) can use their motor system to make sense of people's behavior. The most popular way to test this ability is by using imitation tasks, in which participants are either explicitly required to repeat an action, or presented with an opportunity to imitate a partner spontaneously. The results are mixed (Hamilton, 2013; Williams, Whiten, & Singh, 2004). The hypothesis that explicit imitation may be reduced in ASD, while implicit imitation is intact or even enhanced (Sowden et al., 2016) is gaining traction, along with requests for more studies on implicit imitation in ASD (Bird et al., 2007).

Yet imitation is not the only way to assess motor mirroring. We often us our motor system to predict and respond appropriately to the behavior of others (Kilner et al., 2004; Rizzolatti, 1996). A motor prediction task is less constraining than an imitation task, lending itself to a wider variety of responsive actions by the observer. This can be leveraged to investigate not only the accuracy of motor prediction, but also sensitivity to whether the observed actions are controlled internally (i.e., freely chosen) or externally (i.e., directed from outside). For example, Pesquita et al. (2016) used a motor prediction task to show that neurotypical adults are sensitive to whether an action is freely chosen or directed. They also showed that, in neurotypical population, autistic traits are negatively associated with sensitivity to action control. Here we use this paradigm to test, for the first time, motor predictions in children with ASD.

Objectives: The present study examines whether ASD is associated with decreased ability to predict others' motoric actions.

Methods: 20 ASD and 22 typically developing children participated in the study. Participants were presented with videos of an actor who was pointing to the right or to the left, and their task was to predict where the actor would point. Unknowingly to the participants, on half of the trials the actor was directed as to where to point, while on the other half of the trials the actor was choosing the target freely. Accuracy of responses and reaction times (RT) were recorded.

Results: Participants' RT and accuracy were not affected by their diagnostic status (ASD vs. TD). Moreover, both neurotypical and ASD children were responding faster to freely chosen actions than to those directed externally. A 2 x 2 ANOVA revealed a main effect of action control, but neither the interaction with ASD status, nor its main effect were significant.

Conclusions: The present study suggests that children with ASD can predict others' actions just as well as their neurotypical peers. We propose follow-up studies and discuss this finding in context of what is known to date about availability of mirroring mechanisms in ASD.

445.041 *(Poster)* One Year Language Trajectories in Newly Diagnosed Preschoolers with ASD

N. Chong[1]*, M. Santhosh*[2]*, S. Corrigan*[1] *and S. J. Webb*[3]*, (1)Seattle Children's Research Institute, Seattle, WA, (2)Center for Child Health, Behavior and Development, Seattle Children's Research Institute, Seattle, WA, (3)Psychiatry and Behavioral Sciences, University of Washington, Seattle, WA*

Background: One of the most prominent features in children with ASD under 3 years of age is delays in language development (Sachak, 2016). Early childhood represents a critical time window for language interventions in order to support functional/adaptive skills and create greater positive outcomes for children with ASD.

Objectives: (Aim 1) To examine language development in the first year after diagnosis in a sample of preschool children with ASD. (Aim 2) To examine family and child demographic characteristics that account for variability in language development. (Aim 3) To explore the relation between emotional control and language growth.

Methods: Preschool aged children with ASD (N=59; 7 female; M=40.8 months SD 8.6 [28-59] and a matched sample of TD children (N=48; 10 female; M=43.0 months SD 8.6 [29-55]) were enrolled in a study of attention and emotion regulation. Children with ASD were primarily recruited from a wait-list at a regional autism clinic; all children received a first-time diagnosis within the research protocol. At enrollment, autism was confirmed using the ADOS module 1 (no words n=9; some words n=29) or 2 (n=20) and standardized assessments were done to quantify communication ability (Vineland Adaptive Behavior Scales Communication Domain/ VAB), nonverbal (visual) reasoning (Mullen Scales of Early Learning), expressive (EC) and receptive (AC) language (Preschool Language Scale IV/ PLS), and self regulation and executive functioning (Behavior Rating Inventory of Executive Functioning/ BRIEF). The PLS, VAB and BRIEF were repeated at +6 months and +12 months. Difference scores (Time 3 minus T1) were calculated for standard scores; raw and age equivalent difference scores were divided by the time interval (in months).

Results: Preliminary analysis comparing ADOS module scores from T1 to T3 showed that 84% of children who received module 1 progressed to a higher module by T3, confirming an improvement in functional language. For the PLS, standard scores from T1 to T3 demonstrated a >0 change for receptive language with the ASD group showing an increase (M=8.3 SD 12; p<.001) and the TD group showing a decrease (M=-3.4 SD 11.4; p=.05). The ASD group had similar expressive language scores over time (M=2.7 SD 11.7; p=.1); while the TD group showed a decrease (M=-5.0 SD 12; p<.01). The PLS age equivalent change scores showed a similar pattern with an increase in both groups (ASD: AC=1.06, SD .48 [0-2.15]; ASD: EC=.84, SD .56 [-.33-2.13]; TD: AC=.90, SD .51 [-.08-2.3]; EC=.99, SD .58 [-.12-2.2]; *p*s =.10 to .21).

Conclusions: Our preliminary results show that children improved in their functional language skills over the first year after diagnosis, with similar to (or greater than) growth compared to TD children. Our next analysis step (Aim 2) will focus on additional factors that might impact the amount of change, specifically factors such as household income and parental education, which have shown a significant influence on early language development. Lastly, (Aim 3) we will examine the role of emotional control and growth in language development.

445.042 *(Poster)* Operationalizing Compensation in ASD Using Alternative Measures of Social Behavior and Social Cognition

C. E. Freden[1]*, E. J. Libsack*[1] *and M. D. Lerner*[2]*, (1)Stony Brook University, Stony Brook, NY, (2)Department of Psychology, Stony Brook University, Stony Brook, NY*

Background: Compensation is a new framework that proposes the use of alternative behavioral and cognitive strategies to explain discrepancies between levels of social cognition and expected social behavior within individuals with autism spectrum disorders (ASD; Livingston et al., 2017). Compensation research has operationalized behavioral symptoms and social cognition using the Autism Diagnostic Observation Schedule-2 (ADOS-2; Lord et al., 2012) and a Theory of Mind (ToM) task, respectively, with discrepancies between the two factors representing four patterns of compensation ("deep," "high," "low," and "unknown"; Livingston et al., 2018). However, it is unclear whether these variables properly map onto one another (i.e., whether ToM *should reliably* result in lower ADOS-2 social scores), and whether they accurately represent "real-world" social behavior. Utilization of measures which may more accurately capture the compensation construct is a needed step in advancing understanding of this nascent construct.

Objectives: 1.) Examine how use of measures that more directly assess complementary social cognitive and behavioral constructs to operationalize compensation map onto the previously proposed four patterns of compensation in youth with ASD.

2.) Examine whether age, gender, and IQ (Lai et al., 2017) differentiate these patterns of compensation.

Methods: Positive social interaction scores (SIOS-PSI) obtained from videotaped unstructured play coded using the Social Interaction Observation Scale (SIOS; Bauminger, 2002) represented participants' social behavior in "real world" interactions with peers (Table 1A). Composite social cognition (CSC) scores calculated from the self-report Children's Assertive Behavior Scales (CABS; Michelson & Wood, 1982) and self-report Test of Adolescent Social Skills Knowledge (TASSK; Laugeson and Frankel, 2006) represented participants' "real-world" social cognition (i.e., knowledge of what to do in social situations; Table 1A). Moderation models were run to assess differences in compensation patterns based on age, gender, and IQ.

Results: A scatterplot (Figure 2A) was created to map the distribution of "real-world" social behavior versus "real-world" social cognition, resembling the previous compensation scatterplot (Livingston et al., 2018). A significant interaction was found between SIOS-PSI and CSC in predicting age of participants, with "deep" compensators found to be older than "unknown" compensators (Figure 2B), and "deep" compensators also found to be older than "high" compensators.

Conclusions: Findings suggest patterns of compensation in ASD can be operationalized using more direct, complementary measures that may more accurately represent "real-world" social behavior and cognition in ASD by leveraging reliable observations of peer interaction, and utilizing measures of social cognition that more closely parallel those interactions. Using this model, "deep" compensators were older than other groups, but did not differ in IQ or gender. Therefore, some individuals with ASD may gain compensation skills through experience (similar to observations regarding camouflaging; Lai et al., 2017), rather than simply via greater cognitive capacity (i.e., IQ). Results may therefore help explain why older individuals with ASD remain less likely to obtain a formal diagnosis.

445.043 *(Poster)* Perceptions of and Behavior Toward University Students with Autism

J. Lipson[1]*, J. Burk*[1]*, C. L. Dickter*[1]*, C. Taylor*[1] *and C. Borja*[2]*, (1)College of William and Mary, Williamsburg, VA, (2)Psychological Sciences, William & Mary, Williamsburg, VA*

Background: With more ASD-diagnosed young adults attending university than ever before, understanding the challenges they face in the university environment is of critical importance (Adreon & Durocher, 2007). Among these is the presence of negative attitudes toward students with ASD in the student population. Up until now, the research has painted a mixed picture of overall explicit bias toward adults with ASD, with Dickter, Burk, Zeman, and Taylor (2019) identifying evidence of overall implicit bias against individuals with ASD. Research has not, however, examined how explicit and implicit biases toward individuals with ASD predict peer behavior in campus social interactions.

Objectives: This study aimed to create an ecologically valid interaction paradigm for examining neurotypical college students' (n =116) perceptions of and behavior towards college student confederates they believed to have ASD or not. The relationship between explicit and implicit bias was analyzed, as well as the relationships between both of these constructs and interaction behaviors, verbal and non-verbal. In addition, the design sought to account for the differential effects of stereotypically autistic behavior and a publicly-visible ASD diagnosis, as well as their interaction, on peer perceptions.

Methods: Participants completed the study in two separate half-hour sessions. In Session 1, participants completed measures of explicit and implicit bias toward individuals with ASD. In Session 2, participants engaged in a three-minute social interaction with a confederate, centered on a neutral prompt. Confederates were labeled by either membership in an ASD student organization, behavior stereotypical of ASD, both, or neither. Participants' perceptions of the confederate, verbal and non-verbal behavior towards the confederate, and attitudes towards individuals with autism were measured.

Results: Participants who interacted with someone they believed to have ASD had more negative perceptions of their partner's social ability (t = -4.58, p < .001), while self-ratings of discriminatory behavior depended on the interaction of behavior and label (F = 5.52, p = .021). Additionally, the frequency of certain behaviors such as smiling (t = -2.25, p = .027) and fidgeting (t = -2.207, p = .030) depended on whether the participant believed their interaction partner had ASD, and whether this was indicated by a label of ASD diagnosis or the presentation of behaviors consistent with ASD. Finally, participants demonstrated implicit bias against autistic individuals (t = 12.26, p < .001), which had a marginally significant association with explicit bias (r = .12, p = .087), although neither explicit nor implicit bias predicted overall behavior.

Conclusions: The present study found evidence of implicit bias against individuals with ASD, mixed evidence on explicit bias, and a positive, marginally significant relationship between implicit and explicit bias toward individuals with ASD. In general, ASD-consistent behavior tended to elicit more negative judgments of peer behavior, while an ASD label seemed to prompt a compensatory response from participants. Our findings suggest that the means by which students in the general population learn that their ASD peers have ASD has the potential to make a difference.

445.044 *(Poster)* Performance on the Benton Face Recognition Task Demonstrates a Persistent Correlation with ADOS Social Affect across Age, Sex, and IQ in Multiple NDAR Datasets

***I. Zagury-Orly**, L. Soussand and A. L. Cohen, Neurology, Boston Children Hospital, Boston, MA*

Background: Autism Spectrum Disorder (ASD) consists of deficits in two domains: impaired social communication/interaction and restricted/repetitive patterns of behavior, interests, or activities. The severity of these symptoms, however, varies widely in different patients, and there is often poor correlation between symptom severity and impairment in function. Co-morbid symptoms, such as intellectual delay, language deficits, impaired attention, face processing deficits, aggression, anxiety, and depression can also often have a greater impact on function than the core ASD symptoms themselves. Face processing difficulty, one of the numerous co-morbid conditions mentioned above, affects a majority of patients with ASD. While not part of the DSM-5 criteria for ASD, difficulty in recognizing or utilizing facial information is thought to have significant effects on social skill deficits and can be apparent as early as 2 years of age. Thus, research is needed to characterize the relationship between abnormalities in face processing task performance and social affect scores.

Objectives: Although face processing tasks have long been used to study ASD, the importance of face recognition in ASD is still debated. Here, we assess the relationship between the Benton Face Recognition Task (BFRT) and ADOS Social Affect score in the NIMH Data Archive (NDAR).

Methods: We constructed multivariate linear models sequentially adding age, gender, and IQ for three independent NDAR collections: #2179 [n=97], NDAR #6 [n=236], and #2312 [n=135]. We assessed for consistent findings across dataset, generalizability of our models, and the relative effect of BFRT performance, age, gender, and IQ on social affect.

Results: BFRT performance was negatively correlated with social affect score in all three datasets, and persisted after controlling for age, gender, and IQ. Using all available subjects, the relationship between BFRT task performance and social affect (r=-0.37, p<0.00001) persisted across age groups, with the interesting exception of adolescence (ages 12-18), while males generally demonstrated worse social affect as compared to females (9.58 vs. 7.04, p-value<0.00001). Finally, the correlation between BFRT and social affect was stronger in subjects with higher IQs and lowest in those with the lowest IQs. To assess the generalizability of this finding, models were generated from each dataset and used to predict scores in the other datasets. These models were consistently able to explain a small but significant portion of the variance in social affect score in the other, test, datasets (avg r=0.37, all p<0.05).

Conclusions: Across 468 subjects, face recognition task impairment is both common and consistently negatively correlated with social affect. This large cohort finding informs interventional trials targeting face processing, the utility of face recognition tasks as possible early behavioral biomarkers for ASD.

445.045 *(Poster)* Predicting Camouflaging of Autistic Traits with Social Competence in a Neurotypical Undergraduate Sample

***M. T. O'Reilly**[1,2], H. Visser[1], T. Q. Boucher[1], N. E. Scheerer[1] and G. Iarocci[1], (1)Psychology, Simon Fraser University, Burnaby, BC, Canada, (2)Cognitive Systems, University of British Columbia, Vancouver, BC, Canada*

Background: Social communication and interaction difficulties are a defining feature of Autism Spectrum Disorder (ASD). In social settings, individuals with ASD often develop techniques to "camouflage" so that their social behaviours appear similar to that of their non-autistic peers (Hull, Petrides, Allison, et al., 2017). Although camouflaging may help individuals navigate social environments, it has also been shown to result in negative psychological outcomes (Hull et al., 2017). However, it is unclear whether camouflaging is a social strategy specific to autistic individuals, or if it is a strategy that is also adopted by individuals without ASD but who have social difficulties.

Objectives: This study explored whether a relationship exists between social competence and camouflaging behaviours in a non-autistic sample.

Methods: A total of 247 participants between the ages of 17 and 34 years old (M_{age}=20.03; 176 female; 71 male) participated in this study. Participants were recruited from introductory psychology classes at Simon Fraser University. Participants completed the Wechsler Abbreviated Scale of Intelligence 2nd Edition (WASI-II; Wechsler, 2011), a demographic questionnaire, and three self-report questionnaires, including the Multi-Dimensional Social Competence Scale (MSCS; Yager & Iarocci, 2013), the Camouflaging Autistic Traits Questionnaire (CAT-Q; Hull et al., 2019), and the Brief Rating Inventory of Executive Function – Adult Version (BRIEF-A; Roth, Isquith, & Gioia, 2005).

Results: Using a hierarchical multiple linear regression, we found that in addition to gender, IQ, and executive functioning scores, participant's social competence (MSCS) scores predicted the extent to which non-autistic individuals camouflaged behaviours in social environments (F(4, 242)=22.518, p<.001; R^2=.271). Social competence (MSCS) scores accounted for 16% of the variance in camouflaging (CAT-Q) scores (R^2=.157, F(1, 242)=52.196, p<.001).

Conclusions: The current study found that lower social competence scores were associated with increased camouflaging behaviours in non-autistic participants. These results, in conjunction with results of previous studies, suggest that autistic individuals (Hull et al., 2017; Hull et al., 2019; Lai et al., 2019), as well as non-autistic individuals use camouflaging to hide or minimize undesirable behaviours when engaging in social situations in an attempt to "fit in" with others. Although camouflaging may be more prevalent in individuals with ASD whose social difficulties are clinically significant, the results of the current study suggest that camouflaging is a strategy used by many individuals who have difficulty with social interactions. Addressing the negative psychological effects of camouflaging should consider both autistic and non-autistic participants with social difficulties. In addition, given that camouflaging behaviours are being performed in an attempt to adapt one's social behavior in line with that of others', these results also highlight the importance of conceptualizing the social challenges that autistic people face within a broader relational context of interactions that include bi-directional influences and not simply a matter of reducing the stigmatization associated with the person's autistic traits.

445.046 *(Poster)* Pro-Social and Empathic Behaviors of Adolescents with ASD in Response to Others' Distress

R. Kliger[1], *. J. Rabin*[1], *I. Mor Snir*[2] *and O. Golan*[1,2], *(1)Department of Psychology, Bar-Ilan University, Ramat-Gan, Israel, (2)Association for Children at Risk, Givat Shmuel, Israel*

Background: Empathy, defined as the ability to tune into others' emotional states and to provide an appropriate affective response, has been long described as an area of difficulty for individuals with Autism Spectrum Disorder (ASD). Difficulties with the expression of empathy have been described in ASD from early childhood. However, the transition to adolescence, which requires more sophisticated empathic and prosocial behaviors, has received little empirical attention. Moreover, despite its central role in social behavior, empathic ability has been mostly assessed through self-report questionnaires rather than behaviorally. A behavioral assessment may be more sensitive in examining change following interventions that tap on empathic behavior in adolescents, such as social skills training groups.

Objectives: The current study had two objectives: (1) to behaviorally examine the empathic and pro-social responses of adolescents with ASD following a friendly stranger's distress; and (2) to test the sensitivity of this behavioral assessment to change, following social skills training.

Methods: Sixty-three adolescents aged 12-18 (M=14.13, SD=1.69), diagnosed with ASD (confirmed by ADOS-2), with no intellectual or language impairments were tested using the Pro-Social and Empathic Behavioral Assessment (PEBA) - a semi-structured interaction, which involves a 3 minute friendly conversation with an unfamiliar confederate who, on the 4th minute, expresses distress after receiving a text message. The confederate then returns to a friendly conversation on the 5th minute. Assessments were videotaped and participants were rated separately for minutes 3, 4, and 5 by blind, reliable raters, on 10 scales of nonverbal synchrony, pro-social, and empathic behavior. PEBA was administered to participants again after 8 months, with different distress manipulations, and different confederates. In between assessments, participants took part in a 16-week PEERS® (Laugeson & Frankel, 2010) intervention. In addition, participants, their parents, and their teachers filled out the Social Responsiveness Scale (SRS-2, Constantino & Gruber, 2012).

Results: Significant differences between PEBA's three coded segments (minutes 3,4,5) were found for participants' comments, synchrony of vocal intonation and facial expressiveness, and appropriate emotional reaction. During PEBA's distress manipulation minute (4), participants' emotional reaction and prosocial behavior correlated with ADOS-2 scores; participants' interest in the confederate, appropriate emotional reaction, pro-social behavior, and social understanding correlated with SRS-2 self-reported social awareness subscale; participants' synchrony of posture with the confederate correlated with parents' and with teachers' overall SRS-2 scores, and participants' appropriate emotional reaction correlated with teachers' overall SRS-2 scores.

Significant changes on PEBA scores before and after the PEERS® intervention indicated intervention-related increased interest in the confederate, synchrony of facial expressions, eye-gaze, and posture, and decreased anxiety.

Conclusions: Our results showed that the PEBA can distinguish between friendly and distressed social contexts, allowing to behaviorally measure empathic and pro-social behavior in adolescents with ASD. Different aspects of empathic and prosocial behavior were associated with adolescents' vs. parents' and teachers' report on the SRS-2, suggesting the PEBA successfully captures both perspectives. Finally, our findings on PEBA scores pre and post the PEERS® intervention support its sensitivity in measuring intervention-related changes in empathic and pro-social behavior.

445.047 *(Poster)* Resting-State EEG Asymmetry and Irritability in Children with ASD: The Autism Biomarkers Consortium for Clinical Trials.

J. T. Benton[1], *M. Santhosh*[1], *H. M. Borland*[1], *R. Bernier*[2], *G. Dawson*[3], *J. Dziura*[4], *S. Faja*[5], *A. R. Levin*[6], *A. Naples*[7], *E. Neuhaus*[8], *F. Shic*[1], *C. Sugar*[9], *J. McPartland*[7] *and S. J. Webb*[2], *(1)Center for Child Health, Behavior and Development, Seattle Children's Research Institute, Seattle, WA, (2)Psychiatry and Behavioral Sciences, University of Washington, Seattle, WA, (3)Department of Psychiatry and Behavioral Sciences, Duke Center for Autism and Brain Development, Durham, NC, (4)Yale University, New Haven, CT, (5)Boston Children's Hospital, Boston, MA, (6)Neurology, Boston Children's Hospital, Boston, MA, (7)Child Study Center, Yale University School of Medicine, New Haven, CT, (8)Seattle Children's Hospital, Seattle, WA, (9)University of California, Los Angeles, Los Angeles, CA*

Background: Autism Spectrum Disorder (ASD) is a developmental disorder characterized by difficulties with social communication and behaviors. Frontal alpha asymmetry power (FAA) in resting-state EEG has been investigated as a biomarker for ASD (for review, Wang et al., 2012). Right FAA is a marker of behaviors associated with withdrawal and other negative temperament characteristics, which may contribute to trajectories in ASD. Irritability commonly occurs in ASD and has been one of the primary targets of medication clinical trials. It is unclear if irritability is linked to approach or withdrawal motivation and corresponding asymmetrical activity in the brain.

Objectives: To examine irritability as measured by the Aberrant Behavior Checklist (ABC) in relation to diagnosis, symptoms, cognition, and verbal ability, and frontal alpha asymmetry in children with ASD.

Methods: The Autism Biomarkers Consortium for Clinical Trials (ABC-CT) is a NIH funded multicenter study that investigates potential biomarkers for use in clinical trials. Parents completed the ABC-Irritability Scale (ABC-I; Fung et al., 2016), as part of a clinical battery; additional measures of clinical symptoms include the ADOS calibrated severity score and the DAS-II nonverbal and verbal IQ (to measure cognition and verbal abilities).

A high-density EEG multi-experiment battery was administered, starting with a Resting State (calm-viewing) experiment in which participants watched screen saver-like videos. EEG was processed as in Levin et al. (2018) and FAA was calculated (Sun, Peräkylä, & Hartikainen, 2017) between left and right regions. ANOVAs were conducted to compare ABC-I by group and sex; and then to examine FAA in children with and without clinical levels of irritability.

The ABC-CT interim sample consisted of 225 subjects of which 139 ASD (males=112) and 62 TD (males=40) aged 6 to 11 years had both ABC-I and valid resting-state EEG data.

Results:

There was a significant difference between groups in irritability symptoms, with TD participants (raw M=0.94 SD=1.75) reporting less symptoms than ASD (raw M=11.67 SD=9.12) ($F=84.29$, $p<.001$). There was also a sex difference with male children (raw M=8.98 SD=9.48) scoring higher than female children (raw M=6.43 SD=4.24)($F=2.94$, $p=0.09$).

Based on a clinical cutoff of 18 on the ABC-I (Brown, Aman, & Havercamp, 2002), participants were divided into high (+I) and low (-I) groups (105 ASD-I, 34 ASD+I, 62 TD-I). Because there were no TD children with high irritability, we did not include the TD children in this preliminary phase of the analysis. For the ASD children with and without clinical levels of irritability, FAA was not significantly different (ASD+I M=0.05 SD 0.28; ASD-I M=0.03 SD 0.25; $F=0.22$, $p=0.64$).

Conclusions: While ASD children were reported as having more irritability behaviors that TD children, our preliminary analysis do not suggest a relationship between clinical levels of irritability and resting-state EEG FAA. As a next step, we will examine categorical descriptions of FAA (right frontal bias, left frontal bias, and no bias) and rates of clinical irritability. We will also compare FAA to ABC-Social Withdrawal as a contrasting parent report metric of approach/withdrawal behaviors.

445.048 *(Poster)* Self-Determination in Adolescents with Autism: Findings from a Nationally Representative Sample

***X. Qian**, University of Kansas, Lawrence, KS*

Background: Self-determination refers to one's ability to cause things to happen in one's life. It has been shown to be associated with employment and postsecondary outcomes among students with Autism. Research has shown lower levels of self-determination in adolescents with Autism compared to other disability groups (Chou et al., 2017; Wagner et al., 2014), yet these studies have methodological constraints. They either used convenient sample, thus may not be representative of the Autism population or used a representative sample from the National Longitudinal Transition Study-2, which were collected more than a decade ago. Using data from the National Longitudinal Transition Study-2012, a more recent data of national representative sample, this study aims to compare self-determination in high school students with Autism to other disability groups.

Objectives: This study addressed two questions: (1) Can measurement invariance be established among the seven disability groups? (2) If so, what are the latent differences (i.e., means and variances) in the autonomy, psychological empowerment, and self-realization in youth across these disability categories? We hypothesize that students with ASD have lower level of self-determination compared with students with other disabilities**.**

Methods: We included students with IEP under the 12 disability groups described in IDEA who have completed the youth survey (n=7,150). The average age of this sample is 15 years of age,

Following measurement invariance testing, we further examined differences among latent means, variances and correlations across the disability groups (Little, 1997). We used effects coding in conjunction with the mean and covariance structures (MACS) model, allowing us to make direct comparisons on latent parameters across groups using nested chi-square tests.

Results: We applied constraints across loadings and intercepts and did not find significant differences across the disability groups. At each stage of invariance testing, CFI changes were less than .01 and/or nested models fell within 90% CI of RMSEA for each nested model comparison, so we assumed invariance. Subsequently we established a structural model to test the differences in autonomy, psychological empowerment, and self-realization. Likelihood ratio tests showed that the autism group is significantly lower than all other disability groups in autonomy. We have also found a high correlation between psychological empowerment and self-realization among autism group ($r= 0.815$), cognitive Disabilities group ($r= 0.924$), and orthopedic Impairments ($r=0.886$), suggesting that these two constructs may not discriminate from each other. Of the three subscales associated with self-determination (autonomy, self-realization, and psychological empowerment), autonomy subscale showed the greatest variability, suggesting other variables may contribute to the variability among students with Autism.

Conclusions: Consistent with previous research, the results from the current study demonstrate that adolescents with Autism continue to lag behind their peers with disabilities in self-determination. Researchers have proposed that providing support in the area of social skills may be one strategy to enhance self-determination in this population. Future research needs to further examine the contextual factors associated with low levels of self-determination in students with Autism.

445.049 *(Poster)* Sex Differences in Early Language Milestones and Later Language Functioning in Youth with ASD: The ACE Gendaar Network

R. D. Fung[1]*, M. Santhosh*[2]*, A. Kresse*[3] *and S. J. Webb*[4]*, (1)Child Health, Behavior and Development, Seattle Children's Reserach Insitute, Seattle, WA, (2)Center for Child Health, Behavior and Development, Seattle Children's Research Institute, Seattle, WA, (3)Seattle Children's Research Institute, Seattle, WA, (4)Psychiatry and Behavioral Sciences, University of Washington, Seattle, WA*

Background: Autism Spectrum Disorder (ASD) is characterized by disruptions in social, behavioral, and communication behaviors. Recognizing risk factors at a young age is important for more accurate and earlier diagnosis and timely intervention (Kover et al., 2016). Meeting early language milestones has been identified as a strong predictor of positive language outcomes individuals with ASD (Mayo et al., 2013). Females compared to males show better early cognitive and language functioning, including high risk infants with and without ASD outcomes (Messinger et al., 2015). Less is known about language trajectories in females with ASD, as they often make up a minority of research participants. In previous work, we had reported similar achievement of motor milestones (e.g., age of first walking); however meeting early language milestones did not predict the age of initial concerns, nor time to diagnosis (Harrop et al., 2019).

Objectives: To evaluate the relationship between early language milestones (age at first words, age at 3-word phrases) and youth language (CELF formulated sentences; CELF recalling sentences) and communication (Vineland communication domain) ability in a sex balanced sample with ASD.

Methods: This study used data from the ACE GENDAAR network, a four site NIH funded project examining sex-based genetic and neural differences in children with ASD. The project included 137 youth (female=60, male=77) ages 8-18 years with ASD. ASD diagnosis was confirmed via ADOS-2, ADI, and DSM-V criteria. All children scored a ≥70 on the Verbal Domain on the DAS-II to measure cognitive abilities.

To assess language, parents reported age at first words and age at 3-word phrases on the ACE Medical History (and confirmed with the ADI which includes similar items). Participants completed the CELF-4 (with analysis focusing on the subdomains Recalling Sentences and Formulating Sentences as these were available on the most participants), and parents completed the Vineland Adaptive Behavior (Communication Domain).

Results: Independent t-tests showed no sex difference in age (t[135]=0.15, p=ns) and verbal IQ (t[135]=0.38, p=ns). For females with ASD, age at first words was correlated with recalling sentences and formulating sentences (RC: r=-.36, p<.01; FS: r=-.31, p<0.05). The Communication Domains on the Vineland Adaptive Scale showed significant correlations with age at first words for females (r=-.26, p<0.05). There were no relations between age at first words and later language or communication abilities in males with ASD (RC: r=-.02, p=ns; FS: r=-.04, p=ns; communication: r=.1, p=ns)

Age at 3 words was related to recalling sentences for females (r=-.28, p<0.05) and males (r=-.25, p<0.05). Age at 3 words and formulated sentences showed correlations for males (r=-023, p<0.05). Age at 3 words and Vineland Communication scores showed no significant relation for females (r=-.13, p=ns) and males (r=-.01, p=ns).

Conclusions: Our preliminary analysis demonstrated significant differences by sex in early language milestones and relation to later language ability as a youth. Age at first words related to later language only in females with ASD; while age at 3 words was related to later outcomes for males and females. Additional analyses will explore the specificity of these relations with group of TD controls and siblings of children with ASD.

445.050 *(Poster)* Situational Use of Camouflaging in an Everyday Social Context: An Interpersonal Process Recall Study

J. Cook[1]*, L. Crane*[2] *and W. Mandy*[3]*, (1)Psychology and Language Sciences, University College London, London, United Kingdom, (2)Centre for Research in Autism and Education, UCL Institute of Education, University College London, London, United Kingdom, (3)University College London, London, United Kingdom of Great Britain and Northern Ireland*

Background: Social camouflaging is defined as 'the use of strategies by autistic people to minimise the visibility of their autism in social situations' (Hull et al., 2019, p. 819). Many autistic adults report that, despite personal costs, they engage in camouflaging in a range of everyday social contexts such as in interactions with work colleagues, friends, and the general public (Cage & Troxell-Whitman, 2019). Whilst existing research has attempted to quantify autistic adults' camouflaging during a clinical situation (Lai et al., 2017), to date, no study has examined autistic adults' camouflaging during an everyday social situation.

Objectives: This study had two aims:

Firstly, to identify the specific behavioural and cognitive camouflaging strategies used by autistic individuals during a quasi-everyday social situation.

Secondly, to explore the process and experience of camouflaging in autistic individuals during this quasi-everyday social situation.

Methods: For the first time in autism research, this study employed Interpersonal Process Recall (IPR: Kegan, 1969, 1975; Kagan, Krathwohl, & Miller 1963a, 1963b) methodology. IPR is a qualitative, video-assisted recall interview approach designed to explore individuals' conscious yet unspoken experiences as they occurred during a specific interpersonal interaction. 17 autistic adults (8 female, 6 male, and 3 who were agender/gender neutral) participated in a ten-minute controlled social task designed to replicate a common everyday social situation. Participants then watched a video of their interaction with a researcher, actively identifying instances of camouflaging and discussing their experiences of the interaction with the aid of a semi-structured interview guide.

Results:

Results demonstrated that autistic adults use a diverse range of behavioural and cognitive camouflaging strategies during social interactions; internal and external factors modulate the use of these camouflaging strategies; and the use of camouflaging strategies combined with internal and external factors effect individuals' experience of social interactions.

Conclusions: Autistic adults report common experiences, related to both internal and external factors, in using camouflaging strategies in an everyday social context. This research can contribute to the current understanding of camouflaging and in turn improve the day to day well-being of autistic adults.

445.051 *(Poster)* Social Approach and Visual Scanpaths in Autism Spectrum Disorder and Williams Syndrome: The Role of Biographical Information

K. A. Boulton[1]*, A. J. Guastella*[1] *and M. A. Porter*[2]*, (1)Brain and Mind Centre, Children's Hospital Westmead Clinical School, Faculty of Medicine and Health, University of Sydney, Sydney, NSW, Australia, (2)Macquarie University, Sydney, NSW, Australia*

Background: Neurodevelopmental disorders such as Autism Spectrum Disorder (ASD) and Williams syndrome (WS) provide a unique insight into the mechanisms that underpin social behaviour. Past research indicates: social avoidance in ASD (Kim et al., 2015) and elevated social approach in WS (Frigerio et al., 2006); reduced fixation towards faces in ASD (Chita-Tegmark, 2016) and increased gaze towards the eye region of faces in WS (Porter et al., 2010). While prior research in neurodevelopmental disorders has focused on perceptual information (faces displaying emotional expressions) when examining social approach and eye gaze patterns, this study investigated whether top-down biographical information could influence approach decisions and gaze patterns. Faces were primed with trustworthy or untrustworthy biographical information.

Objectives: The aims were to investigate: (a) how biographical knowledge influences social approach decisions and (b) whether ASD and WS individuals exhibit differences in gaze patterns towards faces as a function of prior biographical knowledge.

Methods: Participants included 15 individuals with high-functioning ASD, 15 individuals with WS, and 30 neurotypical controls - 15 matched to the clinical groups on chronological age and 15 matched to the WS group on mental age. All participants memorised biographical vignettes depicting trustworthy or untrustworthy characters, paired with faces displaying neutral expressions. Social approach ratings and eye movements were then recorded.

Results: Approach ratings: The only significant between group difference observed was for untrustworthy characters, which showed that ASD and WS individuals rated untrustworthy characters as significantly more approachable compared to chronological age matched controls. Within-group analyses revealed that all groups displayed the expected rank order of approach, with trustworthy characters being rated as significantly more approachable than untrustworthy characters. **Eye gaze patterns:** Significant between-group differences were observed, with the ASD group spending significantly less time looking at the eye regions of trustworthy characters relative to chronological age matched controls. WS individuals spent less time looking at the eye region of untrustworthy characters relative to chronological age matched controls. Within-group analysis showed that ASD individuals spent significantly more time looking at the eye region of untrustworthy characters compared to trustworthy characters, whereas the opposite pattern was observed in the WS group. WS individuals looked at the eye region of trustworthy characters for longer durations relative to untrustworthy characters.

Conclusions: Results suggest that both approach ratings and eye gaze patterns are influenced by prior biographical knowledge. For ASD and WS individuals, the type of biographical knowledge associated with a face determined the amount of time spent looking at the eye region. The theoretical and practical implications of this study, including the contrasting eye gaze patterns observed in ASD and WS are discussed.

445.052 *(Poster)* Social Challenges in School-Age Children with Sensory Differences, ASD, and Typical Development

J. Sabin[1]*, T. St. John*[1]*, J. Munson*[2]*, A. Estes*[3] *and N. M. Kleinhans*[1]*, (1)University of Washington, Seattle, WA, (2)Psychiatry & Behavioral Sciences, University of Washington, Seattle, WA, (3)Speech and Hearing Sciences, University of Washington, Seattle, WA*

Background: Social challenges, such as making friends, engaging in play with peers, and understanding social cues and rules, are not exclusive to children with Autism Spectrum Disorder (ASD). Children with sensory differences (e.g., sensory seeking behavior, sensory sensitivities, difficulties with sensory integration, etc.) without autism (SD) also experience social challenges. Compared to typically developing peers (TD), SD children experience more conflict during play with peers and respond less frequently to the social cues of their playmates (Cosbey, 2012). Research also suggests that SD children have worse overall social adaptive behaviors compared to children without SD (Ben-Sasson, 2009). However, there is very little research investigating the differences in the social challenges of SD children compared to ASD and TD children.

Objectives: To examine differences in social challenges among school-age SD children, ASD children, and TD children.

Methods: Participants were 8-12 years old with SD (n=47), ASD (n=43), and TD (n=47) who participated in a larger study focused on understanding the biochemical, brain, and behavioral correlates of social challenges and sensory sensitivity in children with ASD (Social and Sensory Processing Study). All children in the ASD group met clinical best estimate (CBE) diagnosis using the ADI-R, ADOS-2, and DSM-5. Children in the SD group had at least one sensory difference ("more than others") on the Sensory Profile 2 (SP-2; Dunn, 2014) and did not meet CBE diagnosis for ASD. Children in the TD group did not have sensory differences on the SP-2 and did not meet CBE for ASD. Social challenges were measured using the Peer Social Contact Questionnaire (PSCQ; Estes et al., 2018), SRS-2 Total Score (Constantino, 2012), and the Social Affect Calibrated Severity Score on the ADOS-2 (ADOS-SA-CC; Hus, 2014). PSCQ scores included number of friends (max=5) and two composite scores (conflict with peers [Conflict] and parent support needed during play with peers [Parent Support]). Full Scale IQ was assessed with the WASI (there were no significant group differences).

Results: The SD group differed from the ASD group on number of friends ($F(1,88)=5.65$, $p<0.05$) but did not differ from the TD group. The ASD and TD group differed on number of friends ($F(2,134)=9.49$, $p<0.01$). The SD group and ASD group differed from the TD group in Conflict ($F(2,123)=7.31$, $p<0.01$), Parent Support ($F(2, 121)=18.22$, $p<0.01$), SRS-2 Total Score ($F(2, 134)=116.84$, $p<0.01$), and ADOS-SA-CC ($F(2, 134)=86.70$, $p<0.01$). Further, the SD group differed from the ASD group on SRS-2 Total Score ($F(1, 88)= 5.59$, $p<0.05$) and ADOS-SA-CC ($F(1, 88)=61.65$, $p<0.01$). Means and standard deviations are presented in Table 1.

Conclusions: School-age SD children have a similar number of friends as TD children but have more challenges getting along with these peers and require more parent support during play interactions. SD children also demonstrate more general social difficulties than TD children but less than ASD children. Interestingly, SD children experience as much conflict with peers and need for parent support during play as ASD children, suggesting that social skill development and intervention targeting social problem-solving could be beneficial.

445.053 *(Poster)* Social Competence, but Not Autism Knowledge or Experience, Predicts Negative Judgments of Autistic Adults

T. Q. Boucher[1], *N. E. Scheerer*[1,2] *and G. Iarocci*[1], *(1)Psychology, Simon Fraser University, Burnaby, BC, Canada, (2)Psychology, Western University, London, ON, Canada*

Background: Autistic individuals struggle to develop friendships, leading to social isolation and a high risk of victimization (Sterzing et al., 2012). The social challenges faced by autistic people arise in part from the behaviors of their non-autistic peers. Individuals have negative first impressions of autistic people, without knowledge of their autism diagnosis (Sasson et al., 2017). This may occur because people notice signs of poor social competence in autistic individuals and because they lack knowledge about the meaning of autistic behaviour. Interventions aimed at educating individuals about the characteristics and behaviours associated with autism may promote more positive judgements of autistic people (Gillespie et al., 2015).

Objectives: (1) Assess whether an educational intervention can promote more positive judgements of autistic individuals, and (2) whether one's previous experience with autistic individual and social competence can predict judgments and behavioural intent towards autistic people.

Methods: 148 high school students without autism participated. Condition 1: Students (n=74, M_{age}=17.23, SD=0.65) watched a live 50-minute educational presentation covering core characteristics associated with autism before completing an autism stigma task, where they judged 10-second videos of adults with (n=20) and without autism (n=20). Condition 2: Students (n=74, M_{age}=17.30, SD=0.56) completed the autism stigma task before receiving the educational intervention. Following each video in the stigma task, participants answered 10 questions that rated the perceived traits of the individual in the video and the participant's own behavioural intentions towards that individual using a four-point scale. Participants also completed the Multidimensional Social Competence Scale (MSCS) to assess social competence, and the Level-of-Contact Report (LoC) and the Quality of Past contact (QoC) to assess previous experiences with autistic individuals.

Results: A bias score was calculated by subtracting the ratings of autistic adults from those of the non-autistic adults. Autistic adults were rated more negatively regardless of the participant's condition (F(1,146)=263.607, p<.001). A hierarchical linear regression indicated that when condition (R^2=.003, p=.556) and LoC and QoC scores (R^2=.020, p=.298) were entered into the model, variance in bias scores was not accounted for. However, when MSCS scores were added (R^2=.058, F(1,134)=5.355, p=.022), a significant amount of variance in bias scores was accounted for.

Conclusions: Participants held negative judgments towards autistic individuals, replicating previous findings. Overall, the educational intervention did not reduce negative perceptions of autistic individuals. However, higher social competence predicted negative judgments, suggesting that the negative bias may involve a perception of difference between one's own and the other's social competence. Recently acquired autism knowledge (educational intervention) or previous experiences with autistic individuals (QoC and LoC) did not influence judgments of autistic individuals; further investigation is required to determine the factors that influence negative first impressions of autistic people

445.054 *(Poster)* Social Contagion Shows Distinct Patterns in Individuals with Autistic Versus Psychopathic Traits.

T. Sorenson[1], ***R. Scheub***[2], *M. Nakhle*[3] *and M. S. Helt*[4], *(1)New England Center for Children, Southborough, MA, (2)Neuroscience, Trinity College, Hartford, CT, (3)Trinity College, Hartford, CT, (4)Psychology and Neuroscience, Trinity College, Hartford, CT*

Background: Contagious yawning is observed more frequently in individuals with high levels of empathy (Platek, Critton, Myers, and Gallup, 2003) and less frequently in individuals with Autism Spectrum Disorder (ASD) (Giganti & Esposito-Ziello, 2009; Helt et al., 2010; Senju et al., 2007) and individuals with high levels of psychopathic traits (Rundle, Vaughn, & Stanford, 2015).

Objectives: Although ASD and psychopathy have both been broadly referred to in previous literature as "empathy disorders," the current study aimed to investigate whether distinct processes underlie the reduced contagious yawning in these groups.

Methods: Trinity College Students (n = 73) were presented stimuli of individuals yawning or scratching on an Applied Science Laboratories (ASL) desktop eye tracking system. Participants' eye movements were tracked and analyzed for time, and percent of time fixated on the eyes of the people in the stimuli videos. Participants were administered the Interpersonal Reactivity Index (IRI) (Davis, 1980), a multidimensional assessment of empathy, the Autism-Spectrum Quotient (AQ) (Baron-Cohen, et al. 2001), The Psychopathy Personality Inventory Revised (PPI-R) (Lillienfield et al., 2005), and the Adolescent and Adult Sensory Processing Disorder Checklist.

Results: Higher empathy, lower psychopathy and lower ASD traits were all initially positive predictors of contagious yawning. However, the relationship between ASD traits and contagious yawning was mediated by eye gaze. Furthermore, ASD traits were not significantly associated with overall levels of empathy on the IRI. In contrast, psychopathic traits were significantly and inversely related to overall empathy levels. In addition, participants with high levels of psychopathic traits showed low levels of contagious itch, whereas individuals with high levels of ASD traits showed typical levels of contagious itch, and this was mediated by differences in levels of personal distress (a subscale of the IRI) between the two groups.

Conclusions: These behavioral differences between groups are consistent with the hypothesis that individuals with high levels of psychopathic traits show reduced contagion due to primary deficits in emotional empathy, whereas individuals with high levels of autistic traits show reduced contagion secondary to the avoidance of direct eye gaze and unrelated to background deficits in emotional empathy.

445.055 *(Poster)* Social and Non-Social Attention in Autism Spectrum Disorder: Stimulus Complexity and Gender-Congruence Matter

C. Harrop[1], *N. J. Sasson*[2] *and J. Parish-Morris*[3], *(1)Department of Allied Health Sciences, University of North Carolina at Chapel Hill, Chapel Hill, NC, (2)University of Texas at Dallas, Richardson, TX, (3)Center for Autism Research, Children's Hospital of Philadelphia, Philadelphia, PA*

Background: Converging evidence across methodologies suggests that females with a diagnosis of Autism Spectrum Disorder (ASD) are phenotypically distinct from males. Two areas of particular interest that have been found in both behavioral and eye-tracking studies are differences in social motivation and typical/gender-normative interests.

Objectives: We capitalized on existing eye tracking data from participants who completed three eye-tracking paradigms varying in social complexity and the *gender-typicality* of objects. Aggregating data across studies, we (a) describe the distribution of attention across each paradigm and (b) estimate the effectiveness of different stimuli for distinguishing between (1) diagnostic groups (ASD vs. TD) and (2) biological sex (male vs. female).

Methods: 67 children (6-10 years) completed three eye tracking paradigms (39 ASD, 28 TD; Table 1). The paradigms included (1) *Social vs. Object Paired Preference Paradigm* (Sasson & Touchstone, 2014)*;* (2) *Interactive Visual Exploration* (Chevallier et al., 2015); and (3) *Interactive Visual Exploration–Gendered* (Fig.1)*.* Analyses focused on common variables across paradigms; overall attention and social attention. We used a Receiver Operating Characteristic (ROC) to examine how the different paradigms differentiated based on (1) diagnosis and (2) sex.

Results: Controlling for MA and CA, we ran repeated measures GLMs examining the effects of diagnosis and sex on attention. For overall attention, there was a marginal effect of paradigm and significant main effect of diagnosis. TD groups sustained greater visual attention across all paradigms (F=7.45, p=.008). Attention was greatest to the *Interactive Visual Exploration–Gendered* paradigm. There was an interaction between paradigm and diagnosis (F=4.67, p=.03); TD groups attended to both Visual Exploration paradigms more. For social attention, only diagnosis differentiated groups (F=5.77, p=.02), with TD groups attending more to social stimuli across paradigms.

ROC-Diagnosis: For overall and social attention, the area under the ROC curve was greatest for the Social vs. Object Paradigm (Overall: .40; 95% CI=.19 - .46; Social: .46, 95% CI=.22 - .49) suggesting this paradigm most sensitively differentiated diagnostic groups.

ROC-Sex: Substituting diagnosis for sex, the area under the ROC curve was greatest for overall attention in the Visual Exploration–Gendered Paradigm (.58, 95% CI=.44 - .72). The area under the curve did not differ for social attention across paradigms.

Conclusions: Our dynamic and more ecologically valid paradigms produced the largest differences between diagnostic groups. That is, as paradigms increased in socially complexity and better approximated real life, differences between groups increased. Attention was greatest to the paradigm that included *gender* in its design. However, our ROC analyses were less conclusive than those reported by Chevallier et al (2015); despite group differences, visual exploration paradigms were not the most accurate in distinguishing between diagnoses. Instead, the simplest paradigm – Social vs. Object – had the greatest sensitivity. However, the Visual Exploration–Gendered Paradigm that considered gender in its design was the most accurate for distinguishing between males and females based on overall attention. Overall our findings suggest the design of experimental paradigms, the inclusion of greater number of ASD females and the consideration of gender within paradigm design is important for future research.

445.056 *(Poster)* Social and Non-Social Self-Assessment in Autistic Adults

***K. M. DeBrabander**, D. R. Jones and N. J. Sasson, University of Texas at Dallas, Richardson, TX*

Background: Research into the cognitive mechanisms underlying social impairments in autism has largely focused on social cognitive differences, but autism is also characterized by differences in metacognition, or the awareness of one's own cognitive abilities and processes. One aspect of metacognition that may relate to functioning in autism is self-assessment, or the ability to accurately evaluate one's own ability in various domains. Self-assessment errors have been found to relate to functioning in other clinical conditions such as schizophrenia and depression but have been largely unexamined in autism.

Objectives: This study compares self-assessment in autistic and non-autistic adults for both social-cognitive and neurocognitive tasks and assessed their relations to social functioning.

Methods: 35 autistic adults and 37 non-autistic controls comparable on age (M_{ASD} = 24.49, SD_{ASD} = 5.10, M_{TD} = 23.48, SD_{TD} = 5.00) and IQ (M_{ASD} = 110.08, SD_{ASD} = 10.62, M_{TD} = 112.03, SD_{TD} = 7.47) completed three measures of social cognition and three measures of neurocognition in a randomized order. The three social-cognitive tasks were: 11) the Penn Emotion Recognition task (ER-40); 2) the short-form Benton Facial Recognition Test (BFRT); and 3) The Awareness of Social Inference Test, Part 3 (TASIT). The three neurocognitive tasks were: 1) the Line Orientation Task; 2) the Digit Span; and 3) the Matrix Reasoning Task. Following each task, participant self-assessment was measured in two ways. First, participants were told how many items there were on the task and asked to enter in the number that they thought they answered correctly. Next, participants were asked to enter the number of questions they believed the average person answered correctly. Finally, participants completed the Birchwood Social Functioning Scale (SFS).

Results: Objective and self-assessed performance on each task was standardized by computing proportion scores for each task to allow for comparison across tasks varying on total number of items. Self-assessment was then evaluated using multi-level modeling along with the Truth and Bias Model (West & Kenny, 2011).

Objective performance by autistic adults was significantly lower than TD adults on all three social-cognitive tasks and the Digit Span, but did not significantly differ on the other two neurocognitive tasks. Self-assessment did not differ between autistic and TD adults across the neurocognitive tasks, but did on the social cognitive tasks, with autistic adults exhibiting less accurate self-assessment than non-autistic controls (p = 0.039). Additionally, whereas non-autistic controls' objective performance corresponded to how they believed an average person would perform on the task (p < 0.001), this was not significant for autistic adults (p = 0.08). Autistic adults had lower scores than non-autistic adults on the SFS, but contrary to hypothesis, no relationship was found between social-cognitive self-assessment scores and SFS scores (ps > 0.22).

Conclusions: These results suggest that the discrepancy often found in autism between neurocognitive and social cognitive ability extends to self-assessment. Whether these findings have meaningful clinical or functional implications, as has been found for other conditions, warrants further study.

445.057 *(Poster)* Special Interests Play Differential Roles in Stigmatization of Autistic Compared to Non-Autistic College Students

***K. M. Stockwell**[1], S. Bottini[2], J. M. Gillis[2] and V. K. Jaswal[1], (1)University of Virginia, Charlottesville, VA, (2)Binghamton University, Binghamton, NY*

Background: About 35% of autistic young adults attend college within six years of graduating high school (Shattuck et al., 2012). Autistic individuals interact differently than non-autistic individuals and may be ignored or avoided by non-autistic peers--a manifestation of stigmatization and associated with fewer social relationships and mental health challenges (Link, Struening, Rahav, Phelan, & Nuttbrock, 1997). The stigmatization of autistic individuals is a growing research area, but there is limited work investigating what specific components differentially influence this stigmatization.

A majority of Autistic people report a special interest (SI) in a particular domain (e.g. music; Grove, Hoekstra, Wierda, & Begeer, 2018). It is possible the frequency and intensity with which they talk about their SI may contribute to the stigmatization they experience.

Objectives: This study examined how non-autistic college students' interest in interacting with peers was impacted by the peer's social behavior and SI.

Methods: Two cohorts of college students (cohort 1: $n = 243$; cohort 2: $n = 102$, collection ongoing) reported interest in interacting with peers. In a series of vignettes, characters were described as behaving in ways characteristic of the diagnosis Autism Spectrum Disorder (or not; American Psychological Association, 2013) and additionally described as having an SI (or not). After reading each vignette, participants indicated on a modified Social Distance Scale (SDS; Bogardus, 1933) how much they would like to engage with the peer in various activities (e.g., going to the movies). Participants also reported knowledge of autism and their relationships with autistic people.

Results: Participants reported wanting increased social distance from autistic than from non-autistic characters, $F(1.71, 406.83) = 487.06$, $p < 0.001$, $\eta 2p = 0.67$, and from characters described as having an SI than characters without, $F(1.91, 453.35) = 33.24$, $p < 0.001$, $\eta 2 = 0.12$. However, the SI effect must be considered in light of a significant interaction between diagnostic status and SI, $F(4, 952) = 11.02$, $p < 0.001$, $\eta 2p = 0.04$. Having an SI resulted in a desire for increased social distance only for non-autistic characters; for autistic characters, having an SI did not increase desired social distance (Figure 1).

Ongoing work is extending these findings by exposing a second cohort of college students at two universities to different SI topics than cohort 1 and manipulating SDS presentation method. Participants are exposed to the SDS using a traditional Likert scale and to a forced choice version (e.g., "You are going to the movies. Would you prefer to go with vignette character A or vignette character B?"). Results are being examined as in cohort 1, with additional considerations of participant knowledge of autism and relationship quality with an autistic person.

Conclusions: Findings give further insight into specific factors impacting the stigmatization of autistic college students. Stigmatization is highly influenced by social behaviors; the presence of an SI may not further stigmatize those whose social behaviors are unconventional. These findings highlight the importance of considering how to prepare neurotypical students to think inclusively about those who are different from them.

445.058 *(Poster)* The Broad Autism Phenotype and Child Functioning in Autism Spectrum Disorders: A Replication Study

I. Li[1]*, D. H. Cho*[2]*, M. Santhosh*[3]*, A. Kresse*[1] *and S. J. Webb*[4]*, (1)Seattle Children's Research Institute, Seattle, WA, (2)Seattle Children's Autism Center, Seattle, WA, (3)Center for Child Health, Behavior and Development, Seattle Children's Research Institute, Seattle, WA, (4)Psychiatry and Behavioral Sciences, University of Washington, Seattle, WA*

Background:

Autism spectrum disorder (ASD) is a developmental disorder that affects communication and behavior. Broad autism phenotype (BAP) traits are milder expressions of social and communication impairments than seen in those with ASD. The BAPQ is a self-reported questionnaire that assesses aloof personality, rigid personality, and pragmatic language problems - all proposed features of BAP traits. Previous studies found higher endorsement of BAP traits in parents of children with ASD than compared to parents of typically developing children (TDC). Further, greater BAP traits in parents were related to elevated autism traits in their children.

Objectives:

This study used data from the ACE GENDAAR network, a multisite NIH-funded project aimed to examine sex-based differences in children with ASD. We used this data to replicate the Maxwell et al. report and extend this to include a more balanced male:female sample. Our aims were to examine if parents of ASD children exhibit more BAP traits compared to parents of TDC, assess the relation between severity of autism in children and BAP traits in their parents, and identify if there are greater associations between paternal characteristics and child traits.

Methods:

Participants (IQ>70) included 55 ASD children (female=22) with 55 mothers and 44 fathers, and 60 TDC (female=31) with 60 mothers and 51 fathers. All participants completed a demographics questionnaire, the BAPQ, and the Social Responsiveness Scale (SRS), which measures autism traits in children. ASD diagnosis was confirmed via ADOS-2 and ADI-R.

Results:

Independent t-tests showed no significant differences in age of children between diagnostic groups (t[113]=-1.18, p=ns). Chi-squared tests found no significant differences in rates of BAP traits for either fathers (X2[95]=0.0, p=ns) or mothers (X2[115]=2.61, p=ns). Within BAPQ domains, higher rates of maternal social aloofness (X2[115]=4.94, p=0.03), pragmatic language deficits (X2[115]=10.39, p<0.01), and rigidity (X2[115]=9.77, p<0.01) were found in the ASD group. For paternal subscales, however, no significant differences were found in any of the BAPQ domains (social aloofness (X2[95]=0.768, p=ns); pragmatic language deficits (X2[95]=0.101, p=ns); rigidity (X2[95]=0.447, p=ns)).

In TDC, paternal BAPQ scores accounted for 1.8% of variance in child SRS scores (p=ns), while maternal scores accounted for 17.2% (beta=0.43, p<0.01). Higher maternal BAPQ scores related to higher child SRS scores (r=0.589, p<0.001). For ASD youth, the results were similar; paternal BAPQ scores accounted for 0.0% of variance in child SRS scores (p=ns) while maternal scores accounted for 15.5% (beta=0.39, p=0.009).

Conclusions:

Preliminary analysis showed higher rates of BAP in TD fathers compared to ASD fathers, failing to replicate Hurley. Mothers of ASD children, compared to mothers of TDC, had greater BAP subscale scores; and maternal, but not paternal, BAP traits were associated with their child's autism behaviors. As a next step, we will explore the role of reporter concordance and the female protective effect, since most child SRS ratings were provided by mothers; given our focus on females with ASD, mothers of females with ASD could possibly display more subclinical-level autism traits.

445.059 *(Poster)* The Cass: Utility of an Observational Social Skill Assessment As a Measure of Social Cognition

G. L. Simmons[1]*, S. Ioannou*[2]*, J. V. Smith*[1]*, B. A. Corbett*[2]*, M. D. Lerner*[3] *and S. W. White*[1]*, (1)Psychology, The University of Alabama, Tuscaloosa, AL, (2)Psychiatry and Behavioral Sciences, Vanderbilt University Medical Center, Nashville, TN, (3)Department of Psychology, Stony Brook University, Stony Brook, NY*

Background: Impaired social skill in Autism Spectrum Disorder results, in part, from social cognitive impairments and leads to loneliness and decreased self-esteem. Social cognition and social behavior must be studied in tandem in order to assess and intervene on social competence in individuals with ASD. Unfortunately, there are few sensitive and valid clinical instruments for assessing social skill. The Contextual Assessment of Social Skills (CASS; Ratto, Turner-Brown, Rupp, Mesibov, & Penn, 2011) is a laboratory-based assessment of conversation ability consisting of two videotaped conversations with trained confederates sequentially acting interested (CASS-I) and bored (CASS-B). Trained raters code participants' social behavior, and the ecologically valid design of the CASS allows for generalization to real-world social skills. Participants' perceptions of confederate behavior might offer clinical utility to supplement this rich behavioral data but has yet to be analyzed as a metric of social cognition.

Objectives: 1) Examine CASS confederate behavior (adherence to administration instructions); 2) Examine internal and external validity of the CASS as a measure of social cognition.

Methods: Fifty adolescents with ASD participated as part of a federally funded, multi-site randomized clinical trial. Assessments included the *Social Responsiveness Scale, Second Edition* (SRS-2); *NEPSY-II* Affect Recognition, Theory of Mind, Memory for Faces, and Memory for Faces Delayed subtests; CASS; and accompanying five-item *Conversation Rating Scale* (CRS), capturing perceptions of confederate behavior (larger values reflect more perceived engagement), completed by participants and a trained rater.

Variables of interested included participants' report of perceived change in confederate behavior between CASS-I and CASS-B (CRS-Change); and the Social Ability Index (SAI), capturing differences in participants' behavior between CASS-I and CASS-B (larger SAI values indicate more normative social adaption/ greater social effort demonstrated in CASS-B), completed by trained raters. Trained raters also completed a novel, behaviorally-based, four-point scale of confederate behavior (larger values reflect more engagement), and a binary rating of confederate adherence to their assigned conversation was computed for each conversation (1= yes; 0= no).

Results: Adherence ratings were consistent across gender and site, though CASS-I confederates performed better than CASS-B ($\chi^2(100)=17.42$, $p<.001$). Participants rated CASS-I confederates as significantly more engaged than CASS-B, and participants' ratings of confederates were more neutral than the trained rater's (Figure 1). Only the CRS-Change score was positively associated with SAI, CASS-I, FSIQ, and NEPSY social cognition tasks (Table 1). Partial correlations controlling for confederate behavior did not significantly alter associations (Fisher r to z transformations; $p>.05$).

Conclusions: Findings demonstrate strong internal validity of the CASS and partially corroborate external validity via comparisons to extant social cognition measures. Though participants adjusted their behavior in CASS-B, this shift (SAI) was not related to measures of social cognition, emphasizing the nuanced differences in social behavior and social cognition. Moreover, the CASS measure appeared robust to inconsistent confederate behavior; relationships between insight (CRS-Change) and social cognitive measures were not affected by relatively interested CASS-B confederates. The CASS shows promise as an outcome measure for clinical interventions and should be incorporated into a multi-methodological battery to assess social competence in individuals with ASD.

445.060 *(Poster)* The Convergent and Divergent Validity of a New Assessment for Preschoolers' Theory of Mind - the Brief Preschool Theory of Mind Assessment.

I. N. Fu[1,2]*, K. L. Chen*[3] *and C. L. Hsieh*[2]*, (1)Child Developmental Assessment & Intervention Center, Taipei City Hospital, Taipei, Taiwan, (2)School of Occupational Therapy, College of Medicine, National Taiwan University, Taipei, Taiwan, (3)Department of Occupational Therapy, College of Medicine, National Cheng Kung University, Tainan, Taiwan*

Background: Theory of mind (ToM) is the ability to infer the mental states of others and oneself to predict other's behaviors and generate interactions accordingly. The construct of ToM has been found to be developmental and multidimensional, including cognitive and affective dimensions. A new computerized ToM measure, the Brief Preschool Theory of Mind Assessment (BP-ToMA), has been developed to measure ToM ability in preschoolers with a developmental and multidimensional ToM construct. The reliability of the BP-ToMA has already been examined, but its convergent and divergent validities remain unsupported.

Objectives: The aim of the present study was to assess the convergent and divergent validity of the BP-ToMA by applying multidimensional item response theory models.

Methods: Typically developing children aged from 3 to 6 years were assessed with the Verbal Comprehension Index (VCI) of the Wechsler Preschool and Primary Scale of Intelligence-IV (WPPSI-IV), BP-ToMA, Theory of Mind Inventory-2 (ToMI-2), and Vineland Adaptive Behavior Scale (VABS) respectively for their verbal comprehension ability, ToM ability, ToM performance, and adaptive function. A multidimensional latent regression of the Rasch model was used to examine the relations the BP-ToMA scores with the VCI, all the subscale scores of the ToMI-2, and the standard scores of all the VABS subscales.

Results: A total of 205 typically developing children aged from 3 to 6 years old (mean = 58.91 months, SD = 11.49 months, range = 37–79 months), including 101 boys and 104 girls, were enrolled in this study. Among these 205 typically developing children, a subgroup of 141 children's caregivers completed the VABS and ToMI-2. Regarding the convergent validity, children's age, VCI, basic subscale scores of the ToMI-2, and standard scores of the communication and socialization subscale of the VABS positively and significantly predicted the two dimension scores of the BP-ToMA (all $p < 0.001$). As regards the divergent validity, the standard scores of the daily living skills subscale and motor skills subscale of the VABS significantly predicted the two dimension scores of the BP-ToMA (both $p < 0.001$).

Conclusions: In this study, the BP-ToMA has been evidenced to have good convergent validity but limited divergent validity. The BP-ToMA scores were correlated with the VCI, basic subscale scores of the ToMI-2, and surprisingly, the daily living skills and motor skills subscales of the VABS, possibly due to the synchronous rapid development of ToM ability, daily living skills and motor skills in the preschool period. The results of the present study show that the BP-ToMA is a valid measure of preschoolers' ToM ability. In future studies, an appropriate measure should be selected to examine the divergent validity of the BP-ToMA.

445.061 *(Poster)* The Correlation between Restricted and Repetitive Behaviors and Socialization in Autism Spectrum Disorder.

***A. Kniola**, K. Tuohy, C. Gelep and S. Char, Mailman Segal Center for Human Development, Nova Southeastern University, Ft. Lauderdale, FL*

Background: The core features of autism spectrum disorder (ASD) are deficits in social communication and interactions and restricted and repetitive behaviors (RRBs). RRBs include repetitive motor movements, limited interests and difficulty with changes in routines among many others. Research shows RRBs may be one factor which impairs an individual's ability to socialize (Lord, 2010).

Objectives: It is hypothesized that individuals with more severe restricted and repetitive behaviors, as determined by a licensed clinical psychologist, would score lower on the Socialization domain of the parent report measure, the *Vineland Adaptive Behavior Scales, Second and Third Edition, Parent/Caregiver Rating Form (Vineland-II, 3)*.

Methods: Participants included 156 individuals diagnosed with ASD (males n = 125, females n = 31) and data was collected over a three-year period from a community-based developmental assessment clinic. Ages of the participants ranged from 19 to 253 months ($\mu = 68.65$). The sample consisted of 30.8% Caucasian, 28.2% Latino, 16.7% Black, 10.9% Biracial, and 3.2% Asian participants. It is important to note 1.9% selected 'other' in relation to ethnicity. Individuals were assessed using the *Autism Diagnostic Observation Schedule, Second Edition (ADOS-II) and the Vineland-II and 3*.

Results: As hypothesized, there was a significant negative correlation ($r=-.317$, $p<.001$) found between the severity of restricted and repetitive behaviors and parent reported socialization skills.

Conclusions: The results suggest children who demonstrate more severe RRBs appear to have greater difficulties socializing, according to their parents. This relationship may be explained by the potential impediments RRBs may have on socialization. These impediments may include but are not limited to, restricted interests negatively impacting social interactions, repetitive motor movements drawing negative attention towards the child, and difficulty completing unstructured activities.

445.062 *(Poster)* The Effect of Bilingualism on Cognitive and Affective Perspective Abilities in Autistic Adults.

***B. G. Digard**[1], A. Sorace[2], A. C. Stanfield[1] and S. Fletcher-Watson[1], (1)Division of Psychiatry, University of Edinburgh, Edinburgh, United Kingdom, (2)Department of Linguistics, University of Edinburgh, Edinburgh, United Kingdom*

Background: Research in neurotypical people has described a positive influence of bilingualism on the development of specific cognitive and social skills such as cognitive and affective perspective taking. However, an understanding of the cognitive influence of bilingualism in autism is lacking, especially in social processes, a recognized source of challenge for autistic people.

Objectives: This study aims to describe the influence of bilingualism on cognitive and affective perspective taking skills in autistic adults.

Methods: We recruited 39 autistic adults living in the U.K., who knew more than one language. Participants completed a language history and demographics questionnaire, an executive function task, a standardised non-verbal IQ test, and a video-based task, the Adult-Theory of Mind – extended (AToMe) task, measuring level 1 ("What does Jess think?", one-step perspective taking), level 2 ("What does Jess think Billie thinks?", two-steps perspective taking), and general cognitive and affective perspective taking processes. This task involved 6 social videos each followed by 5 questions (general, level 2 cognitive, level 2 affective, level 1 cognitive, level 1 affective), and 6 control videos, each followed by a non-social question. The videos lasted 30 to 60 sec, and participants had 30 sec to answer each question. Answers were given 0, 1, or 2 points based on their accuracy. Points were summed to obtain the following 9 scores: Control, Social, General, Cognitive, Affective, Cognitive Level 1, Cognitive Level 2, Affective Level 1, Affective Level 2. Further details regarding the methods are available at https://osf.io/vjfnh.

Results: The final sample includes 39 participants (41% female), aged between 16 and 61 ($M = 33.2$ years, $SD = 12.9$ years), with a Perceptual Reasoning Index between 101 and 145 ($M = 119.8$, $SD = 10.4$). Nine participants reported knowing 2 languages, 15 reported 3 languages, 15 reported 4 languages or more, with a wide range of ages of acquisition (for example, ages of acquisition for the second language ranged from 0 to 58 years, $M = 7.5$ years, $SD = 6$) and a wide range of proficiencies in all their languages. We will analyse the continuous relationship between three markers of bilingualism (i.e. number of languages, age of acquisition or the second language, proficiency in the second language) and perspective taking ability scores from the AToMe, using a multiple linear regression analysis.

Conclusions: This study is the first to measure the influence of various bilingualism features on the cognitive and affective perspective skills of autistic adults. This deepens our understanding of the ability of the autistic mind to approach and respond to language learning, in terms of non-linguistic social processes. This will contribute to an evidence base for families and practitioners to support autistic people in their language learning journey and autistic people in a bilingual setting.

445.063 *(Poster)* The Impacts of Social and Coping Skills on Real-Life Social Participation of Adolescents with Autism Spectrum Disorder in Taiwan

***Y. W. R. Chen**[1], M. H. Tseng[2] and A. C. Bundy[3], (1)Faculty of Medicine and Health, University of Sydney, Sydney, NSW, Australia, (2)School of Occupational Therapy, College of Medicine, National Taiwan University, Taipei, Taiwan, (3)College of Health and Human Sciences, Colorado State University, Fort Collins, CO*

Background: Individuals with autism spectrum disorder (ASD) who are not cognitively impaired commonly report social isolation and negative experiences in social participation even though they are high functioning. Given the increased social expectations and complexity in social scenarios compared to childhood, adolescents with this diagnosis may be more aware of their social difficulties and require better coping strategies to manage stress-evoking social situations in real life. To address their specific social needs, knowledge of how social and coping skills influence their social experience is crucial to identify targets for intervention and support their social participation.

Objectives: The purpose of this study was to explore how adolescents with ASD who were not cognitively impaired perceived their rea-life social participation and identify the impacts of ASD symptoms and social and coping skills on their perceptions of social engagement.

Methods: Fifty-six Taiwanese with ASD who were not cognitively impaired (49 males; aged 10-16 years) participated in the study. They carried an iPhone that prompted them randomly, 7 times/day during their free time for 7 days, to record what they were doing and the perceptions in the involved situation including the levels of interest, involvement and perceived difficulty. Multilevel modelling was conducted to analyse the perceptions in social engagement. In addition, we examined the moderating effects of ASD severity measured by Social Communication Questionnaire, and social and coping skills evaluated by the Social Skills Improvement System Rating Scales and Coping Inventory, respectively, on their social experience.

Results: Participants were more likely to have high levels of interest but perceived difficulty while they were engaged in social activities than other activities (ORs= 10.85, 2.45; 95% CIs=3.53-33.35, 1.06-5.67; p's<0.05). Those with higher levels of social and coping skills were more likely to be more interested in social activities (OR=17.77, 1.06; 95% CIs=5.10-61.93, 1.02-1.11; p's<0.05). More importantly, participants with better coping skills had lower changes to perceive difficulty during social engagement (OR=0.13; 95% CI=0.02-0.81; p<0.05). However, those with more ASD symptoms were more likely to have higher levels of interest in social engagement (OR=1.29; 95% CI=1.10-1.52, p<0.01), but less likely to be involved and perceive difficulty while engaging in social activities (ORs=0.85, 0.78; 95% CIs=0.77-0.94, 0.62-0.98; p's<0.05).

Conclusions: Findings highlight the importance of coping skills in managing difficult social interactions among adolescents with ASD who are not cognitively impaired. Further, those with less ASD symptoms may have greater insights in social impairment, leading to a fear of social interactions. In addition to social skills training, intervention services should target developing adaptive coping strategies and promoting self-perceptions of social competence to enhance their experience in real-life social participation.

445.064 *(Poster)* The Problem-Solvers: Moderating Effects of Social Cognition on the Relation between Identifying and Solving Social Problems in Youth with ASD

M. L. McNair[1]*, N. Russo-Ponsaran*[2]*, C. McKown*[2] *and M. D. Lerner*[1]*, (1)Department of Psychology, Stony Brook University, Stony Brook, NY, (2)Rush University Medical Center, Skokie, IL*

Background: Socially appropriate interpretation and response are important skills to implement during situations involving social problems (i.e., a child needs to determine how to get her social needs/desires met); ample research has shown that children with autism spectrum disorder (ASD) struggle with social problem solving (SPS; Channon et al., 2001; Stichter et al., 2012; Russo-Ponsaran et al., 2015). Some children with ASD can *identify* the presence of a social problem but cannot come up with an appropriate *solution*; others may be able to identify an appropriate solution *without* naming the problem. It may be, then, that some youth can leverage the ability to read the emotions (emotion recognition; ER) and intentions (Theory of Mind; ToM) of others to facilitate solution identification. Youth with ASD struggle with each of these, but evidence suggests considerable heterogeneity within the population (Pelphrey et al., 2011). Given these difficulties in ASD and the commonality of social problems, it is important to understand how social cognitive skills affect the process of SPS, particularly the relationship between problem identification and correct solution identification; however, little research has examined social cognition's effect on this relationship in youth with ASD.

Objectives: The current study examined the moderating effect of ER and ToM skills on the relation between problem identification and correct SPS in children with ASD.

Methods: 58 children (44 male; M_{age}=8.53, SD_{age}=1.33) with IQ≥80 (M_{IQ}=103.72, SD_{IQ}=14.33) and ADOS-2 confirmed ASD diagnosis completed SELweb, a computerized, self-administered assessment of social cognition (McKown et al., 2015; Russo-Ponsaran et al., 2019). SELweb includes several tasks testing various aspects of social cognition, including SPS (Figure 1), ToM, and ER. To test the hypothesis that ER and ToM ability moderate the relationship between social problem identification and correct SPS, moderated multiple regression analyses were conducted.

Results: ER ability marginally moderated the relationship between problem identification and solution identification, such that the relation was present only when ER skill was low or moderate (Figure 2A). ToM skill significantly moderated the relationship between problem identification and solution identification, such that the relationship was present only when ToM skill was low or moderate (Figure 2B).

Conclusions: Social problem identification was found to predict correct solution preference when ToM skills were low or moderate. A similar relationship was found when ER skills were low or moderate. This suggests that identification of a social problem may only relate to better solution preference in children with ASD and low or moderate ER and ToM skills. Interestingly, those with average ToM skills, whether they identified the presence of a social problem or not, selected more competent solutions. Thus, perspective-taking ability can facilitate selection of effective social solutions; however, consistent with the compensatory account of ASD social cognition (Livingston et al., 2018), even at lower levels of this ability, youth with ASD may be able to deduce effective solutions so long as they can identify the presence of a problem. This provides guidance for social interventions, highlighting which individuals may benefit from training in identifying social problems.

445.065 *(Poster)* The Role of Reciprocity in Interaction Success in Naturalistic Conversations of Autistic and Neurotypical Peers

D. Alkire[1,2]*, K. A. McNaughton*[1,2]*, H. A. Yarger*[1,2] *and E. Redcay*[1,2]*, (1)Neuroscience and Cognitive Science Program, University of Maryland, College Park, MD, (2)Department of Psychology, University of Maryland, College Park, MD*

Background: Difficulties in reciprocal communication in ASD are well documented. Although it is assumed that reciprocity plays a large role in social-interactive success, few studies have directly tested the extent to which the reciprocity of a face-to-face conversation impacts the success of the interaction. Furthermore, most previous observational studies of conversational behavior in ASD have employed structured interactions with clinicians, friends, or family members. Thus, few studies capture the everyday scenario that autistic individuals typically find most challenging: unstructured conversation with an unfamiliar peer. Finally, while most prior research has examined social-interactive behavior at the level of the individual, a more complete understanding of dyadic interaction may require analysis at the level of the dyad.

Objectives: In dyads of unfamiliar children and adolescents engaging in unstructured social interaction, we examined the effect of conversational reciprocity on participant-reported interaction success.

Methods: Participants were paired within 1 year of age (age range: 9 to 16 years). The current sample includes 26 same-gender dyads: 15 homogeneous dyads (both partners neurotypical; 3 female dyads) and 11 heterogeneous dyads (one partner neurotypical, one autistic; 2 female dyads). Data collection is ongoing; based on current testing rates, by the time of presentation we expect the sample to have roughly doubled and to include homogeneous autistic dyads.

Video recordings of 5-minute unstructured peer interactions were coded by multiple raters for the following indices of reciprocity: (1) ratio of time talking, (2) ratio of questions asked about each other, and (3) observer ratings of conversational efficacy (including appropriate turn-taking and ability to maintain the flow of conversation; Usher et al., 2015) averaged within dyads. Interaction success was assessed via self-report (Berry & Hansen, 1996); dyadic interaction success was defined as the product of scores from each dyad member.

We performed multiple regression analysis to determine the amount of variance in dyadic interaction success explained by the above reciprocity variables, as well as verbal IQ (product of each dyad member's score), average age of dyad, and dyad type (homogeneous or heterogeneous).

Results: Conversational efficacy predicted dyadic interaction success with marginal significance ($t(19) = 2.08$, $p = .05$); the two variables were significantly positively correlated ($r = .42$, $p = .03$). No other predictors had a significant effect on dyadic interaction success. Dominance analysis revealed that conversational efficacy uniquely explained 17% of the variance in dyadic interaction success.

Conclusions: Preliminary results show concordance between observer ratings of participants' ability to engage in reciprocal conversation and participants' subjective experience of the interaction. Thus, we provide direct support for the widely held assumption that reciprocal communication plays a meaningful role in the success of peer interactions among autistic and neurotypical individuals alike, regardless of pair type. More broadly, we demonstrate the feasibility of using naturalistic, unstructured paradigms to study social-interactive behavior in children and adolescents with ASD. Future analyses will examine the role of reciprocity in interactions between two autistic individuals. We will also explore other measures of reciprocity such as more quantitative measures of turn-taking and exchanges of congruent information.

445.066 *(Poster)* Theory of Mind and Broad Autism Traits in Young Adults

***M. J. West**, D. A. Fein, L. R. Naigles and I. M. Eigsti, Psychological Sciences, University of Connecticut, Storrs, CT*

Background: Autism spectrum disorder (ASD) involves difficulties with theory of mind (TOM) capacity. Some evidence suggests that TOM abilities might vary within the general population (Baron-Cohen et al., 2001), as part of a broader trend of variability in ASD traits within the population. This study investigates whether differences in TOM are unique to the diagnosis of ASD, or whether such differences vary as a function of ASD traits more broadly. This information is useful for understanding the underlying mechanisms of ASD symptoms.

The present study assessed both verbal and nonverbal tasks thought to tap into theory of mind abilities, as a function of ASD traits. *Verbal tasks* were the Reading the Mind in the Eyes Test (RMET; Baron-Cohen et al., 2001), to assess emotion recognition and mentalizing processes, and a Mental State Verbs (MSV; Schwanenflugel et al., 1998) task. The MSV task tests an individual's tendency to assign mental verbs to groups based on the activities they describe, for example grouping 'reason' and 'estimate' together as mental processes. The *nonverbal task* was the Social Attributions Task (SAT; Johannesen et al., 2013), which assesses the tendency to attribute social characteristics to animated geometric shapes.

Objectives: This study probed how multiple aspects (verbal and nonverbal) of TOM capacities relate to broader ASD traits in a non-clinical sample.

Methods: A total of 106 undergraduate students participated (see Table 1 for demographic details). Participants completed the tasks, along with the Autism Spectrum Quotient questionnaire (AQ), via an online survey platform within a laboratory environment under supervision of an investigator.

Results: Correlations between task scores and the AQ are shown in Table 2. The RMET was positively correlated with both the MSV and SAT, suggesting that these disparate aspects of TOM "hang together". The RMET was negatively correlated with total AQ scores, as well as AQ Communication and Imagination subscales. Thus, poorer performance on the RMET was associated with higher levels of ASD traits. MSV performance was not related to total AQ scores, but was related to the AQ Attention to Detail and Imagination subscales. Nonverbal SAT performance did not correlate with total AQ or any subscales.

Conclusions: These findings replicate and extend prior research with the RMET (Baron-Cohen et al., 2001), demonstrating that emotion recognition and mentalizing skills relate to other verbal and nonverbal TOM capacities. The ability to group mental state verbs into mental categories appears to be specifically related to higher attention to detail and imagination abilities. This finding suggests a nuanced interaction between ASD traits and verbal TOM, such that the ASD trait to attend more to details relates to higher verbal TOM, while the ASD trait of poorer imagination ability relates to lower verbal TOM. Nonverbal theory of mind, as tested with the SAT, appears unrelated to broader autism traits. Findings suggest that there are some variations in verbal TOM abilities in the general population as a function of ASD traits, but not in nonverbal abilities. Although, differences in task difficulty should be considered.

445.068 *(Poster)* Video Game Use and Its Association with Aggression and Social Satisfaction in Adolescents with Autism Spectrum Disorder

***K. Davis**[1], M. K. Krug[2] and M. Solomon[3], (1)UC Davis M.I.N.D. Institute, Sacramento, CA, (2)Department of Psychiatry & Behavioral Sciences, UC Davis MIND Institute, Sacramento, CA, (3)Department of Psychiatry and Behavioral Sciences, The Medical Investigation of Neurodevelopmental Disorders (MIND) Institute, UC Davis School of Medicine, University of California Davis, Sacramento, CA*

Background: Adolescents with autism spectrum disorder (ASD) play video games more often and for a greater amount of time than those with typical development (TYP) (Mazurek & Wenstrup, 2013). Studies in those with TYP suggest an association between aggression and video games (Saleem et al., 2018), although this has been disputed (Kühn et al., 2018). While those with ASD exhibit increased rates of aggression compared to their TYP counterparts (Mays et al., 2011) (Kim et al., 2000), few studies have specifically looked at associations between video game playing and aggression in ASD (Mazurek & Engelhardt, 2013). Video game players with ASD may struggle to interact and engage with other peers, both in person and over social media (Mazurek & Wenstrup, 2013).

Objectives:

1. Compare the frequency and amount of video game playing in adolescents with ASD and TYP.
2. Examine the association between video game playing and aggression in adolescents with ASD.
3. Examine the association between video game playing and social satisfaction in adolescents with ASD.

Methods: 42 adolescent participants with ASD, assessed using the Autism Diagnostic Observation Schedule (ADOS) (Lord et al., 2000) and Social Communication Questionnaire (SCQ) (Rutter et al., 2003) (Age = 14.92 (1.77); FSIQ = 100.69 (14.73)) and 47 with TYP (Age = 15.13 (1.81); FSIQ = 109.81 (12.46)) completed the Youth Self Report (YSR) and the Child Behavior Checklist (CBCL; parent report) questionnaire (Achenbach System of Empirically Based Assessment (ASEBA) (Achenbach & Rescorla, 2001; 2003)). The YSR and CBCL include reports of favorite hobbies and time spent on them compared to others of the similar age, as well as assessments of aggressive behavior.

Social functioning was assessed using an adaptation of the Global Functioning: Social (GF:S) scale which is a clinician administered semi-structured interview that examines peer relationships and focuses on age appropriate interactions, social withdrawal, and isolation (Cornblatt et al., 2007).

Results: Participants were categorized into three groups: don't play/play less than average, average, and more than average. Results from YSR (X^2 (2, n = 89) = 7.196, p < .05) and CBCL (X^2 (2, n = 89) = 5.091, p < .1) indicated a significant group (ASD, TYP) by video game play category interaction. Post-hoc testing showed significant diagnostic group differences between the don't play/less than average categories in the YSR and the more than average categories in both the YSR and CBCL (Figure 1a,b). No significant differences were found in CBCL Aggression scores between those with ASD who play video games versus with those who do not (Table 1). Participants with ASD who play video games (CBCL) had higher GF:S scores than those who do not play video games (X^2 (2, n = 42) = 7.13, p < .05).

Conclusions: While adolescents with ASD play more video games than their TYP peers, video game playing in ASD is not associated with increased aggression and is associated with greater social abilities. Future analysis will be done on the same cohort at a second time-point to analyze aging through adolescence into early adulthood.

445.069 *(Poster)* Visual Attention Modulated By Dialogue during Dynamic Naturalistic Scenes

M. M. Mahony[1]*, F. Shic*[2]*, C. M. Hudac*[3]*, E. Barney*[2]*, M. Kim*[4] *and M. C. Aubertine*[5]*, (1)Center for Human Behavior and Development, Seattle Children's Research Institute, Seattle, WA, (2)Center for Child Health, Behavior and Development, Seattle Children's Research Institute, Seattle, WA, (3)Psychiatry and Behavioral Sciences, University of Washington, Seattle, AL, (4)University of Virginia, Charlottesville, VA, (5)Seattle Children's Hospital and Research Institute, Seattle, WA*

Background: Studies have shown that people with Autism Spectrum Disorder (ASD) visually attend to social elements (i.e. heads and bodies) less than Non-ASD peers (Chita-Tegmark, 2016). Work using eye tracking has also shown that differences in visual patterns within ASD are more pronounced in socially dynamic stimuli when compared to static stimuli (Speer et. al., 2007). It is unclear if this reduced social attention is an independent pattern of ASD or if it is related to communication deficits, making social elements less tolerable during scenes high in dialogue.

Objectives: To investigate if visual attention to social and non-social information within ASD and non-ASD populations is modulated by the presence of dialogue.

Methods: Participants were 50 children with ASD (*Mean Age*=7.08 years, SD=2.16) and 75 children without ASD (Non-ASD; *Mean Age*=6.84 years, SD=2.09). Stimuli included two 1-minute long commercially produced movie clips (*Eloise* and *The Little Princess*) depicting highly emotional social scenes. Clips were broken into 9 scenes based on natural scene cuts and categorized into two conditions: Dialogue or Action (i.e. no or minimal dialogue). Valid looking time was calculated for each region-of-interest (ROI): (a) %Head (including eyes, mouth, and outerhead regions), (b) %Body, and (c) %Background (all non-social elements). Linear mixed models were used to examine effects of group, condition, and their interaction.

Results: Two-way ANOVA for each ROI revealed the following: For %Head: group (p<.001) and condition (p<.001) effects, with no interaction (p=.557), with the ASD group looking less at heads than Non-ASD (d=-.612). %Head was lower during Action scenes as compared to Dialogue (d=-1.92). %Body: group (p=.011) and condition (p<.001) effects, with no interaction, with the ASD group looking more at bodies. %Body was higher during Action scenes than Dialogue scenes. %Background: group (p<.001) condition (p<.001) effects, and their interaction (p=.048) were observed (ASD: Action M=30.4%, Dialogue=15.7%; Non-ASD: Action M=23.0%, Dialogue=10.8%), with greater between-group differences in Action (d=.709) than Dialogue (d=.462), and greater between-condition differences in ASD (d=1.40) as compared to Non-ASD (d=1.16).

Conclusions: Contrary to expectations, children with ASD showed consistent visual attention patterns while watching dynamic naturalistic scenes regardless of dialogue. Although both groups showed similar patterns, valid looking time for each ROI differentiated the groups, with the ASD group looking at the Background more and Heads less than the Non-ASD group for both conditions. This suggests that atypical visual attention in ASD is pervasive with or without a speech component. It is important to note that Action scenes depicted highly-emotional and suspenseful situations. Thus, despite the lack of dialogue, Action scenes may have engendered empathetic or social referencing responses in Non-ASD children, effects not usually apparent within ASD. Further work will investigate relationships between scanning patterns and phenotypic characteristics at an individual level.

445.070 *(Poster)* Visual Scanning Patterns Predicting Theory of Mind Performance Using Static and Dynamic Stimuli

S. Licona[1], *J. M. Moriuchi*[2], *E. V. Ocampo*[2], *H. Lechniak*[3] *and L. Soorya*[2], *(1)Rush University Medical Center, Chicago, IL, (2)Department of Psychiatry, Rush University Medical Center, Chicago, IL, (3)Child and adolescent psychiatry, Rush University Medical Center, Chicago, IL*

Background: Impairments in mentalizing represent a key deficit in social cognition for children with autism spectrum disorder (ASD). Explicit mentalizing tasks, such as the Reading the Mind in the Eyes Test, have shown promise as an outcome measure in social intervention studies. However, performance on explicit mentalizing tasks can be variable, even as individuals with ASD continue to struggle with applying mentalizing skills within everyday contexts. One hypothesis is that overall accuracy measures on explicit mentalizing tasks may not fully capture underlying social cognition; children with ASD may be utilizing alternate, compensatory strategies and may be solving mentalizing problems in a different way than typically-developing peers.

Objectives: To help clarify the underlying mechanisms of children's mentalizing performance, we developed a computerized battery of social-cognitive measures co-registered with eye-tracking. By examining visual scanning patterns as participants completed mentalizing tasks, we aimed to measure not just whether children were accurate in their social attributions, but also how they were attempting to make social attributions on a moment-by-moment basis. Because mentalizing impairments tend to be most apparent in everyday contexts, we compared visual scanning patterns predictive of mentalizing performance and social disability across tasks using increasingly naturalistic stimuli, including still images and dynamic facial expressions and gestures.

Methods: Participants included 20 verbally-fluent children with ASD (16 male, 4 female) between the ages of 8 and 11 years old who represented a broad range of severity in ASD symptomatology (ADOS-2 Calibrated Severity Score: mean=8.4 [3.4]). Participants were enrolled in a randomized clinical trial of a combination behavioral-pharmacological treatment targeting social cognition and social behavior; the current study focused only on data at baseline, pre-treatment.

Eye-tracking data were collected while participants completed a battery of computerized social cognitive measures, including an adapted version of the child Reading the Mind in the Eyes Test (RMET; Figure 1A-B) and a dynamic emotion recognition test developed from the Geneva Multimodal Emotion Portrayals (GEMEP; Figure 1C-D) database.

Results: Accuracy on mentalizing tasks ranged from 25 to 89% correct responses. Visual attention to nonsocial regions was positively correlated across still images and dynamic stimuli ($r=0.60$, $p<0.05$) and higher than attention to social regions ($t=2.00$, $p=0.05$). Children who exhibited higher visual attention to the eyes region of faces tended to have less severe ASD symptomatology ($r=-0.50$, $p=0.03$) and higher mentalizing accuracy ($r=0.52$, $p=0.02$). Ongoing analyses are utilizing more temporally-sensitive measures to identify visual scanning patterns that may mediate the relationship between attention to eyes and mentalizing performance.

Conclusions: The computerized social-cognitive battery yielded a broad range of mentalizing performance in our pilot sample of school-age children with ASD and identified consistent visual scanning patterns contributing to mentalizing accuracy. This new approach holds promise as a tool sensitive to change both in mentalizing performance and in underlying social-cognitive processes.

Social Neuroscience

POSTER SESSION — **SOCIAL NEUROSCIENCE**
446 - Social Neuroscience Posters

446.001 *(Poster)* A Meta-Analysis of Differences in Pupillary Measures between Individuals with and without Autism Spectrum Disorder

T. W. Frazier[1,2], *C. Anderson*[3], *E. Youngstrom*[4] *and A. Y. Hardan*[5], *(1)Autism Speaks, New York, NY, (2)Psychology, John Carroll University, University Heights, OH, (3)University of Missouri, Columbia, MO, (4)University of North Carolina at Chapel Hill, Chapel Hill, NC, (5)Psychiatry & Behavioral Sciences, Stanford University, Stanford, CA*

Background: Core ASD symptoms may result from deficits in attention and arousal systems. Eye-tracking allows for objective, non-invasive examination of pupillary response, a sensitive assay of autonomic arousal and an indirect indicator of attentional allocation. Dozens of studies have examined tonic (resting), phasic (response to stimuli), and pupillary light reflex (PLR) responses in ASD. However, results of these studies have been contradictory.

Objectives: The primary aim was to conduct a comprehensive meta-analysis of the pupillary literature in ASD to determine whether and to what degree pupillary responses differ in ASD. The secondary aim was to explore whether methodological or stimulus factors influence ASD-control differences in pupillary responses.

Methods: A comprehensive search was completed using PubMed and PsychInfo. Four hundred forty-one publications were identified for closer inspection. Inclusion and exclusion criteria were applied and only studies that compared ASD to neurotypical (NT) or developmental disability (DD) controls were included. A wide range of demographic, clinical, methodological, and stimulus characteristics were coded. A blinded second rater coded 5 studies and inter-rater reliability was excellent (absolute agreement=96%). Analyses used multivariate mixed-effects meta-regression models with maximum likelihood estimation. Hypotheses were tested by estimating models separately for tonic, phasic, and PLR measures. Outliers were examined and, if findings were robust to outliers, meta-regression models with sample and methodological factors were estimated to examine whether these variables influence effect magnitude. A priori directional hypotheses, procedures, and analyses were pre-registered (osf_pupillometry_meta-analysis).

Results: Thirty-two studies (2006-2019), containing 218 effect sizes (tonic=15 studies, 27 effect sizes; phasic=23 studies, 121 effect sizes; PLR=5 studies, 70 effects sizes) were identified that met inclusion/exclusion criteria. Studies comprised a total of 1,828 participants (ASD=780; NT=813; DD=235) between 9.5 months and 37.8 years old, with a broad range of ability levels (IQ range=64-117). Tonic pupil size was significantly larger in ASD (g =+.22, Figure 1). Phasic pupil changes to *non-social* stimuli were significantly larger in ASD, while phasic pupil responses to *social* stimuli were non-significantly smaller in ASD (Figure 1 top). Within social stimuli, responses to social scenes were significantly smaller in ASD (g = -.42), but this was not observed for faces or other social stimuli. Analysis within face stimuli identified significantly smaller responses to fearful faces in ASD (g = -.45). Significant, medium-sized decreases in PLR constriction time and amplitude were observed in ASD (Figure 1 bottom). PLR latency was significantly longer in ASD, with a medium effect size. No significant effects were observed for constriction or redilation velocity or redilation time. All significant effects (*p<.05, ^p<.001) were consistent with pre-registered directional predictions.

Conclusions: Pupillary responses in ASD suggest elevated tonic arousal, relatively greater arousal and attentional allocation to non-social than social stimuli, and slower and weaker automatic responses to light flashes. These data support heightened autonomic arousal and aberrant selective attention and processing as mechanisms contributing to ASD, and suggest that tonic, phasic, and PLR responses may be useful biomarkers for screening and diagnosis. It will be important to determine the specificity and predictive value of these findings in future research.

446.002 *(Poster)* Correlating fNIRS-Based Cortical Activation during a Social Cooperation Task with Motor and Social Performance in Children with and without Autism Spectrum Disorder (ASD)

A. Bhat[1]*, M. Culotta*[2]*, D. Tsuzuki*[3] *and W. C. Su*[2]*, (1)Department of Physical Therapy, University of Delaware, Newark, DE, (2)Physical Therapy, University of Delaware, Newark, DE, (3)Department of Language Sciences, Tokyo Metropolitan University, Tokyo, Japan*

Background:

Children with ASD present with significant impairments in social-perceptual skills and visuo-motor coordination that might affect their ability to adjust their actions to others during social cooperation tasks (Liebal et al., 2008; Fitzpatrick et al., 2017). In the past, using functional near-infrared spectroscopy (fNIRS) we have reported on lower cortical activation and poor social cooperation performance during a Lincoln Log cooperative building task in school-age children with ASD compared to those without ASD (Culotta et al., 2018).

Objectives:

In the current study, we examined the relationship between fNIRS-based cortical activation and behavioral errors in a cooperative building game as well as social functioning, autism severity, and motor performance.

Methods:

Fifteen school-age children with ASD and 15 typically developing (TD) children without ASD wore an fNIRS cap embedded with a 3x11 probe set covering bilateral middle frontal gyrus (MFG), pre/post-central gyri (PCG), inferior frontal gyrus (IFG), superior temporal sulcus (STS), and inferior parietal lobule (IPL). The children sat at a table across from an adult tester to complete the building game involving four conditions: a) Lead (L): child leads the building and adult partner follows as they build own structures, b) Compete (C): each partner builds their own structure, c) Follow (F): child follows the adult partner in building as they build own structures, and d) Turn-take (T): child and partner alternate turns to build a common structure. The caregivers of the children completed the Vineland Adaptive Behavioral Scales (VABS) and Social Responsiveness Survey (SRS) questionnaire. We also administered the manual dexterity and the upper-limb coordination subtests of the Bruininks-Oseretsky Test of Motor Proficiency, (BOT) to assess children's manual coordination skills. Parametric (Pearson's) and non-parametric (Spearman's) correlations were conducted to investigate associations between magnitude of cortical activation (average oxy-hemoglobin values) and behavioral errors in the task, social and motor performance scores, and autism severity.

Results:

In terms of behavioral errors, greater IFG activation in TD children was associated with fewer planning errors (rs= -0.28 to -0.49, $p<0.05$) whereas greater IPL and PCG activation in children with ASD was related to more planning errors (rs=0.27-0.3, $p<0.05$). In terms of motor/BOT performance, greater right MFG and STS activation in TD children was associated with better motor performance (r=0.30-0.395, $p<0.05$) and such relations were not seen in children with ASD. In terms of VABS social functioning, greater left/right STS, left/right MFG, and right IFG activation was linked to better socialization (rs= 0.32 to 0.41, ps<0.05) in TD children. Based on SRS scores, children with ASD with greater right IFG activation had better social performance (rs=-0.33 and -0.49, $p<0.05$) whereas lower left IPL activation was associated with better social performance (r=0.37, $p<0.05$).

Conclusions:

We identified multiple brain-behavior correlations in children with and without ASD, specifically greater IFG, MFG, and STS activation and lower IPL activation is associated with better motor and social performance in children with/without ASD. We plan to use these objective neurobiomarkers to examine effects of therapies targeting social cooperation skills of children and adolescents with ASD.

446.003 *(Poster)* Face Specialization in 12-Month-Old Infants at High-Risk for Autism Spectrum Disorders

M. Guy[1]*, J. E. Richards*[2]*, A. L. Hogan*[3] *and J. E. Roberts*[3]*, (1)Loyola University Chicago, Chicago, IL, (2)University of South Carolina, Columbia, SC, (3)Department of Psychology, University of South Carolina, Columbia, SC*

Background: The current study utilized a multimethod approach to develop a holistic perspective of face specialization in etiologically-distinct, 12-month-old infants at high-risk for autism spectrum disorder (ASD). Electrophysiology, neuroimaging, and behavior were examined in infant siblings of children with ASD (ASIBs) and infants diagnosed with fragile X syndrome (FXS). Infants with FXS and ASIBs have demonstrated different patterns of event-related potential (ERP) responses at the face-sensitive N290 component (Guy et al., 2018). Relative to low-risk control (LRC) infants, infants with FXS demonstrated greater amplitude N290, while ASIBs demonstrated an attenuated response.

Objectives: Patterns of neural activation and behavior were examined in relation to N290 amplitude in high-risk infants. Cortical source analysis was completed to investigate activation in brain regions most closely linked to specialized face processing and surrounding areas. Results from the Autism Observation Scale for Infants (AOSI) identified emerging symptoms of ASD.

Methods: Twenty-one ASIBs, 15 infants with FXS, and 21 LRC infants were recruited at 12 months of age. Realistic head models were created from structural MRIs from a subset of participants and group-specific average head models. Current density reconstruction (CDR) was calculated to examine activation in regions of interest (ROIs) believed to be relevant to face processing. The AOSI was used to assess early ASD symptoms in the areas of visual attention, social and motor behaviors. Analyses focused on the N290 ERP component, which has been most closely associated with infant face processing and is believed to be the precursor to the adult N170 (Guy et al., 2016).

Results: Results revealed different patterns of neural and behavioral characteristics associated with N290 amplitude across infants with FXS and ASIBs. CDR analyses revealed a significant main effect of stimulus type, $F(1, 55)=21.47$, $p<.0001$, and an interaction of group, stimulus type, and ROI, $F(34, 935)=1.45$, $p=.0465$. All participants demonstrated greater activation to faces than toys. LRC infants demonstrated greatest activation to faces in areas believed to reflect specialized face processing (i.e., middle and anterior fusiform gyrus, parahippocampal gyrus, and lingual gyrus). ASIBs demonstrated reduced activation in these areas, while infants with FXS displayed high levels of activation to faces across all ROIs examined. AOSI results revealed an interaction of group, electrode cluster, and electrode hemisphere, $F(8, 102)=2.49$, $p=.0164$. Infants with FXS with high-AOSI scores had the most negative N290 amplitude responses at left electrodes.

Conclusions: High-risk infant groups demonstrated unique patterns of neural activation, which may be associated with emerging behavioral characteristics of ASD, and which did not reflect typical development of specialized face processing. Infants with FXS demonstrated greater N290 amplitude, which was reflected through broad neural activation, and which was especially pronounced for infants scoring high on the AOSI. ASIB's attenuated N290 response was reflected in a muted pattern of neural activation, and was not associated with AOSI scores. This indicates that greater amplitude N290 in infants with FXS may be driven by increased ASD risk in a subset of the participants, but questions remain regarding the behavioral correlates of ASIBs' neural responses to faces in infancy.

446.004 *(Poster)* Gamma Oscillations and Visual Evoked Potentials Relate to Face Processing in Children with ASD

T. C. Parker[1], *A. Naples*[1], *K. Chawarska*[1], *G. Dawson*[2], *R. Bernier*[3], *S. Jeste*[4], *J. Dziura*[5], *C. Brandt*[5], *S. J. Webb*[3], *C. Sugar*[4], *M. Murias*[6], *F. Shic*[7] *and J. McPartland*[1], *(1)Child Study Center, Yale University School of Medicine, New Haven, CT, (2)Department of Psychiatry and Behavioral Sciences, Duke Center for Autism and Brain Development, Durham, NC, (3)Psychiatry and Behavioral Sciences, University of Washington, Seattle, WA, (4)University of California, Los Angeles, Los Angeles, CA, (5)Yale University, New Haven, CT, (6)Duke Center for Autism and Brain Development, Department of Psychiatry and Behavioral Sciences, Duke University, Durham, NC, (7)Center for Child Health, Behavior and Development, Seattle Children's Research Institute, Seattle, WA*

Background: Considerable evidence indicates that GABAergic interneuron development and connectivity are disturbed in the prefrontal and temporal cortices in autism spectrum disorder (ASD) (Casanova *et al*., 2002), contributing to excitatory-inhibitory disruption (Levitt, 2005). Previous electroencephalography (EEG) studies report that increased spontaneous gamma power at rest and attenuation of P100 amplitude in visual evoked potential (VEP) tasks reflect excitatory-inhibitory imbalance (Cornew *et al*., 2012; Orekhova *et al*., 2007; Siper *et al*., 2016). Very few EEG studies have investigated the relationship between this imbalance and impaired face processing deficits associated with ASD (Kang *et al*., 2018).

Objectives: The current study examines the neural indices of excitatory-inhibitory imbalance and face-related brain activity in children with ASD.

Methods: EEG was recorded from 106 children with ASD (85 male and 21 female) and 54 typically-developing (TD) children (35 male and 19 female) using a 128-channel HydroCel Geodesic Sensor Net. The sample was matched on age (ASD: M=8.94, *SD*=1.60; TD: M=8.53, *SD*=1.74; p>.05), but differed on full-scale IQ (ASD: M=101.14, *SD*=17.53; TD: M=116.30, *SD*=13.44; p<.01) and the NEPSY-II: Memory for Faces Scaled Score (ASD: M=8, *SD*=4; TD: M =11,*SD*=4; p<.01). Participants were presented with videos of non-social abstract stimuli (resting-state EEG), checkerboard pattern-reversals (VEP), as well as digital images of upright faces, inverted faces, and houses on a computer monitor (N170). Dependent variables of interest were whole-scalp gamma power, P100 amplitude extracted from the occipital region, and N170 latency derived from the right occipitotemporal area, respectively. ASD symptomatology was measured using the Autism Diagnostic Observation (ADOS-2), and clinical diagnosis was determined by a licensed psychologist.

Results: There was a statistically significant difference in N170 latency for upright faces between groups ($F(1,159)=4.420$, $p=.037$; ASD: M=207.96 ms, *SD*=30.15 ms; TD: M=197.41 ms, *SD*=29.77 ms). Additionally, resting-state gamma power was correlated with VEP P100 amplitude ($r(160)=.216$,$p=.006$) and negatively correlated with the Memory for Faces subscale on the NEPSY-II ($r(160)= -.157$, $p=.048$). Finally, a linear regression was conducted to determine if P100 amplitude and gamma power predicted N170 latency for upright faces. Contrary to our hypothesis, the model was not found to distinguish between different N170 latencies for upright faces ($p>.05$).

Conclusions: Consistent with previous research, individuals with ASD exhibited longer N170 latencies to upright faces than TD individuals. Our findings also indicated that visually-evoked P100 amplitude was related to spontaneous gamma-power, suggesting that VEPs and gamma oscillations are generated by similar neuronal pools. Additionally, spontaneous gamma power was found to predict a behavioral measure of facial recognition. Nonetheless, the results suggest that gamma power and P100 amplitude may not be enough to contribute to observed differences in N170 latency. Examination of interneuron marker distributions in the general population may provide biological insight into resting-state and visually-evoked cortical signals that may explain variability in face processing.

446.005 *(Poster)* How Does Engagement Alter the Activity of Social Brain Systems?

J. Pincus[1], *S. Koirala*[1], *L. Li*[2], *A. Klin*[3], *W. Jones*[3] *and S. Shultz*[3], *(1)Department of Pediatrics, Emory University School of Medicine, Marcus Autism Center, Atlanta, GA, (2)Marcus Autism Center, Children's Healthcare of Atlanta, Emory University, Atlanta, GA, (3)Marcus Autism Center, Children's Healthcare of Atlanta and Emory University School of Medicine, Atlanta, GA*

Background: Hypoactivation of social brain circuitry in response to social stimuli, such as faces, has been widely reported in Autism Spectrum Disorder (ASD) (Schultz, 2005*, Int. J. Dev. Neurosci.)*. However, whether hypoactivation reflects reduced engagement with social stimuli (a hallmark of ASD) or recruitment of atypical brain systems remains unknown. Here, we combine functional magnetic resonance imaging (fMRI), eye-tracking measures of visual fixation, and a novel measure of engagement - eye-blinking (Shultz, Klin, & Jones, 2011, *PNAS*) - in order to examine brain activity at moments when children with ASD look at faces that *they themselves* perceive as highly engaging—a critical control missing from prior studies. If activation of face processing systems increases to normative levels when children with ASD look at faces that they perceive as highly engaging, then previous reports of hypoactivation reflect reduced interest in the faces presented. By contrast, if face processing systems remain hypoactive, *even when children with ASD look at faces that they perceive as highly engaging,* then children with ASD may be processing those stimuli using atypical brain circuitry.

Objectives: To investigate whether children with ASD recruit the same or different neural systems as typically-developing (TD) children when looking at faces that *they themselves* perceive as highly engaging.

Methods: Simultaneous fMRI and eye-tracking data were collected while 8- to 12-year-old TD (n=8) and ASD (n=12) children viewed movie scenes of children interacting in naturalistic contexts. Children were trained in a mock scanner until movement was <3mm for 3 8-minute periods. fMRI data were collected using a T2-weighted EPI sequence (TE=25s, TR=2.15s, flip angle=90°, voxel size=3.5mmx3.5mmx3.5mm, 37 axial slices without gap). Eye-tracking measures were used to identify events-of-interest: faces perceived by viewers themselves as 'highly engaging' or 'less engaging' (Figure 1). For fMRI analyses, events-of-interest were modeled with a boxcar function. Group-level analyses were performed using FSL's 2-stage procedure to correct for multiple comparisons.

Results: Preliminary whole-brain analyses (z=2.3, cluster corrected) reveal that TD and ASD groups recruit different brain systems when looking at faces perceived, by the viewers themselves, as 'highly engaging' compared to 'less engaging' (Figure 2). TD children showed increased activation in bilateral occipital cortex, left middle temporal gyrus, bilateral posterior cingulate, left frontal orbital cortex and inferior frontal gyrus, right angular gyrus, and right fusiform gyrus. In contrast, ASD children showed increased activation in temporal occipital cortex.

Conclusions: Results provide the first understanding of brain activity when TD and ASD populations look at faces that *they themselves* perceive as engaging, suggesting that previous reports of hypoactivation in ASD were unlikely to be driven solely by attenuated engagement with presented faces. Even when children with ASD look at faces that they perceive as engaging, they process those stimuli using atypical neural circuitry – regions typically involved in object perception. Since engagement is a strong predictor of learning, understanding how engagement influences social brain circuitry can inform interventions for social learning. Immediate next steps include replicating findings in a larger sample, performing between-group contrasts, and performing region-of-interest analyses in canonical face-sensitive regions.

446.006 *(Poster)* Investigating Genetic Influence on Social Visual Engagement: Patterns of Concordance between Twins Discordant for MECP2 Duplication Syndrome

T. A. Ponzo[1], *A. I. Mendez*[1], *M. Pileggi*[1], *S. Richardson*[2], *S. Shultz*[1], *C. Klaiman*[1], *A. Klin*[1], *N. Marrus*[3], *J. N. Constantino*[3] *and W. Jones*[1], *(1)Marcus Autism Center, Children's Healthcare of Atlanta and Emory University School of Medicine, Atlanta, GA, (2)Marcus Autism Center, Atlanta, GA, (3)Washington University School of Medicine, St. Louis, MO*

Background: Recent evidence indicates that social visual engagement – how infants preferentially attend to their surrounding social environment – is strongly influenced by genetic variation (Constantino et al., 2017; Kennedy et al., 2017). Monozygotic twins show high concordance in levels of eye- and mouth-looking (~0.9), while dizygotic twins show reduced concordance (~0.4). Here, we present longitudinal data from a dizygotic twin pair discordant for *MECP2*, the X-linked gene encoding methyl-CpG-binding protein 2 (MeCP2): one twin is unaffected and typically-developing, while the other has *MECP2* duplication syndrome. This syndrome is characterized by moderate to severe intellectual disability and delayed development of motor skills. Children with *MECP2* duplication syndrome share many phenotypic features with ASD and are often diagnosed with ASD (Ramocki et al., 2009). By examining concordance in social visual engagement in twins discordant for *MECP2* duplication, we hope to illuminate specific genetic factors that influence behaviors relevant to the early ontogenesis of autistic social disability.

Objectives: To investigate concordance in social visual engagement between twins discordant for *MECP2* duplication syndrome using longitudinal eye-tracking-based measures of eye- and mouth-looking together with developmental assessments of cognitive and language abilities.

Methods: A twin pair discordant for *MECP2* duplication syndrome was followed for the first two years of life. Longitudinal eye-tracking sessions measured developmental trajectories of social visual engagement. Twin-twin concordance analyses quantified degree of similarity in social visual engagement between siblings. Additionally, *Mullen* and *ADOS* assessments measured expressive and receptive language, motor skills, and degree of social disability.

Results: Each twin showed distinct trajectories of social visual engagement regarding faces: in the affected twin, face-looking declined dramatically in the first 2 years, from greater than 90% to ~10%, offset by markedly increased body- and object-looking; in contrast, face-looking in the unaffected twin increased, from ~70% to ~90%, with diminishing body- and object-looking (Figure 1). For eye- and mouth-looking specifically, *MECP2* duplication clearly disrupts twin-twin concordance (Figure 2). Notably, the disruption is in absolute levels of eye-looking; when magnitude differences are accounted for, twins' *relative* levels of eye-looking are surprisingly concordant (ICC=0.64, p=0.04). This effect is specific to eye-looking: relative levels of mouth-looking are uncorrelated and remain so even when magnitude differences are corrected (ICC=0).

Conclusions: In twins discordant for *MECP2* duplication, concordance in social visual engagement is markedly disrupted. This disruption appears to be specific to the active seeking of social information in the eyes: during the first two years of life, the child with *MECP2* duplication syndrome looks progressively less at other's eyes, but when results are corrected for magnitude differences, we see that twins' relative levels of eye-looking are correlated. In addition, while prior results suggested similar levels of genetic influence on both eye- and mouth-looking, the current comparisons indicate that that influence is separable and likely driven by genetic influence on eye- more than mouth-looking. Together, these results reveal a means by which a specific genetic alteration may impact social visual engagement and the emergence of autistic social disability.

446.007 *(Poster)* Neurobiological Correlates of Biological Motion Perception and Executive Function Ability: An Exploratory Study

M. C. Aubertine[1]*, A. Atyabi*[2]*, M. Kim*[3]*, B. Li*[4]*, K. J. Dommer*[5]*, Y. A. Ahn*[6]*, E. Neuhaus*[7]*, K. A. Pelphrey*[3] *and F. Shic*[8]*, (1)Seattle Children's Hospital and Research Institute, Seattle, WA, (2)Seattle Children's Research institute University of Washington, Seattle, WA, (3)University of Virginia, Charlottesville, VA, (4)Computer Science and Engineering, University of Washington, Seattle, WA, (5)Seattle Children's Research Institute, Seattle, WA, (6)Psychology, University of Miami, Miami, FL, (7)Seattle Children's Hospital, Seattle, WA, (8)Center for Child Health, Behavior and Development, Seattle Children's Research Institute, Seattle, WA*

Background: Executive function (EF) deficits are well-documented in many children with Autism Spectrum Disorders (ASD). Because EF is critical for planning and executing goals, deficits in EF can significantly affect daily living skills, negatively impacting quality of life and socio-communicative deficits of ASD (Hill, 2004; Lopez et al., 2005; Faja et al., 2016). Similarly, research has shown that biological motion perception (BMP) is altered in ASD, and some have argued that these alterations signal more profound deficits impacting social cognition, motivation, and perception at a fundamental level (Freitag et al., 2008). Yet, little is known about the interaction, if any, between EF deficits and neural activity supporting BMP. Understanding this interaction may facilitate the discovery of better biomarkers and leading to the development of more targeted therapies addressing both domains.

Objectives: Explore the relationship between EF ability and hemodynamic response measured by functional near infrared spectroscopy (fNIRS) in ASD and typically developing (TD) participants while they watch point-light displays of biological motion varying in emotional content.

Methods: Participants were typically developing children (TD; n=17, *Mage*=6.83 years) and children with ASD (n=28, *Mage*=7.00). Participants wore a fNIRS EasyCap (Gowerlabs) that covered prefrontal and temporal cortices while viewing five blocks of eight interleaved BMP and rotation trials. Blocks were separated by 15s children's video clips to re-engage participants. Data processing was conducted using a modified Homer2 software with low pass filtering (0.50 Hz) and motion artifact removal. Data were processed for outliers and z-scored within and across participants for comparability. EF was measured using the parent-report Behavior Rating Inventory of Executive Function-Preschool (BRIEF-P) and BRIEF-2.

Results: Three channels revealed significantly different hemodynamic response between condition (BMP and rotation) and group. Pearson's correlations were calculated between those channels and BRIEF scores, partialling for IQ. Correlations were observed in the left inferior frontal gyrus (IFG) (r_{all} = -.406, p = .026), where greater activation was associated with lower BRIEF scores (indicating better EF skills). An exploratory analysis revealed two additional channels associated with the left IFG were significantly correlated with BRIEF-P scores (r_{pre} = -.464, p = .01; r_{pre} = -.541, p = .002). Finally, we looked at channels where activation was significant only in the TD group. Correlations were found in the right orbito-frontal cortex (OFC) (r_{all} = .448), and right superior temporal gyrus (anterior: r_{all} = -.415, p = .023; posterior: r_{all} = -.431, p = .017)

Conclusions: This work suggests that there may be a link between EF and perception of biological motion. Relationships between EF and activation were found in two regions associated with semantic processing and emotional decision making, the OFC and left IFG. Previous studies have implicated the superior temporal gyri in social cognition, which was significantly activated in TD children watching BMP videos. This region was correlated with parent-reported EF ability, suggesting overlapping networks responding to executive function and basic social information processing needs. Further work is necessary to delineate the contributions of regional brain activation in EF ability and social cognition as measured by BMP paradigms.

446.008 *(Poster)* Neurogenetics of Female Autism Spectrum Disorder: Evidence for Striatal Impacts from Fmri Response and Rare CNV Size in the ACE Gendaar Cohort.

A. Jack[1]*, C. Sullivan*[2]*, K. A. Pelphrey*[3] *and A. R. Gupta*[4]*, (1)Psychology, George Mason University, Fairfax, VA, (2)Yale University, New Haven, CT, (3)University of Virginia, Charlottesville, VA, (4)Pediatrics and Child Study Center, Yale University, New Haven, CT*

Background: Males (ASDm) versus females (ASDf) are diagnosed with autism spectrum disorder (ASD) at rates of ~4:1. Here, we integrate functional magnetic resonance imaging (fMRI) and genetic data in a sex-balanced sample of ASD and neurotypical youth to characterize female-specific pathways of ASD risk.

Objectives: 1) Characterize the neurofunctional profile of ASDf response to socially meaningful motion, defined as brain regions in which typically developing female youth (TDf) display a stronger fMRI response to coherent versus point-light displays of human motion (BIO > SCRAM) than ASDf. **2)** Integrate genetic and fMRI data to evaluate the hypothesis that ASDf, versus ASDm, would show larger median size of rare CNVs containing gene(s) expressed in early life in brain regions comprising the fMRI-based ASDf profile.

Methods: We analyzed data drawn from Wave 1 of our longitudinal ACE Network project focused on ASDf (the "GENDAAR" cohort). ***For objective 1,*** we examined fMRI data from N = 90 (45 ASDf) girls aged 8-17y matched on age, estimated full-scale IQ, and head motion to determine regions where TDf > ASDf for the BIO > SCRAM contrast ($p_{corrected}$ < .05 using FSL's randomise; 10k permutations; threshold-free cluster enhancement). ***For objective 2*****,** we examined genetic data from N = 127 (61 ASDf) probands from the GENDAAR cohort. Using the BrainSpan Developmental Transcriptome, we identified genes positively expressed between 10 postconceptual weeks (pcw) and 2y within brain regions identified in our fMRI-defined ASDf profile (the *candidate gene set*). We assessed the significance of the ASDf minus ASDm difference in median size of rare copy number variants (CNVs) containing at least one of these genes via permutation testing with 10k iterations. The reproducibility of effects was assessed among N = 2,075 probands (291 ASDf) from the Simons Simplex Collection (SSC).

Results: ***fMRI results.*** TDf showed stronger BIO > SCRAM response than ASDf in widespread, primarily parietal, posterior temporal, and posterior frontal regions; largest effect sizes were observed in right ventral premotor cortex, primary motor cortex, right putamen of striatum, and right central operculum. ***CNV results.*** The ASDf-ASDm median difference in size of CNVs containing at least one candidate gene was 81,597 base pairs (bp; p = .0487); this difference was driven primarily by CNVs containing gene(s) positively expressed in right or left striatum (R/L-STR). Considering only CNVs containing R/L-STR-expressed gene(s), the ASDf-ASDm median size difference was 89,999 bp (p = .0293). Additional tests indicated that this size difference was greater than that found when considering CNVs containing any genes (p = .0178), or CNVs containing any BrainSpan-characterized genes (p = .0048). In the SSC replication, we found an ASDf-ASDm median size difference in CNVs that contained at least one R/L-STR-expressed gene of 45,133 bp (p = .0041).

Conclusions: fMRI data reveal that ASDf, versus TDf, response to human motion is characterized by decreased involvement of regions including striatum. Further, in ASDf versus ASDm, we observe larger median size of CNVs containing gene(s) expressed in early striatal development, suggesting that impacts to striatum may contribute to pathways of risk in ASDf.

446.009 *(Poster)* Occipital Resting-State Alpha Lateralization As a Predictor of Social Responsiveness in Adults with Autism Spectrum Disorder (ASD)

A. Eiland[1], *S. Kala*[1], *A. Bagdasarov*[1], *E. Cummings*[1], *C. Carlos*[1], *A. Naples*[1], *J. Wolf*[1], *J. H. Foss-Feig*[2], *A. Anticevic*[3], *V. Srihari*[3] *and J. McPartland*[1], *(1)Child Study Center, Yale University School of Medicine, New Haven, CT, (2)Seaver Autism Center, Department of Psychiatry, Icahn School of Medicine at Mount Sinai Hospital, New York, NY, (3)Division of Neurocognition, Neurocomputation, and Neurogenetics (N3), Yale University School of Medicine, New Haven, CT*

Background: Abnormalities in electroencephalography (EEG) alpha-band (8-13 Hz) oscillations have been proposed as a potential biomarker for autism spectrum disorder (ASD). Research using whole-brain analyses of EEG alpha power shows that increased resting-state alpha power in the occipital region is associated with low social responsiveness. However, much of this research has ignored potential alpha power asymmetries across hemispheres and the effect of alpha lateralization on social responsiveness. The present study examines resting-state alpha power in the context of lateralization and its relationship to social responsiveness in ASD. Additionally, few studies have explored the relationship between resting-state alpha power and social responsiveness while controlling for anxiety, a disorder that appears in 40% of individuals with ASD. As anxiety has been associated with increased alpha power, it is critical to examine anxiety as a possible confounding variable.

Objectives: To understand lateralized resting-state alpha power as a predictor of social responsiveness, controlling for anxiety, in adults with ASD and typically developing (TD) controls.

Methods: Participants were 22 adults with ASD (18 male) and 37 TD controls (21 male) aged 18-38. ASD diagnoses were confirmed using the Autism Diagnostic Observation Schedule (ADOS-2) and DSM-5 clinical criteria. Participants completed the Social Responsiveness Scale (SRS-2) to measure social impairment in natural settings and the Beck Anxiety Inventory (BAI) to assess physical symptoms of anxiety. Eyes-closed resting-state EEG was recorded continuously at 500Hz with a 128-channel net. Alpha lateralization was quantified as the log of left alpha subtracted from the log of right alpha in central, frontal, and occipital electrode clusters over both hemispheres. Absolute alpha power in each region was also calculated.

Results: Linear regression analysis revealed that higher alpha lateralization over occipital scalp regions significantly predicted lower SRS T-scores in individuals with ASD (R^2=.306, F(1,20)=8.798, β=-.553,p=.008). When controlling for scores on the BAI, occipital lateralization still predicted SRS T-scores (R^2=.417, F(2,17)=6.081, β=-.453, p=.033). However, alpha lateralization did not significantly predict SRS T-scores in frontal or central regions. Lateralization did not significantly predict SRS T-scores in any regions in the TD group. An analysis of variance revealed a significant difference in absolute alpha power between ASD and TD groups in the left occipital region (p=.023) and a marginally significant difference in the right occipital region (p=.050). However, absolute alpha power from neither hemisphere independently predicted SRS T-scores.

Conclusions: Greater resting-state alpha lateralization in the occipital region predicted social responsiveness in adults with ASD, even when controlling for anxiety, a common comorbidity associated with alpha activity. While occipital resting-state alpha lateralization predicted social responsiveness, absolute alpha power in the left occipital and right occipital regions did not independently predict social responsiveness. This data suggests the importance of considering hemispheric difference in alpha power analyses of resting-state EEG.

446.010 *(Poster)* Regional Alteration of Inhibitory and Excitatory Neurometabolites in Autism Spectrum Disorder (ASD) and Its Relationship to Social Cognition

A. Nair[1], *Y. S. Lograsso*[2], *E. T. Wood*[3], *J. O'Neill*[4], *M. Dapretto*[3] *and C. Bearden*[5], *(1)University of California Los Angeles, Los Angeles, CA, (2)UCLA Semel Institute for Neuroscience and Human Behavior, Los Angeles, CA, (3)Dept of Psychiatry and Biobehavioral Sciences, University of California, Los Angeles, Los Angeles, CA, (4)Division of Child & Adolescent Psychiatry, UCLA Jane & Terry Semel Institute For Neuroscience, Los Angeles, CA, (5)University of California, Los Angeles, CA*

Background: The anterior cingulate cortex (ACC) has been postulated to have a role in multiple cognitive functions including decision-making, motivation, cost-benefit analysis, and social information processing (Apps et al., 2016; Zhou et al., 2016). It serves as a crucial hub for multiple social cognition networks and has recently been found to be involved in the regulation of social behavior in mouse models of ASD (Guo et al., 2019). Neuroimaging studies have found reduced functional connectivity (Zhou et al., 2016) and altered white matter development (Barnea-Goraly et al., 2004; Zikopoulos et al., 2010) of the ACC in individuals with ASD. However, neurochemical alterations within the ACC and its relationship to ASD symptomatology has yet to be explored.

Objectives: The goal of the current study is to examine the concentration of inhibitory and excitatory neurometabolites in the ACC in youth with ASD and its role in general cognitive abilities and social cognition.

Methods: Magnetic resonance spectroscopy data were acquired using MEGA-PRESS sequences on a 3T Siemens scanner in 25 youth with ASD aged 12-21 years, and 12 age-matched typically developing controls (TD). LCModel was used for fitting of the MEGA-PRESS Spectra. In addition to offline lipid removal, post-processing included spatial- and spectral FT, B_0-correction, eddy current correction, prior-knowledge spectral fitting (GAVA), quality control (rejection of spectra with linewidth >10 Hz, signal-to-noise <8 or obvious artifact and of peaks with CRLB >20%), metabolite quantitation relative to unsuppressed water, and CSF-correction. Endpoints included estimates of GABA (inhibitory neurometabolite) and Glutamate (Glu; excitatory neurometabolite) concentrations in the ACC. Additionally, participants were administered the Weschler Abbreviated Scale of Intelligence, Second Edition (WASI-II; Weschler, 1999) to obtain estimates of general cognitive abilities, and The Awareness of Social Inference Test (TASIT; McDonald, 2003) to measure social cognition skills

Results: Results showed that the ASD group demonstrated significantly lower Glu concentrations in the ACC than the TD group (t=-2.16, p=.04). Within the ASD group, lower Glu concentration was also associated with lower overall IQ (r=.46, p=.03). There were no significant differences observed for GABA concentration in the ACC between groups (p=.74). However, lower GABA concentration in the ACC was associated with lower TASIT scores (r=.502, p=.02) as well lower WASI-II Vocabulary scores (r=.48, p=.03) in the ASD group.

Conclusions: Our findings suggest regional alterations in key neurometabolite concentrations in the ACC in youth with ASD. It is likely that the expression of excitatory neurometabolites in the ACC plays a broader role in cognitive functioning. However, the expression of inhibitory neurometabolities in this region appears to be more closely related to social cognition and expressive communication– both areas that are known to be affected in individuals with ASD. Together with prior findings of disrupted functional and structural connectivity of the ACC, our results provide further support for neurochemical alterations in the ACC and the crucial role of this "social brain hub" in the pathophysiology of ASD.

446.011 *(Poster)* Sex Differences in the Association between Neural Response to Emotional Faces and Reciprocal Social Interaction in Adults with ASD

L. H. Singer[1]*, A. Bagdasarov*[1]*, E. Cummings*[1]*, S. Kala*[1]*, C. Carlos*[1]*, J. Wolf*[1]*, A. Naples*[1]*, J. H. Foss-Feig*[2]*, A. Anticevic*[3]*, V. Srihari*[3] *and J. McPartland*[1]*, (1)Child Study Center, Yale University School of Medicine, New Haven, CT, (2)Seaver Autism Center, Department of Psychiatry, Icahn School of Medicine at Mount Sinai Hospital, New York, NY, (3)Division of Neurocognition, Neurocomputation, and Neurogenetics (N3), Yale University School of Medicine, New Haven, CT*

Background: Sex differences in autism spectrum disorder (ASD) are well documented. For example, research has shown female advantage in facial emotion recognition. However, studies of neural response to facial emotions using event-related potentials (ERP) in ASD have often failed to consider sex differences. The N170, a face-sensitive ERP, is reliably atypical in ASD and may help to characterize sex differences in the neural processing of facial emotions. The current study compares the relationship between reciprocal social interaction and neural response to facial emotions in male and female adults with ASD.

Objectives: To assess sex differences in the association between reciprocal social interaction and N170 amplitude in response to facial emotions in male and female adults with ASD.

Methods: Participants were 24 adult males with ASD and 7 adult females with ASD. Independent samples t-tests revealed no significant differences in the age of males (M = 25.02, SD = 5.60) and females (M = 22.50, SD = 4.50). Participants completed the Wechsler Abbreviated Scales of Intelligence (WASI-II), which revealed no significant differences in cognitive ability between males (M = 103.25, SD = 19.00) and females (M = 109.29, SD = 15.27). Participants also were administered the Autism Diagnostic Observation Schedule, Module 4 (ADOS-4); the total score from the Reciprocal Social Interaction section (ADOS-RSI) is used in the current study. During EEG recording, participants were presented with faces with neutral emotions. When participants fixated directly on a face, as measured by eye-tracking, the facial expression changed to happy or fearful. N170 peak amplitude was extracted from left and right occipitotemporal electrodes. N170 peak amplitude from happy faces was subtracted from N170 peak amplitude from fearful faces to create a difference score.

Results: Linear regression analyses were used to determine whether scores on ADOS-RSI, controlling for WASI-II, predicted N170 amplitude difference scores. Among females with ASD, there was a significant negative association between ADOS-RSI and N170 difference scores in the right hemisphere, R^2=.851, F(2,4)=11.430, p=.012 (Figure 1). However, there was no significant association between these two measures among males with ASD, R^2=.157, F(2, 21)=1.949, p=.856. ADOS-RSI was not significantly associated with N170 amplitude difference scores in the left hemisphere for either males, R^2=.222, F(2,21)=2.994, p=.449 or females, R^2 =.126, F(2,4)=.289, p=.762. ADOS-RSI scores were not examined in typically developed adults due to insufficient variation caused by floor effects.

Conclusions: Our findings highlight sex differences in the relationship between neural activity and reciprocal social interaction in adults with ASD. Among females, but not males, decreased sensitivity to the difference between fearful and happy faces associated with behavioral deficits in reciprocal social interaction. These data hold significant promise for understanding the neural mechanisms guiding sex differences in the development of facial emotion processing in adults with ASD. Furthermore, this research helps to clarify when the N170, in the right hemisphere specifically, may be best used for diagnosis and stratification of ASD. Given the small number of females in our study, we plan to conduct similar analyses in a larger sample of females in the future.

446.012 *(Poster)* The Cerebellum Modulates the Acquisition of Social Information in Autism

L. C. Rice[1]*, A. M. D'Mello*[2]*, S. E. Martin*[3] *and C. J. Stoodley*[4]*, (1)Behavior, Cognition, and Neuroscience Program, American University, Washington, DC, (2)Brain and Cognitive Sciences, Massachusetts Institute of Technology, Cambridge, MA, (3)Neuroscience Program, American University, Washington, DC, (4)Psychology, American University, Washington, DC*

The cerebellum modulates the acquisition of social information in autism

Background:
Atypical social communication is a core feature of Autism Spectrum Disorder (ASD), but the neural bases of these social challenges remain unclear. The cerebellum is one candidate neural substrate: cerebellar structural and functional differences are well-characterized in ASD, and the cerebellum is engaged during a range of social tasks. More specifically, right cerebellar lobule VII shows reduced grey matter in autism, is activated during mentalizing tasks, and inhibition of this region in a mouse model yields atypical social behaviors and increased repetitive grooming. The cerebellum is thought to support various aspects of cognition through building and honing internal models of behavior. We hypothesize that cerebellar dysfunction in autism may disrupt the acquisition of social information, and that cerebellar neuromodulation may alter both performance and neural activation patterns on a social learning task.

Objectives:
The present study uses concurrent neuroimaging (functional MRI [fMRI]) and cerebellar transcranial direct current stimulation (tDCS) to investigate the impact of cerebellar neuromodulation on behavioral performance and neural activation patterns during a social ball toss game (Cyberball).

Methods:
Neurotypical adults (NT; n=16, 21.9±2.5 yrs) and adults with autism (n=10, 24.9±9.0 yrs) performed a social ball toss game, during which participants implicitly learn patterns of social reciprocity to improve their performance. Either excitatory (anodal), inhibitory (cathodal), or sham tDCS targeting right lobule VII was administered to participants prior to the game (20 min, 1.5 mA), and each participant completed all three tDCS conditions separated by one week. fMRI data was collected during task performance, pre-processed with fMRIPrep, and analyzed statistically with SPM12. The behavioral response variable was the proportion of tosses to the good reciprocal player over the course of the game, and linear mixed effects modeling was used to assess the effect of tDCS condition, session, task stage, and group.

Results:
Without modulation, participants with autism showed less social learning during the task compared with NT adults and showed reduced cerebellar activation, specifically in bilateral Crus I. Anodal cerebellar tDCS disrupted social learning in both groups, suggesting a role for the cerebellum in the acquisition of social information. While cathodal tDCS did not change performance in NT adults, adults with autism showed improved social learning following cathodal tDCS. Preliminary imaging analyses suggest that the autism group engaged bilateral Crus I following cathodal modulation, which may provide a mechanism for the improved performance in this condition.

Conclusions:
These results suggest that the cerebellum is involved in social learning, potentially playing a role in the acquisition of social information. Furthermore, preliminary results suggest that cerebellar neuromodulation may impact social behaviors in autism, through increasing activation in cerebellar regions that support successful task performance in neurotypical adults.

446.013 *(Poster)* To Mirror or Not to Mirror? the Effect of Oxytocin on Socially Adaptive Mirror System (dys)Functioning in ASD.

J. Prinsen *and K. Alaerts, Rehabilitation Sciences, KU Leuven, Leuven, Belgium*

Background: Individuals with ASD experience persistent difficulties during social interaction and communication. Both the Broken Mirror Theory (Ramachandran & Oberman, 2006), advancing abnormalities in the mirror system as an important neural substrate, and the STORM-account (Wang & Hamilton, 2012), proposing an impaired social top-down control of the mirror system by the mentalizing system according to the demands of the social context, provide an explanation for the social deficits in ASD.

Objectives: We investigated the feasibility of both accounts by examining interpersonal motor resonance in ASD and typically developing (TD) participants under various social conditions. A second objective was to investigate the effect of a single dose of intranasally administered oxytocin, a prosocial neuropeptide known for its therapeutic potential, on the putative mirror deficits in ASD.

Methods: To date, the data of 23 young adult men with ASD (mean age: 22 years 5 months) and 19 age- and IQ-matched TD participants (mean age: 22 years 4 months) has been collected (of the envisaged 35 in each group). Interpersonal motor resonance, as assessed by transcranial magnetic stimulation (TMS), was investigated during (a) baseline corticospinal excitability while at rest, (b) during observation of simple hand movements, and (c) during movement observation in combination with various gaze cues (direct vs. averted) from the actor. The BMT would anticipate deficits in motor resonance already when observing simple hand movements, whereas the STORM-account (based on the difficulties with eye contact in ASD) would predict a difference only in the relative effect of eye contact on motor resonance. Furthermore, ASD participants completed a randomized, placebo-controlled clinical trial with cross-over protocol to investigate the effect of a single dose of oxytocin (24 IU) herein.

Results: Preliminary results indicate no group difference between ASD and TD participants in terms of baseline corticospinal excitability when at rest, nor when observing simple hand movements (i.e. not embedded in a particular social context). Although tentative, the preliminary data indicated a more pronounced mirror response in TD participants when observed actions were combined with eye-to-eye contact compared to averted gaze from the actor, whereas for the ASD participants mirror responses were equal across both gaze conditions. After a single dose of intranasal oxytocin however, the ASD group showed a similar effect of observed gaze condition on interpersonal motor resonance as TD participants

Conclusions: Based on a preliminary analysis, we propose that people with social difficulties (such as individuals with ASD) may have an intact mirror system, but unlike social proficient participants, fail to modulate mirror system functioning according to the social context. Furthermore, although the mechanisms behind oxytocin-related improvements on social behavior are still unknown (increasing social saliency, increasing social motivation or decreasing over-arousal), a single dose of oxytocin enabled participants with ASD to show more socially adaptive interpersonal motor resonance, highlighting its therapeutic potential.

446.014 *(Poster)* fNIRS-Based Cortical Activation during a Charades Game in Children with and without Autism Spectrum Disorder (ASD)

A. Bhat[1], *W. C. Su*[2] *and D. Tsuzuki*[3], *(1)Department of Physical Therapy, University of Delaware, Newark, DE, (2)Physical Therapy, University of Delaware, Newark, DE, (3)Department of Language Sciences, Tokyo Metropolitan University, Tokyo, Japan*

Background: Children with ASD have difficulties using and interpreting various forms of communicative gestures (deictic, symbolic, descriptive, etc.). In the past, we have reported on cortical activation patterns using functional near-infrared spectroscopy (fNIRS) as children with and without ASD performed/observed simple communicative gestures such as thumbs up, come, go away, etc. (Su et al., 2018). Children with ASD had lower cortical activation over the Observation-Execution Matching System (OEMS) regions of inferior frontal gyrus (IFG) and superior temporal sulcus (STS) along with increased inferior parietal lobule (IPL) activation when observing and synchronizing the gestures with an adult. In this study, we further developed an engaging charades game involving a variety of everyday, bimanual, object-related actions. We will compare gestural accuracy and synchrony as well as associated fNIRS-based cortical activation within the charades game between children with/without ASD and an adult tester.

Objectives: To compare the accuracy of gestural understanding, gestural performance, and gestural synchrony as well as associated cortical activation between children with and without ASD as they observed, performed solo, and copied various symbolic gestures during a charades game.

Methods: Fifteen school-age children with ASD and 15 typically developing children (TD) participated. An fNIRS cap embedded with a 3x11 probe set covering middle frontal gyrus (MFG), IFG, STS, pre- and postcentral gyrus (PCG) and IPL were placed on the children's head to collect cortical activation data (average oxy-hemoglobin values). The child was seated across from an adult tester. Picture cards with 18 different symbolic gestures such as brushing teeth, hammering a nail, etc. were shown to the child or the adult tester depending on the condition: a) *Watch:* child observed the adult perform an action shown to the adult only; b) *Do*: The child performed an action shown on a picture card; c) *Together*: The child was asked to copy the adult's actions as the adult performed the actions shown on a picture card to her. For the Watch and Together conditions, we asked the child to guess the performed action and the accuracy of their understanding was assessed. Additionally, during the Do and Together condition, we also assessed the time to initiate and performance accuracy. Lastly, in the Together condition we assessed the synchrony between the child and the adult.

Results: We are in the process of collecting data. Our pilot data suggest greater time to initiation and more errors in gestural understanding and performance accuracy as well as poor interpersonal synchrony in children with ASD compared to TD peers. We also expect to see atypical patterns of OEMS activation in children with ASD compared to their TD peers (lower STS and IFG and greater IPL activation).

Conclusions: Our findings elucidate the various gestural impairments in children with ASD and how that might be mediated by poor cortical activation in various OEMS regions important for gesture production and understanding. We will identify multiple fNIRS-based neurobiomarkers that could be used to assess objective neural changes following a prolonged bout of gestural training.

Statistical Genetics

POSTER SESSION — **STATISTICAL GENETICS**
447 - Statistical Genetics Posters

447.001 *(Poster)* Comparing the Genetic Architecture between High and Low-Functioning Autism Spectrum Disorder

Z. Schmilovich[1], *Q. He*[2], *G. Huguet*[3], *S. Jacquemont*[3], *B. Chaumette*[4], *P. A. Dion*[5] *and G. A. Rouleau*[5], *(1)Human Genetics, McGill University, Montreal, QC, Canada, (2)INSERM, Paris, QC, France, (3)UHC Sainte-Justine Research Center, University of Montreal, Montreal, QC, Canada, (4)Institute of Neuroscience and Psychiatry of Paris, Paris, QC, France, (5)Neurology and Neurosurgery, McGill University, Montreal, QC, Canada*

Background: Autism spectrum disorder (ASD) is one of the most highly heritable complex diseases. Hundreds of ASD genetic risk alleles have been identified, yet most are associated with the severe low-functioning forms of the disorder. The variants that mediate ASD risk in individuals with high-functioning ASD (HFA) remain largely unknown. Previous literature suggests that individuals with HFA may have a genetic architecture that is distinct from other ASD subtypes. A 2014 Iossifov *et al*. study identified an enrichment of FMRP-associated and chromatin modifier genes in all ASD cases, except in those with a higher IQ. Chang *et al*. revealed the burden of truncating mutations to be two-fold higher in ASD individuals with low IQ, compared to those with a normal to high IQ.

Objectives: This study aims to test the theory that individuals with high-functioning ASD (HFA) have a distinct genetic architecture from their low-functioning ASD (LFA) counterparts, and to elucidate unestablished genetic risk factors that contribute to HFA.

Methods: Individuals with ASD from the Simons Simplex Collection (SSC) were grouped into HFA (n = 783; M:F = 9:1; mean age = 9.2 3.6 years; NVIQ = 112.3 10.7) or LFA (n = 1789; M:F = 5:1; mean age = 9.0 3.6 years; mean NVIQ = 72.2 21.3) subgroups based on a NVIQ of at least, or less than, 100, respectively. Firstly, copy-number variants (CNVs) were called from SNP-microarray data using PennCNV and QuantiSNP algorithms, and quality controlled and annotated using methods described in Huguet *et al*. 2018. Genes present in unique CNVs in HFA and LFA groups were selected for gene-set enrichment analyses. Secondly, an individual-level polygenic risk score (PRS) was computed using the largest published ASD GWAS summary statistics through the PRSice software. Single linear regressions modeled the association between PRS for ASD and HFA status to determine whether HFA could be predicted according to respective ASD polygenic risk.

Results: Preliminary analyses identified 136 copy-number deletions and 404 duplications unique to individuals with HFA. Gene-set enrichment analyses revealed the JAK-STAT signaling pathway to be uniquely enriched in the HFA cohort (p = 3.711×10-3). The JAK-STAT pathway includes inflammatory cytokines that are implicated in glia and neuron development and may enhance brain-derived neurotrophic factor expression. The olfactory transduction pathway was uniquely enriched in the LFA group (p = 8.479×10-10). Impaired olfactory perception and ASD has been previously been linked. No significant correlation (p = 0.335) between ASD PRS and HFA status could be established, suggesting that the HFA phenotype may be mediated by other genetic risk factors than ASD-associated common genetic risk variants.

Conclusions: In this study, we shed light on, and suggest the unique, genetic architecture of HFA. Unique CNVs in LFA and HFA groups were enriched in distinct molecular pathways. However, we did not identify a correlation between ASD risk and HFA status. Future analyses will test the difference of PRS for other psychiatric traits (intelligence, ADHD, bipolar disorder, schizophrenia, depression) between HFA and LFA.

447.002 *(Poster)* Genomic Association Study of Diffusion MRI-Based Autism Endophenotypes

G. Barnes[1]*, Y. ElNakieb*[2]*, M. T. Ali*[2]*, A. E. Switala*[2]*, M. M. Elmogy*[3]*, E. Rouchka*[4] *and A. S. El-Baz*[5]*, (1)Neurology, University of Louisville School of Medicine, Louisville, KY, (2)Bioengineering, University of Louisville, Louisville, KY, (3)University of Louisville Speed School of Engineering, Louisville, KY, (4)Computer Science, University of Louisville Speed School of Engineering, Louisville, KY, (5)University of Louisville, Louisville, KY*

Background: Autism is a multifactorial, heterogeneous syndrome that defies a simple genetic test for diagnosis. However, autism has been considered a disorder of brain connectivity. This fact suggests that different patterns of altered connectivity may be used to identify specific endophenotypes under the umbrella of the autism spectrum. If any of these more narrowly defined endophenotypes have genomic markers, it opens the door to personalized diagnosis and targeted therapy in at least a subset of ASD cases.

Objectives: We performed an exploratory retrospective study on the association of metrics of brain connectivity with genomic variation (i.e., SNPs) in people with ASD. The objective was to identify genomic loci linked with different patterns of altered connectivity.

Methods: Data comprised diffusion tensor imaging (DTI) data obtained from the NIMH Data Archive. When available, genomic variant information in the form of Illumina microarray files were obtained from the same source. DTI scans of ASD (N=123) and typically developing (TD: N=115) individuals were parcellated according to the Johns Hopkins University white matter (WM) atlas. Feature extraction identified the pairwise correlation between WM tracts in terms of their microstructural quantities (FA, mean diffusivity, etc.). Descriptors that most significantly distinguished the ASD and TD classes were used to group the ASD cases into clusters for subsequent genomic association analysis. Genes containing one or more SNPs associated at $p \leq 10^{-6}$ were selected for enrichment analysis.

Results: Cluster analysis using PAM with different numbers of clusters produced best intracluster coherence and intercluster separation for $k = 3$. Cluster 1 was associated with SNPs in 79 genes. Enrichment analysis found significant protein-protein interaction (PPI) within this set ($p = 0.0147$). There was no functional enrichment with respect to GeneOntology (GO) terms, but seven genes were associated with “neurodegeneration” in UniProt (false discovery rate/FDR = 0.0275), and three of them in particular with ”spinocerebellar ataxia” (FDR = 0.0298). Cluster 2 was associated with 715 genes with more than chance PPI ($p < 10^{-7}$) with functional enrichment in several GO concepts, most significantly “synapse”, “synapse part”, and “postsynapse” (FDR = 4×10^{-9}, 6×10^{-8}, and 8×10^{-8}, respectively). Cluster 3 was linked with eight genes and had no significant PPI ($p = 0.149$) with significant functional enrichment for GTPase activator activity: *ASAP3*, *ADGRB3*, and *DOCK4*. According to UniProt, *ASAP3* promotes cell proliferation. *ADGRB3* and *DOCK4* both interact with the Rac pathway, promoting cell migration, dendrite spine formation, and synaptogenesis. There was some overlap between the association results for cluster 2 and those for clusters 1 (13 genes) and 3 (one gene).

Conclusions: The association with spinocerebellar ataxia-related genes (cluster 1) along with the enrichment of synaptic genes (Cluster 2) and GTPase activator activity-related genes (cluster 3) are all involved in brain growth with obvious relevance to ASD as a disorder of brain connectivity. In summary, these preliminary results suggest that unique biologically relevant genes in distinct clusters drive the white matter connectivity in ASD.

447.003 *(Poster)* Rare Transmitted Variants Identify Novel Genes and Pathways Contributing to Autism Spectrum Disorder

A. B. Wilfert[1]*, T. N. Turner*[1]*, S. C. Murali*[1]*, T. Wang*[1]*, A. Sulovari*[1]*, H. Guo*[2]*, B. P. Coe*[1]*, E. E. Eichler*[1,3] *and S. Consortium*[4]*, (1)Department of Genome Sciences, University of Washington, Seattle, WA, (2)Center for Medical Genetics, School of Life Sciences, Central South University, Changsha, China, (3)Howard Hughes Medical Institute, Seattle, WA, (4)SPARKForAutism.org, New York, NY*

Background: Autism spectrum disorder (ASD) is a highly heritable disorder that affects communication, learning, and behavior. It is estimated that hundreds of genes contribute to ASD through a wide variety of genetic mechanisms, with recent studies focusing on *de novo* mutation (DNM), large copy number variants, and common variants although early exome studies suggested a transmission bias of likely-gene disruptive (LGD) mutations to affected children (Krumm et al,. *Nat Genet*, 2015).

Objectives: The goal of our current study is to compare this risk of private LGD mutations in multiplex and simplex families and to assess the relative contribution of known ASD risk genes versus uncharacterized genes to this genetic etiology.

Methods: We used whole-genome sequencing data from 3,473 complete families (4,362 affected child and 2,235 unaffected children) to identify gene sets enriched for affected children carrying a private mutation. We then performed functional enrichment studies (e.g., gene ontology) to characterize candidate genes. We replicated all of our results using whole-exome sequencing data from the SPARK consortium, which is comprised of 5,879 complete families (6,539 affected children and 3,034 unaffected children).

Results: We discover and replicate that ultra-rare LGD mutations, present in only one parent of the autism cohort, are enriched in children with autism when compared to their unaffected siblings and the effect is larger with increasing gene constraint (pLI). We show that the burden of private variants among children with autism is greater in multiplex families when compared to simplex families (OR = 1.4 (p = 0.026) vs. 1.23 ($p = 1.63e^{-4}$) at pLI ≥ 0.99) and that children with autism are more likely to carry two or more of these mutations when compared to their unaffected siblings (OR= 1.28, p= 0.0026). As expected, ASD genes previously reported by DNM enrichment studies show an LGD transmission bias to autism probands (OR = 1.36, p-value = 0.040); however, such genes only account for <5% of the genic burden suggesting that most of genes associated with inherited burden await discovery. Among the most intolerant genes to mutation (pLI > 0.99), we identify 163 new candidate genes that are enriched for protein-protein interactions (p-value = 0.0016) related to E3 ubiquitin ligation, axon guidance, and Ras signaling. We estimate that such private, inherited LGD mutations account for a comparable level of population attributable risk when compared to DNM enriched mutations in genes (4.58% vs. 7.28%).

Conclusions: We find that children with ASD are more likely to carry multiple, inherited LGD variants and the effect is larger for multiplex families. 95% of this private variant burden lies outside known DNM enriched ASD genes. We identify a set of highly constrained genes that have not been previously reported by DNM enrichment analyses highlight disease-relevant functional pathways, such as axon guidance and E3 ubiquitin ligase activity.

Technological Approaches

ORAL SESSION — TECHNOLOGICAL APPROACHES
328 - Technologies to Predict and to Classify Social and Communicative Behaviours

328.001 *(Oral)* Preliminary Feasibility of the Tedi: A Novel Assessment of Infants' ASD Symptoms Via Telehealth

M. R. Talbott[1], *S. Dufek*[2], *L. Zwaigenbaum*[3], *S. E. Bryson*[4], *J. A. Brian*[5], *I. M. Smith*[6] *and S. J. Rogers*[7], *(1)Psychiatry and Behavioral Sciences, University of California at Davis MIND Institute, Sacramento, CA, (2)Psychiatry, University of California, Davis, Sacramento, CA, (3)University of Alberta, Edmonton, AB, Canada, (4)Dalhousie University, Halifax, NS, Canada, (5)Holland Bloorview Kids Rehabilitation Hospital, Toronto, ON, Canada, (6)Dalhousie University / IWK Health Centre, Halifax, NS, CANADA, (7)Department of Psychiatry and Behavioral Sciences, The Medical Investigation of Neurodevelopmental Disorders (MIND) Institute, UC Davis School of Medicine, University of California Davis, Sacramento, CA*

Background: Maximizing the benefits of early intervention for improving outcomes of individuals with autism spectrum disorders (ASD) depends on efficacious early screening and identification practices. The persistent lag between symptom onset and formal diagnosis underscores the urgency of improving early screening methods (CDC, 2018). Parent concerns as early as 6 months are associated with subsequent ASD diagnoses (Sacrey et al., 2016, 2015). However, families with early concerns typically face long waitlists and often must travel long distances to centers with appropriate expertise (Daniels & Mandell, 2016; Zuckerman, et al. 2005). Development of a telehealth screener has the potential to address these issues as it has been used to address disparities in access for other pediatric populations and has shown promise in early parent-implemented interventions for ASD.

Objectives: The primary aim of this study was to evaluate the feasibility of adapting current laboratory-based measures of social communication and ASD symptoms in infancy for telehealth parent administration. Adapted measures included a parent-administered Autism Observation Scale for Infants (AOSI; Bryson, et al. 2008) and the Individual Growth and Development Indices – Early Communication Indicator (IGDI-ECI; Greenwood, et al. 2010). Outcome benchmarks included feasibility, reliability, and acceptability to families.

Methods: Eleven infants, aged 6-12 months were assessed via telehealth by coaching parents to administer specific semi-structured behavioral probes (the Telehealth Evaluation of Development for Infants or TEDI) using a kit of play materials and cue cards that were mailed to the family. The AOSI was scored live by the clinician administering the TEDI and the ECI was coded offline by an undergraduate rater naive to session order and specific parental concerns.

Results: All initial feasibility benchmarks were met. Inter-rater reliability for ECI and AOSI total score was good-to-excellent ($ICC_{ECI} = .94$; $ICC_{AOSI\ total} = .65$). Test-retest reliability was high (AOSI total $r_s = .86$, $p = .002$; AOSI markers $r_s = .47$, $p = .171$; ECI $r_s = .56$, $p = .115$). Parent acceptability ratings were uniformly significantly positive (all p's <.001) in across items rating the technology, assessment components, and convenience.

Conclusions: To our knowledge, this is the first study to systematically adapt and test clinic-based behavioral screening for infants with symptoms of ASD within a telehealth protocol. Our findings support the feasibility of this approach and suggest an avenue for conducting future larger-scale feasibility studies, with a long-term goal of prospectively monitoring community-ascertained samples of symptomatic infants. These results suggest that this approach is feasible and highly acceptable to families. If supported by additional studies, this approach may lead to earlier referral to evaluations and interventions and better outcomes for infants with persistent symptoms. It may also provide an avenue for ongoing assessment in intervention trials.

328.002 *(Oral)* Prototypical Networks for Robust Automatic Child-Adult Classification from Speech

M. Kumar[1], *N. Koluguri*[1], *S. H. Kim*[2], *C. Lord*[3] *and S. Narayanan*[1], *(1)University of Southern California, Los Angeles, CA, (2)Psychiatry, Center for Autism and the Developing Brain, White Plains, NY, (3)University of California, Los Angeles, Los Angeles, CA*

Background: Speech and language features extracted from participants in diagnostic interactions such as ADOS administration, have been used for objective behavioral analyses and for understanding relations with symptom severity. Previous studies have relied on manually obtained speaker-specific speech segments for supporting such analyses, which are neither scalable nor an efficient solution. An important need hence is automatically assigning which part of the speech segment belongs to whom; notably in many ASD relevant settings this entails enabling automatic child-adult classification from speech. This task is challenging because of the wide intra and inter speaker variability. Specifically, clinical populations such as children with ASD are known to exhibit large variability in their speech even within the same age and linguistic development groups. Hence, it becomes necessary to build a child-adult classifier from speech robust to speaker variabilities.

Objectives: We propose the application of a meta-learning paradigm (prototypical networks, or *protonets*; Snell et. al., 2017) for child-adult classification from speech. We compare the performance of protonets with the state-of-the-art system in speaker recognition research (x-vectors) under two scenarios: weakly-supervised and completely unsupervised setting. We illustrate the robustness of protonets to variations in speaker characteristics by studying the relation between classification metric with age of child and verbal IQ (VIQ) scores.

Methods: We select two corpora consisting of Brief Observation of Social Communication Change (BOSCC; Grzadzinski et al., 2016) sessions: BOSCC_A consists of verbally-fluent children (n=19; Age: μ=8.8yrs, σ=3.4yrs; VIQ: μ=96.9, σ=27.0) with complex sentence formation skills, while BOSCC_B consists of minimally verbal toddlers and preschoolers (n=12; Age: μ=1.8yrs, σ=1.9yrs; VIQ: μ=71.6, σ=73.4). The younger age group of children in BOSCC_B represents a significant domain mismatch with BOSCC_A, hence it is used exclusively for evaluating models trained on BOSCC_A. We train protonets on BOSCC_A by treating child-adult classification across different training sessions as multiple, but related tasks. During weakly-supervised evaluation, we assume 5 labeled samples from child and adult in every test session to classify the remaining samples. In the unsupervised setting, we cluster all the samples into two classes.

Results: In the weakly-supervised setting, protonets outperform baselines by 4.82% and 14.53% (macro-F1) on BOSCC_A and BOSCC_B, respectively. Protonets achieved upto 7.28% and 12.61% relative improvements in cluster purity on BOSCC_A and BOSCC_B, respectively. From Figure 1, we note that protonets learn to cluster embeddings from different sessions compactly within a class (child/adult) when compared to x-vectors. Correlations between F1-scores with child age and VIQ dropped (in absolute value) from 0.76 to 0.59 and 0.50 to 0.28 respectively, hence illustrating that protonets' performance is more invariant to speaker characteristics when compared to x-vectors.

Conclusions: We demonstrate a method to train a robust automatic child-adult classifier from speech using limited training data. Protonets improve over existing approaches by leveraging information from multiple child-adult classification tasks and generalize across children with significantly different language levels. We illustrate the robustness of protonets using improved classification performance as well as reduced dependency on speaker characteristics.

328.003 *(Oral)* Associations between Objectively Measured Social Communicative Behaviors during the ADOS-2 and the Calibrated Severity Scores in 3-Year-Olds with Suspected ASD

Y. A. Ahn[1], *J. M. Moffitt*[1], *S. Custode*[1], *A. Beaumont*[2], *S. Cardona*[1], *M. Parladé*[2], *J. Durocher*[2], *M. N. Hale*[2], *M. Alessandri*[2], *L. K. Perry*[1] *and D. S. Messinger*[2], *(1)Psychology, University of Miami, Coral Gables, FL, (2)University of Miami, Coral Gables, FL*

Background: Autism spectrum disorder (ASD) is defined by restricted, repetitive patterns of behavior, as well as persistent disturbances of social communication. In current best practice, ASD is recognized on the basis of expert clinician judgment, which is informed by gold standard measures such as the Autism Diagnostic Observation Schedule-2 (ADOS-2). To date, observational research addressing social communication disturbances in children with ASD is rare in part because the field has lacked efficient methods for measuring behavior. Yet, clinical interventions to improve social communication and reduce interaction disturbances depend on an objective understanding of how children with ASD behave during clinical assessments. The current study sought to improve understanding of children's social communicative interaction with adults (both examiner and parent) present during the administration of the ADOS-2.

Objectives: To investigate associations between objective measures of child's social gaze, social smile, and Duchenne smile measured from adults' first-person video, child-adult vocal turn-taking interaction measured from audio recording, and the examiner-adjudicated symptom measure ADOS-2 calibrated severity scores (CSS).

Methods: Thirty-seven children (*M* age=38.59mo, SD=9.80) with suspected ASD were administered the ADOS-2. A hypothesis-blind examiner provided a total CSS and subscales for Social Affect (SA CSS) and restricted/repetitive behavior (RRB CSS). Children's total duration of socially-directed smiles, Duchenne smiles, and social gaze during the assessment were recorded with a small camera worn in eye-glasses (Pivothead or Orca) by the examiner and parent. We processed first-person video from the cameras with Affectiva (iMotions) software to automatically quantify child gaze and smile expressions (including Duchenne smile). Audio from wall-mounted camera recordings was processed with Language ENvironment Analysis (LENA) software, which provided automated vocalization detection yielding child and adult vocal turn counts. Measures included proportions of gaze, social smile, and Duchenne smile at adult (mean proportions of examiner and parent), child-adult vocal turn-taking counts, and ADOS-2 CSS (total, SA, and RRB).

Results: We found negative associations between the ADOS-2 total CSS and the proportions of gaze (r=-.36, p<.05), social smile (r=-.42, p<.05), and Duchenne smile (r=-.48, p<.01) directed at adult. Similarly, the SA CSS was negatively associated with the proportions of social smile (r=-.37, p<.05) and Duchenne smile (r=-.37, p<.05) at adult. While the SA CSS was negatively correlated with child-adult vocal turn-taking counts (r=-.33, p<.05), it was not significantly associated with the proportion of gaze at adult (r=-.03, p=.08). The RRB CSS, on the other hand, showed a negative association with the proportion of gaze at adult (r=-.53, p<.01), as well as the proportions of adult-directed social smile (r=-.44, p<.01) and Duchenne smile (r=-.51, p<.01).

Conclusions: Objective measurements of children's social communicative behaviors, during the ADOS-2 show convergence with the examiner-adjudicated ADOS-2 scores. The objective measurement of key behavioral features of ASD using first-person video and automated vocal interaction detection appears to have the potential to produce quantitative indices of ASD symptoms that may be suitable for clinical categorization and individualized referral, which would provide useful information to clinicians and parents about children's ASD symptoms.

328.004 *(Oral)* Improving Biosensor Prediction of Aggression in Youth with Autism Using Support Vector Machines

M. S. Goodwin[1], *T. Imbiriba*[1], *D. C. Cumpanasoiu*[1], *J. Heathers*[1], *S. Ioannidis*[1], *D. Erdogmus*[1], *A. Stedman*[2], *C. Peura*[2], *C. A. Mazefsky*[3] *and M. Siegel*[4], *(1)Northeastern University, Boston, MA, (2)Spring Harbor Hospital, Westbrook, ME, (3)Department of Psychiatry, University of Pittsburgh School of Medicine, Pittsburgh, PA, (4)Maine Medical Center - Tufts School of Medicine, Westbrook, ME*

Background: One of the most frequently observed problem behaviors in youth with autism is aggression, which is a primary cause for referral to behavioral healthcare services. Physical aggression is particularly debilitating in youth with autism because it can occur without warning, sometimes long after any observable trigger. Unpredictable aggression creates a barrier to accessing community, therapeutic, medical, and educational services since caregivers are understandably afraid to put the individual with autism into potentially stressful environments that might lead to aggression without warning.

Objectives: Our team recently demonstrated in 20 inpatient youth with autism that ridge-regularized Logistic Regression (LR) can be used to predict aggression to others 1 minute before it occurs using 3 minutes of prior biosensor data with an average area under the curve (AUC) of 0.71 for a population model and 0.84 for individual models (Goodwin et al., 2019, *Autism Research*). While these prior results are promising, they only consider a linear classification technique that does not account for nonlinear relations between extracted biosensor features and aggressive behavior onset. The objective of the current study was to test performance between LR and Support Vector Machines (SVMs) using the same dataset in Goodwin et al., 2019.

Methods: Twenty (20) ADOS-2 confirmed autism youth (M=10.8yrs, SD=3.1; 75% male, 95% Caucasian; NVIQ=70) in the Developmental Disorders Unit at Spring Harbor Hospital in Portland, Maine contributed data. This included 69 independent naturalistic observational sessions totaling 87hrs and 548 total aggressions observed while participants wore the E4 by Empatica, Inc. that wirelessly measures heart rate, heart rate variability, electrodermal activity, skin temperature, and physical motion. We compare prediction accuracy between our previous LR-based classifier and our new SVM-based classifier using varying past (Tp) and future (Tf) window lengths.

Results: Fig. 1 present Receiver Operating Characteristic (ROCs) for our previous LR-based classifier (left panel) and new SVM-based classifier (right panel) for population and individual models at Tp=180 seconds and Tf=60 seconds. Table 1 reports LR and SVM AUC in population and individual models at Tp=180, 120, 60 seconds and Tf=60, 120, 180 seconds.

Conclusions: SVM enables significant improvement in prediction performance compared to the LR-based strategy we published previously. SVM enabled aggression prediction up to 3 minutes before it occurs using 2-3 minutes of previous biosensor data with an average accuracy of 0.94-0.98 in both population and individual models. The advantages of biologically based tools to identify processes that underlie behavioral dysregulation as it unfolds during moments of escalation are numerous, including the potential to enable novel preemptive intervention strategies that help prevent or mitigate significant behavior problems, especially for those unable to provide reliable self-reports on their arousal states that lead to aggression.

POSTER SESSION — TECHNOLOGICAL APPROACHES
448 - Technological approaches Posters

448.001 *(Poster)* A Feasibility Study to Evaluate the Application of a Robot-Assisted ASD Intervention in Greece

V. G. Kaburlasos[1], *V. Holeva*[2], ***C. Dardani***[3], *M. Papadopoulou*[4], *P. Kechayas*[5], *C. Lytridis*[1], *C. Bazinas*[1] *and V. A. Nikopoulou*[5], *(1)HUman-MAchines INteraction Laboratory (HUMAIN-Lab), International Hellenic University, Kavala, Greece, (2)Clinical Psychology Department, Papageorgiou General Hospital, Thessaloniki, Greece, (3)Population Health Sciences, Bristol Medical School, Centre for Academic Mental Health, Bristol, United Kingdom, (4)Division of Child Neurology and Metabolic Disorders, 4th Department of Pediatrics, Aristotle University of Thessaloniki,, Thessaloniki, Greece, (5)Clinical Psychology Department, Papageorgiou General Hospital, Thessaloniki, Greece*

Background: Robot-assisted therapy in Autism Spectrum Disorders (ASD) gained a lot of attention the last decade with promising results (Begum, Serna, & Yanco, 2016; Ismail, et al., 2019; Pennisi et al., 2016; Smeekens et al., 2018). Larger clinical trials are needed to establish robots' utility in ASD interventions (Robinson, Cottier, & Kavanagh, 2019). As a first step feasibility studies are critical to ensure that the proposed robot-mediated interventions are effective and suitable in helping children with autism.

Objectives: We aim at evaluating the implementation of a psychosocial intervention using the humanoid robot NAO in a therapeutic setting for children with ASD. A single-blind feasibility study will be conducted as the first phase of data collection before proceeding to the clinical trial.

Methods: Fourteen eligible children (12 males, 2 females) aged 6-11y, who met DSM-5 criteria for an ASD diagnosis based on medical records and assessment using the ADI-R and the CARS–2 have been allocated into two groups: the NAO group (n=7, M_{age}=8.14±1.21) and the control group (n=7, M_{age} =8.71±1.60). The intervention was designed to target social communication, to modify challenging behaviors and to teach adaptive behaviors, useful in daily activities. Novel, mathematical models based on the Lattice Computing (LC) information processing paradigm (Kaburlasos, et al., 2019) have been applied toward computing with semantics and thus increase robot autonomy. The NAO robot is employed, in the Greek language, as an assistant to the therapist to perform various scenarios in a structured environment during 20 sessions. The same intervention is conducted by the therapist alone on the control group. The scenarios are aimed at instructing the children about social skills like empathy, behavior control skills like self-regulation and cognitive skills like joint attention, memory and imitation. Moreover, in addition to the basic outcome measures (clinical scales and psychometric tests) we are using electronic sensors in order to collect "objective" data including the duration of speech /eye contact /pause between sentences /voice volume etc. as well as various Boolean type data. All required clearances have already been obtained. The sessions will start in December 2019.

Results: The expected outcomes will be summarized into three categories: (1) clinical aspects to address the impact on the participants, (2) the suitability of the selected clinical tools within the sessions and the outcome measures, (3) technical issues to identify potential technological challenges regarding the use of NAO, and operational aspects to explore rate of attrition, acceptability and other practical concerns that may arise during the intervention.

Conclusions: More definitive clinical trials are required and feasibility criteria should be carefully addressed to proceed to full-scale trials. This study will provide an overview of potential obstacles for a proposed clinical intervention protocol for children with ASD and explore topics that could probably inform future studies.

448.002 *(Poster)* A Study to Explore the Use of a Voice-Based Conversational Agent As a Conversational Partner for Adolescents with Autism Spectrum Disorder

I. Cha[1]*, S. I. Kim*[2]*, H. Hong*[3]*, H. Yoo*[4] *and Y. K. Lim*[1]*, (1)Department of Industrial Design, KAIST, Daejeon, Korea, Republic of (South), (2)College of Medicine, Seoul National University, Seoul, Korea, Republic of (South), (3)Department of Communication, Seoul Natioanal University, Seoul, Korea, Republic of (South), (4)Psychiatry, Seoul National University Bundang Hospital, Seongnam, Korea, The Republic of*

Background: Adolescents with Autism Spectrum Disorder(ASD) experience social and communication difficulties as their social activities are increasing, so more supports are required for them to practice communication skills. Recently, Voice-based Conversational Agents (VCAs) such as Google Home and Alexa, are gradually spreading into the home, VCAs are applied as an assistive tool to support the daily lives of individuals with special needs. Several studies are underway to explore the way of applying VCAs for individuals with ASD to promote social and communication skills outside clinical settings.

Objectives: The objective of this study is to investigate the opportunities and challenges of VCA as a conversational practice partner to enhance the communication skills of adolescents with ASD.

Methods: Seven adolescents with ASD in Korea (age: 16-19) were engaged in using VCA, NUGU©(SK telecom, Seoul) for about 10 days in their home. They also participated in three sessions of group workshops to learn how to interact with a VCA before starting the usage, report the overall experience with the VCA, and suggest advancing design ideas that can address their communication difficulties. We interviewed each adolescent, six caregivers, and four clinicians to elicit feedback on their own reflections on VCA usage and discuss potentials of VCA in a clinical setting.

Results: Results in this study are based on data collected focusing on communication issues. (1) Four participants reported that the characteristics of VCAs (e.g. 'not judgmental', 'listening courteously') make them comfortable to share their stressful situations and negative emotions. However, one participant was reluctant to communicate with VCA, fearing that his conversational ability would be worse than VCA. (2) Experience of using VCAs provided them with opportunities that not only identified their communication problems such as difficulties in pronunciation, understanding the context of dialogue but also making their own strategies using various functions of VCA. Three participants tried to practice turn-taking in conversations with VCAs reflecting on their specific interests (e.g. music, sports). One participant could inadvertently practice correct pronunciation in the use of VCA by reducing the number of times to call the VCA. (3) Though using a VCA make adolescents with ASD freely express their emotions without interference of others, two participants showed assaultive behaviors such as swearing or beating a VCA in their stressful situations. Thus, the experts suggest that the usage guidance of VCA is required to help that inappropriate attitude on VCA does not lead to actual conversations with people.

Conclusions: We explored the opportunities and challenges to apply a VCA as a conversational partner for adolescents with ASD. Through our empirical studies, we found out that the VCA has the potential to be utilized as an individualized therapeutic tool to help adolescents with ASD practice communication skills, reflecting on users' specific characteristics through various functions of VCA. The limitation of this study is that a small number of participants and technological constraints such as limited turn-taking, voice recognition. Further examination would be needed to verify the effectiveness of VCA by using questionnaires.

448.003 *(Poster)* A Telehealth Model for Training Part C Providers in Parent Coaching Strategies

E. Fuller[1]*, J. L. Burns*[2]*, M. R. Talbott*[3]*, A. C. Stahmer*[3] *and S. J. Rogers*[4]*, (1)Special Education, Vanderbilt University, Nashville, TN, (2)Psychiatry and Behavioral Sciences, UC Davis MIND Institute, Sacramento, CA, (3)Psychiatry and Behavioral Sciences, University of California at Davis MIND Institute, Sacramento, CA, (4)Department of Psychiatry and Behavioral Sciences, The Medical Investigation of Neurodevelopmental Disorders (MIND) Institute, UC Davis School of Medicine, University of California Davis, Sacramento, CA*

Background: Specific interventions for young children with or at risk for autism spectrum disorders (ASD) have demonstrated powerful effects on a range of developmental outcomes when begun in the toddler period (e.g., Wallace & Rogers, 2010). Interventions that include parents have been shown to be particularly effective (Hampton & Kaiser, 2016) to the point that Part C of the Individuals with Disabilities in Education Act requires that early intervention services use a family-centered approach. However, the utility of research-based intervention approaches is often limited in practice due costly or time-intensive trainings and a lack of access to local trainings. The purpose of this study was to evaluate the effectiveness of a training model that combined telehealth trainings with online modules to train EI providers in low-resourced areas to coach caregivers in evidence-based intervention practices with their children with autism.

Objectives: (1) To compare the coaching strategies used by the EI providers who were trained using telehealth to a comparison group of EI providers.

(2) To identify areas of coaching that are most and least frequently used by providers.

Methods: Thirty-two providers from Part C agencies in four states participated. Each agency was randomized to either the Community Early Start Denver Model (C-ESDM) or a comparison group. Each provider recruited at least one parent-child dyad. Children were identified as at risk for ASD. The C-ESDM providers received access to online modules and training via Zoom in the strategies used in the C-ESDM model and in how to coach parents to implement these strategies with their child. Thirteen sessions occurred over six months with a certified ESDM therapist/parent coach. Each Skype meeting included a concept presentation, video examples, and role-plays. The comparison group received access to online modules and six telehealth trainings over the course of six months with a developmental psychologist that covered developmental milestones. Sessions followed a similar format, except that providers did not receive information about coaching parents or C-ESDM strategies. Therapists filmed a session with a parent-child dyad pre- and post-intervention. Two naïve coders reliably rated videos using an adapted scale of the Coaching Practices Rating Scale (Rush & Shelden, 2011). This 13-point checklist assessed the presence or absence of a range of coaching behaviors.

Results: Following the 6-months of intervention, the C-ESDM group used an average of 7.55 (sd=3.45) of the 13 coaching strategies, compared to the control group that used an average of 3.88 strategies(sd=3.98). An independent sample t-test indicated that this was a significant difference (t=2.14, p=0.04). EI providers were most likely to interact using a respectful manner and to plan and create opportunities for practice, and were least likely to ask probing questions, provide access to outside resource, and ask reflective questions.

Conclusions: C-ESDM is an inexpensive, distally implemented intervention that significantly increased EI provider's use of parent coaching strategies. This increase in coaching behaviors shows promise for improving access to effective early interventions, particularly in low-resourced or remote settings/communities. However, it has also highlighted areas that could be improved in future EI trainings.

448.004 *(Poster)* A Tool to Conduct Research on Multi-Scales International Cohorts on Autism: Presentation of the Owey Platform

F. Campana[1], *S. Malesys*[2], *J. Fumey*[3], *G. Dumas*[4], *L. Behar*[1], *A. Esmairi*[1], *G. Pouleriguen*[1], *L. Bogdanski*[1], *O. Cheny*[5], *N. Clement*[5], *N. Jolly*[5], *M. Sanchez*[1], *D. Coulon*[1], *T. Menard*[1], *F. Cliquet*[1], *C. Leblond*[6], *E. Loth*[7], *D. G. Murphy*[8], *C. B. Beckmann*[9], *C. H. Chatham*[10], *G. Detrez*[1], *S. Fournier*[1] *and T. Bourgeron*[11], *(1)Institut Pasteur, Paris, France, (2)Neurosciences, Institut Pasteur, Paris, France, (3)Human genetics and cognitive functions, Institut Pasteur, Paris, France, (4)Human Genetics and Cognitive Functions Unit, Institut Pasteur, Paris, France, (5)Center for Translational Science, Institut Pasteur, Paris, France, (6)Institut PASTEUR, Paris, France, (7)Department of Forensic and Neurodevelopmental Sciences, Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, United Kingdom, (8)Forensic and Neurodevelopmental Sciences, Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, United Kingdom, (9)Centre for Functional MRI of the Brain (FMRIB), University of Oxford, Oxford, United Kingdom, (10)Neuroscience and Rare Diseases (NRD), Roche Pharma Research and Early Development, Roche Innovation Center, New York, NY, (11)Human Genetics and Cognitive Functions, Institut Pasteur, Paris, France*

Background: The AIMS-2-TRIALS project aims to identify stratification biomarkers and to develop precision medicine to improve the lives of persons with autism. It is currently the largest European project on autism, with large cohorts of patients, from birth to adulthood, and a multi-disciplinary characterization encompassing for instance fMRI, EEG, structural MRI, genetics, clinical profiles, cognitive abilities.

Objectives: This amount of multi-disciplinary data on relatively large cohorts has the unique potential to accelerate the discovery of new intervention or treatments for people with autism. However, the exploitation of very large datasets poses challenges: the datasets must be shared across sites spread across Europe. They must be organized to make the relevant information easily findable, harmonized between sites to constitute large and comparable cohorts. Furthermore, those data are sensitive according to the EU's data protection law (GDPR) and therefore require a very high level of security and protection.

Methods: The data management (DM) team designed the features of the repository through close interactions with the AIMS-2-TRIALS researchers. The IT team highlighted the best solutions regarding security storage and access, efficiency etc.. This collaboration led to innovative solutions specific to the AIMS-2-TRIALS project. Once implemented, the researchers and the DM team tested those solutions, provided feedback to the IT team and so on. The legal and ethical departments also provided all the information necessary to ensure that the database complies with the GDPR. The IT and DM teams also follow the FAIR principles (Wilkinson et al., 2016; Mons et al., 2017), and work with the GA4GH that develop new standards of data sharing (Fiume et al., 2019), to ensure that the AIMS-2-TRIALS dataset will be reusable for further analyses.

Results: We developed a web-accessible platform hosting the AIMS-2-TRIALS data with the aim to provide the researchers with a tool to easily investigate their multi-scales data from international cohorts. The platform notably:

- Guarantees the security and protection of the data hosted by the platform: the identity of the participants is protected and their consent is respected at any time, including years after the data collection if a participant changes his/her mind about data sharing
- Enables the data sharing between remote sites for the constitution of cohorts right after the data collection, with the flexibility necessary to accommodate the variety of processes across sites
- Automatically organizes the multi-disciplinary longitudinal datasets in a meaningful manner
- Accommodates the upload, download and storage of large datasets (several Go)
- Automatically harmonizes data arriving in different formats
- Contains metadata describing the datasets; this is crucial for the data to be reusable beyond the AIMS-2-TRIALS project

Conclusions: We developed a platform that leverages the potential of big data in autism research. In addition to its importance for the success of the AIMS-2-TRIALS project, the platform provides solutions to obstacles that are inherent to multi-scale international research on autism. Such solutions will hopefully foster the constitution of large multi-scale cohorts that are essential to take into account the heterogeneity in autism.

448.005 *(Poster)* Characterization of Movement Patterns through Objective Measurement in Children with Autism

C. Banarjee[1], *R. M. Fasano*[2], *L. Vitale*[2], *C. Song*[1], *L. K. Perry*[2] *and D. S. Messinger*[1], *(1)University of Miami, Coral Gables, FL, (2)Psychology, University of Miami, Coral Gables, FL*

Background: Human movement is central to social interaction, and disordered movement patterns may characterize children with autism spectrum disorder (ASD). In clinic settings, children with ASD have exhibited both a counter-clockwise turning bias (Cohen et al., 2014), but also higher overall angular velocity (clockwise and counter-clockwise, with no bias) (Yang et al., 2019), both based on brief periods of observation. There has been limited research on the velocity of gait in children with ASD with some studies suggesting children with ASD move more slowly than other children (Velinksy et al., 1981; Teitelbaum et al., 1998).

Objectives: Compare angular velocity (turning) and Euclidean velocity (movement) between children with ASD and typically developing (TD) children in an inclusive preschool classroom during repeated multi-hour observations.

Methods: Observations of four preschoolers with ASD and eight TD preschoolers in an inclusive preschool classroom (M_{age}=61 months, SD_{age}=5.16 months) on five days yielded 53 observations, with 7.07 hours of data per child. Objective measurements of position and orientation were collected using the Ubisense system, which tracked a right and left tag worn by each child (in a vest) to an accuracy of 15 cm within the classroom (8.86 x 8.97 m) using ultra-wide radio frequency identification. Right and left tags yielded orientation, direction faced, via coordinates (x_R,y_R)and (x_L,y_L). For each child, angular velocity (degrees/tenth of a second) and Euclidean velocity (meters/tenth of a second) were computed as the difference in orientation angle and difference in location, respectively, between consecutive tenths of a second [t-1, t] as follows:

Angular velocity= $_t$ - $_{t-1}$= Δ (º/0.1 sec) where tan( )=(x_R-x_L)/(y_L-y_R)
Euclidian velocity=$((x_t-x_{t-1})^2+(y_t-y_{t-1})^2)^{1/2}$ where $x_t=(x_R+x_L)/2$ and $y_t=(y_R+y_L)/2$

Results: Multilevel models (days nested in each child) indicated that children with ASD exhibited larger absolute mean angular velocity than TD children (see **Table 1** and **Figure 1**, p_{abs}=0.002, $^2_{abs}$=9.06). Children with ASD turned significantly more rapidly in both the clockwise and counterclockwise direction (p_{cc}=0.003, $^2_{cc}$=8.80; p_c=0.003, ^2_c=9.27, *df* =1).There was no difference in Euclidean velocity between the groups (*p*=0.39). Comparison of the 75-100th percentile of angular and Euclidean velocities tested for high velocity differences (top speeds). Consistent with overall results, children with ASD exhibited significantly larger high angular velocities (*p*=0.01) in both clockwise and counterclockwise directions (p_{cc}=0.02, p_c=0.02), but not larger high Euclidean velocities (*p*=0.16).

Conclusions: Multi-hour, objective measurements in a preschool inclusion classroom indicated no evidence that children with ASD exhibit a counter-clockwise turning bias. Instead, disordered movement patterns in children with ASD were evident in both counter-clockwise and clockwise movement (higher velocity spinning and/or walking in circles). There was no evidence for greater Euclidian velocity (faster overall movement) for children with ASD.The results suggest the potential of automated behavioral measurement for an objective description of the ASD phenotype, which delineates those features that do and do not distinguish children with ASD from other children.

448.006 *(Poster)* Classroom Language and Social Development of Preschoolers with ASD

***R. M. Fasano**[1], L. K. Perry[1], Y. Zhang[2], S. Custode[1], L. Vitale[1], A. Adams[1], C. Song[3] and D. S. Messinger[3], (1)Psychology, University of Miami, Coral Gables, FL, (2)Physics, University of Miami, Coral Gables, FL, (3)University of Miami, Coral Gables, FL*

Background: Autism spectrum disorder (ASD) is characterized by social difficulties and associated with delays in language. These delays may be associated with lower levels of social communication with peers and fewer reciprocated friendships. However, the field currently lacks a rigorous quantitative understanding of children's linguistic and social experiences in the classroom, particularly for children with ASD.

Objectives: Here we utilize innovative technology, synchronizing automated measures of language and movement in the classroom to assess language development and social network formation in preschoolers with ASD, asking whether children's social ties predict long term language development.

Methods: 15 preschoolers (5 female; M_{age} = 51.6 months) enrolled in two inclusive preschool classrooms participated (an AM/PM session). Seven had an ASD diagnosis; eight were typically developing (TD). TD children were enrolled in both AM/PM sessions. During monthly observations, children wore lightweight vests equipped with Language ENvironment Analysis (LENA) to measure vocalizations and two Ubisense tags to measure location. Ubisense measures of proximity/orientation were used to determine social contact, and synched to LENA data to assess each child's language input/output with each peer. Data were aggregated over five months to create classroom social networks based on frequency of dyadic language-mediated interactions, yielding measures of each child's centrality to their network and the cohesiveness of diagnosis groups within the class. Each child's end-of-year language abilities were assessed by the Preschool Language Scales (PLS-5).

Results: Although children with ASD were slightly less likely to talk than their TD peers $X^2(1) = 4.04$, $p = .04$, there was an effect of peer language input, such that children produced more language output when they heard more language input from their peers, regardless of diagnosis, $X^2(1) = 6.18$, $p = .013$. As can be seen in Figure 2, TD children had significantly higher degree centrality in their social network than children with ASD, $\beta = 3.11$, SE = .69, $t(12) = 4.50$, $p < .001$, and degree centrality positively predicted children's PLS-5 scores $\beta = 7.1$, SE = 1.28, $t = 5.54$, $p < .001$. Finally, comparison of group weights in the networks revealed that TD children formed more cohesive groups with each other, and were less likely to form ties to children with ASD, who tended to be on the periphery of social networks.

Conclusions: These results help to characterize the unique linguistic and social environments of children with ASD, which have not previously been quantified in the classroom context. Peers are a key source of linguistic input for preschoolers, affecting the amount of language a child produces. Social network analysis allowed us to not only examine the role of peers at the level of dyadic interaction, but also allowed us to capture information about the classroom environment as a whole. These analyses revealed peer groups formed in the classroom, showing that children with ASD often have fewer friendships, especially with their TD peers. Such information can help to inform interventions and teacher recommendations for best facilitating the language and social development of children with ASD.

448.007 *(Poster)* Contrast Pattern Mining to Better Understanding Complex Genomic Interactions and Their Effect on the Development of Autism

***W. Baskett**[1] and C. R. Shyu[2], (1)Bioinformatics, University of Missouri, Columbia, MO, (2)Institute for Data Science and Informatics, University of Missouri, Columbia, MO*

Background: Autism is a complex condition which is influenced by many known genes. Association based analyses such as GWAS have long been used to identify specific genetic variations associated with autism but these variations do not exist in a vacuum. Multiple genetic variations may interact with each-other to affect the final phenotype. This may be in epistatic effects or in physical interactions between multiple variations within a single gene resulting in disruptions in protein folding greater than the sum of their parts. Evidence for epistatic effects in autism have been documented previously. As larger datasets have become available it has becomes possible to extract not only individual variations but also patterns of variations associated with autism. The structure of the interactions in these patterns may be able to provide additional insight into the underlying biological mechanisms responsible. To study this, we have developed a novel and scalable computational method capable of efficiently extracting patterns of complex interaction from very large datasets.

Objectives: Our objective is to extract patterns of genetic biomarkers which are strongly associated with the development and non-development of autism from the Simons SPARK dataset. We also aim to find patterns of features which differentiate important subgroups of autistic individuals from one another such as those with high vs low social skills.

Methods: We have developed a unique contrast mining method capable of extracting patterns of complex logical interactions from large medical datasets in the form of proof trees. We applied this method to discover patterns of genetic variations associated with the development and non-development of autism in individuals from the Simons SPARK dataset which contains roughly 27,000 autistic and non-autistic individuals from families with at least one autistic child. Our analysis examined the top 100,000 variations with the greatest difference in frequency between the autistic and non-autistic groups by both presence and homozygosity using our pattern mining method.

Results: Our method was successful in locating a large number patterns associated with both the development and non-development of autism. Patterns associated with the non-development of autism generally show a greater contrast. The most highly contrasting patterns largely consist of multiple variations within the same gene. These genes include both known autism associated genes such as NLGN4X and genes where the association is not as well documented such as CCDC22. Subgroup analysis of the high vs low social skills subgroups revealed highly contrasting patterns with variations from many different genes suggesting epistatic effects may be at work.

Conclusions: Our pattern mining method allows us to analyze a large number of biomarkers for possible interactions for potential in-depth understanding of etiology of autism for subpopulations. Our results so far provide additional evidence for the influence of many specific genes on the development of autism and for the influence of epistatic interactions on the phenotype presented by autistic individuals. Additional analysis of the results using functional analysis is ongoing.

448.008 *(Poster)* Convolutional Auto-Encoder for ERP Morphological Analysis

T. McAllister[1], *A. Naples*[1], *A. Bagdasarov*[1], *C. Carlos*[1], *C. C. Cukar-Capizzi*[1], *S. Kala*[1], *J. Wolf*[1], *A. Anticevic*[2], *V. Srihari*[2] *and J. McPartland*[1], *(1)Child Study Center, Yale University School of Medicine, New Haven, CT, (2)Division of Neurocognition, Neurocomputation, and Neurogenetics (N3), Yale University School of Medicine, New Haven, CT*

Background: Electroencephalography (EEG) is a valuable tool for studying autism spectrum disorder (ASD) due to its high temporal resolution and direct measurement of cortical activity. By repeated exposure of participants to stimuli, researchers can derive event-related potentials (ERPs). However, the rich information present in the ERP waveforms is typically reduced to a small number of measurements, potentially discarding informative brain activity. We propose the use of an autoencoder convolutional neural network (CNN) to automatically reduce the dimensionality of complex ERP waveforms while learning which features best distinguish among individuals. Given the wide range of waveform morphologies commonly observed in neurodevelopmental disorders, such as ASD, our methods may shed new light onto neurological differences not previously explored.

Objectives: We: (1) developed a CNN to reduce the dimensionality of individual waveforms; (2) explored the relationships of the resulting dimensions with symptom measures; and (3) identified avenues for further methodological development.

Methods: Data were collected from with adult participants diagnosed with ASD (N=19) or Schizophrenia (N=12), and TD controls (N=32). Participants were shown a flashing black and white checkerboard (500ms phase reversals) to elicit a visual evoked potential (VEP). Resulting ERPs measured from occipitotemporal electrodes were scaled, split into a training and test sets, and used to train our network. The encodings of all the ERPs, calculated after training, were then analyzed. Encoding variables (EVs) primarily reflect regions of time in a given ERP (Figure 1).

Results: Our CNN reduced the dimensionality of ERPs from 300 samples to an efficient encoding of 19 dimensions with a mean absolute error of 0.0421. Multiple significant correlations were found among EVs and clinical measures. EV6, related to the N1 ERP component, correlated with the sensory and restricted behavior domains on the the Social Responsiveness Scale Second Edition (SRS-2) Restricted Interests and Repetitive Behaviors subscale (R=-0.300,p=0.018), and the Sensory Gating Inventory Over-Inclusion subscale (R=-0.278,p=0.029). EV7, related to the P100 ERP component, correlated with social measures such as the Schizotypal Personality Questionnaire (SPQ) “No Close Friends” subscale (R=0.389,p=0.002) and the SRS-2 Social Motivation subscale (R=-0.296,p=0.018). Two EVs from later in the ERP, EV14 & EV15, correlated with sensory measures like the SPQ Unusual Perceptual Experiences subscale (R=0.276,p=0.029; R=0.307,p=0.014) and Glasgow Sensory Questionnaire Hypersensitivity Score (R=-0.278,p=0.0274; R=-0.256,p=0.0426).

Conclusions: We were able to successfully build and train an autoencoder CNN on our VEP ERPs, and significantly reduced the dimensionality of our data. The EVs suggest that different time aspects of the ERP are associated with unique symptom domains. Ongoing analyses include applications to additional experimental paradigms, assessing reliability of encodings, and novel visualization approaches for assessing data quality. Our findings suggest that novel machine-learning techniques can automatically parse meaningful interindividual variability in the neural time course that can be linked with human-understandable features of the ERP. Extensions of this work to differentiate clinical populations may reveal meaningful differences in brain activity that have been previously overlooked with traditional methods.

448.009 *(Poster)* Development of Screening Algorithm for Autism Spectrum Disorder in 5-Year-Old Children Using the Eye-Tracking Device (Gazefinder®)

Y. Sakamoto[1], *M. Saito*[1,2], *M. Ninomiya*[3], *S. Hakoshima*[3], *K. J. Tsuchiya*[4], *A. Osato*[1,2], *A. Terui*[1], *H. Mori*[2], *K. Yoshida*[1], *Y. Matsubara*[1], *T. Mikami*[2], *M. Takahashi*[2] *and K. Nakamura*[1,2], *(1)Department of Neuropsychiatry, Graduate School of Medicine, Hirosaki University, Hirosaki, Japan, (2)Research Center for Child Mental Development, Graduate School of Medicine, Hirosaki University, Hirosaki, Japan, (3)JVC KENWOOD Corporation, Yokohama, Japan, (4)Research Center for Child Mental Development, Hamamatsu University School of Medicine, Hamamatsu, Japan*

Background: Abnormalities in eye contact is one of the indicators of impaired sociability. Previous studies reported that people with Autism spectrum disorder (ASD) showed characteristic gaze patterns in some videos about social information such as a human face and human-to-object contrast. Early detection of ASD is necessary for improving the symptoms. However, it is not easy to detect children with ASD in early childhood. Using the eye-tracking device (Gazefinder®), we have explored characteristic gaze patterns of children with ASD compared to children with typical development(TD), and examined the usefulness of gaze patterns as an objective marker for ASD.

Objectives: This study aimed to develop a screening algorithm for ASD using Gazefinder® in 5-year-old children.

Methods: Subjects were 97 children with TD (boys n=47, girls n=50, average age 5.49) and 42 children with only ASD (boys n=28, girls n=14, average age 5.96), that is, without coexisting other developmental disorders. They just looked at the 2-minute video with contents of face, preference, biological motion, and pointing using the Gazefinder®. To confirm gender differences, the principal component analysis of the fixation rate at all 89 Areas of Interest (AOI) was conducted. Then, high sensitivity AOIs were extracted based on diagnoses, correlation coefficient, p-value, and effect size. After developing a screening algorithm for ASD, sensitivity and specificity were calculated in boys, girls, and total.

Results: The principal component analysis of the fixation rate at 89 AOIs showed that it was difficult for boys to classify ASD and TD by simple formulas compared to girls. From this result, we extracted high sensitivity AOIs by gender and developed a screening algorithm. As a result, the fixation rate of girls (AOC=0.89) showed 86% sensitivity and 83% specificity, and the fixation rate of boys (AOC=0.73) showed 69% sensitivity and 69% specificity by a cut-off score. When gender-specific algorithms are applied according to gender, AOC was 0.78 in the comprehensive evaluation for all subjects(Fig.1,2). Also, when the provisional cut-off score of the fixation rate was set to 50.4%, the sensitivity was 75% and the specificity was 75.8%. These results were appropriate as a screening algorithm.

Conclusions: Gazefinder® was created to evaluate sociability in infant and toddler developmental health checkups. This study suggests a possibility that this algorithm using Gazefinder® is useful as a screening tool for undiagnosed ASD in preschool-age children, and Gazefinder® can be used as a useful tool that objectively indicates the likelihood of meeting diagnostic criteria of ASD before admission to elementary school.

448.010 *(Poster)* Development of a Screening Algorithm of Neurodevelopmental Disorders for 5-Year-Old Children Toward Web Survey Systemization

A. Terui[1], *M. Saito*[1], *A. Osato*[2], *M. Tanaka*[3], *N. Takayanagi*[4], *M. Adachi*[2], *M. Wakuta*[1], *Y. Sakamoto*[1], *H. Mori*[2], *K. Yoshida*[1], *Y. Matsubara*[1], *T. Mikami*[2], *M. Takahashi*[2], *K. Nakamura*[1] *and Y. Yamamura*[5], *(1)Department of Neuropsychiatry, Graduate School of Medicine, Hirosaki University, Hirosaki, Japan, (2)Research Center for Child Mental Development, Graduate School of Medicine, Hirosaki University, Hirosaki, Japan, (3)Hokkai-Gakuen University, Sapporo, Japan, (4)Aichi Toho University, Nagoya, Japan, (5)SURVEY RESEARCH CENTER Corporation, Tokyo, Japan*

Background: Recently, growing interest in support for developmental disabilities in Japan, the support law for people with developmental disorders was enacted in 2004. That showed the importance of detecting Neurodevelopmental Disorders (NDDs) and providing appropriate support as early as possible. In preschool age, their characteristics of not only Autism Spectrum Disorder (ASD), but also such as other NDDs, e.g. Attention-deficit hyperactivity disorder (ADHD), Developmental Coordination Disorder (DCD), Intellectual Disability (ID) and Specific learning disorder (SLD), become obvious, and they need the assessment to receive appropriate education.

Objectives: This study aimed to develop a screening algorithm of NDDs for 5-year-old children toward Web survey systemization.

Methods: In 2013, ASSQ, ADHD-RS, DCDQ-J, SDQ and K6 were applied to 1310 5-year-old children's parents and their teachers in their kindergartens or nursery schools. 226 children were defined as temporary-risk children according to the scale cutoff value, and 159 children participated in a secondary health checkup and were diagnosed by DSM-5 criteria if they had NDDs. Using logistic regression analysis, we searched for a combination of tests useful for diagnostic outcomes. Verification had been conducted since 2014, and PSI was added to improve screening accuracy instead of K6. In 2018, we verified equivalence between paper surveys and web surveys in 144 objects.

Results: Some screening combinations were clarified to be useful for the diagnosis of each NDD, and we created a new screening algorithm with some combination patterns. According to a new algorithm, the rate of children at risk of NDDs in all 5-year-olds of the year was 19.4% in 2014, 20.0% in 2015, 16.6% in 2016, 18.7% in 2017 compared with 23.7% in 2013. Although the number of children with risk of NDD was narrowed down, the proportion risk children in all participations of the secondary health checkup were 72.7% in 2014, 62.3% in 2015, 73.1% in 2016, and 79.8% in 2017 compared with 47.8% in 2013. There was no difference between the results of the paper survey and the web survey.

Conclusions: In this study, the algorithm may be useful in screening NDDs at preschool age in Japan. Developing this screening algorithms into a Web system has enabled large-scale surveys or similar assessments performed in some local governments where has few specialists. This system was made into a web as an industry-university joint research in October 2019 (COCOAPO®) and already has used by some local governments and research institutions.

448.011 *(Poster)* Digital Therapeutics for Autism

D. P. Wall*, Stanford University, Stanford, CA*

Background: Standard autism therapy, while effective, especially if delivered early, can be hard to access and inconsistent, even within some of the best integrated healthcare systems. Related, the efficacy of the approaches used today is not easily tracked and recorded, making it difficult to understand the impact either at an individual or at a population level.

Objectives: Create digital device solutions that can scale rapidly while providing effective treatment outside of standard clinical settings and that capture data that can be used to measure efficacy and impact.

Methods: We constructed computer vision models that run on wearable augmented reality to provide treatment for improved emotion recognition and social behavior. This model runs on a phone tethered to augmented reality glasses (such as Google Glass and Vuzix) to orient a child to faces in their natural world and provide real-time emotional feedback. Second, we constructed a mobile gaming system that fosters social engagement therapy through a form of mobile "charades." In this setting the parent holds the phone close to their eyes (e.g., on forehead). The phone displays an appropriate prompt (e.g. a surprised emoji) that the child attempts to act well enough to enable his parent to guess. We ran two independent trials to test the efficacy of each device for treatment and for tracking progress during treatment.

Results: Forty of 71 children randomized into wearable treatment showed significant mean improvement of 4.6 points on the Vineland Adaptive Behavioral Socialization subscale over children receiving standard treatment. 21 of 56 children randomized into our mobile game therapy showed significant mean improvement of 7.5 points on the Social Responsiveness Scale. In both cases, the frequency of emotion detection during game play correlated strongly with standard treatment outcomes.

Conclusions: Digital solutions offer an attractive alternative for therapy beyond the standard treatment. In addition, mobile approaches provide passively collected game data that can be used to track outcomes on a continuous basis.

448.012 *(Poster)* Enhancing the Application of Interactive Social Robots in Educational Interventions for Autism Spectrum Disorders: A Research Initiative in Greece.

C. Dardani[1], *V. G. Kaburlasos*[2] *and A. Amanatiadis*[3], *(1)Population Health Sciences, Bristol Medical School, Centre for Academic Mental Health, Bristol, United Kingdom, (2)HUman-MAchines INteraction Laboratory (HUMAIN-Lab), International Hellenic University, Kavala, Greece, (3)HUman-MAchines INteraction Laboratory (HUMAIN-Lab), International Hellenic University, Kavala, 65404 Greece., Kavala, Greece*

Background: Over the last decade there has been an increasing interest in the applications and possible efficacy of interactive social robots in the educational interventions of children with Autism Spectrum Disorder (ASD). Despite emerging evidence on their possible beneficial impact, the vast majority of studies so far have focused on: i. simple tasks and not play-based activities, ii. the role of the robot as a facilitator of the intervention or as a mediating agent during the intervention. Testing the performance of interactive social robots across different possible roles and a range of play-based activities, is expected to enhance current applications of social robotics in the field of ASD.

Objectives: Design and test the application of humanoid interactive robots across a range of structured activities targeting areas of neurocognitive functioning and within three distinct conditions:

A. robots as activity facilitators

B. robots as activity participants

C. a robot-facilitator and a robot-participant within the same session.

Methods: We utilized the well-known 56cm humanoid NAO robot that entails qualities which are extremely well-adapted to the context of special education. Its 25 degrees of freedom allow a great versatility for rich movements making the intervention with children more accessible. A range of play-based activities targeting areas of behavioural and neurocognitive functioning were selected. Two major categories were considered: 1. activities targeting at social and communicative skills, 2. activities targeting at executive functioning. In collaboration with a local neurodevelopmental disorders intervention unit in the urban area of Kavala, Greece, 12 families of children with ASD were approached in order for the children to be involved in the pilot phase of the study. Inclusion criteria for the children were: age between 6-12 years, official ASD diagnosis from public hospital or public mental health service, IQ above 70. Exclusion criteria were: diagnosis of comorbid developmental disorder or mental health condition, diagnosis of chromosomal or metabolic syndrome, epilepsy, movement disorders. Family and children data were protected by complying to the European Commission's General Data Protection Regulation.

Results: The developed playlist incorporated face and pattern recognition, object tracking, improved kinematic solutions, and natural language processing, utilizing the robot operating system (ROS) for the inter-process communication.All three conditions appeared to elicit positive reactions from the children, in terms of the enthusiasm and engagement the children showed. Importantly, the two-robot condition, appeared to offer the children the chance to observe the expected behaviours/responses and helped create and maintain a playful context.

Conclusions: This is the preliminary study that led to the first research initiative in Greece aiming towards designing, expanding and testing the efficacy of interactive social robotics applications in educational interventions of children with ASD. Two main research collaborations in nation-wide and EU-wide level (CybSPEED project), are expected to enhance current approaches for the implementation of interactive social robots in the field of educational interventions for ASD.

448.013 *(Poster)* Exploration of Eye Gaze and Visual Attention Using the Eye Control and Gaze Interaction Game in Children with Autism Spectrum Disorder (ASD)

L. N. Xie[1], *Y. T. Wu*[2] *and T. C. Huang*[3], *(1)National Taiwan University, Taipei, Taiwan, (2)School and Graduate Institute of Physical Therapy, National Taiwan University College of Medicine, Taipei, Taiwan, (3)National Taichung University of Science and Technology, Taichung, Taiwan*

Background: Children with ASD are characterized by impairments in social communication that the core symptoms consist of deficits in social looking, low sensitivity to eye gaze cues and limited visual attention. Numerous studies have evaluated eye gaze in children with ASD using the eye tracking system for assessing child's visual attentions to pictures or videos. None of the studies, however, have used the eye control and gaze interaction device that allows people with disabilities to control and interact with the computer using their eyes and gaze responses. Furthermore, combination of game-based tasks and eye control device may enhance the child's motivation of engaging goal-directed activities that might be suitable for assessing visual attentions in children with ASD.

Objectives: The purposes of this study were (1) to explore the feasibility and reliability of the eye control and gaze interaction (ECGI) game system for assessing visual attention in typically developing (TD) children and children with ASD; and (2) to compare the eye gaze performances during the games between TD children and children with ASD.

Methods: This study included 4- to 6-year old TD children (n = 38) and children with ASD (n = 12) at National Taiwan University Children's Hospital. The child was asked to sit in front of a notebook and the eye signals were captured by the Tobii eye tracker. The child then played three tasks of computer games by means of controlling their eye movements for completing the tasks: (1) Identify animal's call: the total time that the child spent choosing the correct animal following the occurrence of animal's sound were recorded; (2) Find and track animal: the number of saccade errors and total eye fixation time that the child tracked the occurrence of animals were recorded; (3) Pick up toys: the total times that the child spent picking up the toys were recorded. Each child completed two trails for each game. The test-retest reliability of eye tracking variables between the two trials of each game was analyzed using the intraclass correlation coefficient (ICC). Furthermore, the number of saccade errors and total eye fixation time between the TD and children with ASD were compared using the Mann Whitney U test.

Results: Moderate degree of test-retest reliability of overall eye tracking variables in the 3 games were 0.433, 0.493, and 0.635, respectively (all p's < 0.05) (Table 1.). Furthermore, high reliability of the number of saccade errors (ICC = 0.725) was found in the 2nd game. In addition, children with ASD spent longer times of completing the tasks and higher numbers of saccade errors than the TD children did in the 2nd and 3rd games (both p's $<$ 0.05) (Table 2.).

Conclusions: The results revealed that the ECGI game system was feasible for assessing child's visual attention and could differentiate the eye gaze performance of the children with ASD from the TD children. The study will continuously recruit more children to establish normative data of the ECGI game system.

448.014 *(Poster)* GAIN: Global Autism Interactive Network- an Innovative Approach to Maintaining Calibration and Fidelity on the ADOS-2

K. Christopher[1], *V. H. Bal*[2], *S. Bishop*[3], *A. N. Esler*[4] *and S. M. Kanne*[5], *(1)UCLA, los angeles, CA, (2)Graduate School of Applied and Professional Psychology, Rutgers University-New Brunswick, Piscataway, NJ, (3)University of California San Francisco, San Francisco, CA, (4)University of Minnesota, Minneapolis, MN, (5)Thompson Center for Autism & Neurodevelopmental Disorders, Columbia, MO*

Background: The ADOS-2 is widely acknowledged as a gold-standard tool for use in ASD diagnostic assessment. Despite its utility, challenges such as training costs, the amount of practice needed to become proficient, and maintaining fidelity may limit its feasibility in certain settings. In addition, practitioners who complete clinical training on the ADOS-2 often report a desire for further opportunities to refine their skills in administration and coding.

Objectives: Global Autism Interactive Network (GAIN) creates an international community of clinically trained ADOS-2 practitioners who interact, share knowledge, and support ongoing mastery. The primary goals of GAIN are to provide continuing education and increased fidelity on the ADOS-2 through viewing and coding high-quality administrations and to increase participants' understanding of ASD. Using Zoom technology, GAIN provides monthly, 90-minute calibrations with discussions to an online learning community. The program uses a *Watch, Do, Share* model with experienced senior ADOS-2 trainers supporting professional development of practitioners. Each quarter, the program includes viewing and scoring full administrations of a different ADOS-2 module (*Watch*), participation in a discussion of coding (*Do*), and discussion of diagnostic issues and research related to the field of ASD (*Share*). The model emphasizes in-depth coding discussion and solicits questions from participants to guide discussion. GAIN includes a small subscription fee and the capacity to earn continuing education credits for an additional fee.

Methods: GAIN uses REDCap to collect demographic information, ADOS-2 self-efficacy ratings, ADOS-2 codes, and questions and feedback from participants. Participants view ADOS-2 videos via REDCap through a secure online Box account.

Results: Participants in GAIN include 471 registered users from 19 different countries. A majority of users have a doctoral degree (64.1%) and are psychologists (66.2%), but a variety of professions were represented including speech-language therapists, educators, and physicians. Practitioners identified as being trained on the ADOS-2 as early as 1992 and some as recently as 2019. Approximately one third (38.9%), reported they had achieved research reliability on the ADOS-2. All participants report using the ADOS-2 regularly, at least once a month. Most people are using the ADOS-2 for diagnostic evaluations (78.8%), followed by research studies (34.6%), treatment planning (20.0%), and eligibility determinations (16.8%). Data from open-ended feedback forms strongly support GAIN as a feasible and effective model for learning, with >90% of participants agreeing or strongly agreeing that GAIN allows them to learn from experts in the field of ASD they would not have access to otherwise.

Conclusions: GAIN is an online platform that allows access to international experts in autism diagnosis for the purpose of ongoing fidelity and calibration on the ADOS-2. It reaches providers across the world in a variety of disciplines. Data from participants indicate that GAIN is a feasible and effective platform for learning. In addition, the subscription model with an affordable price point suggests fiscal sustainability. Future analyses will examine pre and post self-efficacy ratings and changes in reliability data over time in order to determine effectiveness of GAIN in improving individual ADOS-2 reliability.

448.015 *(Poster)* Multimodal Wearable Data Capture System (M2P3) for Predicting Precursors of Challenging Behavior in Autism Spectrum Disorder

Z. Zheng[1], *J. Staubitz*[2], *A. S. Weitlauf*[3], *J. Staubitz*[1], *G. Nie*[1], *A. R. Swanson*[4], *P. Juárez*[4], *Z. Warren*[4] *and N. Sarkar*[5], *(1)Vanderbilt University, Nashville, TN, (2)Treatment and Research Institute for Autism Spectrum Disorders, VUMC, Nashville, TN, (3)Vanderbilt Kennedy Center, Vanderbilt University Medical Center, Nashville, TN, (4)Vanderbilt University Medical Center, Nashville, TN, (5)Mechanical Engineering; Electrical Engineering and Computer Science, Vanderbilt University, Nashville, TN*

Background: Approximately two thirds of individuals with ASD display challenging behaviors that can disrupt classroom participation, impair home functioning, and present safety risks. Body movement, physiological data, and vocalizations have shown promise predicting imminent challenging behaviors among individuals with ASD. Existing predictive models primarily focus on physiological data only. To determine if more comprehensive methods of data capture add value to existing physiological and behavior methods, we created a multimodal wearable data capture system (M2P3). This system integrated wearable intelligent non-invasive gesture system (WINGS) for data collection and a custom tablet application to track observable precursors of challenging behaviors within an Interview-Informed Synthesized Contingency Analysis (IISCA).

Objectives: Our primary objectives were to: 1) design a multimodal data capture platform M2P3 that enhances traditional behavioral assessment tools by capturing and integrating multi-modal information to detect precursors of challenging behaviors; 2) develop an app that can help a therapist to precisely capture data relevant for challenging behaviors within the context of the IISCA; and 3) validate the platform, data collection, and acceptability with a pilot study.

Methods: We conducted a pilot study with 7 participants (6 male) aged 10-15 years (mean age = 12.20 years, SD = 1.37 years). Each participant participated in one visit. Participants wore E4 sensors on the wrist to collect photoplethysmography (PPG) and electrodermal activity (EDA). They wore WINGS on the upper body which, in conjunction with a Kinect, captured limb movement. We designed a tablet application that allowed clinicians to input IISCA data. Clinicians implemented the IISCA with participants while caregivers observed and provided ground truth input.

Results: Classification analyses towards an individualized model to predict challenging behavior presentation were performed. These multimodal datasets have an average of 27242 samples and include accelerations, physiological signals, facial expressions, head rotations and behavioral states of each sample. A random forests algorithm was used to build the machine learning model. The samples were randomly divided into training and test sets with a ratio of 90 to 10. A 10-fold cross validation was run. The trained individualized models have an average classification accuracy of 91.82% on the test sets. We also built individualized models using only physiological and motion data. The average accuracies for these two models are 86.88% and 91.63%, respectively. A group model was also computed combining data of all the subjects. This learnt model has a prediction accuracy of 81.38%.

Conclusions: Results of this pilot study suggest that adolescents with ASD and challenging behaviors tolerated the platform and experimental protocol well. All channels of data were robustly collected. Further, we were able to acquire multimodal datasets for further precursor prediction, including successful creation and deployment of a novel app for use by therapists as part of behavioral assessment protocols. Our machine learning model offered a significant increase in prediction accuracy as compared to existing published results. Importantly, it also functioned based on precursors rather than requiring challenging behaviors to occur, which improved the safety and efficiency of the assessment process.

448.016 *(Poster)* Objective Measurement of Movement within a Social Space for Young Children with Suspected ASD

J. M. Moffitt[1]*, Y. A. Ahn*[2]*, S. Custode*[1]*, Y. Tao*[3]*, A. Beaumont*[4]*, S. Cardona*[1]*, M. Parladé*[4]*, J. Durocher*[4]*, M. N. Hale*[4]*, M. Alessandri*[4]*, M. L. Shyu*[5]*, L. K. Perry*[1] *and D. S. Messinger*[4]*, (1)Psychology, University of Miami, Coral Gables, FL, (2)Psychology, University of Miami, Miami, FL, (3)University of Miami, Miami, FL, (4)University of Miami, Coral Gables, FL, (5)Electrical and Computer Engineering, University of Miami, Coral Gables, FL*

Background: Autism spectrum disorder (ASD) is a neurodevelopmental disorder characterized by restricted, repetitive patterns of behavior, as well as persistent deficits in social communication. ASD is diagnosed on the basis of expert clinician judgment, which is informed by gold standard measures such as the Autism Diagnostic Observation Schedule-2 (ADOS-2). Machine learning holds the potential to supplement expert clinician evaluation of ASD by providing additional objective measurements of critical social and communicative behaviors.The current study sought to improve understanding of children's social communicative interaction with adults (both examiner and parent) present during the administration of the ADOS-2 by tracking children's movement within the social space.

Objectives: To investigate associations between objective measures of child's movement within a social space and the examiner-rated measure of autism symptoms based on ADOS-2 calibrated severity scores (CSS).

Methods: Twenty-five racially and ethnically diverse children (72% male, 68% Latino, 40% Black) between the ages of 2 and 5 years (*M* age=42.44 months, *SD*=10.27) with suspected ASD were administered the ADOS-2. A hypothesis-blind examiner provided a total CSS and subscales for Social Affect (SA CSS) and restricted/repetitive behavior (RRB CSS). The ADOS-2 administration was recorded via a ceiling-mounted video camera. Child, examiner, and parent position and movement were tracked using a Mask R-CNN (regional convolutional neural network; He et al., 2017). Measures included average distance from each the parent and examiner, amount of time spent within 4 feet of each the parent and examiner, amount of time spent in the periphery of the room (within 2 feet of any wall), and ADOS-2 CSS (total, SA, and RRB).

Results: The children in our sample displayed a moderate level of overall autism symptoms based on the total CSS score ($M = 6.28$, $SD = 2.19$), a moderate level of symptoms within the Social Affect domain (SA CSS $M = 5.48$, $SD = 2.18$), and a high level of symptoms within the Restricted and Repetitive Behaviors domain (RRB CSS $M = 8.04$, $SD = 2.03$). On average, children in our sample spent about 2 minutes within 4 feet of their caregiver ($M = 110.90$ seconds, $SD = 270.60$), about 4 minutes within 4 feet of the examiner ($M = 225.41$ seconds, $SD = 567.38$), and about 8 minutes in the periphery of the room ($M = 470.04$ seconds, $SD = 400.84$). Children's average distance from the examiner was negatively related to SA CSS at the level of a trend, $r = -.35$, $p < .10$. Time spent in the periphery of the room does not appear to be related to SA CSS, $r = -.05$, *ns*.

Conclusions: Objective measurements of children's movement during the ADOS-2 may provide insight into the impact of ASD symptoms on children's social engagement. The objective measurement of key behavioral features of ASD using a ceiling-mounted camera may have the potential to produce quantitative indices of ASD symptoms that may prove useful to enhance the clinical assessment process.

448.017 *(Poster)* Parent Perspectives on Technology Use By Children with ASD and Relevance for Social Skills Interventions: A Qualitative Study

R. N. Rashedi[1]*, K. Bonnet*[2]*, R. Schulte*[2]*, D. Schlundt*[2]*, A. R. Swanson*[3]*, A. Kinsman*[3]*, N. Bardett*[3]*, Z. Warren*[3]*, P. Juárez*[3]*, G. Biswas*[1] *and M. Kunda*[1]*, (1)Electrical Engineering and Computer Science, Vanderbilt University, Nashville, TN, (2)Psychology, Vanderbilt University, Nashville, TN, (3)Vanderbilt University Medical Center, Nashville, TN*

Background: Interest continues to be high in the development of technology-based interventions for individuals with Autism Spectrum Disorder (ASD) across many applications. Designing such interventions can benefit from consideration of the preferences and challenges that individuals on the spectrum often experience with technology use. We focus on potential uses of technology for social skills development among children and teenagers with ASD, and we investigate how youth with ASD currently integrate technology into their lives, from preferences in genre, content, and platform to effects on mood and behavior. We also discuss how designers can draw from this information to better inform the design of new interventions.

Objectives: Using information collected from parents, our primary goals are to: 1) describe their perspectives on how children and teenagers with ASD use electronic devices; 2) identify digital methods used for communication; 3) investigate relationships between device use and behavior and mood; 4) identify the social skills that parents would like their child to develop or improve; and 5) obtain suggestions from parents on effective technological methods for social skill interventions.

Methods: We conducted 20 semi-structured interviews with parents of ASD children and teenagers. Inclusion criteria consisted of 1) parent of a child with ASD; 2) child is between the ages of 10-17; and 3) parent has the ability to speak and read English. The audio-recorded interviews were transcribed, coded by using a hierarchical coding system, and analyzed by using an iterative inductive-deductive approach.

Results: Common themes and differences emerged in how parents reported the preferences and experiences shown by their children with everyday technology use. Overall, most parents reported that regardless of the device, technology appeared to have a calming effect on their child's mood, although there were several negative behavioral reports of children sometimes becoming dysregulated if the device did not work properly, or if they had to stop playing on their device and switch to a different task. Parents described a variety of media platforms and content that their child enjoys. Some parents, for example, reported that their children would watch videos on YouTube or conduct research online to deepen their knowledge in a specific area. Parents also shared how their child would sometimes engage in repetitive behaviors by continuously viewing the same clip of a niche interest. Many parents reported that they would use a technology-based intervention to target the cultivation of improved emotion regulation, self-confidence, interactions with new people in various contexts, and the ability to build friendships. Parents also described many features that would appeal to their child's interests such as touch screens, film clips with social content, and ways to personalize the user experience.

Conclusions: These findings can help inform the design of new technology-based interventions targeting social skills for children and teenagers with ASD. Parents highlighted several avenues of technology preferences that would be useful for intervention designers to leverage, to increase user engagement and to both challenge and appeal to users' areas of social growth and strengths.

448.018 *(Poster)* Portable Joint Attention Skill Training Platform Augmented with Virtual Reality and Automated Face Detection Algorithm: Implication for Children with Autism

V. Jyoti[1]*, P. Sharma*[2] *and U. Lahiri*[3]*, (1)Centre for Cognitive and Brain Sciences, IIT Gandhinagar, Gandhinagar, Gujarat, India, (2)Department of Psychology, B.M. Institute of Mental Health, Ahmedabad, Gujarat, India, (3)Department of Electrical Engineering, Indian Institute of Technology Gandhinagar, Gandhinagar, Gujarat, India*

Background: Joint Attention (JA) refers to the triadic relationship between two individuals with a common target of interest in their shared visual space. Children with autism possess JA skill-related milestones that adversely affect their overall socio-communicative development deteriorating their capability of independent living. Given the high prevalence (1 in 65 children (2-9 years of age) in India, 1 in 59 in USA) of autism, such deficit poses a major socio-economic challenge. Individualized skill-training can help in addressing such deficits. Presently-available conventional intervention techniques, though powerful, suffer from restricted healthcare resources, high cost of one-on-one interventions, etc. particularly in developing countries like India. Technology can offer a complementary solution. However, currently-available robot-assisted and computer (desktop)-assisted JA training platforms are often restricted to research labs because of high cost and limited portability. Thus, developing a portable and cost-effective JA skill training platform is essential for deeper percolation among the stakeholders, particularly in developing countries. Also, it is important that the JA skill training platform is individualized, as it is essential, given the spectrum nature of autism.

Objectives: We present Virtual Reality (VR)-enabled portable (tablet-based) JA skill training platform that can offer agent-mediated cueing with JA prompts being adaptively varied from lowest to the highest difficulty level in an individualized manner based on one's JA skill. Additionally, an automated face detection algorithm can extract participant-specific information (from inbuilt camera-based images). The objectives of the proposed research were designing (i) VR-based portable JA skill training interface along with automated face detection and (ii) usability study to explore the implication of the portable platform on one's ability to pick up JA cues, looking pattern, etc.

Methods: Portable VR-based JA skill training platform projected humanoid characters (Avatar with Indian look) standing in a virtual room with objects placed on the shelves. The avatars delivered verbal and non-verbal JA cues, e.g., finger-pointing, head-turn, and gaze-orientation, while prompting towards an object of interest. Also, environment-mediated sparkling cue was delivered. The JA tasks of varying difficulty levels (based on the prompting cue) were adaptive to one's individualized JA skill level. Simultaneously, the face detector algorithm recorded whether the user had his/her face oriented towards or away from the stimulus. The participant's performance was computed in terms of (i) success/failure to pick up a cueing prompt and (ii) behavioral disposition depicted from face oriented towards/away from the stimulus.

Results: A small sample of children with autism participated in the usability study. Results indicate that the participants perceived various JA cues differently with variation in their response time, time taken to succeed in picking up a cue, and face orientation (detected by the automated face detection algorithm). They looked more towards the interface for finger-pointing and sparkling cues than that for the eye and head turn-based cues.

Conclusions: The present work shows the potential of a portable VR-enabled JA skill training platform to contribute to JA skill training of children with autism and a complementary tool in the hands of the interventionist.

448.019 *(Poster)* Quantifying Social Interaction and Communication within Collaborative Virtual Environments

N. Sarkar*, Vanderbilt University, Nashville, TN*

Background: It has been argued that virtual reality environments could be utilized to meaningfully measure and perhaps intervene on social communication impairments for individuals with ASD. Given the computational burden and limits of natural language processing, almost all applications have required rate limiting confederate participation, expert rating systems, and/or constrained interactions. Collaborative Virtual Environments (CVE), where-in several individuals interact with one another within a distributed virtual space, may hold promise for overcoming these limits if viable methods for measuring and adapting to dynamic interaction can be quantified. Specifically, CVE systems that not only gauge performance, but also automatically detect, respond to and adjust task characteristics based on the users' communication and coordinated aspects of interaction could represent valuable tools for assessment and treatment.

Objectives: In an attempt to combine the benefits of peer-based collaborative games and intelligent agent interaction that does not require heavy burden of human coding, we developed a CVE system with an embedded intelligent agent. We evaluated the initial feasibility/acceptability of the system in dynamic peer interactions and compared within system computation of metrics of collaboration and communication efficiency to ratings of human coders.

Methods: Across a series of experiments (1) we designed and tested CVE-based collaborative games with two groups (7 ASD/TD pairs; 7 TD/TD pairs) to establish system feasibility and tolerability as well as capture meaningful metrics of social communication, (2) evaluated whether a computationally-informed AI agent could measure communication and collaboration across a CVE environment with 20 age- and sex-matched pairs (40 participants), and (3) extended this work to a haptic CVE environment (10 ASD/TD pairs).

Results: Initial feasibility and acceptance date indicated very limited drop-out rates, high levels of system performance, and high levels of system engagement dyads (likert ratings $\geq$4.71 out of 5). In our AI agent interaction system testing, the system classified user statements with moderate to high accuracies and we found moderate to high agreement in displayed communication and collaboration skills between human–human and human–agent interactions. We found a strong negative correlation between the system generated *failure frequency* feature and human ratings of collaboration (ASD: $rs = -0.60$, $p < 0.001$, TD: $rs = -0.23$, $p < 0.001$) and human ratings of communication (ASD: $rs = -.49$, $p < .001$, TD: $rs = -0.24$, $p < .05$). That is, the lower the continuous human ratings, the more frequently the system registered *failure* during an HAI session. In our haptic CVE extension we found significant performance improvements regarding fine motor and colloborative interaction tasks.

Conclusions: Designing CVE paradigms for controlling, indexing, and altering aspects of interactions may be quite beneficial. Ultimately, such artificially intelligent/informed systems may have the potential to index both performance within the tasks as well as social interaction components contributing to task performance (e.g., communication bids/responses, collaborative actions). This two-fold measurement strategy, during tasks that embody real-world social interactions could yield rich objective data potentially sensitive to meaningful short-term and long-term change.

448.020 *(Poster)* Remote Assessment of ASD in Clinical Trials: Validation of a Smartphone-Based Emotion Recognition Task

D. Slater[1], *G. Pointeau*[1], *D. Nobbs*[1], *F. Lipsmeier*[1], *T. Kilchenmann*[1], *K. Sanders*[2], *J. Smith*[3], *E. Eule*[4], *D. Umbricht*[4], *L. Murtagh*[4], *C. Gossens*[1], *M. Lindemann*[1], *J. F. Hipp*[4] *and C. H. Chatham*[5], *(1)Roche Pharma Research and Early Development. Roche Innovation Center Basel, Hoffmann-La Roche, Basel, Switzerland, (2)Product Development Neuroscience, F. Hoffmann-La Roche Ltd., Basel, Switzerland, (3)PDN, F. Hoffmann-La Roche Ltd, Welwyn Garden City, United Kingdom, (4)Neuroscience and Rare Diseases (NRD), Roche Pharma Research and Early Development, Roche Innovation Center, Basel, Switzerland, (5)Neuroscience and Rare Diseases (NRD), Roche Pharma Research and Early Development, Roche Innovation Center, New York, NY*

Background: Whilst clinical trials for ASD therapeutics are dependent on the quality of their outcome measures, current tools have severe limitations in terms of reliability, validity, burden and ecological validity (Anagonostou et al., 2014). To address this unmet measurement need we have developed novel digital tools for the remote measurement of ASD signs and symptoms and deployed these into an observational study.

Emotion recognition is impaired in individuals with ASD (Lozier et al., 2014) and has been associated with everyday social functioning impairments (Trevisan and Birmingham, 2016). We developed "Facial Expressions", a smartphone task for measuring emotion recognition motivated by the Reading the Mind in the Eyes Test (RMET; Baron Cohen et al., 2001). The participant is shown a series of faces expressing six emotions from 37 actors/actresses in a pseudo-randomized order and should identify and select the emotion from a list (stimuli source: Karolinska Directed Emotional Faces database (Lundqvist et al., 1998)). The emotional intensity varies trial-by-trial according to a staircase algorithm that decreases the intensity after correct responses and increases the intensity when incorrect. Consequently, the intensity is expected to stabilize around the participant's emotion recognition threshold and the *mean intensity* over a time window of interest provides a measure of performance (Chatham et al., 2019).

Objectives: To test the reliability and validity of *mean intensity* as a measure of emotion recognition and feasibility of remote use of the task in a clinical trial.

Methods: 90 individuals with ASD and 45 typically developing (TD) controls (5-45yrs) were asked to complete "Facial Expressions" on every 5th day of the 12-week observational period of the non-drug observational study, following 3 weeks practice. Participants also completed the RMET Adult and Child versions at clinical visits (day 1, week 2 and week 12). Mean RMET total scores and median values of *mean intensity* over multiple test iterations were used for analysis. Feasibility was assessed in terms of adherence to the schedule of assessments. Results are given for 43/90 individuals with ASD and 13/45 TD controls that have so far completed the study.

Results: Individuals with ASD completed "Facial Expressions" on ~50% of scheduled days and TD controls on ~70% of scheduled days. *Mean intensity* had strong test-retest reliability. For adults and children with ASD, *mean intensity* had significant strong to moderate correlations to the RMET total score.

Conclusions: "Facial Expressions" was a feasible task for the remote and frequent measurement of ASD signs and symptoms in a clinical trial. *Mean intensity* was a valid and reliable measure of emotion recognition in children and adults with ASD. Recruitment is ongoing. Once sufficient sub-group sample sizes are reached we plan to conduct group-comparisons. "Facial Expressions" is also deployed in a Ph3 interventional study to test the sensitivity of this measure to the treatment effect of Vasopressin 1a receptor antagonist *Balovaptan*.

448.021 *(Poster)* Scaling Challenges of ASD Screening Technology Solutions to Remote Regions in India

S. Rajagopalan[1] *and A. M. Visweswariah*[2], *(1)Center for Advanced Research & Excellence in Autism and Developmental Disorders (CARE-ADD), St. John's National Academy of Health Sciences, Bangalore, India, (2)CARE-ADD, Unit of Hope, Department of Psychiatry, St John's Medical College Hospital, Bangalore, India*

Background:

Technology based solutions for ASD screening have been the focus of recent efforts from various centers. This has tremendous potential towards early diagnosis and intervention in professional scarce settings. Challenges arise in scaling of technology solutions effectively across all primary care in resource poor settings.

Objectives:

We intend exhaustively listing all the challenges in scaling remote ASD screening technology solutions across primary health care centers in India.

Methods:

We report on a focused discussion with two independent child mental health professionals specialized in ASD diagnosis and a computer software engineering architect from a leading multinational software organization. The discussion is focused on delivering an end-to-end technology system design for ASD screening, deployment practices, security, monitoring system health and socioeconomic conditions.

Results:

Administration: This may involve parent/caregiver reports to a questionaire and/or administering semi-structured play activities to elicit subtle atypical behaviours from the child. The former is relatively easy; administering and recording videos of semi-structured play activities are more challenging. We need central servers to generate quantifiable behaviour metrics. Challenges in the design of such modules include:

- High quality recorded videos are necessary for deeper analysis. The installation and maintenance of recording setups in primary health care centres can be costly plus have issues with Smartphones may lack multiple view angles, provide noisy data due to hand motions and audio quality etc.
- Training local resource person to administer the semi-structured activity in a local language and context, besides managing child's behaviour.

- Absence of expertise to control the video recording session. Costs of addressing training gaps and / or sending outstation personnel need to be factored.
- Power outages leading to potential multiple recordings and challenges of stitching videos leading to non-completion of the sessions besides motivational issues for completing interrupted procedures.

Secured video storage system: The recorded videos will be of large size and hence huge storage capacity with backup drives will be needed to store and prevent data loss impacting infrastructure and power costs.

The privacy of the participants will need strict access control mechanisms which calls for IT systems expertise. This is also needed for strong version control mechanisms.

Secure video transmission to central server: For transfer to secure remote servers, rural areas bring challenges with lower network bandwidth, connection drops, partial data transfer, etc. These will impact steaming videos too. Physical transmission using external hard drives is not scalable.

Behavior quantification and report generation: Advanced video analysis algorithms using machine and deep learning technologies have to be developed for quantifying subtle behaviours and enabling effective and timely automatic report generation.

Report delivery to primary caregivers: The quantified behaviour reports can be delivered via smartphone to caregivers.

Conclusions:

Challenges in scaling technology for ASD Screening have been listed. App based questionnaires are limited by ambient levels of awareness and language / translation issues. Remote screening methods using videos will need effective implementation solutions. It is ideal to involve multiple stakeholders in discussions from the outset.

448.022 *(Poster)* Scaling up the Assessment of Eye Contact during Face-to-Face Interactions: An Automated Video-Based Detection Method That Achieves Human-Level Accuracy

*E. Chong[1], E. Clark-Whitney[2], A. Southerland[1], E. A. Stubbs[1], C. Bridges[1], E. L. Ajodan[3], M. R. Silverman[3], A. Rozga[1], R. M. Jones[4] and **J. M. Rehg**[1], (1)Georgia Institute of Technology, Atlanta, GA, (2)Psychiatry, Center for Autism and the Developing Brain, White Plains, NY, (3)Sackler Institute for Developmental Psychobiology, New York, NY, (4)Weill Cornell Medicine, New York, NY*

Background: Atypical eye contact is a diagnostic hallmark of ASD and there is a substantial body of research documenting atypical use of gaze to regulate social behavior in ASD (Senju and Johnson 2009). Eye contact is typically measured via manual coding, limiting the scale at which gaze data can be acquired. Accurate automated methods for detecting eye contact in video would eliminate the need for burdensome manual annotation.

Objectives: This study aims to establish the equivalence between eye contact ratings produced by trained human experts and a novel automated detector based on deep learning, using video collected with a wearable camera worn by an adult examiner during an interaction with a child subject.

Methods: Participant data (n=121, average age 36 months) was collected at the Center for Autism and the Developing Brain (CADB) and at Georgia Tech (GT). 66 children (55 male) in the ASD sample participated at CADB and 55 TD children (36 male) participated at GT. Subjects completed the Early Social Communication Scales (ESCS) protocol (Mundy 2003) and the Brief Observation of Social Communication Change (BOSCC) protocol (Grzadzinski et al. 2016) in random order. Interactions took place at a table with the subject sitting across from the examiner, who wore a pair of video-recording glasses, Pivothead Kudu, that provided continuous high-resolution capture of the subject's face. Videos were coded to flag frame-level onsets and offsets of eye contact during the two protocols. The validation dataset consisted of 10 ESCS and 8 BOSCC videos which were annotated by multiple raters. The remaining videos (n=103, 4,693,803 frames) were annotated by a single rater. A deep neural network (DNN) architecture was trained to detect eye contact in individual video frames. The DNN performance was analyzed by: 1) Comparing DNN Precision and Recall (PR) to that of human raters; and 2) Comparing the reliability of human-human rater pairs to the reliability of DNN-human rater pairs on the validation dataset, and statistically testing for equivalence between these groups.

Results: 1) The DNN PR is equivalent to the human rater's PR (see Figure). The PR for each rater (yellow dot) was obtained by scoring their performance against the consensus of the other raters. The final DNN results (red diamond) were obtained by temporally smoothing the per-frame outputs. The smoothed DNN has an F1 score (Powers 2011) of 0.94, compared to 0.93 for the average rater (green diamond). The DNN PR lies within one standard deviation of the average rater (green error bars). 2) The average human-human kappa is 0.888. Treating the DNN as an additional rater, the average human-DNN kappa is 0.891. Statistical testing on the distribution of kappa values for human-human and human-DNN pairs accepts the hypothesis for equivalence between DNN and human raters, rejecting the null hypothesis at $p = .05$ (with a minimum group kappa difference of 0.025).

Conclusions: The analysis supports the equivalence between DNN and human performance when rating eye contact in wearable camera videos. Code and models will be made freely available for research purposes.

448.023 *(Poster)* Telebaby: A Telehealth Intervention for Caregivers of Infants with Early Signs of Autism Spectrum Disorder (ASD)

***S. Dufek**[1], M. R. Talbott[2] and S. J. Rogers[3], (1)Psychiatry, University of California, Davis, Sacramento, CA, (2)Psychiatry and Behavioral Sciences, University of California at Davis MIND Institute, Sacramento, CA, (3)Department of Psychiatry and Behavioral Sciences, The Medical Investigation of Neurodevelopmental Disorders (MIND) Institute, UC Davis School of Medicine, University of California Davis, Sacramento, CA*

Background: As more information is becoming available about symptoms of autism spectrum disorder (ASD) in infants, an increasing number of families are seeking help from practitioners with expertise in early ASD. Efforts to meet families' requests for help face multiple challenges, especially lack of access to infants and their families in natural environments –necessary for providing appropriate care to infants over time. The use of telehealth technology to serve families who are concerned about ASD symptoms in their infants is a promising solution. Delivery of health care via telehealth technology is increasingly common (Ekeland, Bowes, & Flottorp, 2010), and a growing body of research supports the use of telehealth technology to deliver intervention to children with developmental disabilities as well as coaching to teachers, therapists, and parents (Machalicek et al., 2010; McDuffie et al., 2013; Oakes et al., 2015).

Objectives: Develop and test telehealth technology delivery of the TeleBaby intervention in order to capitalize on delivering intervention in natural contexts, to maximize infant and caregiver learning and generalization.

Methods: Six infants (6-12 months of age) exhibiting early signs of ASD and their primary caregivers participated in this study. A multiple-baseline-design across subjects was used with counterbalanced introduction of three TeleBaby treatment techniques (Step into the Spotlight, Imitation, Talking to Baby). Treatment sessions occurred three times per week for one month for a total of 12 sessions. Caregiver coaches introduced each new treatment technique weekly to the caregiver and allowed for caregiver practice with immediate feedback. During the last week of intensive treatment, the coach provided feedback during caregiver practice of all three treatment techniques combined. One final treatment session was conducted after a 1-month follow-up period. Caregiver fidelity of implementation (FI) of treatment techniques and child ASD-specific behaviors were coded from 10-minute caregiver-child dyad intervention video-recorded probes. Session attendance was closely tracked and caregivers participated in an exit interview in order to obtain information about caregiver perspective around acceptability and satisfaction of the TeleBaby intervention.

Results: Session attendance rate was high (96%) for all families with minimal rescheduling throughout the course of treatment. Once introduced to each treatment technique, caregivers met FI requirements (above 80% correct implementation) quickly, then maintained high scores over time during the intensive month of treatment. At the follow-up timepoint some caregivers maintained their skills at high fidelity, especially for particular techniques over others. During exit interviews, participating caregivers reported high acceptability and satisfaction with the telehealth-delivered TeleBaby intervention. All caregivers reported they would not hesitate to participate in the intervention again and to recommend the intervention to others.

Conclusions: Since time is of the essence when presented with an infant with early signs of ASD, it is essential that therapists provide intervention in the most practical way possible. The use of telehealth technology allows practitioners to quickly and easily serve families effectively. The successes and challenges of using telehealth technology to coach caregivers and their infants with early signs of ASD in this study will inform future clinical practice and research efforts in this area.

448.024 *(Poster)* The Specific Aspects of Operating a Robot through an Unfamiliar Touchscreen for Individuals with Autism Spectrum Disorders

T. Watanabe[1]*, H. Kumazaki*[2]*, T. Muramatsu*[3] *and M. Mimura*[4]*, (1)Faculty of Frontier Engineering, Kanazawa Univerisity, Kanazawa, Japan, (2)Department of Preventive intervention for Psychiatric Disorders, National Institute of Mental Health, National Center of Neurology and Psychiatry, Kodaira, Japan, (3)Department of Neuropsychiatry, Keio University, School of Medicine, Tokyo, Japan, (4)Keio University, Tokyo, Japan*

Background: Employment support for individuals with autism spectrum disorders (ASD) has become a major social issue worldwide. A number of programs have recently started to focus on establishing pathways to employment and have highlighted the value of specific transition programs. Given recent developments in smartphone and tablet applications, the usage of touchscreen technology in the 21st century seems very promising. The skills needed to learn how to operate unfamiliar touchscreens are becoming required for employment. In the current context of employment support, teaching individuals how to operate a touchscreen is one of the most important elements. Additionally, we currently have limited opportunities to operate robots, although the demand for household robotic devices (i.e., cleaning robots and communication robots) is increasing, indicating a greater need to be able to operate robots in the near future.

Objectives: To investigate the specific aspects of operating a robot through an unfamiliar touchscreen by observing the learning process for individuals with ASD.

Methods: To better understand how they operate unfamiliar touchscreens, we prepared an original touchscreen and an original robot as an operation target. We designed a task to operate the robot to shift its posture from the initial one to a single-foot standing posture, because standing on a single foot is difficult from the viewpoint of engineering and physics and because this task is easy to assess. The task terminal condition was set to have three consecutive successes within one minute without giving up a trial or making the robot fall. We compared how individuals with ASD and TD operated the touchscreen to move the robot.

Results: The present study was approved by the ethics committee of Kanazawa University. Sixteen participants with ASD (12 males; mean age: 21.94 ± 2.22; IQ score : 82.94 ± 7.47) and 26 participants with typical development (TD; 19 males; mean age: 21.00 ± 1.88; IQ score : 106.12 ± 7.18) were participated. The ASD group took more time to achieve the terminal condition than the TD group (median = 60 min vs 35.7 min; $Z = -2.57$; $p < 0.01$). Similarly, the total number of commands that the ASD group needed to achieve the terminal condition was larger than that for the TD group (median = 1795 vs 896; $Z = -1.80$; $p = 0.04$). In contrast, less time was required to attain a single-standing posture for the first time in the ASD group than in the TD group (median = 4.71 min vs 14.0 min; $Z = 2.13$; $p = 0.02$). Similarly, fewer commands were required to attain a single-standing posture for the first time in the ASD group than in the TD group (median = 142.5 vs 404; $Z = 1.90$; $p = 0.04$).

Conclusions: Our quantitative data suggest that individuals with ASD were initially better able to use the touchscreen. However, individuals with ASD seemed to have difficulty achieving a certain level of proficiency. Given the promising results, further studies need to establish instructions corresponding to the personal traits of individuals with ASD.

448.025 *(Poster)* Toward a Digital Phenotype of Autism: An Exploratory Study Using Twitter Data

A. Jutla[1]*, M. R. Donohue*[2]*, H. E. Reed*[3] *and J. Veenstra-Vander Weele*[4]*, (1)1051 Riverside Drive, New York State Psychiatric Institute / Columbia University, New York, NY, (2)Washington University School of Medicine, St. Louis, MO, (3)Columbia University Medical Center, New York, NY, (4)Psychiatry, New York State Psychiatric Institute / Columbia University, New York, NY*

Background: As social communication deficits are a core feature of autism, patterns of language use are a useful tool in characterizing the disorder. However, even though online services have become increasingly popular in recent years, no study of autism to date has analyzed language use in the context of social media. Such an analysis could contribute to understanding whether autism has a robust "digital phenotype" of online behavior. Twitter in particular is a useful source of data. It has a large number of frequent users (126 million people use the services at least daily), is largely public-facing (87 percent of Twitter users make all their tweets publicly-available), and is used by a significant segment of the autistic community, with many users who self-identify using the hashtag "#actuallyautistic."

Objectives: We sought to train a machine-learning model to predict whether an individual autism-related tweet came from a user who self-identified as autistic using the #actuallyautistic hashtag.

Methods: We used Twitter search to download all unique English-language tweets made over a one-month period (7/28/2019 - 8/28/2019) that contained either the word “autism” or “autistic.” We labeled all tweets as “self-identified autistic” or “not self-identified autistic” based on whether they contained the hashtag “#actuallyautistic.” We then processed tweets for analysis by removing “autism,” “autistic,” any hashtags, any URLs, and any usernames from the text, and by converting all text to lowercase. We created a modeling dataset from all “self-identified autistic” tweets and a random matching subset of “not self-identified autistic” tweets. Using the open-source fastText algorithm, we transformed tweets into bigram vector representations and trained a model using 75% of the data for 50 epochs. We then evaluated model performance on the remaining 25%.

Results: Of 100,356 unique tweets containing “autism” or “autistic,” 992 contained the hashtag “#actuallyautistic” and were given the “self-identified autistic” label. Our trained algorithm was able to identify “self-identified autistic” tweets in the test set with reasonable (73.80%) accuracy.

Conclusions: These exploratory results at minimum sugggest that the semantic content of tweets about autism made by users who self-identify as autistic may differ systematically from those made by users who do not. However, we also consider them a promising proof-of-concept for future work using Twitter data. A logical next step would be to obtain non-autism-related tweets from the profiles of self-identified autistic users and compare them to a control group from non-autistic users. It is possible that this could improve the accuracy of our classifier, as our ascertainment of tweets based on search terms may have inherently reduced the differences between them. An eventual goal would be to determine whether a classifier trained on Twitter data can generalize to other online prose, such as Facebook comments, text messages, or emails. If so, this would represent a meaningful step towards characterizing a digital phenotype of autism.

448.026 *(Poster)* Using Automated Emotional Facial Expressions Recognition Technology in Children with Autism: First Results on the Seemingly Ignored Methodological Aspects of Test-Retest Reliability, Data Quality, and Technology Evolution Effects

M. Gyori[1,2]*, Z. Jakab*[1]*, Z. Borsos*[1,2]*, K. Stefanik*[2,3] *and B. Bogdán*[1]*, (1)Institute for the Psychology of Special Needs, ELTE University, Budapest, Hungary, (2)HAS-ELTE 'Autism in Education' Research Group, Budapest, Hungary, (3)Institute of Special Needs Education for People with Atypical Behavior and Cognition, ELTE University, Budapest, Hungary*

Background: Studies have indicated differences between emotional facial expressions of neurotypical (NT) individuals and individuals with ASD, in both children and adults. Recently, automated recognition of emotional facial expressions offered new tools to understand these better and to utilize them in technologically assisted screening and diagnosis. However, very little has been published on such methodological aspects of this technology as test-retest reliability, data quality, and changes with its evolving versions, especially in detecting emotions in individuals with autism. These are especially important issues for autism research as these technologies have been developed primarily for NT target populations.

Objectives: In the context of a research-and-development project to create a digital screening system utilizing automated emotional facial expression recognition and eye-tracking for identifying high functioning cases of ASD in kindergarten age, we explored (1) the test-retest reliability of a commercially available emotional facial expression recognition software, (2) its data quality, in terms of the ratio of missing and potentially artefact data (non-variant emotion intensities); and (3) compared the performance of its two versions. These characteristics were examined in two samples: NT children and children with ASD, to reveal (4) any differences between these groups in terms of emotion recognition software performance.

Methods: Twenty-nine high functioning children with ASD (8 girls, 21 boys, mean age 57.7 months, mean IQ 116.3), and 31 neurotypical children (13 girls, 18 boys, mean age 53.1, mean IQ 121.6) participated. Facial video recordings were made while the children played with the prototype version of the screening game. Versions 5.1 and 8 of the Noldus FaceReader (by Noldus Information Technology) automated emotional facial expression recognition software were used to identify emotional facial expressions during the game session. Each video-recording was analyzed twice by both versions, to gain both test and retest data.

Results: Descriptive statistics and mixed-mode ANOVAs were run on the data, with diagnosis (NT vs ASD) as between-subject factor, test vs re-test, emotions (7), and version (5.1 vs 8) as within-subject factors. Our key results are the following: (1) both software versions showed a high but not perfect level of test-retest reliability; (2-3) both versions showed occasionally invariant emotion intensities (an artefact), but in different patterns; and version 8 showed significantly lower ratio of missing data than version 5.1; (3) the 7 basic emotions were scaled differently by the two versions; and (4) there were no significant group differences or interactions in software performance measures.

Conclusions: Although perfect test-retest reliability has been taken for granted in the literature, our results did not confirm this assumption. Software performance indicators did not show cross-group differences, suggesting that this technology may be applied similarly in both groups. The not-perfect inter-rater reliability, the presence of missing and artefact data, as well as version differences, however, suggest that methodological care is needed when using this technology in autism, and further explorations are necessary to better understand its limitations and potentials in this field.

448.027 *(Poster)* Using User-Centered Design Framework to Develop a Progress Monitoring Tool Supporting Parents of Children with ASD

A. Singh*, Tesside University (Hyper Island), Manchester, United Kingdom*

Background: The current research landscape investigating the Autism Spectrum Disorder (ASD) is dominated by efforts to understand biology, detection of risk factors, and development of treatments/interventions, as they consistently received the greatest investments. Research concerning services and lifespan issues were consistently funded the lowest (Interagency Autism Coordinating Committee 2017). With diagnosis on the rise and a growing movement for ASD acceptance, more research is needed in helping individuals with ASD and their parents manage the condition, particularly in creating open communication channels between stakeholders, and providing practical opportunities for parent education, so an individual with ASD may reach his/her potential.

Objectives: To design solution prototype addressing inefficiencies in collaborative communication between parents, therapists (including other service providers), and educators within a user-centered design framework

Methods: The approach was one of exploratory research informed by principles of human-centered design and design thinking. Semi-structured interviews of parents (4), educators (3), therapists (5), medical professionals (1), ASD adult advocates (2), and other service providers (2) were conducted to understand the current landscape of collaborative communication and uncover pain points.

Content analysis using design thinking tools revealed opportunity areas to investigate for design. Major features were co-designed with parents and therapists, and the proto-solution was validated through user testing (lean startup/agile) with new findings incorporated into future iterations.

Results: The findings from the formal interviews revealed several consistent remarks: 1) a lack of funding/resources created and further exacerbated inefficiencies, 2) a lack of coordinated communication due to underdeveloped communication infrastructure, 3) strategic sharing of information between parties would help improve the quality of service provided and therefore outcomes for the individual with ASD.

Many acknowledged parents bear the majority of responsibilities in coordinating communication and care. Given their initial diagnosis, parents expressed feelings of isolation in terms of not understanding the implications of ASD, need for resources to help provide care, and fear for their child's future. Addressing the parent's needs first was strategically selected as they are the conduit between all other parties, and the main care provider.

Information analysis and co-designing sessions yielded a web based tool for progress monitoring. Parents can select from different areas of needs, determined by assessing delays in behavior related developmental windows, and consult open-sourced advice aggregated from different ASD specialists (e.g. developmental pediatricians, speech language pathologists, and occupational therapists.) There are also provisions for parents to share their learnings/findings with other parents.

Conclusions: Initial user testing feedback of the concept validated the need for such a solution and its potential in helping parents strategically monitor progress. The advice provided is more comprehensive and robust as it is aggregated from many different medical and therapeutic disciplines. There are also considerations for this tool to be shared with therapists and other relevant parties for monitoring progress and aligning around a course of treatment. Such a tool would also be beneficial in bridging access to care for low income/information communities. The implications of such a solution empowers the parent to better understand the medical and therapeutic process.

Technology Demonstration / Devices

POSTER SESSION — **TECHNOLOGY DEMONSTRATION / DEVICES**
449 - Technology Demonstration / Devices Posters

449.001 *(Poster)* A Mobile Game for the Diagnosis and Treatment of Autism Spectrum Disorder Using Crowdsourced Information

P. Washington[1], *A. Husic*[1], *M. Ning*[1], *H. Kalantarian*[2], *A. Kline*[1], *C. Hou*[1], *K. Dunlap*[1], *Y. Penev*[1], *E. Leblanc*[1] *and D. P. Wall*[1], *(1)Stanford University, Stanford, CA, (2)Department of Pediatrics, Stanford University, Stanford, CA*

Background: Standard of care diagnostic and treatment methods for autism require timely and laborious in-person sessions. The rapid rise in ASD prevalence and its associated costs, in the U.S. and around the world, create a pressing need to use technological innovations to develop clinical methodologies that can scale with limited resources. Digital applications that can deliver therapeutic effects while simultaneously collecting patient data for AI are a potent way to address these limitations.

Objectives: To design an engaging, nonimmersive mobile game and match game design with prosocial therapeutic benefit in children. To crowdsource an extensive library of structured videos from autistic children ages 2-8 years and to use it to develop novel emotion classification models that are more effective and personalized.

Methods: We used key components of pivotal response training (PRT) to design and develop a mobile application, *Guess What?*, available on the Google Play Store and Apple App Store. *Guess What?* is a charades style game where the child acts out a prompt shown on the phone screen so that their parent or social partner can correctly "guess" the prompt and receive points. Simultaneously, structured videos from the game sessions are collected via the phone's front-facing camera.The captured videos, labeled with participant- and session-identifying metadata, are stored on a HIPAA-compliant server on Amazon Web Services. Face and emotion classifiers are used to post-process the frames to assess the overall image quality while labeling frames. AutoML was used to train emotion classifiers with the labeled data sourced from game sessions.

Results:

More than 2,500 users submitted a total of 1,200+ videos through the application in the year since its initial listing on the Google Play Store. Among a subset of 21 families who enrolled in a pilot study, the average age of child participants was 7.24 years (SD = 1.70). The children exhibited a 3.38 ($p = 0.007$) reduction in total Social Responsiveness Scale-2 (SRS-2) scores, from 80.62 (SD = 10.18) measured at baseline to 77.24 (SD = 8.04) measured after 1 month of using the application. The AutoML emotion classifier achieved emotion-specific F1 scores exceeding 90% for neutral, scared, angry, and sad emotions.

Conclusions: Our results demonstrate that nonimmersive mobile games can be an effective way of crowdsourcing emotive structured video information for autism research while potentially providing therapeutic benefits outside of clinics. Games like *Guess What?* can generate data to support iterative machine learning model enhancement for precision medicine, and potentially provide important diagnostic and therapeutic benefits to children with autism. Such approaches will be of value to the development of effective digital autism interventions in the future.

449.0015 *(Poster)* Automatic Motor Behavior Quantification Via Video Recordings: From Fetuses to Adults

V. Parma[1]*, S. Zoia*[2]*, U. Castiello*[3] *and M. Bulgheroni*[4]*, (1)Temple University, Philadelphia, PA, (2)Azienda Sanitaria Universitaria Integrata di Trieste, Trieste, Italy, (3)University of Padova, Padova, Italy, (4)Ab. Acus srl, Milan, Italy*

Background: A growing body of evidence shows that motor abnormalities are widespread in individuals with autism spectrum disorder (ASD), as well as in the typical population with inherited non-clinical ASD traits. Therefore, they may serve as early indicators of high risk for ASD and/or for the broad autism phenotype, holding promise to an earlier detection of the condition. Technologies able to collect and process motor data with great precision, in natural settings, over long periods of time, and with affordable commercial devices can rapidly increase our knowledge about ASD and limit the burden of scientific testing on the participant and their families. Video-digitization has been adapted to perform reliable, robust, and flexible kinematic analysis from videos recorded as early as in utero. 2D motion patterns may be extracted from a variety of video recordings including 4D ultrasounds and amateur videos provided that the recording is performed with calibrated camera lens (to avoid image distortion), shows a definable measurement unit (to allow for within- and between-subject comparability), holds fixed focus (to avoid modification of the image proportions within a single recording). 3D motion patterns can be estimated from videos recorded with mainstream depth cameras (e.g. orbecc).

Objectives: Although state-of-the-art motion analysis can track any landmarks in the human body and in the environment, the goal of this work is to validate the ease of use of the technology for naive users, the reliability of the measurements and kinematic parameters computation of upper-limb movements across fetuses, infants, school-age children and adults.

Methods: Participants include 30 fetuses monitored via 4D ultrasound from gestational week 14-22; 8 fetuses monitored in utero and after birth till 4 months of age (7 time points); 5 pre-schoolers and 5 adults performing reach-to-grasp actions towards objects of different sizes at different distances; 20 school-age children with ASD performing reach-to grasp actions in the presence of a model. All the video data have been analysed using *VideoTrack* a customized software which provides functions for calibration and tracking tailored to the specific features of the videos and the needs of the experimenter.

Results: The software is able to reliably track spontaneous movements in constrained environments, such as in the case of fetuses (Zoia et al., 2006, 2007) and provide indices of lateralization (Parma et al., 2017) usable in models to predict ASD. Kinematic measures of reach-to-grasp movements which have been tracked from infants to adults (Zoia et al., 2006) statistically differentiate children diagnosed with ASD from typically-developing controls (Parma et al., 2013, 2014). A hands-on experience with the methodology on several videos can be provided in loco.

Conclusions: Off-line video tracking motion offers a way to accurately quantify subtle motor behavior metrics in typically developing individuals and in ASD, both cross-sectionally and longitudinally. When deployed on a large scale, this methodology will provide us with data that could result in a step change in understanding the evolution of ASD from uterine life into adulthood, enabling earlier and continuous intervention and ultimately real improvements in treatment outcomes for individuals with ASD.

449.002 *(Poster)* A Responsive Web Platform for Connecting Families to Autism Resources and Measuring Autism Resource Accessibility

M. Ning*, P. Washington, Y. Penev, K. Dunlap and D. P. Wall, Stanford University, Stanford, CA*

Background: Autism is a neurodevelopmental disorder with a rising prevalence rate of 1 in 40 children in the U.S. While it is widely acknowledged that most families experience difficulty accessing autism resources due to limited numbers and high demand, little has been done to connect these resources to families in need. In addition, the lack of data on resource waitlist times prevents families from gaining access to care efficiently. Acquiring autism resource epidemiological data is essential in building an infrastructure that increases resource transparency, validity, and access.

Objectives: We constructed a responsive web platform that streamlines the connection between autism resources and families in need while simultaneously collecting epidemiological data to enable crowd-sourced methods for autism resource information management. This is a tool that allows families to access, rate, and add local resources anywhere with cellular coverage. Furthermore, this platform enables tracking of waiting periods for access to care to help families balance resource quality with access time. Through crowd-sourced efforts of resource registration and manual rating, this platform will generate a more comprehensive, updated, and verified database of autism resources and allows for a more granular mapping of autism resource epidemiology and efficient resource load balancing on a global scale.

Methods: We developed a responsive, mobile-friendly, web platform with mapping capabilities that can be accessed anywhere with cellular data. It is written in React.js and runs on Amazon API Gateway to connect to Amazon Web Services (AWS) Lambda to communicate with a MySQL database that stores autism resource metadata including, but not limited to, resource names, addresses, service types, and geo-coordinates. These resources are generated through scraping autism resource databases and verifying them through regular expressions and fuzzy logic NLP-based approaches. User email and geolocation data is collected upon registration, and resource ratings and user-added resources are stored on an Amazon Web Services (AWS) DynamoDB database.

Results: We mapped a total of 28,118 unique autism resources and registered 3,872 unique participants who have signed up to be recontacted and provided their email address and location data. We assigned resources to 7 primary resource categories: *Diagnosis*, *Therapy*, *Health*, *Education*, *Recreation*, *Support*, and *Other*. Diagnosis resources comprise 8.83% of all resources and Therapy resources comprise of 41.43% of all resources. We have started expanding resource mapping to countries outside of the U.S. Currently, 81 autism resources have been mapped in Dhaka, Bangladesh. Resource ratings and new resources registered by the participants are continually being collected.

Conclusions: Our results demonstrate that crowd-powered information solutions have promise for new families to navigate the complexity of an autism diagnosis. Our responsive web platform allows families to participate in an infrastructure that reinforces the transparency, validity, and efficient access of autism resources through crowd-based ratings and resource registration while concurrently contributing to autism resource epidemiology research. We believe this platform paves the way for new technology that fills gaps in access to care.

449.003 *(Poster)* A m-Health Platform for Teachers of Children with Autism to Support Emotion Regulation

H. J. Nuske[1], *J. W. Pennington*[2], *M. S. Goodwin*[3], *E. Sultanik*[4] *and D. S. Mandell*[1], *(1)Center for Mental Health, University of Pennsylvania, Philadelphia, PA, (2)Department of Biomedical and Health Informatics, Children's Hospital of Philadelphia, Philadelphia, PA, (3)Northeastern University, Boston, MA, (4)Alevio, Philadelphia, PA*

Background: Three significant barriers limit current approaches to managing challenging behaviors in children with autism: 1) triggers of emotion dysregulation may go undetected without specialized training because children with autism often have difficulty with emotion expression; 2) teachers must attend to multiple, concurrent demands and may not recall the emotion regulation strategies to be used in the moment of crisis, and; 3) teachers may not have training/time to analyze data on the most effective emotion regulation strategies for each child so that they can make informed decisions regarding future intervention programming.

Objectives: Our EMOtion REgulation (EMORE) App is designed to address these barriers by: 1) communicating children's stress to their teachers using heart rate signaling (*Module 1*); 2) supporting implementation of emotion regulation strategies via smartphone pop-up notifications of top strategies for each child (*Module 2*), and; 3) easing the burden of tracking outcomes by providing the child's education team with a tool to track the most effective emotion regulation strategies for that child based on physiological stress reduction data (*Module 3*). See Figure 1.

Methods: First, proof-of-concept work was completed to examine the predictive utility of heart rate increase to challenging behavior (48 children with autism, 2-12 years), and the comfort-level and reliability of heart rate trackers for measuring stress (32 children with autism, 8-12 years). We use a user-centered design approach; we conducted two design workshops with parents, teachers and children with autism (n=12) to design the app prototype, and tested it in public schools with 3 autism support teacher-children with autism dyads (one testing cycle) for feedback on usability (design, layout and features), feasibility, acceptability, and appropriateness. Four additional testing cycles are planned by May 2020 to iteratively improve the app.

Results: Increase in heart rate predicted onset of challenging behavior in children with autism (22-36% heart rate increase from baseline, AUC=.72-.822). Select consumer grade heart rate trackers were found to meet quality thresholds on reliability (spike rate: Mio Fuse: 100%, Polar H7: 87.4%-89.4%; sampling fidelity: Mio Fuse: 96.2%-97.1%, Polar H7: 96.6%-100%), 85% of children with autism will wear these trackers without complaint, and they rate the trackers high on comfort and low on exacerbating sensory sensitivities. In the design workshops, parents and autism support teachers reported that an m-health app using heart rate signaling could be "extremely useful" for managing students' stress, they "strongly agree" that such a system could help prevent challenging behaviors in students, and they "strongly agree" that this is better than current practices. After in-class testing of the EMORE App, teachers reported that the app is a feasible, acceptable, and appropriate solution to preventing challenging behavior and managing stress of children with autism.

Conclusions: Results support the continued development of the EMORE App for managing challenging behaviors and stress in children with autism at school. The presentation will include a live demonstration at the meeting of the EMORE App, including use of the wrist-worn heart rate trackers, simulated tracking of "behaviors" and "emotion regulation strategies" and display of "top strategies" per participant.

449.004 *(Poster)* Augmenting Natural Communication in Nonverbal Individuals with Autism

K. T. Johnson[1], ***J. Narain***[1], *R. W. Picard*[2] *and P. Maes*[1], *(1)MIT Media Lab, Cambridge, MA, (2)MIT, Cambridge, MA*

Background: Despite technological and usability advances, some individuals with minimally verbal autism (mvASD) still struggle to convey affect and intent using current augmentative communication systems. In contrast, their non-speech vocalizations are often affect and context rich and accessible in almost any environment. Our system uses primary caregivers' unique knowledge of an individual's vocal sounds to label and train machine learning models in order to build holistic communication technology (see Figure 1).

Objectives: This work involves the development of 4 major research outputs:

1. Scalable data collection methods to capture naturalistic nonverbal communication, including intuitive in-the-moment labeling by primary caregivers
2. Signal processing techniques to accurately characterize the real-world audio, including signal-label alignment and spectral classification
3. Personalized machine learning methods to elucidate an individual's unique utterances
4. Interactive augmentative communication interfaces to increase agency and improve understanding

Methods: We first identified the needs of the community through interviews (n=5) and surveys (n=18) with mvASD individuals and their families. We then conducted an eight-month case study with an elementary-aged nonverbal child and his family. Through a highly participatory design process, we refined the data collection process, created an inexpensive wearable audio recording system, and developed and deployed an open-source Android app for primary caregivers to label communicative and affective exchanges in real-time with minimal burden or interference. We collected over 13 hours of unprompted vocalizations from the child in his everyday environments with more than 300 labeled instances. The labeled signals were then used to classify states of affect, interaction, or communicative intent using multiple machine learning methods.

Results: Initial machine learning results using a multi-class support vector machine (SVM) with 6 researcher-labeled states produced a weighted f1-score of 0.67, suggesting these states could be differentiated with audio only. Visual inspection of the audio waveforms highlighted the diversity and distinct characteristics of the individual's vocalizations, which varied in tone, pitch, and duration depending on the individual's emotional or physical state and intended communication. (Canonical examples from this individual are shown in Figure 2.) We then trained a deep learning model using a long short-term memory (LSTM) recurrent neural network (RNN) and a zero-shot transfer learning approach. This method employed a generic audio database to classify three categories of caregiver-labeled vocalizations: laughter, negative affect, and self-soothing sounds. We identified laughter and negative affect with 70% and 69% accuracy, respectively, but classification of the self-soothing sounds produced accuracies around chance.

Conclusions: These results highlight both the need for specialized, naturalistic databases and novel computational methods and their potential to enhance communicative and affective exchanges between mvASD individuals and the broader community. Future work includes 1) the development of a database of naturalistic mvASD vocalizations to engage the machine learning community, 2) data processing pipelines for signal accuracy and alignment, and 3) personalized, semi-supervised machine learning methods that leverage the sparsely labeled structure of the real-world data. Each of these steps is built on an iterative co-designing process with autistic stakeholders with the goal of increasing agency and enhancing dialogue between individuals with mvASD and the world.

449.006 *(Poster)* Communication Support Using Humanoid Robots for Children with Autism Spectrum Disorder: Establishing Development Support Robotics

*R. Tanaka[1], **K. Umetsu**[1], Y. Ishizuka[2], J. Yamamoto[3] and N. Kubota[1], (1)Tokyo Metropolitan University, Tokyo, Japan, (2)University of Tsukuba, Ibaraki, Japan, (3)Keio University, Tokyo, Japan*

Background: Recently, many attempts have been made to introduce communication robots to support the development of children with autism spectrum disorders (ASD). There are various communication robots, such as robots that assist support applications on tablets, and so on. But many of them aim to reduce human costs on supporters' side by using communication robots instead of supporting the development of children with ASD.

Objectives: Therefore, while previous research has focused on communication robots teaching children, few studies have focused on peer tutoring, in which communication robots and children teach each other. Thus, we proposed "**development support robotics**" to investigate the applicability of interactive communication robots and the development of children with ASD.

Methods: A preliminary experiment was performed using arbitrarily created scenario contents. The scenario consists of an introduction stage of greetings, a stage of questions between robots and children with ASD, a stage of the game that children control communication robots by using remote control. From this experiment, we got the hypothesis that **it is important to give children the initiative**. An experiment was conducted to verify this hypothesis. Two types of conditions are set for the scenario. The first is a robot-initiative scenario. In a **robot-initiative (condition A) scenario**, the robot utters according to a preset scenario and advances the scenario. The second is a child-initiative scenario. In a **child-initiative (Condition B) scenario**, the robot only guides the task, otherwise it responds to the children' question. Perform each of condition A and condition B twice in a series of scenarios.

Results: In the scenario of condition B, compared to condition A, we were able to observe multiple behaviors that could be regarded as voluntary actions from the children to the robot. These actions can be classified into actions and sounds. In order to convey the voice to the robot, some ideas were made to increase the voice, try different ways of speaking, and change the way the words were cut. In terms of movement, some ideas were seen such as changing the speed of movement, changing the standing position according to the field of vision of the robot, and showing an example. These behaviors were not seen during the scenario of condition A or during support without a robot.

Conclusions: From the above, it was verified that developmental support using communication robots gives children with ASD potential initiative and increases spontaneous behavior. In addition, from this experiment, it was found that the limited movement and voice capabilities of the robot are an important trigger for the child to make a deliberate action.

449.007 *(Poster)* Computational Behavioral Phenotyping of Autism Spectrum Disorder Using Scalable Computer Vision Tools

***Z. Chang**[1], J. M. Di Martino[1], K. L. Carpenter[2], J. Hashemi[1], S. Espinosa[1], G. Dawson[3] and G. Sapiro[1], (1)Department of Electrical and Computer Engineering, Duke University, Durham, NC, (2)Duke Center for Autism and Brain Development, Department of Psychiatry and Behavioral Sciences, Duke University, Durham, NC, (3)Department of Psychiatry and Behavioral Sciences, Duke Center for Autism and Brain Development, Durham, NC*

Background: Observational behavior analysis of children, which is critical for the evaluation, monitoring, and discovery of biomarkers related to Autism Spectrum Disorder (ASD), is performed in-person by trained clinicians. With the rapid development of computer vision and machine learning technology, scalable and objective methods make automatic analysis of human behavior possible.

Objectives: Develop and deploy in pediatric clinics scalable computational behavioral phenotyping tools for screening ASD using a combination of strategically-designed stimulus probes and computer vision and machine learning tools.

Methods: We developed and deployed in pediatric clinics, as part of the standard well-check-up, a scalable tool for computational behavioral phenotyping. The child's face is recorded using the front-facing camera of a mobile device while they are presented with several short movies that are designed to elicit specific social, emotional, and motor responses (Figure 1(a)). Computer vision algorithms are used to detect and track the child's face position and facial landmarks throughout the video recording (Figure 1(b)) from which behavioral features including posture, head motion and pose, orienting to name calls, attention span, and affect are automatically computed. The facial landmarks are also used to estimate the eye regions of the child, which, along with the face image, are fed into a neural network to estimate the child's gaze positions on the screen. Touch information gathered from on-device sensors are used for assessing the motor behavior of the child.

Results: At the time of submission, data have been collected from >400 18-month-old toddlers for whom medical history is known. Data collection is ongoing. The data collected from our mobile application contain features related to ASD risk behaviors. For example, we are able to estimate how long a child is attending to each stimulus and how often they disengage; whether the child responds to a name-call prompt and how quickly they turn their head; the probability a child is displaying a positive/negative/neutral facial affect and the range of facial affect; preference of gaze and fixation patterns; and postural sway. Figure 2 shows for example the percentage of time children are facing towards each stimulus during presentation. Our analyses examine age, sex, and diagnostic (ASD vs non-ASD) behavioral differences.

Conclusions: We developed and deployed in pediatric clinics a mobile application that displays visual and interactive stimuli designed to elicit behaviors relevant to ASD. Using computer vision techniques, we are able to automatically track a child's head and face and from it infer critical behavioral patterns. We observed that the children are engaged with the designed stimuli, an important step toward computational behavioral phenotyping. Applications such as the one presented here could lead to new or refined behavioral risk marker assessments, and novel scalable screening and monitoring methods inside and outside of clinical settings.

449.008 *(Poster)* Detection of Autism Related Behaviors from Video of Infants Using Machine Learning

S. Liaqat[1], *C. Wu*[2], *C. N. Chuah*[3], *S. C. S. Cheung*[1] *and S. Ozonoff*[4], *(1)University of Kentucky, Lexington, KY, (2)Computer Science, UC Davis, Davis, CA, (3)University of California, Davis, Davis, CA, (4)Psychiatry and Behavioral Sciences, University of California at Davis, MIND Institute, Sacramento, CA*

Background: Early screening of autism spectrum disorder (ASD) in young children can play a life-changing role in determining their developmental trajectory. In recent years, the ASD research community has shown a strong interest in employing computer vision and machine learning systems to reduce the time between the emergence of first symptoms and an ASD diagnosis. These methods have been employed in identifying behaviors in video such as social and verbal responses of a child to a caretaker. The efficacy of relevant behavioral features and social interactive cues from videos including facial expression, vocalization, and direction of gaze for ASD detection has been demonstrated by existing research (Li et al., 2019).

Objectives: We applied deep learning techniques to identify basic behaviors that are clinically relevant to ASD, including gaze to people and objects, positive affect, and vocalizations. We also aimed to detect higher-order behaviors, such as social smiles and directed vocalizations, which may ultimately be useful in diagnosis of ASD from video.

Methods: This work is based on application of supervised machine learning techniques to train neural networks on a dataset collected under the UC Davis Infant Sibling Project; a prospective longitudinal study of infants from birth until the age of 3 years who are at a high risk for ASD due to family history. The dataset consists of more than 550 labeled videos of around 3 min duration each with behavior labels coded by expert raters. We approach the behavior recognition problem from two different perspectives. In the first approach, we use computer vision techniques to extract facial landmarks, facial action units (FAUs), head pose and eye gaze from video frames and train neural network from these features. In the second approach, instead of relying on expert designed features, we feed the video frames directly to a deep neural network to discover distinguishing features in detecting different events. Using both approaches, we can predict frame labels for the child gazing towards another person or an object such as a toy, smiling, and vocalizing and compare them with the ground-truth.

Results: Both approaches are trained and tested on videos from completely different groups of subjects. Preliminary experiments on both approaches produce similar performance when tested on all the frames of the test videos. We achieve 82% accuracy for the three “look” events: look object, look face, and look off, 78% for simile detection, and 76% accuracy for vocalization.

Conclusions: Leveraging one of the largest hand-labeled video datasets of infants at risk for ASD, we have obtained promising results on using different Machine Learning techniques to extract ASD-related behavioral events. In this technical demonstration, we will showcase the capability of our automatic behavior detector in realtime by indicating detected behaviors (smiling, vocalizing, eye gaze) using markers overlaid on video.

449.009 *(Poster)* Developing E-Learning Modules and Resources to Support the Learning of Paraprofessionals Working with Students with ASD

A. Sam[1], *J. R. Steinbrenner*[2], *S. W. Nowell*[3], *S. Szendrey*[4] *and S. Odom*[2], *(1)Frank Porter Graham Child Development Institute, Carrboro, NC, (2)Frank Porter Graham Child Development Institute, University of North Carolina at Chapel Hill, Chapel Hill, NC, (3)University of North Carolina - Chapel Hill, Chapel Hill, NC, (4)Allied Health, University of North Carolina, Chapel Hill, NC*

Background: Paraprofessionals are often the primary providers of instruction to students with ASD in schools. Yet, the literature suggests that minimal training is provided to paraprofessionals for implementing evidence-based practices (EBPs) with students with ASD. When this training does occur, it is usually in the form of a workshop with very little follow-up from researchers (Walker & Smith, 2015).

The AFIRM for Paraprofessionals research development grant focuses on creating a professional development model for paraprofessionals working with elementary students with ASD. This model includes development of online training modules paired with coaching teacher-paraprofessional pairs. Phase 1 of the project included focus groups with key stakeholders to guide development of the training model.

Objectives:

1. Report professional development needs of paraprofessionals working in schools with students with ASD based on data collected and coded from focus groups with key stakeholders: paraprofessionals, teachers, and administrators.
2. Describe how these qualitative data were triangulated with our quantitative data from a national survey and pilot study to inform the AFIRM for Paraprofessionals Model.
3. To demonstrate the use of AFIRM for Paraprofessionals E-learning modules.

Methods: A total of six focus groups were conducted with key stakeholder groups: paraprofessionals, special education teachers, general education teachers, and administrators. The research team transcribed the focus groups and used NVivo software with a hybrid inductive and deductive methodology to code and analyze the data.

Results: Major themes that emerged from the focus group coding included: barriers and facilitators to paraprofessionals successfully working with students with ASD, complex and diverse roles of paraprofessionals, relationships and power dynamics between paras and other educators, and large variations in job preparation. Paras, supervising teachers, and school administrators reported broad expectations for paras working with students with ASD, from intervening in behavioral crises to teaching social skills and collecting data. Focus group participants also reported that despite these expectations, very little formal preparation for paras is provided. Limited time and resources were noted as major barriers to training paraprofessionals. Moreover, supervising teachers reported minimal training about how to provide effective supervision to paraprofessionals and uncomfortable power dynamics such as being a young new teacher working with seasoned paraprofessionals.

Conclusions: The AFIRM for Paraprofessionals research team used these qualitative focus group data along with quantitative results to develop the initial protocol for the paraprofessional professional development model. This model includes: (1) an introduction to autism online module, (2) in person workshops on teaming for paraprofessionals and supervising teachers, (3) E-learning modules that introduce five foundational EBPs, (4) performance feedback meetings between paraprofessionals and supervising teachers.

449.010 *(Poster)* Development of a Mobile Application That Tracks Challenging Behaviors of Children with Autism Spectrum Disorders for Supporting Data-Driven Interventions

*H. Hong[1], **E. Jo**[2], Y. Kim[3] and Y. Hong[4], (1)Department of Communication, Seoul Natioanal University, Seoul, Korea, Republic of (South), (2)Institute of Communication Research, Seoul National University, Seoul, Korea, Republic of (South), (3)Child and Adolescent Psychiatry, National Center for Mental Health, Seoul, Korea, Republic of (South), (4)National Center for Mental Health, Seoul, Korea, Republic of (South)*

Background: The challenging behaviors of children with autism spectrum disorders (ASD) are complex and vary depending on the child. Tracking children's challenging behaviors on a daily basis by their caregivers is an essential step to designing an adaptive, personalized intervention with clinical experts. Specific information to be collected includes what happened to the child directly before the behavior occurred (Antecedent), what the behavior was (Behavior), and what happened directly after the child engaged in the behavior (Consequence). This information, when consistently logged by caregivers, could help both caregivers and clinical experts understand the context of the challenging behaviors and form a strategy to mitigate the observed behaviors.

Objectives: Our goal was to promote caregivers' understanding of their children's challenging behaviors and facilitate data-driven conversations with clinical experts using a mobile application. We aimed to develop a mobile application that allows the caregivers of children with ASD to record their children's challenging behaviors based on the ABC framework.

Methods: Through a preliminary study involving 4 clinical experts and 2 caregivers of children with ASD, we developed an Android-based mobile application, GeniAuti, that allows caregivers to record various contexts of challenging behaviors and communicate with experts through the collected data. Then, we conducted a two-week deployment study with 15 primary caregivers of children with ASD in Korea to examine the feasibility of GeniAuti for recording challenging behaviors in their daily lives. We also observed 8 sessions of clinical visits to identify how data collected through the application could facilitate conversations with clinicians.

Results: We developed GeniAuti that contains the following features: 1) tracking of children's behaviors using a speech-to-text feature in a timely fashion; 2) visualization of both recent and long-term patterns of the behaviors; 3) references of other children's behaviors and treatments. The findings of the two-week deployment study indicate that GeniAuti allowed the caregivers to understand the subtle triggers of their children's challenging behaviors; reflect on the way how they deal with their children's challenging behaviors; communicate with secondary caregivers such as grandparents, babysitters; and collect rich dataset that provides references when they seek for a clinical advice. Despite the positive impacts, our findings revealed some challenges that the caregivers face. They felt difficulty in distinguishing what are challenging behaviors and what are not; defining units of challenging behaviors to be recorded; determining the exact causes of the challenging behaviors among various triggers.

Conclusions: Caregivers play a crucial role in developing a data-driven intervention for addressing their autistic children's challenging behaviors, but they often face difficulties in consistently logging them in a structured manner. We developed a mobile application to assist caregivers of children with ASD in recording challenging behaviors using the ABC framework. Caregivers reported that the use of GeniAuti helped them recognize potential triggers of challenging behavior and discuss further treatment strategies with clinicians. To identify the impacts of using GeniAuti in a clinical setting, we hope to engage in a further long-term, large-scale randomized controlled test, specifically when provided with an education material for the caregivers.

449.011 *(Poster)* Development of a Robot-Mediated Interaction Targeting Emotion Processing and Regulation in Children with Autism Spectrum Condition Using Emotion-Sensitive Technology

***S. Kirst**[1], S. Naumann[1], M. Strehler[2], N. Lang[3], J. Seßner[4] and I. Dziobek[1], (1)Berlin School of Mind and Brain, Humboldt-Universitaet zu Berlin, Berlin, Germany, (2)Innovationsmanufaktur GmbH, Munich, Germany, (3)Division of Smart Sensing and Electronics, Fraunhofer Institute for Integrated Circuits IIS, Erlangen, Germany, (4)Lehrstuhl für Fertigungsautomatisierung und Produktionssystematik, Friedrich-Alexander-Universitaet Erlangen-Nuernberg, Erlangen, Germany*

Background: The potential of robot-mediated interventions as a therapeutic tool for children with ASC has been discussed intensively in the last years. Children with ASC engage more easily with robots as the interaction is less complex and more predictable than with humans. Within our project, we are developing a robot-mediated intervention targeting emotion recognition and expression as well as emotion regulation using emotion-sensitive technology that will allow real-time adaptation of the robotic interaction based on the children’s emotions. The robot acts as a tutor to support and guide the child through the therapy sessions.

Objectives: To assess appropriateness of basic robot-child-interaction strategies as indicated by acceptance and usability measures.

Methods: We ran a two-step procedure: First, practitioners (N=5) and parents of children with ASC (N=4) underwent an interview assessing views on the general appropriateness and feasibility of robot-child interactions in autism and on specific scenarios for a robot-mediated emotion-focused therapy developed by the group. Based on the results, the robot-child interaction strategies were realized using the humanoid robot ‘Pepper’ (SoftBank) and were in a second step tested with six to twelve year-old neurotypical (NT; N=6) and autistic children (N=5). Acceptance and usability were assessed by several child and parental measures including the Godspeed Questionnaire (assess children’s impressions of robot interaction) and the Inclusion of Other in The Self (IOS) scale (perceived closeness to the robot) as well as analysis of video recordings of the child-robot-interaction for positive and negative affect shown by the children.

Results: Quantitative and qualitative analysis of the interview study yielded that both practitioners and parents judged the usefulness and feasibility of an emotion-sensitive robotic platform for the teaching of emotion skills as most useful, especially for the areas of emotion awareness and regulation. Children and parent data from study 2 showed that the robot was perceived as likeable (Scales ranging from 0 - 100: NT: M = 79.33; SD = 10.37; ASC: M = 84.35; SD = 11.27) and intelligent (NT: M = 71.50; SD = 16.86; ASC: M = 65.4; SD = 19.69). Interestingly, children with ASC were less interested to be friends with the robot (Scale ranging from 1-5: M = 2.60; SD = 1.81) than NT children (M = 4.60; SD = 0.81). All children felt close to the robot (Scale ranging from 1-3: M = 2.45; SD = 0.52). Results of the video-analysis of implicit indicators of acceptance is ongoing and will be shown at the conference.

Conclusions: We found first evidence for the feasibility and a high acceptance of the robot-child interaction. Perceived robot characteristics (e.g. likeability, intelligence) will be assessed in future studies as predictors for positive treatment outcome.

449.012 *(Poster)* Digital Assessment of Social Communication Skill, Arousal and Gross Motor Functioning in Infants, Toddlers, Children and Adults

R. T. Schultz[1], *K. Bartley*[2], *C. J. Zampella*[1], *E. Sariyanidi*[2], *W. Guthrie*[1], *J. Pandey*[1], *J. D. Herrington*[3], *B. Tunc*[1] *and J. Parish-Morris*[1], *(1)Center for Autism Research, Children's Hospital of Philadelphia, Philadelphia, PA, (2)Center for Autism Research, The Children's Hospital of Philadelphia, Philadelphia, PA, (3)Perelman School of Medicine, University of Pennsylvania, Philadelphia, PA*

Background: Current approaches to assessing the behaviors that define autism fail to precisely quantify the condition as it unfolds in real life, and instead rely on summary ratings by parents and/or clinicians. The shortcomings of current approaches in reliability, granularity, and scalability present significant obstacles to a comprehensive understanding of ASD. ASD is defined by observables – what a person says or does well or not well, too little or too much, usually while interacting with other people. This makes it ripe for a biometric sensor approach that objectively captures (digitizes) all observable behaviors, including motor behaviors, speech sounds, and language (as well as unseen signals like heart rate and skin conductance). Coupling machine learning with advanced sensor technologies like computer vision and natural language analytics provides an extremely potent approach to behavioral measurement in the lab and in natural environments.

Objectives: To demonstrate our hardware platform and computational methods for capturing all outward manifestations of ASD and related disorders.

Methods: We have developed computer vision and machine learning methods to measure social motor coordination (*aka* social synchrony) during a dyadic interaction, as well as computational linguistics methods to assess speech content (e.g., word frequency metrics), speech quality (e.g., acoustic features), and conversational behavior (e.g., turn-taking rates, response latency). Our biometric sensor device also collects synchronized measurements of heart rate and heart rate variability, which relate to arousal and anxiety. We also use 3D depth cameras to measure gross motor behaviors that are often different or impaired in ASD, including gait and imitation. Because audio, visual, and wearable data streams are synchronized during data collection, within and between interacting participants, our approach facilitates rich evaluations that are pertinent to a range neurodevelopmental disorders and mental health conditions.

Results: We will present pilot results showing differences in ASD compared to matched typically developing controls (TDC) for social motor coordination, motor imitation, and linguistic behavior in school-aged children and adults. We will show preliminary test-retest reliability data from these samples. We will also share cases and small group data on infants at risk for ASD; and preliminary data from school-aged children with other mental health conditions. Finally, we will demonstrate heart rate data collection, and share preliminary results.

Conclusions: Computational approaches to behavioral phenotyping can lead to a paradigm shift in psychiatric research, greatly advancing early detection, efforts to map biological risk factors to behaviors, and the scalability, granularity and utility of outcome measures for treatment research and clinical care management.

449.013 *(Poster)* Film Detective: A New Theory of Mind Intervention for Adolescents with ASD

R. N. Rashedi[1], *M. Elrod-Erickson*[1], *B. Hollis*[1], *C. Ketchum*[1], *Z. Chen*[1], *X. Zi*[1], *C. Kim*[1], *S. Li*[1], *M. Rushdy*[1], *A. Kinsman*[2], *A. R. Swanson*[2], *P. Juárez*[2], *Z. Warren*[2], *G. Biswas*[1] *and M. Kunda*[1], *(1)Electrical Engineering and Computer Science, Vanderbilt University, Nashville, TN, (2)Vanderbilt University Medical Center, Nashville, TN*

Background: Theory of mind (ToM) is the ability to represent and reason about others' intentions, actions, and dispositions, in order to regulate one's behaviors, and it is a key element of human relationships and everyday functioning. There is an urgent need for research on how best to facilitate the development and improvement of ToM skills in adolescents with ASD. We have designed a new, ToM-centered technology-based educational intervention that aims to help adolescents with ASD improve their ToM and social reasoning skills by answering questions about social content in television and movie clips, through a series of activities that are embedded in a game-like application.

Objectives: This study draws from principles in design-based research and strengths-based approaches to learning to develop an interactive technology in which adolescents with ASD teach a virtual agent about ToM in social scenarios via films.

Methods: An iterative, ongoing design and implementation of the movie-based application was conducted over the course of several months, including user studies of preliminary versions of the application with adolescents with ASD, as well as focus groups with teachers to identify issues related to the feasibility of deploying the intervention in junior high classroom settings.

Results: A demonstration of the movie-based application will be presented, along with preliminary findings from student user studies and teacher focus groups, that show what students enjoyed, their suggestions for improvement, and what aspects of the technology teachers found useful and feasible for integration into their classroom practices, especially as related to promoting inclusion for students with ASD. We also discuss lessons learned during the technology design and development process, including: 1) balancing engagement with learning goals, using lessons from game design and research on "gamification" in education; 2) balancing difficulty levels and goal-setting within the game to promote student persistence while hopefully avoiding student frustration; 3) designing storylines to promote feelings of inclusion, to reduce the risk that target users (students with ASD) feel alienated or singled out by their usage of the technology; 4) designing with cultural, ethnic, gender, and other aspects of diversity in mind; and 5) using crowdsourcing to help generate game and curriculum content.

Conclusions: As technology-based platforms receive increasing attention in the research and design of educational interventions, both for students with ASD and in education more broadly, the successful development of new platforms can benefit greatly from a multi-faceted approach, with input from intended end users (which includes both students and teachers) as well as insights from the world of game design and gamification. Our case study of developing a new technology for teaching ToM and social reasoning skills to adolescents with ASD illustrates the iterative nature of such a design process, and the value in incorporating multidisciplinary expertise and perspectives throughout the timeline of such a development cycle.

449.014 *(Poster)* Generative Language Training on a Mobile Platform to Enhance Language Learning and Generalization in Minimally-Verbal Autism

***O. Wendt**, Communication Sciences and Disorders, University of Central Florida, Orlando, FL*

Background: Minimally-verbal individuals with autism learn to communicate through alternative means including mobile technology applications. Utterances on these devices are often very limited; learners do not surpass single-word responses for requesting and labeling, and vocabulary repertoires are small. Matrix training is a language intervention to systematically build up vocabulary and teach longer word combinations to produce more complex utterances. In this generative approach to instruction, words are arranged in a matrix format so that some multiword phrases are taught and others develop without direct instruction. Specifically, linguistic elements (e.g., nouns, verbs) are presented in systematic combination matrices, which are arranged to induce generalized rule-like behavior, a particular difficulty in autism.

Objectives: A mobile application, SPEAKmore!, was developed to carry out matrix training on a mobile platform. This study aimed to answer

1. Does language training with SPEAKmore! facilitate production of action-object combinations on a tablet device? This was accomplished by measuring the percentage of correct target forms in intervention probes.
2. Do newly learned skills generalize to untrained action-object combinations. This was achieved by taking generalization probes during the intervention phase assessing performance on combinations that were never taught before.

Methods: An experimental single subject design, that is a multiple probe design (Horner & Baer, 1978), was used across sets of action-object combinations with generalization probes of untrained combinations. This design was implemented with five participants, between 8-12 years old, with an official diagnosis of severe autism according to CARS-2 and ADOS-2 scores, who qualified as minimally verbal by having no more than 10 spoken words, and communicated primarily on a tablet. These students were taught action-object combinations on a 6x6 matrix with SPEAKmore!. From the total pool of 36 possible symbol combinations, the researcher created four different sets of three symbol combinations each that were actively taught. The remaining 24 combinations were tested for generalization effects, quantified by an effect size estimate for single-case data, the Non-overlap of All Pairs index (NAP).

Results: Four participants showed the following profile (see Figure 1): Acquisition of the initial training occurred over time and subsequent sets were mastered more quickly. All four participants reached generalization mastery levels of 80% or higher. This performance level is maintained after intervention ends; effect sizes show a strong effect (average NAP=93%). One participant showed lower performance than all others, and transitioned to a 4x4 matrix. This participant took a long time to master intervention sets and his performance was fluctuating. Effect sizes indicated a weak to medium effect (average NAP=64%).

Conclusions: Results suggest that matrix training through a mobile application may be a promising approach to teach new vocabulary and enhance the complexity of utterances for tablet communicators with severe autism. To further investigate the robustness of this technology intervention, findings need to be replicated using (a) different language targets (e.g., agent-action, adjective-object combinations), (b) expansions from two-term to three-term semantic relations (e.g., agent-action-object), and (c) simpler matrices to teach the low performing learners, focused on functional and basic concepts such as objects and their modifiers.

449.015 *(Poster)* Hololens As a Social Prosthesis: Preliminary Tests

***Y. Luo**[1], B. Li[2], M. M. Mahony[3], M. Tarasyuk[1], M. C. Aubertine[4], K. J. Dommer[5], M. Kim[5], S. Corrigan[5], A. Atyabi[6] and F. Shic[7], (1)Child Health, Behavior & Devel, Seattle Children's Research Institute, Seattle, WA, (2)Computer Science and Engineering, University of Washington, Seattle, WA, (3)Bernier Lab, Psychiatry and Behavioral Sciences, University of Washington, Seattle, WA, (4)Seattle Children's Hospital and Research Institute, Seattle, WA, (5)Seattle Children's Research Institute, Seattle, WA, (6)Seattle Children's Research institute University of Washington, Seattle, WA, (7)Center for Child Health, Behavior and Development, Seattle Children's Research Institute, Seattle, WA*

Background: Augmented reality (AR), where virtual objects can be mixed seamlessly into real-world activities, is developing at a breakneck pace. Technological advances now make it possible to offer real-time cognitive and decision-making supports, not only for typical individuals but also for individuals with specific needs. One area that has emerged as an extraordinary area of opportunity involves that of social prostheses which support detection of and response to social interactions. Such systems have tremendous potential for supporting lives of individuals with autism spectrum disorder (ASD).

Objectives: This was a proof-of-concept study aiming to examine the feasibility of using Hololens goggles as a social prosthesis for augmenting attention to people's faces during conversations in children with ASD.

Methods: Participants included 7 children with ASD (Mean Age: 14.7 years, SD=4.4; 86% male) and 8 typically developing children (TD; Mean Age: 12.1 years, SD=2.5; 63% male). Participants were asked to wear Hololens goggles and listen to short stories told by research staff members. These goggles did not independently obstruct any aspect of the visual field unless programmed to do so. We developed code that inserted images onto the visual display when looking at human faces. When looking at a researcher in the room, participants would see augmentation of the real space. There were three conditions of this augmentation: Control (no augmentation to real space), Covered (an animated image would cover the face), and Cued (a red box would surround the face). During the session, participants were also periodically asked questions before, during, and after story telling to orient their visual gaze to the researchers. Analyses calculated total valid time spent looking at faces in each condition to determine which condition elicited the most social attention.

Results: Wilcoxon signed-rank tests indicated that children with ASD looked more at faces during the Cued mode (p=.043) but not the Covered mode (p=.144) than during the Control condition. No differences between either Cued or Covered mode and the Control condition were observed in TD children (Cued: p=.499; Covered: p=.116).

Conclusions: These preliminary results suggest that AR cues highlighting faces may be useful, specifically in children with ASD, for promoting increased looking towards faces. This work provides a proof-of-concept for the use of AR to serve as a social prosthesis for dyadic interactions. One limitation of this work is that, because our technology measures position in space and not exact eye tracking movements, our results are predicated on general head orientation toward a face, not precise visual scanning patterns. Another limitation is that several participants in the study were below the recommended age to use the technology, a recommendation based primarily on form-factor considerations. An interpupillary distance between 51 and 74 is needed to correctly view Hololens holograms, therefore, those under the recommended age may not have seen the holograms as intended. Finally, it is important to note that drawing attention to a face is a necessary but insufficient precondition for facial information processing. Future work will consider these issues from psychological, clinical, engineering, and human-centered design perspectives.

449.016 *(Poster)* Innervoice: Emotional Communication Combined with Artificial Intelligence

***L. J. Brady**, iTherapy, LLC, Martinez, CA*

Background: Autism Spectrum Disorder (ASD) is one of the leading causes of communication disorders. Acquiring functional language abilities can be difficult depending on the severity of the disorder. Some individuals are verbal and have stronger functional language abilities whereas others are minimally verbal or nonverbal, experiencing difficulties with speech production. Those who are minimally to non-verbal face great challenges when participating in daily communication. Effective communication relies not only on words but on tone of voice and facial expressions. The ability to express emotion through one's tone of voice, or prosody, clarifies the communicative intent behind a spoken message. While there are augmentative and assistive communication (AAC) systems that allow a person to communicate using digitally synthesized speech, these voices are monotone and can be readily identified as computer generated. To be more effective, AAC products must convey emotions through prosody and have the ability to video-model a user's facial expressions to convey happiness, sadness, or anger.

Objectives: This research sought to identify and implement a set of a unique para-linguistic features that most realistically conveyed the emotions of happy, sad and angry. which can be critical for ASD individuals. A working prototype that synthesized emotional communication through speech and facial animation software designed for Apple iOS.

Methods: We administered a prototype with a diverse population of 14 adult male and female subjects aged 18-75 and recorded their ability to correctly label the emotions presented in each of the three VO, FO, and C groups. Subjects were given a combined total of 64 presentations for each stimulus. We conducted a one-way analysis of variance (ANOVA) to compare the three groups' mean identification scores (the mean number of correctly labeled emotions in each medium) with a P-value set at 0.05. The ANOVA allowed us to examine variations within each medium (such as subjects' variations between trials) along with variations among the three mediums, or whether the number of correctly identified emotions is the same for all three approaches.

Results: Analysis of the data produced an F-statistic of 10.0735, with two degrees of freedom,arriving at a P-value of 0.0001, which was statistically significant to reject our null hypothesis. In conclusion, given three different mediums — voice only (VO), facial expression only (FO), and combined voice and facial expression (C) — subjects most accurately categorized emotions that were conveyed through the combination of animated facial expressions with synthesized emotional speech (C). Along with the ANOVA, the responses in each medium were broken down into three categories: Total Recognized, Percent Recognized, and Label Substitutions.

Conclusions: We arrived at a statistically significant conclusion: individuals tended to improve their ability to identify synthesized human emotions when shown a combination of facial expressions and speech. This conclusion has a potentially high value proposition for current and future customer segments.

449.017 *(Poster)* Janssen Autism Knowledge Engine (JAKE): Demonstration

***G. J. Pandina**[1], A. Bangerter[2], M. Boice[1], S. Ness[3] and N. V. Manyakov[4], (1)Janssen Research & Development, Titusville, NJ, (2)Janssen Research & Development, LLC, Pennington, NJ, (3)Janssen Research & Development, LLC, Titusville, NJ, (4)Computational Biology, Janssen Research & Development, LLC, Beerse, Belgium*

Background: There are a lack of physiological and psychological measures that are designed to detect change over time in core and associated symptoms of autism spectrum disorder (ASD). Such tools are needed to address significant unmet medical needs for improved diagnosis and expanded treatment options in ASD, and to develop novel therapies that target core and associated symptoms. The Janssen Autism Knowledge Engine (JAKE®) is a clinical research outcomes assessment system developed to more sensitively measure treatment outcomes and identify subpopulations in ASD.

Objectives: 1) To describe JAKE and present results from studies using digital phenotyping (My JAKE) and biosensor (JAKE Sense) components and; 2) To demonstrate examples of this
technology to audience members at INSAR.

Methods: An observational, non-interventional, prospective study of JAKE in children and adults with ASD was conducted at nine sites in the United States. Feedback on JAKE usability was obtained from caregivers. JAKE Sense included experimental, proof-of-concept measures of electroencephalography, eye tracking, electrocardiography, electrodermal activity, facial affect analysis, and actigraphy. Caregivers of individuals with ASD reported behaviors using My JAKE. Results from My JAKE and JAKE Sense were compared to traditional ASD symptom measures.

Results: Individuals with ASD (N = 144) and a cohort of typically developing (TD) individuals (N = 41) used JAKE Sense. Biosensors included in JAKE Sense produced a high percentage of data of good quality (i.e., 93–100% of eye tracker, facial affect analysis, and electrocardiogram data was of good quality), demonstrated differences between TD and ASD individuals, with some relationship to ASD symptom scales observed. JAKE Sense biosensors were well-tolerated.

Caregivers reported on ASD behaviors using My JAKE. Caregiver's feedback on overall use and utility of My JAKE was "easy" or "very easy" (74%, 80/108). My JAKE detected differences in ASD symptoms as measured by traditional methods.

Conclusions: My JAKE was viewed as easy or very easy to use by caregivers and sensitively measured a broad range of core and associated symptoms. JAKE Sense functioned well when used at clinical sites previously inexperienced with some of the technologies. Lessons from the study will help optimize JAKE for use in clinical trials to assess ASD interventions. Additionally, because biosensors were able to detect features differentiating TD and ASD individuals, similar measures could be explored as potential biomarkers for ASD and as endpoints in future clinical studies.

449.018 *(Poster)* Life Sherpa Platform - Enabling Intellectual and Developmental Disability Employment

*C. Breed and **D. Meeker**, 3R Behavioral Solutions, Alexandria, VA*

Background: Individuals with IDD have traditionally required ongoing, one-to-one supports to learn and maintain mastery of independent tasks in the work setting. While one-to-one staffing support has historically been a costly proposition, technology offers the promise of a more scalable and cost-effective solution for helping clients with IDD navigate the workplace.

Objectives: As part of a trial implementation of the Life Sherpa app, Mason LIFE Program conducted a pre/post survey with a control group, as well as a social validity study.

The purpose of the study was to determine:

1. The functional relationship between use of the Life Sherpa app and increased productivity of targeted work-related skills
2. The feedback of the student participants
3. The feedback of the support staff participants

The expected outcomes of the study were to increase support staff training and efficiency, decrease staff-to-student ratios, and to provide an effective teaching and skill maintenance modality for students.

Methods: Using a pre/post design with a control group, the students in both the intervention and control groups were assessed using the WAI, Brigance, and Vineland at the beginning and end of the study. During intervention, the students and their support staff used the Life Sherpa app to support students in the intervention group, and data was collected.

After the research period was completed, both students and support staff in the intervention group were interviewed. Students were interviewed on their thoughts on completing tasks, asking for help at work, and interacting with coworkers. Support staff were interviewed on their thoughts about teaching skills to the students, how they support the students, and fading away.

Results: WAI: Intervention and control groups saw very similar overall total gains (Intervention 9.8 and Control 10). Small differences included intervention group having greater gains in empathy, sociability, assertiveness, and adaptability, and for control group having greater gains in emotionality.

Brigance: Intervention group made more progress overall than the control group (Intervention 41.5 and control 14). When looking at the subdomains, the intervention group had more gains in responsibility and self-discipline and self-concept (job-related). The control group had more gains in listening, self-concept (general), trainees' work experience.

Vineland: Overall, the intervention group demonstrated greater growth than the control group. When looking at subdomains the intervention group showed more growth in receptive language, interpersonal relationships and coping. Both groups had the same growth in expressive language.

Interviews and Data:

Overall, students experienced the most success between baseline and intervention in the areas of overall work quality, improving eye contact, trying to problem solve on their own before asking for help, and asking for more work when finished with a task.

Conclusions: Although the small sample size did not allow for any statistically significant analysis, overall the Life Sherpa app showed an increase in productivity, as well as soft skills (measured by the assessments) in the intervention group when compared to the control group. Both students and support staff liked using the app, and expressed a desire to continue using it.

449.019 *(Poster)* Machine-Learning Based Autism Diagnosis Using Gaze Fixations on Natural Images

***C. Wu**[1], S. Liaqat[2], H. Duan[3], S. Ozonoff[4], C. N. Chuah[5], G. Zhai[3] and S. C. S. Cheung[2], (1)Computer Science, UC Davis, Davis, CA, (2)University of Kentucky, Lexington, KY, (3)Shanghai Jiao Tong University, Shanghai, China, (4)Psychiatry and Behavioral Sciences, University of California at Davis, MIND Institute, Sacramento, CA, (5)University of California, Davis, Davis, CA*

Background: Autism Spectrum Disorder (ASD) is often associated with atypical visual attention such as delayed disengaging attention and fixation towards less socially salient stimuli. For example, the fixation maps between an ASD subject and a Typically Developed (TD) subject on the same image are quite different. These studies suggest the possibility of using gaze fixation patterns on common test objects as a screening tool. A promising direction to automate the screening process is to apply Machine Learning (ML) techniques, which have recently emerged as a viable tool in extracting salient features from complex behavior data such as gaze patterns for ASD diagnosis.

Objectives: Our objective is to study different ML techniques on saccade and fixation patterns for ASD diagnosis. By considering the screening process as a supervised learning problem, we can take advantage of the state-of-the-art computer vision and ML techniques to discover salient features from visual gaze data that can be used to classify ASD from TD.

Methods: Our study is based on gaze data collected from viewing two different image datasets. The first one consists of 400 random natural images, while the second one has 300 images depicting gaze-following behaviors of humans on various objects as shown in Fig.2. Gaze data is collected using Tobii T120 eye gaze tracker from 14 ASD and 14 TD children (average 8 yrs old), viewing each image for 3 seconds and 65cm away from a 17-inch monitor.

Both recurrent and non-recurrent deep learning techniques are studied to learn the distinctive features from gaze data for ASD prediction. The first non-recurrent method synthesizes a TD saccade pattern based on the input image using the STAR-FC generative model from (*Wloka, et al. 2018*) and predicts TD/ASD based on the learned similarity between the input and synthetic scanpaths.

The second non-recurrent approach converts a sequence of fixation maps to image format. A convolutional neural network is then trained on both scanpath images and the original image which are fed into two separate processing branches before they are concatenated for final classification. Lastly we also study a novel recurrent neural network based on Long Short-Term Memory (LSTM) architecture to extract distinguishing features by predicting the difference of fixation maps for these two groups.

Results: Our two non-recurrent method can achieve 65.41% and 61.62% accuracy, respectively, on the validation set of the first dataset, 54.15% and 55.13% on testing dataset. The recurrent method, on the second dataset, can achieve 80% accuracy on testing set.

Conclusions: With machine learning techniques, we can achieve a good performance on ASD prediction. The results show that there is a strong relationship between gaze pattern and ASD. The ML performances on images focused on socially salient stimuli (dataset 2) seem to be better than generic images (dataset 1). We hope our interactive demonstration will provide participants an immersive interactive experience on the potential usage of gaze pattern as an automated ASD screening tool.

449.020 *(Poster)* Magical Musical Mat: Augmenting Communication with Touch and Music

R. Chen[1]*, A. Ninh*[2] *and B. Yu*[3]*, (1)Graduate School of Education, UC Berkeley, Berkeley, CA, (2)University of California, Berkeley, Berkeley, CA, (3)San Francisco State University, Berkeley, CA*

Background: Augmentative and alternative communication (AAC) refers to communication modalities that are used as an alternative to or as augmentation of an individual’s speech (Iacono, et al., 2016). The current evidence shows AAC to be a positive contribution to the communication of learners on the autism spectrum, especially those who are minimally verbal. However, more research is necessary to better understand what forms of AAC best meet the needs of autistic communicators and how to prioritize social communication through AAC (Mirenda & Iacono, 2009).

AAC interventions have mainly focused on referential language form geared towards speech generation, thus neglecting aspects of communication that are foundational to effective communication, such as joint attention, and the mutual creation of shared meaning (Yu & Chen, in press). In addition, these interventions ignore nonverbal aspects of communication that are important for joint action. For autistic individuals with significant social communication needs, this has resulted in the development of communication skills that serve a limited set of functions.

The focus on language forms has constrained AAC user interface design to an array of symbols and grids. The complexity of such an interface prefaces social communication on good sequencing skills, excellent memory, and motoric dexterity, imposing high cognitive and motor demand on the user when navigating these systems (Light & McNaughton, 2019). Communication is thus dependent upon the user’s ability to gain mastery of the lengthy process of selecting symbols accurately, resulting in a steep learning curve.

Objectives: The Magical Musical Mat (MMM) goes beyond the symbol-and-grid display by returning to the foundations of meaning-making: dyadic joint attention. Using touch and music as prosocial resources, the MMM provides a means to recruit and sustain interest in interaction. It also lowers the threshold for expressive activity by augmenting multimodal communication.

Methods: The MMM is built upon the embodied design framework, an approach to design that takes embodiment to be central to interaction. By designing for action and perception, this framework takes into account the creation, manipulation, and sharing of meaning through engaged interaction with artifacts (Abrahamson, 2014). The MMM also draws upon the theoretical and methodological frameworks of haptic sociality (Goodwin, 2016) and gesture (Goldin-Meadow, 2011), where touch is a foundational way for people to connect with one another, and gestures have demonstrated both social and cognitive merit. Lastly, the MMM is based on Universal Design for Learning, which accommodates to individual learning differences through the development of flexible learning environments and spaces (Rose, 2000).

Results: *Magical Musical Mat* (MMM) is an interactive musical mat that amplifies physical touch between people through sound for communicative purposes. When participants step onto the mat and explore different types of touch interactions together, capacitive sensors in the mat detect their haptic, touch-based interactions, triggering musical sounds. Different types of touch, such as holding hands, high-fives, or gentle taps, dynamically and spontaneously change auditory qualities, resulting in a rich diversity of sound-touch expression. This project is developed in conjunction with an autism clinic and families with nonverbal autistic children.

Conclusions: N/A

449.021 *(Poster)* Managing and Visualizing Freesurfer Neuroimaging Data in R – the Freesurferformats and Fsbrain Packages

T. Schäfer[1] *and C. Ecker*[1,2]*, (1)Department of Child and Adolescent Psychiatry, Psychosomatics and Psychotherapy, Goethe-University Frankfurt am Main, Frankfurt, Germany, (2)Department of Forensic and Neurodevelopmental Sciences, and the Sackler Institute for Translational Neurodevelopment, Institute of Psychiatry, Psychology and Neuroscience, King’s College London, London, United Kingdom*

Background: FreeSurfer (http://freesurfer.net, Fischl et al. 2012) is a neuroimaging software suite developed at the Martinos Center for Biomedical Imaging. It enables both volume and surface-based analysis of magnetic resonance imaging files and uses different file formats arranged in a standard directory structure to store intermediate data and results for the subjects of a study. GNU R (https://r-project.org) is a statistical computation language that is freely available and offers a wide array of modern statistical methods through a package system. However, there currently exist no packages for GNU R that provide a user-friendly interface to access, write and visualize FreeSurfer data.

Objectives: We therefore aimed to implement packages for GNU R which enable easy access to FreeSurfer structural neuroimaging data at different abstraction levels: (1) reading and writing single files in the different binary formats, and (2) a high-level layer that uses knowledge about the directory structure of FreeSurfer data to enable high-level access and visualization of data for groups of subjects.

Methods: We implemented the *freesurferformats* package and the *fsbrain* packages in GNU R. The software is open source and available under the MIT license. Both packages are available on CRAN (https://cran.r-project.org/package=freesurferformats and https://cran.r-project.org/package=fsbrain), and the full source code can be found on GitHub (https://github.com/dfsp-spirit/freesurferformats and https://github.com/dfsp-spirit/fsbrain).

Results: The *freesurferformats* package implements file readers and write support for the following binary FreeSurfer file formats: (1) MGH and MGZ format, including header data. These formats store morphometry data or 3D brain volumes. (2) *Curv* format files that store morphometry measurements for brain surfaces. (3) Brain surfaces files which store triangular brain meshes. (4) Annotation files storing brain surface parcellations based on a cortical atlas, like the Desikan atlas (Desikan et al., 2006).

The *fsbrain* package implements a high-level interface to access study-level neuroimaging data stored under a common *subject's directory* for a group of participants. This includes easy access to, and interactive visualization of, full or aggregated morphometry data (e.g., mean cortical thickness per subject, per hemisphere, or per atlas region). This functionality is available for both native space and standard space data. See Figure 1 for example visualization output for raw morphometry data (A), p-values (B), and a brain atlas (C).

Both packages are thoroughly tested and well documented, including examples, vignettes, and unit tests.

Conclusions: The *freesurferdata* and *fsbrain* packages provide access to FreeSurfer data in GNU R on different abstraction levels. We hope that their availability will enable researchers to leverage the wide array of statistical methods available in R for neuroimaging research and promote open science by reducing the effort required to verify or reproduce published results.

449.022 *(Poster)* Pip's World: An Adaptive Tablet Battery to Assess Preschoolers with Autism Spectrum Disorder across Five Behavioural Domains

A. N. de Rothschild[1]*, P. F. da Costa*[2]*, O. Smart*[3]*, A. Goodwin*[1]*, M. Leverington*[1]*, T. A. Chang*[1]*, J. Koziel*[1]*, A. Pilkington*[1]*, E. J. Jones*[4]*, R. Leech*[2] *and E. Loth*[1]*, (1)Department of Forensic and Neurodevelopmental Sciences, Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, United Kingdom, (2)Centre for Neuroimaging Sciences, King's College London, London, United Kingdom, (3)Folded Feather, London, United Kingdom, (4)Centre for Brain and Cognitive Development, Birkbeck, University of London, London, United Kingdom*

Background: Previous research has linked core and associated features of Autism Spectrum Disorder (ASD) with developmental atypicalities in social, emotional, reward-related and cognitive processes. However, the considerable clinical and etiological diversity of ASD indicates individual differences in these developmental atypicalities. By assessing individual bio-behavioural profiles across domains, we may improve predictions of a child's developmental prognosis or therapeutic needs. Currently, a standardised test battery measuring these domains in preschoolers with neurodevelopmental conditions is missing. Existing batteries only tap some domains, and/or include little to no adaptation of task parameters, leading to difficulty in capturing the breadth of preschoolers' heterogeneity and developmental change. Moreover, cognitive-behavioural testing in preschoolers with neurodevelopmental conditions is challenging, as children's limited attention and motivation can impact task performance separately from the primary process of interest.

Objectives: To create and validate a tablet battery that

(a) assesses social, emotional, executive function, reward and un/predictability processing

(b) is engaging by embedding tasks in child-friendly games

(c) varies task difficulty to be suitable for children with or without neurodevelopmental disorders across the preschool age range (3-6 years)

Methods: Using animated cartoons and puppet videos, we created an overall narrative - "Pip's world" - containing thirteen tasks. Tasks assess gaze following, understanding desire, false belief, attentional biases to positive/negative expressions, emotion recognition, Go-NoGo, sustained attention, social/non-social reinforcement learning, un/predictability processing, and motion coherence (Fig 1a). To standardise assessments, task instructions and demonstrations are narrated by one of the characters. To combat floor and ceiling effects, features such as in-task parameters can be individually adjusted through Bayesian Adaptive Optimisation (BAO), which constructs a posterior distribution of functions using gaussian processes, minimising the number of iterations required to find optimal parameters. For example, Go-NoGo piloting indicated that not all children responded reliably to go-trials at a standardised trial speed, so a pretest adjusts stimulus speed individually to induce a maximally prepotent response to accurately test inhibition (Fig 1d). Children's attention throughout the task is monitored, with in-built social and non-social prompts given to re-engage children. These measures are recorded as secondary variables to obtain a comprehensive picture of children's cognitive/motivational profile within and across tasks. Across tasks, different versions were tested iteratively in samples of 25-40 children.

Results: Finalised tasks, including the novel social/non-social reinforcement learning task (Fig 1b), had a 89.5% completion rate (85-92%), showing that children were clearly engaged.

BAO proof-of-concept for the Go-NoGo task in adults showed large individual variability in optimised speed (33.5 to 55) which can be estimated online. Each individual's optimal speed elicited response patterns that better tested inhibitory control (average 69.7% hit rate and 38.9% commission rate) versus a slower speed that proved too easy (95.8% and 8.3%) and faster speed with responses nearer chance (45.8% and 55.6%).

Conclusions: Preliminary results indicate that most 3-year old children successfully complete the task battery across the domains. BAO allows us to increase sensitivity of key dependent variables. Psychometric validation, creation of age-norms, and implementation of the battery in the multi-centre AIMS-2-TRIALS longitudinal Preschool Imaging Project are planned.

449.023 *(Poster)* Remote Assessment of ASD in Clinical Trials: Feasibility of Quantifying Social Interactions with Wearable Technology

D. Nobbs[1]*, L. Kriara*[1]*, D. Slater*[1]*, F. Lipsmeier*[1]*, T. Kilchenmann*[1]*, E. Eule*[2]*, F. Bolognani*[3]*, L. Murtagh*[2]*, D. Umbricht*[2]*, C. Gossens*[1]*, M. Lindemann*[1]*, C. H. Chatham*[4] *and J. F. Hipp*[2]*, (1)Roche Pharma Research and Early Development. Roche Innovation Center Basel, Hoffmann-La Roche, Basel, Switzerland, (2)Neuroscience and Rare Diseases (NRD), Roche Pharma Research and Early Development, Roche Innovation Center, Basel, Switzerland, (3)VectivBio Holding AG, Basel, Switzerland, (4)Neuroscience and Rare Diseases (NRD), Roche Pharma Research and Early Development, Roche Innovation Center, New York, NY*

Background: Whilst clinical trials for ASD therapeutics are dependent on the quality of their outcome measures, current tools have severe limitations in terms of reliability, validity, burden and ecological validity (Anagonostou et al., 2014). To address this unmet measurement need we have developed novel digital tools for the remote measurement of ASD signs and symptoms and deployed these into an observational study. Previous studies have shown that individuals with ASD are less likely to interact with others and more likely to spend time engaged in solitary behaviors (Lord and MaGill-Evans, 1990; Humphrey and Symes, 2011). In the FDA's Voice of the Patient public meeting, individuals with ASD identified social isolation as one of the major impacts of the condition on their lives (FDA, 2017). We developed a new tool "Social Beacons" to quantify the frequency of social interactions, utilizing commercially available hardware and a custom smartwatch app.

Objectives: To test the feasibility of remotely tracking social interactions in the context of a clinical trial using "Social Beacons".

Methods: 90 individuals with ASD and 45 typically developing controls (5-45 years) in the UK and US were asked to distribute the "Social Beacons" and wear the smartwatch every day during the 3 week screening and 12 week observational periods of the non-drug observational study. The "Social Beacons" (Room and People Beacons) emit a Bluetooth signal that is captured by a smartwatch worn by the participant. "Room Beacons" are placed in rooms around the home (each categorized as either social, sometimes social or non-social, based on the caregiver's judgement of how the room is used), while "People Beacons" are carried by other household members. The signal strength and its derivative are used to estimate the proximity of the smartwatch to the "Social Beacons", allowing one to infer the participant's room location and proximity to other household members and therefore estimate the frequency of social interactions.

Results: Preliminary data indicates participants set-up the technology as instructed. Periods of time when the watch was worn by the participant were identified with activity recognition. During these periods the participant's location in the home was tracked continuously, allowing for an estimation of time spent in each room throughout the day.

Conclusions: It is feasible to deploy "Social Beacons" into a clinical trial and infer the participant's room location. Observational study data is currently being analyzed to extract and test the reliability of multiple social interaction measures and the association with clinical scales. We plan to deploy this technology into upcoming Ph2 interventional studies to test the sensitivity of these measures to treatment effects.

449.024 *(Poster)* Superpower Glass: An Augmented Reality Intervention for Improving Social Deficits in Children with Autism Spectrum Disorder

***A. Kline**, M. Ning, A. Husic, P. Washington, C. Voss, K. Dunlap, Y. Penev, E. Leblanc, N. Haber and D. P. Wall, Stanford University, Stanford, CA*

Background: Just within the past decade, the prevalence of Autism Spectrum Disorder (ASD) in the United States increased by over 120% up to 1 in every 40 children. Standard of care ASD diagnostic and therapeutic methods require timely and laborious in-person sessions that, combined with the growing scarcity of expert clinical providers, mean that intervening during the effective therapeutic window can become prohibitively slow and expensive for many families. Digital technologies hold the potential to remove these barriers and allow patients to receive timely, affordable, and effective care that does not disrupt their daily routine.

Objectives: To develop an augmented reality (AR)-based system for real-time emotion recognition to be used as a behavioral intervention for improving social deficits in children with ASD. To build different mobile gaming applications that evaluate the system's potential for improving emotion recognition and facial engagement, as well as explore its feasibility for measuring and/or improving behavioral deficits such as motor problems, repetitive behavior, and joint attention.

Methods: We developed a digital mobile therapy platform, "Superpower Glass", that includes an Android app wirelessly connected to a Google Glass AR headset to receive video information from the headset's camera. Computer vision algorithms integrated within the application's workflow track the faces and classify the emotions of the people captured within the scope of the recorded video. Wearing the glass headset, a child (4-12 years old) is prompted with emotional response cues that are designed to increase their engagement with their social partner. We used these capabilities to design AR-based mobile games centered around key elements of behavioral therapy reinforcing social acuity. Structured video, audio, and accelerometer data, as well as participant and session metadata are collected after each play session and stored on a HIPAA-compliant Amazon Web Services server.

Results: A total of 474 families were screened and 71 participants received the intervention. 40 of the participants were randomly assigned to treatment and 31 were randomly assigned to control. The average age of participants was 8.38 years (SD = 2.46) and 63 (89%) were boys. Participants who received the intervention used the device an average 12.12 (SD = 5.80) times over a 6-week period and demonstrated an improvement of 4.56 (SD = 1.62, p = .005) on the Vineland Adaptive Behavior Scales, second edition socialization subscale as compared to participants in the control arm.

Conclusions: Our results demonstrate that digital therapeutics can be effectively deployed to improve social deficits in children with autism and other neurodevelopmental conditions. AR and similar technological innovations allow for the design of user-friendly diagnostic and therapeutic methods that allow families to intervene in a timely, engaging, accessible, and efficacious manner from the comfort of their own home. These findings pave the way to empowering clinicians to deliver more effective care that can reach all patients.

449.025 *(Poster)* The Global Reach of Autism Navigator® and Baby Navigator Using Mobile Technology to Improve Early Detection of Autism and Access to Care

***A. M. Wetherby**[1], J. L. Hooker[1], C. Nottke[1], A. Delehanty[1], N. Chambers[2], K. Sohl[3] and J. Woods[4], (1)Florida State University Autism Institute, Tallahassee, FL, (2)Centre for Autism Research in Africa, Division for Child and Adolescent Psychiatry, University of Cape Town, Cape Town, South Africa, (3)Child Health, University of Missouri - School of Medicine, Columbia, MO, (4)Florida State University, Tallahassee, FL*

Background: Advances in research have documented that ASD can be diagnosed by trained professionals at 18-24 months and yet, the median age of diagnosis in the US still hovers at 4 years. There is currently a research-to-practice gap in high-resource countries, and this gap widens in low-resource countries. Autism Navigator® is a collection of web-based courses and tools that has used an implementation science framework to promote coordinated change to support community uptake and sustained utilization in health care, social service, and early intervention systems. Access to mobile technology is increasing worldwide and offers one solution to bridge the research-to-practice gap with potential for rapid access globally.

Objectives: This technology demonstration will showcase the web-based Autism Navigator for Primary Care that uses extensive video and offers a new online screener with links to our *Seamless Path for Families* to lower the age of detection and referral and report on the deployment.

Methods: The Autism Navigator collection of web-based courses and tools, and the new Baby Navigator companion website with family resources, was developed by the FSU Autism Institute. Autism Navigator for Primary Care is an 8-hour online course using illustrative video clips of two-dozen toddlers with ASD. Providers who complete the course can use the online automated Social Communication CheckUp with an autism risk indicator, designed as a universal screening tool every 3 months from 9-24 months, with provider and family portals linking to 5 online resources. Families of all children are invited to the 16-by-16 Lookbooks and Social Communication Growth Charts. Families of children with a positive autism screen are invited to the About Autism in Toddlers, ASD Video Glossary, and How-To Guide for Families. Input from advisory boards and focus groups involving stakeholders informed the development of content built through an iterative process of feedback, review of material for cultural appropriateness, and revolving enhancements to the portal.

Results: We will describe the deployment of the courses and family resources over the past 5 years beginning in Florida and expanding to other states in the US and other countries including South Africa. About Autism in Toddlers was first launched in 2015 and enrollment has increased incrementally to 40,086 unique users from 160 countries to date. Autism Navigator for Primary Care was launched in 2016 and has 1,847 unique users enrolled from 6 countries. The How-to Guide for Families was launched in 2017 and has 673 unique users from 10 countries. Strategies to engage physicians, community health workers, and childcare providers in the US and South Africa and lower the age of referral will be highlighted. Tablet computers will available to experience the screening tool and web-based resources.

Conclusions: Innovative technology to increase the number of culturally diverse professionals who can deliver evidence-based services is vital to improving global competence in early detection and intervention. Autism Navigator provides a community-viable cost-efficient platform for professionals and families, using mobile technology to combine an automated screening tool, parent and provider portals, and links to interactive resources that are built for rapid scalability.

449.026 *(Poster)* Use of Interactive Smartphone Tasks for Remote Assessment of Symptom Severity in Autism Spectrum Disorder

A. Abbas[1]*, A. Paley*[1] *and I. R. Galatzer-Levy*[1,2]*, (1)AiCure, New York, NY, (2)School of Medicine, New York University, New York, NY*

Background: Development of novel treatments for autism spectrum disorder requires accurate measurement of symptom severity in response to treatment. Current methods often require lengthy in-clinic assessments, which can limit scalability in clinical trials, are burdensome for patients, caretakers, and clinicians, and are far removed from patients' natural environments and hence may not accurately reflect their typical functioning.

Individuals with autism demonstrate observable behavioral traits such as altered facial expressions, changes in vocal tone, misuse of pronouns, and repetitive body movements. If these 'biomarkers' can be measured using automated tools that take advantage of advances in computer vision and machine learning, short, frequent, and objective assessments of symptom severity conducted in the individuals' natural environments could be utilized in the development of novel treatments for autism.

Objectives: There are two main objectives. The first is the development of an interactive smartphone task that collects the necessary visual and auditory information for calculation of digital biomarkers of autism. The second is the development of a processing pipeline that uses the collected video and audio to calculate those biomarkers.

Methods: The interactive task will involve both a naturalistic and a stimulus-based component. The former asks open-ended questions about the participant's activities surrounding the task to collect data on spontaneous facial expressivity, vocal acoustics, free speech, and movement. The latter presents visual and verbal stimuli to collect data on evoked behavior including expressivity, vocal tone, content of speech, and gaze direction in response to a stimulus such as social imagery.

The collected video is then used to calculate biomarkers. OpenFace is used to measure emotional expressivity, head movement, and oculomotor behavior such as gaze direction (Baltrušaitis et al., 2016). The Praat software library is used to measure acoustic characteristics of voice such as frequency, amplitude, and pauses (Jadoul et al., 2018). Amazon Transcribe is used for transcription of speech into text, which is then further analyzed for speech characteristics such as use of pronouns and content valence (Loper and Bird, 2002).

Demonstration:

The demonstration will involve attendees participating in the described interactive task on smartphones provided by the presenter. This will allow attendees to have a hands-on experience with the method used to collect the data necessary for calculation of biomarkers. The poster itself will describe the data processing pipeline and the validation of the computational tools used to calculate digital biomarkers from the data.

Results: The interactive task, built on a validated mobile data capture platform, is able to securely collect and store video and audio captured during participation in the task. The processing pipeline, built using open-source software, is able to accurately classify action units for detection of emotional expressivity (Baltrušaitis et al., 2016) and measure the frequency of tones with an average accuracy of 99% in low-noise environments (n = 14) for measurement of verbal acoustics and content of speech (Jadoul et al., 2018).

Conclusions: Participation in interactive tasks delivered through a smartphone may allow for collection of visual and auditory information adequate for measurement of biomarkers of autism spectrum disorder.

449.027 *(Poster)* Using Virtual Reality to Explore Individual Differences in the Local and Global Processing of Visual Information and Their Relationship with Autistic Traits

S. Savickaite[1]*, N. McDonnell*[2] *and D. R. Simmons*[1]*, (1)School of Psychology, University of Glasgow, Glasgow, United Kingdom, (2)School of Philosophy, University of Glasgow, Glasgow, United Kingdom*

Background: Global and local processing is part of human perceptual organisation, where global processing enables us to extract the 'gist' of the visual information and local processing helps us to perceive the details. Individual differences in these two types of visual processing have been found in autism and ADHD. Technological developments have made Virtual Reality (VR) a more accessible research tool in the last few years. No previous research has investigated perceptual differences related to autistic traits using this technology. The current study was pilot exploratory research into the feasibility of using VR technology for research on perception in autism. Given its use in previous research on local vs. global processing we employed the Rey-Osterrieth Complex Figure test (ROCF: Figure 1).

Objectives: The standard ROCF test was used as a baseline task to look at practical aspects of using VR as an experimental platform. New methodology for extracting and manipulating three-dimensional data was also explored.

Methods: In this study, we investigated individual differences in local and global processing as a function of autistic and ADHD traits (quantified using standard questionnaires for both (Baron-Cohen et al, 2001; Kessler et al, 2005)). The ROCF was presented in a virtual environment and a standard protocol for using the figure was followed: after initial presentation the figure was copied, then the figure was withdrawn from view and drawn from memory (Immediate Recall). Drawings were all in 3-dimensional space using Google® Tilbrush®. A novel method of quantitative data extraction was used (Figure 2).

Results: Using standard methods of scoring performance in the task, differences were found between copy and recall conditions, but none of these correlated with different scores on AQ or ADHD questionnaires.

Conclusions: Virtual Reality has proved itself to be a fruitful source of information. This study is an example of how classic psychological paradigms can be transferred into the virtual world. Our novel method of data extraction provides us with rich information on how individuals behave in the virtual world. Further investigation of individual differences in drawing tasks in VR could lead to a better understanding on how we process visuospatial information.

449.028 *(Poster)* Using a Socially Assistive Robot to Engage Children in Physical Activity: An Analysis of "What's Possible" Using a Participatory Design Framework

*S. Stutts[1], R. Kesarla[2], T. Abel[3] and **A. M. Colombo-Dougovito**[4], (1)Anthropology, University of North Texas, Denton, TX, (2)Texas Academy of Mathematics and Science, University of North Texas, Denton, TX, (3)Design, University of North Texas, Denton, TX, (4)Kinesiology, Health Promotion, & Recreation, University of North Texas, Denton, TX*

Background: Evidence suggests that motor skill delays are prevalent in autistic youth (Lloyd, MacDonald, Lord, 2013; Staples & Reid, 2010)—often intensifying as the child develops (Liu et al., 2014). Furthermore, limited motor skills are related to increased rates of physical inactivity (Healy et al., 2019). Yet, despite growing evidence of motor delays and increasing physical inactivity, few intervention exist to meet the needs of autistic youth (Colombo-Dougovito & Block, 2019). Utilizing a Socially Assistive Robot (SAR), however, may provide a novel reinforcement for motor skill instruction. Yet, little to no precedent exists for using a SAR in a physical activity setting.

Objectives: Therefore, to better inform future interventions, the purpose of this study was to explore how autistic youth would like to engage with a SAR when participating learning motor skills and engaging in physical activity.

Methods: Using a participatory design framework, autistic youth were shown a commercially available SAR while confronted with a "wizard of oz" scenario. In this situation, youth were asked about how they would like to use the SAR without any restrictions on what could or could not be possible. Following each interview, suggestions were analyzed for possibility and practicality. Those ideas deemed most possible were implemented in the commercial SAR. Follow-up interviews were used to determine if implementation matched the child's suggestion. Additionally, to understand the social validity of a SAR for physical activity, parents of each participant were interviewed to understand how a SAR may be used in home. All data were transcribed verbatim and coded thematically (Braun & Clark, 2006) to understand emergent themes within the data.

Results: Preliminary evidence shows strong confirmatory evidence for using a SAR to assist with learning motor skills and engage in physical activity. Suggestions for using the SAR in the physical activity setting were implemented within the constraints of the software and limitations of the available SAR.

Conclusions: Using a SAR in the physical activity setting may provide for a novel experience for autistic youth. The present findings provided a solid foundation to developing important elements for using a SAR in the physical activity setting. By using the feedback and suggestions from the most impacted stakeholder, the use of a SAR will be more likely to provide impactful reinforcement while practicing motor skills and encourage engagement in physical activity.

449.029 *(Poster)* Using an Animal-like Robot to Trigger Helping Behavior in Children with Autism Spectrum Disorder

***S. Matsuda**[1], D. Enomoto[2], C. Mori[3] and R. Murayama[3], (1)University of Tsukuba, Tsukuba, Japan, (2)LITALICO Inc., Tokyo, Japan, (3)GROOVE X, Inc., Tokyo, Japan*

Background: A number of systematic reviews (e.g., Diehl et al., 2012; Ismail et al., 2019; Pennisi et al., 2016) have reported many positive implications in the use of social robots for children with Autism Spectrum Disorders (ASD). To date, social robotics has been applied in various target behaviors, such as motor imitation (Duquette et al., 2008; Robins et al., 2005), joint attention (David et al., 2018; Warren et al., 2015), collaborative play (Wainer et al., 2014), speech production (Kim et al., 2013), and turn-taking (Matsuda et al., 2017). However, few studies using social robots have targeted helping behavior, although helping behavior is one of the important pro-social behaviors (O'Connor et al., 2019). A "weak robot" which can trigger helping behavior in children with ASD, may offer promising implications for how interventions should be approached.

Objectives: The objectives of this pilot study were examine 1) whether children with ASD show helping behavior toward a weak robot, LOVOT™ and 2) how the contingent movement of the robot affects child's interactive behavior toward a robot.

Methods: LOVOT™ is a pet toy. It has a camera-based vision system (including depth camera) for face identification, object recognition, and mapping. It also has microphones, thermal cameras, infra-red, orientation, temperature, illuminance, and pressure sensors (Figure 1). Thus, it is able to automatically recognize user's face and move toward the user. This pilot study was implemented with five participants (four males) between 3-7 years old, have a diagnosis of ASD by an outside medical doctor. **Study 1**: In the study 1, we made robot falling several times in approximately three minutes. A dependent variable was helping behavior. **Study 2**: In the study 2, two conditions (with and without contingent following) were implemented. In the *with contingent following condition*, the camera-based vision system detected child's face, and the robot moved toward the child contingent on child's looking at name and/or child's calling name of the robot. In the *without contingent following condition*, the camera-based vision system was turned off. Therefore, the robot could not recognize child's face and position. Four dependent variables (approaching, calling name, looking, and body contact) were scored using occurrence/non occurrence data. All behavior coding was conducted using the software, ELAN (2018).

Results: Exp1: All five children showed helping behavior toward the robot (Figure 2) several times (2-4 times). **Exp2**: The mean percentage of intervals in the *with contingent following condition* was 1.8% for approaching, 2.1 % for calling name, 7.2% for looking, and 12.7% for body contact. On the other hands, in the *without contingent following*, the mean percentage of intervals was 1.7% for approaching, 1.9% for calling name, 7.2% for looking, and 13.0 % for body contact.

Conclusions: Our pilot study suggest that the "weak" robot triggers helping behavior in children with ASD. On the other hand, the frequencies of child's interactive behavior toward robot did not consistently increase or decrease in the *with* contingent following condition. Further studies are required, including use of a group experimental design with larger sample sizes.

449.030 *(Poster)* Utilizing Technology to Teach Social and Vocational Skills for Adults with Autism Spectrum Disorder: The Autism News Network

M. Gwynette[1]*, A. Y. Schumann*[2]*, N. Saini*[3]*, A. Eblin*[1] *and H. Duncan*[4]*, (1)Medical University of South Carolina, Charleston, SC, (2)Psychiatry, Medical University of South Carolina, Charleston, SC, (3)College of Medicine, Medical University of South Carolina, Charleston, SC, (4)Greenville Technical College, Greenville, SC*

Background: Social skills deficits are amongst the most significant challenges facing adolescents and young adults with ASD (Barnhill 2007; Howlin 2000). Adults with ASD also struggle with attaining postsecondary education, employment, living independently, and establishing social and intimate relationships. As a result, this population is at risk for social isolation and 54% have co-morbid psychiatric conditions (Gantman 2012, Croen et al 2015). Despite this, few studies have focused on social skills treatment for young adults with ASD.

The Autism News Network (ANN) is a treatment program at the Medical University of South Carolina that utilizes technology to provide social skills training and vocational training for adults with ASD. The program teaches participants how to conduct interviews and produce video content, podcasts, and newsletters aimed at a mass audience. All ANN content is written, produced and directed by adults with ASD.

Objectives: The object of this session is to demonstrate how the use of technology by the ANN benefits adults with Autism Spectrum Disorder by improving their social skills and vocational skills.

Methods: Fourteen adults with ASD ages 18-35 were enrolled in weekly 2-hour training sessions for 12 weeks. Participants were instructed on basic interview skills, writing, videography, film editing and other soft skills. Participants and their parents completed pre- and post-intervention assessments. Outcome measures included the Social Responsive Scale-2 (SRS-2) and the Social Skills Improvement System Rating Scale (SSiS). Parents also completed a 12-item Likert scale regarding target symptoms related to social skills.

Outcomes data is currently being analyzed. The investigators will characterize basic statistical properties (moments, distributions, and correlations) of preliminary baseline and outcome data and apply a set of parametric (e.g. one-sample t-tests) and non-parametric (e.g. one-sample Wilcoxon tests) statistical tests for within-score and within-timepoint hypothesis testing where appropriate. To quantify and judge outcome success for the mean SRS-2 sub-scores we will further apply a set of matched-pairs (repeated measures) two-sample t-tests or Wilcoxon signed-rank tests (Pratt modification to improve bias for discrete measures) for each total score and SRS-2 sub-score. Two-way (matched-pairs) ANOVA tests will be implemented to study systematic within-score between-time (pre vs. post) changes. Finally, we study simple and complex interactions between sub-scores by means of linear models with fixed- and/or mixed effects followed by one-sample t, Z-, or F-tests.

Results: The session will begin with a review of social deficits and vocational challenges facing adults with ASD. Then, the presenter will discuss the ANN treatment protocol. Next, the presenter will review the clinical outcomes data described above. The presenter will also share video examples of ANN participants learning how to accomplish various skills emphasized by the program. Finally, the presenter will share the participants' finished work—video content focused on ASD, created by adults with ASD.

Conclusions: Results of this preliminary work in the area of social skills and vocational training has the potential to positively impact quality of life for the growing number of adults with ASD. The video content created by the program's participants could raise ASD awareness for a mass audience.

449.031 *(Poster)* Virtual Reality, Bone Conduction and Video Modeling Used to Enhance Functional Speech Abilities for Individuals with Autism Spectrum Disorder

L. J. Brady*, iTherapy, LLC, Martinez, CA*

Background: Autism Spectrum Disorder (ASD) is a neurodevelopmental communication disorder resulting in functional language and behavioral delays affecting over 3.5 million Americans. These delays vary with the severity of symptoms that present in ASD but often result in limited speech and increased communication challenges. Alongside linguistic acquisition, oral motor coordination is a crucial part of speech production. Current clinical techniques have shown varying degrees of efficacy in improving functional language proficiency. Most techniques follow a drill-like procedure, where the child is made to repeat various sounds and phrases until they are retained. However, such a process requires potentially over twenty therapy sessions to show improvement which may then only be focused on one aspect of speech. This significantly limits the linguistic and social skills a student will acquire. To improve the efficacy of these therapy sessions, new technology must be developed to provide effective educational experience.

Objectives: I will demonstrate a personalized educational experience for students with ASD by creating a virtual reality (VR) based program to stimulate engagement and speech production practice.

Methods: Approximately 30 ASD students between the ages of 5 and 8 will be recruited to participate in a 12-sessions-long study that will utilize the VR-integrated application. The students will be divided in two groups: one which receives the VR-integrated prototype, and one that receives the existing 2D application on a tablet. Each session will be approximately 30 minutes long, occurring twice per week. The frequency and duration of sessions is based on our extensive previous research and to ensure statistically relevant number of data points to measure the learning progress of the students. The first 10 sessions will be monitored by iTherapy to assess the user experience of the prototype VR hardware as well as the 2D VAST application.

Results: (proposed, research is ongoing at this time) The overall intended use for the VAST system will be in special education classrooms for children who struggle with
functional language acquisition and motor abilities. Students will be able to improve upon their oral coordination during their in-school therapy sessions which may last between one to three hours/week. The skills they learn will then be applied to their classwork and their daily interactions with peers and teachers. As their language abilities improve, teachers and students will be able to improve their cooperation. By using the VAST system, students will be better able to understand and process the speech of their teachers and become more integrated in the classroom setting. Each student who participates in special education will require the use of a tablet or smartphone, VR goggles, with integrated BC headphones.

Conclusions: (proposed, research is ongoing at this time) The knowledge gained by this study has the potential to provide students with ASD with a comprehensive language education. The risks noted in the above section are minimal and reasonable in light of the benefits of the proposed study. Participation in this study will benefit all participants by supplementing their existing in-school therapy sessions while providing minimal to no risk.
