TABLE OF CONTENTS

The International Society for Autism Research (INSAR) is the professional organization that oversees the Annual Meeting. INSAR is responsible for appointing all committees that govern the organization and approving the content and format of the Annual Meeting.

INSAR BOARD OF DIRECTORS (2019 – 2021)

President
Peter Mundy
MIND Institute
University of California, Davis

President-Elect
Connie Kasari
Semel Institute
University of California, Los Angeles

Vice-President
Cheryl Dissanayake
Olga Tennison Autism Research Centre

Secretary
Petrus de Vries
University of Cape Town

Treasurer
Marjorie Solomon
MIND Institute
University of California, Davis

Past-President
Simon Baron-Cohen
University of Cambridge

Past-Treasurer
Diana Robins
Drexel University
A.J. Drexel Autism Institute

Journal Editor-in-Chief
Autism Research
(Ex-Officio)
David Amaral
MIND Institute,
University of California, Davis

Communications Chair
(Ex-Officio)
Alison Singer
Autism Science Foundation

Community Advisory Chair
(Ex-Officio)
John Robison
College of William and Mary

Annual Meeting Executive Program Committee Chair
(Ex-Officio)
Joseph Buxbaum
Seaver Autism Center for Research and Treatment
Icahn School of Medicine at Mount Sinai

INSAR COMMITTEES

Awards Committee
Chair: Stephan Sanders

Autistic Researchers Committee
Co-Chair: Patrick Dwyer
Co-Chair: TC Waisman

Communications Committee
Chair: Alison Singer

Community Advisory Committee
Chair: John Robison

Cultural Diversity Committee
Co-Chair: Marshalyn Yeargin-Allsopp
Co-Chair: Sandra Vanegas
Co-Chair: Gulnoza Yakubova

Early Career Committee
Co-Chair: Kimberly Carpenter
Co-Chair: Subhashini Jayanath

Fellows Committee
Chair: Sally Rogers

Finance Committee
Co-Chair: Marjorie Solomon
Co-Chair: Deborah Hilibrand

Global Senior Leaders Committee
Co-Chair: Petrus de Vries
Co-Chair: Declan Murphy

Membership Committee
Chair: Susan Bookheimer

Nominations & Elections Committee
Chair: Kasia Chawarska

Standards Committee
Chair: David Amaral

Special Interest Group (SIG) Committee
Co-Chair: Laura Anthony
Co-Chair: Mayada Elsabbagh

Student & Trainee Committee
Chair: Marika Coffman
Co-Chair: Alana McVey
Secretary: Alan Gerber
Past-Chair Mentor: Kristina Cottle Feldman

INSAR 2020 Meeting Committee
Chair: Sara Jane Webb

INSAR 2020 Program Committee
Co-Chair: Joseph Buxbaum
Co-Chair: Evdokia Anagnostou

STRATEGIC INITIATIVES

INSAR Mission Statement

To improve the lives of people affected by autism
by promoting the highest quality research.

BUILDING IDENTITY

Promote INSAR as the premier society for autism researchers.

DIVERSE AND GLOBAL

Represent and serve a diverse and global community.

INTERDISCIPLINARY AND TRANSLATIONAL

Cultivate interdisciplinary and translational research, public-private partnerships, and relationships with industry.

NEXT GENERATION

Foster opportunities for leadership and career development for a diverse next generation of autism researchers.

PARTNERSHIPS

Foster understanding, communication, and collaboration between autism researchers and people affected by autism.

RESEARCH TO PRACTICE

Disseminate scientific knowledge to inform research priorities, policy, practice, and public understanding.

SETTING THE BAR

Increase the quality, diversity, and relevance of research promoted through annual meetings, journal, educational, and other year-round activities.

INSAR Travel Awards 2020

Travel Awardees for 2020 are listed below by category. We want to congratulate and acknowledge these individuals on being selected for these travel awards. Due to the cancellation of the in-person INSAR 2020 Annual Meeting, funding was not provided.

Autistic Researcher Travel Awards

Jacquiline den Houting	Macquarie University
Patrick Dwyer	University of California, Davis
Dena Gassner	Adelphi University
David Mason	King's College London
Lisa Morgan	
Emily Richard	George Mason University
Jacalyn Ryan	University of Alberta
Rachelle Wicks	Griffith University
Zachary Williams	Vanderbilt University School of Medicine

Diversity Travel Awards

Monica Abdul-Chani	University of Alabama at Birmingham
Mary Agyapong	King's College London
Camile Borja	College of William & Mary
Aaron Dallman	UNC Chapel Hill
Lucia Florindez	University of Southern California
Damaris Lorenzo	Univ of North Carolina, Chapel Hill
Magdalena Szura	Medical College of Rzeszow University

Professionals from Low Income Countries Travel Awards

Emmanuel Bonney	University of Makerere
Fei Chen	The Hong Kong Polytechnic University
Marija Čolić	University of Belgrade, Serbia
John-Joe Dawson-Squibb	University of Cape Town
Nazia Jassim	University of Cambridge
Olumuyiwa Kehinde	University of Zululand
Fathima Kodakkadan	Anglia Ruskin University
Flavio Murahara	McGill University
Kritika Nayar	Northwestern University
Liezl Schlebusch	University of Cape Town
Jannatara Shefa	Bangabandhu Sheikh Mujib Medical University
Lin Sun	Indiana University
Suma Suswaram	University of Kansas
Divya Swaminathan	St John's Medical College Hospital
Deepali Taneja	University of Delhi
Cong Tran	Vietnam National University
Qi Wei	University of Oregon
Baishun Zhou	Tsinghua University

Student and Trainee Travel Awards

Yeojin Ahn	University of Miami
Zeena Ammar	Emory University
Stacy Arbuckle	University of Oregon
Armen Bagdasarov	Yale University
Anke Bletsch	Goethe University
Katharina Boegl	Humboldt-Universität zu Berlin
Kaitlyn Breitenfeldt	University of Pittsburgh
Emily Bremer	University of Toronto
Alexis Brewe	University of Alabama
Yael Brukner	Bar-Ilan University
Simone Capp	King's College London
Carter Carlos	Yale University
Merve Çelebi	Acibadem University
Jennifer Chang	Baylor College of Medicine/Texas Children's Hospital
Alison Chavez	University of Massachusetts Boston
Yun-Ju Chen	University of Southern California
Elysha Clark-Whitney	Weill Cornell Medicine
Kevin Cook	Georgetown University
Michal Cook	University of North Carolina at Chapel Hill
Elise Cummings	Yale University
Alexa Curhan	Johns Hopkins Bloomberg School of Public Health
Angela Dahiya-Singh	Virginia Tech
Konnor Davis	University of California, Davis
Simrina Desar	University of California, Los Angeles
Nicholas Fears	University of North Texas Health Science Center
Kyle Frost	Michigan State University
Joseph Giacomantonio	Stony Brook University
Rachel Greene	University of North Carolina
Luke Grosvenor	Johns Hopkins Bloomberg School of Public Health
Gabrielle Gunin	Rutgers University
Rachel Hantman	Boston University
Dorothy Hoang	University of California, Davis
Katie Howard	University of Alberta
Alaa Ibrahim	McGill University
Xiangbin Jia	Central South University
Amandeep Jutla	Columbia University
Shannon Kelly	University of Kansas
So Yoon Kim	Boston College
Kathryn King	University of California, Davis

Claire Klein	Weill Cornell Medicine
Alexis Lafleur	Université du Québec à Montréal
James Lee	University of Illinois
Kaya LeGrand	Emerson College
Kimberly Lin	Emerson College
Xinyue Liu	Indiana University
Stephanie Lung	McGill University
Keren MacLennan	University of Reading
Caroline Mann	Goethe University
Ting Mei	Radboud University
Kelly Mo	University of Toronto
Meredith Pecukonis	Boston University
Mirabel Pelton	Coventry University
Ohad Regev	Ben-Gurion University of the Negev
Charlotte Rimmer	McGill University
Helen Root	University of Alabama at Birmingham
Nicole Rosen	University of California, Los Angeles
Jessica Schwartzman	Palo Alto University
Grace Simmons	University of Alabama
Jennie Sotelo Orozco	University of California, Davis
Gavin Stewart	King's College London
Briana Taylor	Maine Medical Center
Kimberly Tomeny	University of Alabama
Isita Tripathi	University of California, Los Angeles
Bahar Tuncgenc	Johns Hopkins University
Dévina Ung	Icahn School of Medicine at Mount Sinai Hospital
Elizabeth Weir	University of Cambridge
Melina West	University of Connecticut
Molly Winston	Northwestern University
Nichol Wong	King's College London
Rachel Wulff	University of California, Davis
Ivry Zagury-Orly	Harvard Medical School; University of Montreal

Student and Trainee Workshop Travel Awards

Janina Brede	University College London
Teresa Girolamo	University of Kansas
Taylor Halligan	Purdue University
Shashwat Kala	Yale University
Orly Kerub	Ben Gurion University in the Negev
Talia Liu	Vanderbilt University Medical Center
Alana McVey	Marquette University
Hillary Schiltz	Marquette University
Lauren Singer	Yale University
Ellen Wilkinson	Rutgers University

INSAR 2020 Virtual

Launching June 3, 2020

Live Webinars

e-Posters
& Abstracts

On Demand
Content

The INSAR 2020 Annual Meeting to be held May 2020 in Seattle, Washington, USA was cancelled. In efforts to continue sharing and advancement of autism research, INSAR 2020 Virtual was launched on June 3, 2020. Our four planned Keynotes for the in-person event, agreed to present live via webinar with archived recordings to be hosted online for on-demand viewing. In addition to the Keynote Webinar, all individuals with accepted abstracts (Panel, Oral and Poster) were given the opportunity to submit an e-Poster. The abstract and e-Poster online, searchable content also launched on June 3, 2020. To date, we also have various INSAR Committee Chairs developing virtual content from planned INSAR 2020 sessions. Updates for additional webinars and content can be found on the INSAR 2020 Virtual landing page. Some additional content will be available exclusively to current INSAR Members.

Keynote Webinar
June 3, 2020
Recordings available at www.autism-insar.org after June 10, 2020 (open access)

Abstracts and E-Posters
June 3, 2020
Online searchable platform
Opens June 3, 2020 (open access)

Special Interest Groups (SIG) Webinars
(dates to be announced) INSAR Membership Required

Meet the Expert Webinars
(dates to be announced) INSAR Student Membership Required

Keynote Webinar - June 3, 2020

Sven Bölte, PhD
A Pluralistic View of Autism Using the ICF

While there is strong agreement that autism is a heterogeneous condition and requires individualized understanding, traditionally, autism has been looked at predominantly a clinical symptomatology perspective. Still, for autistic individuals, their families and large parts of society, the dimensions of functioning and quality of life are both more significant and accessible. In addition, In recent years, the concept of neurodiversity has challenged the biomedical model of autism, demanding a more balanced view of autism and favoring social and environmental responsibility model of autism. In this keynote lecture, the WHO International Classification of Functioning, Disability and Health (ICF), and the recently developed ICF Core Sets for autism are introduced that allow to integrate different approaches to autism and a pluralistic view of the strengths and weaknesses of autistic individuals and how they emerge in facilitative and hindering environments.

Joshua A. Gordon, MD, PhD
Research Towards the Early Screening and Treatment of Autism

NIMH Director Dr. Joshua Gordon will provide an update on federal support for research towards identifying and treating autism as early in life as possible. He will provide an overview of the Autism Biomarkers Consortium, a public-private partnership aimed at developing new clinical tools for the study of autism, and the Interagency Autism Coordinating Committee, a Federal advisory committee that helps to coordinate research efforts and provides a forum for diverse perspectives. He will also highlight NIMH-supported advances and ongoing research, including clinical tools for the early detection of autism, progress toward understanding the neurobiology of genetic and environmental risk for autism, and increased attention on autism among adults and youth in transition to adulthood.

Keynote Recordings will be available after June 10, 2020
visit www.autism-insar.org/insarvirtual
for details

Lamya Shihabuddin, PhD
Developing Gene therapy for Genetic Neurologic Diseases: Optimizing Targeting and Transgene Expression

Among the most promising new therapeutic innovations are gene-targeted therapies using Adeno-associated viral vectors (AAV). Gene-targeted therapies can be designed to replace the mutant gene in case of loss of function mutations such as spinal muscular atrophy and lysosomal storage diseases or inhibit the expression of a mutant gene in case of mutations leading to toxic gain of function such as Huntington disease, as well as gene modulation by gene editing. The transgene must be delivered to the physiologically relevant target tissue or tissues and cell types, must be stably expresses without interfering with the functional integrity of those cells. The safety and tolerability of chronic expression or regulated expression are also important considerations for all gene targeted therapies. AAV gene therapies are defined by multiple characteristics: (1) the capsid, which determines what cells to target; (2) the transgene, which can be altered and optimized for better translation; (3) the promoter, which regulates gene expression and transcription within the cells; (4) mode of production can impact vector qualities and thus transduction efficiency. In developing gene therapy strategies, matching the specific disease indication to the capsid and route of administration that achieves the biodistribution goal and transduction efficiency required for therapeutic benefit is critical for clinical success.

Emily Simonoff, MD, FRCPsych
Mental Health in Autistic People: Setting a Research Agenda for the Coming Decade

At the end of the last century, our awareness of the great heterogeneity in autism increased and there was a new interest in studying its multi-faceted dimensions. This was partly responsible for conceptualizing the presentation and challenges experienced by autistic people as mental health problems in the early 2000s. While it is now generally accepted that autistic people have higher rates of virtually all psychiatric conditions, we still have a limited understanding of why this is the case, how best to identify and measure mental health problems, what interventions are most promising and what "success" in prevention and intervention would look like. In this keynote, I will explore these issues and suggest some research priorities for the coming decade.

INSAR Recognition Awards 2020-2021:
*These awardees will be officially recognized in Boston at INSAR 2021.

Lifetime Achievement Award
Helen Tager-Flusberg, PhD

Helen Tager-Flusberg received her Bachelors in Science in Psychology from University College London, and her doctorate in Experimental Psychology from Harvard University. Since 2001 she has been at Boston University, where she is now Professor of Psychological and Brain Sciences, and Director of the Center for Autism Research Excellence. She has devoted her lengthy career to conducting research on autism and other neurodevelopmental disorders including children with developmental language disorders and genetic syndromes, exploring variability in phenotypic expression and investigating developmental and intervention-based changes in language and social cognition using behavioral and brain imaging methodologies.

Her research has been funded by the National Institutes of Health and private foundations and she has had the good fortune to lead several multi-site multidisciplinary autism research programs including CPEA, STAART and ACE Centers. She has edited seven books and written over 200 journal articles and book chapters. She is the Past President of INSAR (2011-2013), serves on the editorial board of several professional journals and is Section Editor (Cognition and Behavior) for the Journal of Neurodevelopmental Disorders. She regularly presents her work at scientific and professional conferences and to parent advocacy groups and other stakeholders in the US and in countries around the world.

Advocate Award
John Robison

John Robison is the Neurodiversity Scholar in Residence at The College of William & Mary in Williamsburg, Virginia. He is also a visiting professor of practice at Bay Path University in Longmeadow, MA and is the neurodiversity advisor to Landmark College in Putney, VT. John is an autistic self-advocate and an appointed member of national and international scientific and science policy-making bodies, including the federal government's Interagency Coordinating Committee on Autism, the World Health Organization, and is a part of the Board of Directors for INSAR as the Chair of the Community Advisory Committee.

John is very active in his efforts to support and promote research leading to therapies or treatments that will improve the lives of people who live with autism in all its forms today. He is widely known as an advocate for people with autism and neurological differences. John's service to the community and INSAR has been truly outstanding over the years and is why he was selected for the 2020 INSAR Advocate Award.

Cultural Diversity Research Award
Dr. Waganesh Zeleke

Dr. Waganesh Zeleke was selected for this award due to her significant work with culturally diverse individuals with ASD across the United States and Ethiopia. Dr. Zeleke's work focusses on advancing culturally relevant issues in the epidemiology, diagnosis and treatment of children with autism in Ethiopia and Zimbabwe. She is also engaged in research on disparities in diagnostic, educational and health care services of minority children with autism and children with autism in poverty in the United States. Dr. Zeleke is an Associate Professor at Duquesne University in Pittsburgh.

Young Investigator Awards

Meghan Miller, PhD (UC Davis): "Sibling Recurrence Risk and Cross-aggregation of Attention-Deficit/Hyperactivity Disorder and Autism Spectrum Disorder." *JAMA Pediatr.* 2019;173(2):147-152. doi:10.1001/jamapediatrics.2018.4076

Vanessa H. Bal, PhD (Rutgers University): "Predictors of longer-term development of expressive language in two independent longitudinal cohorts of language-delayed preschoolers with Autism Spectrum Disorder." *J Child Psychol Psychiatry.* 2019 Aug 19. doi: 10.1111/jcpp.13117

Dissertation Awards

Katherine E. Lawrence, PhD (University of Southern California): Dissecting Brain-Based Variability in Autism: Impact of Sex, Polygenic Risk, and Age.

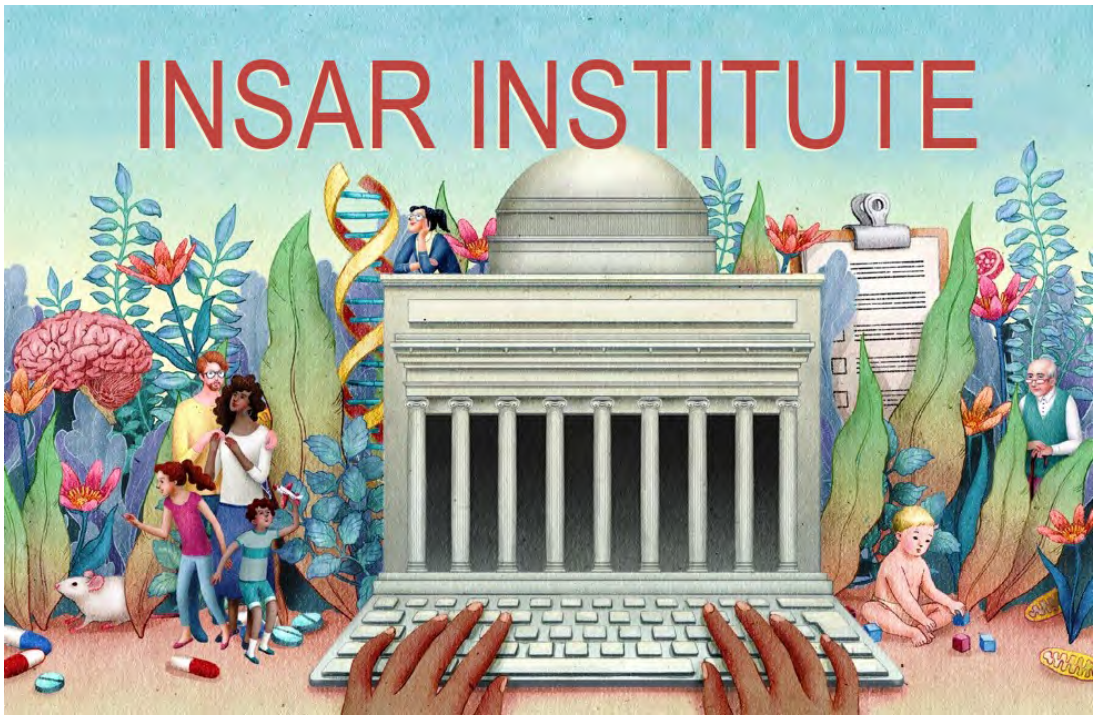
Sophie Schwartz, PhD (Boston University): Characterization Of Central Auditory Processing In Minimally And Low Verbal Adolescents With Autism.

Save the Date for the 2020 INSAR Institute!

(formerly INSAR Summer Institute)

Developmental Stages of Autism through a Research Lens

July 11 - July 16th



This 6-week webinar series takes place on Thursdays from June 11th to July 16th.This series will focus on understanding barriers and facilitators that influence autistic individuals' transition through different life stages, integrating research and clinical practice. Broadening our understanding of autism across the lifespan also has implications for policy making to ensure that autistic individuals reach their full potential in an increasingly neurodiverse society. The initiative to consider autism across the lifespan is reflected by recent INSAR Special Interest Groups (SIGs). In 2018/2019, popular SIGs examined advancing and adapting interventions to aid transition to college for autistic students, understanding gender and sexuality in adulthood, as well as a focus on increasing neurodiversity by engaging directly with autistic individuals in research and clinical practice.

INSAR Institute webinars are designed for students, post-doctoral fellows, early-career investigators, families, service providers, and autistic people and their families. The live sessions of the 2020 Institute are free to attend; pre-registration is required. Each session will be recorded and available to current INSAR Members as a benefit of society membership.

Registration is free and available worldwide to those interested in autism research. Clinicians, established researchers and stakeholders who want to get a snapshot of the current state of science in topics outside their area of expertise may also find these sessions of value.

Adult Outcome: Medical, Cognitive, Behavioral, Social, Adaptive, Vocational

PANEL SESSION — **ADULT OUTCOME: MEDICAL, COGNITIVE, BEHAVIORAL, SOCIAL, ADAPTIVE, VOCATIONAL**

201 - Capturing the Complexity of Young Adulthood for Individuals with ASD: Considerations for Measuring, Understanding, and Maximizing Outcomes

Panel Chair: Jan Blacher, *Graduate School of Education, University of California Riverside, Riverside, CA*

Research has consistently indicated that, as compared to their typically developing peers, young adults with ASD struggle in young adulthood across multiple domains. This panel aims to expand the current understanding of young adult outcomes through the utilization of multiple methodological approaches and the consideration of less well studied phenomena. The first paper addresses outcome measurement in adulthood across the wide spectrum of abilities in ASD. The second paper explores the role of social-emotional factors in both understanding and predicting adult outcomes. The third paper highlights systems factors in higher education settings that may exacerbate challenges faced by neurodiverse young adults. Finally, the fourth paper addresses moderators of treatment outcomes for young adults with ASD. These varied research questions recognize and illuminate the complexities inherent in how individuals with ASD navigate adulthood, and in how researchers must examine this period. This panel is strengthened by multiple methodological factors. Two papers include longitudinal data with comparison groups of neurotypical individuals, producing insight into universal processes and those specific to young adults with ASD. The other two papers consider contextual factors as important correlates of outcomes, underscoring the ways in which the environment can explain variance in functioning on the individual level.

201.001 *(Panel)* Assessing Longitudinal Adult Outcomes: A Comparison of Three Approaches

***J. B. McCauley**[1], A. Pickles[2] and C. Lord[1], (1)University of California, Los Angeles, Los Angeles, CA, (2)King's College London, Institute of Psychiatry, Psychology and Neuroscience, London, United Kingdom*

Background: There is a great need for supports that enhance the outcomes of adults with autism spectrum disorder (ASD), but defining quality outcomes in a heterogeneous population remains a difficulty. This is an important endeavor, and generating meaningful outcomes from longitudinal studies will help define needs for clinical practice and planning.

Objectives: The current study aims to typify adult outcomes from a longitudinal study of children referred for autism at 2 using three distinct approaches: 1) comparisons of three groups: people who received a diagnosis of ASD at one point with higher IQs (ASD-High IQ), a diagnosis of ASD and lower IQs (ASD-Low IQ), and people who have never been diagnosed (Never ASD), 2) using a latent class approach to identify commonalities in adult profiles, and 3) defining outcome categories by creating an ordinal variable of the number of objective outcomes met, defined separately for higher and lower IQ adults.

Methods: 123 young adults, mean age of 26, referred for neurodevelopmental disorders in early childhood were administered a battery of diagnostic and cognitive measures, as well as standardized interviews and questionnaires assessing employment status, living situation, friendships, affective problems, and well-being.

Results: Using the three groups approach we found marked similarities between the ASD-High IQ group and the Never ASD group across adult outcomes (Work p=.351, Living p=.128, Friends p=.326, Living Skills p=.250), although the Never ASD group had significantly higher well-being and less depressive symptoms than either ASD group. In the latent class approach across all measures of adults, data were reduced to four classes, though these did not account for much of the variation in affective measures (See Figure 1). The classes were predicted accurately from childhood IQ and symptom severity measurement taken at age 2 years to age 9 years. In the ordinal outcome approach, outcomes were defined separately for more and less cognitively able adults (See Figure 2). For more cognitively able adults, higher verbal IQ, higher daily living skills, and higher well-being were significantly associated with increased odds of moving up in the number of positive outcomes met; higher CSS, and higher internalizing symptoms and externalizing symptoms were all significantly associated with decreased odds of moving up in the number of positive outcomes met. Having received a formal ASD diagnosis in the past (in contrast to current ADOS CSS scores) was associated with lower odds of positive outcomes, and higher verbal IQ and well-being (although not after diagnosis and IQ were accounted for) were associated with more positive outcomes for less cognitively able individuals.

Conclusions: Not surprisingly, IQ was a significant predictor of adult outcome in cross-sectional and longitudinal analyses. In addition, ASD diagnosis and symptom severity were significant predictors of outcomes across approaches. Using an objective, ordinal count of outcomes met, defined separately for less and more cognitively able adults, was the only method that demonstrated significant associations between subjective well-being and outcome categories, although not for less cognitively able adults once we accounted for ASD diagnosis and IQ.

201.002 *(Panel)* Understanding and Predicting Young Adult Outcomes for Individuals with ASD: A Focus on Mental Health

C. Moody[1]*, J. Blacher*[2] *and B. L. Baker*[3]*, (1)University of California Los Angeles, Los Angeles, CA, (2)Graduate School of Education, University of California Riverside, Riverside, CA, (3)Psychology, UCLA, Los Angeles, CA*

Background: Previous research has documented pervasively poor outcomes in employment, post-secondary education, and social functioning for individuals with autism spectrum disorder (ASD) during adulthood (Howlin et al., 2004; Shattuck et al., 2012). In explaining these negative outcomes, the literature has largely focused on disability characteristics, such as IQ, autism severity, and language ability, while neglecting the role of social-emotional factors (Magiati et al., 2014; Kirby et al., 2016). However, the study of social-emotional factors is warranted, given that individuals with ASD are at much higher risk for psychopathology than the general population (Eaves & Ho, 2008; Buck et al., 2014).

Objectives: In the current study, we plan to 1) examine the role of mental health in explaining concurrent young adult outcomes, and 2) explore social-emotional predictors in adolescence of mental health outcomes in young adulthood.

Methods: Participants are part of the Collaborative Family Study, a longitudinal study of development. Families of youth with typical development (TD) or ASD completed assessments at 15 (n=162), and are currently being recruited for a follow-up assessment at age 21. Recruitment is ongoing; preliminary data in this abstract draw upon 63 young adults (n_{TD}=33, n_{ASD}=30).

Mental health was assessed through self-report in adolescence and young adulthood through the Youth Self Report (Achenbach & Rescorla, 2001) at age 15 and the complementary Adult Self Report (Achenbach & Rescorla, 2003). A young adult functional outcome composite was created based on level of independence, involvement in professional activities (i.e., paid work, post-secondary education), and quality of peer relationships.

Results: Consistent with prior literature, preliminary results indicate that young adults with ASD are significantly more likely than TD young adults to endorse clinically significant mental health problems, $\chi^2(1)=8.54$, p=.003. In a two-way ANOVA, significant main effects of both diagnostic status, $F(1,58)=41.18$, $p<.001$, and presence of clinical levels of mental health problems, $F(1,58)=6.22$, p=.015, on young adult functional outcome emerged, with no significant interaction. Thus, although young adults with ASD had poorer functional outcomes on average than young adults with TD, clinically significant mental health problems further contributed to reductions in functioning for both groups.

Multiple regression was used to perform an initial examination of adolescent predictors of young adult mental health outcome. Social acceptance in adolescence emerged as a significant predictor, $t(53)=2.04$, p=.046, over and above diagnostic status and adolescent mental health. A non-significant interaction between diagnostic status and social acceptance suggests that this relationship functions similarly for both TD and ASD individuals. However, this relationship was in the unexpected direction, such that greater adolescent social acceptance predicted poorer young adult mental health.

Conclusions: Future analyses will confirm findings with a larger sample and explore additional adolescent predictors of young adult outcomes. Current findings suggest multiple commonalities across TD and ASD populations. Additionally, results may suggest that the transition period is especially risky for youth who developed positive social relationships in adolescence, regardless of diagnosis. For these youth, loss of social support when exiting high school may result in mental health deterioration over the course of this developmental period.

201.003 *(Panel)* Autism and the College Experience: An Empirical Base for Faculty Preparation in Autism

Y. Bolourian[1]*, S. Zeedyk*[2] *and J. Blacher*[3]*, (1)Graduate School of Education, University of California, Riverside, Riverside, CA, (2)CSUF, Fullerton, CA, (3)Graduate School of Education, University of California Riverside, Riverside, CA*

Background: College students with autism spectrum disorder (ASD) represent increasing neurodiversity in our society. Even though they are attending college at higher rates, they have a lower likelihood of graduating than their neurotypical peers (Volkmar et al., 2017). Yet, engagement with knowledgeable faculty may improve the college experience for these students (Bolourian et al., 2018; Zeedyk et al., 2019), and lead to more positive postsecondary outcomes.

However, in the context of ASD, professors often lack knowledge of, and experience with, students' specific needs and reasonable accommodations (i.e., Americans with Disabilities Act). Precisely how knowledgeable are faculty about students with ASD? This paper will include data from faculty at four major colleges who responded to a survey about ASD and is a follow-up to a series of studies in this area (Bolourian et al., 2018; Zeedyk et al., 2019).

Objectives:

- To gain a broader perspective of faculty experiences with students with ASD.
- To compare these perspectives of faculty at teaching versus research institutions.

Methods: Two California State University campuses (CSU; *n*=123) and one University of California campus (UC; *n*=133) were included. While CSUs are largely teaching institutions, the two samples did not differ on participant demographics, except that the UC contained more Full Professors and fewer Adjunct Professors. Data collection is underway at a third CSU, and will be included in this presentation.

Campus-wide surveys were administered to faculty (Zeedyk et al., 2019), using the online platform, Qualtrics. A series of Yes/No, Likert-type and open-ended items addressed issues such as: connections with ASD, teaching practices, and interest in an ASD-specific training.

Results: Based on the three universities included, about a third of faculty had some personal connection to ASD; about half had taught a student who self-disclosed as having ASD. Professors indicated a limited understanding of the needs of students with ASD. Notably, significantly fewer UC faculty provided information about disability supports on their syllabus or announced in class that accommodations were available. From the majority of faculty (86-96%) who had been approached by a student with disability documentation, a small percentage (5-6%) reported asking a student specifically what type of disability they had. Faculty across campuses (83-85%) also indicated their willingness to participate in a training program. Results from open-ended items indicated that faculty were interested in learning more about their obligation under the law and inclusive learning practices.

Conclusions: It is not a question of whether a faculty member will have a student with ASD, it is a question of *when*. This study provides evidence for heightening awareness and adequately educating faculty about neurodiversity on college campuses. In this effort, our research team has engaged in two innovative approaches to reach the instructional community: (1) the production of a documentary, featuring five students on the spectrum who voice their experiences in college, including their interactions with faculty; (2) the development of a training program to educate faculty, e.g., on how to recognize ASD, provide instructional accommodations. An overview of these platforms will be provided.

201.004 *(Panel)* Examining the Benefit of Parent-Mediated Social Skills Training: The UCLA PEERS® for Young Adults Program

***N. E. Rosen**, M. Jolliffe, Y. S. Lograsso and E. A. Laugeson, UCLA Semel Institute for Neuroscience and Human Behavior, Los Angeles, CA*

Background: Research suggests impaired social skills are often the most significant challenge for those with ASD (Reichow & Volkmar 2010), with adults often experiencing the greatest social barriers. While there is a dearth of evidence-based social skills interventions for this highly underserved population (Rao, Beidel, & Murray 2008), caregiver-mediated interventions have shown promise in teaching social skills to adults with ASD (Gantman et al. 2012; Laugeson et al. 2015). Including parent and non-parent caregivers as social coaches is thought to be an important mechanism of change in social skills training (Laugeson 2017), yet little is known about the differences in treatment outcomes depending on the type of caregiver utilized.

Objectives: The purpose of this study is to: (1) examine changes in social functioning following caregiver-mediated social skills training for young adults with ASD; and (2) examine differences in treatment outcomes when parent or non-parent social coaches are included in treatment.

Methods: Participants included 60 cognitively-able adults with ASD (77% male) ranging in age from 17-35 (*M*=23.22; *SD*=3.87). Participants attended 90-minute weekly social skills instruction for 16-weeks using the PEERS® for Young Adults curriculum (Laugeson 2017). Skills focusing on relationship development were targeted. In vivo social coaching was provided by parents (*n*=44) or non-parent caregivers (*n*=16) for the duration of the study. Non-parent caregivers included life coaches, peer mentors, and other family members, nominated by the participant. Treatment outcome was measured using the Social Responsiveness Scale-Second Edition (SRS-2; Constantino 2012), Social Skills Improvement System (SSIS; Gresham & Elliott 2008), Empathy Quotient (EQ; Baron-Cohen & Wheelwright 2004), Quality of Socialization Questionnaire-Young Adult (QSQ-YA; Laugeson 2017), and Social and Emotional Loneliness Scale for Adults (SELSA; DiTomasso & Spinner 1993).

Results: Paired sample t-tests examining outcomes in the parent-mediated group revealed significant improvement in T-scores on the SRS-2 Total score (pre-test: *M*=66.52, *SD*=9.07; post-test: *M*=58.82, *SD*=8.29; $t(43)=5.97$, $p<0.01$), standard scores on the SSIS Social Skills Subscale (pre-test: *M*=79.64, *SD*=12.05; post-test: *M*=87.93, *SD*=11.16; $t(43)=4.38$, $p<0.01$), empathy on the EQ (pre-test: *M*=24.25, *SD*=10.44; post-test: *M*=31.43, *SD*=11.68; $t(43)=4.57$, $p<0.01$), social engagement on the QSQ-YA (pre-test: *M*=2.07, *SD*=2.10; post-test: *M*=4.73, *SD*=3.87; $t(43)=4.63$, $p<0.01$), and loneliness on the SELSA (pre-test: *M*=58.18, *SD*=18.95; post-test: *M*=46.23, *SD*=19.58; $t(43)=5.39$, $p<0.01$).

Paired sample t-tests examining outcomes in the non-parent-mediated group revealed significant improvement in T-scores on the SRS-2 Total score (pre-test: *M*=69.62, *SD*=8.14; post-test: *M*=61.75, *SD*=7.71; $t(15)=3.96$, $p<0.01$), standard scores on the SSIS Social Skills Subscale (pre-test: *M*=78.19, *SD*=14.13; post-test: *M*=88.12, *SD*=11.88; $t(15)=2.59$, $p<0.05$), and empathy on the EQ (pre-test: *M*=20.44, *SD*=7.02; post-test: *M*=25.94, *SD*=11.26; $t(15)=2.53$, $p<0.05$). Significant improvements were not observed on the QSQ-YA or SELSA.

In order to compare differences in treatment outcome across the two groups (parent-mediated v. non-parent-mediated), independent samples t-tests were conducted. Significant differences in change scores were observed across the groups on social engagement on the QSQ-YA (parent-mediated: *M*=2.66, *SD*=3.81; non-parent-mediated: *M*=-0.07, *SD*=5.75; $t(20)=2.16$, $p<0.05$). There were no other significant differences between the two groups.

Conclusions: Findings reveal that involving parents as social coaches results in greater social engagement following the PEERS® for Young Adults curriculum.

ORAL SESSION — ADULT OUTCOME: MEDICAL, COGNITIVE, BEHAVIORAL, SOCIAL, ADAPTIVE, VOCATIONAL
301 - A Window into the Life of Adults with Autism

301.001 *(Oral)* The Effect of Competitive Integrated Employment on the Independence of Young Adults with Significant Impact from Autism

***C. Schall**[1] and L. Avellone[2], (1)Virginia Commonwealth University, Richmond, VA, (2)School of Education, Rehabilitation Research and Training Center, Virginia Commonwealth University, Richmond, VA*

Background: Employment provides opportunities for individuals with ASD to learn life skills beyond required job duties. Therefore, sustained participation in employment offers individuals with ASD perpetual opportunities for skill development over time. This is important because findings from several studies indicate that when the provision of stimulating activities is absent in adulthood, skill growth plateaus.

Objectives: The primary research objective driving this study was to identify the impact of competitive integrated employment (CIE) on the overall independence of youth and young adults with significant impact from autism between the ages of 18 – 24.

Methods: This study was part of a larger prospective multi-site, parallel block randomized clinical trial of Project SEARCH plus ASD Supports (PS+ASD, Wehman et al., 2019). Participants were eligible for the study if they; a) had a medical diagnosis or educational eligibility label of ASD; b) attended local public school where research was being conducted; c) were between the ages of 18 – 21 by the first day of school; d) displayed independent self-care including using the bathroom, eating, and moving from place to place; e) were eligible for funding through the state VR office; and f) had continued eligibility for public school services in the coming school year. Randomization occurred at a 1:1 ratio to the treatment (81 participants, Project SEARCH plus ASD Supports, [PS+ASD]) or control (75 participants, high school) arms. Participants in both groups reported requiring significant prompts to learn tasks, remain on task, demonstrated low reading and math literacy, and were inconsistently able to communicate basic wants and needs verbally. They were all also seeking a special education certificate of completion and not a standard diploma. In short, the individuals in both conditions were significantly impacted by their disabilities.

Results: Support needs were measured using the Supports Intensity Scale, Adult Version (SIS-A, Thompson, et al., 2004) at three points during the study; baseline, graduation, and 1-year follow-up. Participants in the PS+ASD group gained CIE and further exhibited improvement on all scales of the SIS. Total scores were 4.5 and 5.1 units lower at graduation compared to baseline and 5.3 and 6.1 units lower at 1-year follow-up. Similarly, graduation to baseline improvement of standardized subscale scores ranged between 0.6 and 1.1 units lower, with the Lifelong Learning (Difference=-1.0), Employment (Difference=-1.1), and Health Safety (Difference=-0.7) having the largest magnitude of change. Meaningful improvements between baseline and either graduation or 1-year follow-up in the control group were observed only in the Community Living subscale.

Conclusions: The present study provides strong evidence that CIE results in increased independence in young adults with ASD. This is an impressive finding that suggests two important points. First, employment is likely a therapeutic pursuit for youth with significant impact from ASD. In other words, the youth who acquired employment continued to develop in most areas while their peers in the control condition displayed plateaued growth. Second, after nine months of intervention followed by approximately one year of employment, youth with ASD showed impressive improvement in their overall independence.

301.002 *(Oral)* Health Status of Medicare-Enrolled Autistic Older Adults in the United States

B. N. Hand[1]*, A. M. Angell*[2]*, L. Harris*[3] *and L. Carpenter*[4]*, (1)Health and Rehabilitation Sciences, The Ohio State University, Columbus, OH, (2)Occupational Therapy, University of Florida, Gainesville, FL, (3)The Ohio State University, Columbus, OH, (4)Medical University of South Carolina, Charleston, SC*

Background: While there is emerging evidence on the prevalence of physical and mental health conditions among autistic adults, less is known about this population's needs during older adulthood (aged 65+). Much of what is known about the autistic older adult population is based on: 1) self-report studies, which exclude those for whom survey methods are not accessible; or 2) studies with limited generalizability due to fairly small sample sizes of autistic older adults or restriction to a single geographic region. Moreover, some studies have grouped autistic older adults together with younger age groups, making it challenging to draw conclusions about the unique needs of those over 65 years of age. To our knowledge, no studies to date have used United States data at the national level to characterize the prevalence of health conditions in autistic older adults.

Objectives: To compare the prevalence of physical and mental health conditions in a United States national sample of Medicare-enrolled autistic older adults to an older adult population comparison (PC) group.

Methods: We conducted a cross-sectional retrospective cohort study of Medicare Standard Analytic Files for the years 2016-2017 to compare the prevalence of physical and mental health conditions in a national sample of autistic older adults (n=4,685) to a matched population comparison (n=46,850) cohort. We identified mental and physical health conditions from inpatient and outpatient medical claims using the Healthcare Cost and Utilization Project Beta Multilevel Clinical Classification Software for ICD-10, which identifies conditions based on the diagnosis codes included in the medical billing record and groups them into a smaller number of clinically-relevant categories. Logistic regression models were performed to compare autistic and PC older adults on the odds of each condition while controlling for sex, race/ethnicity, age, rural residence, and estimated household income.

Results: Autistic older adults had significantly greater odds of nearly all physical health conditions including epilepsy (OR=18.9; 95% CI=17.2-20.7), Parkinson's disease (OR=6.1; 95% CI=5.3-7.0), and gastrointestinal conditions (OR=5.2; 95% CI=4.9-5.5). Most mental health conditions were more common among autistic older adults, including schizophrenia and psychotic disorders (OR=25.3; 95% CI=22.4-28.7), attention deficit disorders (OR=24.4; 95% CI=16.2-31.0), personality disorders (OR=24.1; 95% CI=17.8-32.5), and suicidality or self-inflicted injury (OR=11.1; 95% CI=8.9-13.8). Health conditions commonly associated with advanced age in the general population (e.g., osteoporosis, cognitive disorders, heart disease, cancer, cerebrovascular disease, osteoarthritis) were also significantly more common among autistic older adults.

Conclusions: This study provides a comprehensive comparison of the prevalence of physical and mental health conditions in a national sample of Medicare-enrolled autistic older adults and a PC group. Our results, which suggest that autistic older adults have significant physical and mental health care needs when compared to their peers, underscore the importance of developing innovative person-centered healthcare approaches to evaluate and address the specific healthcare needs of this population. Future research is warranted to determine the contributions of both intrinsic (e.g., genetic conditions), and extrinsic (e.g., lack of access to quality health care) factors that may influence the prevalence of mental and physical health conditions.

301.003 *(Oral)* "It's Something I Have" or "It Defines Who I Am": What Language Do (autistic) Australian Adults (on the autism spectrum) Prefer?

S. M. Bury[1]*, R. Jellett*[1]*, J. Spoor*[2] *and D. Hedley*[1]*, (1)Olga Tennison Autism Research Centre, La Trobe University, Melbourne, VIC, Australia, (2)La Trobe Business School, La Trobe University, Melbourne, Australia*

Background: When describing autism, language is more than a system of communication, rather it reflects how individuals understand and experience autism, and how they would like that to be expressed to others. Many autism advocates have rejected person-first (person with autism) in favour of identity-first (autistic) language. However, as highlighted at the 2019 strategic planning meeting of the International Society for Autism Research (INSAR), there is no clear consensus within the autism community on which approach should be adopted (Robison, 2019). As stated by Robison, "Language that is appropriate to one person is offensive to another" (2019, p. 1006).

Objectives: (1) To investigate which labels commonly used to describe autism are most preferred, and which seem most offensive, to adults with an autism diagnosis. (2) To explore reasons behind label preferences.

Methods: Participants were 198 Australian adults aged 18 to 71 who reported a clinical diagnosis of autism. Participants completed an online survey rating their preference for, and the offensiveness of, six common autism labels (person with autism, person on the autism spectrum, autistic, autistic person, person with autism spectrum disorder [person with ASD], person with autism spectrum condition [person with ASC]) on a 7-point Likert scale. Participants were also asked to rank these labels in order of preference and offensiveness, and were provided free text to explain why they chose their most preferred and offensive labels. Data were analysed using mixed methods.

Results: Overall correlations between label preference ratings showed significant positive relationships between person-first labels (*r*s = .38– .54), and between identity-first labels (*r* = .79), and negative correlations between person-first and identity-first labels (*r = -.19– -.25),* suggesting a split within the sample. Mean ratings (Figure 1) of label preference showed *autistic, person on the spectrum* and *autistic person* rated significantly higher than other labels, with labels with diagnostic terms rated lowest. Ratings of offensiveness mirrored the preference ratings. Regarding label rankings (Table 1), *autistic* was most often ranked most preferred, but was also frequently ranked least preferred, with few rankings in between. *Person on the autism spectrum* was ranked most often in the top three, with weighted mean rankings indicating it most preferred, and significantly different from other labels. Labels with *condition* and *disorder* were ranked least preferable. Qualitative results reflected the split between person-first and identity-first language, with themes stressing the individual ('autism is only a part of my identity' and 'unique in a broad spectrum') or identity ('being autistic is core to my identity'). Other themes stressed 'difference not disorder', 'stigma and stereotype', and 'pragmatism'.

Conclusions: Overall there was no clear consensus on what label participants preferred or why. However, ratings clearly showed *autistic, person on the autism spectrum* and *autistic person* were most preferred. Rankings of labels suggest a split in the sample on identity-first labels, with *person on the autism spectrum* ranked most favourably overall. This suggests that while many may prefer identity-first, unless otherwise specified, *person on the autism spectrum* may currently be the most inclusive option.

301.004 *(Oral)* Lifestyle Choices of Autistic Adults: Exercise, Diet, and Sleep

E. Weir*, S. Baron-Cohen and C. Allison, Autism Research Centre, Department of Psychiatry, University of Cambridge, Cambridge, United Kingdom*

Background: Autistic individuals experience higher rates of physical health conditions, which can affect both quality and length of life. In addition, autistic children and adolescents are also at increased risk of experiencing dietary restrictions and/ or eating disorders, sleep disturbances, and decreased participation in physical activity. However, no existing studies broadly consider the lifestyle choices of autistic adults, and specifically those without intellectual disability.

Objectives: To better understand lifestyle choices of autistic adults to identify potential targets for improving health outcomes.

Methods: We developed an anonymous, online health survey that asked about demographics, self-reported autism diagnosis, lifestyle choices, personal medical history, and family medical history. We utilized binomial logistic regression and covaried for age, sex, ethnicity, and education-level in all models. Our final sample included n=1,110 autistic individuals (females n=703) and n=1,174 controls (females n=797), comprising a total of n=2,284 individuals. Across both groups, the mean age was 41.50 years (sd = 15.00) and females, UK residents, and white individuals were overrepresented.

Results: *Exercise*: Autistic individuals were less likely to meet recommended weekly exercise goals (at least 75 minutes of exercise per week) and were less likely to exercise at least once per week compared to controls.

Sleep: Compared to controls, autistic individuals were more likely to have difficulty falling asleep, difficulty staying asleep, frequent night terrors, excessive daytime drowsiness, narcolepsy, sleep apnea, sleepwalking, sleep talking, wetting the bed, and were less likely to sleep at least 6 hours per night.

Diet: Autistic individuals were more likely than controls to eat high calorie foods 6 or more times per week and were more likely to have at least one dietary restriction (including vegan or vegetarian, lactose free, nut free, gluten free, no fish, or other dietary restriction). They were less likely to meet daily fruit and vegetable goals at least 4 days per week, but also less likely to drink 7 or more caffeinated beverages per week. There were no significant differences between the likelihood of autistic people drinking at least 7 cups/ glasses of water per day, drinking 7 or more high sugar beverages each week, or being soy free.

Conclusions: This is the first study to investigate lifestyle factors of diet, exercise, and sleep patterns in a large population of autistic adults, and particularly in those without intellectual disability. Overall, autistic individuals are less likely to meet crucial sleep, exercise, and dietary goals, but are more likely to experience sleep disturbances and have dietary restrictions. Differences in quality of sleep, diet, and exercise may contribute to patterns of increased health risk and premature mortality. Future research should focus on confirming these findings, as well as identifying potential means of reducing these disparities among autistic adults.

ORAL SESSION — **ADULT OUTCOME: MEDICAL, COGNITIVE, BEHAVIORAL, SOCIAL, ADAPTIVE, VOCATIONAL**

302 - Anxiety: Measures, Effects, and Interventions

302.001 *(Oral)* Cognitive Behavioral Intervention for Driving (CBID) Intervention for Reducing Driving Anxiety and Improving Driving Outcomes for Autistic Teens and Adults

M. Baker-Ericzen[1]*, L. Smith*[2]*, A. Tran*[3] *and K. Scarvie*[1]*, (1)Rady Children's Hospital San Diego, San Diego, CA, (2)Neurosciences, University of California, San Diego, La Jolla, CA, (3)Child and Adolescent Services Research, Rady Children's Hospital, San Diego, CA*

Background: Many autistic individuals are approaching adulthood; however, interventions to promote skills towards independence are lacking. Driving is a critical step towards independence and social, vocational, and educational opportunities are substantially enhanced when individuals can transport themselves to and from activities (Curry et al 2018). Due to common autistic behaviors, AS individuals may experience difficulty in acquiring driving skills (Bian et al, 2013). It may be related to the common challenges as: 1) cognitions (attention modulation, shifting, flexibility, contextual awareness), 2) emotions (anxiety, frustration) and 3) motor abilities (coordination, planning) (Cox et al 2017). A survey showed only 24% of able individuals with AS were driving and fear to drive was a common reason for not driving (Cox et al, 2012).

Objectives: This study tested through a pilot open trial a novel, community-based intervention teaching executive functioning and emotion regulation skills required to drive through a manualized group program paired with individualized graded exposures on a driving simulator. Multiple outcomes were assessed (ratings and simulator performance) across informants (self, parent) and satisfaction.

Methods: A total of 19 teen/adults (μ= 20.53 SD=4.40 yrs; 15-29 yrs) participated. The participants were male (95%), somewhat race/ethnically diverse (26%), 32% teens (<18 yrs), 47% in High School, 26% graduated with diploma or certificate and 26% participated in college. The CBID curriculum was delivered over 10 weeks with 90minutes active group sessions. The curriculum combines cognitive-behavioral therapy strategies such as 1) identifying and changing anxious or negative thoughts to positive, rational thoughts, 2) emotional awareness and management skills, and 3) use of practicing behavioral skills through graded step by step exposures with cognitive enhancement strategies that targeted executive functioning (EF) skills of contextual awareness, sustaining attention, shifting attention, cognitive flexibility, problem-solving and goal-oriented thinking and behaviors. EF skills were taught first. The simulator consisted of a steering wheel with turn signals, a wide screen monitor and foot pedals (gas and brake). Pre and post assessments include a full battery of assessments including: Anxiety (STAI), Driving Cognitions (DCQ), Driving Attitude (DAS) and Driving Simulator performance.

Results: Overall there was high completion rates with 53% of the participants attending every session and another 30% missing only 1 session. 100% of the participants reported an attitude change towards driving to be more positive about learning to drive and less anxious or apprehensive about driving. 94% demonstrated improved driving skills as recorded on the driving simulator (refer to results below). 100% of participants demonstrated increased motivation by participating in 1 or more driving related activity (practice driving, studying for driving exam, enrolling in course, reading DMV book, taking driving test, etc.) 100% of families reported usefulness of the CBID intervention. After the program, up to 2 months post group 47% of the participants obtained either their drivers permit or license.

Conclusions: This study demonstrates that CBID intervention is feasible, acceptable and positively impacts teens/ adults with ASD towards obtaining a drivers' license. Participants reduced driving anxiety, increased driving attitudes and behaviors and almost half pursued and obtained their driver's license.

302.002 *(Oral)* Towards a Measure of Anxiety for Autistic Adults: Development and Evaluation of the Anxiety Scale for Autism- Adult (ASA-A)

J. Rodgers[1]*, K. J. Farquhar*[2]*, D. Mason*[3]*, S. Brice*[4]*, S. Wigham*[4]*, B. Ingham*[5]*, M. Freeston*[6] *and J. R. Parr*[7]*, (1)Institute of Neuroscience, Newcastle University, Newcastle Upon Tyne, United Kingdom, (2)Newcastle University, Newcastle, United Kingdom, (3)Social, Genetic and Developmental Psychiatry Centre, Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, United Kingdom, (4)Institute of Neuroscience, Newcastle University, Newcastle upon Tyne, United Kingdom, (5)Northumberland Tyne and Wear NHS Foundation Trust, Newcastle upon Tyne, United Kingdom, (6)Newcastle University, Newcastle upon Tyne, United Kingdom, (7)Population Health Sciences Institute, Newcastle University, Newcastle upon Tyne, United Kingdom*

Background: Autistic adults display elevated rates of anxiety, significantly higher than in the general population. Anxiety in autistic adults impacts on quality of life and functioning and is associated with lower life satisfaction. It is essential that anxiety can be identified accurately to inform research and clinical practice. Questionnaires developed to identify anxiety in a neurotypical population may not be suitable for use with autistic people. Emerging evidence suggests that the presentation of anxiety may be different for autistic people compared to the general population and yet most of the tools used to assess anxiety in autism were developed for neurotypical adults. The lack of measures that have been validated in this population hinders attempts to evaluate treatments. An anxiety measure developed and validated specifically for autistic children is the Anxiety Scale for Children – Autism Spectrum Disorder (ASC-ASD). The ASC-ASD consists of four subscales (Performance Anxiety, Uncertainty, Separation Anxiety, and Anxious Arousal.

Objectives: The objectives of this study are

- Through consultation with autistic adults to modify the ASC-ASD for autistic adults
- Investigate the factor structure, further refine the scale, and explore its psychometric properties

Methods: Through consultation with autistic adults and professionals working with autistic people a preliminary self-report anxiety measure was developed. 551 autistic adults were recruited from the Adult Autism Spectrum UK-Cohort study and completed the measure and another measure of anxiety and depression (The Hospital Anxiety and Depression Scale; HADS). The measures were completed again after one month to determine test-retest reliability. The sample was split (stratified by age and gender) to enable exploratory and confirmatory factor analyses to be undertaken on different samples. Internal consistency and convergent and divergent validity analyses were undertaken and receiver operator curve (ROC) analyses were completed to investigate sensitivity and specificity and identify an indicative clinical cut-off.

Results: Factor analyses identified three factors; Anxious Arousal, Uncertainty and Social Anxiety with confirmatory factor analyses indicating that a bi-factor solution with orthogonal general and specific factors was an adequate fit. Bi-factor analyses suggested that minimal measurement bias would occur if the scale was treated as unidimensional so the total score could be used as a valid measure of anxiety. There is good evidence of convergent and divergent validity for the total score against the HADS, an established measure of anxiety and depression. A ROC analysis indicates a score of 28 could be considered as an indicative clinical cut-off. Test-retest reliability of the final scale was excellent.

Conclusions: The Anxiety Scale for Autism – Adults (ASA-A) is the first self-report anxiety questionnaire specifically developed and validated for autistic adults. The ASA-A was found to have promising psychometric properties. Preliminary evaluation of the measurement properties indicate that the scale will be a useful tool in research and clinical contexts.

302.003 *(Oral)* Evaluating How Social Anxiety, Autistic Traits, and Social Network Changes Influence University Transition Outcomes Amongst First-Year Autistic Students

J. Lei[1]*, M. Brosnan*[2]*, C. Ashwin*[3] *and A. Russell*[4]*, (1)Centre for Applied Autism Research, University of Bath, Bath, United Kingdom, (2)Centre for Applied Autism Research, University of Bath, Bath, United Kingdom of Great Britain and Northern Ireland, (3)University of Bath, Bath, United Kingdom of Great Britain and Northern Ireland, (4)Psychology/Centre for Applied Autism Research, University of Bath, Bath, United Kingdom*

Background: Students transitioning to first year of university face significant changes in their social network structure (SNS) and access to support. Between 28-50% of autistic students also experience high levels of social anxiety, further affecting their ability to establish a new supportive SNS at university. Using a longitudinal design to help partition the long-term impact of social anxiety, autism symptom severity, and changes in SNS and perceived social support (PSS) on transition outcomes can help stakeholders develop more focused interventions supporting autistic students.

Objectives: Longitudinal study assessing:

1) Changes in SNS/Perceived Social Support (PSS) across first-year of university

2) How changes in SNS/PSS relate to university transition outcomes

3) Whether social anxiety or autism symptom severity influence transition outcomes

Methods: 21 first-year autistic students (age: M(SD) = 18.33(0.48) years; 11 Male) completed self-report measures on 3 occasions with 3-month intervals, during October (T1), December (T2), and March (T3) of first year at university (Table 1). At T1, students completed: 1) Autism Quotient-28; 2) Social Anxiety Scale for Adolescents (SAS-A); 3) Social Network and Perceived Social Support (SNaPSS). SNaPSS measures a) SNS: name up to 20 network members who are important to you; b) PSS: the frequency and quality of support each network member provides across academic, daily-living, and socialisation areas. At T2 and T3, students completed SNaPSS and SAS-A to assess changes in SNS, PSS, and social anxiety over time, and Student Adaptation to College Questionnaire (SACQ) to assess university transition outcomes. Due to small sample size, we used non-parametric data analyses included Friedman's Test with Bonferroni-corrected Wilconxon signed-rank test as a post-hoc, and Kendall's tau-b correlations.

Results: Objective 1: Overall, students reported no significant changes in social network size or density over time, though networks contained a significantly greater proportion of friends than family/university staff (Z = -2.52, p = .012; Z = -.384; p < .001, respectively) (Figure 1 shows one example network highlighting individual differences). For PSS, students found family and friends provided more frequent and better-quality support than university staff (Z = -3.53 to -3.10, p <.002). Students perceived they received more frequent and better-quality support in daily-living tasks relative to academic and socialisation areas (Z = -3.04 to -2.62, p <.01). Objective 2: Changes in SNS/PSS over time were not associated with transition outcomes at T2/T3. Objective 3: Higher levels of social anxiety over time, not autism symptom severity, was associated with poorer academic, personal/emotional adjustments, and attachment to institution (t_b=-.34 to 0.41, p = .009 to .034) across T2/T3.

Conclusions: Although autistic students sought support from new friendships during first-year university transition, family members continued to provide high levels of support. Changes in SNS/PSS did not buffer against the negative impact of having high co-occurring levels of social anxiety on autistic students' university transition outcomes. Directly targeting social anxiety (a frequently co-occurring condition in autistic young people) during university transition might encourage better transition outcomes for autistic students. Future studies with larger sample size can compare social network changes against typically developing students.

302.004 *(Oral)* Are Elevated Autistic Traits Associated with Greater Risk of PTSD in Older Adults?

G. R. Stewart[1]*, R. A. Charlton*[2] *and F. Happé*[1]*, (1)Social, Genetic and Developmental Psychiatry Centre, Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, United Kingdom, (2)Goldsmiths, University of London, London, United Kingdom*

Background: Research with young adults has begun to explore possible associations between autism/autistic traits and vulnerability to Post Traumatic Stress Disorder (PTSD). Large scale studies have not been conducted, however, nor have associations been explored in older adults.

Objectives: This study will explore differences in the frequency and types of traumatic experience and symptoms of post-traumatic stress among older adults with/without elevated autistic traits.

Methods: Using baseline cross-sectional data from the ongoing online PROTECT study, a total of 20,220 adults age 50 years+ reported whether they experience behavioural qualities commonly observed in the autistic spectrum. Approximately 1%, 251 individuals, were identified as endorsing elevated autistic traits in childhood and currently, referred to henceforth as the Autism Spectrum Trait (AST) group. Differences between the AST and an age mean/range and sex ratio matched Control Older Adults (COA; n = 9,179) group were explored in self-reported traumatic experience throughout their lives and current symptoms of post-traumatic stress.

Results: The experience of childhood and adulthood trauma and symptoms of post-traumatic stress were found be negatively associated with age in the COA group, but not in AST. Individuals in the AST group demonstrated significantly higher rates of self-reported traumatic events both childhood and adulthood, including emotional, physical and sexual abuse. Furthermore, elevated current symptoms of post-traumatic stress were reported by AST when compared to COA. An interaction was also observed between autistic traits and severity of traumatic experience, with those in the AST group reporting elevated rates of current post-traumatic stress symptoms increasing with severity of traumatic experience when compared to COA. This interaction remains significant when controlling for current depression and anxiety symptoms.

Conclusions: The findings from the current study suggest that elevated autistic traits may increase the likelihood of experiencing trauma throughout childhood and adulthood. Furthermore, older adults with elevated autistic traits may be at a greater risk for experiencing post-traumatic stress symptoms in later life when compared to those with few autistic traits. Further work is needed to see whether these results extend to individuals meeting diagnostic criteria for autism.

POSTER SESSION — ADULT OUTCOME: MEDICAL, COGNITIVE, BEHAVIORAL, SOCIAL, ADAPTIVE, VOCATIONAL

401 - Adult Outcome: Medical, Cognitive, Behavioral, Social, Adaptive, Vocational Posters

401.001 *(Poster)* "You Have to Find It Yourself": Experiences of Support Following Adult Autism Diagnosis

Y. Huang[1,2]*, S. Arnold*[1,2]*, K. R. Foley*[1,3] *and J. Trollor*[1,2]*, (1)The University of New South Wales, UNSW Sydney, NSW, Australia, (2)Cooperative Research Centre for Living with Autism (Autism CRC), Brisbane, QLD, Australia, (3)Southern Cross University, Bilinga, QLD, Australia*

Background: Changes in autism awareness and diagnostic criteria over time has led to increasing numbers of adults undergoing autism assessment. Although adults generally described receiving an autism spectrum diagnosis as a positive experience, accessing formal support services is often difficult. Research in the UK (e.g. Crane et al., 2018; Jones et al., 2014) identified problems including a lack of clear pathways to support following diagnosis and mismatches between available services and adult needs. Existing studies also identified informal sources of post-diagnosis support such as families and online autism groups, but these have not been explored in detail. There is little known about support experiences of adults receiving an autism spectrum diagnosis in Australia and elsewhere. A qualitative exploration would help elucidate the roles of various sources of support and provide insights into ways which services could provide optimal support to these adults.

Objectives: To understand adults' experiences of seeking and receiving support from formal and informal sources following an autism spectrum diagnosis.

Methods: Australian adults (*n*=6, age 26-83, 3 male, 2 female, 1 non-binary; at time of abstract submission) who received first-time autism diagnoses at age ≥18 took part in individual semi-structured interviews. Participants were recruited via the Australian Longitudinal Study of Adults with Autism (ALSAA), the Study of Australian School-Leavers with Autism (SASLA), autism diagnostic services, and various autism and disability-related organisations in Australia. The interview schedule was developed with advisory support from autistic adults, and contained seven questions on initial diagnosis, support received, and desired areas of support. To support participants' communication needs and preferences, these interviews were conducted via a choice of formats including face-to-face (*n*=1), video link (*n*=1), telephone (*n*=2), and email (*n*=2). Thematic analysis was conducted to identify recurrent patterns of meaning across responses. Participant recruitment, interview and analysis are ongoing.

Results: Preliminary analysis identified several themes relating to formal support, informal support, barriers, and support needs. Participants generally viewed formal support as either unnecessary or inaccessible, with inadequate provisions from both mainstream mental health and autism-specific services. Informal support from family and social relationships served the functions of emotional connection, guidance, and acceptance. Participation in online autistic support groups uniquely provided a sense of community and belonging, though excessive sharing of negative experiences was viewed as a detrimental aspect of these environments. Barriers to obtaining support included confusion navigating support pathways, concern over not qualifying for services, stigma, and financial difficulties. Participants expressed the need for clear signposts to service providers, autism-informed adult psychological services, face-to-face peer support groups, and assistance finding and negotiating suitable employment arrangements.

Conclusions: Inadequate support may potentially lead to detrimental outcomes in terms of mental health, social connectedness, and employment. There is a need for support services to recognise and adapt to the needs of late-diagnosed autistic adults, as well as for improved connection between diagnostic and support services. Considering the prevalence of mental health difficulties and dissatisfaction with mainstream treatment, further research on adapting psychotherapies to the autistic population would be invaluable.

401.002 *(Poster)* #Takethemaskoff: Unmasking Autistic Representation

E. Radulski*, Olga Tennison Autism Research Centre & Department of Social Inquiry, La Trobe University, Bundoora, VIC, Australia*

Background: In June 2018, a collective of Autistic Autism activists initiated the #TakeTheMaskOff campaign on Twitter. The campaign highlights and problematises the expectation that Autistic people 'mask' their Autistic traits and present as Neurotypical (non-Autistic) to achieve social inclusion. Contemporary understandings of Autism are situated predominantly within the Medical Model of disability, which understands Autism as a biologically disabling condition that poses its own barriers to good outcomes. However, literature on masking indicates that it leads to poor outcomes for Autistic people by increasing stress, anxiety, depression, and poor self-image (Sasson and Morrison 2019). Furthermore, many Autistic adults report feeling pressured to mask to achieve social inclusion and obtain jobs (Cage 2019). Accordingly, the #TakeTheMaskOff campaign raises the following questions: What are the social drivers of masking, and can they be conceptualised as oppressive social constructs which disable Autistic people through enforcing Neurotypical Normativity? This study aims to address these issues through the Social Model of Disability. It explores whether masking may constitute a form of assimilation reflective of Neurotypical privilege, and how this relates to social, educational, and employment outcomes for Autistic adults.

Objectives: As an Autistic researcher, I aim to respond to expert and community concerns that the under-representation of Autistic researchers hinders Autism research (Pellicano 2014). Furthermore, this is an intersectional study with a strong focus on cultural, gender, sexual, and ethnic diversity, and their relationship to masking. This presentation will address the social drivers of masking and their consequences for Adult outcomes —ranging from subjective to socio-economic wellbeing—by adopting a sociological approach, thereby taking existing research on masking in new directions.

Methods: Two key methodological approaches are used. Firstly, Participatory Action Research (PAR), which relies upon participant engagement to understand culture and produce social change. The research findings which will be presented are gathered from an online survey representing a diverse selection of autistic participants, who are questioned on their social identities and experiences of masking, alongside techniques that might help them unmask. These data on the social drivers of masking will inform the development of a set of Best Practice Principals—which will be tested in a follow-up study—to facilitate unmasking and improve socioeconomic and wellbeing outcomes.

Secondly, an autoethnographic approach is used, which relies on critical reflection from the author's lived experience of socioeconomic marginality and inequality as an Autistic person, to shape both the overall structure and method of the study, alongside the analysis of its data, and shaping of its outcomes in response to the needs of the Autistic community.

Results: Data collection is currently underway, and will indicate how, why, and in which situations Autistic adults mask, alongside which factors contribute to facilitating unmasking.

Conclusions: In response to the #TakeTheMaskOff campaign this project seeks to improve Autistic socioeconomic outcomes by shifting the focus from assimilatory masking to external understanding. This project also contributes an Autistic perspective to research which begins to address community concerns over Autistic underrepresentation in the field. An intersectional approach produces findings sensitive to the diversity of the Autistic community.

401.003 *(Poster)* A Comparison of Functioning between Young Adults with and without Employment History

K. Coleman[1]*, A. Lyon*[1]*, M. Mitchell*[1]*, C. J. Smith*[2] *and N. L. Matthews*[1]*, (1)Southwest Autism Research and Resource Center, Phoenix, AZ, (2)Southwest Autism Research & Resource Center, Phoenix, AZ*

Background: The majority of young adults with autism are unemployed or underemployed (Chen et al., 2015). Whereas some research has examined predictors of competitive employment in this population (Chiang et. al, 2013), there is a gap in the literature regarding potential differences in functioning between adults with and without employment history.

Objectives: To compare young adults with and without employment history on measures of autism symptoms, intelligence, adaptive functioning (AF) and executive functioning (EF).

Methods: Participants were 21 young adults with a DSM-IV or DSM-5 ASD diagnosis (M age = 24.19, SD = 4.36) and at least one parent of each participant who participated in a larger mixed-methods study. Participants with employment history (n = 11) had been competitively employed for at least one year during adulthood. Participants without employment history had never been employed (n = 8) or had been previously employed, but for < 4 months (n = 2). All but one participant met criteria for autism or autism spectrum on the ADOS-2 (Lord et al., 2012) and all participants had a composite IQ of 70 or above (KBIT-2, Kaufmann & Kaufmann, 2004). Each parent reported on their young adult's AF and EF by completing the Adaptive Behavior Assessment System (ABAS-3; Harrison & Oakland, 2017) and the Behavior Rating Inventory of Executive Function – Adult Version (BRIEF-A; Roth et. al, 2013).

Results: Reported in Table 1, participants with employment history were significantly older than participants without employment history and the effect size was large. There were no significant differences in composite IQ, AF, or EF. There was a difference on the behavior regulation index (BRI) of the BRIEF-A that was approaching statistical significance and the effect size was large. Specifically, participants without employment history had less impaired behavioral regulation than participants with employment history. Post-hoc independent samples t-tests on the clinical scales that make up the BRI indicated that participants with employment history were significantly more impaired on the inhibit ($t(18) = -2.12$, $p = .05$) and self-monitor ($t(18) = -2.11$, $p = .05$) subscales.

Conclusions: Participants with employment history were, on average, five years older than participants without employment history. This may reflect a high level of vulnerability for unemployment in the years immediately after high school (Shattuck et al., 2012). Surprisingly, young adults with autism who had sustained employment history demonstrated less behavioral regulation than participants without employment history. It is possible that reduced inhibition and self-monitoring may be adaptive for individuals with autism such that they may be more likely to seek out employment opportunities than individuals who are more behaviorally inhibited. This interpretation is consistent with evolutionary theories of ADHD that suggest that impulsiveness, high energy, and risk-taking were adaptive as the human species evolved, and may continue to be adaptive in modern society (Shelley-Tremblay & Rosen, 1996). With replication, the current findings suggest that young adults with autism with relatively high levels of behavioral regulation may need additional support in the form of initiating and maintaining meaningful contacts related to employment.

401.004 *(Poster)* A Continuum of Learning and Attention Difficulties in Females, Extending from FMR1 Premutation to Full Mutation

L. V. Gabis[1], *Y. Levy Bannet*[2], *S. David*[3], *M. Shaham*[4], *O. Leon Attia*[5] *and S. Shefer*[6], *(1)Pediatrics, Sheba Medical Center, Rehovot, ISRAEL, (2)Child Development Center, Sheba Medical Center, Ramat Gan, Israel, (3)Child Development Center, Sheba, Ramat Gan, Israel, (4)Statistics, University of Haifa, Haifa, Israel, (5)Child developement Center, Sheba Medical Center, Tel Hashomer, Israel, (6)Shild Development Center, Sheba Medical Center, Tel Hashomer, Israel*

Background: Although once thought to be asymptomatic, it is now well documented that both female as well as male premutation carriers of Fragile X expanded gene might suffer from associated medical comorbidities, beyond Fragile X Associated Tremor and Ataxia (FXTAS) and Fragile X Associated Premature Ovarian Failure (FXPOI).

Autism Spectrum Disorder and Intellectual Disability are a hallmark of Fragile X Syndrome (FXS). However, when examining other presumably asymptomatic female family members of a patient with FXS, such as mothers, sisters and aunts, insidious deficits and complains occur. Wether fragile-X premutation has a subtle effect on cognition has been under debate for several years.

Objectives:

We assume that there is a continuum of specific learning and attention deficits that correlate with increased number of CGG repeats on FMR1 gene.

Methods: 98 women were referred to our center due to a related Fragile X Syndrome (FXS) patient, mainly offspring or sibling. Variable data was collected from index cases and relatives. This is an ongoing project. The information included genetic results of CGG repeats, demographic information, structured questionnaires for ADHD, learning disabilities of language and mathematics, and independence. The group carrying FMR1 premutation was analyzed separately and compared to the group carrying full mutation. Females with fully symptomatic Fragile X Syndrome, were excluded.

Results: When analyzed as a continuum, there was a significant increase in the following complaints correlated with higher number of repeats:

- labor difficulties and C-Section
- FXPOI
- Not being able to drive a car
- ADHD severity
- Learning disabilities and specifically - language difficulties, dyscalculia, inattentiveness, spelling difficulties
- Executive dysfunction

79 women carried premutation of 56-199 repeats and 19 women carried a full mutation of more than 200 CGG repeats on the FMR1 gene. When observed within the premutation group as compared to full mutation group, we found a linear correlation FXPOI, ADHD, spelling and organization skills. Distractibility correlated inversely with CGG repeats.

Conclusions: Our study supports the findings that the premutation of FMR1 allele may lead to other disorders in addition to FXTAS and FXPOI. ADHD and learning difficulties correlate with increased number of CGG repeats and are prevalent features of premutation and of full mutation in females.

401.005 *(Poster)* A Critical but Understudied Aspect of Adulthood: Autism Traits Differentially Predict Parenting Behavior

E. A. DeLucia*, K. Stanton and C. G. McDonnell, Department of Psychology, Virginia Polytechnic Institute and State University, Blacksburg, VA*

Background: Although it has long been acknowledged that individuals with autism spectrum disorder (ASD) often become parents, very little is known about how distinct ASD traits relate to parenting style. This is a striking gap in the literature, as understanding how ASD traits relate to parenting would allow for the development of appropriate supports for parents with ASD. Although the small existing literature suggests that overall ASD traits may be related to lower parental involvement, more difficulty with parenting, and lower parenting satisfaction, it is imperative to (1) examine a wider range of parenting outcomes, (2) specify which particular aspects of ASD symptoms most strongly predict parenting, and (3) consider whether ASD traits predict parenting over and above other variables critical to parenting behavior, such as comorbid internalizing and ADHD symptoms.

Objectives: The current study aimed to examine the association between self-reported ASD trait domains and a diverse range of parenting practices and beliefs. We also aimed to examine whether ASD traits predicted parenting above and beyond cooccurring ADHD and internalizing symptoms.

Methods: Community parents (n=138; 72% female) with children under the age of 18 years completed the Broad Autism Phenotype Questionnaire (BAPQ) to assess core ASD traits (aloofness, pragmatic language difficulties, rigidity). To examine parenting practices and beliefs, participants completed the Alabama Parenting Questionnaire (APQ) and the Parental Emotional Styles Questionnaire (PESQ). Parents reported on comorbid ADHD symptoms using the Adult ADHD Self-Report Scale (ASRS) and internalizing psychopathology (e.g., depression, social anxiety, panic, and obsessive-compulsive symptoms) using the Inventory of Depression and Anxiety Symptoms (IDAS-II). First, Pearson correlations between BAPQ subscales and the parenting measures were examined. Second, hierarchical regressions were used to examine the effects of ASD traits on parenting attitudes over and above comorbid ADHD and internalizing symptoms.

Results: Correlations among study variables are presented in Table 1. The BAPQ subscales demonstrated unique patterns of correlations with the parenting outcomes. BAPQ Pragmatic Language Difficulties were correlated with nearly all of parenting outcomes, whereas BAPQ Aloofness and Rigidity related more specifically to unique parenting outcomes. Hierarchical regression results are presented in Table 2. For all parenting outcomes except Inconsistent Discipline, the BAPQ subscales explained significantly more variance than ADHD and Internalizing symptoms. In particular, above and beyond all control variables, pragmatic language difficulties predicted less emotion coaching, more inconsistent discipline, and worse monitoring. Aloofness predicted less emotion dismissing, less positive parenting, and less involvement. Rigidity uniquely predicted more emotion dismissing.

Conclusions: Overall, results indicate that ASD traits strongly predict parenting practices over and above the effect of other relevant factors including ADHD and internalizing symptoms. Moreover, these findings suggest that distinct dimensions of ASD traits show unique patterns of relations with parenting practices. In particular, Pragmatic Language difficulties were associated with difficulties across a range of different parenting domains. Replication in a clinical population would further support the importance of developing targeted parenting supports for adults with ASD, perhaps with an emphasis on pragmatic language deficits.

401.006 *(Poster)* A Narrative Approach to Career Identity Construction of Adults with ASD

Y. Goldfarb[1]*, E. Gal*[2] *and O. Golan*[3]*, (1)Department of Occupational Therapy, University of Haifa, Haifa, Israel, (2)University of Haifa, Haifa, Israel, (3)Department of Psychology, Bar-Ilan University, Ramat-Gan, Israel*

Background: Transition into adulthood presents many challenges for individuals with ASD. Supports provided through childhood and adolescence are no longer available, and the structured educational environment is substituted with an uncertain and ambiguous reality. While educational programs support and promote success, the labor-market has a stricter set of rules, expecting job seekers to adjust and conform in order to achieve stable employment (Siegel 2018). Career identity is considered one of the core foundations for employability (Fugate et al. 2004). It derives from sequences of work-related experiences, assimilated into a meaningful structure of ‘‘who I am’’ in relation to employment. Self-perceptions of goals; values, interaction styles, and more can form a clear career identity that provides a compass, pointing to personal goals or aspirations. While some theorists understand career identity as an internal cognitive structure, others argue a constructivist approach, situating career identity within social-cultural concepts and norms (LaPointe, 2010). This theoretical lens, illuminating the intersection between self and society, seems highly relevant for expanding our knowledge on employment of adults with ASD, where difficulties in integration are known to occur.

Objectives: The study aims to explore how adults with ASD perceive their work experiences and construct their career identities.

Methods: Participants were 12 individuals (3 females, aged 28-47y), with a formal ASD diagnosis, and work experience of at least six consecutive months. Educational level ranged from a high-school diploma to a master's degree. Narrative interviews were carried out (Rosenthal, 1993), given that narratives are considered a primary genre for discovering the dynamics of identity (LaPointe, 2010). Participants were invited to share their work experience, with minimal interruption. Following, specific questions were asked, covering subjects or narrative gaps that called for further inquiry. Dialogical data analysis was employed, taking into account different aspects of the narratives such as: content, structure, function and context (smith 2016).

Results: Data analysis revealed that career identity is crafted through a process of *negotiation* between self-concepts and work-related social constructs. Participants portrayed various *dynamics of positioning* within the negotiation process: resistance; contingency; compromise; and integration. Most narratives demonstrated movement between at least two of these dynamics, expressing the complex, evolving nature of career identity. Socially acceptable work constructs were often challenged by the participants, from questioning common career trajectories and goals, through criticizing the employer-employee balance of power, to undermining the very idea of work as the only mean for subsistence. Data analysis further found ASD diagnosis to be a key component in the narratives provided. Specifically, when diagnosis was received in the midst of the career story, it usually influenced a positive shift in career identity.

Conclusions: The processes of *negotiating* and *positioning* suggested by the results in this study, enhance the role of individuals with ASD as active agents, constructing their career identity within labor market constraints (Mclean & Syed 2016). Applications of the narrative approach can offer a therapeutic opportunity for adults with ASD to reflect on work experiences and form a meaningful construct, establishing a clear career identity and increasing employability.

401.007 *(Poster)* A Qualitative Analysis of Employers’ Perspectives on the Hiring and Employment of Autistic Individuals

J. Albright*, S. Kulok and A. Scarpa, Virginia Polytechnic Institute & State University, Blacksburg, VA*

Background: Despite recent federal and state initiatives to promote inclusion of people with disabilities into the workforce, employment rates for individuals with a disability remains low (up to 76.8%; Lauer & Houtenville, 2018); and even lower for autistic individuals (<38%; Roux, Rast, Anderson, & Shattuck, 2017). The impact of contextual factors, such as the organizational culture of the employer, are important to consider when attempting to address the issue of unemployment (Erickson, Von Schrader, Bruyere, & VanLooy, 2014); however, studies have yet to thoroughly examine employer perspectives of hiring individuals with ASD in the United States (Black et al., 2019).

Objectives: To understand: 1) employers’ perspectives on factors that influence the decision to hire an autistic individual, 2) employers’ needs in order to hire and integrate an employee with ASD into the workplace, and 3) the skills employers perceive as important to workplace success.

Methods: Hiring personnel from thirteen businesses in the U.S. were interviewed (age range = 29-64 years; 53.85% male, n=7; 46.15% female, n=6). Three participants reported having had previous experience hiring an autistic individual. Businesses were either ‘small’ (i.e., ≤250 employees; *n*=11) or ‘large’ (i.e., 500-1,000 employees; *n*=2).

Audio recordings of the interviews were transcribed. Data were analyzed using a data-driven thematic approach at the semantic level (Braun & Clarke, 2006). Interview transcripts were read, content was discussed, and preliminary codes were identified. Each transcript was independently coded by two trained coders using QSR NVivo 12 Plus software (2018). Any coding discrepancies were resolved through discussion and consensus. Codes were then reviewed, content themes were generated, and themes were refined as needed.

Results: Employers were able to identify several benefits of hiring an autistic individual, including preference for routine and repetitive work tasks and attention to detail. In addition to individual skills, employers identified the added benefits that hiring individuals with ASD can have on their broader workplace and community (i.e., promote diversity in the workplace). In addition to these benefits, employers also described the reservations they would have about hiring an autistic individual, which were largely related to symptomology (i.e., social communication challenges, cognitive inflexibility, sensory sensitivities) and the ways that these symptoms may negatively impact work performance.

Employers also identified what they would need in order hire an autistic individual and integrate them into the workplace successfully. Employers described a desire to understand more about the individual whom they are hiring, including the individual characteristics of the person, as well as information about their diagnosis. Employers also reported a desire to understand the types of workplace accommodations that are needed to support an employee with ASD.

Employers identified five skill areas that are important to workplace to success, with an emphasis on soft skills such as emotion regulation, social skills, problem solving, and planning.

Conclusions: Results suggest there are numerous benefits to employing individuals with ASD that should be emphasized during the hiring process. Several concerns also emerged, which can be addressed through workplace accommodations, employment preparation programs, and workplace disability diversity trainings.

401.008 *(Poster)* A Qualitative Study on Permanent Employment with Talents Rehabilitation and the Life of Individuals with Autism Spectrum Disorders: Based on the Experiences and the Perceptions of Autistar Designers and Their Parents

S. Lee[1], *S. A. Yoon*[2], *H. Park*[1,3], *J. Na*[1] *and Y. Lee*[1,4], *(1)Special Education, Ewha woman's Univ., Seoul, Korea, Republic of (South), (2)Child and Adolescent Hospital, Seoul National Univ. Hospital, Seoul, Korea, Republic of (South), (3)Autistar Corporation, Seoul, Korea, Republic of (South), (4)Job coaching team, Autistar Corporation, Seoul, Korea, Republic of (South)*

Background: Successful employment is perhaps the primary aspiration for most individuals. Postsecondary employment opportunities, however, have traditionally been very limited for individuals with ASD(O'Brien & Daggett, 2006). The reason is based on particularly complicated for an adolescent or adult with ASD due to unique communication and social impairments (Müller, Schuler, Burton & Yates, 2003). Job opportunities are also limited and employment outcomes revealed negatively in Korea. Seven years ago first social enterprise, Autistar was estabilished to support individuals with ASD in Korea. Autistar is a design company, appreciating the artistic ability of young people with ASD. They recruit and train designers with ASD. All products of AUTISTAR are developed with their precious artistic senses and abilities.

Objectives: This study was implemented to inquire into the permanent work experiences with talents rehabilitation and their impact on the life of individuals with autism spectrum disorders and their families.

Methods: For the purpose of the study, we conducted in-depth interviews and focus group interviews of designers working at the company Autistar which recruits individuals with autism spectrum disorders based on their talents and their parents. Six out of 10 designers who were able to communicate sufficiently for the purpose of the study and 10 parents were participated.

Results: As the results of the qualitative analysis, four major themes and 13 sub-themes were emerged. Four major themes are the following: (1) past job-related experiences, (2) Autistar work experiences, (3) future growth and development, (4) difficulties and support needs based on characteristics of autism spectrum disorders.

Conclusions: Based on the results of the study, implications and suggestions were discussed centering around expanding employment based on talents rehabilitation of individuals with autism spectrum disorders, providing continuing support in work site, increasing high-quality outcome of employment, and establishing a systematic supporting system

401.009 *(Poster)* Achieving Employment Success in Adult Autism-Specific Medicaid Programs

L. Shea[1], *S. Nonnemacher*[2], *P. F. Turcotte*[3], *K. Verstreate*[4] *and R. Wall*[5], *(1)A.J. Drexel Autism Institute, Philadelphia, PA, (2)Pennsylvania Bureau of Autism Services, Harrisburg, PA, (3)Drexel University, Philadelphia, PA, (4)Drexel University, Policy and Analytic Center, A.J. Drexel Autism Institute, Philadelphia, PA, (5)Office of Developmental Programs, Department of Human Services, Pennsylvania Bureau of Supports for Autism and Special Populations, Harrisburg, PA*

Background: Employment is key marker of success during the transition to adulthood and maintaining employment is critical throughout adulthood. However, poor employment outcomes for individuals on the autism spectrum have been documented across the US and multiple systems that share a goal of supporting autistic individuals throughout the employment process. In one large northeastern state in the US, two programs funded through Medicaid (public health insurance) formulated to serve adults on the spectrum have served as emerging models for structuring service delivery to adults, including employment support services. Examining employment outcomes across service models is an important step to identifying policies and programs that may be replicable to improve employment outcomes among autistic adults.

Objectives:

- Describe the employment rate among autistic adults in two Medicaid-funded programs.
- Identify the characteristics of individuals and employment support services among autistic adults who achieved employment and maintained it over time compared to those who did not gain or maintain employment.

Methods: A series of seven monitoring questions focused on employment status and characteristics of individuals enrolled in two adult autism-specific Medicaid programs was implemented in 2017 to regularly track employment outcomes among individuals enrolled. The seven monitoring questions ask if an individual was employment in competitive integrated employment. Competitive integrated employment is defined as employment that pays at or above federal or state minimum wage (whichever is higher) and is based in a location where employees interact with people without a disability. Additional employment monitoring questions ask about the number of hours worked per week, if the individual receives benefits, the type of job, and if the individual is self-employed. Demographic characteristics of individuals enrolled in the autism-specific Medicaid programs were identified using descriptive analyses. Logistic regression was used to identify characteristics of individuals who were employment compared to individuals who were not employed.

Results: The sample included 738 adults on the spectrum with continuous employment monitoring questions completed over a two year span (2017 – 2019). The average age of the adults included was 29.9 years old, with a range of 21-64. Most participants were male (78.2%) and white (83.3%). Almost forty percent (39.7%) of the individuals had successful employment during the observation period. The most common job types were Food Preparation and Serving Related (25.6%), Sales and Related (22.9%), and Building and Grounds Cleaning and Maintenance (18.43%). Most individuals (71.9%) worked 21-35 hours per week. Regression results showed that adults on the spectrum who identify as African American were more likely to have employment (OR=1.98 CI 1.095-3.594) compared to those were white. Additional data analytics will include analysis of employment maintenance over time, seasonality trends, and self-employment compared to traditional employment models.

Conclusions: The national rate of employment among autistic adults in the US has been estimated at 22%. Identifying policies and programs that can boost employment among adults on the spectrum provides opportunity to grow and replicate models of success. By doubling the national employment rate among autistic adults, two Medicaid programs provide promising practices and opportunity for growth.

401.010 *(Poster)* An Autistic-Led Cross-Sectional Survey of the Barriers to Healthcare Experienced By Autistic Adults: Consequences & Policy Implications.

M. E. Doherty[1]*, J. D. O'Sullivan*[2] *and S. D. Neilson*[3]*, (1)Anaesthesia, Our Lady's Hospital, Navan, Ireland, (2)Anaesthesia, Waterford General Hospital, Waterford, Ireland, (3)Independent Researcher, Cork, Ireland*

Background: Autism is associated with reduced life expectancy, poor physical and mental health, and increased prevalence of gastrointestinal & sleep disorders, epilepsy, obesity, hypertension, diabetes and stroke. In-hospital mortality is also increased. Previous studies have shown that barriers to healthcare are multi-factorial including challenges in communication, physician knowledge of autism, and sensory issues.

Objectives: To compare the self-reported barriers to healthcare amongst autistic adults with parents of autistic children and with non-autistic controls, and the self-reported consequences of such barriers.

Methods: A survey, "What do you wish your GP knew about autism?" was conducted at Autscape 2018, a conference organised by and for autistic people. Thematic analysis of N=75 responses was used to develop a 57-item online survey with recruitment of autistic participants, parents of autistic children and non-autistic controls via social media. Three main themes emerged: communication issues (notably difficulty using the telephone), sensory issues (e.g. crowded waiting areas), and executive functioning (notably difficulty planning appointments in advance). The online survey (N=1,980) was completed by 1,271 (64.2%) autistic adults, 406 (20.5%) parents and 303 (15.3%) control adults. 63.7% of autistic adults, 93.8% of parents and 85.0% of control respondents were female. Non-binary gender was expressed by 17.6% of autistic adults, 1.1% of control respondents and none of the parents.

Results: Difficulty visiting a GP when required was reported by 78.2% of autistic adults, 51.4% of parents and 34.9% of controls. The highest-rated barriers by autistic adults were deciding if symptoms warrant a GP visit (71.9%), difficulty using the telephone to book appointments (60.7%), not feeling understood (55.5%) and difficulty communicating with the doctor during appointment (53.0%). 74.3% of autistic adults reported that anxiety increased communication difficulty, significantly more than parents (25%) or controls (23.2%).

78.1% of autistic respondents avoid using the telephone, 61.1% avoid voicemail and 29.7% avoid face-to-face verbal communication, all significantly more frequently than parents or controls. Autistic adults more frequently experience physical mobility needs (15.8%), having nobody available to support hospital admission (15.1%), collection following surgery (17.7%), home care following discharge (24.9%), and childcare when unwell (5.8%).

Adverse health outcomes were reported by autistic adults substantially and significantly more frequently than parents or control respondents. These included untreated physical and mental health conditions, not attending specialist referral or screening programmes, requiring more extensive treatment or surgery due to late presentations, and untreated potentially life threatening conditions.

To facilitate attendance, autistic adults reported a need for online or text based appointment booking, first or last appointment of the day, a quiet place to wait, facility to email in advance the reason for consultation, and a sensory box in the waiting room, in all cases significantly more often than parents or control respondents. A significant level of non-registration with a general practitioner was noted.

Conclusions: Reduction of healthcare inequalities for autistic people requires that healthcare providers understand autistic culture and communication needs. Reasonable accommodations are legally and morally required, and adjustments for autistic communication needs are analogous to wheelchair ramps for the physically disabled.

401.011 *(Poster)* Are Elevated Autistic Traits Associated with Greater Self-Reported Self-Harm and Suicidal Ideation and Behaviours in Older Adults?

G. R. Stewart[1]*, R. A. Charlton*[2] *and F. Happé*[1]*, (1)Social, Genetic and Developmental Psychiatry Centre, Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, United Kingdom, (2)Psychology, Goldsmiths University of London, London, United Kingdom*

Background: Suicide has been identified as a leading cause of premature death in autistic populations. Studies have also documented that elevated autistic traits are associated with self-harm, suicidal ideation, and suicide attempts in the general population.

Objectives: This study will explore differences in the frequency and type of self-harm behaviours, and in prevalence rates of suicidal ideation and suicide attempts among older adults with/without elevated autistic traits.

Methods: Using baseline cross-sectional data from the ongoing online PROTECT study, a total of 20,220 adults age 50 years+ reported whether they experience behavioural qualities commonly observed in the autistic spectrum. Approximately 1%, 276 individuals, were identified as endorsing elevated autistic traits in childhood and currently, referred to henceforth as the Autism Spectrum Trait (AST) group. Differences between the AST and an age mean/range and sex ratio matched Control Older Adults (COA; n = 10,495) group were explored in self-reported frequency and type of self-harm behaviours, and in prevalence rates of suicidal ideation and suicide attempts.

Results: Self-harm and suicidal thoughts and behaviours were found be negatively associated with age in the AST and COA groups.Individuals in the AST group demonstrated significantly higher frequencies of self-reported self-harm behaviours than COA, including self-injury (e.g. self-cutting, scratching, hitting), intoxication (e.g., ingesting medication in excess of the normal dose, ingesting excessive alcohol, or ingesting recreational or illicit drug), swallowing dangerous objects or products, and stopping prescribed medication without consulting a medical professional. Furthermore, a higher total number of self-harming behaviours were reported by the AST group than COA. The AST group also report higher frequencies of suicidal ideation and suicide attempts, with a five to six-fold increase in likelihood of experiencing these behaviours when compared to the COA group. This pattern of results remains significant when controlling for current depression and anxiety symptoms.

Conclusions: The findings from the current study suggest that elevated autistic traits may increase the likelihood of self-harming behaviours, as well as the experience of suicidal thoughts and behaviours, including suicide attempts. Further work is needed to see whether these results extend to older adults meeting diagnostic criteria for autism.

401.012 *(Poster)* Associations between Coping and Mental Health Outcomes in Autistic Adults

M. Muniandy[1,2]*, A. L. Richdale*[1]*, S. Arnold*[3]*, J. Trollor*[2] *and L. P. Lawson*[1]*, (1)Olga Tennison Autism Research Centre, La Trobe University, Melbourne, VIC, Australia, (2)Cooperative Research Centre for Living with Autism (Autism CRC), Brisbane, QLD, Australia, (3)The University of New South Wales, UNSW Sydney, NSW, Australia*

Background: Mental health difficulties in autistic adults are common, with high prevalence rates of anxiety and depression. Coping literature suggests that an individual's approach to coping with stress can have a substantial impact on their mental health. Avoidance-oriented coping strategies have been associated with poorer psychological well-being, while approach-oriented coping strategies, with increased positive affect and mental health. Research into coping and its association with mental health in the autistic population is limited, especially in adults. Studies with autistic youth report mixed findings, with some suggesting an association between avoidance coping and fewer depressive symptoms, or a lack of relationship between approach/engagement coping and better emotional outcomes, both opposite to the general trend in the literature. These mixed findings raise the possibility of different trajectories from coping strategies to mental health outcomes in the autistic population. Understanding the coping-mental health relationship in autistic adults is critical to allow us to provide evidence-based support for the mental health difficulties prevalent in this population.

Objectives: To examine the relationship between coping style and mental health outcomes in a sample of autistic adults.

Methods: Our sample consisted of 255 autistic adults, aged 15-80 years, recruited through two longitudinal studies. Autism traits, coping style and psychological well-being were measured using the abridged version of the Autism-Spectrum Quotient (AQ-Short), Brief COPE, Patient Health Questionnaire-9 (PHQ-9), The DSM-5 Generalized Anxiety Disorder Dimensional Scale (DSM-5 GAD-D) and The Warwick-Edinburgh Mental Well-being Scale (WEMWBS). Three multiple regression models examined the six coping dimensions of the Brief COPE (i.e., Engagement, Support-seeking, Disengagement, Substance-use, Religious and Humour coping) as potential predictors of variance in depression, anxiety and positive well-being. Age, gender and autism traits were included as co-variates. Due to some non-normal distributions, analyses were performed using 2,000 resamples bootstrapping.

Results: For levels of depression: gender ($\beta = 0.103$), AQ-short ($\beta = 0.132$) and disengagement coping ($\beta = 0.601$) were significant predictors in the final model, accounting for 45.6% of total variance in the PHQ-9, $R^2 = 0.456$, $F(4, 224) = 46.97$, $p<0.001$.

For levels of anxiety: age ($\beta = -0.255$), gender ($\beta = 0.109$), AQ-Short ($\beta = 0.145$) and disengagement coping ($\beta = 0.589$) were significant predictors in the final model, accounting for a total variance of 47.7% in the GAD-D, $R^2 = 0.477$, $F(6, 225) = 34.17$, $p<0.001$.

For levels of positive well-being: AQ-Short ($\beta = -0.216$) and disengagement coping ($\beta = -0.435$) were significant predictors in the final model, accounting for a total variance of 28.1% in the WEMWBS, $R^2 = 0.281$, $F(3, 228) = 29.77$, $p<0.001$.

Conclusions: Our findings support existing literature reporting strong associations between disengagement coping and poorer levels of mental health. A lack of relationship between engagement coping and mental health outcomes suggests that these strategies, although adaptive in theory, may not have a significant beneficial impact for mental health in autistic adults. Our findings offer novel information regarding coping strategies to consider (i.e., a focus in reducing disengagement coping) when addressing support options for mental health difficulties in this population.

401.013 *(Poster)* Atypical Top-Down Processing in People with Autism Spectrum Disorder Revealed By Repeated Verbal Stimuli Under Noise

C. Itoi[1]*, N. Kato*[2] *and M. Kashino*[3]*, (1)Chuo University, Hachioji, Japan, (2)Medical Institute of Developmental Disabilities Research, Showa University, Tokyo, Japan, (3)NTT Communication Science Laboratories, Kanagawa, Japan*

Background: Individuals with autism spectrum disorder (ASD) often experience atypical sensory-perceptual processing. Our previous study compared the characteristics of an auditory illusion, called the verbal transformation effect (VT) between individuals with ASD and typically developed (TD) individuals. In VT, listeners perceive illusory changes for a repeated, physically unchanging verbal form. For example, the forms reported by a TD participant during a five-minute presentation of a word "banana" were "banana... banaN... panaN... panana... panaN... banaN" ("N" is a special mora in the Japanese phonological system). On the other hand, an ASD participant, for instance, reported "aru... danana... haiNnaino... hairando... heNnano ...panama", and another one reported "banana... peNdaNto... banama... tadano... peNdaNtu... pedanu", for the repeated presentation of "banana". We found that individuals with ASD perceive illusory changes more drastically deviated from the original form, and, to explain this, we assumed the existence of strong, unique top-down processing. This finding challenges the conventional view that people with ASD tend to perceive sensory signals as they are (i.e., less susceptible to illusions).

Objectives: In this study, we investigated the reason why individuals with ASD show such strong and unique top-down effects in perception in VT. To explore whether bottom-up information is less reliable in individuals with ASD, we conducted an ambiguous VT experiment by presenting background noise.

Methods: We conducted a listening test to compare perception of a repeated sound pattern, namely a spoken word, between ASD and TD groups. Prolonged listening to a repeated word without a pause may induce perceptual changes, which is known as the verbal transformation effect. To explore whether bottom-up information is less reliable in individuals with ASD, we conducted an ambiguous VT experiment by presenting background noise. For five minutes, participants diotically listened through headphones to the word "banana" spoken repeatedly by a female Japanese native speaker in the clean condition. In the noise condition, pink noise was presented with VT stimuli (signal to noise ratio was 0 dB). In the count task, participants pressed a key on a keyboard when they perceived transitions from one verbal form to another. In the report task, participants reported the forms when they perceived transitions from one verbal form to another. We recorded the participants' reports with a voice recorder and transcribed them, and analyzed the quantitative and qualitative nature of the VTs in the clean and noise conditions.

Results: We found that TD individuals perceived less deviated changes in VT with noise than individuals with ASD did. On the other hand, individuals with ASD perceived more drastic changes with noise. Some individuals with ASD reported drastically deviated forms due to the presence of noise.

Conclusions: These results suggest that the drastic illusory changes in VT are not solely induced by bottom-up sensory processing, but are induced by atypical top-down processing in individuals with ASD as well.

401.014 *(Poster)* Autism Friendly - What Does It Mean?

***V. K. Korhonen**, Autism Foundation Finland, Helsinki, Finland*

Background: Autism friendly society is evidently something to strive for in order to have autistic individuals able to live meaningful lives. There are campaigns around the world promoting the idea, and even giving certificates awards for autism friendly acts. What does it mean and who determines the content?

Objectives: We strove to clarify what autistic individuals and professionals thought the term means for them.

Methods: A convenience sampling method was used. An online web survey and phone interview survey was conducted to ask directly what the term autism friendly means. The person could choose which method to use for answering. We contacted professionals who work with autism via listed organisation working with autistic individuals, for example, social and healthcare organisations, employmency offices, youth services, universities and so forth. We also conducted a workshop asking the same question, using pen and paper, at a seminar organised by autistic individuals about autism.

Results: The survey was answered by 152 autistic individuals and by 586 professionals. The workshop had 25 participants. The most common terms the professionals used to describe the term were: simplified language, more knowledge, equality, let people be different, equality for services, more services, altering services, acceptance. The autistics individual's similarly described the term to mean: general acceptance, tolerance, no expectations that everyone understands the same way, being understood, getting support, recognising sensory sensitivity, not only 'rehabilitate' to society but also the other way around, worklife flexibility, but also that there is no such a thing as autism friendly. At the workshop the descriptions were: simplified language, pictorial instructions, forethought/action, individual needs, sensory sensitivity, equality, patience, accepting people as they are, possibility to alter surroundings, and allowed to socialise differently.

Conclusions: It was found that autistic individuals and professionals had similar thoughts what autism friendly means. It seems that the common theme is acceptance and ability to have adaptable environments, and to have information beforehand with visual help.

401.015 *(Poster)* Autism Traits Moderate the Effects of Cognition and Adaptive Behavior Discrepancy on Psychopathology in Young Students with Autism Spectrum

***G. Zukerman**[1], G. Yahav[1] and E. Ben-Itzchak[2], (1)Ariel University, Ariel, Israel, (2)Bruckner Center for Research in Autism, Communication Disorder, Ariel University, Ariel, Israel*

Background: , Among individuals with high functioning autism (HFA), the gap between cognitive ability and adaptive function was postulated to enhance anxiety and depression, due to the high self-awareness level (Kraper et al., 2017). Such psychopathology can impede social and academic adaptation. In addition, the level of autistic features was previously associated with cognitive flexibility (Albin-Urious et al., 2018) and metacognition (Carpenter et al., 2019), features which may affect daily coping.

Objectives: , 1. To examine the association of the gap between cognitive ability (specifically, a scholastic understanding of social conventions) and adaptive behavior to psychopathology in young university students with HFA. 2.To examine whether the level of autistic traits moderates the association between the cognitive-adaptive ability discrepancy and psychopathology.

Methods: , The study included 53 HFA university students (4 females) with a mean age of 23.5 years, (*SD*=2.81). Cognitive ability (knowledge and understanding of social convention and norms) was measured using the Comprehension sub test of the Wechsler Adult Intelligence Scale (WAIS). Adaptive skills were measured using the Adaptive Behavior Assessment System (ABAS-II). Autistic traits were assessed using the Autism Spectrum Quotient (AQ), and Social Anxiety was measured with the Liebowitz Social Anxiety Scale (LSAS).

Results: , A significant positive correlation was found between the gap of the WAIS Comprehension subtest and the ABAS Social Composite Score (cognition – social adaptive skills) and total $r(47) = .40$, $p<0.001$) and avoidence $r(47)=.48$ $p<0.001$) LSAS scores. However, this association was moderated by AQ scores. Among HFA students with relatively high autism traits (AQ score above median =>46), a greater gap between cognition and social adaptive skills was associated with more avoidance symptoms of social anxiety $r(23) = .74$, $p<0.001$). However, such an association was not evident among HFA students with relatively low autism traits (AQ<46) $r(24) = .15$, $p=.24$) . In a regression analysis, the interaction term of the Comprehension subtest and the ABAS Social Composite Score (cognition-social adaptive skill) X AQ score (below/above the median) significantly predicted 31.1% of the variance in social anxiety avoidance symptoms (LSAS avoidance).

Conclusions: , The study's findings suggest that in HFA, the effects of cognitive/adaptive ability discrepancy on psychopathology are moderated by the level of autistic features. One possible explanation for this interesting finding relates to cognitive flexibility (i.e the ability to disengage from one task and adapt to a new situation) and metacognition (the ability to attribute mental states to oneself), both of which have been previously negatively associated with autistic features. Thus, it is possible that individuals with HFA and relatively low autistic traits can cope more efficiently with a cognition/adaptive behavior gap due to their ability to display more flexible and adapted social behaviors, and reflect on their mental states. These abilities may lead to a reduction of the negative effects of such a discrepancy on daily situations. The findings may have important clinical implications for understanding adaptive functioning of young students with HFA.

401.016 *(Poster)* Autistic Adults Using Autonomous Vehicles: Analysis from Autonomous Shuttle Rides Followed By Focus Group Discussions

C. Feeley[1]*, A. Lubin*[2]*, A. L. Kornhauser*[3]*, J. Hwang*[4,5] *and B. Tobin*[6]*, (1)School of Engineering, Rutgers CAIT, Piscataway, NJ, (2)Alan M. Voorhees Transportation Center Edward J. Bloustein School of Planning and Public Policy, Rutgers, The State University of New Jersey, New Brunswick, NJ, (3)Princeton Autonomous Vehicle Engineering, Princeton University, Princeton, NJ, (4)Department of Landscape Architecture and Urban Planning, Texas A&M University, College Station, TX, (5)Transit Mobility Program, Texas A&M Transportation Institute, Bryan, TX, (6)Center for Advanced Infrastructure and Transportation, Rutgers, The State University of New Jersey, Piscataway, NJ*

Background: There is a growing body of literature that focuses on autonomous vehicles for persons with disabilities, however there is no known active research or published literature focused on autistic adults. This research study was conducted with autistic adults that both rode an autonomous shuttle and discussed their experiences and feelings afterwards in focus groups.

Objectives: To conduct research focused on investigating strategies for designing and deploying self-driving vehicles so they can best accommodate the often-diverse needs of persons on the autism spectrum.

Methods: The research was conducted through series of three autonomous shuttle rides followed by structured focus group sessions convened with 14 autistic adults and 2 with related developmental disabilities. Demographic data of the 16 study participants can be found in Table 1. The goal was to document their direct experience as passenger using a shuttle type of Autonomous Vehicle (AV). The research was conducted during Princeton University's 2019 SmartDrivingCar Summit. The core intent of this research was to gather feedback and recommendations on AVs from persons with autism who had acquired a level of familiarity with the technology through a direct vehicle encounter, transcending their knowledge of AV solely as an abstract concept. The IRB of record was with Rutgers University. The sessions were digitally recorded, uploaded in NVivo12 then transcribed, coded and analyzed.

Results: Key findings based on the questions and prompts are presented in Table 2. Significant findings were that only 31% of the participants knew about AVs prior to the study but 87% liked the ride, 93% liked the vehicle, 81% wanted to ride in autonomous vehicle again, with 6% wanting additional practice and only 13% unsure. Many of the participants communicated that availability and usage of AV would also help to decrease feelings of "isolation," "depression," and even "jealousy" that they often feel when they cannot access a ride to a desired or needed destination. In discussing AV in comparison to other modes they currently utilize, participant support and preference for AV was clear. Many felt that an AV would reduce the burden to their parents. Others noted they preferred AV travel to community transit options and ADA complementary paratransit they have utilized, mainly because they envision the former as a more on-demand, user friendly travel option. The two participants who drive discussed that AV would be less stressful overall compared to driving themselves, especially when traveling in unfamiliar locales. The most cited concerns were price, payment options, vehicle interface, and the option to be the sole passenger.

Conclusions: The authors captured invaluable information on participant initial impressions of AV; their in-vehicle trip experience; interest in utilizing AV in the future; and AV-related concerns. Findings demonstrate that the majority of participants had both positive initial and post-trip impressions of AV and were extremely interested in utilizing AV to meet their current trip needs. Participants also offered insightful recommendations that can contribute to continued development of AV technology so that it can more fully accommodate the travel needs of autistic individuals.

401.017 *(Poster)* Autistic Priorities for Future Research on Autism and Employment in the UK

B. Heasman[1]*, J. Cumin*[2,3]*, J. Davies*[4]*, A. Remington*[1] *and E. Pellicano*[5]*, (1)UCL Centre for Research in Autism and Education, London, United Kingdom, (2)Université de Montréal, Montréal, QC, Canada, (3)Autism Research Group, CIUSSS du Nord-de-l 'Île-de-Montréal, Montréal, QC, Canada, (4)Centre for Research in Autism and Education, UCL, Institute of Education, London, United Kingdom, (5)Macquarie University, Sydney, Australia*

Background: The employment gap for autistic adults in the UK has led to an increase in research examining barriers to access. Studies have focused on a variety of issues including transition from education, autism-specific employment schemes, and socio-economic background. The present study investigates autistic priorities for future research on autism and employment including attitudes towards the scope of such research to change employment practice. In doing so it contributes to an increasing understanding of how to align future research with stakeholder needs and identifies potential challenges with translating research effectively into practice.

Objectives: Our first objective was to understand attitudes towards the role of research and potential challenges in addressing the research-practice gap. Our second objective was to explore and document the range of autistic priorities for future research on employment.

Methods: Through an online survey, autistic adults (n = 204) were asked about the amount of contact-time they had experienced with researchers and, via a rating scale, participants indicated their perception about the effectiveness of research to change employment outcomes for autistic people. Participants also provided open text responses about priorities for research on employment and their perceived impact of research on practice in the future, which was analyzed using thematic analysis.

Results: Results show participants perceive research will only have moderate success in changing employment outcomes in the future (mean = 2.6; 'not successful at all' = 1, 'very successful' = 5), while 67% of participants reported that they had not experienced any opportunity to discuss their thoughts about research priorities with a researcher (3% reported they had not tried; 2% were researchers themselves). Thematic analysis of the open text responses revealed three priority areas for future research including: (1) research on making organizational culture and practice more accessible to neurodiversity (58% of responses) including research on successful adjustments, career development and sustainable employment; (2) research on socio-economic and legal frameworks for providing support (28% of responses) including research on autistic people belonging to additional minority status groups, research across sectors and the effectiveness of the benefit and welfare system; and (3) critical reflections on the research-practice gap (14% of responses), including topics to avoid, more participatory research strategies and a focus on positive case studies.
Conclusions: Findings demonstrate priorities which are focused on achieving sustainable employment for autistic people over time. Sustainable employment can also be achieved through creating more enabling systems of support at the organizational and socio-economic level that are focused on the wide-scale recognition of autistic strengths and support needs, improved access and alignment of job roles, and the impact of employment on well-being. In addition, there remains an ongoing challenge with improving the current knowledge-base underscoring employment initiatives, with a need for more pathways for autistic involvement in research. The contribution of the present study is to present a list of themes, subthemes and examples, ranked in terms of coding frequency, as a guide to help shape future research agenda.

401.018 *(Poster)* Career Interview Readiness in VR (CIRVR): Feasibility of an AI-Driven Platform for Employers and Neurodiverse Talent

J. W. Wade[1]*, A. Itzkovitz*[2]*, D. Adiani*[2]*, D. Bian*[3]*, H. Katz*[2]*, M. Breen*[2]*, A. R. Swanson*[4]*, A. S. Weitlauf*[5]*, Z. Warren*[4] *and N. Sarkar*[6]*, (1)Vanderbilt University, Nashville, TN, (2)Mechanical Engineering, Vanderbilt University, Nashville, TN, (3)Electrical Engineering & Computer Science, Vanderbilt University, Nashville, TN, (4)Vanderbilt University Medical Center, Nashville, TN, (5)Vanderbilt Kennedy Center, Vanderbilt University Medical Center, Nashville, TN, (6)Mechanical Engineering; Electrical Engineering and Computer Science, Vanderbilt University, Nashville, TN*

Background: An estimated 85% of individuals with Autism Spectrum Disorder (ASD) are under- or unemployed, thus resulting in greater reliance on caregivers and support systems and hindering personal growth and self-satisfaction. Recent evidence reveals that this significant employment disparity is attributable not to a lack of employable skills and talents, but rather to the significant and unaddressed barriers to employment faced by individuals with ASD at all stages of the employment process (e.g., candidate identification, the job interview, and on-the-job training). The current work focuses on the unique challenges that the traditional job interview poses to individuals with ASD.
Objectives: Researchers have recently begun exploring the use of simulated job interview systems to prepare individuals with ASD for real-world interviews. However, existing systems have not fully utilized digital platforms to deliver engaging, adaptive, and individualized training to this population, nor have they been designed with the aim of providing insightful feedback to both candidates *and* employers. In response, we have developed Career Interview Readiness in VR (CIRVR) with the aim of improving candidates' performance in simulated job interviews while simultaneously providing meaningful data for potential employers to ultimately gain a better understanding of the accommodations needed for this population of candidates. CIRVR can sense an individual's affective state through physiological sensing, attention through eye gaze, and facial expressions from real-time video capture and utilizes a set of AI modules using Microsoft Azure to create an adaptive and smooth interview protocol.
Methods: We conducted a preliminary, IRB-approved investigation of the feasibility and usability of CIRVR. Fifteen participants were recruited for this study: nine with ASD (mean age = 22.11; SD = 9.10) and 6 neurotypical peers (mean age = 20.17; SD = 3.43). All participants interacted with CIRVR while multi-modal data were collected from several channels including speech, eye gaze, facial image capture, and psychophysiology as measured by a wrist-worn biosensor. Additionally, the System Usability Scale (SUS) as well as an open-ended interview were used to collect qualitative measures of usability and acceptability of the novel system.
Results: All but one participant completed the study. Responses to the SUS by the ASD group were in the "Okay" range (M = 53.61; SD = 17.24) while responses from the neurotypical group were in the "Good" range (M = 73.33; SD = 15.86). The post-interview discussions revealed that participants' experiences with CIRVR were generally positive.
Conclusions: In a preliminary evaluation, CIRVR successfully captured the multi-modal user data and was favorably received by participants. Our preliminary results provide insight into how CIRVR can be extended and enhanced in the next phase of research. In the future, we will implement two important new features: (a) an employer dashboard that will provide key insights to employers, with the ultimate aim of fostering a more inclusive workplace environment; and (b) a real-time adaptive mechanism to provide a more individualized training experience to interviewees.

401.019 *(Poster)* Changes in ADOS Calibrated Severity Scores between Adolescence and Young Adulthood in a UK Population Based Twin Sample

S. J. Capp[1]*, F. Happé*[1] *and E. Colvert*[2]*, (1)Social, Genetic and Developmental Psychiatry Centre, Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, United Kingdom, (2)SGDP, Institute of Psychiatry, Psychology and Neuroscience, KCL, London, United Kingdom*

Background: Across development, autistic individuals may show fluctuations in their presentation of symptoms. This can be examined using Autism Diagnostic Observation Schedule (ADOS) Calibrated Severity Scores (CSS) (Gotham, Pickles & Lord, 2009; Hus & Lord, 2014). Adolescence to young adulthood (YA) is an important transition period with many new challenges and opportunities. Identifying factors that influence change in this period could be helpful to improve outcomes and identify groups needing extra support.
Objectives: This study used data from a population-based twin sample covering the whole autism spectrum. Objectives were to examine factors associated with CSS scores in YA and change in CSS between adolescence and YA.
Methods: In the first phase of testing, adolescents (M_{age} 12 years 11 months, SD= 10 months) completed ADOS assessments, IQ and cognitive testing. Families in this sample were included if one or both twins met diagnostic criteria for autism. Sixty-nine individuals (from 42 families; 61.87% male) were revisited in YA (M_{age} = 22 years 5 months, SD= 12 months). Multi-level models were used to account for family clustering within the data.

Results: Results demonstrated that 39.13% showed reductions in CSS between adolescence and YA, while 30.43% showed increases and 30.34% showed no changes in CSS over this period.

Family level factors (i.e. shared genetic and environmental effects) had a significant impact on young adult CSS. Intraclass correlations suggest that around 22% of variability is attributable to family clustering. After accounting for this, adolescent CSS (p< .001), adolescent IQ (p< .001) and current age (p= .016) were all significantly associated with YA CSS. Individual sex showed no significant association (p= .968), although future samples with greater numbers of females are needed. Greater adolescent IQ and current age were both associated with lower CSS in YA, while higher adolescent CSS was associated with higher CSS in YA.

Changes in CSS between adolescence and YA were also related to family clustering (15.90% variance attributable). Adolescent CSS (p< .001), adolescent IQ (p= .001) and length of follow-up (p= .002) were all significantly associated with change in CSS. Individual sex showed no significant association (p= .832). Higher adolescent IQ, higher adolescent CSS and greater time between assessments were each associated with increased reductions in CSS between adolescence and YA.

Conclusions: These data demonstrate the utility of CSS for mapping changes across the lifespan for autistic individuals. Observed trajectories are diverse and varied, although some general influencing factors have been identified. On average, symptoms seem to improve with increasing age and time. Adolescent IQ is associated with lower young adult CSS and greater reductions between adolescence and YA. Although CSS show some degree of stability, large changes (both positive and negative) can also be seen. Therefore, future work may wish to explore additional factors to better identify those who would most benefit from additional/continued support during the period of between adolescence and YA. It is hoped that this may be used to help some capitalize on their gains during this period while giving greater support to those experiencing increasing challenges.

401.020 *(Poster)* Childhood Predictors of Depression and Anxiety in Autistic Adolescents and Adults and Their Siblings

***G. B. Gunin**, E. Wilkinson, M. Turley and V. H. Bal, Graduate School of Applied and Professional Psychology, Rutgers University-New Brunswick, Piscataway, NJ*

Background: Higher rates of depression and anxiety are reported in autistic individuals (Croen et al., 2015) and their siblings (O'Neill & Murray, 2016) than the general population. Little is known about the stability of elevated symptoms from early childhood to adolescence/young adulthood. Gotham and colleagues (2015) found that gender predicted greater increases in symptoms across adolescence and that greater emotion regulation difficulties in later childhood predicted internalizing symptoms in autistic adults. Additional studies are needed to understand predictors of depressive and anxiety trajectories in autistic individuals and their siblings.

Objectives: To examine childhood predictors of depression and anxiety in adolescents and young adults with ASD and their siblings.

Methods: Analyses included 158 individuals with ASD (*M* age=16.09, SD=2.63) and 131 designated siblings (*M* age=16.03, SD=2.70 from the Simons Simplex Collection who completed an online follow-up through the Interactive Autism Network 6 years later (SD=1.06). McNemar's $\chi 2$ test were used to compare the proportion of children who changed clinical classification (i.e., Borderline-to-Clinical range T$\geq$60 vs. Non-Clinical range T<60) on the ASEBA Depressive Problems and Anxiety Problems DSM-Oriented Scales from T1 to T2. Logistic regressions were used to explore predictors of T2 classification; T1 classification, gender, group (proband or sibling) and externalizing symptoms (as a proxy for emotion regulation) were explored in the initial analysis.

Results: Figure 1 shows distributions of clinical classifications on the Depressive and Anxiety scale. Of autistic individuals with elevated T1:Depressive scores, 62% had Non-Clinical T2:T-scores and 29% with T<60 at T1 had elevated T2:T-scores (p=.01). Fifty-seven percent of siblings with elevated T1:Depressive scores were Non-Clinical at T2, and 14% moved from Non-Clinical at T1 to elevated at T2 (p=.70). Within autistic individuals with elevated T1:Anxiety, 46% had Non-Clinical scores at T2 and 21% who were Non-Clinical at T1 had elevated T2:T-scores (p<.001). In contrast, 65% of siblings with elevated T1:Anxiety had T2:T<60, and only 10% moved from Non-Clinical at T1 to elevated at T2 (p=1.00).

Females were less likely (OR=.04, 95%CI[.002, .77]) to have elevated T2:Depressive scores, controlling for group and T1 classification. Males with higher T1 externalizing symptoms were somewhat more likely to have elevated T2:Depressive scores (OR=1.06, [1.00, 1.12]). T1 externalizing symptoms (OR=1.05, [1.01, 1.08]), but not gender (OR=.95 [.45, 1.97]), predicted T2:Anxiety, controlling for group and T1 classification.

Conclusions: More than sixty percent of autistic individuals fell in the Borderline-to-Clinical range on the ASEBA Depressive and Anxiety scales at T1. Somewhat surprisingly, fewer had elevated scores at T2; 46-62% of those with T1 scores in the Borderline-to-Clinical range continued to have elevated scores as adolescents and young adults, six years later. In contrast, fewer than 20% of siblings had elevated scores at either time point. Additional analyses will seek to identify potential protective factors (i.e., characteristics of individuals who do not exhibit depression or anxiety) and predictors of trajectories (e.g., persistence vs. reduction of symptoms). Within family analyses will examine the influence of characteristics of the sibling with ASD on depression and anxiety in non-autistic siblings.

401.021 *(Poster)* College from an Autistic Viewpoint

***A. Donaldson**[1], E. Idomskaya[2], J. E. McCoy[1], D. M. Raymaker[3] and C. Nicolaidis[3], (1)Speech & Hearing Sciences, Portland State University, Portland, OR, (2)Sammamish Children's Therapy, Bellevue, WA, (3)School of Social Work, Portland State University, Portland, OR*

Background: Students on the autism spectrum are increasingly attending college; yet there has been limited research related to their experiences. Gelbar et al, 2014 completed a systematic review of autistic student experiences in higher education. Of the 20 articles reviewed, the majority were case studies of only one or a few autistic students. They concluded that there is a paucity of research in this area and advocated the need for increased representation in such studies through interviewing and surveying in order to move towards empirically based recommendations for specific higher education programming.

Participatory approaches that include community members as members of the research team can ensure that research projects, from ideation to dissemination are rooted in community contexts and priorities, and shaped by immediate community feedback. As such, the current study design and key components were developed in consultation with the Academic Autism Spectrum Partnership in Research and Education (AASPIRE), which is an academic-community partnership which includes autistic individuals as equal partners in research. It was created in 2006 by Drs. Raymaker and Nicolaidis.

Objectives: The project uses interviews to address the following research questions: 1) What challenges and successes do college students on the spectrum report related to academic and social life at PSU? 2) What resources and/or supports might improve the experiences of autistic students at PSU?

Methods: Prior to study initiation, the full research team met to discuss research questions, propose methods and measures, and study design. Based on discussion, particularly input from the AASPIRE group, the research questions and methods were finalized. The interview guide was then developed by the first two authors, in consultation with the Drs. Raymaker & Nicolaidis. Following collection of several interviews, the full team provided key suggestions regarding several areas to include in further interviews. The semi-structured interview guide included a number of topics related to academics, social, living situation, autism, services, etc. Demographic information was also collected. Participant inclusion criteria (n=19): 1) registered student for at least 6 months; 2) diagnosis on the autism spectrum; and, 3) communicate in English or American Sign Language (ASL).

Data analysis: An inductive approach was used for data analysis (Thomas, 2006). All interviews were recorded and transcribed. The first three authors completed close reading of the text and in vivo coding to create preliminary categories. The categories were refined through multiple readings and revisions of codebook. Summary categories were created. Consistency checks were completed at each stage.

Results: Key themes included: 1) successes and challenges; 2) people who provide support or create barriers; 3) contexts where successes and challenges occur; 4) communication; 5) identity; and 6) institutional structures. Some co-occurring topics include: positive experiences through challenges; student organization recommendations; and seeking accommodations related to executive function skills.

Conclusions: The study provides increased understanding of autistic student experiences at a PNW urban university; use of a participatory approach increased trustworthiness and supports autistic-lead programming modifications. Next steps include development of survey questionnaire for large-scale examination of neurodivergent student experiences.

401.022 *(Poster)* Community Engagement and Lifelong Learning: The Alyssa Burnett Center Model

*M. R. Cates[1], **V. R. Unger**[2] and G. Stobbe[3], (1)Seattle Children's Hospital Alyssa Burnett Center Adult Life Center, Bothell, WA, (2)Seatte Children's Hospital Alyssa Burnett Center Adult Life Center, Bothell, WA, (3)Psychiatry & Behavioral Medicine, Seattle Children's Autism Center, Seattle, WA*

Background: In the next 10-15 years, The Washington State Department of Health estimates 8,000 to 12,000 children with autism will age into adulthood with access to fewer opportunities to continue community participation and lifelong learning. Evidence demonstrates a significant decrease in community participation as individuals with autism transition to adulthood (Myers E, et al, *JADD;* 2015; DOI 10.1007/s10803-015-2403-z).

The Alyssa Burnett Adult Life Center (“the ABC”) was established in 2014 to address the gap in educational, recreational, and social services for adults with autism and other developmental conditions. Operated by Seattle Children’s Hospital, the ABC is a center offering non-accredited classes with a focus on skill building, independence and socialization. The ABC is popular and currently serves 170+ adults with ASD and other developmental conditions per quarter.

Objectives: Our goal is to highlight quantitative and qualitative data to better understand the population being served through the ABC model and the impact of participation on quality of life (QoL).

Methods: The ABC model is based on classes designed by instructors with stakeholder input. Accessibility and accommodation are integral to the design of these specialized classes. Programing is classroom and community-based maintaining an intentional 1:4 staff to student ratio. Classes run weekly over a 12-week session with class size ranging from 5-15 students. Classes vary in baseline skill level and in the amount of support needed to attend (e.g. some classes require participants to provide their own 1;1 caregiver; other classes are attended independently). All students attend an intake evaluation with ABC staff to identify baseline skill level and interests.

QoL Survey data collection is ongoing, beginning in 2019. *Baseline Surveys* are collected during intake evaluations and *Longitudinal Functional Surveys* are sent quarterly to returning students. Surveys include demographic, daily living, community participation, and employment questions.

Results: According to our *Baseline Survey (N=51)*, 29.5% of adults have paid employment and 51% are involved in community-based activities prior to attending ABC. Our *Longitudinal Functional Survey (N=52)* indicates 52% of returning adults have paid employment and 61.5% are involved in community-based activities in addition to attending ABC. When asked to rate how each student's diagnosis has been affecting their daily living, 61% of *Baseline* responses indicated “marked, severe, or extreme” effects, whereas 40% of the *Longitudinal* responses indicated “marked, severe, or extreme” effects.

Regarding demographics, 158 students are enrolled in the current Fall 2019 quarter. 75% are between the age of 20 and 29, with 56% of the total being male. 52% of the students are diagnosed with ASD. 45.5% live within 0-10 miles of ABC, 44% live within 11-20 miles of ABC, and 10% live beyond 20 miles away.

Conclusions: The ABC model is a feasible and popular option for adults with autism and other developmental conditions to continue their community engagement and skill building. Preliminary evidence supports the role of community participation and lifelong learning in improving QoL. Future research is needed to better understand the quality and quantity of participation necessary to impact QoL for specific participant groups.

401.023 *(Poster)* Comparison of Three Coding Schemes for Analyzing the Interaction and Engagement Motivations of Adults on the Autism Spectrum.

T. A. M. McDonald[1]*, Z. J. Williams*[2] *and B. A. Malow*[1]*, (1)Sleep Disorders Division, Department of Neurology, Vanderbilt University Medical Center, Nashville, TN, (2)Medical Scientist Training Program, Vanderbilt University School of Medicine, Nashville, TN*

Background: Studies investigating autistic adults' perceptions and attitudes, such as motivation, are sparse and remains a priority for research. Understanding the motivations of autistic adults is critical for developing meaningful programs, services and interventions for this population. However, differing theoretical coding schemes for examining motivations have strengths and limitations that can affect the focus and meaning of their findings. For example, life domains derived from Life Course Theory (LCT) are often used for categorizing emergent adult motivations but may fail to categorize important dimensions, such as self-determination, survival, avoidance, or meaningfulness, that may be better captured with other motivation theories. To date, it is unclear which theories best capture and characterize the motivations of autistic adults.

Objectives: To investigate the utility of three coding schemes, this study compared three coding systems derived from LCT, Self-Determination Theory (SDT), and Motivation Taxonomy (MT) to examine the self-reported life goals, as well as the motivations and barriers to community engagement, reported by 42 adults on the autism spectrum.

Methods: Participants (ages 18 – 34 years) completed an anonymous online survey that included multiple-choice, multiple-response, and open-ended items related to demographic questions, interests, goals, and barriers to activities or social engagement. This study examines the following open-ended items: "Please list one or two of your most important goals", "What motivates you to engage in activities outside the home?", and "What motivates you to engage with others?" Comments were coded independently and through consensus. A competing theories method was used to compare the utility of the coding schemes.

Results: Both LCT and the MT coding systems outperformed SDT in terms of utility for this population. For LCT, many comments could be coded within traditional life domains (desire to increase independence, education, employment, and social relationships), however, many items related to passions and meaning were not codable and required additional "domains". For SDT, many motivations did not fit the theoretical definitions of autonomy, competence or relatedness. However, MT, which provided both a condensed coding scheme (meaning, communion, and agency) and a highly granular scheme (44 codes), revealed important personality differences in motivation while encompassing ideas from both LCT and SDT. While some participants emphasized a desire for a meaningful life (pursuing passions and humanitarian causes, career, intellectual growth, deep relationships), other participants focused on obtaining survival related goals (getting a job, making money, transportation, addressing physical or mental health, battling isolation).

Conclusions: LCT and SDT may not be as useful as MT to capture the ways autistic adults express self-determination including drives related to survival, desires to meet external expectations, and desire for a meaningful life. While MT demonstrated the greatest utility for coding motivation in this population and highlighted the importance of individual differences in this population, it did not adequately account for motivations related to psychological health, transportation, and basic necessities. Future research on autistic adult motivation should carefully consider the utility of theoretical frameworks that guide the examination of motivation in this population.

401.024 *(Poster)* Dental Experiences of Autistic Adults in the United Kingdom

A. McMillion[1]*, A. Remington*[2]*, J. Van Herwegen*[3]*, A. Cronin*[4]*, J. Monteiro*[5] *and A. Johnson*[5]*, (1)Psychology and Human Development, Institute of Education, University College London, London, United Kingdom, (2)UCL Centre for Research in Autism and Education, London, United Kingdom, (3)Institute of Education, University College London, London, United Kingdom, (4)King's College Hospital, London, United Kingdom, (5)Eastman Dental Hospital, London, United Kingdom*

Background: Previous research has suggested that autistic people have difficulty accessing dental care, due to sensory processing, anxiety and communication issues. To date, however, research on autistic people's dental experiences in the United Kingdom has focused solely on autistic children's experiences as reported by their parents. This study sought to better understand autistic adults' (aged 18 and up) dental experiences in the UK.

Objectives: This study looked at whether autistic adults report different dental experiences compared to those of non-autistic adults: what autism-specific challenges occurred when going to the dentist, what autistic adults reported as positive at the dentist, and what autistic people would like to improve about their dental experiences.

Methods: A questionnaire comprised of quantitative and qualitative questions was completed online by self-selecting autistic (n=37) and non-autistic adults (n=43) in the UK. Quantitative questions asked about dental satisfaction, dental anxiety (adapted from the Modified Dental Anxiety Scale, Humphris, Dyer, & Robinson, 2009) and experiences with patient-practitioner communication (adapted from the NHS Adult Dental Health Survey and the 2007 Health Information National Trends Survey (Cantor, Covell, Davis, Park & Rizzo, 2007; NHS, 2009)). Quantitative responses were analysed using Pearson chi-square tests and unstandardised residuals to identify significant differences between autistic and non-autistic respondents. Independent t-tests compared autistic and non-autistic adults' experiences on the satisfaction scale, and Cohen's *d* was used to calculate effect size on these items. Qualitative questions asked about autism-specific challenges at the dentist, what works well for autistic people and what would improve their experience. These responses were analysed using thematic analysis.

Results: Overall, the results demonstrated that autistic adults in the UK more frequently reported negative overall dental experiences than non-autistic adults. These appeared to be related to sensory atypicalities, communication difficulties and anxiety. Themes that arose from the qualitative data revealed that many autistic people dislike the sensory environment at the dentist, that they may feel misunderstood when they try to express a concern, and that anxiety about the dentist impacts their communication. Other themes were related to the importance of consistency in the dental experience, disclosure of autism at the dentist, and cost of treatment. Autistic participants recommended sensory environment adaptations, having longer appointments and accommodating for individual needs.

Conclusions: This study's findings highlight the importance of dentists working directly with autistic individuals throughout their careers, as one autistic respondent recommended, 'the only way to get familiar with autistic people is by interacting with autistic people'. This study also provides concrete recommendations for dentists to improve their treatment for autistic patients, including allowing pre-visits and being told ahead of time of what procedures involve.

401.025 *(Poster)* Development and Validation of a New Suicidality Assessment Tool in Partnership with Autistic Adults.

S. A. Cassidy[1]*, L. Bradley*[2]*, H. Cogger-Ward*[1]*, R. Shaw*[3]*, E. Bowen*[4]*, M. Glod*[5]*, S. Baron-Cohen*[6] *and J. Rodgers*[5]*, (1)School of Psychology, University of Nottingham, Nottingham, United Kingdom, (2)University of Bedfordshire, Luton, United Kingdom, (3)NHS Coventry and Warwickshire Partnership Trust, Warwickshire, United Kingdom, (4)University of Worcester, Worcester, United Kingdom, (5)Institute of Neuroscience, Newcastle University, Newcastle Upon Tyne, United Kingdom, (6)Autism Research Centre, Department of Psychiatry, University of Cambridge, Cambridge, United Kingdom*

Background: Autistic adults are a high-risk group for suicide. Our systematic review showed no suicidality assessment tool had yet been validated in autistic adults. However, the Suicide Behaviours Questionnaire – Revised (SBQ-R), is a brief four-item, open source self-report measure, validated and widely used in general population suicidality research. Autistic people interpreted and responded differently to the items of the SBQ-R compared to the general population, suggesting that the SBQ-R needs to be adapted for autistic people.

Objectives: 1) to adapt the SBQ-R in partnership with autistic adults; 2) to explore the appropriateness and measurement properties of this adapted tool in autistic compared to non-autistic adults.

Methods: First, cognitive interviews with fifteen autistic adults co-produced adaptations to the SBQ-R to improve the clarity and relevance of the items. Second, 251 autistic adults (77 male, mean age = 41.9 years) rated the clarity, importance and provided qualitative feedback for each item in the original and adapted version of the SBQ online to inform further adaptations. Third, 289 autistic (80 male, mean age = 39.2 years) and 258 non-autistic adults (82 male, mean age = 41.3 years) completed an online survey including the original and adapted SBQ, autistic traits (AQ-28), Anxiety (ASA-A), Depression (PHQ-9), Social Camouflaging (CAT-Q), and Interpersonal Needs (INQ-15). Participants also provided feedback on the clarity and qualitative feedback on the original SBQ-R, and the final version of the adapted SBQ.

Results: Qualitative feedback from the interviews and two online surveys identified consistent interpretation and response issues with the original SBQ-R, and that the adaptations addressed these issues. These adaptations included simplifying multi-clause sentences, ensuring that scales were clear and captured the full range and intensity of suicidality, and making questions more concrete and less abstract. Exploratory factor analysis of the adapted SBQ supported a one-factor solution with excellent internal consistency in both autistic and non-autistic adults (alpha > .8). Multi-group confirmatory factor analysis showed that unlike the original SBQ-R, the adapted version was measurement invariant at the scalar level when excluding item two (Table 1). In the autistic group, the adapted SBQ significantly correlated with all other variables (autistic traits, anxiety, depression, social camouflaging, interpersonal needs, and original SBQ-R) (Table 2). The adapted SBQ was also more highly correlated with autism constructs (autistic traits and social camouflaging), than the original SBQ-R (Table 2). Adapted SBQ scores at time one significantly correlated highly with scores two weeks later (r = .815). A cut-off score of 12.5 on the adapted SBQ correctly classified 78.9% of autistic people who reported attempted suicide.

Conclusions: Results suggest that co-producing a new suicidality assessment tool in partnership with autistic adults, not only better captures suicidality in this group, but also addresses measurement differences between autistic and non-autistic people. This means that the newly developed SBQ-ASC can be used in future research to better understand suicide in autistic compared to non-autistic people.

401.026 *(Poster)* Diagnosis Disclosure in Employment and Academic Settings: Experiences and Attitudes of Young Adults and Their Parents

N. L. Matthews[1]*, K. Christenson*[1]*, S. Kiefer*[1] *and C. J. Smith*[2]*, (1)Southwest Autism Research and Resource Center, Phoenix, AZ, (2)Southwest Autism Research & Resource Center, Phoenix, AZ*

Background: Young adults with autism (ASD) often face difficulties finding and maintaining competitive employment (Roux et al., 2015). Additionally, they may struggle with demands introduced by post-secondary academic settings (Anderson & Butt, 2017). Whether, when, and how to disclose a diagnosis are important decisions that, if answered thoughtfully, may contribute to success in employment and academic settings (Lindsay et al., 2019). Little research exists on this topic, which makes it difficult for stakeholders to make informed decisions.

Objectives: To qualitatively examine disclosure experiences and attitudes among young adults with ASD and their parents.

Methods: Participants were 21 young adults with ASD and at least one parent of each young adult (20 mothers; 4 fathers) who participated in larger study on the transition to adulthood. See Table 1 for participant demographics. All young adults had an IQ ≥ 70, an independent DSM-IV/5 ASD diagnosis, and all but one met criteria for autism/autism spectrum on the ADOS-2. We oversampled for young adults who had been employed consecutively for at least one year at some point during adulthood (n = 11).

Young adults and their parents completed separate semi-structured interviews about the transition to adulthood. The current analysis focuses on responses related to diagnosis disclosure in employment and post-secondary academic settings. Grounded theory methodology (Strauss & Corbin, 1990) was used to analyze interview responses.

Results: The conceptual model derived from grounded theory analysis is reported in Figure 1. The core concept was *Types of Disclosure*, which included full disclosure (immediate, delayed, and forced), limited disclosure (e.g., if needed for accommodations; if the recipient is trustworthy; mixed feelings resulting in mixed behavior), parent(s) disclosing for the young adult, and no disclosure. Five other main categories contributed to, or resulted from, the core concept: (1) *young adult attitudes*, (2) *parent attitudes;* (3) *uncertainty regarding disclosure;* (4) *professional advice,* and (5) *outcomes* (e.g., positive, negative, and surprise).

Conclusions: Participants reported diverse experiences and attitudes. Six young adults and most of their parents endorsed the importance of immediate, full disclosure. They believed that the young adult's autism would disclose itself, and/or that employers, coworkers, teachers, and peers would be more understanding if they knew the young adult had ASD. Multiple participants reported examples of forced disclosure, which resulted from settings tailored to individuals with disabilities. Nine young adults reported limited disclosure for a variety of reasons, including fear of stigma, fear of victimization, and feeling that their diagnosis was not relevant to success in the respective setting. Some parents reported conflict between attitudes (i.e., parent encouraging disclosure and adult choosing not to, or vice versa). A sense of uncertainty was also reported; participants believed the young adult would benefit from accommodations but expressed concerns about negative outcomes of disclosure (e.g., discrimination). Participants reported both positive (e.g., job recovery after being fired; meaningful accommodations; increased understanding) and negative outcomes (i.e., not being offered a job) of disclosure, although negative outcomes were rare. Two of the three participants who reported negative outcomes changed their disclosure strategy.

401.027 *(Poster)* Ecological Momentary Assessment of Physical Activity, Sedentary Time and Anxiety in Adults with Autism Spectrum Disorder

D. Lee[1]*, D. J. Cothran*[1]*, S. Bellini*[2]*, P. C. Shih*[3]*, K. Han*[4]*, B. Kim*[4]*, A. Min*[3]*, S. Paik*[4] *and G. C. Frey*[1]*, (1)Kinesiology, Indiana University Bloomington, Bloomington, IN, (2)Counseling and Educational Psychology, Indiana University Bloomington, Bloomington, IN, (3)Informatics, Indiana University Bloomington, Bloomington, IN, (4)Software and Computer Engineering, Ajou University, Suwon, Korea, Republic of (South)*

Background: Participation in regular physical activity (PA) helps reduce anxiety in the neurotypical population, but there have been no attempts to use PA as part of a treatment approach for anxiety in people with ASD. Anxiety is one of the most common and debilitating co-occurring conditions in adults with autism spectrum diagnoses (ASD) and there are few, effective treatment options for this symptom. Research is needed to explore the potential of using PA participation as an adjunct treatment to alleviate anxiety in adults with ASD.

Objectives: The objective of this pilot study was to examine the relationship between PA, sedentary time, and anxiety in adults with ASD using a modified ecological momentary assessment.

Methods: Fourteen adults with ASD and anxiety (10 females; mean age = 28.9, SD = 8.5) were recruited via ASD support groups in social media. A Qulatrics self-report survey addressing PA (modified International Physical Activity Questionnaire), sedentary time, and anxiety occurrence and triggers (Ozsivadjian, Knott, & Magiati 2012) was delivered daily via text message to study participants at 8 pm for seven days. Participants with at least 3 days of valid responses were included in the analyses. Descriptive and correlational analyses were performed using SPSS and significance level was set at $p < 0.05$.

Results: 65 responses were included in the analyses. Median moderate to vigorous PA and sedentary times were 15 min/day (IQR = 52.5) and 540 min/day (IQR = 420), respectively. The most frequently reported anxiety triggers were specific fears and phobias (46.2%), confusion and worries about social and communication situations (41.5%), and too many demands or expectations (26.2%). Also, participants experienced frequent anxiety feelings during 3 – 5 pm (50.8%), 11 am – 1 pm (40%), and 1 – 3 pm (38.5%). Moderate to strong correlations were found between sedentary time and anxiety ($r_s = 0.34$, $p = 0.005$) and between moderate to vigorous PA and physical health satisfaction ($r_s = 0.61$, $p = 0.027$). Moderate to vigorous PA and sedentary time were also moderately negatively correlated ($r = -0.42$, $p = 0.001$).

Conclusions: Adults with ASD show low levels of daily PA and are highly sedentary. High levels of sedentary time are associated with anxiety in adults with ASD. Interventions that target reducing sedentary time, rather than PA, as a way to manage anxiety in adults with ASD warrant further study.

401.028 *(Poster)* Efficacy of Depression Screening Tools in Young Adults with Symptoms of Autism

A. Sirsikar[1] *and I. M. Eigsti*[2]*, (1)University of Connecticut, Storrs, CT, (2)Psychological Sciences, University of Connecticut, Storrs, CT*

Background: Autism spectrum disorder (ASD) is a neurodevelopmental condition that is characterized by challenges with communication and social interaction. Autism severity is associated with increased loneliness and symptoms of depression (Hedley *et al.*, 2018), indicating an increased susceptibility to depression in this population. However, depression in ASD is significantly underdiagnosed (Bitsika, 2015). High rates of undetected depression in people with autism could reflect the unique presentation of depression in this population, potentially associated with reduced insight into symptoms (Hill & Frith, 2004), as well as the lack of autism-specific diagnostic tools.

Objectives: This study tests the efficacy of depression screeners in a non-clinical sample of individuals with low or high rates of autism traits.

Methods: University undergraduates (n=173) ages 18-24 years old [*M(SD)*=19.8(1.3)] completed the Autism Questionnaire (AQ) and Beck-Depression Inventory-II (BDI-II). A total of 153 students completed the survey and endorsed paying close attention to the questions and instructions; of these, we also received 30 parent-report Adult Behavior Checklist (ABCL) scores describing symptoms of depression in their children. Analyses tested whether higher levels of ASD traits co-occurred with more symptoms of depression and also examined convergence of self- and parent-reported depression symptoms in individuals with higher versus lower levels of autism traits.

Results: Symptoms of autism and depression were significantly correlated, $r(153)=.35$, $p=.001$, such that participants reporting more symptoms and traits of ASD also endorsed more symptoms of depression; Figure 1. Child and parent depression scores were significantly correlated in individuals in the low ASD traits group, $r(17)=.53$, $p=.03$; in contrast, child and parent report were uncorrelated in the high ASD traits group, $r(13)=.10$, $p=.74$; see Figure 2.

Conclusions: Findings extend work (Hedley *et al.*, 2018) documenting increased rates of depression in ASD in a non-clinical sample of college students. Furthermore, self- and parent-reported symptoms of depression were less concordant for individuals who self-reported higher rates of ASD traits. That is, participants with more ASD traits perceived their own emotions and mental health differently than did their parents. This result is consistent with two possibilities: individuals with more ASD traits may have less insight into their own symptoms and therefore report symptoms differently; or parents may have less awareness of these symptoms in such individuals, because they are less sensitive to symptoms, because the individuals are less likely to verbalize their feelings, or because the experience of symptoms actually differs. These results do suggest a need for more examination of depression screeners for use in clinical ASD referrals. We are currently collecting additional data in a college group for more robust interpretation, as well as in a cohort of individuals with diagnosed ASD to determine whether the present results extend from ASD traits to frank ASD diagnoses.

401.029 *(Poster)* Emotion Dysregulation, Internalizing Symptoms, and Perceived Driving Difficulties in Emerging Drivers with and without ASD

M. Fok[1]*, J. Owens*[2] *and A. Scarpa*[3]*, (1)Psychology, Virginia Tech, Blacksburg, VA, (2)Virginia Tech, Blacksburg, VA, (3)Virginia Tech Autism Clinic & Center for Autism Research, Blacksburg, VA*

Background: Driving is central to independent living and autonomy in adulthood for adults with a disability or ASD (Cox et al., 2012, Schultheis et al., 2002). However, only a third of adolescents with ASD acquire drivers' licenses (Curry et al., 2018) and independent driving is not commonly included in the goals of transition planning (Huang et al., 2012). Many factors influence successful driving outcomes; specifically, emotional dysregulation can impair the ability to manage difficult driving situations (Trogolo et al., 2014). It is important to understand how young autistic drivers experience driving differently than their non-autistic peers since those with ASD experience higher rates of emotion dysregulation (Mazefsky et al., 2013).

Objectives: The current study's objective is to investigate perceived driving difficulty (DD), emotion dysregulation, and internalizing problems in emerging drivers with and without ASD, and how emotion dysregulation and internalizing symptoms relate to DD. We expected 1) greater DD and emotion dysregulation/problems in those with versus without ASD, and 2) a positive correlation between DD and both emotion dysregulation and internalizing symptoms in the whole sample.

Methods: Thirty-seven adolescents and young adults (65% male, age range: 15-24 years, n=15 with ASD) were recruited for a study of driving readiness in autistic individuals. Participants rated themselves on DD in 14 various driving situations and completed two questionnaires: Difficulty in Emotion Regulation Scale (DERS) and Depression, Anxiety, and Stress Scale (DASS). DD items were rated on a 4-point Likert scale from very easy to very difficult, and then averaged. The DERS assesses the recognition and management of negative affect resulting in a total sum and 6 subscales: Nonacceptance, Goals, Impulse, Awareness, Strategies, Clarity. The DASS assesses internalizing symptoms across 3 indices for a total sum and 3 subscale scores: Depression, Anxiety, Stress. For both questionnaires, higher scores indicated greater impairment. T-tests compared mean DD, DERS, and DASS between the ASD and non-ASD groups. Correlational analyses compared scores on the DERS and DASS with mean DD.

Results: Autistic participants scored higher than non-autistic on mean DD, DERS Impulse subscale, DASS total and DASS Stress subscale scores (Table 1). Higher total scores on the DERS and DASS, as well as all DASS subscales and DERS Nonacceptance, Goals, and Impulse subscales, were correlated with higher DD scores across the whole sample.

Conclusions: These findings highlight the important roles that emotion dysregulation and internalizing symptoms play in DD in emerging drivers with ASD. In particular, stress symptoms and dysregulation related to impulsivity may map onto mechanisms of over-reactivity to negative affect and begin to explain why autistic people face particular challenges when driving, since driving requires regulation of behavior in response to difficult driving situations. Future research could include caregiver-report data for a more comprehensive understanding, and a larger sample where mediational analyses can be conducted to understand if these symptoms explain DD in adolescents and young adults with ASD or if other driving metrics, such as interest in driving and licensure obtainment, contribute as well.

401.030 *(Poster)* Employee, Employer, and Job Coach Perceptions of the Importance of Specific Employment Support Services

F. K. Murahara[1]*, C. Di Francesco*[2]*, V. Martin*[3]*, T. Flanagan*[1] *and A. Nadig*[4]*, (1)Educational and Counselling Psychology, McGill University, Montreal, QC, Canada, (2)Psychology, McGill University, Montreal, QC, Canada, (3)École de psychoéducation, Université de Montréal, Montreal, QC, Canada, (4)School of Communication Sciences and Disorders, McGill University, Montreal, QC, Canada*

Background: The high level of unemployment of individuals with autism and/or intellectual disabilities (ID) in Canada (Statistics Canada, 2018) holds negative consequences for the individual and their families, as well as society at large. Conversely, employment can confer several benefits including greater self-confidence and development of a sense of community (Lindsay, 2018). Job coaching services offer a bridge to employment; employers identify them as the key facilitator for hiring a person with disabilities (Morgan & Alexander, 2005). Yet, little is known about how this support matters to employees with disabilities and employers.

We partnered with a non-profit organization, Action main d'oeuvre, that provides employment support to individuals with autism or ID, and their employers. We co-created a multiple case research study to investigate the impact and perception of their services. Ward, Dowrick & Weyland (1993) previously analyzed both employer and job coach perceptions of specific employment service components to recommend best practices for support. Scott et al. (2015) compared the perspectives of employers and adults with autism. To our knowledge, ours is the first study to incorporate three key perspectives: employee, employer and job coach.

Objectives: Examine how job coach support facilitates job placement and retention, and what the most helpful components are from employee, employer, and job coach perspectives.

Methods: Nine employee-employer-job coach triads (27 participants total) were recruited. Employees were adults with autism (n = 6), autism and ID (n = 1), or ID (n = 2). Triads completed questionnaires at two time points: (1) the month the employee started a new job; (2) three-to-four months after the start. We used a mixed-methods approach to explore the impact of job coach services, and its perception by all three members of the triad. This included (1) an evaluation of the employee rated by employer; (2) job satisfaction rated by employee; and (3) an evaluation of the importance of specific service components received. Specific components prior to job placement (Figure 1, rated by employee and job coach) and post job placement (Figure 2, rated by all three parties) were rated on a Likert scale reflecting perceived importance.

Results: With respect to pre-job placement services, both employees and job coaches rated all components highly. Ratings of employees and job coaches agreed highly, with two exceptions (see Figure 1). For specific service components post-job placement, ratings by all 3 parties (employees, employers and job coaches) were 3.5 or higher on the 5-point scale and often agreed highly. Exceptions are highlighted in Figure 2.

Perception of service components will be complemented by a detailed case analysis including triangulation of measures of the impact of employment support, from the triad's perspectives to highlight both the most beneficial practices, and factors that contributed to dissatisfaction/job loss.

Conclusions: Our data evaluating specific employment service components indicates that employees, employers, and job coaches find all services provided to be important. Analysis of areas of divergence can be applied to improve services. Detailed multiple case analysis will elucidate best practices and barriers to employment success.

401.031 *(Poster)* Evaluation of the Australian Modified Vocational Index for Adults with Autism (M-VIAA)

D. Hedley[1], *E. Sahin*[1], *S. M. Bury*[1], *R. L. Flower*[1], *L. P. Lawson*[1,2] *and A. L. Richdale*[1,2], *(1)Olga Tennison Autism Research Centre, La Trobe University, Melbourne, VIC, Australia, (2)Cooperative Research Centre for Living with Autism (Autism CRC), Long Pocket, QLD, Australia*

Background: Autistic individuals are under-represented in employment and post-secondary education. Research is hampered by a lack of psychometrically valid instruments that asses the vocational activities of autistic people. This study examined the psychometric properties of an Australian modified version of the Vocational Index for Adults with Autism (M-VIAA), an assessment of vocational independence.

Objectives: Examine the psychometric properties of an Australian modified version of the Vocational Index for Adults with Autism (M-VIAA), an assessment of vocational independence.

Methods: Participants were 105 autistic and 106 non-autistic young adults aged 16 to 26 years recruited from the longitudinal Study of Australian School Leavers with Autism. Psychometric properties of the M-VIAA were examined by a) comparing scores between autistic and non-autistic participants, b) examining convergent validity with daily living skills, c) divergent validity with autistic traits, and d) change over time by comparing baseline and 24 month follow-up scores in autistic participants.

Results: Vocational independence was found to be significantly higher in non-autistic compared to autistic participants. No relationship was found between daily living skills and the M-VIAA, thereby convergent validity was not supported. There was a small but significant relationship between the M-VIAA and autistic traits, which was contrary to our prediction regarding discriminant validity. Scores on the M-VIAA remained stable over time for a sub-sample of autistic participants.

Conclusions: The present study provides preliminary support for the M-VIAA with some limitations. Construct validity was questionable as results were not supportive of the hypothesized relationships between the M-VIAA, daily living skills, and autistic traits. Our findings suggest the M-VIAA may not capture the complexity of vocational challenges of autistic people. There is a need for development of a new instrument that builds on the structure of the VIAA, but that is applicable across cultures and contexts, and provides a richer picture of the vocational activities of autistic people.

401.032 *(Poster)* Examining Fear of Negative Evaluation in Young Adults across a Range of Self-Reported ASD Symptomatology

A. W. Gigler[1], *Y. S. Lograsso*[2], *E. Denluck*[3], *H. R. Goodman*[1] *and E. A. Laugeson*[2], *(1)UCLA PEERS Clinic, Los Angeles, CA, (2)UCLA Semel Institute for Neuroscience and Human Behavior, Los Angeles, CA, (3)UCLA Department of Psychiatry, PEERS lab: UCLA PEERS Clinic, Los Angeles, CA*

Background: Prior research has found that adults with autism spectrum disorder (ASD) are at a significantly greater risk of social anxiety than the general population (Seltzer, Shattuck, Abbeduto, & Greenberg, 2004). Fear of Negative Evaluation (FNE) operationalizes the cognitive symptoms of social anxiety, but there are limited empirical studies examining individuals with ASD in this domain (Capriola, Maddox, & White, 2017). However, there is evidence that self-awareness of social difficulties is associated with anxiety in individuals with ASD (Seltzer et al., 2004), and an acute awareness of their impairments may result in heightened anxiety (Capriola et al., 2017).

Objectives: Considering the role of self-awareness and perception in social anxiety and the need for further study of FNE in individuals with ASD, the current study seeks to examine the relationship between FNE and ASD in this vulnerable population. We hypothesized that increased ASD symptoms would be associated with increased FNE.

Methods: Participants included 119 young adults, (73.9% male; mean age=22.52, *SD*=3.987) presenting for social skills treatment through the UCLA Program for the Education and Enrichment of Relational Skills (PEERS®; Laugeson, 2017). PEERS® is an evidence-based, caregiver-assisted social skills program for young adults with ASD and other social challenges (Laugeson et al., 2015). ASD symptoms were measured using self-report scores on the Social Responsiveness Scale-Second Edition (SRS-2; Constantino & Gruber, 2012), and individuals were divided into three groups based on their scores. Those with scores ranging from 0-59 were categorized as the "Within Normal Limits" group; scores ranging from 60-66 were categorized as the "Mild ASD" group; and scores above 66 were categorized as the "Moderate-Severe ASD" group. FNE was measured using self-report scores on the Social Anxiety Scale (SAS) Fear of Negative Evaluation subscale (La Greca, 1999). All assessments were conducted at baseline prior to treatment. An analysis of variance (ANOVA) was conducted to examine whether individuals with higher self-reported ASD symptomatology would show greater FNE.

Results: Results from the ANOVA reveal significant variation in FNE scores across each of the three symptom profiles [$F(2,116)=14.657$, $p<.001$]. The "Within Normal Limits" group scored the lowest ($M=19.32$, $SD=7.84$), followed by the "Mild ASD" group ($M=25.06$, $SD=6.52$), while the "Moderate-Severe ASD" group scored the highest ($M=27.42$, $SD=6.56$).

Conclusions: Results indicate that as self-reported ASD symptoms increase, FNE also increases. However, FNE appears to level off at the highest levels of ASD symptoms, which is surprising considering that the literature suggests that increased awareness of social difficulties results in heightened anxiety (Capriola et al., 2017). One explanation for these results may be that they were obtained through self-report measures, which may reflect subjects' inaccurate appraisal of their actual symptom presentation as it relates to social difficulties and impairments. These findings raise questions about the role of self-awareness and perception in social anxiety in ASD, and suggest that other factors may be increasingly influential in driving social anxiety at higher levels of ASD symptoms. Further research is needed to identify and understand these factors in order to inform the development of more targeted treatment and interventions.

401.033 *(Poster)* Examining Physical Activity and Quality of Life in Adults with Autism Spectrum Disorder

M. Savage[1]*, B. Tomaszewski*[2,3,4] *and K. Hume*[2]*, (1)Educational Psychology, University of North Texas, Denton, TX, (2)Frank Porter Graham Child Development Institute, University of North Carolina at Chapel Hill, Chapel Hill, NC, (3)Psychiatry, University of North Carolina at Chapel Hill, Chapel Hill, NC, (4)TEACCH Autism Program, University of North Carolina at Chapel Hill, Chapel Hill, NC*

Background: When individuals with autism spectrum disorder (ASD) participate in exercise programs, research consistently indicates improvements in physical fitness levels, health, and a range of behavioral and social/emotional improvements (Sowa & Muelenbroek, 2012). Self-reported physical activity is also associated with quality of life in young adults with ASD (Hamm & Yun, 2019). While some have examined the relationship between subjective levels of physical activity and quality of life for adults with ASD, few studies have examined the relationship between objective measures of physical activity and quality of life.

Objectives: To (a) describe physical activity levels and quality of life and (b) examine the relationship between step counts and quality of life for adults with ASD.

Methods: Forty-three potential participants with autism spectrum disorder (ages 18–47) were recruited for this study. Of the 43 potential participants, 35 met inclusion criteria. Participants completed demographic and health information. Researchers administered the quality of life questionnaire, measured nonverbal IQ using the Leiter International Performance Scale-Third Edition, observed participants to determine severity of autism symptoms using the Childhood Autism Rating Scale-2 (CARS-2), obtained current height and weight measures to determine body mass index (BMI), and asked participants to wear a Fitbit Flex2 activity tracker for one week.

Results: The average BMI for participants fell in the overweight category (Mean = 29.1, SD = 7.6). Most participants were in the obese category, followed by normal and overweight categories. Overall, participant average daily steps were in the *low active* range (Mean = 6,981, SD = 3,480). Increased average daily step count was significantly associated with overall quality of life, controlling for age and nonverbal IQ ($r = .55$, $p = .001$). The quality of life competence and social belonging domains were associated with baseline step count ($r = .58$, $p < .001$ and $r = .35$, $p = .04$ respectively) and BMI ($r = -.42$, $p = .01$ and $r = -.43$, $p = .01$ respectively).

Conclusions: This study highlights the use of an objective measure of physical activity and provides support for increasing our understanding of the relationship between physical activity and quality of life in this population. Activity trackers are becoming a popular tool for measuring activity to promote positive behavior change. More than 80% of the sample recruited for this study accepted the Fitbit Flex 2. This finding adds to the limited body of literature on the feasibility/acceptability of using Fitbit trackers to measure step counts for adults with ASD (LaLonde, MacNeill, Eversole, Ragotzy, & Poling, 2014).

Hamm, J., & Yun, J. (2019). Influence of physical activity on the health-related quality of life of young adults with and without autism spectrum disorder. *Disability and Rehabilitation, 41*(7), 763–769.

Sowa, M., & Meulenbroek, R. (2012). Effects of physical exercise on autism spectrum disorders: a meta-analysis. *Research in Autism Spectrum Disorders*, *6*(1), 46-57.

401.034 *(Poster)* Exercise Among Adults with Autism: Frequency of Participation, Attitudes and Barriers

D. Schena[1]*, A. Hillier*[2] *and A. Buckingham*[3]*, (1)University of Massachusetts, Lowell, Lowell, MA, (2)University of Massachusetts Lowell, Lowell, MA, (3)Psychology, University of Massachusetts Lowell, Lowell, MA*

Background: Children and adolescents with autism spectrum disorder (ASD) have low levels of physical fitness and are more likely to be overweight compared to typically developing children. This puts them at risk for health-related problems associated with inactivity, such as increased risk of obesity. Previous research on exercise in persons with ASD has focused more on children than adults but has demonstrated that exercise has a wide variety of benefits for all ages. We used the Theory of Planned behavior, which states that intent for actions is composed of the individual's attitude towards the behavior, subjective norms, and perceived behavioral control, as a model with which to study attitudes towards exercise and potential barriers individuals with ASD experience.

Objectives: The aim of this study was to examine participation in exercise, attitudes towards exercise, and barriers to participation among adults with ASD as compared to typically developing peers.

Methods: The Godlin-Shephard Leisure-Time Physical Activity Questionnaire (2011) was used to assess frequency of weekly physical activity. Kerner and Grossman's (2001) scales assessed fitness attitude, perceived expectations of others, perceived behavioral control, and desire to exercise. Finally, the Barriers to Physical Exercise and Disability survey (add author name, 2000) was modified to assess possible barriers to exercise participants may encounter. These measures were completed by a group of 30 participants with ASD (18-27 years old, mean 22) and 30 participants without ASD in a matched comparison group (18-28 years old, mean 21).

Results: Findings indicated that those in the comparison group participated in strenuous or moderate physical activity significantly more frequently than those with autism (p = 0.01), had significantly more positive attitudes towards fitness (p=0.001), greater perceived behavioral control over ability to perform physical fitness activities (p=0.006), and indicated fewer barriers to participating in exercise (p=0.017). There were no significant differences between the groups for intent to exercise (p=0.11) or their beliefs about others' expectations regarding their exercising (p=0.969).

Conclusions: These findings suggest that more opportunities to exercise are needed for adults with ASD, particularly given that many challenges including anxiety and stress, could potentially be attenuated through exercise. Within the context of the Theory of Planned Behavior, two of the three aspects of intent to exercise, those being attitude towards exercise and perceived behavioral control of exercise, were significantly weaker in the ASD group. Future research will be conducted to investigate ways to strengthen these aspects of intention in adults with ASD.

401.035 *(Poster)* Exploring the Diagnostic Disclosure Experiences of Autistic Individuals in the Workplace

A. M. Romualdez[1]*, A. Remington*[2] *and Z. Walker*[1]*, (1)Psychology and Human Development, UCL Institute of Education, London, United Kingdom, (2)UCL Centre for Research in Autism and Education, London, United Kingdom*

Background: The employment rate for autistic individuals in the UK is estimated at only 16% for full-time employment and 32% for any kind of paid work, compared to 47% for other disability groups (National Autistic Society, 2016). Autistic individuals struggle to find and maintain suitable employment, and those without intellectual impairment actually have a lower employment rate than those with an intellectual disability in addition to autism. These individuals often experience social communication differences and autism-related stigma in workplace situations, but may also want to ask for reasonable adjustments related to their disability. One of the biggest employment challenges for autistic individuals is deciding whether or not to disclose their diagnosis and, if they choose to do so, how and when they should disclose to their supervisors and colleagues. Studies on autism disclosure in the workplace are scarce, but even scarcer still is research that elicits the views and experiences of autistic individuals who have struggled with the decision to disclose during the recruitment process and at work.

Objectives: This study aims to answer the question, "What are the lived experiences of autistic individuals who have chosen to either disclose or not disclose their diagnosis while seeking or maintaining employment?"

Methods: Semi-structured interviews focusing on diagnostic disclosure were conducted with 24 autistic adults either over the phone, online, or via e-mail. Transcripts from the interviews were analysed by two independent coders using *thematic analysis* (Braun & Clarke, 2006).

Results: The themes that emerged from the analysis were those found to be common across interviews. Global themes include: experiences around diagnosis, struggle as motivation to disclose, challenges after disclosure, successes in the workplace, and disclosure as integral to autistic community and identity.

Conclusions: Several factors may influence an individual's decision to disclose their autism diagnosis while seeking or maintaining employment, and experiences surrounding disclosure may vary. The experiences of individuals who have gone through the struggle of choosing whether or not to disclose provide valuable insights about autism disclosure in the workplace, including both the successes and challenges resulting from disclosure.

401.036 *(Poster)* Exploring the Intersection of Gender Identity and Sexual Orientation in Autism Spectrum Disorder through a Patient-Centered Lens

S. N. Brasher[1]*, S. Woodmansee*[2]*, R. Stapel-wax*[3] *and J. L. Stapel-Wax*[4]*, (1)School of Nursing, Emory University, Atlanta, GA, (2)Nursing, Children's Healthcare of Atlanta, Atlanta, GA, (3)Southern Jewish Resource Network for Gender and Sexual Diversity, Atlanta, GA, (4)Emory University School of Medicine, Atl, GA*

Background: Despite research suggesting a need for a better understanding of the key issues encountered by adults with autism spectrum disorder (ASD), there is a dearth of research on gender identity and sexuality in women with ASD. Moreover, little is known regarding the intersection of ASD, gender identity, and sexuality in terms of their needs and the outcomes of these needs being unmet. Research suggests that individuals identifying as Lesbian, Gay, Bisexual, Transgender, or Queer/Questioning (LGBTQ) are at increased risk for depression, suicidal ideations, and self-harm. Similarly, research has found that individuals with ASD are already at an increased risk of depression, suicidal ideations, and self-harm. Thus, females with ASD of intersecting marginalized gender and sexual identities are at an increased risk of mental health conditions and poorer health outcomes-to what extent is unknown.

Objectives: To engage females with ASD to create a better understanding of the issues encountered at the intersection of gender identity and sexuality in ASD, as well identify patient-centered ways to address their needs.

Methods: A Patient-Centered Outcomes Research (PCOR) design was used to build the infrastructure necessary to engage females with ASD ages 18-38 and identify future research responsive to their needs. Sampling procedures did not specify LGTBQ+ identification, but instead was inclusive to all females with ASD. Monthly engagement sessions were conducted over a 2-year time frame. Each session included 6-12 females with ASD for a total of 32 females (n=32). Sessions were audio recorded, transcribed verbatim, and analyzed by two independent qualitative researchers.

Results: Results highlight the unique needs of females with ASD identifying as LGTBQ. More than half (n=20) of the females identified as LGTBQ. All of the participants identifying as LGTBQ noted significant health disparities as a result of their intersecting gender identity, sexuality, and ASD diagnosis. The following themes were identified as significantly impacting the health and health outcomes of these individuals: insufficient training of providers on LGTBQ and ASD, mental health outcomes (e.g., isolation, depression, suicidal ideations) for those feeling unsupported, and the cost of having to see two or more providers (e.g., ASD-specific and LGTBQ-knowledgeable).

Conclusions: Little research has been conducted to understand gender identity and sexual orientation in ASD. Moreover, the limited research that does exist has focused on sexuality in males with ASD. Anecdotal evidence suggests that more females with ASD may identify as LGTBQ than expected in the general US population. However, the impact this intersection has on health and health outcomes is unknown. Thus, this two-year study provides initial insight from the patient perspective and ways to minimize health disparities within this group. Future research is currently being planned to better understand this topic, as well as a series of educational conferences to address the needs of females with ASD.

401.037 *(Poster)* Exploring the Social Cognition Network in Young Adults with Autism Spectrum Disorder Using Graph Analysis

M. C. Pino[1], *M. Mazza*[1], *F. Masedu*[2], *R. Vagnetti*[3] *and M. Valenti*[3], *(1)Department of Applied Clinical Sciences and Biotechnology, University of L'Aquila, L'Aquila, Italy, (2)University of L'Aquila, Italy, L'Aquila, Italy, (3)University of L'Aquila, L'Aquila, Italy*

Background: Autism Spectrum Disorder (ASD) is characterised by an impairment in Social Cognition (SC). SC is a cognitive construct that refers to the capacity to process information about social situations. It is a complex network that includes distinct components. Exploring how SC components work together leads to a better understanding of how their interactions promote adequate social functioning.

Objectives: Our main goal was to use a novel statistical method, graph theory, to analyse SC relationships in ASD and Typically Developing (TD) individuals.

Methods: we applied graph theory to SC measures to verify how the SC components interact, and to establish which of them are important within the interacting SC network for TD and ASD groups.

Results: the results showed that, in the TD group, the SC nodes are connected; their network showed increased betweenness among nodes, especially for the Theory of Mind. By contrast, in the SC network in the ASD group the nodes are highly disconnected, and the efficient connection among the components, mediated by cognitive elaboration, is absent.

Conclusions: ASD adults have not developed SC competencies and functional communication among these skills. We suggest intervening in the development of SC skills in the early years of ASD children, using rehabilitation interventions; in this way, we could supplement their development of complex social skills and avoid their typical social isolation.

401.038 *(Poster)* Factor Structure and Psychometric Properties of the Brief COPE in Autistic Adults

M. Muniandy[1,2], *A. L. Richdale*[1], *S. Arnold*[3], *J. Trollor*[2] *and L. P. Lawson*[1], *(1)Olga Tennison Autism Research Centre, La Trobe University, Melbourne, VIC, Australia, (2)Cooperative Research Centre for Living with Autism (Autism CRC), Brisbane, QLD, Australia, (3)The University of New South Wales, UNSW Sydney, NSW, Australia*

Background: Autistic adults may experience higher levels of stress and more frequent stressful encounters compared to the general population. However, research into coping with stress in the autistic adult population remains limited, with no standardised coping assessment tools validated specifically for this population. This is concerning as there may be intricacies to the experience of stress and coping that may be unique to autistic individuals. Evidence from non-autistic populations suggests that exposure to stressful experiences and how one copes with stress can have a substantial impact on well-being and mental health. Furthering our understanding of coping in autistic adults has the potential to allow new perspectives to be taken when considering the challenges many autistic adults face (e.g., in employment, personal relationships, and well-being).

Objectives: To explore the factor structure and psychometric properties of the Brief COPE in a sample of autistic adults. Utilising an age-matched sample of non-autistic adults, the factor structures for the two samples were also compared.

Methods: Total sample size was 420, comprising 255 autistic adults and 165 non-autistic adults, aged 15-80 years, recruited through two longitudinal studies. Coping behaviour and psychological well-being were measured using the Brief COPE, Patient Health Questionnaire-9 (PHQ-9) and the Warwick-Edinburgh Mental Well-being Scale (WEMWBS). Principal components analysis (PCA) with Varimax rotation was used to explore the Brief COPE factor structure in each sample. A score for each coping dimension identified was obtained using the sum of its constituent items.

Results: A six-factor model best represented coping responses in both groups, explaining 60.3% and 63.7% of variance in the autistic and non-autistic samples respectively. These factors were 1) Engagement coping, 2) Support-seeking coping, 3) Disengagement coping, 4) Substance-use coping (autistic sample)/Escapism coping (non-autistic sample), 5) Religious coping and 6) Humour coping. High internal consistency for these factors were found (α range: 0.75- 0.95 for autistic group; α range: 0.74- 0.89 for non-autistic group). While both samples had comparable factor structures, minor differences were noted. Self-distraction coping strategies loaded with Disengagement coping in the autistic sample, but with Engagement coping in the non-autistic sample. Substance-use coping, which emerged as a distinct factor in the autistic group, loaded with coping through denial in the non-autistic group, forming a factor more suggestive of Escapism coping. Relevant coping factors (i.e., Disengagement coping and Substance-use/Escapism) showed good convergent validity with the PHQ-9 (i.e., r = 0.673, 0.278 in the autistic group; r = 0.524, 0.286 in the non-autistic group) and divergent validity with the WEMWBS (i.e., r = -0.495, -0.196 in the autistic group; r = -0.445, -0.270 in the non-autistic group).

Conclusions: This is the first study to examine the factor structure of the Brief COPE in autistic adults. A six-factor structure with good psychometric properties was reported. Though there were differences (i.e., self-distraction and substance-use strategies) between samples that may be explored further, these preliminary indications about the compatibility of coping responses in autistic and non-autistic adults, suggest that the Brief COPE may be used to make comparisons between coping in the two populations.

401.039 *(Poster)* Factors That Influence Career Choice: Insights from a Participatory Study with Autistic and Non-Autistic College Students

C. Cheriyan[1], *S. Shevchuk*[2], *A. Riccio*[3], *J. Vincent*[4], *S. K. Kapp*[5], *P. Dwyer*[6], *E. Cage*[7] *and K. Gillespie-Lynch*[8], *(1)CUNY, NY, NY, (2)College of Staten Island, CUNY, Staten Island, NY, (3)Department of Psychology, The Graduate Center, City University of New York (CUNY), New York, NY, (4)York St. John University, York, United Kingdom, (5)Department of Psychology, University of Portsmouth, Portsmouth, United Kingdom, (6)Department of Psychology, University of California, Davis, Davis, CA, (7)University of Stirling, Stirling, United Kingdom, (8)Department of Psychology, College of Staten Island; CUNY Graduate Center, Brooklyn, NY*

Background: Autistic individuals are *less* likely to obtain employment than people with other disabilities (Shattuck et al., 2012). Past research highlights environmental factors that keep some autistic people from succeeding in the workplace, including discrimination (Pfieffer et al., 2017). According to Antonak and Livneh (2000), autistic employees may feel isolated at work due to difficulties with social communication. Despite this challenge, autistic individuals have many strengths that can assist them in the workplace (Sperry & Mesibov, 2005). Little remains known about how possible strengths and challenges influence the career choices of autistic individuals. In addition, factors that shape the career goals of the growing population of autistic college students have been overlooked.

Objectives: To identify factors autistic college students consider before selecting a career and determine how autistic students intend to use their strengths to overcome challenges seeking work.

Hypothesis a: Autistic students will place more emphasis on helping others and passion for their interests as motivating their career goals than non-autistic students.

Hypothesis b: Autistic students will describe detail orientation and writing skills as job-related skills more than non-autistic students.

Hypothesis c: Autistic students will expect social skills, executive functioning, and discrimination to impact their success obtaining career goals more than non-autistic students.

Methods: Autistic college students and academics and non-autistic researchers collaboratively developed hypotheses and an online survey. Autistic students (*n*=85; 50.6% male; 64.0% White) recruited across multiple college campuses and non-autistic students (*n*=56; 35.7% male; 48.2% White) from a single-subject pool answered open-ended questions: Why is this job of interest to you? What skills do you have that could help you succeed in your dream job? What challenges might you face getting or keeping your dream job? Responses were coded after establishing reliability.

Results: Autistic and non-autistic college students expressed similar reasons for selecting a career (Table 1). Autistic students identified writing and pattern matching as skills that could help them get their dream job and discrimination, and social challenges and psychological difficulties as barriers that might prevent them from getting their dream job more frequently than non-autistic students did (Table 2).

Conclusions: Despite the stereotype that autism is defined by "fixated interests," both autistic **and** non-autistic students were guided toward their dream jobs by a passion for their interests and a frequent desire to help others. Although autistic students felt that their strengths in pattern matching and writing would help them obtain their dream jobs, they were also more likely to expect that discrimination, psychological, and social challenges would be barriers to obtaining their dream jobs relative to non-autistic students. These findings indicate that programs to help autistic university students obtain meaningful jobs should build from their strengths, should provide mental health supports and help adapting to workplace social norms, and should focus on combatting discrimination among potential employers and coworkers.

401.040 *(Poster)* Healthcare Utilization Among Transition-Age Youth with Autism Spectrum Disorder (ASD) in the U.S. Inpatient Healthcare Setting

S. N. Brasher *and Y. Li, School of Nursing, Emory University, Atlanta, GA*

Background: Little is known about the healthcare utilization of individuals with autism spectrum disorder (ASD), particularly transition-age youth and young adults with ASD. Each year, an estimated 50,000 youth transition to adulthood in the United States. In addition to the expected health conditions associated with aging, young adults with ASD experience a higher number of medical and psychiatric comorbidities (e.g., seizures, anxiety, depression, sleep disturbances, gastrointestinal disorders, bipolar disorder) compared to young adults without ASD. Of great concern is how these medical and psychiatric comorbidities impact their overall health and health outcomes during transitioning and beyond.

Objectives: The objective of this study was to describe the healthcare utilization of young adults with ASD.

Methods: This study incorporated a cross-sectional design to explore the 2016 State Inpatient Databases (SID). Variables within the SID examined included the following: age (15-35), race, gender, diagnosis of ASD (ICD-10 codes F84.0, F84.2, F84.3, F84.5, F84.8, F84.9), admitting diagnosis, number of diagnoses (comorbidities), length of stay, mortality, and readmission.Descriptive statistics were analyzed for the following variables: age, gender, race, ethnicity, length of stay, chronic conditions, marital status, and readmission. Frequency data were analyzed to determine the types and frequency of admitting diagnoses.

Results: A total of 979,099 (n=979,099) patient encounters were explored in the SID. Within this sample size included patients with ASD (n=2822) and patients without ASD (n=976277). Significant differences existed between healthcare utilization in terms of age of healthcare utilization ($p < 0.0001$), length of stay ($p < 0.0001$), gender-based healthcare utilization ($p < 0.0001$), chronic conditions ($p < 0.0001$), marital status ($p < 0.0001$), and readmission ($p < 0.0001$). Of particular note were the significant differences in healthcare utilization during the transition to adulthood (ages 15-35), where a majority of individuals with ASD utilized healthcare during this time (66.86%) compared to those without autism (27.15%). Admitting diagnoses were classified categorically as Medical versus Psychiatric. Top 10 admitting diagnoses for those with ASD were depression, seizures, schizophrenia, bipolar disorder, suicidal ideations, sepsis, psychosis, impulse disorder, unspecified mood disorder, and pneumonia.

Conclusions: Findings of this study support existing research, indicating the reasons why young adults with ASD are being hospitalized. These included a high prevalence of psychiatric (e.g., depression, schizophrenia, suicidal, bipolar) and neurologic (e.g., seizures) conditions among other reasons. When compared to individuals with ASD being hospitalized to those without ASD, the top 10 diagnoses were vastly different between groups. Individuals without ASD were more likely to be hospitalized for common medical conditions (e.g., chest pain, sepsis) compared to those with ASD who were largely hospitalized for psychiatric conditions. These findings of high prevalence of psychiatric disorders is consistent with other studies and offers a better understanding of the various types of psychiatric disorders presenting on admission. Further research is needed to explore racial, ethnic, and socioeconomic status differences in healthcare utilization, as well as the impact these variables have on health outcomes. Future research is being planned with expanded datasets to increase the sample size of individuals with ASD.

401.041 *(Poster)* Heterogeneity in Adults with an Autism Spectrum Condition (ASC): Identification of Subgroups By Means of Community Detection

T. A. Radhoe[1]*, J. Agelink van Rentergem*[2] *and H. M. Geurts*[3]*, (1)Brain & Cognition, University of Amsterdam, Amsterdam, Netherlands, (2)Psychology, University of Amsterdam, Amsterdam, Netherlands, (3)University of Amsterdam, Amsterdam, Netherlands*

Background: Autism spectrum condition (ASC) is often considered to be marked by heterogeneity, which complicates the search for causes and support for individuals with an ASC diagnosis. This led to the idea that different subgroups may exist in the population of autistic individuals with separate outcomes.

Objectives: We aim to identify homogeneous subgroups based on behavioral data in adults with ASC by means of community detection and testing of the subgroups' validity.

Methods: Questionnaire data were collected as part of a larger longitudinal study. The input for the community detection analyses are fourteen variables collected at T1: behavioral measures of ASC traits, demographic, and psychological characteristics. The officially preregistered analysis plan consists of six steps. Step 1: We determine subgroups in a training data set of N=167 adults aged 31 to 89 years with 62% males (113 ASC, 54 controls). Step 2: We repeat the community detection analysis for just the autistic participants to gain more insight into heterogeneity within ASC. Step 3: We compare subgroups based on the ASC sample on three measures not included in subgroup detection (i.e., external validation): cognitive failures, wellbeing and mental health problems. Step 4: We replicate our results from step 1 by determining subgroups in a test data set of at least N=470 additional participants. Step 5: We replicate our results from step 2 by determining subgroups only in participants with ASC in the test data set (i.e., N= 250). Step 6: We replicate our results from step 3 by comparing subgroups in the test data set on the aforementioned external validators. Thus, step 1 to 3 are exploratory, and step 4 to 6 are confirmatory.

Results: Step 1: Two distinct subgroups were obtained. Subgroup 1 includes mainly controls (98%) while subgroup 2 includes mainly autistic adults (79%). Step 2: Within the ASC group, three distinct subgroups were identified ($N_{subgroup1}$ =30 (27%), $N_{subgroup2}$=32 (28%) and $N_{subgroup3}$=51 (45%)). These subgroups did not differ in age, gender and educational level attained. Step 3: The ASC subgroups differed significantly on all three external validation measures. Participants in subgroup 3 experienced the most cognitive failures, mental health problems, and reported the lowest wellbeing compared to subgroup 1 and 2. Participants in subgroup 2 experienced the least cognitive failures, but experienced more mental health complaints than adults in subgroup 1. There were no differences in wellbeing between subgroup 1 and 2. The independent replication of these findings in step 4, 5 and 6 will be presented at the conference as data collection will be finished before February 2020.

Conclusions: Application of community detection on behavioral data, seems to result in identification of three distinct and valid ASC subgroups. If we replicate these findings, this would imply that knowledge regarding behavioral heterogeneity in ASC can be clinically meaningful when shaping support for autistic adults.

401.042 *(Poster)* High Functioning Autistic Adults in India: Their Narratives about Self

D. Taneja[1]*, N. Singhal*[1]*, T. Behl*[1]*, R. Pradhan*[1]*, M. Barua*[1]*, T. Daley*[2] *and T. S. Weisner*[3]*, (1)Action For Autism, New Delhi, India, (2)Westat, Durham, NC, (3)UCLA, Los Angeles, CA*

Background: Autism remains a highly stigmatized condition, especially in a low income country like India. Even today many adults with high functioning autism continue to be undiagnosed and/or hidden. Even once the diagnosis is received, parents and therapists rarely disclose or share the diagnosis with the individuals with autism. So, what do our young people know about their autism? How do they perceive and understand themselves and their differences? Not many studies have explored this from the perspective of people with autism. The RAFIN Adult Study is the first to systematically examine adults with ASC in India.

Objectives: This paper reports initial data on explanations by high functioning adults about their similarities and differences and their understanding of the reasons behind them.

Methods: Thirteen high functioning adults with ASC were interviewed in their homes. The interactions with the adults were carried out through semi-structured interviews in the preferred language and lasted for about 2-3.5 hours. Amongst several other topics, individual's understanding of their own self, their perceptions of similarities and differences from others around them, the nature of these differences (if any), as well as the kind of support they may like were discussed. This data is a part of a larger study of 54 adults and their families in Delhi & NCR region where we spoke to adults and their families about their journey since receiving the diagnosis as well as plans for the future. The interviews were audio recorded and the transcriptions were Qualitatively analysed.

Results: Almost all participants had specific thoughts about how they were similar to and different from non-autistic people. The responses were categorised in various themes, such as concrete attributes, personality attributes, interests and preferences, specific skills, diagnoses, disclosure about diagnoses, strengths and limitations of being different.

Conclusions: In one of the first studies of adults with autism in India, the authors present self-reports of verbally fluent adults with ASC about their understanding of their similarities and differences. The study highlights that every person on the autism spectrum is aware of his/her differences – some of them recognised them as early as primary school. However, an understanding and explanation of this difference comes much later, if at all. Most participants in our sample needed further clarity in understanding their difference.

The study emphasizes the need for active involvement of people with ASC in all life aspects, including research and interviews, aimed at understanding their unique life experiences; need for development of self-report measures and interview strategies; and most importantly the process of disclosure of diagnosis to individuals with autism.

401.043 *(Poster)* How Much Do Disability Service Office Staff of US Higher Education Institutions Know about ASD, and How Do They Think about ASD?

***S. Y. Kim**, Lynch School of Education, Boston College, Chestnut Hill, MA; Department of Psychiatry, Seoul National University Bundang Hospital, Seongnam, Korea, Republic of (South)*

Background: While disability support office (DSO) staff are responsible for providing appropriate support, many academically qualified autistic students continue to experience difficulties on campus and drop out prematurely. If DSO staff members have accurate knowledge and positive attitudes about ASD, they may be more effective in providing a more inclusive environment, and autistic students may be more likely to disclose their disability and any related concerns. Therefore, this study will explore DSO staff members' attitudes and knowledge about ASD and potential variables that may be associated with their attitudes and knowledge about ASD.

Objectives: The purpose of this exploratory study was to assess DSO staff members' attitudes (attitudes toward autistic symptoms, levels of openness, and social distance from autistic individuals) and knowledge about ASD to address the following research questions:

RQ1. Among four blocks of putative predictors, including knowledge about ASD, contact, demographic variables, and institutional variables, which variables are unique predictors of DSO staff members' attitudes about ASD?

RQ2. Among three blocks of putative predictors, including contact, demographic variables, and institutional variables, which variables are unique predictors of DSO staff members' knowledge about ASD?

Methods: One hundred fifty-three DSO staff members completed a Qualtrics online survey (See Table 1 for demographic characteristics). Participants first completed the attitudes and knowledge surveys, which were administered in random order, and the quality and quantity of contact scales were then administered in random order. Items within each scale were also randomized. Four separate multiple regressions were also conducted, with scores on either Attitudes toward Autistic Symptoms, Openness, Social Distance, or Knowledge measures entered as the outcome variable. Predictors were entered by block into each regression model after addressing potential multicollinearity among the predictors.

Results: The means of the summed scores for the Attitudes Toward Autistic Symptoms, Openness, Social Distance, and Knowledge about ASD scales were 8.56 (*SD* = 2.84) 28.56 (*SD* = 3.22), 40.68 (*SD* = 5.13), and 64.26 (*SD* = 7.98), respectively, while the maximum score for each measure was 35, 45, 16 and 70, respectively. From the regression analyses (Table 2), staff members working at 4-year institutions more strongly believed that reducing autistic symptoms would benefit autistic individuals. Staff members with higher-quality contact with autistic people showed more Openness. Staff members with more positive and frequent previous contact, more accurate knowledge about ASD, and who worked at private institutions reported less Social Distance. Finally, staff members with more positive contact and working at institutions with higher average annual costs and a larger number of undergraduate students had more accurate knowledge about ASD.

Conclusions: The quality of previous contact was shown to be relatively consistently associated with Openness, Social Distance, and Knowledge about ASD, reinforcing the importance of high-quality contact. The underlying mechanisms behind the significant associations between institutional variables and attitudes and knowledge about ASD need to be explored. Understanding what kinds of institutional supports and context-appropriate training should be provided to promote collaborative relationships between DSO staff members and autistic students is a promising avenue for future studies.

401.044 *(Poster)* Hypermobility Spectrum Disorders in Mothers of Children with Autism

***E. L. Casanova**[1], R. Baker[2], D. Everman[3], R. K. Kurfman[4], D. P. Kelly[5] and M. Casanova[6], (1)University of South Carolina, School of Medicine, Greenville, SC, (2)Prisma Health, Greenville, SC, (3)Greenville Office, Greenwood Genetic Center, Greenville, SC, (4)ATI Therapy, Greenville, SC, (5)University of South Carolina School of Medicine Greenville, Greenville, SC, (6)University of South Carolina School of Medicine, Greenville, SC*

Background: Evidence suggests links exist between autism and hereditary connective tissue disorders like Ehlers-Danlos syndromes (EDS)/hypermobility spectrum disorders (HSD), both in terms of comorbidity and familial overlap. In particular, we have found that approximately 20% of EDS/HSD mothers report having autistic children and that these mothers, compared to EDS/HSD mothers without autistic children, experience more immune symptoms. Therefore, in this study we have elected to investigate mothers of children with autism (with or without ADHD) vs. those with children who have ADHD to determine to what extent these two groups display symptoms indicative of hereditary connective tissue disorders like EDS/HSD.

Objectives: To determine whether differences in EDS/HSD-linked traits exist between mothers of children with autism vs. mothers of children with ADHD.

Methods: In this ongoing study, we have currently recruited 47 mother-child pairs from the Department of Developmental-Behavioral Pediatrics at Prisma Health in Greenville, SC, to participate. Mothers received a physical assessment involving the Beighton Scoring system, which is used to diagnose generalized joint hypermobility (GJH) in EDS/HSD and related conditions, as well as a supine-to-standing test, which addresses issues of orthostatic intolerance as measured by a sphygmomanometer (blood pressure, heart rate). Mothers were also interviewed for ongoing medical concerns, including chronic musculoskeletal pain/instability. Finally, mothers received three surveys: one that addressed immune, hormonal, and autonomic issues, and the Autism-Spectrum Quotient (AQ) and Social Responsiveness Scale-2 (SRS-2), the latter two which were used to estimate the Broader Autism Phenotype (BAP) within these populations.

Results: Although data collection is not yet complete, preliminary analyses indicate divergence between the autism and ADHD groups along the lines of body-mass index (BMI) ($p < 0.0001$) and hypermobility-associated musculoskeletal (MSK) pain and instability ($p = 0.0417$), with the autism mothers experiencing more problems overall. (BMI and MSK pain/instability did not share a significant interaction indicating the pain is unrelated to weight.) Within the autism group, hypermobility-associated MSK pain/instability was strongly associated with reported immune symptoms ($p = 0.0121$, $r = 0.5776$), although immune symptoms did not share a similar relationship with hypermobility in this group ($p = 0.2979$, $r = 0.2155$). MSK pain also was a negative predictor of maternally reported autistic regression in the child ($p = 0.0323$, $r = -0.3678$). Finally, autism mothers with lower AQ scores were more likely to report autistic regression in their children ($p = 0.0311$, $r = -0.4827$).

Conclusions: Though these data are extremely preliminary, they suggest a relationship may exist between maternal hypermobility-associated MSK pain/instability, immune disorders, and BMI and a child's risk for developing autism. Meanwhile, autistic regression appears to occur less frequently in families that already have a significant hereditary load (i.e., BAP), which has been reported previously. With further data collection we hope to continue to shed light on the potential relationship between hypermobility-related MSK pain/instability and immune disorders in autism families.

401.045 *(Poster)* Implementation Strategies to Maximize Inclusion of Young Adults across the Autism Spectrum in Social Network Data Collection

E. McGhee Hassrick[1]*, S. Murphy*[2]*, S. J. Fernandes*[2] *and R. Turchi*[3]*, (1)A..J. Drexel Autism Institute, Drexel University, Philadelphia, PA, (2)A.J. Drexel Autism Institute, Drexel University, Philadelphia, PA, (3)Dornsife School of Public Health, Drexel University, Philadelphia, PA*

Background: While decades of sociological research confirms that social networks provide critical social capital for seeking and securing employment, to our knowledge, few research studies in the field of autism have investigated how the social networks of young adults with ASD impacts employment (McGhee Hassrick et. al. 2017). Disconnection from institutional resources represents a significant loss of valuable social capital, defined as informal employment assistance for youth, post high school. We need more information about the social networks of youth on the spectrum. One key barrier is our lack of knowledge about how to successfully collect social network data from youth on the spectrum, including minimally verbal youth (approx. 25-35% of the ASD population; Rose et al. 2016) and youth with intellectual disability (ID) (approx. 31% of the ASD population; CDC 2018). While we have some data about how to successfully consent participants with ID (Hamilton et al, 2016) and assess minimally verbal populations with autism (Kasari et al. 2013), no studies have developed effective implementation approaches for collecting social network data from this population. For this project, we identified implementation strategies (Powell et al., 2011) to improve the recruitment, consent and participation of autistic youth in social network research.

Objectives: To maximize inclusion across the spectrum, we used implementation strategies to develop an inclusive process with 3 accommodation components. We then conducted feasibility pilots (n=16 young adults; n=5 minimally verbal and 13 with ID)) of the accommodation components to measure the social capital of youth on the autism spectrum.

Methods: First, we conducted a literature review of evidence-based practices to support the inclusion of young adults on the autism spectrum. Second, we partnered with a trained developmental psychologist who specializes in working with the ASD population to adapt our instruments based on our review findings and finalize our accommodation strategies. Third, we implemented our adapted strategies with pilot participants and iteratively revised and improved our accommodations through each pilot study, based on observation and participant feedback.

Results: We developed 11 accommodation strategies for recruitment, consent, and protocol implementation (see Table 1). The following implementation strategies (Powell et al., 2011) were utilized: Plan strategies (gathering info, selecting strategies, develop relationships); Educate strategies (develop materials); Restructure strategies and Quality Management strategies. All 11 strategies were utilized by pilot study participants at least once (Table 2). All participants utilized recruitment accommodations, revised language, and location choice. All MV participants with ID utilized adapted consents and pictures during the protocol, while no other groups of participants used these accommodations. Participants with ID across both studies utilized comprehension questions during the consent process and breaks/ reinforcements during protocol implementation.

Conclusions: When youth with ASD provide self-report, we can gain access to new knowledge about how to connect youth on the spectrum with opportunities for work or schooling in the first few years after high school. Implementation strategies for accommodations incorporated into the protocol allows young adults from across the spectrum to successfully provide self-report.

401.046 *(Poster)* Improving Outcomes of Preschool High Function Autism Spectrum Disorders in a Chinese Community：Protocol for the Social Cognitive Training Randomized Controlled Trial

M. Xu*, Developmental and Behavioral Pediatric Department & Child Primary Care Department, Brain and Behavioral Research Unit of Shanghai Institute for Pediatric Research and MOE Shanghai Key Laboratory for Children's Environmental Health, Xinhua Hospital, Shanghai, China*

Background: Autism spectrum disorder (ASD) is characterised by impairments in social communication. Core symptoms are inappropriate daily social behaviours, including unable to interact with others in a socially expected manner, and effectively share space with others. There is a new sense of urgency to develop social treatments for ASD who are going to primary school. Social Thinking®, a framework based in social-cognition has broadly used in western culture, but there is no report in the Chinese ASD preschoolers. We designed a group intervention which is based on "WE THINKERS™" and combined with dialogic reading strategies for preschool high functional Autism spectrum disorders in a Chinese Community.

Objectives: It is designed to train individuals with ASD to facilitating social cognitive skills and social interactions among peers. We predict that the intervention will improve the social competence and undermine the underlying neuroscience mechanism.

Methods: The Social competence group intervention for preschool high functional Autism spectrum disorders is a preliminary, randomized controlled trial comparing the group intervention with await list control condition. 60 preschoolers (4–6 years) with ASD with a Full-Scale IQ between 70 and 130, and their parents will be randomly assigned (equally to intervention or the control condition) following baseline assessments. The 16-session intervention program comprises 16 half-hour home-based therapeutic sessions in two 8-week blocks, an outcome assessment.

Results: Primary outcomes are assessed with Autism Diagnostic Observation Schedule（social communication domain），ABAS-II(Communication domain and the Socialization domain)，Developmental Neuropsychological Assessment（emotion and TOM domain）;Secondary outcomes are assessed with questionnaires such as childhood autism rating scale, Behavior rating scale of executive function, strength and difficulty questionnaire social responsiveness scale and clinical global impressions scale and fnirs. The analyses will focus on evaluating the feasibility and preliminary effectiveness of the intervention.

Conclusions: A key strength of this robust study is the implementation of a group therapeutic framework that provides a standardized tailored approach for each child, with a focus on social competence in China mainland community. A framework based in social cognitive strategies, with appropriate linguistic and cultural adaptations, appears to be a promising tool for Chinese preschoolers with social learning issues and improve the social behaviours across school and home settings.

401.047 *(Poster)* Insights from Neurodiverse College Students in a Participatory Mentorship Program

K. Gillespie-Lynch[1], *B. Kofner*[2], *C. Frka*[3], *S. Shevchuk*[4], *A. Riccio*[5], *D. DeNigris*[6] *and S. K. Kapp*[7], *(1)Department of Psychology, College of Staten Island; CUNY Graduate Center, Brooklyn, NY, (2)CUNY, NY, NY, (3)CSI, Staten Island, NY, (4)College of Staten Island, CUNY, Staten Island, NY, (5)Department of Psychology, The Graduate Center, City University of New York (CUNY), New York, NY, (6)Psychology & Counseling, Fairleigh Dickinson University, Madison, NJ, (7)Department of Psychology, University of Portsmouth, Portsmouth, United Kingdom*

Background: As autistic students increasingly enter college, they often exhibit academic strengths (Bakker et al., 2019) yet face social, executive functioning and self-advocacy challenges (Elias & White, 2017). While autistic students are *less* likely to enroll in college than students with most other disabilities (Shattuck et al., 2017), they are *more* likely to *persist* in college than students *without* disabilities (Wei et al., 2013). However, little remains known about factors that support their *success*. Supports for autistic college students are often neither evidence-based nor informed by their perspectives (Barnhill, 2016). Although promising programs for autistic students have emerged (Kudder & Accardo, 2018), prior research has *not* provided sufficient opportunities for neurodivergent students to develop self-advocacy skills by guiding program development.

Objectives: Evaluate a *participatory* mentorship program in which neurodivergent students play leadership roles in developing, delivering, and evaluating programming.

Methods: Our no-cost program is designed for autistic students but open to those with other disabilities. Students can complete assessments for gift cards, but are under no obligation to provide data. Students choose to attend an hour per week of one-on-one mentorship, structured group meetings, or both. Group curriculum is selected/developed based on individualized assessments and group discussions. The highest ranked group needs this term were planning (M = 8.92 out of 10), communication (M = 8.68), and relationships (M = 8.52). In response to feedback, we added a half-hour of unstructured time prior to group meetings this fall.

Although our goal since program inception was for it to be participatory, becoming truly participatory took time. Sixteen students/alumni with disabilities (11 autistic) have become mentors thus far. An autistic student and an alumni with ADHD now lead group meetings. To better understand their new roles, they coded mentors' and mentees' open-ended responses (collected from Fall 2016-Spring 2018) to the question "How can we improve Project REACH?"

Our participatory research group also led development of a cross-institutional online survey, assessing QoL (ASD-QoL), camouflaging, self-esteem, belonging, and social support; 66 students from other institutions and 19 from REACH participated.

Results: Students in REACH reported higher QoL and reduced camouflaging relative to students from other institutions (ps < .03) but no differences in self-esteem, belonging or social support.

The most common recommendation for improving REACH was to broaden its structure and impact (e.g., start programs at other schools; 34.6% of responses expressed this theme), followed by providing more/better social support (20.5%) with a sub-code improving the mentor-mentee match (14.1%). Students expressed a desire to learn about more topics (15.4%; e.g., STEM; 3.8%). Some felt the curriculum could be more engaging (10.3%), while others felt the program was "good as it is" (30.8%) or were unsure how to improve it (10.5%).

Conclusions: By collaborating with neurodivergent students, we have developed a program that may promote QoL and self-acceptance. Students have gained valuable skills as mentors, researchers, and public speakers. Student feedback highlights the need for more strategic collaborations to develop participatory programming across institutions and research to develop more effective strategies for matching mentors and mentees.

401.048 *(Poster)* Machine Learning for Differential Diagnosis between Conditions with Social Difficulty

E. A. Demetriou[1], *S. H. Park*[1], *N. Ho*[1], *K. L. Pepper*[1], *Y. J. Song*[1], *S. L. Naismith*[1], *E. E. Thomas*[2], *I. Hickie*[3] *and A. J. Guastella*[4], *(1)University of Sydney, Camperdown, NSW, Australia, (2)Anxiety Clinic Australia, Sydney, Australia, (3)Brain and Mind Centre, Central Clinical School, Sydney Medical School, University of Sydney, Sydney, NSW, Australia, (4)Brain and Mind Centre, Children's Hospital Westmead Clinical School, Faculty of Medicine and Health, University of Sydney, Sydney, NSW, Australia*

Background: Differential diagnosis in adult cohorts with social difficulty is confounded by comorbid mental health conditions, common aetiologies and shared phenotypes. Identifying shared and discriminating profiles can facilitate intervention and remediation strategies.

Objectives: The objective of the study was to identify salient features of a composite test battery of cognitive and mood measures using a machine learning paradigm in cohorts with social interaction difficulties and assess whether youth and adults with Autism Spectrum Disorder (ASD), Social Anxiety Disorder (SAD) and Early Psychosis (EP) may be differentiated based on a set of composite features.

Methods: We recruited participants who met standardised diagnostic criteria for ASD: N=62, EP: N=48 or SAD: N=83 and compared them with a neurotypical comparison group (TYP: N=43). Using five machine-learning algorithms and repeated cross-validation, we trained and tested classification models using measures of cognitive and executive function, lower and higher order social cognition and mood severity. Performance metrics were the AUC and Brier scores.

Results: Sixteen features successfully differentiated between the groups. The control versus social difficulty cohorts were differentiated by social cognition, visuospatial memory and mood measures. Importantly, a distinct profile cluster drawn from social cognition, visual learning, executive function and mood, distinguished the neurodevelopmental cohort (EP and ASD) from the SAD group. The mean AUC range was between 0.892 and 0.915 for social difficulty versus control cohorts and, 0.731 to 0.777 for SAD vs neurodevelopmental cohorts.

Conclusions: This is the first study that compares an extensive battery of neuropsychological and self-report measures using a machine learning protocol in cohorts characterised by social difficulty. Findings are relevant for diagnostic, intervention and remediation strategies for these groups. They are particularly important in facilitating differential diagnosis in undiagnosed youth and adults with ASD compared to individuals with likely EP or SAD.

401.049 *(Poster)* Methods Matter: Why a Multivariate Approach Is a Fruitful Addition to Univariate Approaches When Investigating Cognitive Profiles in ASC Adults.

C. Torenvliet*, A. P. Groenman and H. M. Geurts, University of Amsterdam, Amsterdam, Netherlands*

Background: Researchers often define groups of people as “typical” or “deviant” and use mean-derived statistics to infer something about these groups. By doing so, known heterogeneity within a group is ignored. Autism Spectrum Condition (ASC) is a good example of this, as the cognitive heterogeneity seen in ASC is often observed, but not easily captured. This makes it challenging to define patterns of cognition in heterogeneous groups such as autistic adults.

Objectives: We have two goals (1) showing how univariate and multivariate normative approaches can be implemented in clinical research to detect differences between autistic and non-autistic adults on an individual level instead of on a group level; (2) assessing whether taking a multivariate approach is better at capturing cognitive variation in ASC.

Methods: Our pre-registered analysis plan consists of three major steps. Step 1: Comparing 111 autistic adults with a comparison group of ~220 adults (age range: 30-80 years) on 6 different cognitive tasks (11 dependent measures of visual and verbal memory, working memory, generativity, theory of mind and processing speed) using (a) univariate methods without familywise error correction- as commonly used in clinical practice- and with familywise error correction (i.e., multiple case series analyses) and (b) a multivariate normative comparison method in order to investigate entire cognitive profiles, instead of singular task performances. Step 2: Exploring whether we can predict which autistic adults show a deviant cognitive profile based on age, gender, self-reported autistic traits and psychological distress. Step 3: Repeating Step 1 and 2 in a replication sample of ~100 autistic adults.

Results: As data collection still continues (expected to be finished feb2020) we here used the full autistic sample, but only a subset of the comparison sample, N=118/220. In step 1 we observed no significant group differences in the number of univariate cognitive deviations using the uncorrected multiple case series approach. After correcting for familywise errors nearly all deviations disappeared in both groups. However, multivariately, we detected a distinct group of 31 out of 111 autistic individuals (29%) with a deviant cognitive profile, whilst in the comparison group only 5 out of 118 individuals (3,3%) showed a deviant cognitive profile. The deviating group of autistic individuals scored significantly lower on almost all cognitive measures when comparing them to the non-deviating group of autistic individuals. In step 2 we observed no significant predictors for these deviant cognitive profiles in ASC adults. Analyses based on the full comparison sample and the replication sample (Step 3) will be presented at INSAR 2020.

Conclusions: We have found preliminary evidence for a systematically lower performing group within our ASC sample. This group seemed to perform lower on most cognitive measures, yet this was only detected when using a multivariate approach and not when using univariate approaches which are commonly used in clinical practice. This shows the importance of using advanced statistical techniques to deal with the known heterogeneity within the autistic population.

401.050 *(Poster)* Narrative Orientation and Autistic Identity: Fiction As a Channel for Authentic Expression

J. Delos Santos[1]*, A. Riccio*[2] *and K. Gillespie-Lynch*[3]*, (1)Hunter College, City University of New York, New York, NY, (2)Department of Psychology, The Graduate Center, City University of New York (CUNY), New York, NY, (3)Department of Psychology, College of Staten Island; CUNY Graduate Center, Brooklyn, NY*

Background: Since the 1970s, autistic people have been assumed to lack imagination and to interpret things concretely, a premise that studies have borne out until recently (Wing & Gould, 1979; Low et al., 2009). However, the population from which these studies have drawn has primarily been children. More contemporary studies have noted that autistic individuals are in fact capable of imagination, and that prior observations of deficit may have overlooked nuances (Ten Eycke & Müller, 2015). Fictional characters may be exceptionally salient for autistic people (Grelotti et al., 2005) who may develop fictional alter-egos to deal with challenging situations (Williams, 1996). Fiction may also help people develop understanding of others (Kidd & Castano, 2013).

Objectives: This study, led by an autistic undergraduate honors student, examines the extent to which autistic individuals absorb and take on fictional personas as paths to self-realisation rather than camouflaging.

Methods: Autistic college students (*n*=18; M 60% White; 20% Female) were recruited primarily from a mentorship program. A non-autistic (*n*=197; 39.1% White; 60.5% Female) comparison group was recruited at the same campus. Through an online survey, students responded to questions: "I think about my life as a story," "I feel like the main character in my life," "I understand my life by reading about other people and/or characters," "I interact with others using fictional characters,” and “How often do you try to ‘camouflage’ or mask your autism in social situations?” (Cage & Troxell-Whitman, 2019).

Results: Autistic students (*M*=3.06, *SD*=1.59) reported more frequently interacting with others as a fictional character than non- autistic individuals (*M* = 1.61, *SD*=1.48; *t*(213) = -3.93, p<0.01). No differences between groups were observed in understanding life through stories or feeling like a main character. Among autistic students, interacting as a fictional character and camouflaging were unrelated constructs.

Conclusions: This study has important implications for understanding how autistic adults use fiction in their lived experiences. Autistic individuals were more likely than non-autistic individuals to use fictional personas to interact with others; having a fictional persona was a separate construct from camouflaging. This implies that imagination in autistic young adults has utility beyond its use in therapy or teaching social skills; if anything, fiction and imagination may be instrumental to the autistic young adult’s identity development, should they choose to nurse their interest in it. Though our questions didn’t focus on the causes of this phenomenon, I — an autistic young adult — can offer a few possible explanations. Intrinsic to fiction is a hypothetical, character-driven framework for social interaction. For some, this framework may be easier to engage with than real-time interactions laden with overwhelming sensory cues. Consumers of fiction may find characters’ thought processes to be more internally consistent than in reality, providing certainty in an arena where they normally find none. Fiction is also more accessible than social interaction: One need not be invited into a character’s story, whereas social relationships are governed by complex rules and social customs that one might consider arbitrary or confusing.

401.051 *(Poster)* Outcome Studies of Autistic Adults- Quantifying Effect Size, Quality, and Meta-Regression

D. Mason[1]*, G. R. Stewart*[1]*, S. J. Capp*[1]*, F. Happé*[1]*, P. Howlin*[2] *and K. Glaser*[3]*, (1)Social, Genetic and Developmental Psychiatry Centre, Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, United Kingdom, (2)King's College London, London, United Kingdom, (3)Global Health & Social Medicine, King's College London, London, United Kingdom*

Background: Longitudinal studies of autism have sought to measure and predict the outcomes of autistic adults. Early accounts of outcome were based on clinician judgement; were often based on normative criteria (e.g. living a "normal" or "near-normal" social life); and generally indicated a poor prognosis for most autistic people. More recent studies with empirical criteria (e.g. does the autistic person have a job?) have likewise revealed poor outcomes from many (but not all) autistic samples. A recent meta-analysis of outcome studies (up to 2015; Steinhausen et al, 2016) identified a small proportion of good outcomes (19.7%), and a large proportion of poor outcomes (47.7%) for autistic people. However, this review did not examine the quality of outcome studies, not did it explore childhood predictors of adult outcome (e.g. IQ).

Objectives: To update the findings of Steinhausen et al. (2016), report on the quality of outcome studies and risk of bias, and examine the effect of childhood predictors in a meta-regression model.

Methods: The following databases were searched up to the 21st October 2019: CINAHL, MEDLINE, Embase, and PsychINFO. Search terms were generated by looking at keywords in previous reviews and existing outcome studies. Examples of search terms used: autis*, adult*, longitudinal*, and predict*. Example inclusion criteria were: studies reporting primary data (e.g. a study reporting empirical data), studies involving autistic adults (mean age 18+ at follow-up), and studies reporting a composite outcome score (employment/education, living status, friendships/relationships). For the meta-analysis a random-effects meta-analysis will be conducted, with inverse variance weighting of each study. The Q-statistic and T^2 will be used to examine the heterogeneity of the observed effect sizes; the I^2 statistic will be used to examine the proportion of variance that is due to true effects.

Results: 7,903 records were returned by the search strategy. After removing duplicates (N=3,815) 4,088 records were screened at the title and abstract level by the first author. From this, 49 records were carried forward for a full-text read through. Initial results have identified 15 papers that meet inclusion criteria. GS will perform a reliability check on a random 10% of the 4,088 records to establish reliability. DM and SC will be performing data extraction for the meta-analysis, and quality and risk of bias assessments. Both authors will compare findings to ensure reliability of effect size calculation for the meta-analysis.

Conclusions: Initial results from full text read throughs indicate that the proportion of good, fair, and poor outcomes is comparable to Steinhausen et al. (2016). Of note is the finding that newer studies (those published in 2017 and 2018) are exploring different variables that may be related to outcome (e.g. cognitive level factors). However, this review will add to the literature in two ways: the quality assessment and risk of bias will highlight to researchers the current strengths and limitations of existing outcome studies, and the meta-regression will examine the pooled effect size of childhood predictors of outcome (e.g. childhood IQ) since data from individual studies are often conflicting.

401.052 *(Poster)* Overweight and Obesity across Time in Young Adults with Autism Spectrum Disorder

K. Byrne[1]*, J. B. McCauley*[1]*, V. H. Bal*[2] *and C. Lord*[1]*, (1)University of California, Los Angeles, Los Angeles, CA, (2)Graduate School of Applied and Professional Psychology, Rutgers University-New Brunswick, Piscataway, NJ*

Background: Rates of overweight and obesity are higher in the ASD population than in the general population. Those with ASD face challenges that are risk factors for the development of obesity, including higher incidences of psychotropic medication use (which can cause weight gain), reduced physical activity sometimes related to motor or social difficulties, and food selectivity associated with sensory aversions or ritualistic patterns (see Hill, Zuckerman, & Fombonne, 2015).

Objectives: Using a longitudinal sample, we describe the rates of overweight and obesity across time to asses change throughout adolescence and into adulthood, as well as factors that might be associated with obesity, within our sample of young adults who have been followed since childhood.

Methods: 253 individuals, referred for possible autism at young ages, completed assessments including recurring height and weight measurements starting in early adolescence, again in mid-adolescence, and in adulthood. Height and weight measurements were converted to a Body Mass Index (BMI), which we used to classify the participants into one of four categories based on the CDC classifications: underweight, normal weight, overweight, and obese. Analyses here include BMI at three time points: early adolescence, mid-adolescence, and adulthood.

Results: In adulthood, 53% of our sample was classified as being overweight or obese. Repeated measures ANOVAs were conducted to examine change in adult BMI over time as a function of age and IQ. There was a significant effect of age, indicating increases in BMI from early adolescence to mid-adolescence ($p < .001$) and from mid adolescence to adulthood ($p < .001$; $F(2, 292) = 82.45$, $p < .001$). While there was no main effect of IQ, there was an interaction between age and adult IQ (VIQ >70 or ≤ 70), which indicated a significantly greater increase in BMI from mid-adolescence to adulthood for individuals with higher adult IQs compared to individuals with lower adult IQs ($F(2, 292) = 75.29$, $p = .01$, see Figure 1). Linear regressions revealed significant positive associations between adult BMI and the number of neuropsychiatric medications taken in adulthood ($\beta = .19$, $p = .003$), which remained significant after controlling for adult IQ ($p = .004$).

Conclusions: More than half of our adult sample was classified as overweight or obese, making clear that weight poses a prominent health problem for the individuals in our sample. Additionally, some unexpected changes in weight were observed. For example, BMI continued to increase throughout adolescence and adulthood, especially for those with higher IQs. Not surprisingly, however, is the association between neuropsychiatric medication use (common within this population) and overweight or obesity status. The prevalence of this health issue in our sample across time suggests the need for ongoing health monitoring well into adulthood.

References: Hill, A. P., Zuckerman, K. E., & Fombonne, E. (2015). Obesity and autism. *Pediatrics*, *136*(6), 1051–1061. https://doi.org/10.1542/peds.2015-1437

401.053 *(Poster)* Perceptions of Autistic Job Candidates: The Role of Verbal and Non-Verbal Communication

R. L. Flower*, D. Hedley and E. Wood, Olga Tennison Autism Research Centre, La Trobe University, Melbourne, VIC, Australia*

Background: Autistic individuals experience significant challenges finding and maintaining employment, as evidenced by internationally low rates of employment and high rates of underemployment comparative to other groups. Although there is evidence that autistic individuals are perceived more negatively than their non-autistic counterparts (e.g., Sasson et al., 2017; Sasson & Morrison, 2019), few studies have explored this within an employment context (e.g., Cage & Burton, 2019). Further, while verbal and non-verbal behaviour is expressed differently among the autistic population (American Psychiatric Association, 2013), to our knowledge the role of these types of behaviours in employment has not been examined experimentally.

Objectives: To a) examine employment ratings of autistic and non-autistic job candidates and b) the relative impact of verbal and non-verbal behaviour on ratings.

Methods: Participants were 476 individuals (73% female, M_{age} 35.34, SD_{age} 11.44) recruited online. We examined participants' first impressions, ratings of employability, hiring decision and key word descriptions of autistic and non-autistic actors presented in 10s extracts of simulated job interviews. To examine relative impact of verbal and non-verbal behaviour, participants were allocated to one of three conditions (verbal, visual, combined).

Results: A main effect of group was found for first impressions, $F(1, 453) = 64.55$, $p < .001$, $\eta p^2 = .13$, whereby autistic individuals were rated more poorly than non-autistic. There was no effect of condition indicating ratings were similar between verbal, visual and combined conditions. There was a significant interaction effect between group and condition, $F(2, 453) = 6.45$ $p = .002$, $\eta p^2 = .03$; however, post-hoc tests failed to reveal significant differences. There was a main effect of group for employability, $F(1, 453) = 61.40$, $p < .001$, $\eta p^2 = .12$, with autistic individuals rated as less employable. There was no effect of condition, and no interaction effect. Overall, and within each condition, autistic individuals were 'hired' less frequently (148 times) than non-autistic candidates (317 times), $^2(2) = 6.75$, $p < .05$. The most common words used to describe the autistic candidates were 'nervous', 'confident', and 'awkward', while those used to describe non-autistic candidates were 'confident', 'scruffy', and 'passionate'.

Conclusions: Regardless of the type of information presented, autistic job candidates were given less favourable first impression and employability ratings and were 'hired' at a rate lower than their non-autistic counterparts. Further, differences were evident in the words used to describe the autistic candidates, with words tending to be more negative compared to non-autistic. These results provide further evidence of bias toward autistic job candidates suggesting disadvantage associated with traditional recruitment process and knock on effects for employment participation amongst autistic job seekers.

401.054 *(Poster)* Perceptions of Rude and Unattractive, Intrusive, Distant, and Autistic Behaviors on a First Date

C. McMahon[1]*, S. Henry*[2]*, B. Stoll*[1] *and M. Linthicum*[1]*, (1)Miami University, Hamilton, OH, (2)Wright State University, Dayton, OH*

Background: Autistic individuals often express interest in being in a romantic relationship. However, most autistic adults are not currently in a romantic relationship (e.g., Strunz et al., 2017), often reporting anxiety and uncertainty about what behaviors are expected in a dating context.

Objectives: The study had two main objectives: (1) To assess how potential dating partners respond to a variety of dating behaviors in a first date context, with the goal of providing practical dating advice to autistic individuals and (2) To examine whether potential dating partners' biological sex and self-endorsed autistic traits affect their perceptions of dating behaviors.

Methods: Participants were recruited via Amazon's Mechanical Turk platform. After screening for inclusion/exclusion criteria, 236 participants remained in the final sample. Participants completed the Dating Behaviors Questionnaire to indicate their willingness to continue dating someone across 50 dating behaviors (e.g., "asks too many questions about you") and the Short Autism Spectrum Quotient (Allison et al., 2012) to index autistic traits. A principal components analysis (promax rotation) was conducted to determine the factor structure of the Dating Behaviors Questionnaire. Regressions were conducted with gender, autistic traits, and the interaction term as the independent variables and the components of the Dating Behaviors Questionnaire as the dependent variables.

Results: Four components were retained for the Dating Behaviors Questionnaire (see Table 1): Rude and Unattractive Behaviors ($\alpha = 0.94$), Intrusive Behaviors ($\alpha = 0.87$), Distant Behaviors ($\alpha = 0.85$), and Autistic Behaviors ($\alpha = 0.85$). The regression models (see Table 2) significantly predicted variability across all behaviors (Rude and Unattractive, $F(3, 232) = 13.90$, $p < 0.01$, Intrusive, $F(3, 232) = 37.00$, $p < 0.01$, Distant, $F(3, 232) = 6.37$, $p < 0.01$, Autistic, $F(3, 232) = 9.97$, $p < 0.01$). Compared to males, females were less willing to date someone displaying any of these behaviors, particularly intrusive behaviors (Rude and Unattractive, $t(232) = -3.90$, $p < 0.01$, Intrusive, $t(232) = -10.03$, $p < 0.01$, Distant, $t(232) = -2.39$, $p = 0.02$, Autistic, $t(232) = -3.54$, $p < 0.01$)). Individuals with greater autistic traits were more willing to date someone displaying Rude and Unattractive Behaviors, $t(232) = 3.96$, $p < 0.01$ and Autistic Behaviors, $t(232) = 2.23$, $p = 0.03$. In addition, females with greater autistic traits were more willing to date someone with Intrusive Behaviors, $t(232) = 2.40$, $p = 0.02$.

Conclusions: Females are more sensitive to unexpected dating behaviors than males, especially behaviors or conversations that seem overly intimate for a first date. Given that autistic individuals often express anxiety and confusion about appropriate dating behaviors (e.g., Strunz et al., 2017), these results suggest that heterosexual, autistic males may benefit from showing less intimate and intrusive, rather than more intimate and intrusive, behaviors in an early dating context. Also, individuals who are autistic or have elevated autistic traits may be more receptive to romantic relationships with other autistic individuals; such individuals, though, may have difficulty recognizing rude or inappropriate behaviors in a dating context, potentially leading to a heightened risk of sexual victimization.

401.055 *(Poster)* Prevalence, Incidence, and Prodromal Presentation of Dementia in Autistic Adult Medicaid Beneficiaries

L. Bishop[1] *and E. Rubenstein*[2]*, (1)University of Wisconsin - Madison, Madison, WI, (2)Waisman Center at UW Madison, Madison, WI*

Background: Autistic adults now have the opportunity to live long lives in their communities, yet it is unknown whether autism spectrum disorder (ASD) confers increased risk for dementia. Known dementia risk factors—including depression, hypertension, hyperlipidemia, and diabetes—are elevated in autistic adults, and these factors may contribute to the emergence of dementia. Population-based epidemiological work is needed to clarify the extent of clinical dementia in autistic adults and assess prodromal risk factors.

Objectives: Our objective was to describe prevalence and incidence of dementia in autistic adults compared to adults with intellectual disability (ID) and to assess the impact of prodromal dementia risk factors (depression, diabetes, hypertension, hyperlipidemia) on incident dementia.

Methods: We assessed Medicaid claims for adults (≥21 years) who ever had two claims for ASD or ID on two different days during their Medicaid enrollment. Our sample included 3,336 autistic adults without ID, 2,524 autistic adults with ID, and 13,482 adults with ID. We excluded adults with Down syndrome because of the known link between Down syndrome and dementia. We analyzed claims from January 1, 2008 to December 31, 2018. Dementia claims were extracted from codes for any dementia from the Center for Medicaid Services Chronic Conditions Data Warehouse Condition Categories. We required ≥3 years Medicaid enrollment to ensure validity of dementia claims; therefore, beneficiaries entered our cohort at any point between 2008 and 2015. We categorized age at first claims by age group (<40, 40-54, ≥55) to account for confounding by age and compared dementia prevalence and incidence by diagnostic group using an age category-adjusted Poisson regression. Finally, we compared prevalence of prodromal risk factors (depression, diabetes, hypertension, hyperlipidemia) as identified in claims prior to incident dementia by group.

Results: We report descriptive statistics in Table 1. In adults aged 55 and older, 19.09% (N=61) of autistic adults without ID, 21.6% (N=132) of autistic adults with ID, and 24.9% (N=1,623) of adults with ID had claims for dementia. In the ASD groups, dementia was 0.48 times as prevalent (95% Confidence interval: 0.4, 0.6) in the non-ID compared to the ID group in an age-adjusted Poisson regression. Incidence did not differ between ASD without ID, ASD with ID, and ID groups in the 40-54 (log rank test P=0.06) or ≥55 age group (P=0.3). Prevalence of prodromal depression (45.7%) was highest in the ASD only group while prevalence of prodromal diabetes (26.9%), hypertension (49.1%), and hyperlipidemia (41.5%) were highest in the ID group.

Conclusions: While our interpretation is limited by reliance on claims rather than direct assessment and a lack of non-developmental disability control group, our findings from a state-wide health service system indicate that dementia is highly prevalent in autistic adults after the age of 55. High dementia prevalence in Medicaid beneficiaries with ASD underscores the need to develop dementia services and supports for autistic adults as they age and reside in Medicaid-funded assisted living and/or skilled nursing facilities. Findings also stress the need for exploration into how dementia manifests in autistic adults.

401.056 *(Poster)* Psychiatric and Medical Characteristics of Independent Adults with Autism in SPARK

B. Vernoia[1]*, L. Green Snyder*[1] *and W. K. Chung*[2]*, (1)Simons Foundation, New York, NY, (2)Department of Pediatrics, Columbia University, New York, NY*

Background: SPARK is an online study of individuals with a professional diagnosis of autism and their family members. As of December 2018, 8,713 participants aged 18 years or older were registered in SPARK. 5,025 were registered as dependents by a legally authorized representative, while 3,688 registered as legally independent. A previous study described the psychiatric and medical characteristics of dependent adults with autism in the SPARK cohort (Fombonne & Green Snyder, in submission). This companion study examines medical and psychiatric comorbidities in independent adults with autism.

Objectives: To describe medical and psychiatric comorbidities in independent adults with ASD in SPARK.

Methods: Subject characteristics including ASD diagnosis and psychiatric and medical comorbidities were collected by self-report in 2,315 independent adult participants aged 18-85 years (M=34, SD=12). Medical screening data included factors such as birth or pregnancy complications, neurological conditions, growth conditions, vision or hearing conditions, and birth defects. Additionally, developmental diagnoses and psychiatric disorders also were used for analysis. Sex differences were examined using Chi square analyses.

Results: Participants were 56% female and 44% male, and the majority of the sample was of European ancestry (89%). Mean age of ASD diagnosis was 22 years. Estimates of income and education in SPARK (N=1,600) suggest 13% earn over $101,000 and 62% have completed at least some college. Almost half of the sample reported they were diagnosed with Asperger Disorder (49%), while 35% reported Autism Spectrum Disorder. Anxiety and depression were the most common psychological conditions occurring with autism and were reported in nearly half the sample (48% for each), followed by ADHD (39%), Social Anxiety (31%) and OCD (23%). Intellectual disability or delay was self-reported by 6% of adults, and history of speech/language disorder/delay or learning disability in 15% and 20% respectively. The most frequent medical diagnoses were neurological conditions (25%) and sleep disorders (25%). History of birth complications was 10%. Female subjects had higher levels of medical and psychiatric comorbidities overall, and frequently reported mood disorder or OCD (45%). Chi square analyses showed mood disorder, OCD, anxiety, depression, and sleep disorders all showed significant sex differences, with greater preponderance in females ($p<.05$).

Conclusions: The SPARK cohort provides the opportunity to investigate the profile of medical and psychiatric co-morbidities in a large cohort of adults with autism. It also permits us to examine the challenges unique to independent adults, who are often presumed to be higher functioning. Results suggest that independent adults with ASD are three times more likely to have certain mental health issues than the general population. Despite independent legal status, educational attainment, and a high rate of self-reported Asperger Disorder which is considered to have intact verbal and cognitive ability, there are some adults in this group that report cognitive, language and learning impairments. Limitations to the current study included potential sampling bias in terms of greater participation by females and Caucasians, and higher income levels than average. Further understanding of the extent of psychiatric issues in independently functioning adults with ASD will identify service needs for supporting the population.

401.057 *(Poster)* Rating the College Experience: Feedback from College Students with and without Autism Spectrum Disorder

D. Davidson[1]*, E. Hilvert*[2] *and I. Misiunaite*[3]*, (1)Psychology, Loyola University Chicago, Chicago, IL, (2)Loyola University, Chicago, IL, (3)Loyola University Chicago, Chicago, IL*

Background: Studies have shown that the transition into higher education for young adults with ASD can be a precarious life stage (Pinder-Amaker, 2014; Van Hees, Moyson, & Roeyers, 2015). Despite the potential to perform well, college students with ASD are at a heightened risk for academic difficulties during these years. As the number of students with ASD is expected to increase substantially in the upcoming years (Ames et al., 2015), it is imperative that we understand the challenges these students face.

Objectives: The primary objective of this study was to obtain information from college students with and without ASD about their college experiences.

Methods: Seventy students participated, 31 students with ASD and 39 neurotypical (NT) students (see Table 1 for demographic information). Participants with ASD were recruited through the accessibility office at the host university, a psychology participant pool, and through college ASD listservs. NT students were recruited through the participant pool and accessibility office. Following informed consent, participants completed a 5-point (1 = Strongly Disagree; 5 = Strongly Agree) Likert scale questionnaire with 39 items that tapped into students' experiences with others, their participation in extracurricular activities, and mental health. The survey was administered through a secure on-line platform.

Results: Mean ratings and the percent agreeing or strongly agreeing with a statement are shown in Table 2. Independent-samples t-tests conducted on the rating data showed a number of differences between the ASD and NT groups, $t(60 - 68) \geq 1.32$, $p < .05$. Students with ASD reported more difficulty interacting with their peers than NT students, whereas students with and without ASD did not differ in their ratings of their interactions with their professors. Students with ASD felt more isolated and desired more friendships. Although students with ASD felt that extracurricular activities were less accessible to them, they were also less likely to want to be involved in extracurricular activities. Students with ASD reported more anxiety and depression as a result of the social demands of college but showed fewer differences from NT students in terms of how they felt about the academic demands. Overall, students with ASD felt more negative about their college experiences than NT students (see Table 2).

Conclusions: A number of significant differences in the reporting of college experiences were found between students with and without ASD. Most differences centered on experiences with peers, feeling more isolated, and reporting more anxiety and depression due to social demands in students with ASD. These results are in line with past studies (e.g., Cai & Richdale, 2015). However, students did not differ in their ratings of their interactions with faculty and displayed fairly similar feelings associated with academic demands. Thus, the social aspect of college may be perceived to be more challenging to students with ASD than the academic demands, informing the type of support programs and assistance that may be most beneficial to students.

401.058 *(Poster)* Reconceptualizing Behavior Outbursts in ASD: The Role of Anxiety

K. M. Dudley[1]*, M. R. Klinger*[2]*, P. S. Powell*[3]*, A. T. Meyer*[4]*, R. K. Sandercock*[5]*, E. M. Lamarche*[6] *and L. G. Klinger*[7]*, (1)Department of Psychology & Neuroscience, UNC Chapel Hill; TEACCH Autism Program, Carrboro, NC, (2)UNC TEACCH Autism Program, Chapel Hill, NC, (3)School of Psychology, Georgia Institute of Technology, Atlanta, GA, (4)JFK Partners, University of Colorado School of Medicine, Aurora, CO, (5)Department of Psychology & Neuroscience, University of North Carolina at Chapel Hill, Chapel Hill, NC, (6)TEACCH Autism Program, University of North Carolina, Chapel Hill, NC, (7)TEACCH Autism Program; Psychiatry, University of North Carolina, Chapel Hill, NC*

Background: Behavior outbursts are the leading cause of psychiatric hospitalizations for those with autism spectrum disorder (ASD) (Mandell, 2008) and relate to poor quality of life (QOL) (Chiang & Wineman, 2014). The majority of research has examined behavior outbursts in ASD as an indication of an externalizing behavioral disorder, with little research examining the potential for internal mechanisms (e.g., anxiety) as a potential driver.

Objectives: Caregiver survey data was used to examine the role of anxiety as a mechanism through which behavior outbursts occur and its impact on QOL in an intellectually diverse adult sample. The study examined whether anxiety is a mediator between an aspect of ASD symptoms (insistence on sameness) and behavior outbursts, and whether anxiety is a mediator between behavior outbursts and QOL.

Methods: A survey was completed by 274 parents or guardians of adults with ASD (20-58 years of age, *M* age=35.4, 80% male) Adults were diagnosed during childhood between 1970-2000. Caregivers completed forms assessing their adult's ASD symptoms (SRS-2), behavior outbursts (Reiss Screen for Maladaptive Behavior), anxiety (Anxiety, Depression, and Mood Scale), and QOL (QOL-Questionnaire). An insistence on sameness construct was created by summing 6 questions from the RRB scale of the SRS-2 (see Figure 1). Structural Equation Modeling (SEM) steps included: 1) Confirmatory Factor Analysis (CFA) to test the measurement model; and 2) Path Analysis to evaluate hypothesis model fit.

Results: CFA of insistence on sameness indicated that all items demonstrated significant factor loading (p's $< .001$) and that the measurement model indicated good latent variable model fit (see Figure 1). Path Analysis of hypothesis model indicated good model fit with significant direct relationships between insistence on sameness, anxiety, and behavior outbursts (p's $\leq .001$) (see Figure 2). Higher levels of insistence on sameness predicted higher levels of behavior outbursts and more anxiety. Higher anxiety predicted significantly higher levels of behavior outbursts. Insistence on sameness accounted for 41% of the variance in anxiety, and anxiety accounted for 43% of the variance in behavior outbursts. There was a significant indirect relationship between insistence on sameness and behavior outbursts through anxiety ($p < .001$), indicating that anxiety is a partial mediator between these two constructs. Additionally, insistence on sameness ($p < .001$) and behavior outbursts ($p < .001$) directly predicted QOL and predicted 24% of the variance in QOL, with higher levels of insistence on sameness and behavior outbursts associated with significantly lower levels of QOL. Lastly, there was a significant indirect relationship of insistence on sameness on QOL through anxiety and behavior outbursts ($p = .003$), indicating that anxiety and behavior outbursts are partial mediators between insistence on sameness and QOL.

Conclusions: The results of this study are the first of its kind to demonstrate the clear importance of anxiety in impacting behavior outbursts and QOL. Anxiety directly predicted more behavior outbursts, and behavior outbursts and anxiety were key mechanisms through which insistence on sameness decreased QOL. Results suggest the importance of treating anxiety as a potential mechanism underlying behavioral outbursts in adults with ASD.

401.059 *(Poster)* Relationship of Mental Health, Well-Being, and Problem Solving to Degree of Autistic Traits in Students Transitioning to University

J. E. Norris[1]*, C. Knight*[2]*, M. Brosnan*[3] *and C. Ashwin*[4]*, (1)Centre for Applied Autism Research, University of Bath, Bath, United Kingdom, (2)Department of Psychology, Centre for Applied Autism Research (CAAR), University of Bath, Bath, United Kingdom, (3)Centre for Applied Autism Research, University of Bath, Bath, United Kingdom of Great Britain and Northern Ireland, (4)University of Bath, Bath, United Kingdom of Great Britain and Northern Ireland*

Background: A recent survey by the UK's National Union of Students found that high levels of stress and symptoms of anxiety and depression were reported by university students. For autistic students, the transition to university can be particularly challenging, with a disproportionate number dropping out in their first year. Higher autistic-like traits and a diagnosis of autism have been found to predict unsuccessful transition to university, as well as poorer well-being and mental health. However, higher autistic traits and autism have also been related to effective problem-solving within formal assessments which, in turn, is related to successful transition and positive well-being.

Objectives: This study aimed to investigate whether autistic traits in students transitioning to university could be predictive of mental health measures and problem-solving ability. We also sought to investigate to what extent mental health measures and problem solving abilities interacted with each other and autistic traits.

Methods: 114 new first-year students from the University of Bath (39 males, 75 females, mean age = 19, SD = 1) completed an online survey measuring autistic traits (AQ-28) and 4 measures of mental health including social anxiety (Liebowitz Social Anxiety Scale), well-being (The Warwick-Edinburgh Mental Wellbeing Scale), depression (Patient Health Questionnaire), and anxiety (Generalised Anxiety Disorder Assessment), and 4 visual-analogue scales including current stress, university satisfaction, coping, and problem-solving abilities, and finally a measure of problem solving orientation (Social Problem-Solving Inventory).

Results: Data were analysed by 3 multiple regressions, with total AQ as the dependent variable, and sex and IQ in step 1. In the first analysis with social anxiety, depression, anxiety, and well-being as predictors, higher autistic-like traits were related to greater depression (p = .017), anxiety (p = .033), and social anxiety symptoms (p < .001), with a trend toward lower well-being (p = .077), F(6,112) 10.74, p < .001. In the second analysis with the 4 visual-analogue scales as predictors, higher AQ was related to lower university satisfaction, p = .048, F(6,112) 4.33, p = .001 (other ps > .273). In the third analysis with social problem solving inventory total score as the predictor, higher AQ was related to lower scores, i.e., a more negative problem-solving orientation, F(3,112) 7.63, p < .001. A final analysis was conducted to further investigate this relationship, with scores on the social-problem solving inventory for positive, rational, negative, impulsive/careless, and avoidant orientations entered as predictors. Higher AQ was related to both negative (p < .001) and rational (p = .022) problem-solving orientations, F(7,113) 5.92, p < .001 (other ps > .137).

Conclusions: Our findings demonstrate poorer mental health and reduced university satisfaction in students with higher autistic traits transitioning to university, as well as poorer social problem-solving. Moreover, those with higher autistic traits were characterised by a negative, but rational, problem-solving orientation. Our ongoing research investigates the efficacy of a problem-solving intervention to improve mood and well-being in a randomised sample of the above cohort, and will examine whether negative problem-solving orientations may be reduced.

401.060 *(Poster)* Role of Polygenic Risk on the Association of Maternal Smoking in Pregnancy with Autism Spectrum Disorder and Attention Deficit Hyperactivity Disorder

K. S. Benke[1]*, A. Kalkbrenner*[2]*, C. Ladd-Acosta*[3]*, C. Zheng*[4]*, G. Henion*[4]*, T. E. Jenson*[4]*, B. Vilhjalmsson*[5]*, C. Albiñana Climent*[6]*, M. D. Fallin*[3]*, C. B. Pedersen*[5]*, S. Dalsgaard*[7]*, P. Mortensen*[8] *and D. Schendel*[3]*, (1)Mental Health, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, (2)University of Wisconsin-Milwaukee, Milwaukee, WI, (3)Wendy Klag Center for Autism and Developmental Disabilities, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, (4)Zilber School of Public Health, University of Wisconsin-Milwaukee, Milwaukee, WI, (5)Aarhus University, Aarhus, Denmark, (6)(4) The Lundbeck Foundation Initiative for Integrative Psychiatric Research, Arhaus, Denmark, (7)National Centre for Register-based Research, Aarhus University, Aarhus, Denmark, (8)National Centre for Register-based Research, Aarhus University, Denmark, 8210 Aarhus V, Denmark*

Background: Prenatal exposure to maternal smoking is considered neurodevelopmentally harmful. Evidence does not support a link with autism spectrum disorder (ASD), but for attention deficit hyperactivity disorder (ADHD), maternal smoking may be a risk factor, although many recent findings suggest genetic confounding of this association.

Objectives: To further elucidate the role of maternal smoking on neurodevelopment, we evaluated these associations in the context of inherited genetic liability using SNP-based polygenic risk scores (PRS) for ASD and ADHD. We addressed confounding by PRS given that smoking behavior is in part genetic, and also whether smoking-neurodevelopment links differed depending on PRS liability (interaction).

Methods: From iPSYCH, a population-based Danish case-cohort study of singleton births with known mothers residing in Denmark at age 1 year, we included births 1991-2005 when maternal smoking (any vs. none, obtained from the birth registry) was available. A 2% random subcohort sample comprised controls, and cases comprised persons with an ICD-10 diagnosis of ASD and/or ADHD in the Danish Psychiatric Central Research Registry prior to emigration, death, or December 31, 2012: 42,837 eligible persons. We excluded 22% due to missing smoking, genetic, or covariate data, yielding 33,769 analyzed.

PRSs were trained using the full iPSYCH sample, and built using LDpred with the infinitesimal model. We analyzed the dataset as a cohort study, estimating hazard ratios (adjHRs) up-weighting the subcohort, using inverse probability weighted Cox proportional hazard models, with bootstrap standard errors from 100 replicates to construct 95% confidence intervals and p-values. We adjusted for birth year, parity, inter-pregnancy interval, marital status, degree of urbanicity, the diagnosis-specific PRS, ten principal components for genetic ancestry and maternal and paternal: income, employment, education, immigration status, age, and any previous psychiatric diagnosis. We tested interactions between continuous PRS and maternal smoking.

Results: Maternal smoking in pregnancy was more common in ADHD (42% of 11,233), than in ASD (30% of 10,431) and the subcohort (26% of 14,703). When adjusted for covariates including PRS, maternal smoking in pregnancy was not associated with ASD (adjHR=0.97 [0.81-1.17], p=0.74), but was associated with increased risk of ADHD (adjHR=1.25 [1.10-1.43], p=0.001), We found almost identical results when not adjusted for PRSs. For ASD, our test of smoking*PRS interaction was suggestive albeit not statistically significant (p_{int}=0.087). Results within ASD-PRS strata were: adjHR=1.13 [0.88-1.46] for high ASD-PRS, adjHR=0.82 [0.65-1.05] for low ASD-PRS. There was no significant interaction for the ADHD-PRS and maternal smoking on ADHD (p_{int}=0.39).

Conclusions: Our results are consistent with a marginal effect of maternal smoking in pregnancy for ADHD, but not ASD. Alternate explanations include selection bias due to exclusion of 22%, or failure to fully account for genetic confounding by using diagnosis-related genetic scores. Although a smoking-ADHD association has been reported previously, some studies show the association can be explained by a failure to control for familial factors. Our finding suggests that a psychiatric PRS is not a proxy for these familial factors. Our observation that impacts of maternal smoking on ASD differed by inherited liability for ASD was suggestive but without clear, statistically resolved results.

401.061 *(Poster)* Social Participation and the Role of Family Relation According to Autistic Adults

I. Courcy *and M. Charron, Sociology, University of Quebec in Montreal, Montreal, QC, Canada*

Background: Social participation results from multiple influences between a person's characteristics and their physical and social environment. It presupposes the full exercise of everyday activities and social roles (Fougeyrollas et al. 1998). Parents play an important role in young children and adolescents' social participation (Liptak et al. 2011) but little is known about their role in adulthood.

Objectives: This paper focuses on social participation as reported by autistic adults and aims to answer 3 questions:

- What are the expectations of autistic adults regarding their social participation?
- What are the facilitators and barriers to their social participation?
- What is the family's role regarding the person's desired social participation?

Methods: A qualitative research and interview method was conducted among 25 adults with autism (16 women, 9 men) aged 19 to 67 living in the Montreal area (Canada). The majority is employed or studying, 4 are parents and 11 are in a relationship. A thematic analysis with an analysis grid was conducted with N'Vivo software.

Results: Participants described their social participation in different ways like volunteering, employment, recreation, sports, participation in autism research, art, mutual aid, militancy, involvement in clubs, political parties or community organizations. Expectations: Being able to relate to others and meet new people without having to hide their autistic behavior is a shared wish. All want to see the potential and abilities of autistic people in employment better known and valued. Facilitators: The possibility of practicing activities or getting a job connected to their passions and interests emerged as a contributing factor to social participation and personal fulfillment. Also contributing were employment insertion, support services and peer social support on the web. Obstacles: Microaggressions, particularly in public transport and in classrooms, hinder everyday activities. Perceived lack of awareness of autism in the general population and stereotyped autism understandings from general service workers are major barriers in accessing employment, social services and medical care. Many said they experienced bullying at school or a situation of abuse that led them to "shut themselves out". Family's Role: The spouse is described as a central pillar of the successful realization of daily activities and the exercise of social roles by providing significant emotional support. More than half report strong ties to their families that promote recreational social participation and provide financial and domestic support. Participants with an immigrant background receive little support for social participation from their family back home. Others reported relational tensions with a parent or sibling, which had escalated during adolescence. The youngest said they felt constrained in their lifestyle choices and older ones said they had progressively moved away from "painful" family relationships.

Conclusions: This research contributes to a better understanding of Canadian autistic adults' expectations of their social participation. The results highlight the importance of raising awareness about autism and the heterogeneity of people's life conditions and situations, especially among health and social services stakeholder. Development of social policies must take into account that not all autistic adults receive support for social participation from their families.

401.062 *(Poster)* Some 'deeper' Issues to Consider for the Autism-Psychosis Diametric Model: Trade-Off Versus Co-Occurrence

A. M. Abu-Akel*, Institute of Psychology, University of Lausanne, Lausanne, Switzerland*

Background: The diametric model characterizes autism and psychosis spectrum disorders as two conditions that are etiologically and phenotypically diametrical, predicting opposing effects on functional outcomes. However, independent lines of evidence suggest that both conditions can lead to similar adverse effects in several domains affected by both conditions. Thus, the effect of their co-occurrence is commonly hypothesized to worsen functional outcomes.

Objectives: To test these two competing hypotheses, we investigated the combined effect of autism and psychosis on psychosocial and executive functioning difficulties, central features of both conditions.

Methods: In Study I, we investigated executive functioning using the Sustained Attention to Response Task (SART) in a total of 88 adults with autism spectrum disorder (ASD), schizotypal personality disorder (SPD), comorbid ASD and SPD, and neurotypical adults. In Study II, we examined the concurrent impact of autism and positive symptom expressions on psychosocial functioning in 174 patients with schizophrenia, as well as the impact of genetic risk factors conferring risks for both autism and schizophrenia in 139 healthy risk carriers. Psychosocial functioning was assessed using the Global Assessment of Functioning.

Results: In Study I, group analyses revealed better performance on the SART in the co-morbid group compared to the ASD- or SPD-only groups. Independent of diagnosis, individual difference analyses revealed better performance on the SART in individuals high on both autism and positive symptoms. In Study II, better functioning was observed in schizophrenia patients with balanced autism and positive symptoms. A similar effect was observed among healthy carriers of genetic risks that confer equal risks for autism and schizophrenia.

Conclusions: We show that co-occurring autism and psychosis, at both the dimensional and categorical level, can be associated with benefits in three different populations along the autism-psychosis spectra. The findings from the genetic data suggest that these influences are possibly mediated by the relative dominance of genetic risk factors associated with these conditions. Inter-individual differences in autism and schizophrenia may be better explained in terms of the relative dominance of risks/traits/symptoms associated with one disorder vis-à-vis the other, and that some individuals may present better functioning abilities due to a balanced expression of autistic and psychosis liability.

401.063 *(Poster)* The Change in Classification of Asperger Syndrome: An Exploration of Its Effects on Self-Identity

A. McCrimmon[1] *and S. Huynh*[2]*, (1)Werklund School of Education, University of Calgary, Calgary, AB, Canada, (2)University of Calgary, Calgary, AB, Canada*

Background: Changes in diagnostic frameworks have occurred with each revision of the *Diagnostic and Statistical Manual of Mental Disorders* (*DSM*). Among the changes in the fifth edition (American Psychiatric Association [APA], 2013) is the elimination of Asperger's disorder (syndrome; AS) and its integration into autism spectrum disorder (ASD). Although scientific evidence supported this modification, the reclassification may have unintended effects. Specifically, there are people who strongly self-identified with and understood that they *are* AS because of their diagnosis (Giles, 2014; Singh, 2011). A clinical identity arises when someone self-categorizes and accepts the characteristics associated with the diagnosis as being part of the self (Charland, 2004). In some sense, the *DSM-5* may have implications for individuals whose identity is comprised in part by their diagnosis. Such self-identification and personal identity are often evident for those with AS partially because there is a community that also self-identifies that way.

Objectives: We explored the elimination of AS in the *DSM-5* with respect to personal identity implications that AS-diagnosed individuals associate with this change. Specifically, this qualitative study examined the identity-related opinions of adults with AS on what the elimination of AS means with respect to clinical identity.

Methods: Twelve participants previously diagnosed with AS completed a demographic questionnaire, the Wechsler Abbreviated Scale of Intelligence – 2nd Edition (Wechsler, 2011), and a 25-item semi-structured interview to ascertain their understanding, appreciation, opinions, and identity related to the changed diagnostic framework. Interviews were transcribed verbatim and analyzed via Thematic Analysis. Malterud's (2001) guidelines, considerations, and standards for conducting and reviewing qualitative research were implemented, as was a second coder, to enhance credibility and minimize researcher bias.

Results: Six primary themes (with several subthemes within each) were identified: (a) Derived meaning from their experiences with the disorder; (b) Knowledge and understanding about AS, Autism, ASD, and *DSM-5*; (c) Perceptions associated with labels; (d) Social identity; (e) Opinions regarding the reclassification of PDD and the *DSM-5*; and (f) Barriers to funding and service provision.

Conclusions: Many participants socially identified and self-categorized as part of the AS community; they derived personal meaning and identity from their diagnosis and the removal of the AS term threaten[ed] their identity. Many expressed concern regarding if they would meet criteria for ASD and described feeling stigma by being grouped with individuals with more severe symptomatology. They were also concerned about eligibility for education or employment supports if they did not meet criteria for ASD. Clinical self-identity was most apparent for those who received their diagnosis at least several years prior to the *DSM-5*; those more recently diagnosed described not having such an identity. Overall, although the APA states that those with AS should receive an ASD diagnosis (APA, 2013), it is the reported invalidation of an AS culture, loss of a clinical identity, and AS-related way of being that are central to this study's outcomes. As one participant explained, "it's not a matter of *what was done* but rather *what the diagnosis meant"* and the impact of this change that is of importance.

401.064 *(Poster)* The Impact of Vocational and Educational Disengagement on Autistic Young Adults' Quality of Life and Vulnerabilities

M. Kovacs[1]*, S. Griffiths*[1]*, C. Allison*[2]*, P. Smith*[1] *and S. Baron-Cohen*[2]*, (1)University of Cambridge, Cambridge, United Kingdom, (2)Autism Research Centre, Department of Psychiatry, University of Cambridge, Cambridge, United Kingdom*

Background: Successful transition to adulthood poses a challenge for many autistic young people leaving secondary education. In contrast with the general population, autistic people are over twice more likely to be classified as 'not in employment, education or training' (NEET) (Bancroft et al., 2012). Being NEET has wide-ranging implications, from poor mental health and suicidal ideation to low economic viability and limited independence in the general population (O'Dea et al., 2014). However, there is still more research needed on how disengagement impacts autistic young people specifically.

Objectives: The current study aims to explore how educational or occupational disengagement impacts autistic young people's quality of life and their vulnerabilities.

Methods: We recruited 16-25-year-old young people via the Cambridge Autism Research Database (CARD), social media and support groups. All data were collected using an anonymous online survey. Quality of life (QoL) was measured using the WHO-BREF questionnaire which distinguishes between physical, psychological, social and environmental QoL. The questionnaire has previously demonstrated acceptable psychometric properties in autistic populations (Mason et al., 2018). To evaluate young people's recent vulnerabilities, we developed a questionnaire jointly with the autistic community and professionals. This questionnaire examines social support, mental health, physical health, social isolation, illegal activities and abuse. Data analysis utilised multivariate and univariate analyses of variance as well as hierarchical linear regression modelling to determine how disengagement is linked to QoL and vulnerabilities.

Results: The online survey was launched at the end of September and has recruited 54 autistic young people to date. (NEET=17, Not NEET=37) Recruitment is ongoing until March 2020. Initial analysis of data showed that NEET status had a significant impact on physical QoL ($F=7.017$, $p=0.011$), psychological QoL ($F=4.231$, $p=0.046$) and environmental QoL ($F=6.984$, $p=0.012$), even after controlling for demographic variables and pre-existing vulnerabilities. In addition, the overall vulnerability score was also significantly impacted by NEET status ($F=8.533$, $p=0.005$) where those who were NEET, on average, exhibited higher vulnerability scores. Univariate tests on each sub-domain established that disengagement was significantly linked to domains of 'Social isolation' and ($F=6.567$, $p=0.014$) and 'Physical health' ($F=4.995$, $p=0.031$). Hierarchical linear regression was performed to gauge variables predictive of QoL and vulnerabilities, where NEET status and presence of multiple special needs were significant predictors of the overall vulnerability score ($R^2 = .196$, $p = .004$).

Conclusions: After adjusting for demographic variables and pre-existing vulnerabilities, we found that NEET status was significantly associated with worse physical, psychological and environmental QoL, indicating that NEET status affects the lives of autistic young people independently of other factors. We also found that being NEET negatively impacted young people's vulnerabilities overall. A limitation of this study is the low number of participant due to the survey's recent launch, which means that more data needs to be collected to confirm these preliminary results. Future work will examine how autistic young people compare to those with other special educational needs and those who are neurotypical in terms of their QoL and vulnerabilities after leaving secondary education.

401.065 *(Poster)* The Multi-Media Social Skills Program for Autistic Adults: Efficacy of Video Modeling and Peer Generalization Despite Differing Needs

M. Murray[1]*, B. Morgan*[2]*, D. Alexander*[3]*, J. Nagle*[3] *and A. Pearl*[1]*, (1)Department of Psychiatry/Division of Autism Services, Penn State Hershey/Penn State College of Medicine, Hershey, PA, (2)Penn State College of Medicine, Hershey, PA, (3)Psychiatry, Penn State College of Medicine, Hershey, PA*

Background: Previous work has established that many autistic adults struggle to establish and maintain desired social relationships. Lipak and colleagues (2011) reported than half of their sample of 725 young autistic adults had not spent time or spoken on the phone with a friend in the past year. Increased social isolation is thought to be a significant contributor to mental health challenges. Shatayermman and colleagues (2009) found that in large cross-sectional study over 50% of autistic adults with mental health issues had recently considered suicide.

Objectives: This study adapted a successful social skills program for adolescents, The Multi-Media Social Skills Program (MMSSP), to adults. The MMSSP adolescent version utilizes video modeling paired with peer generalization; the curriculum and generalization experiences focus on conversation and interaction skills and demonstrated good efficacy for improvements in targeted skills, integration of verbal and non-verbal communication, and greater social impact. Objectives for the adult adaptation include similar increased use of targeted skills following intervention with generalization of these skills into community settings

Methods: Twenty-nine autistic adults and 26 NT adults were recruited for this study (see Table 1). Autistic participants were separated in to either Social Acquisition (SA; 48.3 percent) or Social Refinement (SR; 51.7 percent) tracts. The focus of the SA group was to gain new skills while the focus of the SR group was to fine-tune existing skills. Individuals were sorted into the tracts based on their cognitive abilities and life experiences. Individuals in the SA group generally had lower estimated intelligence, slower processing speed, more executive functioning challenges, and were less independent compared to individuals in the SR group. The two tracts received the same 16-week curriculum and video models with different teaching points highlighted depending on the skills level of the group. The two tracts also participated in the same peer generalization activities with differing skills practice opportunities identified and supported. All participants were videotaped in 5-minute dyadic unstructured conversations with a novel peer at pre-, post-intervention, and 3-month follow-up. These taped conversations were coded for a variety of verbal and non-verbal social behaviors using NOLDUS Observer.

Results: Over 85% of autistic adults who enrolled in the study successfully completed the 16-week intervention. Positive changes in simple and complex behaviors were noted at post-intervention and 3-month follow-up (see Table 2). During post-intervention feedback, participants listed the self-video models at the end of each 4-week module and the weekly peer generalizations during post-study feedback sessions as being most helpful.

Conclusions: Improvements occurred in social skills acquisition, maintenance, and generalization for participants in both tracts. The chief focus of this study was to determine whether adaptation of a social skills intervention for adolescents which utilizes video modeling and peer generalization would have efficacy for autistic adults. Assigning participants to differing tracts depended on their skills need(s) appears to have heightened the impact of this intervention. Additional work needs to be done to further explore potential modifications to the two tracts for even greater efficacy and potential unique impact of each intervention component.

401.066 *(Poster)* The Prevalence of Suicidal Behavior in Autism and Its Relationship to Psychotic Disorders

S. J. Wood*, Orygen & University of Melbourne, Melbourne, VIC, Australia*

Background: Lack of social integration, unemployment and psychiatric disorders have been found in adults with ASDs, the same factors that are also associated with suicidal behaviour, which could suggest a particular risk for suicide in those with ASDs. These factors may also be exacerbated by mental health problems, particularly psychotic disorders which co-occur more frequently than would be expected by chance.

Objectives: We aimed to investigate; whether people with ASDs had higher rates of suicidal behaviour and suicide when compared to people with no ASD; whether this was also the case in people with psychosis with autism traits; and further, whether the same pattern was shown in the general population.

Methods: We conducted several studies; a cohort design applied to nationwide register data in Denmark, a naturalistic study of individuals with first episode psychosis, and a study of autism and positive psychotic traits in young undergraduates.

Results: Our cohort study revealed that persons with ASDs had more than a three-fold higher rate of suicidal behaviour and suicide compared to those without ASDs. Persons only diagnosed with ASDs had an incident rate ratio (IRR) of 2.50 (95%CI:2.14-2.94), and those diagnosed with additional psychiatric disorders had an IRR of 9.55 (95%CI:8.89-10.26), when compared to those without ASDs. We also showed a significant relationship between the presence of autism traits and suicidal ideation in people with first episode psychosis, that was mediated through hopelessness. This pattern was also found in a sample of young undergraduates.

Conclusions: Our study is the first to show an elevated rate of suicidal behaviour and suicide in persons with ASDs in a nationwide cohort study. This elevated risk appears to be associated with psychiatric disorder, and perhaps with psychosis in particular. Several risk factors identified are different from risk factors in general population, which indicates the need for tailored suicide prevention activities.

401.067 *(Poster)* The Relation between Structural Learning, Short-Term Memory Span and Integration and Emotion Recognition in Children with Autism Spectrum Disorder

M. Ring[1], *N. Vetter*[1], *D. M. Bowler*[2], *S. B. Gaigg*[2], *C. L. Thomas-Derwent*[2], *B. Guillery-Girard*[3], *P. Quinette*[4], *J. Mack*[1], *N. Wolff*[5] *and V. Roessner*[1], *(1)Department of Child and Adolescent Psychiatry, University Hospital Carl Gustav Carus, Technische Universität Dresden, Dresden, Germany, (2)Autism Research Group, City, University of London, London, United Kingdom, (3)Normandie Univ, UNICAEN, PSL Research University, EPHE, INSERM, U1077, CHU de Caen, Neuropsychologie et Imagerie de la Mémoire Humaine, 14000 Caen, France, Caen, France, (4)Inserm—EPHE, Université de Caen-Normandie, Unité E0218, Laboratoire de Neuropsychologie, CHU Côte de Nacre, 14033 Caen Cedex, France, Caen, France, (5)Department of Child and Adolescent Psychiatry, Department of Child and Adolescent Psychiatry, University Hospital Carl Gustav Carus, Technische Universität Dresden, Dresden, Germany*

Background: Following Perner (2000), Theory of Mind (ToM) and memory are closely related. Episodic memory is an important factor influencing ToM but ToM is also a pre-requisite for episodic memory in that remembering the past necessitates that somebody recognises something as experienced previously, which is provided by causal self-referentiality, which develops in typical children between 4-6 years. Individuals with Autism Spectrum Disorder (ASD) have consistently been reported to show difficulties with episodic memory (Boucher & Bowler, 2008), ToM and emotion recognition (Uljarevic & Hamilton, 2013). We have recently suggested that the fundamental mechanism underlying these difficulties in ASD is atypical structural learning based in the hippocampus (Ring et al., 2017). So far, there is only one study published showing difficulties in structural learning in ASD (Ring et al., 2017) and one on children is in preparation (Derwent et al., in preparation). In addition to the difficulties in long-term episodic memory, we recently showed difficulties in short-term relational memory in ASD adults (Ring et al., under revised review). Studies on children with ASD are lacking. Only few studies have so far tested the relation between episodic memory and ToM in ASD and show inconsistent results (e.g. Lind & Bowler, 2009).

Objectives: We aimed to test structural learning, short-term memory span, short-term memory integration and emotion recognition within the same sample of children with ASD to investigate potential difficulties in these processes and whether these are related to one another.

Methods: We used four tests for this study. In the structural learning test (Ring et al., 2017), children are presented with black and white mirror images of simple geometric shapes and are asked to learn three pairs over four blocks until a criterion. In Block 5, participants are presented with re-pairings of these images and their memory for the correct shapes is tested. In the short-term span test (Quinette et al., 2006), participants are presented with sequences of crosses in the cells of a grid and after having seen each sequence, they have to indicate the locations and the order of cross-presentation. In a short-term memory integration test (Quinette et al., 2006), participants are presented with coloured letters in the centre of a grid and crosses in the cells of the grid. They are asked to memorise the letters in the grid cells where the crosses of the same colours are presented and to recognize the letters in the correct cells at test. In the emotion recognition paradigm (Vetter et al., 2018), participants are presented with images of faces and have to indicate which of four emotions they see.

Results: So far we tested 16 children with ASD with an average age of 9,9 years (range: 8 – 12 years) and an average Intelligence-quotient of M = 77,5 (SD = 19,8, range: 51-108). Data collection is ongoing. There are significant positive correlations among all measures (r = .53 - .72).

Conclusions: We interpret results in terms of a general cognitive mechanism developing atypically in ASD underlying ToM and episodic memory difficulties.

401.068 *(Poster)* The Support Services College Students with Autism Spectrum Disorder May Need

Y. H. Lin[1] *and* ***H. M. Chiang***[2], *(1)Quanzhou Normal University, Quanzhou, China, (2)University of Macau, Taipa, Macao*

Background: More and more young adults with autism spectrum disorder (ASD) are pursuing a college degree. However, limited research has focused on this population as the number of the studies addressing the needs of these students is fewer than that of the studies addressing the needs of young autistic children. To assist college students with ASD successfully obtain a college degree, it is important to understand what support services they may need.

Objectives: This study was conducted to explore the support services that college students with ASD may need through examining their cognitive ability and adaptive skills.

Methods: All the universities that have students with ASD in Taiwan were contacted. A total of 30 Taiwanese college students with ASD (27 males and 3 females), including 12 individuals with Autistic Disorder and 18 individuals with Asperger's Disorder aged 18-23 years (mean = 20.13, SD = 1.28), participated in this study. The measures used in this study included: (a) Wechsler Adult Intelligence Scale, Third Edition-Chinese Version (WAIS-III-Chinese; Chen & Chen, 2002), and (b) Adaptive Behavior Assessment System, Second Edition-Chinese Version (ABAS-II-Chinese; Lu & Chen, 2008). The university counselors who had known the autistic students were trained by the researchers of this study to conduct the two assessments.

Results: On average, the college students with ASD in this study had average Full Scale IQ (FSIQ). None of these students had very superior, superior, or extremely low FSIQ. Verbal IQ was not significantly different from Performance IQ ($t_{(29)} = 2.31$, $p = .03$). Compared to the normed population, the autistic college students showed below average communication skills, low socialization skills, and below average functional academics skills. Functional academics was significantly higher than communication ($t_{(29)} = 3.96$, $p < .001$) and communication was significantly higher than socialization ($t_{(29)} = 4.07$, $p < .01$). The top three weakest sub-skills in communication were: "Takes turn talking during conversations with people is not too talkative or too quiet", "Talks about realistic future educational or career goals", and "Answers complex questions that require careful thoughts and opinions, for example, questions about politics or current events.". The top three weakest sub-skills in socialization were "Says when he/she feels happy, sad, scared or angry.", "Personally makes or buys gifts for family members on major holidays.", and "Refrains from saying something that might embarrass or hurt others." The top three weakest sub-skills in functional academics were: "Balance checkbook", "Reads classified ads for purchases and services.", and "Budgets money to cover expenses for at least a week."

Conclusions: The findings from this study suggested that there was a gap between intellectual ability and adaptive skills in college students with ASD. These students may need support services to help them improve their skills in communication, socialization, and functional academics.

401.069 *(Poster)* The Teaching Model: Academic and Functional Skill Outcomes of an Intervention through Continuing Education Among Adults with Low-Functioning Autism Spectrum Disorder

M. Melamed[1], *D. A. Zachor*[2], *Y. Mazan*[3], *Y. Schindler*[3], *L. Cooper*[4] *and E. Ben-Itzchak*[5], *(1)The intervention unit for adults with Autism spectrum disorder, The Autism Center/ Alut, Givataym, Israel, (2)The Autism Center/ALUT, Pediatrics, Tel Aviv University /Shamir (Assaf Harofeh) Medical Center, Zerifin, Israel, (3)The intervention unit for adults with Autism spectrum disorder, The Autism Center/ ALUT, Givataym, Israel, (4)The intervention unit for adults with autism spectrum disorder, The Autism Center/ ALUT, Givataym, Israel, (5)Bruckner Center for Research in Autism, Communication Disorder, Ariel University, Ariel, Israel*

Background: Very few studies have examined intervention programs aimed to advance knowledge acquisition and social-communication skills among adults with low-functioning autism spectrum disorder (LF-ASD). Applied Behavioral Analysis (ABA) has proved to be very effective in children with ASD, but the few studies to examine its effectiveness in adults with LF-ASD have primarily focused on adaptive skills and on decreasing challenging behaviors.

Objectives: -To establish an innovative teaching model (TM) for adults with LF-ASD in a classroom setting.

-To examine outcomes of this TM in knowledge acquisition of the taught subjects and in self-help, adjusted behavior, and social-communication skills.

Methods: The TM was based on ABA strategies and offered courses on music, photography, recognizing emotions, and geography. Topics were taught in small groups of 2-4 participants, for one hour twice a week for four months. In each class, social-communication, organization and self-help skills were practiced.

The study included 86 participants (males=61; females=25) with an age range of 22:0 - 57:6 years (M=34:6, SD=9:1 years).

All the participants were previously diagnosed with ASD based on their medical records and on current scores of the Social Responsiveness Score, and had Vineland Adaptive Behavior Scales scores <70 (LF-ASD). All currently live in sheltered residences for adults with LF-ASD. The TM group (n=66) was compared to a control group (n=20) that later also participated in the TM.

Outcomes of the TM and control groups were assessed by two measures designed for this research, including knowledge examination of the teaching topics and assessment of self-help, adjusted behaviors and social communication skills. Data were collected before (T1) and after the TM intervention (T2) for the TM group. For the control group data were collected at T1 (baseline), after four months without the TM intervention (T2) and after four months with the TM intervention (T3).

Results: First, we compared the T2 knowledge and skills scores between the TM and the control groups. Since T1 scores differed between the groups, we used them as covariates. The TM group, as compared to the control group, significantly increased their skills scores [$F(1,55) = 11.4$, $p = .001$, $\mu^{2=}.17$] and knowledge scores [$F(1,83) = 21.9$, $p < .001$, $\mu^{2=}.21$] from T1 to T2. In all the TM courses, the increase in the knowledge and skills scores from T1 to T2 was significant (repeated measures analyses). The control group did not show significant changes in these measures.

For the control group, a comparison of the two pre-intervention (T1, T2) and the post-intervention (T3) times revealed a time effect for the knowledge test [$F(2,14) = 15.9$, $p < .001$, $\mu^{2=}.69$] and for the skills test [$F(2,14) = 8.7$, $p = .001$, $\mu^{2=}.55$]. For both tests, scores were significantly higher at T3 than at T1 and T2.

Conclusions: The teaching model is an effective continuing education intervention for both acquiring new knowledge and for improving self-help, adjusted behavior, and social-communication skills. The improvements are noticeable in all the courses, regardless of topic. It appears that a specialized program, given in a structured learning environment while simultaneously practicing various skills, is very effective among adults with low-functioning autism.

401.070 *(Poster)* Trait Emotional Awareness in Autistic Adolescents and Young Adults

A. Haschek[1,2], *R. L. Flower*[1,2], *A. L. Richdale*[1,2], *M. Uljarevic*[3], *R. Y. Cai*[4] *and* ***L. P. Lawson***[1,2], *(1)Olga Tennison Autism Research Centre, La Trobe University, Melbourne, VIC, Australia, (2)Cooperative Research Centre for Living with Autism (Autism CRC), Long Pocket, QLD, Australia, (3)Department of Psychiatry and Behavioral Sciences, School of Medicine, Stanford University, Stanford, CA, (4)Autism Spectrum Australia (Aspect), Melbourne, VIC, Australia*

Background: The transition from adolescence to adulthood is a significant period of change, marked by an increased expectation of independence, new experiences, and a decline in support. This period has been identified as challenging for autistic youth. Emotional awareness, which is the extent of an individual's ability to identify the emotional state of yourself and others, is a fundamental social skill used in everyday life. The Levels of Emotional Awareness Scale (LEAS) measures trait emotional awareness performance by assessing the complexity of open-ended responses to evocative scenarios and has been validated in non-autistic populations. While there are a growing number of autism-specific publications relating to emotional regulation; performance based emotional awareness has not been explored.

Objectives: The aim of this study was to determine the reliability of a modified, abbreviated LEAS (LEAS-M) and compare the level of emotional awareness of autistic and non-autistic individuals.

Methods: Individuals aged 15-25 years were invited to take part in the Study of Australian School Leavers with Autism (SASLA), which involved completing an online survey measuring a range of demographic and outcome variables. This study focuses on 85 autistic and 85 non-autistic control participants who completed the LEAS-M. The LEAS-M comprised of eight emotion driven scenarios that were modified to be more appropriate for young adults transitioning from high school. The LEAS-M was scored by two trained scorers who were blinded to the diagnosis of the participant. A random sample of responses (n = 57, 34.13%) were double scored to assess inter-rater reliability. The LEAS-M generates a Self and Other subscale score, and a Total score. To assess the reliability of the LEAS-M both intraclass correlations and cronbach's alpha were examined. Differences between autistic and non-autistic participants were assessed using Mann-Whitney U.

Results: Intra-class correlation coefficients [ICC (2, 1)] on double scored cases ranged between .98 - .99. For the autistic group, all cronbach's α coefficients were acceptable, Other (autistic α = .83), Self (autistic α = .70,) and Total (autistic α = .70). For the non-autistic group, cronbach's alpha was acceptable for both Other (α = .78) and Total (α = .70) but was low for Self (α =.55). Autistic participants scored significantly lower on Total score than non- autistic participants (U = 2457.5, p = .038). Autistic participants also scored lower on Other (U = 2247.5, p = .005), but there was no significant group difference on Self (U = 2775.0, p = .346).

Conclusions: The LEAS-M had excellent inter-rater reliability. The scale had acceptable internal consistency for the autistic group. However, the internal consistency for the Self score was poor in the non-autistic group, suggesting that the LEAS-M used be used with caution among non-autistic individuals. Exploring group differences, autistic individuals were comparable to non-autistic individuals when identifying their own emotions, but had more difficulty identifying the emotions of others. The difficulty identifying emotions in other people may be contributing to the challenges experienced by young autistic adults in navigating their transition into adulthood.

401.071 *(Poster)* Transportation Barriers and Community Participation for Individuals with Autism Spectrum Disorders

***B. Pfeiffer**, Rehabilitation Sciences, Temple University, Philadelphia, PA*

Background: Individuals with Autism Spectrum Disorders (ASD) often face serious transportation challenges that impede healthcare access, community participation, and employment opportunities (Risser et al., 2015). One study identified that 72% of individuals with ASD missed at least some their desired activities due to lack of available transportation (Feeley, Deka, Lubin, & McGackin, 2015). Driving is not always a viable option due to the impact of the disability or financial resources. When it is available, public transportation provides a low-cost option that allows for independence to access services and community activities, although its use is often limited by barriers such lack of training and environmental factors. In order to identify and implement appropriate supports and services, it is essential to understand the barriers to public transportation use and the impact on participation.

Objectives: The objective of this study was to understand the types of supports and services needed to improve access to public transportation and reduce barriers for individuals with Autism Spectrum Disorders. Specifically, the study examined types of transportation used, barriers to transportation, and impact of transportation on community participation and employment from the perspective of individuals with ASD and their caregivers.

Methods: Researchers used a cross-sectional descriptive design. Self-identified adults with ASD (n = 158) completed on-line surveys using Qualtrics survey software to acquire information about basic demographics, transportation use, community participation, barriers to transportation, and other pertinent questions regarding their transportation use. Survey data was analyzed using SPSS**.**

Results: There were ninety (57%) men, fifty-seven (36%) women and seven (7%) people identifying as "other" who participated in the study. Participants had a mean age of 26 and represented all regions of the United States. Over 65% of participants reported that the use of independent transportation options would improve their quality of life and 73% reported that they would be more likely to use these transportation options if they had special training. The majority of participants identified that lack of transportation impacted their participation in the community (56%) and employment (52%). Barriers to the use of public transportation included: lack of transportation services or connections (41%); lack of knowledge on how to navigate transit system (21%); hours of operation (19%); expense (13%); safety concerns (12%); and lack of knowledge on how to use the system (12%). Additionally, results suggested a preference for self-reliance and self-efficacy, as the majority of participants indicated a need to reduce dependence on others for transportation.

Conclusions: This study identified important considerations in understanding participation and use of public transportation for individuals with ASD. Future studies investigating transportation barriers, community participation, and specialized transportation training are necessary to better serve this population and contribute to the lack of research in this area.

401.073 *(Poster)* Understanding How Social Anxiety and Empathy Impact Young Adults with ASD

***L. D. Solouki**[1], Y. S. Lograsso[2], M. Jolliffe[3], N. E. Rosen[4] and E. A. Laugeson[2], (1)UCLA PEERS Clinic, Los Angeles, CA, (2)UCLA Semel Institute for Neuroscience and Human Behavior, Los Angeles, CA, (3)UCLA Department of Psychiatry, PEERS lab: UCLA PEERS Clinic, Los Angeles, CA, (4)UCLA Department of Psychiatry and Biobehavioral Sciences, UCLA PEERS Clinic, Los Angeles, CA*

Background: Prior research suggests that individuals with autism spectrum disorder (ASD) often have higher rates of social anxiety (Bellini 2004) and lower levels of empathy (Baron-Cohen and Wheelwright, 2004) than the general population. Social anxiety may lead to social avoidance and decreased opportunities for social interactions (White & Roberson-Nay 2009), while deficits in empathy may make it difficult to understand and connect with others (Baron-Cohen & Wheelwright 2004). Though research on the independent effects of social anxiety and empathy with regard to people with ASD is prevalent in the literature, there is a dearth of research examining the relationship between social anxiety and empathy in individuals with ASD, especially among young adults.

Objectives: In this study we explored the relationship between social anxiety and empathy in young adults with ASD. We hypothesized that young adults with social anxiety would have lower levels of empathy.

Methods: Participants included 119 young adults (89 males) between the ages of 17 to 35 (M=22.42, SD=3.679) presenting for treatment through the UCLA Program for the Educational and Enrichment of Relational Skills (PEERS®), an evidence-based, caregiver-assisted social skills intervention for young adults with ASD (Laugeson 2017). All participants had clinically elevated ASD symptoms as determined by a caregiver-reported total score ≥ 60 on the Social Responsiveness Scale-Second Edition (SRS-2; Constantino & Gruber 2012). In order to assess the relationship between social anxiety and empathy, young adult participants completed the Social Anxiety Scale (SAS; La Greca 1999) and the Empathy Quotient (EQ; Baron-Cohen & Wheelwright 2004) at baseline.

Results: Pearson correlation coefficients were calculated to examine the relationship between self-reported SAS and self-reported EQ prior to treatment. Results indicate that there is a significant negative correlation between self-reported social anxiety and self-reported empathy (r(119) = -.329, p<.001), revealing that young adults who report higher social anxiety also report lower empathy.

Conclusions: Results support the hypothesis that young adults with ASD endorsing higher levels of social anxiety also tend to exhibit lower levels of empathy. One possible explanation for this finding may be that heightened anxiety, which may cause a hyperawareness of one's own internal state, may hinder an individual's ability to attend to cues related to another person's emotional state. Understanding the relationship between social anxiety and empathy may be important towards developing targeted treatments for this population. Future studies might examine the relationship between social anxiety and empathy across other developmental groups with ASD.

401.074 *(Poster)* Understanding Perceptions and Experiences of Autistic Undergraduate Students Toward Disability Support Offices of Their Post-Secondary Institutions

S. Y. Kim[1] *and S. Crowley*[2]*, (1)Lynch School of Education, Boston College, Chestnut Hill, MA, (2)Boston College, Chestnut Hill, MA*

Background: Despite the increased interest in the college experiences of autistic undergraduate students and research gathering their perceptions on a range of support services, few studies have examined how autistic students in the US utilize and perceive support services provided by disability support offices (DSOs) in higher education institutions (HEIs). A better understanding of their experiences with DSOs may aid in developing effective DSO services that cater to the specific needs of autistic undergraduate students.

Objectives: This study solicited college experiences of autistic undergraduate students to address the following research questions:

RQ1. How do students perceive their experiences with DSOs to have influenced their college experience?

RQ2. What patterns emerge among responses of autistic students who did not or do not receive DSO accommodations?

RQ3. How do autistic students perceive that DSOs could support them better?

Methods: This study qualitatively examined 27 autistic undergraduate students' responses to semi-structured interviews soliciting their perceptions of a range of support services provided by DSOs in US HEIs. Table 1 presents demographic characteristics. Two doctoral-level students were involved in the analysis of the interview transcripts. As an initial pass, structural coding was applied to create descriptive codes. Then, thematic analysis was conducted to examine overarching, emerging high-level themes from the descriptive codes.

Results: Participants appreciated receiving academic support coordinated by DSOs, such as extended time on exams or taking exams in separate locations; being housed in a single rather than a shared room; and having opportunities to meet other autistic students. At the same time, some students reported negative experiences with DSOs, including lack of helpfulness when professors refused to grant requested accommodations, lack of non-academic social support, DSO staff member's lack of autism knowledge, and their impersonal or delayed responses to autistic students' requests. Students who chose not to receive services reported they did so because they wanted to have a typical college experience, felt that they were academically competent without accommodations, overwhelmed by the complexity of the submission process, or did not believe that DSO services could properly support them, especially when their difficulties were not academic. Students indicated that DSOs need to organize events to increase autism awareness on campus, educate faculty and facilitate student-faculty communications, and address their susceptibility to sensory overstimulation by creating quiet spaces for them to calm down. Finally, students wanted DSO staff to provide more individualized services, opportunities to meet other autistic students or students with various disabilities.. See Table 2 for exemplary quotes illustrating each theme.

Conclusions: Most of the students' requests such as increasing institutional awareness, providing required faculty professional development, and creating sensory time-out rooms, cannot be fulfilled by DSOs alone. Institution-wide support and revised policies are necessary. The findings bear implications for ways in which all campus community members can collaborate to promote autism awareness on campus and improve college experiences for autistic students. Finally, ways to provide the needed supports during the registration process (e.g., peer mentors who already underwent the same process) need to be considered.

401.075 *(Poster)* Uniting Patients, Caregivers, and Stakeholders to Address Transitioning to Adulthood in Autism Spectrum Disorder

S. N. Brasher[1] *and M. J. Segall*[2]*, (1)School of Nursing, Emory University, Atlanta, GA, (2)Emory Autism Center, Emory University, Atlanta, GA*

Background: Autism spectrum disorder (ASD) is a lifelong pervasive developmental disorder with symptoms of communication deficits, social interaction impairments, and repetitive behaviors. Estimates reveal that ASD is the fastest growing neurodevelopmental disorder, currently affecting 1 in 59 children and more than 5 million Americans. In addition to the core symptoms of ASD, transition-age youth with ASD experience multiple medical and psychiatric comorbidities (e.g., seizures, gastrointestinal disorders, sleep disorders, depression, anxiety). Of great concern is how these medical and psychiatric comorbidities impact their overall health, health-care decision making, health outcomes, and quality of life during transitioning and beyond. Given that ASD emerges in early childhood, traditional research and interventions have largely focused on children with ASD. Thus, there is a knowledge gap on the complex transition needs of young adults with ASD and how or when to intervene.

Objectives: To form partnerships between patients and stakeholders to gain insight into challenges encountered during the transition phase of ASD and develop comparative effectiveness research (CER) questions alongside them to address these challenges.

Methods: A PCOR approach was used to develop research capacity, build infrastructure, and conduct future research responsive to the needs of transition-age youth with ASD. Young adults with ASD ages 15-40 and caregivers were identified using purposive sampling to participate in monthly engagement groups over 2 years. A diverse advisory board of patients and stakeholders met monthly to provide project guidance. Members of the advisory board included young adults with ASD, educators, caregivers, legislative experts, advocates, ASD researchers, clinicians, patient care coordinators, special needs trust lawyers, and housing experts. Meetings were audio recorded, transcribed, and analyzed for recurrent themes.

Results: This study identified seven key areas of transition in ASD (e.g., healthcare, self-advocacy, independent living skills, safety, career/job, social/relationships, and education) that have not been addressed in research from the patient and stakeholder viewpoint. Patients and stakeholders identified five CER questions to address these seven key areas of transition. Additionally, this study identified the presence of racial and gender differences present in the transition phase that equated to unique challenges and needs. As a result, an overwhelming number of gender, racial, and sexual minority adults with ASD participated in this study to ensure their unique challenges were known. A series of co-learning conferences brought together patients and stakeholders of various key areas to learn from each other (e.g., police officers, adults with ASD, caregivers, emergency medical responders). Lastly, patients and caregivers worked alongside ASD researchers to develop patient-centered database inquires to explore large datasets.

Conclusions: The transition from childhood to adulthood represents a tumultuous time for most, but especially for young adults with ASD and their families. This project demonstrates the importance of using a PCOR approach to unite underrepresented patients and stakeholders towards the common goal of identifying ASD transition needs and shaping future research responsive to their needs. Results of this study have the ability to generate future patient-centered research and potentially close the gap on transitioning to adulthood in ASD, as well as improve health outcomes.

401.076 *(Poster)* Utilizing the Information, Motivation, and Behavioral Skills Model to Examine the Associations between Autism Symptoms, Sex, and Dating Behaviors

B. Kohn[1]*, D. Solomon*[2]*, D. W. Pantalone*[3]*, I. Schichter*[2]*, M. Armstrong*[2] *and S. Faja*[2]*, (1)Labs of Cognitive Neuroscience, Boston Children's Hospital, Boston, MA, (2)Boston Children's Hospital, Boston, MA, (3)Psychology, University of Massachusetts Boston, Boston, MA*

Background: Research has begun to examine whether people with ASD experience unique challenges in their pursuit of romantic and sexual relationships. Solomon et al., (2019) suggests that the Information-Motivation-Behavioral Skills (IMB) Model (Fisher et al., 1994) provides a useful framework for understanding the dating and sexual experiences of young adults with ASD (2019). While some published studies have looked at these three factors individually in this context, examination of the associations between and among all three factors of the IMB Model in the context of ASD has not been done.

Objectives: To investigate the associations among autism symptoms, information, motivation, and behavior as it relates to dating and sex in adults on the spectrum.

Methods: 15 adults with ASD (4 women; *M*=21.47±1.92 years) completed quantitative and qualitative measures assessing their knowledge, motivation, and behaviors related to sex and dating. All participants met criteria for ASD on the SRS-2 and the ADOS-2 and had IQ >70 (*M*=108.13 ± 20.7). The Knowledge of Sexual Health Questionnaire, Anatomy Vocabulary Test, and Perceived Knowledge Questionnaire measured information. The Sexual Activities questionnaire measured behavior. The Sexual Desire Inventory measured motivation in total, as well as desire for solitary and partnered activities. Additionally, adults (*n*=13) and their parents (*n*=11) participated in separate qualitative interviews about the adult's dating and sexual experiences. Interviews were audio recorded, transcribed verbatim, and coded using conventional content analysis.

Results: Pearson correlations between ADOS-2 scores (*M*=42.53, ±14.53) and total sexual vocabulary scores (*M*=11.27, ± 4.0), suggest that the relation between greater autism severity and lower knowledge approached significance, *r*(13)= -.507, *p*=.055. Correlations between SRS-2 scores (*M*=71.13, ±6.24) and total sexual desire (*M*=55.93, ± 27.24), suggest a trend between higher autism severity and motivation, *r*(13)= .45, *p*=.09. Total vocabulary scores (*M*=11.27, ± 4.0) and total solitary sexual desire (*M*=11.87, ± 5.475), were significantly related, *r*(13) = .543, *p*=.045. Autism severity was not related to sexual behavior (*p*=.92). However, most participants reported no exposure to situations in which partnered sexual activities would be possible. Only 27% of participants reported having ever been on a date and only 20% reported engaging in any type of partnered sexual activity. Participants reporting more experiences (sexual activity count, *M*=2.86, ±4.13) tended to have higher perceived knowledge of sexual activities (total perceived knowledge, *M*=3.67, ±1.35), *r*(12)= .477, *p*=.085. In qualitative interviews, participants cited social challenges as the largest obstacle that adults with ASD face when trying to pursue intimate relationships.

Conclusions: Data collection is ongoing, yet, even in this limited sample, autism severity was related to self-reported information, motivation, and initiation of intimate relationships—although unrelated to sexual or romantic behaviors. Reduced social engagement, a core feature of autism, appears to be a significant barrier to engagement in sexual and romantic relationships. This study will continue to collect data to more fully understand the social factors, social perceptions, cognitive abilities in the context of the IMB model. Understanding how the challenges encountered by adults on the spectrum impact dating and sexual health may improve future intervention efforts.

401.077 *(Poster)* Wellbeing in Autism Is Tied to Relationship Experience

M. Stokes[1]*, L. Pecora*[2]*, G. Hancock*[3] *and G. Mesibov*[4]*, (1)Psychology, Deakin University, Burwood, Australia, (2)School of Psychology, Deakin University, Burwood, VIC, Australia, (3)Deakin University, Burwood, Australia, (4)University of North Carolina at Chapel Hill, Chapel Hill, NC*

Background: Wellbeing in all individuals is desirable. It has been understood for some time that within the general population those with various protective factors, have improved subjective wellbeing. Among others, these protective factors include the presence of a meaningful romantic relationship. Autistic individuals have long been at a disadvantage in this regard, many having much greater difficulty in obtaining a relationship. However, it has not been clear that the presence or absence of a relationship has the same meaning or similar outcomes as it does for the general population.

Objectives: This study aimed to establish what were the proportions of autistic individuals who had experienced a relationship, and what impact this had upon their subjective wellbeing.

Methods: A total of 459 autistic (N=232) and typically developing (N=227) adults completed the SBS-III online, a validated and reliable measure of sexual behavior. Self-reported levels of romantic experience, sexual behaviors, and subjective wellbeing of non-autistic and autistic individuals were analyzed for female (Autistic N=111, M=26.16, SD= 8.71; non-autistic N=152, M=21.99, SD=4.59), male (Autistic N=95, M=24.35, SD= 7.50; non-autistic N=62, M=22.50, SD=6.57), and nonbinary groups (Autistic N=25, M=23.64, SD=5.70; non-autistic N=13, M=23.33, SD=5.37).

Results: Multiple regression analyses revealed that skills around socializing, formulation of a relationship, concerns about their future, having had a close romantic bond with another person, and the involvement of family in developing this relationship were predictive of between 16% to 68% of the variance of subjective wellbeing, depending upon group. Autistic individuals identifying as nonbinary gender had the least amount of variance accounted for (16%), while autistic males and females had more than 35% of personal wellbeing accounted for by these factors. Non-autistic individuals had between 49% and 68 % of variance accounted for.

Conclusions: These results indicated first that those with autism have their subjective wellbeing improved by having had a relationship. Further, these results also suggest worries about potential future relationships gives rise to concern and a reduction in wellbeing. Last, these results indicate the potential directions for support and assistance that will increase wellbeing among those with autism.

401.078 *(Poster)* "I Thought I Was Going Mad": We Need to Talk about Menopause in Autism

R. Moseley[1]*, T. Druce*[1] *and J. M. Turner-Cobb*[2]*, (1)Bournemouth University, Poole, United Kingdom, (2)Psychology, Bournemouth University, Poole, United Kingdom*

Background: Within the general dearth of ageing research in autism, issues important to women are especially neglected. In non-autistic women, the menopausal transition is a time when women can experience debilitating or disruptive physical symptoms, and when incidence of physical and mental ill-health increase. Depression, anxiety and suicidality are heightened and cognitive abilities falter, with memory and executive function deteriorating. In this context, it is surprising and worrying that research exploring how autistic women cope with the menopausal transition is severely lacking. This raises serious concerns for a group who are already at heightened risk for suicide, mental and physical ill-health; who struggle with emotion regulation and coping with change; who may already struggle with executive function and other cognitive abilities; who may lack social support and the ability to communicate their difficulties; and who may be confront difficulties in access to healthcare.

Objectives: We aimed to explore existing knowledge of and support for the menopause in autistic women, to hear what challenges this time might pose for the female autistic community as a whole, and to explore themes that arose in personal experiences of autistic individuals (not all identifying as female) who were navigating or had completed the menopausal transition.

Methods: In a two-pronged qualitative approach, we conducted a synchronous online focus group with seven autistic individuals, who met in an online chatroom to answer questions posted by two moderators. These questionscovered the state of extant knowledge about menopause in autism; whether autistic people might experience menopause differently; what support exists and is needed; and what questions might guide future research. Thematic analysis of responses allowed us to derive individual interviews to explore physical and psychological experiences around menopause and the perceptions of autistic women regarding this life event. Seventeen participants (6 from the focus group, and 11 additionally recruited) took part in individual interviews, explored using interpretive phenomenological analysis (IPA).

Results: Themes interpreted from the focus group and interviews reflected a lack of professional knowledge, interest and support around autistic menopause, and a lack of menopausal knowledge among autistic participants. The menopause emerged as a time in which "the cracks in the mask started to appear"; sensory sensitivities were heightened while cognitive abilities declined; previously adaptive coping skills failed and self-care deteriorated; participants experienced heightened emotion dysregulation and, for some, suicide ideation and attempts. For some, the increased difficulties led to their late diagnosis as autistic.

Conclusions: The lack of menopausal awareness in the autistic community, the difficulties that participants experienced in communicating their difficulties and getting help, and the lack of knowledge from professionals suggest that the menopausal transition may be a time where the health needs of autistic women are especially unmet. These findings are stark in the face of the increased challenges and mental ill-health experienced by many participants. Participants emphasized the need for further investigation to raise awareness of the particular difficulties, and potential threat to wellbeing, faced by autistic people at this time of life.

401.079 *(Poster)* "Straight Sex Is Complicated Enough!": The Lived Experiences of Autistics Who Are Sexual Minority Orientation

L. Lewis*, University of Vermont, Burlington, VT*

Background: Evidence suggests autistics may be more likely to identify as sexual minority orientation (SMO) compared to neurotypicals. Individuals living as a "double minority" at the intersection of autism and SMO may be more likely to experience discrimination, depression, and suicidal ideation. There has been a call to qualitatively explore the experiences of these individuals.

Objectives: To describe the lived experiences of autistics who are gay, lesbian, bisexual, asexual, or other SMOs.

Methods: In this descriptive phenomenology, a purposive sample of 67 adults who identified as SMO were recruited via online message boards and forums to participate in asynchronous online interviews. Responses were analyzed using Colaizzi's (1978) method. Interview transcripts were read and significant statements were extracted. Meanings for each statement were formulated and clustered to identify themes from the data. Themes informed an exhaustive description and fundamental structure of the phenomenon, which were shared with nine participants for feedback and verification of findings.

Results: Six themes emerged from the data. (1) ***"My self-identity is a fluid and flexible thing":*** **Self-acceptance is a multi-layered journey**: Participants described multiple stages in understanding their own identities and faced shame and discrimination about both autism and SMO.
(2) ***"It's hard to imagine things you've never experienced":*** **Autism complicates understanding of sexual identity:** Participants questioned the relationship between their autistic and sexual identities. Autism often increased initial confusion in recognizing sexual orientation. Some who identified as asexual described feeling invalidated by individuals who claimed that asexuality was caused by autism.
(3) ***"It's like getting an intrusive physical from a doctor":*** **Anxiety, sensory overload, and social stressors affect sexual expression:** Many described struggling with sex-repulsion, hygiene concerns, hypersensitivity, and/or discomfort with physical touch that complicated sexual relationships. Others viewed sex as less complicated than verbal communication and were more likely to engage in high-risk sexual behaviors.
(4) ***"It's hard for people to understand exactly how I feel":*** **Feeling misunderstood and misunderstanding others:** Many described feeling isolated from others due to a lack of shared cultural experiences surrounding dating. Many faced exclusion from both the LGBTQ+ and the autism communities.
(5) "***It's difficult to form relationships of any kind, let alone sexual ones":*** **Concerns about the ability to find mutually satisfying relationships:** Participants described challenges pursuing and maintaining relationships, reading romantic cues from others, expressing interest, and anxiety about meeting the needs of romantic partners. Some struggled to read intentions of others, increasing risk of sexual abuse.
(6) ***"I just don't know how to explain what I need":*** **Inability to effectively communicate intimate desires:** Some described difficulty identifying and articulating their preferences for sex and intimacy with partners, which decreased sexual satisfaction.

Conclusions: Findings provide insight into the essence of the experience of being SMO as an autistic. Individuals who use observation and mirroring behaviors as social strategies may struggle to understand dating norms due to lack of LGBTQ+ role models. Clinicians should be aware of the potential for high risk behavior and sexual abuse within this population.

Affective Neuroscience

POSTER SESSION — **AFFECTIVE NEUROSCIENCE**
402 - Affective Neuroscience Posters

402.001 *(Poster)* Atypical Fronto-Temporal Engagement in Processing Dynamic Faces in ASD

E. J. Choi[1]*, M. M. Vandewouw*[2]*, J. P. Lerch*[3]*, E. Anagnostou*[1] *and M. J. Taylor*[4]*, (1)Holland Bloorview Kids Rehabilitation Hospital, Toronto, ON, Canada, (2)Neuroscience & Mental Health Program, The Hospital for Sick Children Research Institute, Toronto, ON, Canada, (3)Wellcome Centre for Integrative Neuroimaging, University of Oxford, Oxford, United Kingdom, (4)The Hospital for Sick Children, Toronto, ON, Canada*

Background: Facial expressions of emotion are an important source of social information. Autism spectrum disorder (ASD) is classically associated with poor emotional face processing skills and atypical neural processing has been implicated. However, most studies have used static faces and few have used more ecological dynamic stimuli to investigate neural process of emotional faces in ASD. We contrasted fMRI measures of dynamic emotional face processing in ASD compared with typically developing (TD) controls across a wide age-range.

Objectives: To determine a) if the processing of emotional faces differs between those with ASD compared to TD controls, and b) if the age-related trajectories of face processing differ between ASD and TD.

Methods: 168 ASD and 98 TD individuals from 5–42 years of age were recruited to participate, most from the Province of Ontario Neurodevelopmental Disorders (POND) network. Data were collected on a Siemens 3T MRI scanner. The fMRI stimuli were dynamic (480ms-long) emotional faces (neutral-to-happy, neutral-to-angry) and dynamic flowers (closed-to-open), presented in 18 pseudo-randomized blocks (6 each of happy, angry, flowers) of 13.5s. The data were slice-time and motion-corrected calculating framewise displacement (FD), and volumes with an FD>0.9mm were censored and the participants with >1/3 of volumes censored were excluded. Data were smoothed, intensity normalized, temporally filtered, and cleaned of signals from the white matter, CSF, whole-brain and six rigid body motion parameters, and further denoised with FSL's FIX. FSL's FEAT was used to obtain the brain response for each subject to the happy, angry and flower conditions. FSL's FLAME was used to investigate group-by-age interactions and group differences in the task condition contrasts, with sex and mean FD as covariates. Statistical images were thresholded using clusters determined by Z>2.3 and a cluster significance threshold of p_{corr}<0.05.

Results: When contrasted dynamic faces to dynamic flowers, significant group differences were shown in occipital and fusiform gyri regions. The activation to faces compared to flowers in these visual regions was reduced in the ASD group, suggesting that they processed faces and flowers similarly. In contrasting between two emotions (happy and angry), the ASD group demonstrated atypical processing in happy faces with an engagement of sensorimotor regions, including pre- and postcentral gyri and superior temporal gyri, while they showed increased activation to angry faces occipitally. Interestingly, regions which are known to be engaged in emotional processing, such as insula, temporal pole and frontal regions, showed increased connectivity strength with age in the TD group while, in contrast, the ASD group showed decreased connectivity with age.

Conclusions: Using dynamic stimuli, the present study demonstrated that the ASD group processes faces similarly to non-face stimuli at a neural level. The age-related atypicalties were more pronounced to happy faces, with decreasing recruitment with age of fronto-temporal regions in those with ASD, yet increased occipital recruitment to angry faces that did not change with age. Decreased functional connections in typical emotional processing regions in ASD suggested persistent difficulties over the lifespan.

402.002 *(Poster)* Differences in Neural Processing of Social and Nonsocial Fear in ASD Compared to Social Anxiety Disorder

M. Coffman[1]*, L. Antezana*[2]*, M. Maurin*[1]*, C. Brown*[1]*, A. Kirkpatrick*[1] *and J. A. Richey*[1]*, (1)Virginia Tech, Blacksburg, VA, (2)Virginia Polytechnic Institute and State University, Blacksburg, VA*

Background:

Adolescents with autism spectrum disorder (ASD) have higher rates of comorbid Social Anxiety Disorder (SAD) than other psychiatric disorders, with 42-85% of individuals with ASD also meeting criteria for SAD (de Bruin et al., 2007; Simonoff et al., 2008). Overlapping behaviors (e.g., deficits in social reciprocity, limited eye contact, and social avoidance) between ASD and SAD makes differential diagnosis difficult (White, et al., 2014). Currently, treatments are implemented based on diagnosis, despite potentially different fear learning pathways. However, it is unknown whether fear is learned the same in ASD as in SAD alone. Neural mechanisms of fear learning may provide tools to tailor treatments. The classic fear conditioning paradigm is well-suited to investigate mechanisms of fear learning.

Objectives: The purpose of the current project is to characterize the neural correlates of fear acquisition in adolescents with ASD+SAD, SAD alone, and neither condition (CON). The central hypothesis is that groups will show differences in neural pathways of fear conditioning.

Methods: Adolescents (N=57) completed this study, which included a diagnostic appointment (Table 1) and an event-based fMRI with two fear conditioning tasks, Social (face + scream sound) and Nonsocial (shape + startle probe). Conditions were counterbalanced within groups. Scanning was conducted on a Siemens 3T Tim Trio system outfitted with a 45 mT/m gradient system, 8 receive channels, and a 12 channel head coil. Slice time correction, motion correction, and spatial smoothing (Gaussian kernel with full-width-at-half-maximum of 2.0 × the voxel size) were performed on the data. Statistical models set the onset of event into a 2 (Event; paired conditioned stimulus (CS+), unpaired stimulus (CS-)) X 2 (Condition; Social, Nonsocial) X 3 (Group; ASD, SAD, CON) ANOVA.

Results:

Whole brain analyses revealed that groups differed in activation in Event type (CS+, CS-) by Condition (Social, Nonsocial) in the Inferior Temporal Gyrus (ITG; Figure 1). A follow-up Region of Interest analysis, with mean values of activation extracted from the ITG for Event and Condition, indicated the Main effect of Event (p = .009) and Condition (p = 0.005) were driving the significant activation observed (Figure 1). The ASD group exhibited greater activation in the Social condition for the CS+ compared to the CS-, and the SAD group demonstrated greater activation in the ITG in Nonsocial CS+ compared to the CS-. Accordingly, the ITG appears to differentiate anxiety to social compared to nonsocial stimuli in individuals with ASD.

Conclusions:

The current study found significant differences in neural responses in fear conditioned responses to social compared to nonsocial conditions across clinical groups in the ITG. In ASD, the temporal gyrus has consistently been hypothesized to relate to dysfunction in social information processing, including eye gaze, social attention, and language learning (Redcay, 2008). Given the increased ITG activation observed in the ASD group to the social fear conditioning stimuli, the ASD group in particular is likely at greater risk for dysfunction in this brain region. Results suggest that different neural pathways may exist for the development of comorbid ASD+SAD compared to SAD alone.

402.003 *(Poster)* Emotional Face Processing Differences in Autism Spectrum Disorder and Comorbid Attention Deficit Hyperactivity Disorder

***A. Johnson**, J. R. Sweigert, J. Sabin, T. St. John and N. M. Kleinhans, University of Washington, Seattle, WA*

Background: Abnormal activity in the extended face processing system has been implicated in face processing challenges in autism spectrum disorder (ASD). However, the impact of comorbid attention deficit hyperactivity disorder (cADHD) on social impairment and the neural substrates underlying face processing has not been investigated.

Objectives: To address this question, we probed the extended face processing system by exposing children with ASD, cADHD, or typical development (TD) to a rapid fearful face and house paradigm using fMRI.

Methods: All study participants were administered the Kiddie Schedule for Affective Disorders (K-SADS). Autism participants who also met criteria for ADHD were assigned to the cADHD group. All other participants with autism were assigned to the ASD group. The Autism Diagnostic Observation Schedule (ADOS-2) was administered to confirm no TD children met ASD diagnosis. After excluding for excessive motion, 21 children with ASD (Age M (SD) = 10.3 (1.62)), 12 children with cADHD (Age M (SD) = 10.5 (1.75)), and 44 typically developing (TD) controls (M (SD) = 10.4 (1.36)) were included.

MR data were collected on a 3T Philips Achieva system. For the fMRI task, 54 volumes of high resolution data (2.3mm3) were collected. Participants were shown blocks of rapidly-presented (150 ms) fearful faces, houses and scrambled images. To ensure that participants were attending to the stimuli, they were asked to press a button every time the target stimuli appeared on the screen. Target stimuli appeared at pseudo-random intervals (average ISI = 6.13 s; range of ISIs = 2.50 s – 13.00 s). fMRI data were processed in FSL using standard processing methods including motion correction, spike artifact removal, high-pass filter of sigma=50s, and spatial smoothing (FWHM=5mm). Rigid body motion parameters and single point regressors were entered as nuisance regressors. We tested group differences in the contrast faces > houses. Higher-level group analyses were carried out using OLS and corrected for multiple comparisons using a corrected cluster significance threshold of $p < 0.05$.

Results: There was a significant difference between the ASD and cADHD groups on the ADOS-2 social affect domain (ASD M=7.71, SD=1.35, cADHD M=5.91, SD=2.23, $p<0.01$). Children with cADHD exhibited greater right superior temporal sulcus ($p < .001$) and prefrontal cortex ($p = .019$) activity than children with ASD for the faces > houses contrast. The children with ASD showed significantly greater activation in the cerebellum ($p = .001$). Qualitative comparisons indicated that the cADHD children exhibit hyperactivation to faces (cortical regions) and houses (cerebellum) compared with ASD and TD participants (see Figure 1).

Conclusions: These preliminary results indicate significantly altered brain activation during face and object processing in children with comorbid ASD and ADHD when compared to children with ASD alone or TD, suggesting a neurobiological difference underpinning transdiagnostic social difficulties. Further research with a larger group of children with cADHD is required to confirm these findings.

402.004 *(Poster)* Intrinsic Network Connectivity with Interoceptive Sensory Regions Correlates with Autism Severity

***A. Zoltowski**[1], M. D. Failla[2], C. Okitondo[3], A. S. Weitlauf[4], L. E. Mash[5], S. L. Davis[6], B. H. Heflin[7], B. P. Rogers[8] and C. J. Cascio[9], (1)Vanderbilt University, Nashville, TN, (2)Psychiatry, Vanderbilt University, Nashville, TN, (3)Georgia State University, Atlanta, GA, (4)Vanderbilt Kennedy Center, Vanderbilt University Medical Center, Nashville, TN, (5)SDSU/UC San Diego Joint Doctoral Program in Clinical Psychology, San Diego, CA, (6)Vanderbilt University Medical Center, Nashville, TN, (7)Florida International University, Miami, FL, (8)Radiology and Radiological Sciences, Vanderbilt University, Nashville, TN, (9)Vanderbilt University School of Medicine, Nashville, TN*

Background: Each of us consistently receives a wealth of sensory information from outside and inside the body; our brain then decides which signals are most significant in any given moment. In particular, signals from within the body (i.e., interoceptive signals, such as heart rate, breathing, and hunger) often do not reach conscious perception, yet there is evidence that awareness of these sensations closely affects emotions and sense of self (e.g., Craig, 2003; Quadt et al., 2018; Palmer and Tsakiris, 2018). The salience network is thought to be centrally involved in allocating attention to relevant sensory stimuli; there is cross-sectional evidence for a developmental trajectory of hyper- to hypo-connectivity between the salience network and primary interoceptive cortex (posterior insula) in individuals with autism (Uddin, 2015).

Objectives: We aimed to investigate how autism severity relates to salience-posterior insular connectivity in individuals with autism spectrum disorder (ASD), compared to a neurotypical group.

Methods: N=28 individuals with ASD (ages 8-54) and N=45 neurotypical individuals (NT, ages 8-41) completed a resting-state functional magnetic resonance imaging (fMRI) scan. Subject-level networks were identified using independent component analysis and for each subject, the component with the highest overlap with Yeo et al.'s (2011) salience network map was selected. Functional connectivity between the salience network component and left and right posterior insula regions of interest (ROIs) was calculated by averaging the salience network component association score for voxels within each ROI. Nonparametric measures were used to assess correlation with autism severity as measured by the Social Responsiveness Scale, Second Edition (SRS-2) total scores. This association was also tested when covarying for intelligence quotient (IQ), age, and gender.

Results: Correlations between salience network-posterior insular connectivity and autism severity differed by diagnostic group. In the ASD group, salience network-posterior insular connectivity correlated with decreasing SRS-2 scores for both left and right insular ROIs (left: tau=-0.316, p=0.046; right: tau=-0.345, p=0.030). In the NT group, salience network-posterior insular connectivity did not significantly correlate with SRS-2 scores (left: tau=0.225, p=0.093, right: tau=0.094, p=0.485). While IQ, age, and gender were not significant predictors of salience network-posterior insular connectivity in either group, the correlation between salience network-posterior insular connectivity and SRS-2 scores in the ASD group was attenuated when these variables were included in the model (left: coefficient=-0.06, p=0.118; right: coefficient=-0.089, p=0.057).

Conclusions: Only the ASD group showed a significant correlation between salience network-posterior insular connectivity and autism severity ratings. This suggests that there might be diagnostic group-specific relationships between interoceptive processing and social functioning. Particularly, greater interoceptive neural processing may benefit social functioning in ASD, potentially relating to increased emotional or self-awareness. However, the lack of correlation in the NT group suggests that there may not be additional gains from greater interoceptive processing when social skills are typical. While age effects were not significant in our model, future studies may use longitudinal designs to disentangle how autism severity interacts with interoceptive processing across development. Overall, these findings support that the neural circuitry for interoceptive processing is linked to social functioning in ASD.

402.005 *(Poster)* Neural Processing of Emotional Faces in Youth with Autism: Effects of Sensory Distracters and Priming with Own Emotional Expressions

G. Patterson[1]*, K. K. Cummings*[2]*, J. Jung*[2]*, N. J. Okada*[2]*, N. Tottenham*[3]*, S. Y. Bookheimer*[2]*, M. Dapretto*[2] *and S. A. Green*[2]*, (1)University of California, Los Angeles, Los Angeles, CA, (2)Dept of Psychiatry and Biobehavioral Sciences, University of California, Los Angeles, Los Angeles, CA, (3)Psychology, Columbia University, New York, NY*

Background: Autism spectrum disorder (ASD) is characterized by deficits in social interaction, which relies on the ability to process emotional expressions. Individuals with ASD often show atypical neural activation during emotional face processing even in the absence of behavioral deficits (Harms et al. 2010). Individuals with ASD also show high rates of sensory over-responsivity (SOR), which has been associated with social deficits both behaviorally (Glod et al. 2015) and neurobiologically (Green et al. 2017). However, our prior work showed that directing attention to key social cues led to children with autism engaging medial prefrontal cortex (mPFC) and maintaining activation in social processing regions despite sensory distraction (Green et al., 2017). Additionally, while higher autism traits in neurotypical adults have been associated with slower identification of emotional expressions, this difference disappears when participants are primed with videos of their own faces (Li and Tottenham 2013).

Objectives: To investigate how auditory distracters affect neural processing of emotional faces in youth with ASD, and to test whether priming participants with videos of their own emotional expressions changes the effect of sensory distracters during face processing.

Methods: 30 youth with ASD and 24 age-matched typically-developing (TD) controls (age 8-17) completed an emotion identification task while undergoing fMRI. Groups were matched on performance IQ but differed on full-scale IQ which was covaried in analyses. During fMRI, participants watched neutral faces morph into either happy or angry faces. Participants were asked to identify the emotion as quickly and accurately as possible. For half of the trials, participants completed the task during aversive environmental noises (e.g. sirens, lawnmowers). Halfway through, participants watched videos of themselves making happy and angry faces. SOR was measured using the Sensory Processing 3-Dimensions Questionnaire (Miller and Schoen 2004). Whole-brain analyses were thresholded at $Z>2.3$ and corrected for multiple comparisons at $p<0.05$.

Results: There were no group differences in reaction time or accuracy in any condition. When identifying faces without auditory distracters, both groups activated primary and secondary visual areas, as well as thalamus, insula, inferior frontal gyrus (IFG), and anterior cingulate. When completing the task with sensory distracters, both groups increased activation in bilateral Heschl's gryus, IFG, and subcortical regions. The ASD group additionally increased activation in the insula, hippocampus, and visual cortex significantly more than the TD group (Figure1) whereas the TD group decreased visual cortex activation. After being primed with videos of their own emotional faces, both groups increased lateral occipital cortex, hippocampus, lingual gyrus, and frontal regions, but the ASD group displayed even greater increases in mPFC compared to the TD group (Figure2). Within-group ASD correlations with SOR scores will also be examined.

Conclusions: These findings suggest that despite similar behavioral performance, sensory distractions differentially affect neural processing of emotional expressions for youth with ASD. Furthermore, results indicate that seeing videos of their own emotion expressions helped youth with ASD engage prefrontal regions while identifying others' emotion expressions. The role of within-group differences in SOR on neural processing of face processing and implications for intervention will also be discussed.

402.006 *(Poster)* Neural Response to Emotional Faces As a Predictor of Anxiety in Adults with Autistic Traits

E. Cummings[1]*, A. Bagdasarov*[1]*, C. Carlos*[1]*, S. Kala*[1]*, A. Naples*[1]*, J. Wolf*[1]*, J. H. Foss-Feig*[2]*, A. Anticevic*[3]*, V. Srihari*[3] *and J. McPartland*[1]*, (1)Child Study Center, Yale University School of Medicine, New Haven, CT, (2)Seaver Autism Center, Department of Psychiatry, Icahn School of Medicine at Mount Sinai Hospital, New York, NY, (3)Division of Neurocognition, Neurocomputation, and Neurogenetics (N3), Yale University School of Medicine, New Haven, CT*

Background: Adults with autism spectrum disorder (ASD) have high rates of co-occurring anxiety. Both ASD and anxiety have been linked to atypical neural response to visual stimuli, indexed by the P1 event-related potential (ERP) and the face-sensitive N170 ERP. However, the nature of these differences in neural processing and their relationship to behavioral symptoms of anxiety and ASD remain relatively unexplored.

Objectives: To explore how atypical N170 and P1 response to emotional faces, specifically fearful and happy faces, and autistic traits predict anxiety.

Methods: Participants were adults with typical development (TD; *n*=39), ASD (*n*=26), and those that did not meet traditional research standards of ASD diagnosis or those with comorbid conditions (*n*=17). Participants completed the *Social Responsiveness Scale* (SRS-2), a measure of autism-specific social impairment and the *Beck Anxiety Inventory* (BAI), a self-report measure of anxiety. During electroencephalogram (EEG) recording, participants viewed 80 distinct neutral faces that shifted to fearful or happy faces after ~500 ms of fixation on the neutral face, simulating face-to-face interaction.

Results: Autistic traits (SRS-2 raw score) were positively correlated with anxiety (BAI score; R=.589, p<.001). A linear regression model revealed that autistic traits (β=.59, p<.001) and N170 latency for fearful faces (β=-.20, p=.026) explained 38.7% of the variance in reported anxiety (R^2=0.387, F(2,79)=24.94, p<.001). Adding the interaction between autistic traits and N170 latency for fearful faces to the model accounted for an additional 3.6% of variance in anxiety (R^2=.423, F(3,78)=19.03, p<0.001, Table 1, Model 1). Autistic traits (β=.55, p<.001) and N170 amplitude (β=-.194, p=.034) for fearful faces also predicted anxiety (R^2=.383, F(2,79)=24.562, p<.001, Model 2). Notably, these models were emotion-specific, such that latency and amplitude of the N170 elicited by fearful faces, but not happy faces, predicted anxiety. In addition, P1 mean amplitude for fearful or happy faces (fear: β=-.23, p=.012; happy: β=-.24, p=.009) and autistic traits (fear: β=.57, p<.001; happy: β=.53, p<.001) predicted anxiety (fear: R^2=.398, F(2,79)=26.10, p<.001, Model 3; happy: R^2=.402, F(2,79)=26.56, p<.001, Model 4).

Conclusions: Consistent with previous literature, higher levels of autism-specific social impairment were associated with increased anxiety. However, the results also demonstrated that individuals may be even more likely to experience anxiety when social impairment is coupled with atypical emotional face processing (i.e., faster latency or larger amplitude of N170 for fearful faces, and larger P1 mean amplitude for fearful or happy faces.). These results suggest that P1 and N170 responses to emotional faces contribute useful information for identifying subsets of the autism phenotype with higher levels of anxiety.

402.007 *(Poster)* Personal Relevance and Emotional Face Perception in Adults with Autism Spectrum Conditions – a Simultaneous EEG-fMRI Study

M. Bayer[1]*, T. Johnstone*[2] *and I. Dziobek*[1]*, (1)Berlin School of Mind and Brain, Humboldt-Universitaet zu Berlin, Berlin, Germany, (2)Swinburne University of Technology, Melbourne, VIC, Australia*

Background: The ability to recognize emotional facial expressions is an essential component of social communication, and deficits in this area are among the defining symptoms of autism spectrum conditions (ASC). Previous neuroimaging research provides evidence that these deficits are accompanied by both reduced and altered brain activations in response to emotional faces. Our project investigates the role of personal relevance (faces of relevant others) in ASC, since it has been shown to increase neural processing of faces in a neurotypical sample. Therefore, we hypothesize that personal relevance might boosts engagement of the face processing network and enhance emotion processing in ASC.

Objectives: Our aim was to investigate the impact of personal relevance on emotional face processing in ASC and neurotypical controls.

Methods: Participants with ASC (N=18) and matched controls (N=13, data collection ongoing) were presented with photographs of a personally relevant person and a matched stranger, displaying fearful, happy, and neutral facial expressions. Participants performed an emotion categorisation task. During face presentation, we recorded simultaneous EEG-fMRI.

Results: Both participants with ASC and neurotypical controls showed significantly increased hemodynamic activity for relevant versus stranger faces in the face processing network, including fusiform gyrus, precuneus, and ACC, with no significant group differences. In the ASC group, emotion effects were shown in regions previously associated with ‘neurotypical’ emotion processing, including amygdala, insular cortex and ACC. Importantly, these effects were limited to the faces of relevant others and absent for strangers' faces.

Conclusions: Our results speak to the importance of accounting for personal relevance in research on face processing in ASC, as it seems to be able to boost neural responses to faces and to ‘normalize’ the processing of emotional facial expressions. Therefore, face processing in ASC seems to be characterized by reduced attention allocation to stranger’s faces, rather than a general processing dysfunction or alteration. Importantly, co-registration of EEG data allows for investigating the mechanisms behind the specificities of face processing in ASC; these results will be presented at the conference.

402.008 *(Poster)* Reduced Emotion-Specific Neural Response to Faces Relates to Impaired Emotion Recognition in Adults with ASD and Typical Development

E. Gabriel[1]*, E. Cummings*[1]*, A. Bagdasarov*[1]*, C. Carlos*[1]*, S. Kala*[1]*, A. Naples*[1]*, J. Wolf*[1]*, J. H. Foss-Feig*[2]*, A. Anticevic*[3]*, V. Srihari*[3] *and J. McPartland*[1]*, (1)Child Study Center, Yale University School of Medicine, New Haven, CT, (2)Seaver Autism Center, Department of Psychiatry, Icahn School of Medicine at Mount Sinai Hospital, New York, NY, (3)Division of Neurocognition, Neurocomputation, and Neurogenetics (N3), Yale University School of Medicine, New Haven, CT*

Background: Atypicality in emotional face recognition is characteristic of autism spectrum disorder (ASD). Past studies have identified discrepancy in latency of N170, a face-sensitive event-related-potential (ERP), between individuals with ASD and typical development (TD). However, sensitivity of N170 latency to emotional faces is not well defined. The present study was designed to identify emotion-specific variance in N170 latency and consider how this variance may contribute to common ASD symptomatology, specifically impaired emotion recognition.

Objectives: To investigate how neural discrimination of emotional faces relates to emotion recognition, which is commonly impaired in individuals with ASD.

Methods: Participants were adults with typical development (TD; *n*=49) and individuals presenting for ASD evaluation, meeting *Autism Diagnostic Observation Schedule* (ADOS-2) and *Diagnostic Statistical Manual* (DSM-5) diagnostic criteria (ASD; *n*=30) or not meeting research criteria (DNM; *n*=12). Participants were administered the *Reading the Mind in the Eyes Test* (RMET) as a measure of emotion recognition and completed the *Social Responsiveness Scale* (SRS-2) as a measure of autism-specific symptomatology. During the study, electroencephalography (EEG) was collected as participants were presented with neutral faces, which changed to fearful or happy expressions after approximately 500ms of fixation on the neutral face. N170 latency was later extracted from segments based on emotional face presentation in electrode groups over the right hemisphere.

Results: SRS scores ranged from 4 to 158 (*M*=50.40, *SD*=33.11) with significant overlap between diagnostic groups (Figure 1). RMET raw scores ranged from 11 to 34 (*M*=26.54, *SD*=4.83) and also significantly overlapped between diagnostic groups (Figure 2). RMET raw scores were Z-transformed for inclusion as a continuous variable in analysis. Because of heterogeneity of the sample, data were collapsed across all three diagnostic groups. N170 latency was submitted to a 2(condition: fearful, happy) x RMET score(continuous) general linear model, revealing a main effect of condition on N170 latency ($F(1,89)=9.828$, $p=.002$), where happy faces (*M*=174.99, *SE*=2.43) elicited shorter N170 latencies than fearful faces (*M*=179.99, *SE*=2.44). The main effect was modulated by RMET performance, such that high performers (+1 SD) differentiated between happy (*M*=170.89, *SE*=3.44) and fearful faces (*M*=178.50, *SE*=3.46) in N170 latency (p=.001), but low performers (-1 SD) did not ($p=.294$).

Conclusions: Based on these results, high RMET performance is related to discrimination between fearful and happy faces in N170 latency, whereas low RMET performance is related to similar N170 latency for fearful and happy faces. These data suggest that measures of N170 latency to happy and fearful faces may help to identify individuals with impaired emotion recognition. Characterizing these neural patterns may help to inform symptom-specific therapy and treatments of ASD, particularly in cases where impaired emotion recognition affects social functioning.

402.009 *(Poster)* Resting Anterior EEG Asymmetry and Power As a Predictors of Affective and Executive Functioning in Children with ASD, ADHD, and Typical Development

S. R. Edmunds[1,2]*, V. E. Sanchez*[3] *and S. Faja*[1]*, (1)Boston Children's Hospital, Boston, MA, (2)Harvard Medical School, Boston, MA, (3)Division of Developmental Medicine, Boston Children's Hospital, Boston, MA*

Background: Resting left and right anterior EEG power, as well as relative difference between hemispheres (i.e., asymmetry) may be related to global approach and avoidance tendencies and subsequently, problems with executive and affective regulation. There is mixed evidence as to whether the relation between asymmetry and affective regulation differs for children with ASD compared typically developing children or other clinical populations with executive functioning challenges (e.g., ADHD). In children with ASD, greater left frontal asymmetry may or may not be related to increased social anxiety in children with ASD (Sutton et al., 2005; Burnette et al., 2011). The degree to which differences in asymmetry may be related to executive functioning tasks that involve affective processing is unknown.

Objectives: (1) To characterize frontal power and asymmetry in children with ASD, ADHD, and typical development (TD); and (2) to relate power/asymmetry to a behavioral task that indexes executive functioning in an affective context and a measure of affective functioning.

Methods: Children with ASD (n=44), ADHD (n=25), and TD (n=23) participated in 2 minutes of alternating eyes open/closed resting EEG data collection at 7-11 years of age. Participants also completed the Hungry Donkey gambling task, which assesses children's strategic long-term decision making in the heightened emotional context of reward. Participants' parents completed the Child Behavior Checklist (CBCL); the Affective and Anxiety Problems subscales were used (Gotham et al., 2015). Frontal right (F4) and left (F3) hemispheric power as well as asymmetry (F4-F3) were derived from the BEAPP/HAPPE processing pipeline, operationalizing power as the natural log of mean power per hertz within the alpha (8-13 Hz) frequency band (Levin et al., 2018; Gabard-Durnam et al., 2018). IQ differed by group and was controlled for in subsequent analyses.

Results: While there were no diagnostic group differences in degree of asymmetry, $F(2,89)=1.24$, $p>.05$, and direction of asymmetry was not different by group, $X^2(2)=1.97$, $p>.05$, qualitative observations suggested wide variability. There were group differences in both right power, $F(2,89)=3.75$, and left power $F(2,89)=4.90$, such that TD children displayed increased right power compared to children with both ADHD and ASD, $t(47)=2.06$; $t(66)=2.15$, and increased left power compared to children with ASD ($t(47)=3.21$), $ps<.05$. There were diagnostic group differences in Affective Problems, $F(2,128)=24.62$, $p<.001$, and Anxiety Problems, $F(2,128)=11.89$, $p<.001$, such that children with ASD and ADHD were reported to have more challenges with anxiety and mood than TD children. For all children, increased right alpha power related to decreased Anxiety Problem scores, $r=-.21$, $p<.05$, while both increased left and right power related to decreased Affective Problems, $r=-.23$, $r=-.23$, $ps<.05$. Finally, children with right asymmetry made more advantageous selections on the final two blocks of the Hungry Donkey task than those with left asymmetry, $t(86)=2.62$, $p<.05$.

Conclusions: Regardless of clinical diagnosis, frontal power and asymmetry relates to anxiety, affective functioning, and reward contingency learning. More work is needed to understand the relation between frontal power, asymmetry, reward processing, and affective functioning, as well as whether structure or strength of these processes fundamentally differ for children with different clinical diagnoses.

Animal Models

ORAL SESSION — **ANIMAL MODELS**
303 - Functional Assessment in Model Organisms

303.001 *(Oral)* Regulation of Autism-Relevant Behaviors By Distinct Cerebellar-Prefrontal Cortical Circuits

E. Kelly[1]*, F. Meng*[2]*, Y. Kazemi*[3] *and P. Tsai*[4]*, (1)UT Southwestern Medical Center, Dallas, TX, (2)Neurology, UT Austin, Dallas, TX, (3)UT Southwestern, Dallas, TX, (4)University of Texas Southwestern Medical Center, Dallas, TX*

Background: The cerebellum has been increasingly implicated in the pathogenesis of Autism spectrum disorders (ASD); however, the mechanisms by which cerebellar dysfunction results in these behaviors remains unknown. Numerous studies have detailed volumetric changes in the posterior cerebellar vermis and in Rcrus1 in children with ASD, while the degree of volumetric differences in these areas correlates with ASD symptom severity. We recently demonstrated that cerebellar area Rcrus1 plays key roles in social and repetitive behaviors. However, the circuitry which connects Rcrus1 to downstream brain areas to orchestrate these behaviors remains unknown. Polysynaptic connections between the cerebellum and the cortex have been demonstrated both in anatomic tracing studies and from functional connectivity studies. One cortical area shown to be involved in social behaviors and highly implicated in ASDs is the medial prefrontal cortex (mPFC). Changes in cerebellar-mPFC functional connectivity have also been identified in ASD and in cerebellar and ASD mouse models. We and others have further demonstrated functional connectivity between Rcrus1 and the contralateral mPFC in humans, consistent with studies showing disruptions in left mPFC in ASD. Thus, we hypothesize that these cerebellar-mPFC connections play critical roles in the regulation of ASD-relevant behaviors.

Objectives: This study objective is to identify circuits emanating from cerebellar cortical areas such as Rcrus1, which are critical to ASD-relevant behaviors, to the mPFC, and to identify the role these circuits play in social behavior and repetitive behaviors. We also aim to examine these circuits across mouse models of ASD, and in human ASD cohorts. We will also manipulate these circuits in mouse models of ASD to rescue social and repetitive behaviors.

Methods: Here we utilize a combination of mouse and human functional and structural MRI imaging to look at functional and structural connectivity between the cerebellar cortex and the mPFC. We have also utilized retrograde and anterograde tracing techniques in mice to determine the anatomy of these muti-synaptic cerebellar-mPFC circuits.

Results: Here, we highlight connections of Rcrus1 to another domain highly implicated in the regulation of ASD behaviors, the prelimbic/medial prefrontal cortex (mPFC), and show that modulation of mPFC function is sufficient to rescue cerebellar dysfunction induced ASD behaviors. In addition, we delineate the neural circuit bridging these vastly separated regions and show that function of the proximal circuit (Rcrus1, lateral cerebellar nucleus) is sufficient to rescue social impairments in a cerebellar-regulated ASD model, while distal neural circuit underpinnings (vm-thalamus, mPFC) are both necessary and sufficient for both social and repetitive ASD behaviors pointing to an alternative pathway for repetitive behaviors. Lastly, we provide evidence that modulation of another clinically implicated cerebellar domain, the posterior vermis, is both necessary and sufficient for the regulation of repetitive/inflexible behaviors.

Conclusions: These findings highlight critical neural networks between the cerebellum and mPFC that mediate both core diagnostic criteria in ASD and offer the potential for therapeutic benefit of neuromodulation for individuals with ASD.

303.002 *(Oral)* Responses of Oxytocin-Receptor-Mutant Zebrafish to Social Stimulation in Groups and Individually: Support for Zebrafish Autism MODEL

S. Shams[1] *and L. Westberg*[2]*, (1)Pharmacology, University of Gothenburg, Gothenburg, Sweden, (2)Department of Pharmacology, University of Gothenburg, Gothenburg, Sweden*

Background: Recently, intranasal administration of oxytocin has been reported to improve social function in autistic patients and has shown promise as a potential treatment of social impairments seen in autism. Oxytocin is a neuropeptide that regulates a wide range of mammalian social and non-social behaviors relevant to autism, such as bonding, social recognition, anxiety, and aggression. Since the mechanisms underlying autism and oxytocin's role in allaying social symptoms in autistic patients are not well-understood, animal models with capacity for sophisticated genetic manipulation are necessary. Zebrafish (*Danio rerio*) is a highly social vertebrate with phylogenetic conservation in oxytocin and key neurotransmitter systems and we exploit these features to develop an animal model of autism in zebrafish.

Objectives: Importance of the oxytocinergic system in mammalian social behavior is well-established, but less is known about its homologous system in zebrafish. Our aim is to investigate social interaction and neurochemistry in zebrafish mutants with genetically manipulated oxytocin system to further establish a zebrafish model of autism.

Methods: Using adult male and female CRISPR-Cas9-mutants lacking either of the two zebrafish oxytocin receptor genes, *oxtr* and *oxtrl*, we performed two different social behavior tasks. We measured socialization between four fish (same-genotype, $n \geq 20$ for each group) in a large open-field (40x body length). We measured shoaling, schooling, leadership, excursion from the groups, general activity, and specific motor patterns of mutant and wild-type fish in the large pool. We also measured responses of these mutant fish to automated visual-only stimulus when individually placed in a separate tank and compared them with wild-type control fish.

Results: Our data show that zebrafish lacking oxytocin receptors display impairments in shoaling behavior in the large ethologically-relevant open-field. Social behavior was affected by both *oxtr* and *oxtrl* mutation in a similar fashion. In contrast, we found that individual responses to automated visual-only stimulus was affected in *oxtr* mutant fish but not in *oxtrl* mutant fish.

Conclusions: These results suggest that the two oxytocin receptor play important but distinct roles in zebrafish social behavior. Further, these findings advance our understanding of neural mechanisms underlying oxytocin-regulated social interaction in zebrafish and highlight the potential of future investigation of zebrafish oxytocin system towards generating better therapeutic treatments for autism.

303.003 *(Oral)* Constitutional Pten Mutation Alters Alternative Splicing Patterns in the Murine Brain, Contributing to an Autism-like Phenotype

S. T. Thacker[1], *M. Seyfi*[1] *and C. Eng*[2], *(1)Genomic Medicine Institute, Lerner Research Institute of Cleveland Clinic, Cleveland, OH, (2)Genomic Medicine, Cleveland Clinic, Cleveland, OH*

Background: Alternative splicing (AS) is a post-transcriptional mechanism regulating gene expression that is utilized by organisms to expand the functional complexity of their respective proteomes from comparatively simpler exomes. Recent work has increasingly associated changes in alternative splicing event (ASE) diversity with the functional complexity of the central nervous systems, especially in higher order mammals, and neurodevelopmental conditions like autism spectrum disorder (ASD). Due to the strong genetic association between germline mutations in *PTEN* and ASD, we hypothesized that germline mutation in *PTEN*, especially those known to disrupt nuclear localization, will change patterns of AS, resulting in ASEs that likely contribute to the pathophysiology of ASD.

Objectives: In this study, we analyzed ASEs in the neural transcriptome of the $Pten^{m3m4}$ model, a murine model with cytoplasmic predominant expression of Pten, cellular and molecular correlates of ASD, and autism-like behavior. Our objective was to establish that the $Pten^{m3m4}$ mutation alters AS in the brain and that mutant-specific ASEs correlate with known aspects of ASD pathophysiology.

Methods: RNA sequencing was performed on wildtype, heterozygous mutant, and homozygous mutant hemibrain samples at two-weeks of age and cortex samples at six-weeks of age collected from $Pten^{m3m4}$ male mice on a CD1 outbred background (N = 3). Gene expression was analyzed using an in-house pipeline (Kallisto followed by NOISeq), and ASEs were analyzed with rMATS. The significant ASEs were subject to gene enrichment and pathway analysis. We also performed validation of the ASEs identified by rMATS by RT-PCR.

Results: We identified significant differences in the percent-spliced-in (PSI) distributions among different genotype, where the $Pten^{m3m4/m3m4}$ cortices showed an increase in PSI. Interestingly, we identified a mutant-enriched ASE in *Gfap* with a known molecular association with astrogliosis, a phenotype consistently observed in the $Pten^{m3m4/m3m4}$ brain. Moreover, the genes in which the mutant-associated ASEs occurred were generally found to be enriched in biological processes relevant to ASD pathophysiology: mTOR signaling, synaptic transmission, and DNA damage repair. In addition to AS findings, we found that several neural-enriched splicing factors were significantly decreased in expression: *Celf1-6*, *Rbfox1*, and *Srrm4*. Given the existing *Srrm4* model of autism, we decided to assess AS at Srrm4-regulated microexons. We observed a significant decrease in average PSI across these Srrm4-regulated ASEs (average decrease of 10% PSI). Beyond these descriptive findings, we also observed that the interaction between Pten and spliceosome component U2af2 was disrupted by the m3m4 mutation, suggesting a possible mechanism for how disruption of Pten nuclear localization affects AS.

Conclusions: We have described important changes in AS in the brain of $Pten^{m3m4}$ mutant mice. These ASEs have a clear association with ASD pathophysiology. Although the exact mechanisms by which the m3m4 mutation disrupt AS remains partially ambiguous, it is evident that the changes in the expression of neural-enriched splicing factors and the disrupted interaction between Pten and U2af2 likely contributes to the ASEs observed in mutants. This work offers a deeper understanding of the $Pten^{m3m4}$ transcriptome, which ultimately helps illuminate ASD pathophysiology.

303.004 *(Oral)* Understanding the Neurodevelopmental Bases of DDX3X Syndrome

D. C. Ung[1,2,3], *A. Boitnott*[1,2,3], *D. Mendonca*[1,2,3], *K. Niblo*[1,2], *J. Buxbaum*[1,2,4,5,6,7], *E. Drapeau*[1,2], *R. M. Rasin*[8] *and S. De Rubeis*[1,2,3], *(1)Seaver Autism Center for Research and Treatment, Icahn School of Medicine at Mount Sinai, New York, NY, (2)Department of Psychiatry, Icahn School of Medicine at Mount Sinai, New York, NY, (3)Mindich Child Health and Development Institute, Icahn School of Medicine at Mount Sinai, New York, NY, (4)The Mindich Child Health and Development Institute, Icahn School of Medicine at Mount Sinai, New York, NY, (5)Fishberg Department of Neuroscience, Icahn School of Medicine at Mount Sinai, New York, NY, (6)Friedman Brain Institute, Icahn School of Medicine at Mount Sinai, New York, NY, (7)Department of Genetics and Genomic Sciences, Icahn School of Medicine at Mount Sinai, New York, NY, (8)Department of Neuroscience and Cell Biology, Rutgers University, RWJ Medical School, Piscataway, NJ*

Background:

DDX3X syndrome is a recently identified form of intellectual disability (ID). In addition to ID, affected individuals present with behavioral problems (including Autism Spectrum Disorder, ASD), lower weight, movement disorders, hypotonia and brain malformations. Most affected individuals are females with haploinsufficiency of DEAD-box helicase 3 X-linked (*DDX3X*) gene.DDX3X is an RNA helicase, regulating mRNA translation. To date, how DDX3X functions in neurons and at synapses is poorly understood.

Objectives:

The objective of this study is to understand the molecular and cellular functions of DDX3X during neurodevelopment, particularly during corticogenesis and synaptogenesis, and to explore its impact on cognitive and social behavior.

Methods: We have generated a novel conditional knockout mouse modeling *DDX3X*haploinsufficiency. To understand the impact of *Ddx3x*haploinsufficiency on development and behavior we follow a standardized behavioral battery assessing developmental milestones during postnatal life, and cognition, social behavior and motor function in adults. To study the impact of DDX3X haploinsufficiency on cortical development, we assess cortical lamination using layer-specific markers and retrograde tracing to reconstruct intra- and sub-cortical connectivity. To study synaptogenesis, we model DDX3X syndrome using Cre-lox recombination in single-embryo primary cortical neurons. To explore the molecular functions of DDX3X during cortical development and synaptogenesis, we perform translating ribosome affinity purification (TRAP) method and its viral-based development (vTRAP).

Results:

*Ddx3x*null male mice (Ddx3x$^{-/y}$) die *in utero*, compatible with the dearth of boys affected by DDX3X syndrome. *Ddx3x*haploinsufficient females (*Ddx3x*$^{+/-}$)are viable but show physical, sensory and motor developmental delays, as well as anxiety and hyperactivity. DDX3X is expressed in a sex-specific manner in the cortex and at synapses, and *Ddx3x*haploinsufficiency impacts the development of glutamatergic projection neurons in the cortex.

Conclusions:

We have generated a mouse model with construct and face validity for DDX3X syndrome. We are using this mouse model to understand the molecular and cellular neurobiology underlying DDX3X syndrome.

POSTER SESSION — **ANIMAL MODELS**
403 - Animal Models Posters

403.001 *(Poster)* Altered Cortical Development in Mice Harboring Autism-Associated TBR1 Mutations

M. Co[1,2]*, S. Grindstaff*[1]*, J. N. Jahncke*[2]*, R. M. Mulqueen*[1]*, B. A. DeRosa*[1]*, R. Barnard*[1]*, L. Fedorov*[3]*, K. M. Wright*[2] *and B. J. O'Roak*[1]*, (1)Molecular & Medical Genetics, Oregon Health & Science University, Portland, OR, (2)Vollum Institute, Oregon Health & Science University, Portland, OR, (3)Transgenic Mouse Models Core, Oregon Health & Science University, Portland, OR*

Background: Diverse genetic risk factors underlie susceptibility to autism spectrum disorder (ASD). Effective therapeutics will require the development of targeted interventions based on the specific genetics of an individual with ASD. While animal models have greatly informed our understanding of ASD risk gene function, most models were created through multi-exon deletion or insertion of foreign materials. Thus, these models lack the nuance of specific point mutations found in individuals with ASD, which may have diverse functional effects. Here, we report the generation and characterization of mice carrying an ASD-associated *de novo* mutation in the brain-specific transcription factor (TF) *TBR1*. Previous studies in mouse have demonstrated that *Tbr1* is critical for the establishment of normal neuronal identity and cellular architecture within the cerebral cortex, a brain region highly implicated in ASD etiology. However, currently little is known about how altering a single copy of Tbr1 alters cortical development and the Tbr1-regulated transcriptional network.

Objectives: We aim to identify convergent and divergent developmental effects of different types of ASD-associated *TBR1* mutations (i.e., frameshift, missense, and nonsense) on the mammalian cortex, beginning with a frameshift mutation leading to early truncation.

Methods: Using a CRISPR-Cas9 knock-in strategy, a mouse line was generated on a C57BL/6 background that carries an ASD-associated putative frameshift mutation N-terminal to the T-box domain (p.A136PfsX80). Multiple independent F1 lineages were backcrossed for several generations to remove potential off-target mutations. Wild-type, heterozygous mutant, and homozygous mutant littermates were compared at embryonic, postnatal days (P) 0-2, juvenile, and/or adult stages. These data were compared to a putative null allele which removes exons 2 and 3 (Bulfone et al. 1998). Protein expression levels and subcellular localization were measured via Western blotting and immunohistochemistry (IHC). Cortical lamination and development was assessed using IHC, axon labeling, and cell birth dating. To identify changes in gene regulation at single-cell resolution, single-cell RNA-seq (10x Genomics) and chromatin accessibility (sci-ATAC-seq) data were generated.

Results: Tbr1 expression was reduced in *Tbr1*$^{A136Pfs/+}$ mutants and completely absent in *Tbr1*$^{A136Pfs/A136Pfs}$ mutants. There was no evidence of a truncated protein product, and analysis of *Tbr1*$^{A136Pfs/+}$ RNA showed nearly complete absence of the mutation allele, suggestive of nonsense-mediated decay. At P0, *Tbr1*$^{A136Pfs/+}$ mutants exhibited a reduction in anterior commissure thickness as well as alterations in cortical interneuron density. At P21-28, preliminary data on *Tbr1*$^{A136Pfs/+}$ mutants showed ectopic expression of deep and upper layer cortical markers in. At P0, *Tbr1*$^{A136Pfs/A136Pfs}$ mice showed abnormal cortical layering and ectopic axon projections. Genomic analysis are ongoing, however, we expect to uncover dosage-sensitive, cell- and non-cell-autonomous gene expression alterations associated with specific mutations and cortical phenotypes.

Conclusions: Our current results support the conclusion that the ASD-associated TBR1 mutation p.A136PfsX80 is a completely null allele, with findings consistent with previous *Tbr1* knockout studies. These data identified potential molecular and cellular mechanisms underlying ASD etiology in individuals carrying early *TBR1* truncation mutations. Further characterization of p.A136PfsX80 and additional diverse ASD-associated *TBR1* mutations will reveal convergent and divergent mechanisms leading to ASD and provide a foundation for designing targeted interventions.

403.002 *(Poster)* Neuroprotective Effect of Granulocyte Colony Stimulating Factor (GCSF) in VPA Induced Cognitive Deficits in Autistic Rats Via IL-6 /BDNF Pathway

A. Mishra[1]*, R. Singla*[2] *and B. Medhi*[1]*, (1)Pharmacology, Post Graduate institute of Medical Education & Research (PGIMER) Chandigarh, Chandigarh, India, (2)Dept of Pharmacology research block B 4th floor, Post Graduate institute of Medical Education & Research (PGIMER) Chandigarh, Chandigarh, India*

Background: Autism is a group of complex neurodevelopmental and neurobehavioral disorder of unknown etiology which manifests with problems like social interaction, language, communication and behaviour deficits like stereotypic and repetitive behaviour. This inflammatory condition is often linked to immune system dysfunction enhanced inflammatory activity in ASD children has been demonstrated through pro-inflammatory biomarkers analysis. Interleukins are signalling proteins, belonging to the cytokine family, responsible for immune modulation and inflammatory responses and GCSF is a well-known neuro-protectant, anti-inflammatory, anti-apoptotic, and neurogenesis and excitoprotective properties in both human and rodent models of CNS disorders.

Objectives: The aim of present study is designed to investigate the neuroprotective effect of GCSF in experimental model of autism.

Methods: Animals were divided into six groups. Group 1 (Control, received only Normal saline 0.9%), Group 2 (VPA 600mg/kg on PND 12.5), Group 3 (Pups, Risperidone 2.5 mg/kg, PND 23 to 43) and group 4-6 (GCSF 10, 35,70 µg/kg PND 23 to 43). All the groups were subjected to different behaviour (Three chamber sociability test, Morris water maze) ELISA for various inflammatory markers and histopathological examination using 0.1% Cresyl violet (for Nissl staining)

Results: Treatment group showed significant improvement in the behavioural parameters. GCSF decreases inflammation by decreasing levels of inflammatory markers. The histopathological evaluation implied extensive neuronal loss in the CA1 region of the hippocampus in the VPA treated groups. Decrease in the neuronal score was seen with GCSF treatment. Maximum effect was seen with GCSF dose of 70 µg/kg.

Conclusions: It has been concluded that GCSF has attenuated valproic acid induced developmental histopathological and inflammatory processes. However further research is required to explore the full therapeutic potential of the drug

403.003 *(Poster)* Screening for ASD Therapies Using a Drosophila Model of Neurofibromatosis Type 1

A. Dyson[1]*, S. Garg*[2]*, R. A. Baines*[1] *and G. R. Evans*[3]*, (1)Faculty of Biology, Medicine and Health, University of Manchester, Manchester, United Kingdom, (2)University of Manchester, Manchester, United Kingdom of Great Britain and Northern Ireland, (3)Genomics, University of Manchester, Manchester, United Kingdom*

Background: Autism spectrum disorder (ASD) is a neurodevelopmental disorder characterised by social communication deficits, restricted interests, and repetitive behaviours. While there are currently no FDA-approved therapies that target this core symptomatology, animal models of monogenic syndromes associated with a high prevalence of ASD, such as neurofibromatosis type 1 (NF1), have the potential to address this issue. For example, deletion of a functionally conserved ortholog of the human *NF1* gene in the fruit fly, *Drosophila melanogaster*, results in behavioural and cellular impairments reflecting those seen in human ASD.

Objectives: We have carried out a targeted screen for compounds that attenuate ASD-relevant behaviour in a *Drosophila* model of NF1, in order to identify potential therapies for the treatment, or even prevention, of ASD in humans. Compounds were initially screened for their ability to rescue increased grooming in male $NF1^{-/-}$ flies, which has been suggested to correspond to the repetitive behaviours typical of ASD children. Additional ASD-relevant behaviours have been subsequently characterised in the $NF1^{-/-}$ flies, against which hit compounds from the grooming assay can be screened and further validated.

Methods: Grooming behaviour was quantified using the *Drosophila* Activity Monitor 5 (DAM5) from TriKinetics Inc. (Waltham, MA), based on the observation that bouts of high frequency activity in the $NF1^{-/-}$ flies correspond to grooming rather than locomotion. Social interaction was examined by calculating the median inter-fly distance (i.e. the distance between a fly and its nearest neighbour) between male flies in a circular arena. Altered larval mechanoreception was assessed by briefly applying firm pressure to a larva, blind to genotype and/or treatment, and observing whether a nociceptive response was induced.

Results: We confirm previous findings (King et al. 2016) that $NF1^{-/-}$ flies exhibit increased grooming behaviour, and show that this can be robustly quantified using the DAM5 platform, in which bursts of high frequency activity act as a proxy for grooming. In this manner, we identified the mTOR inhibitor rapamycin as able to reduce grooming behaviour when administered throughout development, a finding that was later confirmed via manual observation. Moreover, we report the novel observation that male $NF1^{-/-}$ flies demonstrate an increased inter-fly distance, reflecting the social impairments present in ASD and NF1 individuals. Lastly, we show that the likelihood of a mechanical stimulus evoking a nociceptive response was significantly greater for $NF1^{-/-}$ larvae than for isogenic controls, which typically do not respond to such stimulation. This may reflect the hyper-reactivity of individuals with ASD to certain stimuli, such as touch.

Conclusions: The simplicity of the DAM5 system for activity monitoring, together with the strength of the increased grooming phenotype in $NF1^{-/-}$ flies, render this assay appropriate for a targeted drug screen to identify ASD therapies. Supporting the translatability of this work, rapamycin reduced grooming behaviour, and mTOR disruption has previously been implicated in the pathophysiology of ASD. The assays demonstrating aberrant social interaction and mechanoreception, respectively, can now provide follow-up screens to further validate hit compounds for their potential to ameliorate the core ASD symptomatology.

403.004 *(Poster)* Sensory and Cognitive Behavioural Characteristics of the Cntnap2 Rat Model for ASD

K. Scott*, R. Mann, K. Kazazian, A. Schormans, B. Allman and S. Schmid, Anatomy and Cell Biology, Western University, London, ON, Canada*

Background: Perturbations of brain development can result in developmental disorders such as autism spectrum disorder (ASD) and Specific Language Impairment (SLI). Respective individuals show alterations in how they process basic sensory features, which are important for reacting to stimuli, for social interaction and communication, and for perceiving and learning about the environment. The CNTNAP2 gene, implicated in ASD and SLI, is highly expressed in sensory pathways and the hippocampus, and plays an important role in brain development. We here characterized how the loss of *Cntnap2* affects sensory processing using behavioural testing of rodents in order to understand the gene's overall role in development.

Objectives: To characterize the behavioural phenotype of wildtype, $Cntnap2^{+/-}$, $Cntnap2^{-/-}$ male and female adult rats by assessing (1) perceptual and preattentive responses to basic and complex sensory stimuli, (2) social behaviour, (3) learning and memory, and (4) cognitive flexibility.

Methods: Sensory filtering and sensorimotor gating of auditory and audiovisual stimuli were determined using the acoustic startle response. Using operant conditioning, the ability to discriminate sound intensity as well as perceive the temporal order of auditory and visual stimuli was measured via two-alternative forced judgement tasks. Social behaviour differences between genotypes was examined by assessing an animal's preference for a conspecific over an inanimate object (sociability), and their preference for a stranger rat over a familiar rat (social novelty). Spatial learning and memory abilities were assessed using a two-day Morris Water Maze protocol. Lastly, the ability to respond flexibly to changes in food reward contingencies was determined via an operant-based reversal learning paradigm.

Results: $Cntnap2^{-/-}$ rats can accurately discriminate sound intensities of auditory stimuli, and accurately perceive the temporal order of auditory and visual stimuli. However, they have a general sensory filtering deficit exemplified by an increased acoustic startle response amplitude and poor sensorimotor gating. They do not exhibit typical social behaviours, showing no sociability nor preference for social novelty. They exhibit slower spatial learning; however, their 24-hour spatial memory remains intact. Lastly, $Cntnap2^{-/-}$ rats show normal behavioural flexibility when using operant conditioning.

Conclusions: The general sensory filtering deficit observed in this study is in accordance with research suggesting pathological sensory processing underpins the emergence of some ASD-related phenotypes. While our audiovisual results in rats are consistent with previous studies in the autistic population performing the temporal order judgement task with simple flash-beep stimuli, the lack of differences in sound intensity discrimination appears contrary to reports of moderate sound intensities being distressing. These findings may therefore instead relate more to the emotional valence of loud stimuli, rather than discrimination ability. Differences in social behaviour and spatial learning align with the altered social interaction and spatial learning/navigation seen in children with ASD. Finally, the lack of differences in behavioural flexibility may be due to the operant task design. In general, the behavioural tests that employed operant conditioning, and therefore extensive training, failed to differentiate the genotypes, while those tasks that relied on innate abilities did indeed show the expected differences for an animal model for autism.

403.005 *(Poster)* Social Deficit in shank3 Knockout Zebrafish Models of Autism Are Rescued: Via Low-Dose-Histone Deacetylase Inhibitor (Valproic Acid) Treatmen

***Y. Wang**, C. Liu, C. Hu and X. Xu, Children's Hospital of Fudan University, Shanghai, China*

Background: Social deficit is core clinical feature of autism spectrum disorder（ASD）and SHANK3 is a high-confidence candidate gene. Previous study found that HDAC inhibitor romidepsin and MS-275 could relieves autism-like social deficits in shank-deficient mice model.

Objectives: To investigate whether the autism-like social behavioral deficits could be rescued by Valproic Acid.

Methods: The shank3a and shank3b knockout zebrafish were generated using CRISPR/Cas9 editing, as previously reported, which exhibited the significant reduction of shank3a or shank3b mRNA expression. Shank3a ,shank3b and shank3a&b knockout zebrafish (3.5mpf,male) and age-matched wild type zebrafish(TU strain) were used in this study. Zebrafish of different genotypes were randomly assigned to drug/ 1 × E3, groups. The solution containing low-dose-VPA (5UM Valproic Acid) was removed at 4 dpf, replaced by 1 × E3 until 8dpf. All of larvae were grown until 3.5mpf for behavior testing and other analysis in 3L transparent tanks with system water.

Results: We describes a knockout zebrafish model of the autism-associated *shank3* gene. shank3 MU adult zebrafish exhibited impaired locomotor behaviors in a novel tank assay(open filed, $p<0.05$, bonferrnoni's correction). Sociability (social preference) test was revealed that the WT zebrafish showed a strong group tendency to contact the conspecific group, however, the three types of shank3_MU zebrafish swam around aimlessly and showed reduced social contacts with the conspecific group, which we characterized as a pattern of reduced social interaction($p<0.05$, bonferrnoni's correction).

After the brief (5-day) treatment with low-dose-histone deacetylase inhibitor of shank3 knockout larvae, we then examined social preference and open filed velocity at two different timepoints (2.5m post-exposure of VPA and 3.5m post-exposure of VPA). As shown in data, significant improvement some social impairments persisted until adulthood, ($p<0.01$,bonferrnoni's correction) , no change in WT zebrafish. while no improvement in motor deficits ($p>0.05$,bonferrnoni's correction).

Conclusions: Our research may suggest a potential therapeutic strategy targeted inhibition of HDAC to treat social deficits associated with autism.

403.006 *(Poster)* Structural High-Resolution MRI Assessment of the Neuroanatomy in 9 Novel Mouse Models Related to Autism.

***J. Ellegood**[1], S. Assimopoulos[2], V. Laurin[3], L. M. Nutter[4] and J. P. Lerch[5], (1)Mouse Imaging Centre, Hospital for Sick Children, Toronto, ON, Canada, (2)Department of Medical Biophysics, University of Toronto, Toronto, ON, Canada, (3)Canadian Mutant Mouse Repository, The Centre for Phenogenomics, Toronto, ON, Canada, (4)The Centre for Phenogenomics, Toronto, ON, Canada, (5)Wellcome Centre for Integrative Neuroimaging (WIN), University of Oxford, Oxford, ON, United Kingdom*

Background: Autism is extremely heterogeneous, in behaviour, genetics, and neuroanatomy. We have established an MRI database of mouse models related to autism, which allows the investigation of neuroanatomy in a large model autism population. Recently, we have started to create some models in collaboration with The Centre for Phenogenomics (TCP) and the International Mouse Phenotyping Consortium (IMPC), allowing both behaviour and neuroanatomical screens. This study summarizes the differences found in 9 novel mouse models related to autism, namely, *Katnal2, L2hgdh, Nexmif, Otc, Pah, Rab39b, Ranbp17, Upf3b, and Ypel2.*

Objectives: To assess neuroanatomical differences in 9 novel autism gene candidates with structural MRI.

Methods: Nine novel loss-of-function mouselines related to autism were produced by exon deletion using Cas9 RNA-guided nuclease in C57BL/6NCrl zygotes. These lines were maintained on a C57BL/6NCrl background. In total 163 mice were examined for this study, 40 WT and 10-20 mixed sex from each genotype. The age of the mice was P70 ± 4 (mean ± sd).

MRI Acquisition – A multi-channel 7.0 Tesla MRI scanner was used to acquire anatomical images of the brain. A T2-weighted, 3-D fast spin-echo sequence was used. This sequence yielded an image with 40 µm isotropic voxels (3D pixel) in ~14 h.

Data Analysis – To visualize and compare any differences the images from each group were registered together. Volume differences were then calculated in individual voxels or 182 different regions (Dorr et al. 2008, Ullmann et al. 2013, and Steadman et al. 2014). Multiple comparisons were controlled for using the False Discovery Rate (FDR) (Genovese et al., 2002).

Results: Figure 1 highlights the voxelwise effect size difference for each individual model compared to the WT mice. Regional differences were calculated for each of the 9 different lines, and of the 182 regions examined,15 were found to be significantly different for *Katnal2*, 124 for *L2hgdh*, 4 for *Nexmif*, 0 for *Otc*, 6 for *Pah*, 75 for *Rab39b*, 0 for *Ranbp17*, 112 for *Upf3b*, and 14 for *Ypel2*. The drastic differences are quite intriguing in the L2hgdh, Rab39b, and Upf3b models, but some of the more subtle difference are also interesting. *Katnal2* seems to have a specific deficit in CA3, and the ventricular system, *Nexmif* also show a hippocampal, the differences in *Pah* seem to be localized to the motor cortices and the cerebellum, and differences in *Ypel2* are localized to the striatum. Interestingly, in spite of all the differences found neuroanatomically, minimal behavioural findings are reported for these mice (mousephenotype.org). The only relevant behavioural findings are an increased hyperactivity and fear conditioning deficit in the *Upf3b* mice, but the IMPC behavioural tasks are limited and autism related tasks still need to be assessed.

Conclusions: Mesoscopic neuroanatomy assessed with MRI provides a first look at the differences caused by autism relevant mutations. These nine models highlight several different aspects of autism that warrant further investigation, such as total brain differences common in other mouse models related to autism (Ellegood et al. 2015), and striatal differences possibly relevant to the repetitive restricted behaviours.

403.007 *(Poster)* The Role of Methyl CpG Binding Protein (MeCP) 2 in Parvalbumin-Positive Cortical Interneurons for Processing of Socially-Relevant Sounds

D. Rupert[1] *and S. D. Shea*[2]*, (1)Neuroscience, Cold Spring Harbor Laboratory; Stony Brook University, Cold Spring Harbor, NY, (2)Neuroscience, Cold Spring Harbor Laboratory, Cold Spring Harbor, NY*

Background: Autism Spectrum Disorders (ASD) and Rett Syndrome (RTT) are characterized by impaired communication. RTT is a pervasive, neurodevelopmental disorder previously classified as an ASD and caused by loss of function mutations in the X-linked gene *Mecp2*.

Objectives: Our goal is to determine the contribution of *Mecp2* mutation to disruptions of auditory cortical circuitry and plasticity that degrade social vocal perception in a mouse model of Rett syndrome.

Methods: To achieve this goal, we will use a circuit-specific *Mecp2* mutant mouse model in combination with a behavioral paradigm that relies on vocal communication. We have identified a natural, auditory-dependent, learned maternal behavior that is impaired by *Mecp2* mutation: pup retrieval in response to ultrasonic vocalizations (USVs). USVs are high-pitched distress calls emitted by separated infant pups that trigger a retrieval response in wild-type but not *Mecp2* heterozygous females. Our previous work suggests that this difference is the result of impaired plasticity in the auditory cortex (AC) of *Mecp2* mutant animals, a brain region required to detect and interpret signals. AC inhibitory interneurons seem to be especially important for processing of socially relevant stimuli (e.g. USVs). Here we build on these findings by selectively inhibiting transcription of *Mecp2* in a specific subclass of inhibitory interneurons- those expressing the calcium-binding protein parvalbumin.

Results: We examine the effect of restricted *Mecp2* mutation in parvalbumin positive (PV+) inhibitory interneurons on pup retrieval behavior and *in vivo* neural circuit activity in the AC in response to socially relevant auditory stimuli. We have found *Mecp2* mutation restricted to this cell type is sufficient for impairing pup retrieval behavior. Further, we found AC cellular responses to pup vocalizations are altered in PV-*Mecp2* mutants compared to WT controls. These differences are specific to socially relevant sounds (i.e. USVs) as opposed to pure tones.

Conclusions: This work focuses on functional consequences of *Mecp2* mutation in auditory processing circuitry that expands our understanding of the underlying etiology of RTT, identifies targets for ameliorating the effects of these consequences, and informs pathophysiological mechanisms underlying neurodevelopmental disorders more broadly.

403.008 *(Poster)* Vagus Nerve Stimulation Paired with Sounds Alters Auditory Processing in Rodent Models of Autism

Y. Tamaoki[1]*, K. Adcock*[2]*, C. Chandler*[2]*, M. Borland*[3]*, J. R. Riley*[1]*, M. Nuthi*[1]*, O. I. Olajubutu*[1]*, K. Chawla*[1]*, L. S. Tharakan*[1]*, M. Kilgard*[2]*, S. Hays*[2] *and* ***C. T. Engineer***[1]*, (1)The University of Texas at Dallas, Richardson, TX, (2)University of Texas at Dallas, Richardson, TX, (3)Texas Biomedical Device Center, Richardson, TX*

Background: One of the major obstacles facing individuals with autism spectrum disorders (ASD) is the inability to communicate effectively. While there are many reasons for this inability, an important component appears to be a serious deficit in the ability to process speech sounds effectively. Expensive, time-consuming behavioral interventions can improve behavioral outcomes, but many individuals undergo these interventions and still experience deficits. Rodent models exhibit many of the neural abnormalities and behavioral deficits observed in ASD. Similar to individuals with ASD and Rett syndrome, both speech discrimination ability and auditory cortical responses are impaired in rodent models of ASD. The development of adjunctive interventions that can increase the benefit of rehabilitative therapies is essential to improve the lives of individuals with ASD. Vagus nerve stimulation (VNS) triggers rapid, phasic release of plasticity promoting neuromodulators, which enhances plasticity and neural responses in the auditory pathway when delivered concurrent with sound presentation.

Objectives: The aim of this study was to determine whether VNS paired with auditory training can reverse the neural and behavioral auditory processing deficits observed in two rodent models: 1) female heterozygous *Mecp2* rats, and 2) male and female rats prenatally exposed to valproic acid (VPA).

Methods: For the rodent model of Rett syndrome, heterozygous *Mecp2* females were bred with wild type males, each with a Sprague Dawley background. In our second rodent model, pregnant Sprague Dawley rats received an intraperitoneal injection of either 0.9% saline or 600 mg/kg sodium valproate on embryonic day 12.5. Behavioral and neural processing of sounds was quantified in adult offspring beginning on postnatal day 90. Rats were trained to discriminate speech sounds by responding to a target sound (ex: ‘dad’) and refrain from responding to a non-target sound (ex: ‘tad’), both in quiet and in the presence of varying levels of background noise. VNS was paired with sound presentation 300 times per day for 20 days. Following 20 days of VNS-sound pairing, multiunit responses to tones, noise burst trains, and speech sounds were recorded from primary auditory cortex (A1). Data analysis was performed blinded.

Results: Behavioral discrimination of speech sounds is impaired in both *Mecp2* rats and VPA-exposed rats compared to experimentally naïve control rats. Both models exhibit degraded A1 responses to sounds. Following VNS-sound pairing, the A1 response strength to tones, noise burst trains, and speech sounds was significantly increased compared to sham therapy. Additionally, a nearest-neighbor classifier was better able to correctly identify the sound presented based on the neural response patterns in VNS-sound paired rats compared to sham therapy rats.

Conclusions: These preliminary results suggest that VNS-sound pairing is an effective method to enhance auditory processing in rat models of ASD with degraded behavioral and neural processing of sounds. Ongoing experiments involve optimizing the efficacy of VNS-sound pairing therapy to enhance neuroplasticity and improve auditory processing in the context of ASD. Insights derived from this study may influence the development of new behavioral and sensory techniques to treat communication impairments that result in part from a degraded neural representation of sounds.

403.009 *(Poster)* Vagus Nerve Stimulation Therapy to Restore Auditory Processing in a Rat Model of Rett Syndrome

K. Adcock[1]*, B. R. Solorzano*[2]*, M. Borland*[2]*, C. Chandler*[1]*, E. Buell*[1]*, S. Hays*[1]*, C. T. Engineer*[1] *and M. Kilgard*[1]*, (1)University of Texas at Dallas, Richardson, TX, (2)Texas Biomedical Device Center, Richardson, TX*

Background: Rett syndrome is a rare neurological disorder associated with a mutation in the X-linked gene MECP2. This disorder mostly affects females, who typically have normal early development followed by a regression of skills. The *Mecp2* transgenic rat model of Rett syndrome exhibits similar symptoms shown in patients such as seizures, anxiety, breathing abnormalities, motor and auditory deficits. Individuals with Rett syndrome and *Mecp2* heterozygous rats both exhibit atypical neural and behavioral processing of auditory stimuli, which likely impacts effective speech processing. The development of therapies that can enhance plasticity in auditory networks and improve speech processing has the potential to impact the lives of individuals with Rett syndrome.

Objectives: Evidence suggests that precisely-timed VNS-sound pairing can drive robust neuroplasticity and enhance the benefits of rehabilitation. The aim of this study was to investigate vagus nerve stimulation (VNS) paired with auditory stimuli, to restore auditory processing in *Mecp2* transgenic rats.

Methods: Seventeen female *Mecp2* heterozygous rats and 8 female wild-type (WT) littermates were used in this study, and were obtained by breeding a *Mecp2* heterozygous Sprague Dawley female with a wild-type Sprague Dawley male. Female breeders were obtained from Horizon Discovery (SAGE labs), using zinc-finger nuclease technology that generated a 71 base pair deletion in Exon 4. The rats were exposed to multiple tones paired with VNS 300 times per day for 20 days. VNS was delivered as a 500-ms train of 15 pulses at 30 Hz. Each biphasic pulse was 0.8mA in amplitude and 100 μs in phase duration. These parameters are identical to previous studies. Auditory cortex responses were examined in heterozygous *Mecp2* rats following 20 days of VNS-tone pairing or no therapy. Of the 17 *Mecp2* rats, 2 were excluded from the study due to breathing complications during recording.

Results: Our data shows that *Mecp2* mutation alters auditory cortex responses to sounds compared to WT controls, consistent with a previous study in our lab (Engineer et al 2015). VNS tone pairing in *Mecp2* rats improves response strength to both tones and speech sounds compared to untreated *Mecp2* rats. Additionally, VNS tone pairing improved neural classifier consonant identification accuracy.

Conclusions: VNS is safe, FDA approved, and has already been utilized in clinical trials treating neurological disorders (Dawson et al 2016, Kimberley et al 2018, Kilgard et al 2018). These results demonstrate that VNS could be an effective therapy that could enhance auditory function, and ultimately improve the quality of life of individuals with Rett syndrome.

403.010 *(Poster)* Attention Atypicalities in Prenatal Valproate Rat Model of Autism Spectrum Disorder

K. Anshu[1]*, A. K. Nair*[1]*, S. Srinath*[2] *and L. T. Rao*[1]*, (1)Neurophysiology, NIMHANS, Bengaluru, India, (2)Child and Adolescence Psychiatry, NIMHANS, Bengaluru, India*

Background: Autism is a childhood developmental disorder characterized by deficits in social cognition and communication, restricted interests and repetitive behaviors. In addition, a wide range of changes in attentional abilities are also reported in human studies. Early attentional deficits have been proposed to play a causal role in the development of core symptoms that lead to diagnosis by the age of 3 or beyond. It is not clearly known that whether disruptions in the GABAergic neurotransmitter system during critical developmental time window would cause abnormal oscillatory pattern in the attentional circuit causing attention deficit in VPA rats.

Objectives: The present study aimed to assess attentional functions in a prenatal valproate (VPA) exposure model of autism spectrum disorder (ASD) in male and female rats. The study has also tested the underlying neural mechanisms of changes in attention in these rats.

Methods: The prenatal VPA model was validated by carrying out a battery of behavioural experiments such as social interaction, repetitive behaviour, anxiety, empathy and sensorimotor reflexes. We further carried out a detailed evaluation of attentional functions using five-choice serial reaction time task (5CSRTT), and measured different aspects of attentional and inhibitory control in rodents. We also carried out a large sample study of preattentional functions in order to characterize diversity on the ASD spectrum, and did a detailed evaluation of developmental milestones in VPA rats. To understand the mechanisms underlying attentional deficits in ASD, we did a immunohistochemical evaluation of GAD67, $GABA_A$ receptors α1 and β3 in the orbitofrontal cortex (OFC) and the posterior parietal cortex (PPC) – two regions that are involved in reward and attentional processing and also implicated in ASD pathophysiology. Finally, we carried out simultaneous spike and local field potential recordings in the OFC and PPC during rest and during attentional task performance.

Results: We found impaired 5-CSRTT performance in both male and female VPA rats who also showed abnormalities in social approach and empathy (pro-social behaviour) but no signs of anxiety, motivational or motor deficits. These rats had reduced expression of: GAD67 in OFC, GAD67 and β3 in PPC and increased expression of α1 in both regions suggesting disrupted GABAergic mechanisms. During attentional task, VPA rats showed reduced firing rates of OFC and PPC neurons and reduced coherence between these regions in theta, beta and gamma frequency bands.

Conclusions: The prenatal VPA model of ASD exhibits robust attentional deficits at behavior level associated with dysfunctions in GABAergic system. The impaired functional connectivity between OFC and PPC regions was reflected through asynchronous network interactions. The study, thus, contributes to the field of attention and reward processing network and provides evidence pertaining to the neural mechanisms of atypical attentional processing due to prenatal valproate exposure.

403.011 *(Poster)* Attention Orienting in the Neuroligin-3 Mouse Model of Autism

S. Li[1]*, C. May*[2]*, T. Pang*[2]*, A. J. Hannan*[2]*, K. A. Johnson*[1] *and E. L. Burrows*[2]*, (1)School of Psychological Sciences, University of Melbourne, Parkville, VIC, Australia, (2)Florey Institute of Neuroscience and Mental Health, University of Melbourne, Parkville, VIC, Australia*

Background: A deficit in attention orienting may be one of the earliest features in people with Autism Spectrum Disorder (ASD). Attention orienting is comprised of two components - exogenous and endogenous orienting. Exogenous orienting of attention is a stimulus-driven process in which one's attention is drawn automatically to salient external stimuli. Endogenous orienting of attention represents a goal-directed process in which expectations and/or knowledge of an individual determine where and when one's attention is given. To date, the neural mechanisms underlying the atypical attention orienting in autism remain unclear.

Our previous study successfully developed the Posner task for mice using touchscreen technology. It remains unknown whether ASD-associated genetic mutations will alter the attentional performance of mice in this task. Norepinephrine (NE) has been suggested to increase subjects' alertness in attention tasks. Nevertheless, it is unclear whether NE-modulating medications, such as atomoxetine (ATO), will improve attention orienting in mice with ASD-associated genetic mutations.

Objectives: Our objective was to investigate attention orienting in mice with and without the ASD-associated R451C (arginine to cysteine residue 451 substitution) mutation in neuroligin-3 (NL3) using the newly developed mouse Posner task. This study also aimed to test the effects of NE medications on these mice in this task.

Methods: Twenty NL3 mice and twenty wild-type (WT) mice were trained and tested in automated touchscreen chambers. Half of the mice in each cohort were randomly assigned to either the exogenous and or endogenous condition.

Mice were trained to sustain their nose-poke to a central dim square until the display of a peripheral target (a bright square). They were rewarded with strawberry milkshake for nose-poking the target. The targets were either validly or invalidly cued. In the exogenous tasks, the cue was a flash of light at the sides. In the endogenous tasks, mice were trained to learn a spatially-predictive image presented at the centre. In the probe, the validity of cues was 50% in the exogenous tasks, and 80% in the endogenous tasks. Effects of ATO (3mg/kg) on the response times and accuracy were assessed.

Results: In both tasks, mice showed higher accuracy and shorter response times in the validly versus invalidly cued trials. This effect is consistent with results in the human Posner task. There was no significant difference in performance between NL3 and WT mice on the measures of response times or accuracy. In the exogenous task, ATO increased response times and decreased accuracy similarly in both NL3 and WT mice. In the endogenous task, administration of ATO increased accuracy in NL3 mice compared to WT mice, with no effect on response times.

Conclusions: Our study did not find significant differences between NL3 mice and WT mice in attention orienting. Following the administration of ATO, however, NL3 mice showed better performance relative to WT mice in the endogenous task. Our findings support the use of Posner paradigm in mice, which has implications for understanding the neural mechanisms underlying the attention-orienting network in ASD.

403.012 *(Poster)* Autism Relevant Behavioral Deficits in Mice with Conditional Knockout of Pten in Parvalbumin-Positive Interneurons

S. Shin[1] *and S. Huang*[2]*, (1)Hussman Institute For Autism, Baltimore, MD, (2)Hussman Institute for Autism, Baltimore, MD*

Background: Numerous genes have been implicated in the etiology of autism. *PTEN*, one of the autism-associated genes, originally identified as a tumor suppressor gene, negatively regulates cell proliferation and growth. *PTEN* germline mutations have been identified in individuals with Autism Spectrum Disorder (ASD), and may account for up to 5% of ASD cases. *Pten* is widely expressed in both glutamatergic and GABAergic neurons during development and adulthood. Since deletion of the *Pten* gene is embryonically lethal, conditional knockout mice have mainly been investigated. Mice with neuronal specific knockout of *Pten* in a subset of postmitotic neurons in the cortex, hippocampus, and cerebellum, exhibit abnormal autism-relevant behaviors. Conditional knockout of *Pten* from GABAergic cortical interneurons leads to preferential loss of somatostatin (SST)-interneurons and an increased ratio of parvalbumin (PV)/SST interneurons. In addition, single copy *Pten* deletion from PV-interneurons (PV-INs) impairs the formation of perisomatic inhibition. These lines of evidence demonstrate a central role of *Pten* in inhibitory cell development. However, the functional consequences of *Pten* knockout in PV-INs have not been addressed.

Objectives: Evidence from study of both postmortem human brain tissue and animal models suggests that neural circuits composed of PV-INs are key contributors to the pathology and symptoms of ASD. The aim of this study is to examine behavioral phenotypes in mice with conditional knockout of *Pten* in PV-INs.

Methods: *Pten*$^{loxp/loxp}$ mice were crossed with PV-Cre mice to generate PV-Cre$^{+/+}$/*Pten*$^{loxp/+}$ breeders. Both male and female littermates of PV-Cre$^{+/+}$/*Pten*$^{loxp/loxp}$ (PV-*Pten*-KO), PV-Cre$^{+/+}$/*Pten*$^{loxp/+}$ (PV-*Pten*-Het) and PV-Cre$^{+/+}$/*Pten*$^{+/+}$ (PV-*Pten*-WT) mice (2 - 3 months old) were used for behavioral tests. Locomotion was assessed by open field tests. Motor coordination/learning was assessed during three trials of accelerating rotarod tests for 2 consecutive days. The experimenters were blinded to genotype during data collection.

Results: In rotarod tests, the latency of fall off the rod in PV-*Pten*-Het mice during the first two trials did not differ to that in PV-*Pten*-WT mice. Starting from the third trial, the latency of fall in PV-*Pten*-Het mice was significantly reduced when compared to PV-*Pten*-WT mice. Rotarod performance in PV-*Pten*-KO mice was remarkably impaired, as the latency to fall off the rod was shorter than both PV-*Pten*-Het and -WT mice over six trials. Interestingly, in open field tests, there was no significant difference among genotypes in distance traveled. Compared with PV-*Pten*-WT mice, PV-*Pten*-KO but not PV-*Pten*-Het mice spent more time in the center area of open field tests (KO: n = 5; Het: n = 17; WT: n = 9).

Conclusions: Conditional deletion of autism-associated gene *Pten* in PV-INs results in anxiolytic-like behaviors and deficits in motor coordination/learning. More general locomotion is not affected by *Pten* knock-out in PV-INs. These findings suggest that *Pten* in PV-INs plays an important role in regulating anxiety and motor function. Further investigations will focus on other autism-relevant behaviors.

Support: This project is supported by the Hussman Foundation grant HIAS18001 to SH

403.013 *(Poster)* Cardiac Comorbidities and Their Effect in Autism Spectrum Disorder

S. Assimopoulos[1,2]*, A. Beauchamp*[1,2]*, D. Fernandes*[2] *and J. P. Lerch*[1,2,3]*, (1)Department of Medical Biophysics, University of Toronto, Toronto, ON, Canada, (2)Mouse Imaging Centre, The Hospital for Sick Children, Toronto, ON, Canada, (3)Wellcome Centre for Integrative Neuroimaging, University of Oxford, Oxford, United Kingdom*

Background: Autism Spectrum Disorder (ASD) is a neurodevelopmental disorder with an occurrence rate >1%, highly heterogeneous in etiology and symptomology. Although it is associated primarily with neurodevelopmental and behavioural deficits, it has various associated comorbidities, amongst which cardiac comorbidities are common. Cardiac abnormalities range from mild defects to severe congenital heart disease (CHD). Accumulating evidence suggests that the presence of severe cardiac abnormalities contributes to the observed neurodevelopment.

Objectives: Our work aims to explore the association between neuroanatomy and cardiac abnormalities, in a set of ASD-related mouse models. Here we present findings from the cardiac phenotyping of these models.

Methods: Cardiac phenotyping of 60-day old male mice from 12 prominent ASD-related mouse models is in progress, using ultrasound biomicroscopy (UBM) (VisualSonics Vevo 2100 system; Toronto, ON). Of that data, the sample processed includes: 9 mutant *Chd8*, 9 mutant *Arid1b*, 16 mutant *Shank (exon 4-9)* (Heterozygote), 11 mutant *Shank3 (exon 4-9)* (Homozygote), 3 wild-types. UBM metrics obtained include aorta diameter, EA ratio, velocity time integral (VTI), heart rate (HR), as well as left ventricular (LV) diameter, posterior and anterior wall thickness (systole and diastole). For all metrics, except for HR, the average of three measurements was used, which were taken from different cardiac cycles in the same ultrasound trace. LV measures were obtained in both long and short axis views, while aorta diameter was measured both from the left and right side of the heart. Multiple HR measurements were also obtained from the LV, EA and VTI traces, but were not averaged together (tested individually). A linear model was run on the sample comparing these metrics between the five groups. A significance level of 0.05 was chosen. False discovery rate (FDR) correction for multiple comparisons was performed.

Results: With a significance level of 0.05, significant differences were found for LV anterior wall thickness (Arid1b, Shank3-Het and Shank3-Hom vs wild-type), aorta diameter (Shank3-Hom vs Arid1b) and heart rate (Chd8, Shank3-Het and Shank3-Hom vs Arid1b). For other measures, trending differences were found between all groups, which didn't survive FDR correction.

Conclusions: Cardiac dysfunction is one of the comorbidities of ASD. Moreover, brain development is abnormal in CHD newborns, pre and post operatively. Thus, for a set of ASD-related mouse models, we expect that an abnormal cardiac phenotype would have an effect on neurodevelopment. From the comparative analysis on the sample UBM data (five metrics and five groups), significant differences were found in LV anterior wall thickness, aorta diameter and HR. For all other metrics, differences were found with uncorrected p-values at a 0.05 significance level, which didn't survive FDR correction, probably due to limited sample size. These results may change once the full dataset is collected and the analysis is repeated. Even more, for further analysis, more complex statistical models will be used, accounting for additional factors such as mouse weight and litter size.

403.014 *(Poster)* Circadian Rhythms in Models of Tuberous Sclerosis Complex

***J. Lipton**, Boston Children's Hospital, Harvard Medical School, Boston, MA*

Background: Sleep dysfunction is a common manifestation autism spectrum disorders (ASD) however, the mechanisms underlying this association remain unclear. Tuberous Sclerosis Complex (TSC) is a monogenetic cause of ASD.Tuberous Sclerosis Complex (TSC) is a monogenetic neurodevelopmental disorder that manifests with many cognitive, behavioral, and psychiatric symptoms, including sleep dysfunction that collectively comprise the TSC-Associated Neuropsychiatric Disorders (TAND). Sleep dysfunction is very common in TSC and exacerbates seizures, mood, and daytime function. Little is known however, about the biological mechanisms that link sleep and TSC-related brain abnormalities. The circadian system governs 24-hour oscillations in sleep-wake cycles, hormone secretion, metabolism, and physiology governed by a molecular transcriptional-translational feedback loop in which the transcription factor BMAL1 is essential. We have taken advantage of cellular and mouse models of TSC to identify biochemical, cellular, and behavioral links between dysfunction of the TSC/mTOR signaling pathways and the core circadian clock protein BMAL1.

Objectives: The goals of this presentation are to: 1) review the mechanistic relationships between TSC, mTOR signaling, and the circadian clock; 2) define how abnormal BMAL1's proteostasis and post-translational modifications are associated with TSC; and 3) present findings that link TSC/mTOR dependent gene expression to the circadian clock and; 4) suggest approaches by which we may use circadian biology to identify novel therapeutics for TSC and other ASDs associated with circadian dysfunction.

Methods: We use a combination of cell biology, neurobiology, biochemistry, CRISPR mouse engineering and animal behavior to identify the dysfunction of the circadian clock in TSC mutant cells and animals.

Results: We show that modulation of BMAL1 post-translational state and proteostasis are abnormal in TSC. Manipulation of these molecular defects can mitigate behavioral and lifespan phenotypes in mouse models.

Conclusions: Together, our work suggests that manipulation of the circadian clock may represent a previously untapped therapeutic target for TSC and perhaps other related mTOR-opathies associated with ASD.

403.015 *(Poster)* Developmental Hyperserotonemia Induced Alterations in Cerebellar Neuronal Circuitry and Motor Function.

***L. Hough**[1] and E. Holland[2], (1)Biomedical Sciences, Missouri State University, Springfield, MO, (2)Missouri State University, Springfield, MO*

Background: Developmental hyperserotonemia (DHS) is considered the most consistent neurochemical finding reported in Autism Spectrum Disorder (ASD). This increased level of serotonin is of particular interest during development, at which time the neurotransmitter plays an active role in brain development, by promoting dendritic elaboration, synaptogenesis, neurogenesis, cortical organization and autoregulation of the serotonergic system. Accordingly, it has been hypothesized that during the early stages of neural development, abnormally increased amounts of serotonin could induce developmental abnormalities in various neural networks relevant to autistic behaviors. Of these behaviors are deficits in social cognition, disordered communication, restricted interests and repetitive behaviors. Furthermore, abnormalities in basic motor control, skilled motor gestures, and motor learning, are common in ASD. These behaviors have been attributed to a possible defect in the pre- and postnatal development of neural networks including the cerebello-thalamo-cortical pathway, which is involved in motor learning, automaticity of movements, and higher cognitive functions. It has been well established that cerebellar abnormalities are one of the most common structural and functional changes observed in ASD. Common cerebellar pathologies include dysplasia, variable loss of cerebellar Purkinje cells, and increased numbers of reactive neuroglia in the cerebellum and cortical brain regions. While evidence exists for some genetic underpinning of these changes, our initial work has demonstrated DHS can induce morphological changes in subpopulations of cerebellar neurons. With the investigations presented here, we intend to fill a critical void in our understanding of the role in which serotonin plays in the neuropathological and behavioral changes associated with ASD.

Objectives: The overall goal of this investigation is to better understand the effects of developmental hyperserotonemia (DHS) on cerebellar neuronal populations and behavioral expressions commonly linked to Autism Spectrum Disorder (ASD), and to continue to evaluate the DHS animal model as a model for ASD. We aimed to assess ASD linked behavioral expression through our investigation of motor coordination and motor learning in the DHS animal population. We also aimed to evaluate changes in Purkinje cell population numbers and connectivity following DHS treatment.

Methods: DHS and control animal motor coordination were assessed through repeated balance beam task performance. Animals were divided into groups that assessed the task performance and improvement while comparing the effects of an early motor skill training regimen. Following motor assessments, histological analysis of the posterior lobe of the cerebellum as performed using immunohistochemical and unbiased stereological techniques.

Results: Our preliminary results indicate that DHS treated animals' express decreases in motor task performance as well as a loss of posterior lobe Purkinje cells and glutamatergic climbing fiber synaptic connections. Our initial evaluations indicate some rescue of motor task performance and an increase in climbing fiber synaptic connections through an early intervention motor training regimen.

Conclusions: The current investigation into the DHS animal model for ASD has provided additional evidence of the putative effect excessive serotonin can have on the developing nervous system and subsequent behavioral expressions. We believe this work has furthered our understanding of the complex disorder and opened new lines of inquiry for investigation.

403.016 *(Poster)* Disruption of Csde1 Interferes Neurogenesis in Prenatal Developing Brain and Causes Autistic Behaviors

***X. Jia**, G. Zhang, M. He, B. Du, Q. Zhang, G. Chen, Z. Hu, X. Kun and H. Guo, Center for Medical Genetics, School of Life Sciences, Central South University, Changsha, China*

Background: Autism spectrum disorder (ASD) is a group of neurodevelopmental disorders with substantial genetic and clinical heterogeneity. Our previous study found that disruptive variants of *CSDE1* lead to ASD. *CSDE1* encodes an RNA-binding protein that regulates RNA stability and translation processes. *Csde1* knockout mice are embryonic lethal at embryonic day 10 (E10).

Objectives: Although *CSDE1* is a high-risk ASD gene, the underlying roles and mechanisms of *CSDE1* in neurodvelpment and behaviors are largely unclear. We sought to investigate the roles of *Csde1* in cortical develpment and autistic behaviors using conditional knockout mice.

Methods: Nervous system conditional knockout mice ($Csde1^{fl/fl}$;$Nestin^{Cre}$) were generated by CRISPR-Cas9 techonology ($Csde1^{fl/fl}$) and crossed with Nestin-Cre mice. Immunofluorescence was used to investigate the phenotypes during cortical development. RNA-seq was performed to identify the differential expressed genes in embryonic cortex. $Csde1^{fl/fl}$ mice were then crossed with Nestin-CreERT2 mice to generate $Csde1^{fl/fl}$;$Nestin^{CreERT2}$ mice. Tamoxifen (100mg/kg) was given to induce knockout of Csde1 in $Csde1^{fl/fl}$;$Nestin^{CreERT2}$ mice at P21 via 1 daily intraperitoneal injection for 5 days. Three-chamber test, open-field exploration test, light-dark box test and marble-burying test were used to measure the autistic behaviors on $Csde1^{fl/fl}$;$Nestin^{CreERT2}$ mice.

Results: The $Csde1^{fl/fl}$;$Nestin^{Cre}$ mouse died at postnatal day 0 (P0). By immunofluorescence, we observed significant reduction of proliferating cells (neural progenitor cells and intermediate cells) at E16.5 in KO mice compared with $Csde1^{fl/fl}$ and $Csde1^{fl/+}$;$Nestin^{Cre}$. At E18.5 days, the number of cells in the deeper layer and the upper layer of cortex was significantly reduced in the KO mice compared with WT and HET. Transcriptome analysis at E16.5 revealed a dramatic differential expression pattern between $Csde1^{fl/fl}$;$Nestin^{Cre}$ and $Csde1^{fl/fl}$, while no substantial difference was observed between $Csde1^{fl/fl}$;$Nestin^{Cre}$ and $Csde1^{fl/+}$;$Nestin^{Cre}$. Gene ontology and pathway analysis showed that genes downregulated by Csde1 knockout are involved in regulation of cell cycle, DNA replication, Notch signalling pathway. Upregulated genes by Csde1 knockout were enriched for ribsome and synapse or synaptic plasticity related genesets. Behavior testing on $Csde1^{fl/fl}$;$Nestin^{CreERT2}$ mice were performed at P60. Our preliminary data showed that $Csde1^{fl/fl}$;$Nestin^{CreERT2}$ mice present deficits in social interaction, repetitive behavior and hyperactivity.

Conclusions: Csde1 mediates cortical neurogenesis likely via direct or indirect regulation of cell cycle. Disruption of Csde1 during postnal neurogeneisis might cause a series of autistic behaviors indicating a critical role of Csde1 in the development or function of postnally generated neurons.

403.017 *(Poster)* Effects of Gestational Diabetes and Metformin Exposure on Autism-like Behaviors and Oxytocin Signaling in Mouse Offspring

*Y. R. Sanchez[1], G. Ganeson[2], M. C. Nunn[2], B. L. Pierce[2], N. Hodge[3], B. Rice[3], L. Ferrier[3] and **G. G. Gould**[4], (1)School of Nursing, University of Texas Health Science Center at San Antonio, San Antonio, TX, (2)School of Medicine, The University of Texas Health Science Center at San Antonio, San Antonio, TX, (3)Cellular and Integrative Physiology, University of Texas Health Science Center at San Antonio, San Antonio, TX, (4)Cellular and Integrative Physiology, The University of Texas Health Science Center at San Antonio, San Antonio, TX*

Background: Gestational diabetes mellitus (GDM) was associated with an increased risk of autism was recently reported. In light of this, reports that the anti-diabetic drug metformin may help to control GDM raises the exciting possibility that its use might also curb autism. Yet use of metformin in pregnancy is still new, and it is readily transported across the placenta, so concerns have been raised about potential long-term adverse effects on offspring. A prior study demonstrated gestational metformin exposure reduced social interaction preference of male mouse offspring in absence of GDM. Therefore assessment of the impact of prenatal exposure to metformin in the context of GDM is warranted.

Objectives: To model GDM in mice and examine the effects of prenatal metformin exposure on male and female offspring brain oxytocin receptors, serum oxytocin levels and social interaction preferences and repetitive burying to show how GDM and metformin interact to affect these endpoints.

Methods: Mouse dams with pharmacologically induced GDM (by streptozotocin (STZ)), or high fat-high sucrose (HFHS) diet and their respective controls were treated with metformin (≈200 mg/kg/day) in drinking water or untreated water throughout pregnancy. Mouse offspring were tested for social interaction preferences in three chamber tests at 7-8 weeks old. Behavior data was collected by observers trained to measure a specific behavior (sniffing or time in chambers), and who were unaware of the treatment groups. The offspring mice were also tested for repetitive behavior via a marble-burying test. Following behavior tests the offspring were euthanized and their brain and serum was collected for measures of oxytocin receptor density and oxytocin levels.

Results: Overall the STZ treated dams had fewer litters born than dams from the other groups. No differences in social interaction preference were evident among treatment groups. For males, the mean ± SEM preferences were: control 63.2 ± 7.5 sec, metformin alone 39 ± 12.1 sec, STZ alone 53.3 ± 23.1 sec, and STZ metformin 58.6 ± 14.5 sec (N = 4-14). Female offspring had similar results. Likewise males and females exposed during gestation to HFHS diet ± metformin also exhibited no differences between groups by measure of sniffing time. Small numbers of surviving offspring were found in untreated STZ and HFHS groups. By contrast metformin appeared to increase the fertility of the dams in both the STZ and HFHS diet groups. There were no differences among treatment groups or sexes in marble burying, which averaged 5.6 ± 1.2 for male and 5.9 ± 1.8 for female offspring (N = 4–17). Metformin treatment increased oxytocin receptor density in the cingulate cortex and reduced serum oxytocin levels in male offspring without GDM.

Conclusions: While gestational metformin by itself impaired social interaction preference in male mice, when exposure occurred in the context of STZ or HFHS diet induced GDM, it was without a significant effect. Gestational metformin exposure alone also impacted oxytocin signaling in male offspring, but not in female offspring. However, in context of GDM metformin exposure did not significantly increase autism-like behaviors.

403.018 *(Poster)* Emergence of Sleep Problems in a Shank3 Mouse Model

H. Schoch[1]*, A. M. Ingiosi*[1]*, T. Wintler*[1]*, K. Ford*[2]*, K. Singletary*[2]*, E. Medina*[2]*, M. Frank*[1] *and L. Peixoto*[3]*, (1)Washington State University Elson S. Floyd College of Medicine, Spokane, WA, (2)Washington State University, Spokane, WA, (3)Sleep and Perfromance Research Center, Washington State University, Spokane, WA*

Background: Sleep problems affect a higher proportion of children with autism spectrum disorder (ASD) compared to typically developing children and are a strong predictor of severity of ASD core symptoms as well as behavioral problems. Children with ASD have difficulty falling and staying asleep from very young ages, resulting in chronic sleep deficiency throughout the developmental period. Studies in animal models suggest that sleep is important for brain development and function, but little is known about what causes sleep disturbances in ASD.

We focused our studies on *SHANK3*, a high confidence ASD gene candidate. Individuals with Phelan-McDermid Syndrome (PMS) carry deletions in chromosome 22q13.3, a region that includes *SHANK3.* Approximately 85% of PMS patients have an ASD diagnosis and we found that about half report chronic sleep problems, but the link between *SHANK3* mutations and poor sleep is not understood. Using a mouse model of PMS, we found that adult mice with mutation in *Shank3* (Shank3ΔC) have sleep problems that mirror insomnia symptoms in PMS patients. In PMS, sleep problems increase in early childhood and are maintained to adulthood. We hypothesize that loss of SHANK3 disrupts the normal development of sleep patterns, leading to problems falling and staying asleep.

Objectives: Determine the developmental emergence of sleep problems in Phelan-McDermid syndrome, and in *Shank3* mutant mice.

Methods: In this study, we used questionnaire data to guide our studies in mouse models to understand how sleep problems develop in ASD. We obtained sleep questionnaire data from PMS individuals with *SHANK3* mutations from the PMS Foundation International Registry. Sleep loss in mice and humans elicits specific changes in electroencephalographic (EEG) activity patterns that can be used to track sleep patterns and physiological markers of sleep need. In Shank3ΔC and control mice, we collected EEG and electromyographic (EMG) data to determine sleep-wake patterns, and used sleep-deprivation to induce periods of high sleep need.

Results: We find that *SHANK3* mutations are associated with sleep disturbances in both humans and mice. Children with PMS develop sleep problems between 5-12 years of age, including problems falling asleep, repeated awakening, and reduced sleep time. Similarly, we find that adult Shank3ΔC mutant mice have reduced sleep time, delayed sleep initiation following sleep deprivation, and reduced low-frequency EEG activity in non-rapid eye movement (NREM) sleep relative to littermate control mice. We find that adult responses to sleep deprivation emerge during adolescence in mice. Prior to this transition, low-frequency EEG activity during NREM sleep is normal in juvenile Shank3ΔC mice.

Conclusions: We show that sleep problems in PMS individuals emerge during early childhood. Sleep problems in Shank3ΔC mice also change across development. Adult Shank3ΔC mutant mice sleep less but have difficulty falling asleep following sleep deprivation. Changes in EEG activity in Shank3ΔC mice are present in adults but not juveniles, suggesting that they are the result of abnormal post-natal development. Overall, our study shows that SHANK3 is an important modulator of sleep during development.

403.019 *(Poster)* FMR1 KO Mice Exhibit Abnormal Rearrangements in a Synaptic Protein Interaction Network Following Activation of Glutamatergic Receptors

J. Lautz[1]*, W. E. Heavner*[1] *and S. E. Smith*[2]*, (1)Center for Integrative Brain Research, Seattle Children's Research Institute, Seattle, WA, (2)University of Washington, Seattle, WA*

Background: Cells utilize dynamic signaling networks to process information from multiple signaling inputs and synthesize coordinated responses. Despite the importance of signaling network dynamics, however, the logic underlying information flow through these networks is not well understood. Previously, we developed the quantitative multiplex co-immunoprecipitation (QMI) platform, which allows for the simultaneous and quantitative measurement of the amount of co-association between large numbers of proteins. Using QMI, we characterized the activity-dependent dynamics of a synaptic protein interaction network (PIN), with the goal of understanding the network level mechanisms underlying synaptic plasticity. We show that stimulation of distinct glutamate receptor types results in different modular sets of PIN rearrangements. Interestingly, this same targeted PIN is also disrupted in multiple models of ASD. As altered synaptic plasticity is a hallmark of various forms of ASD, these data raise the possibility that basal network disruptions in synaptic PINs are the result of an inability to correctly process glutamatergic stimuli. We hypothesize that the activity-dependent dynamics of our targeted synaptic PIN are disrupted in many forms of ASD, resulting in altered synaptic plasticity. To test this hypothesis, we will utilize the FMR1-/y knockout (KO) model of Fragile X (FXS) syndrome as this model is well-studied, with clear pathological mechanisms, demonstrated baseline PIN abnormalities, and known defects in mGluR5 signaling

Objectives: To identify specific deficits in information processing underlying altered glutamatergic signaling in the FMR1-/y KO model of FXS.

Methods: FMR1$^{-/y}$ KO and WT cortical neurons were stimulated with NMDA, DHPG, or aCSF control and changes in synaptic protein interactions were quantified by QMI. Similarly, cortical slices from P7, P17, and P60 FMR1$^{-/y}$ KO and WT male mice were treated with NMDA, DHPG, or aCSF control x 5 min and changes in synaptic protein interactions were again quantified by QMI. Principal component analysis (PCA) was utilized to reveal strong patterns in our QMI datasets. Interactions that were significantly different between groups were identified by a combination of weighted correlation network analysis (CNA) and adaptive non-parametric with an empirically determined alpha cutoff (ANC).

Results: PCA analysis of all interactions showed that FMR1$^{-/y}$ KO neurons or cortical slices treated with aCSF were shifted towards WT-DHPG, suggesting hyperbasal mGlur5 signaling. In addition, DHPG treatment failed to elicit separation from aCSF controls in FMR1$^{-/y}$ KO neurons and slices. By comparison, WT-NMDA and KO-NMDA showed both significant separation from controls, and strong overlap with each other.The interactions identified as significantly different between FMR1$^{-/y}$ KO aCSF and WT aCSF showed some variation between neurons and each age of cortical slices. We did however observe a consistent decrease in Homer_mGluR5 co-association.

Conclusions: Here, we showed that in a mouse model of FXS with known deficits in mGluR5 signaling, NMDA induced PIN rearrangements in KO animals was indistinguishable from controls. By comparison, mGluR5 signaling was clearly disrupted. Our results demonstrate a novel way of approaching intracellular signaling at the level of PINs, illustrate the molecular logic with which the synapse encodes its input states, and highlights specific mechanisms of logic-circuit disruption associated with ASDs.

403.020 *(Poster)* Global Electroencephalography and Sleep Characterization As Translational Biomarkers in an Angelman Syndrome Model

N. A. Copping *and J. L. Silverman, Department of Psychiatry and Behavioral Sciences, MIND Institute University of California Davis School of Medicine, Sacramento, CA*

Background: Angelman Syndrome (AS) is a rare (~1:15,000) neurologic disorder characterized by a wide range of symptoms including seizures, sleep disturbances, ataxia, motor deficits, developmental delay, impaired communication skills, intellectual disabilities, and microcephaly (Wheeler et al., 2017; Williams et al., 2006; Jiang et al., 1998). Due to the high prevalence of seizures (>80%) and sleep abnormalities (20-90%) in the AS population, electroencephalography (EEG) is a prominent tool used in clinical work and has shown abnormalities in epileptiform spike-wake discharges, increased delta waves of AS individuals, and reductions in REM sleep and sleep efficiency (Korff et al., 2005; Minassiam et al., 1998; Miano et al., 2004).

Objectives: The present experiments were designed to build upon previous clinical and preclinical findings of abnormal epileptiform spike-wake discharges, power spectral differences, and sleep dysfunctions by applying a scalp-based EEG approach over depth field potentials to the characterize excitability, seizure phenotypes, sleep-wake cycling, and spindle production.

Methods: Inbred, C57Bl/6J males were paired with heterozygous *Ube3a*$^{-/+}$ females, resulting in offspring with the maternal transmission of the *Ube3a* mutant allele (*Ube3a*$^{m-/p+}$) and their wildtype (*Ube3a*$^{m+/p+}$) littermates. At 8 weeks, mice were anesthetized and implanted with a wireless telemetry device designed to measure EEG and EMG in freely moving animals (DSI). To capture global EEG, two biopotential leads were attached to surgical screws 1.0mm anterior and 3.0mm posterior to the left and right of Bregma respectively. EMG activity was measured via two leads placed in the trapezius muscles of the animal. One-week post-surgery, subject EEG, EMG, and temperature were recorded for either a 24 or 48-hour baseline. Mice recorded for 24-hours were induced with 80 mg/kg pentylenetetrazole while EEG data from mice recorded for 48-hours was analyzed for sleep-wake cycles. EEG analysis and seizure characterization were evaluated using custom written scripts in Python.

Results: *Ube3a*$^{m-/p+}$ mice had increased delta power when compared to *Ube3a*$^{m+/p+}$ controls, replicating power spectral differences reported clinically. *Ube3a*$^{m-/p+}$ mice also displayed clear, robust phenotypes of atypical EEG activity and sleep disturbances commonly associated with AS.

Conclusions: Our results extend earlier field potential depth recordings (Sidorov et al., 2017, Born et al., 2017), with the advantage of a translational approach that will provide critical data necessary to further investigate the possibility of a cross-species AS EEG biomarker and will serve as a paramount output measure in numerous innovative therapeutic interventions, including antisense oligonucleotides, artificial transcription factors, and stem cell based viral deliveries.

403.021 *(Poster)* Impaired Oxytocin Release and Altered Synaptic Properties of Hypothalamic Oxytocin Neurons in Shank3-Deficient Rats

K. T Rajamani[1,2]*, A. Leithead*[3,4]*, M. Peruggia*[3,5]*, N. Burlant*[1]*, K. Niblo*[1]*, J. Buxbaum*[1,2,6,7,8,9]*, R. Froemke*[10]*, V. Grinevich*[11] *and H. Harony-Nicolas*[1,2,6,8]*, (1)Department of Psychiatry, Icahn School of Medicine at Mount Sinai, New York, NY, (2)Seaver Autism Center for Research and Treatment, Icahn School of Medicine at Mount Sinai, New York, NY, (3)Icahn School of Medicine at Mount Sinai, New York, NY, (4)Seaver Autism Center for Research and Treatment, New York, NY, (5)Seaver Center for Autism Research, New York, NY, (6)The Mindich Child Health and Development Institute, Icahn School of Medicine at Mount Sinai, New York, NY, (7)Fishberg Department of Neuroscience, Icahn School of Medicine at Mount Sinai, New York, NY, (8)Friedman Brain Institute, Icahn School of Medicine at Mount Sinai, New York, NY, (9)Department of Genetics and Genomic Sciences, Icahn School of Medicine at Mount Sinai, New York, NY, (10)Skirball Institute of Biomolecular Medicine, New York University School of Medicine, New York, NY, (11)Universitat Heidelberg, Mannheim, Germany*

Background: Mutations in the *SHANK3* gene are a leading cause of Phelan McDermid Syndrome (PMS) and account for up to 1-2% of total autism spectrum disorder (ASD) cases. Oxytocin was proposed as a potential therapeutic for treating ASD, although results from clinical trials were ambiguous. It has been suggested that variability in an individual's response to oxytocin could be attributed to underlying neurobiology associated with oxytocin release. We wanted to examine this in a rodent model that carries a mutation in the *Shank3* gene (*Shank3*$^{-/-}$ rat). We have previously demonstrated that lack of *Shank3* in this model impairs long-term social recognition memory and is accompanied by deficits in synaptic plasticity in the hippocampal and medial prefrontal cortex circuitry. Interestingly, both behavioral and synaptic plasticity deficits were reversed by acute treatment with oxytocin.

Objectives: In this project we are testing our hypothesis that social memory deficits in the *Shank3*$^{-/-}$ rats are due to functional impairments in the oxytocin system resulting from the lack of *Shank3*.

Methods: To examine the electrophysiological properties of oxytocin neurons in the *Shank3*$^{-/-}$ rats, we used viral vectors that label oxytocin neurons with a fluorescent marker and recorded electrical activity using in vitro slice electrophysiology. We used immunohistochemistry to quantify the number and intensity of signal from oxytocin neurons. To measure the total levels of oxytocin peptide in the hypothalamus of *Shank3*$^{-/-}$ rats, we used *in vivo* microdialysis.

Results: First, compared to their wild-type (WT) littermates, we found that *Shank3*$^{-/-}$ rats have a statistically significant shift to a larger distribution of amplitudes in both miniature and spontaneous excitatory postsynaptic potentials. These results suggest that *Shank3* mutation impairs synaptic transmission in oxytocin neurons. Second, while we did not observe an overall change in the number of oxytocin neurons, we did observe a statistically significant increase in oxytocin intensity in the hypothalamus of *Shank3*$^{-/-}$ rats, suggesting impaired processing of oxytocin. In order to determine if these changes impact the release of oxytocin, we measured oxytocin levels during the presentation of a social stimuli, as this has been previously shown to stimulate oxytocin release. As expected, we found that oxytocin levels did increase during social interaction in WT littermates. However, we did not detect any increase in *Shank3*$^{-/-}$ rats, suggesting impaired release of oxytocin.

Conclusions: Altogether, our findings suggest that *Shank3* mutation impairs the processing and release of oxytocin and that this may underlie the social memory impairments that we have reported in *Shank3*$^{-/-}$ rats. These findings are significant as they suggest that central release of oxytocin may be also impaired in human subjects with a *SHANK3* mutation and that these subjects may specifically benefit from treatment with oxytocin or with therapeutics that induce the endogenous release of oxytocin. Future studies are aimed at addressing the mechanisms by which *Shank3* deficiency leads to impairments in the oxytocin system and determining if restoring oxytocin neuronal function using chemo-genetic techniques or restoring *Shank3* expression itself in the hypothalamus is sufficient to reverse the social behavioral deficits observed in the *Shank3* rat model.

403.022 *(Poster)* Intranasal Oxytocin Improves Social Behavior in Laboratory Beagle Dogs (Canis familiaris)

V. Roman[1]*, G. Levay*[2]*, B. Lendvai*[3]*, R. Kedves*[1]*, B. Turcsan*[4]*, E. Petro*[4] *and J. Topal*[5]*, (1)Neurodevelopmental Biology, Gedeon Richter Plc., Budapest, Hungary, (2)Cognitive Pharmacology, Gedeon Richter Plc., Budapest, Hungary, (3)Pharmacology and Drug Safety Research, Gedeon Richter Plc., Budapest, Hungary, (4)Research Centre for Natural Sciences, Budapest, Hungary, (5)Institute of Cognitive Neuroscience and Psychology, Research Centre for Natural Sciences, Budapest, Hungary*

Background: Over the past several years the domestic dog (*Canis familiaris*) has become increasingly proposed as a model for comparative and translational neuroscience, including autism spectrum disorder (ASD). The translational value of a dog model stems from the recognition that dogs, during domestication, evolved a human-directed social competence and thus the phenotypic similarity between the dog and human symptoms are much higher than between the rodent and human symptoms. Moreover, these conditions occur naturally in dogs, and as such, the symptoms may be more homologous to the human condition and more likely to have similar etiology. It has also been shown that the oxytocin system plays a key role in modulating social behaviors in both dogs and humans.

Objectives: The aim of the present study was to investigate the effect of intranasal oxytocin in laboratory Beagle dogs in a test battery developed to assess social competence in this species.

Methods: A social competence test battery (short screening test, SCT) was established that included the following 9 indicator situations: free exploration of the testing environment, initiations of social contact by a familiar and an unfamiliar experimenter, food motivation, eye contact training, potentially threatening object (moving toy car), pointing and gaze following, choice based on human emotion, and threatening approach (by human). Thirty-six Beagles (all older than 1 year, 22 males and 14 females) participated in the study. Dogs received a single intranasal dose of 32 IU (8 puffs) oxytocin (Syntocinon, Novartis) and physiological saline (placebo) in a double-blind, cross-over design (using a 1-month wash-out period) 35-45 min before participating in the SCT. Subjects' behavior was video recorded during the SCT and 45 variables of the 9 situations were scored off-line by two independent, blinded observers. Generalized linear mixed model was used to analyse the main effects of treatment and repetition as well as the interaction of these factors on dogs' behavior (using the standard α=0.05 cutoff). This study was approved by the Local Ethical Committee of Gedeon Richter Plc. and was carried out in strict compliance with the European Directive 2010/63/EU regarding the care and use of laboratory animals for experimental procedures.

Results: Significant treatment effects were found in two indicator situations (initiation of social contact and threatening moving object). Dogs, after oxytocin administration, showed an increased responsiveness to social contact initiated by the familiar experimenter. Oxytocin also increased first reaction latency to the potentially threatening object and decreased the frequency of looking at the familiar experimenter.

Conclusions: Oxytocin clearly improved certain aspects of social behavior in a homogenous group of laboratory Beagle dogs based on the indicator situations of the SCT. The SCT can be used to investigate social competence in laboratory dogs and it may have the potential to detect pro-social effects of investigational compounds.

403.023 *(Poster)* Loss of Kmt5b Results in Structural Changes at the Skeletal Muscle Neuromuscular Junction

J. Hulen*, R. Wickramasekara, J. Hallgren, R. L. Black, P. Abel and H. F. Stessman, Pharmacology & Neuroscience, Creighton University School of Medicine, Omaha, NE*

Background: Genomic studies have highlighted the *KMT5B* (*SUV420H1*) gene as a significant target of disruptive variation in humans with intellectual disability, autism spectrum disorder, and developmental delay in motor coordination. KMT5B is a histone methyltransferase enzyme responsible for di-methylation of mono-methylated lysine residues at position 20 of histone H4 tails. Double-knockout of Kmt5b and its paralog Kmt5c in skeletal muscles of mice caused cell necrosis and an increase of internally nucleated muscle fibers, an indication of muscle fiber degeneration. *In vivo* studies further suggested that Kmt5b may maintain the quiescent muscle stem cell pool, which is required in cases of muscle injury. Thus, we hypothesized that motor delays in patients carrying pathogenic germline *KMT5B* variation are due to structural changes in skeletal muscle. Previous studies proposed that Kmt5b loss in mice is associated with muscle degeneration. Myopathies such as Duchenne Muscular Dystrophy, characterized by progressive muscle degeneration, exhibit increased fragmentation of the nerve and decreased synaptic area at the neuromuscular junction (NMJ), the nerve contact point for skeletal muscle innervation, resulting in denervation.

Objectives: To identify NMJ morphological changes associated with constitutive *Kmt5b* loss.

Methods: To model constitutive Kmt5b loss, mice with a lacZ gene trap cassette inserted into the intron between Kmt5b exons 4 and 5 on a C57BL/6N background (KMT5B$^{tm1a(KOMP)Wtsi}$) were used. Littermate breeding produced wild-type (WT) and heterozygous (HET) offspring, which most closely resembled the genotypes observed in the *KMT5B* patient population (disruptive heterozygous).

Due to sex biases in autism diagnosis and in psychomotor development, we chose to study both sexes independently. Eighteen female and 21 male mice (WT and HET), were transcardially perfused at postnatal day 42 with paraformaldehyde before dissection of the soleus (SOL).

Immunohistochemistry used whole-mount muscle tissues with antibodies specific for neurofilament medium and synaptic vesicle 2 for identification of nerve structure and tetrarhodamine α-bungarotoxin for identification of the muscle structure. Confocal imaging (40X; Nikon Ti-E inverted microscope with Yokagawa spinning disk) was used to quantify total NMJ area and fragmentation (discontinuity, continuity, and branch points) of both the nerve and muscle using the BinaryConnectivity plugin with ImageJ software.

Results: Characteristics of SOL muscles were compared using two-way ANOVA (independent factors: sex and genotype). In female mice, nerve branch points were significantly increased in HET mice compared to WT mice (two-way ANOVA $F(1,35) = 9.007$, $p = .004$; Sidak's post-hoc test $p = 0.036$). Other nerve fragmentation measures showed similar trends: discontinuity (two-way ANOVA $F(1,35) = 3.527$, $p = 0.068$) and continuity (two-way ANOVA $F(1,35) = 3.942$, $p = 0.055$). Combining sex groups, muscle discontinuity increased in HET mice compared to WT mice (two-way ANOVA $F(1,35) = 6.460$, $p = 0.015$).

Conclusions: Our results indicate an increase in fragmentation of the nerve and a sex biased effect in our *Kmt5b* HET model, suggesting that structural differences may contribute to motor abnormalities and developmental delays in individuals carrying disruptive *KMT5B* variation. Further studies examining muscle contraction and NMJ health may provide greater insight into Kmt5b's role in developmental motor delay.

403.024 *(Poster)* Maternal Vs. Paternal Mthfr Deficiency As a Risk Factor for Social Deficit and Seizure Susceptibility in Offspring Mice.

*H. M. Golan[1] and **N. Sadigurschi**[2], (1)Physiology, Ben-Gurion University of the Negev, Beer Sheva, Israel, (2)Physiology, Ben-Gurion University of the Negev, Beer-Sheva, Israel*

Background: The pathophysiology behind Autism Spectrum Disorder (ASD) is thought to be multifactorial, involving genetic and environmental factors. Various maternal traits have been linked to the development of ASD, including polymorphism of the *Mthfr* gene, which was found in high prevalence in mothers of ASD patients. Recently, paternal traits, such as age at conception, have also been shown to contribute to the risk of ASD development.

One of the proposed mechanisms for the development of ASD is Inhibitory/Excitatory (I/E) imbalance, supported by significant alternations in the GABA pathway in ASD and animal models of ASD. Further support for this hypothesis is the high incidence of epilepsy seen in ASD patients.

In previous studies we showed that in mice maternal *Mthfr*+/- genotype is correlated with both ASD like behavior and alternation in the I/E balance in the offspring.

Objectives: To investigate the role of paternal vs. maternal *Mthfr* deficiency in the development of ASD in the offspring and on the I/E balance.

Methods: Study design: *Balb/c Mthfr*+/- (HT) mice were mated with C57BL *Mthfr*+/+ (WT) mice to generate WT and HT, F1 offspring. Five groups representing maternal:paternal:offspring genotypes were created: 1.WT:WT:WT (n=6) 2.HT:WT:WT (n=8) 3.HT:WT:HT (n=8) 4.WT:HT:WT (n=5) 5. WT:HT:HT (n=5). Three-month-old male offspring were tested.

Sociability was evaluated using the "Social proximity" test. I/E balance was examined by: 1. susceptibility to seizures induced by Pentylenetetrazol (PTZ). 2. The density of Parvalbumin (PV)+ inter-neurons (sub-population of inhibitory neurons) in the cingulate cortex.

Results: Social deficit was found in all offspring of *Mthfr*+/- parent, affected by maternal and paternal genotypes, both reducing number of social interactions by >40% compared to the offspring of WT ($F_{1,34}= 17.08$, $p<0.001$ and $F_{1,34}= 16.619$, $p<0.001$).

A trend of increased susceptibility to seizures induced by PTZ was found in offspring of *Mthfr*+/- deficient mother ($p=0.07$) and father ($p=0.05$), suggesting alternation in the I/E balance. Lastly, we found changes in the inhibitory system shown by an alternation in the laminar distribution of PV+ neurons in the cingulate cortex in offspring of *Mthfr*+/- parents. Density of PV+ neurons was found to be increased in layer 1 and decreased in layers 4-5 in offspring of *Mthftr*+/- father and mother compared with offspring of two *Mthfr*+/+ parents ($P<0.01$, $P<0.05$).

Altogether, the results of our study show that paternal *Mthfr* genotype influences ASD-like behavior and the I/E balance in the offspring as much as maternal genotype.

Conclusions: These findings could hint that *Mthfr* induced changes in the germ cells mediate the mechanism by which *Mthfr* deficiency affects ASD development. The parental *Mthfr* genotype effect does not seem to be attributed only to the lack of *Mthfr* in the intra-uterine environment as suggested before, but peri-conceptional alternations may be sufficient to predispose the developmental trajectories towards ASD.

We propose our model is multi-factorial, with the development of ASD resulting from several different factors that arise from *Mthfr* genotype.

403.025 *(Poster)* Murine Hearing-in-Noise Testing (HINT) Using Conspecific Ultrasonic Vocalizations (USVs)

***A. E. Luebke**[1], P. Allen[1], P. White[1], H. Beaulac[1] and R. Jonnala[2], (1)University of Rochester Medical Center, Rochester, NY, (2)University of Rochester, Rochester, NY*

Background: Progress on treatments for communication difficulties in ASD has been hindered by lack of animal models with reliable assays of communication processing. Currently, mouse models of ASD have been frequently studied, but the focus has been specifically on the output and repertoire of social vocalizations (Burkett et al. 2015). Moreover, the ability to identify relevant speech signals in one's environment is clearly important for early social development, but also continues to play a critical role in learning and adaptive functioning across the lifespan. For example, a recent study of children with ASDs found that atypical scores on the Short Sensory Profile's Auditory Filtering domain were significantly related to poor academic performance and inattention to cognitive tasks (Ashburner et al, 2008). Children and adolescents with ASD also exhibit significant difficulties hearing in background noise, or auditory filtering.

Objectives: We investigated auditory filtering capabilities using our hearing-in-noise test for the mouse, which makes use of the acoustic startle to assess the mouse's ability to detect prepulse signals/targets presented in quiet or embedded in masking noise. Our prepulse signals/targets were either traditionally used noise bursts or novel conspecific ultrasonic vocalizations (USVs).

Methods: We modified established methods to test acoustic startle abilities behaviorally (Ison et al., 2017) to develop a hearing-in noise test for the mouse (mouse HINT). Our mouse HINT test made use of the acoustic startle response (ASR) and the ability of prepulses to inhibit the ASR [i.e., prepulse inhibition (PPI)] to assess the mouse's ability to detect prepulse signals presented in quiet or embedded in masking noise. We determined signal-to-noise thresholds to both a noise burst (NB) and ultrasonic vocalization (USV) stimuli in quiet and in broadband noise. We assessed these differences to ten different conspecific mouse USVs separately or acoustical combined as "mouse babble" and tested in three mouse strains: C57Bl/6; FVB, 129SvEv, and C57Bl/6 x 129 SvEv. In addition, as mouse pups lacking the CNTNAP2 gene [CNTNAP2 (-/-)] emit less retrieval calls, and exhibit reduced repertoire of syllable vocalizations (Burkett, et al. 2015), we examined USV detection capabilities in mice lacking the CNTNAP2 gene.

Results: We determined there were mouse strain differences in USV discrimination abilities, yet for all strains tested the combination of 10 USVs ("mouse babble") was the most effective startle stimulus in both quiet and background noise, and was more effective as a prepulse stimulus than a noise burst commonly used in ASR testing. Moreover, CNTNAP2 (-/-) mice exhibited less robust startle responses to mouse "babble" in both quiet and background noise.

Conclusions: We conclude conspecific USVs are a more robust and salient auditory target to study prepulse inhibition of acoustic startle than noise burst targets, and the CNTNAP2 (-/-) ASD mouse model not only has limited USV production, but also exhibits limited USV detection and discrimination capabilities. This type of analysis may provide a basis for future therapeutic test platform aimed at reducing auditory behavioral deficits.

Behavioral Genetics

POSTER SESSION — **BEHAVIORAL GENETICS**
404 - Behavioral Genetics Posters

404.001 *(Poster)* Altered Sensory Processing Predicts Reduced Adaptive Functioning in Individuals with and without Autism - a Twin Study

*J. Neufeld[1], **L. Hederos Eriksson**[2], K. Lundin[2], J. Isaksson[2] and S. Bolte[3], (1)Center of Neurodevelopmental Disorders (KIND), Centre for Psychiatry Research; Department of Women's and Children's Health, Karolinska Institutet, & Stockholm Health Care Services, Region Stockholm, Srockholm, Sweden, (2)Karolinska Institutet, Stockholm, Sweden, (3)Center of Neurodevelopmental Disorders (KIND), Centre for Psychiatry Research; Department of Women's and Children's Health, Karolinska Institutet, & Stockholm Health Care Services, Region Stockholm, Stockholm, Sweden*

Background: Altered sensory processing in individuals with Autism Spectrum Disorder (ASD) are gaining increasing attention in recent years and are now included in the DSM-5 diagnostic criteria. Studies indicate that altered sensory processing, such as over-reactivity or hypo-sensitivity to sensory input, can negatively influence an individual's ability to independently master daily living situations (adaptive functioning), which is commonly reduced in individuals with ASD. However, more research is needed to differentiate the effects of sensory processing vs ASD or other neurodevelopmental disorders (NDD) on adaptive functioning. Further, little is known regarding genetic and environmental in influences on this association.

Objectives: We aimed to investigate the potential impact of sensory processing on adaptive functioning beyond the effects of clinical diagnoses and intellectual ability. In addition, we modelled this association both across the sample and within twin pairs in order to assess a potential impact of familial factors.

Methods: We recruited 299 twins (148 pairs; one triplet, 174 monozygotic; aged 10-36 years), of which 62 fulfilled diagnostic criteria for ASD and 61 for other NDDs while 176 did not fulfil diagnostic criteria for any NDD. Sensory processing was assessed using the Adult/Adolescent Sensory Profile (AASP), a 60-item self-report measure differentiating four sub-scales (low registration, sensory sensitivity, sensory seeking and sensory avoiding). Adaptive functioning was assessed using the parent-report Adaptive Behavior Assessment System-II (ABAS-II) and the scaled general adaptive functioning score was used. The association between the four AASP domains and general adaptive functioning was modelled both across the sample and within twin pairs using linear regression analysis while adjusting for ASD as well as other NDD diagnosis and intellectual ability (assessed using the Wechsler Intelligence scale for adults or children). Across individuals, age and sex was also controlled. In order to investigate the possibility that sensory processing affects adaptive functioning differently in individuals with and without ASD, we re-run the models while adding the interaction between AASP sub-scale and ASD diagnosis status (1, 0).

Results: Across the sample, but not within twin pairs, sensory sensitivity and sensory avoiding reduced adaptive functioning beyond diagnoses (b=-.3, SE=.1, p<.005). ASD diagnosis predicted reduced adaptive functioning most strongly, both across individuals (b=-25, SE=3 p<.0001) and within-pairs (b=-19, SE=4, p<.0001). Only the interaction between sensory seeking and ASD diagnosis was significant, and post-hoc analysis revealed a negative association (b=-.8, SE=.3, p<.01) between sensory seeking and adaptive functioning only in individuals diagnosed with ASD but not in individuals with other NDDs or no NDD.

Conclusions: Alterations in certain domains of sensory processing, namely sensory sensitivity and sensory avoiding, predict lower adaptive functioning, even beyond ASD/NDD diagnosis and intellectual ability. This indicates that being unusually sensitive to sensory input or avoiding sensory input more might reduce an individual's ability to independently function in daily life. Only for sensory seeking, the association was different in people with vs without ASD diagnosis, indicating that sensory seeking behaviors in people with ASD diagnoses might be less compatible with adaptive functioning and potentially of a different quality than in individuals without ASD diagnosis.

404.002 *(Poster)* Characterizing the Relationship between Social Impairment and Autism Symptomatology in FOXP1 Syndrome

P. Trelles[1], *H. Walker*[2], *I. Giserman-Kiss*[3], *L. Tang*[2], *D. Halpern*[2], *J. Zweifach*[2], *P. M. Siper*[2], *A. Kolevzon*[2] *and J. Buxbaum*[4], *(1)Icahn School of Medicine at Mount Sinai, New York, NY, (2)Seaver Autism Center, Department of Psychiatry, Icahn School of Medicine at Mount Sinai Hospital, New York, NY, (3)University of Massachusetts Boston, Brookline, MA, (4)Department of Psychiatry, Icahn School of Medicine at Mount Sinai, New York, NY*

Background: FOXP1 syndrome, a rare genetic disorder caused by deletions or mutations of the Forkhead-Box P1 (FOXP1) gene, has been identified as a single gene cause of autism spectrum disorder (ASD). Individuals with FOXP1 syndrome present with an array of neurodevelopmental and behavioral features that span across the spectrum of ASD symptoms, and cause adaptive functioning impairments. Socialization, an adaptive skill at the core of ASD defined as someone's ability to understand and maintain relationships, is universally affected in FOXP1 despite only 25% of individuals meeting full ASD criteria. Factors influencing socialization in ASD broadly are not fully understood and have been the focus of extensive research given its therapeutic implications. To this end, characterizing the relationship between the ASD phenotype in FOXP1 syndrome and socialization impairments stand to provide insight into social functioning in ASD.

Objectives: To characterize the relationship between ASD symptom domains in FOXP1 syndrome and impairment in socialization.

Methods: Eleven caregivers of children with FOXP1 syndrome (7 female; ages 3-15; 25.0% ASD) completed the Social Responsiveness Scale-Second Edition (SRS-2), the Behavior Assessment Symptom for Children (BASC), the Repetitive Behavior Scale-Revised (RBS-R) and the Vineland Adaptive Behavior Scales, 3rd edition (Vineland-3). The SRS-2 provides an objective measure of symptoms associated with autism and produces two subscales which align with DSM-5 criteria: social communication and interaction (SCI), and restrictive interests and repetitive behaviors (RRB). The RBS-R quantifies repetitive behaviors in ASD. The Socialization subscale of the Vineland-3 assesses interpersonal relationships, play and leisure, and coping skills. Associated behavioral features were measured with the BASC. Symptoms known to cause impairments in social functioning were also included for analysis. Pearson coefficient correlations (2-tailed) were used to examine relationships between variables of interest, with significant values compared using Fisher's r to z transformations.

Results: Restrictive and repetitive behaviors were significantly and negatively correlated with the Socialization subscale of the Vineland-3 (SRS-RRB, r = - 0.7, p = 0.009; RBS-R, r = - 0.8, p = 0.03). However, no significant association (all $p > 0.05$) was found between the SRS-SCI subscale, nor with any of the SRS treatment subscales (awareness, cognition, communication and motivation). The adaptive composite of the Vineland was significantly correlated with RBS-R total score (r = - 0.7, p = 0.03). The BASC Hyperactivity was the only clinical scale significantly correlated with the socialization subscale of the Vineland-3 (r = -0.7, p = 0.04). Fisher's transformations didn't find differences between values (all $p>0.5$).

Conclusions: Our results indicate that for children with FOXP1 syndrome repetitive and restrictive behaviors, but not deficits in social communication, are the culprit for impairment in social functioning. Further, as it has been reported in idiopathic ASD, hyperactivity was negatively correlated with social functioning. Interestingly, this association did not extend to other externalizing symptoms. These findings have meaningful implications for the evaluation and treatment of children with FOXP1 syndrome and shed light into the complex interaction between genetics, clinical features and adaptive functioning in ASD. Future studies should include additional observations and measures of cognitive function.

404.003 *(Poster)* Disentangling Autism Heterogeneity through Multivariate Genetic Analyses

M. M. van Donkelaar[1], *C. Figaroa*[1], *E. Verhoef*[1], *S. E. Fisher*[1,2], *D. Rai*[3] *and B. St Pourcain*[1], *(1)Max Planck Institute for Psycholinguistics, Nijmegen, Netherlands, (2)Donders Institute for Brain, Cognition and Behaviour, Nijmegen, Netherlands, (3)Population Health Sciences, Bristol Medical School, Centre for Academic Mental Health, Bristol, United Kingdom*

Background: Autism spectrum disorders (ASD) are complex, heritable and highly heterogeneous neurodevelopmental conditions, and nearly half of the total variance in ASD liability can be attributed to common genetic variation. Clinical symptoms often co-occur with other disorders and there is mounting evidence for a considerable genetic heterogeneity between ASD diagnostic subcategories. Recent research showed that common risk variants appear to be similarly relevant to both high- and low-functioning ASD, as well as to patients with and without *de novo* mutations, involving at least partially distinct aetiological mechanisms. Here, we investigate whether clusters of co-occurring ASD symptoms vary in their common genetic architecture and manifest as multiple, distinct, overarching genetic factors when studying a representative sample of individuals with ASD.

Objectives: In this Simons Foundation-funded study, we aim to disentangle autism heterogeneity through multivariate genetic analysis of co-occurring ASD symptoms using structural models and a case-only design.

Methods: Co-occurring ASD symptoms were collected through online assessment from ~5000 unrelated ASD patients of Caucasian ancestry with genome-wide genetic data (Infinium Global Screening Array-24 v.1.0; Simons Foundation Powering Autism Research for Knowledge (SPARK)). A total of 41 phenotypes related to cognitive, motor, social and language abilities and coexisting psychiatric diagnoses, collected using a Basic Medical Screening Questionnaire, a Background History Form, the Lifetime Social Communication Questionnaire (SCQ), the Repetitive Behavior Scale-Revised (RBS-R), and the Developmental Coordination Disorder Questionnaire (DCDQ), were selected for analysis. Within-sample SNP-heritability (SNP-h_s^2) and genetic correlations (r_{gs}) were estimated using Genome-wide Complex Trait Analysis (GCTA) software, capturing here polygenic heterogeneity. Multivariate genetic-relationship-matrix structural equation modelling (GSEM) was used to model shared and unique genetic aetiologies of co-occurring phenotypes. All traits were adjusted for age, age squared, sex and principal components.

Results: Among SPARK participants with ASD, we find evidence for within sample heterogeneity with respect to RBS-R based ritualistic behaviour (SNP-h_s^2=0.37, SE=0.12, p=0.0016). A similar trend was found for multiple age of onset phenotypes and subscales of the RBS-R and DCDQ (SNP-h_s^2 range=0.18- 0.30), while there was little evidence for within-sample heterogeneity with respect to cognitive ability and trained skills like bladder control, as captured by common variation. The strongest genetic correlations were observed between oppositional defiant disorder and sameness behaviour (r_{gs}=1, SE=0.44, p= 0.0042), between ritualistic and self-injurious behaviour (r_{gs}=0.78, SE=0.25, p= 0.0086), and between reported language delay/disorder and restricted behaviour (r_{gs}=-0.98, SE=0.51, p= 0.0072). Initial GSEM models provide evidence for the existence of a common genetic factor that is shared between language delay/disorder and specific RBS-R subscales.
Conclusions: This study provides evidence for genetic heterogeneity within the common genetic architecture of ASD and identifies genetic links between co-occurring symptoms that suggest symptom-specific overarching genetic factors.

404.004 *(Poster)* The Genetic and Environmental Architecture of the Association between Synesthesia and Autistic Traits - a Twin Study

*M. Taylor[1], T. van Leeuwen[2], R. Kuja-Halkola[1], S. Bolte[3] and **J. Neufeld**[4], (1)Department of Medical Epidemiology and Biostatistics, Karolinska Institutet, Stockholm, Sweden, Stockholm, Sweden, (2)Radboud University, Nijmegen, Netherlands, (3)Center of Neurodevelopmental Disorders (KIND), Centre for Psychiatry Research; Department of Women's and Children's Health, Karolinska Institutet, & Stockholm Health Care Services, Region Stockholm, Stockholm, Sweden, (4)Center of Neurodevelopmental Disorders (KIND), Centre for Psychiatry Research; Department of Women's and Children's Health, Karolinska Institutet, & Stockholm Health Care Services, Region Stockholm, Srockholm, Sweden*

Background: Synesthesia is a non-pathological sensory condition where certain sensory stimuli lead to additional sensations in the same or a different sensory modality. Synesthesia is a heritable condition and prevalent at ~4% of the general population. Further, it co-occurs with Autism Spectrum Disorder (ASD) and similar to individuals with ASD, synesthetes differ from the general population in their perceptual profiles including sensory sensitivity and attention to details. This suggests that there might be a link between the two conditions. However, the genetic and environmental contributions to this association are unknown. Moreover, previous studies indicate that synesthesia is more strongly associated with autistic traits from the non-social domain (restricted/repetitive patterns of behaviors and interests; RRBI), while studies in this research area sparse.
Objectives: We investigated the genetic-environmental architecture underlying the association between synesthesia and ASD in an ongoing population based twin study. Further, we explored whether the association might be restricted to the RRBI trait domain.
Methods: For this preliminary analysis, we selected all to date collected same-sex twin-pairs from the Child and Adolescent Twin Study in Sweden (CATSS) who completed a short screening for synesthesia at age 18yrs (N=288 twin pairs of which 128 were monozygotic and 159 were dizygotic) when filling in a large online survey on mainly their mental and physical health. On the synesthesia screening, participants rated whether and to what extent they believe to experience eight different types of synesthesia and the total sum score was used as synesthesia trait measure. Twins also completed the Autism-Tics, ADHD and other Comorbidities inventory (A-TAC), which assesses autistic traits and co-morbid problems. Classic twin modelling was conducted in R (OpenMx), modelling the impact of additive genetics (A), shared environment (C) and non-shared environment (E) on the association between synesthesia traits and ASD traits. Further, non-parametric correlations were used to explore the association between synesthesia traits and the three domains of the autistic traits measure from the A-TAC.

Results: The association between synesthesia and ASD was largely genetic (95%) and the shared environment component (including all non-genetic factors that make twins similar to each other) was dropped since including it did not improve model fit (p=.9). The correlation between synesthesia and general ASD traits was small (Spearman's rho=.1; p=.008) and driven by the RRBI sub-scale alone (Spearman's rho=.1; p=.003) while the other two sub-scales (social and communication domains) did not correlate with synesthesia (Spearman's rho=.04; p>.1).
Conclusions: We conclude that the association between self-reported synesthesia traits and self-reported autistic traits is small, largely genetic, and driven by the RRBI domain of the autism spectrum. The results need to be replicated in a larger sample. However, they do provide a first insight into the genetic and environmental contribution to the association between synesthesia and ASD.

Behavioral Neuroscience

POSTER SESSION — **BEHAVIORAL NEUROSCIENCE**
405 - Behavioral Neuroscience Posters

405.001 *(Poster)* A Behavioral and Neural Analysis of Inhibitory Control in Toddlers and Preschoolers with and without ASD

***G. A. MacNaughton**[1], A. M. Cremone-Caira[2], V. E. Sanchez[3] and S. Faja[4], (1)Boston Children's Hospital: Labs of Cognitive Neuroscience, Boston, MA, (2)Boston Children's Hospital Labs of Cognitive Neuroscience, Boston, MA, (3)Division of Developmental Medicine, Boston Children's Hospital, Boston, MA, (4)Boston Children's Hospital, Boston, MA*

Background: Impairments in executive function (EF), higher-order cognitive functions that underlie goal-directed behaviors, have been identified in many children with Autism Spectrum Disorder (ASD). However, behavioral studies have not shown how or when EF impairments may develop in this population. Electrophysiological measures (i.e., electroencephalogram (EEG)) may increase understanding of brain-behavior relationships related to prefrontal cognitive processes, such as EF (Bell & Cuevas, 2012). However, this combined approach to measuring EF among preschoolers with ASD has not yet been examined.
Objectives: To compare EF development on a behavioral and neural level in children (two- and four-year-olds) with and without ASD.

Methods: Two- and four-year-old children with ASD (n=31) and typically developing (TD) controls (n=35) completed lab-based tasks that measured EF. Consistent with previous studies, EF behavior was assessed by performance on two looking tasks (A-not-B; Bell & Adams, 1999 and A-not-B with invisible displacement (ID); Morasch & Bell, 2011). The total number of correct reversals summed across both tasks was used as the primary measure of inhibitory control of a prepotent response, a principal component of EF. Higher scores indicated better performance. Additionally, the relation between autism symptoms and EF was assessed based on scores from the Autism Diagnostic Observation Schedule collected at the baseline visit (ADOS-2; Lord et al., 2008). Finally, EEG data was recorded on a 128-channel Hydrocel Geodesic Sensor net during EF tasks (A-not-B: two-year-olds n=17, four-year-olds: n=36; A-not-B with ID: two-year-olds: n=14, four-year-olds: n=28). Four minutes of continuous EEG data was collected using NetStation software (Electrical Geodesics Inc., Eugene, OR) during EF tasks. EEG data will be processed using the BEAPP (Levin et al., 2018) pipeline. The 6-9Hz alpha frequency will be examined following prior studies (e.g., Morasch & Bell, 2011).

Results: A series of ANCOVAs controlling for developmental level showed that the TD group performed significantly better than the ASD group on the collapsed EF score ($F(1,65)=31.29$, $p<.001$; TD: $M=6.80$ $SD=2.157$, ASD: $M=3.48$ $SD=2.35$) and the individual EF tasks: A-not-B ($F(1,58)=21.97$, $p<.001$, TD: $M=5.16$ $SD=1.37$, ASD: $M=3.11$ $SD=2.00$) and A-not-B with ID ($F(1,57)=10.28$, $p=.002$; TD: $M=2.10$ $SD=.98$, ASD: $M= 1.00$ $SD=.85$). Additionally, a bivariate correlation indicated a significant negative moderate relation between the total ADOS Score and EF ($r(15)=-.489$, $p<.05$) among two-year-olds with ASD; no relation was detected among four-year-olds.

Conclusions: Results of the current study suggest that young children with ASD display EF impairment. Results also showed a relation between autism symptoms and EF. Specifically, two-year-olds with more severe autism symptoms showed greater impairments in EF, consistent with the developmental level for which the A-not-B task was designed. Research has indicated that executive dysfunction is common among those with ASD. Individual differences in emerging EF within this population may provide a means of understanding heterogeneity in early symptom expression. In the coming months, we will continue to collect and analyze EEG data from this EF task, which will be presented with behavioral data. This may increase understanding of neurocognitive processes within ASD preschoolers on a behavioral and neural level.

405.002 *(Poster)* Altered ERPs during Reversal Learning Provides Clues to Behavioral Rigidity in Fragile X Syndrome

L. M. Schmitt[1,2], *J. Li*[3], *M. Rogers*[1], *N. Friedman*[1], *D. Chin*[1], *R. Liu*[4], *E. Pedapati*[1,2], *C. A. Erickson*[1,2] *and J. A. Sweeney*[5], *(1)Cincinnati Children's Hospital Medical Center, Cincinnati, OH, (2)University of Cincinnati College of Medicine, Cincinnati, OH, (3)University of Oklahoma, Norman, OK, (4)Psychiatry, Cincinnati Children's Hospital Medical Center, Cincinnati, OH, (5)Psychiatry and Behavioral Neuroscience, University of Cincinnati College of Medicine, Cincinnati, OH*

Background: Fragile X Syndrome (FXS) is the most common inherited intellectual disability and monogenic cause of autism spectrum disorder. Behavioral flexibility, or the ability to shift and maintain new behavioral responses based on changes in environment, is highly impaired in FXS. Behavioral rigidity may look like resistance to change in routines and increased anxiety in novel or unexpected situations. Parent-report measures and neuropsychological test document behavioral flexibility deficits in FXS. Still the component neural processes underlying these deficits remain unclear. With limited mechanistic understanding, treatment development and symptom relief is stalled.

Objectives: Using a Reversal Learning EEG paradigm, we aimed to identify brain processes affecting behavioral rigidity in FXS. Ultimately, we hope to help the identification of potential translational biomarkers of behavioral rigidity in FXS in order to enhance disease understanding and advance treatment development.

Methods: Fifteen participants with full-mutation FXS (8 female, aged 15-45 years) and 15 typically-developing controls (TDC; age- and sex-matched) completed a deterministic reversal learning paradigm during continuous EEG recording using the 128-channel EGI system. Participants were instructed to select the box in the correct location (as indicated by coin). Unexpected reversals in behavioral response preference (as indicated by red 'X') occurred randomly following 3-5 consecutive correct responses. Data were epoched from -500 to 800 ms with respect to the onset of feedback stimuli (coin or red X). We examined three ERP components, each occurring following feedback onset: N1, P3a, P3b. ERPs were defined as the minimum or maximum amplitudes in a time window centered on the grand average peak amplitude +/- 50 ms. Average amplitude and latency of each peak were calculated for each participant.

Results: Individuals with FXS performed as well as TDC based on the number of reversals achieved. N1, P3a amplitudes were greater for FXS than TDC, for both reversal and non-reversal feedback. P3b was of greater amplitude and occurred later in the FXS group relative to TDC group for both trial types. Parent-rated social avoidance and stereotypy predicted P3b amplitude and latency during reversal trials.

Conclusions: Though individuals with FXS performed as well as controls during a reversal learning task, individuals with FXS demonstrated hyper-responsiveness to visual feedback stimuli. This is consistent with findings of sensory hyper-responsiveness previously identified in sensory and association cortices, suggesting cortical hyper-excitability also is present in the frontal-striatum-parietal circuitry critical for behavioral flexibility. Differences in the time course and power related to task updating suggest individuals with FXS may require prolonged duration and use different cortical mechanisms to process feedback when determining whether a subsequent behavior change is needed. Importantly, these brain-based biomarkers were linked to parent-reported clinical features of behavioral rigidity. Clinically, our findings indicate 1) visual feedback regarding the continuation (or not) of behavior may be overwhelming and 2) it may be subsequently harder to decide what to do with the feedback information, thus requiring additional time to process feedback and change behavior. Together, our findings implicate targeting hyper-responsiveness and task updating processes for future therapeutic interventions and translation to preclinical models.

405.003 *(Poster)* Altered Striatum Centered Brain Structures in SHANK3 Deficient Chinese Children with Genotype and Phenotype Profiling

C. Liu[1], *D. Li*[1], *H. Li*[1], *Q. Xu*[1], *C. Hu*[1], *B. Zhou*[1], *Y. Wang*[1], *Y. H. Jiang*[2] *and X. Xu*[1], *(1)Children's Hospital of Fudan University, Shanghai, China, (2)Duke University, Durham, NC*

Background: *SHANK3* deficiency represents one of the most frequent, monogenic risk factor for autism spectrum disorder (ASD) and *SHANK3* caused ASD presents a unique opportunity to understand the underlying neuropathological mechanisms of ASD.

Objectives: To investigate the neuromorphometry and clinical characteristics of Chinese children with *SHANK3* deficiency by neuroimaging and neurobehavioral evaluation.

Methods: This is a case control study. Subjects were recruited and conducted from Aug 1, 2015 to Aug 31, 2017 in the Neurodevelopment Clinic of Children's Hospital of Fudan University. Among the total of 72 children participating in the study, 14 children have confirmed *SHANK3* genetic mutations, 26 have idiopathic ASD without *SHANK3* and other common genetic defect, and 32 were typically developing children as controls. Genetic tests, comprehensive clinical and neurobehavioral evaluations, as well as brain imaging were conducted for these subjects. Genetic mutations including chromosomal deletions and point mutations of *SHANK3* were identified or confirmed by MLPA, chromosome microarray, WES or Sanger sequencing methods. Comprehensive clinical and neurodevelopment evaluations including diagnostic evaluation of ASD were performed by experienced development pediatrician or certified ADOS and ADI-R administrators. Differences in quantitative grey matter indices were assessed using voxel-based morphometry (VBM) while in white matter were analyzed with tract-based spatial statistics.

Results: Phenotypically, we described several previously unreported clinical features and manifestations including nostril eversion (100%), sensory stimulus seeking (64%), dental abnormalities (43%), hematological problem (21%) and prominent granulation tissue (7%), as well as common features of *SHANK3*-related ASD and chromosome 22q13.3 deletion (i.e. Phelan-McDermid syndrome, PMS) consisting of hypotonia, global developmental delay, and mild dysmorphic features.

For the grey matter, VBM analysis revealed decreased gray matter volume (GMV) in dorsal striatum, amygdala, hippocampus and parahippocampal gyrus ($P < 0.05$, corrected for family-wise error, FWE). For the white matter, tract-based spatial statistics (TBSS) results demonstrated decreased FA in multiple tracts mainly with projection fibers and association fibers, including internal capsule, external capsule, cerebral peduncle, sagittal stratum, and etc. ($P < 0.05$, FWE corrected).

Conclusions: For the first time, we report that the disrupted striatum centered brain structures, both in grey and white matter, are associated with *SHANK3* deficient children. Monogenic samples of current study offer specific insights into the neuroimaging studies of ASD. The discovery may suggest a path for future functional connectivity studies to allow for more in-depth understandings of the abnormal neural circuits and the underlying neuropathological mechanisms.

405.004 *(Poster)* Neuroimaging Evidence of Social Subtypes of Autism Spectrum Disorder

D. Cochran[1,2], *C. Haselgrove*[2], *J. Frazier*[1,2] *and D. Kennedy*[1,2], *(1)Psychiatry, UMass Medical School, Worcester, MA, (2)EK Shriver Center, UMass Medical School, Worcester, MA*

Background: Research into the neurobiology of autism spectrum disorders (ASD) is complicated by the broad heterogeneity of the disorder, leading to inconsistent or irreproducible results. The Research Domain Criteria (RDoC) framework proposed by NIMH provides an alternative, dimensional look at social processes affected in ASD, providing a mechanism for exploring the heterogeneity and identifying social subtypes of the disorder.

Objectives: The Social Responsiveness Scale (SRS) provides a measure of dimensions of social cognition that are known to be impaired in ASD. We used the ABIDE database to discover evidence of social subtypes of ASD based on different patterns of profiles of SRS subscale scores (Social Awareness, Social Cognition, Social Communication, Social Motivation), and determined whether these subtypes have distinct neurobiological profiles as evidenced by resting state functional connectivity.

Methods: We extracted clinical and resting state functional connectivity data from the ABIDE database for all subjects with SRS total scores and subscale scores. The resulting sample included 332 individuals with ASD and 396 neurotypical individuals. We analyzed profiles of SRS subscale scores normalized by the total SRS score to control for ASD severity. We used finite mixture modeling to analyze the ASD sample assuming two or more groups with distinct profiles of SRS subscale scores. We performed resting state functional connectivity seed-to-voxel analyses using Conn toolbox with 2 seeds in the default mode network (medial prefrontal cortex and posterior cingulate/precuneus) and 2 seeds in the salience network (anterior cingulate cortex and right anterior insula). We identified regions of significant differences in connectivity between the entire ASD group and neurotypical group, and performed similar analyses between each identified subtype and the neurotypical group.

Results: We identified four distinct social subtypes with different profiles of SRS subscale scores: groups with 1) similar deficits across subscales (low awareness, low motivation; N = 98, 28.5%); 2) relative deficits in social awareness but relative strength in social motivation (low awareness, high motivation; N = 40, 12.8%); 3) relative strength in social awareness but deficit in social motivation (high awareness, low motivation; N = 89; 26.5%); and 4) relative strengths in both social awareness and social motivation (high awareness, high motivation; N = 105, 32.2%). The overall ASD group showed significant underconnectivity within the default mode network, and significant regions of underconnectivity within the salience network and between the salience network and regions in language networks, attentional networks, and visual processing regions. Each subtype had unique connectivity patterns contributing to the overall group connectivity differences, including some differences in connectivity that were not seen in the overall group.

Conclusions: We found evidence of distinct social subtypes of ASD with unique contributions to the overall functional connectivity differences between individuals with ASD and neurotypical controls. These subtypes, identified using a dimensional representation of social processes similar to the RDoC framework, may explain some of the heterogeneity and irreproducibility of neuroimaging findings in ASD. Better characterization of these subtypes may identify more homogeneous groups of individuals with ASD that allows for better development of targeted treatments for these subpopulations.

405.005 *(Poster)* Scaling Motor Output to a Dynamic Visual Target Is Impaired in Children with Autism Spectrum Disorder

D. E. Lidstone *and S. H. Mostofsky, Center for Neurodevelopmental and Imaging Research, Kennedy Krieger Institute, Baltimore, MD*

Background: Visuomotor integration (VMI) impairment may be a core feature underlying social and motor impairments associated with Autism Spectrum Disorder (ASD). In children with ASD, functional connectivity between visual and motor areas is lower vs. TD controls and tasks requiring rapid integration of visual input into motor commands, such as imitation, are impaired. A simple method to examine the nature of VMI impairments in ASD is to examine motor responses when VMI demands are low vs. high. In this study, children were asked to match grip-force output with either a static target force (low-VMI demand) or a dynamic target force (high-VMI demand). It was hypothesized that error in the dynamic task would be greater in the ASD vs. TD groups with no group differences observed for the static task.

Objectives: The purpose of this study was to examine the effect of increasing VMI demands on the motor output of children with ASD.
Methods: Thirty-nine (ASD=18; TD = 21) right-handed children (7-17 years old) participated in this study. There was no significant difference in age between groups (TD = 11.9±2.7; ASD = 12.6±2.7; $p = 0.23$). First, participants completed three maximal voluntary isometric contractions (MVIC) squeezing a force transducer between their index finger and thumb. The best of three attempts was recorded as the MVIC. Next, the static and dynamic force tracking tasks were performed. The static force tracking task involved maintaining a cursor within a target set at 15% of the participants MVIC for 20-s. The dynamic task involved tracking a ramp-up target from 0-25% MVIC over 10-s followed by a ramp-down from 25-0% MVIC over 10-s. The between-trial rest period was 20-s. Five trials were performed and relative root mean square error [rRMSE(%)] was calculated. A two-way ANCOVA was conducted to examine GROUP (ASD vs. TD) and TASK (static vs. dynamic) specific differences on rRMSE. Age was used as a covariate for the two-way ANCOVA.
Results: There was a statistically significant (group x task) interaction observed on relative error, $F_{(1,73)} = 4.418$, $p = 0.039$, partial $\eta^2 = 0.057$. Main effects of task revealed no group differences in the static task ($p = 0.36$), but a significant effect was observed in the dynamic task ($p = 0.0002$).
Conclusions: Here, we show that children with ASD are more impaired during a dynamic vs. a static grip-force control task compared to TD controls. The findings suggest impaired integration of dynamic visual input into motor commands. Future studies should examine: (1) associations of dynamic grip-force tracking with imitation and social skill measures to better understand the link between VMI impairment and core features of ASD; and (2) cortical activation patterns during dynamic force tracking to better understand the neurological basis of dynamic VMI deficits in children with ASD.

405.006 *(Poster)* The Correlation between Parental Stress and Temperament in Young Children at Elevated Likelihood of Autism

*H. Elsayed[1], **M. E. Jaramillo**[2], G. T. Baranek[3] and L. R. Watson[4], (1)Allied Health sciences, University of North Carolina, Chapel Hill, NC, (2)University of North Carolina, Chapel HIll, Chapel Hill, NC, (3)Chan Division of Occupational Science and Occupational Therapy, University of Southern California, Los Angeles, CA, (4)Department of Allied Health Sciences, University of North Carolina at Chapel Hill, Chapel Hill, NC*

Background: Caregivers of children with autism spectrum disorder (ASD) have more parenting stress than those of children with other developmental disorders (Estes et. al., 2009). High parental stress can negatively impact child outcomes and a family's response to early intervention. Furthermore, levels of parent stress may be related to child characteristics, such as temperament. Temperament factors measured in infancy show considerable stability into toddlerhood (Casalin et al., 2012), making child temperament and parental stress important considerations in parent-mediated early interventions.
Prior research indicates that the most affected temperament domain in children with ASD is effortful control, and its subdomains of attention focusing, attention shifting, and inhibitory control (Janes 2001; Konstantareas & Stewart 2006; Landry 1998). Additionally, parents report that children with ASD have greater negative affect, displaying more discomfort and less sootheability than children without ASD (Konstantareas & Stewart 2006). We therefore hypothesized that aspects of temperament that characterize children diagnosed with ASD, namely effortful control and negative affect, would significantly correlate with stress in parents of 14-month-olds at elevated likelihood of ASD (EL-ASD).
Objectives: The aim of the present study was to better understand how child temperament is associated with parent stress in young toddlers at EL-ASD.
Methods: We conducted a correlational analysis to determine the relationship between parent stress and child temperament. Our sample included ninety-six children identified via screening with the First-year inventory as at EL-ASD (65.6% male, 34.4% female, mean age = 13.74 months) and a parent of each child. Parents completed the Early Childhood Behavior Questionnaire (ECBQ) and Parental Stress Scale (PSS). The ECBQ (temperament measure) comprises 107 questions in 3 broad temperament domains: surgency, negative affectivity and effortful control. The PSS has 18 questions answered on a Likert scale, covering topics such as whether the respondent feels overwhelmed with parenting responsibilities, embarrassed by their child's behavior, and happy as a parent.
Results: There was a significant negative correlation between the total parent stress score and the effortful control domain mean score ($r = -.313$, $p < .002$), as well as several subdomain scores under effortful control: cuddliness ($r = -.284$, $p < .005$), inhibitory control ($r = -.245$, $p < .016$) and low intensity pleasure ($r = -.239$, $p < .019$)
Conclusions: Effortful control, one of the most affected temperament domains in children with ASD, was most strongly negatively correlated with parental stress in young toddlers at EL-ASD. The inhibitory control subdomain was significantly negatively correlated with parental stress, whereas attention focusing and attention shifting were not (although these are significantly affected in children with ASD). The effortful control subdomains of cuddliness and low intensity pleasure were also significantly correlated with parental stress; however, no correlation was found between parental stress and negative affectivity, despite reports that children with ASD have greater negative affectivity than children with other disabilities. Future research could investigate whether parent-mediated intervention strategies that target children's development of effortful control, including inhibitory control, cuddliness and low intensity pleasure, may contribute to some reduction in parental stress.

405.007 *(Poster)* Title: Heart Rate Variability in Children with Autism Spectrum Disorder

***R. Thapa**[1], A. J. Guastella[1], E. E. Thomas[2], I. Pokorski[1], M. DeMayo[1], I. Sadeli[1], I. Hickie[3], S. Patel[1], M. Slade[4], Z. Ambarchi[1] and K. A. Boulton[1], (1)Brain and Mind Centre, Children's Hospital Westmead Clinical School, Faculty of Medicine and Health, University of Sydney, Sydney, NSW, Australia, (2)Anxiety Clinic Australia, Sydney, Australia, (3)Brain and Mind Centre, Central Clinical School, Sydney Medical School, University of Sydney, Sydney, NSW, Australia, (4)Faculty of Medicine and Health, Pharmacology, School of Medical Sciences, Sydney, ACT, Australia*

Background: Reduced heart rate variability (HRV) is regarded as one reliable index of autonomic dysfunction for cardiovascular risk. It has been linked to poorer physical, mental and social well-being outcomes and has been suggested as a potential biomarker for social development. Although the pathophysiology of autonomic nervous system (ANS) function in young children with autism spectrum disorder (ASD) is not well understood, a number of studies have found reduced HRV in comparison to neurotypical children.

Objectives: The objective of this current study was to measure and compare resting-state HRV parameters in children diagnosed with ASD and neurotypical children. We predicted that resting–state HRV measures would be reduced in ASD compared to neurotypical cohort. We further predicted that medication status and severity of symptoms would additionally moderate HRV responses.

Methods: A total of 86 children diagnosed with ASD, aged between 3 and 12 years were compared to 44 neurotypical children of similar age. Twenty-seven of participants were prescribed psychotropic medication, which included selective serotonin reuptake inhibitors (SSRIs) (*n*=26) and serotonin and norepinephrine reuptake inhibitors (SNRIs) (*n*=10). Laboratory assessment of HRV involved five minutes of non-invasive baseline electrocardiogram (ECG) assessments while participants viewed an age-appropriate non-verbal animation. Time-domain and frequency-domain HRV measures were analysed. ASD symptoms severity was assessed using the Autism Diagnostic Observation Schedule-Second Edition (ADOS-2) and Social Responsiveness Scale (SRS-2).

Results: Results indicated that children with ASD showed lower HRV compared to neurotypical children on two of the four HRV measures; high frequency (HF) and root mean square of successive difference (RMSSD). Interestingly, however, sub-group analysis suggested this difference was only significant for those children receiving psychotropic medication, in comparison to neurotypical children. Our data also suggested that there was no evidence to suggest a relationship between HRV and social impairment symptoms in the ASD group, with only the repetitive- behaviour domain of the ADOS associated with some HRV measures, RMSSD.

Conclusions: Overall, our finding suggests lower HRV in children with ASD relative to neurotypical children, but this difference may be specific to those children taking psychotropic medication. Moreover, our results only provide limited evidence that HRV was associated with the severity of symptoms. This study supports further investigation of HRV as a possible surrogate physiological marker associated with autonomic dysfunction and, potentially, severity of ASD symptoms. These results may help us understand what underlies autonomic nervous system dysfunction and the potential pathophysiological mechanisms leading to increased cardiovascular risk in ASD.

Biomarkers (molecular, phenotypic, neurophysiological, etc)

PANEL SESSION — BIOMARKERS (MOLECULAR, PHENOTYPIC, NEUROPHYSIOLOGICAL, ETC)
202 - The Autism Biomarkers Consortium for Clinical Trials: Final Analyses

Panel Chair: James McPartland, *Child Study Center, Yale University School of Medicine, New Haven, CT*

Discussant: Lisa Gilotty, *NIMH, Rockville, MD*

The Autism Biomarkers Consortium for Clinical Trials (ABC-CT) is a US-based network designed to develop objective measures to sensitively and validly quantify ASD symptomatology and its change in clinical trials and to stratify ASD into meaningful subgroups. This symposium presents, for the first time, results from analyses of the complete ABC-CT sample, comprising 399 children aged 6 to 11 years, at three time points spanning six months. This panel brings together research centers distributed across the US, with male and female panelists ranging from early career faculty to tenured researchers. The first lecture will provide an overview of study design, with focus on unique elements of the approach to biomarker development and outcomes in terms of FDA biomarker qualification. The second lecture will present clinical data from the full sample with an emphasis on defining and detecting clinically meaningful change during a naturalistic study, and the third and fourth lectures will provide biomarker results obtained from EEG and eye-tracking, respectively, with an emphasis on factors that influence shorter term test-retest reliability and longer term stability. The discussion will focus on the state of biomarker development for ASD, challenges for this field, and novel approaches to overcoming these challenges.

202.001 *(Panel)* The Autism Biomarkers Consortium for Clinical Trials: Study Design and Progress to Biomarker Qualification

J. McPartland[1], *S. J. Webb*[2], *F. Shic*[3], *A. Naples*[1], *C. Sugar*[4], *M. Murias*[5], *G. Hellemann*[6], *D. Senturk*[6], *J. Dziura*[7], *C. Brandt*[7], *R. Bernier*[2], *K. Chawarska*[1], *G. Dawson*[8], *S. Faja*[9], *S. Jeste*[4] *and C. A. Nelson*[10], *(1)Child Study Center, Yale University School of Medicine, New Haven, CT, (2)Psychiatry and Behavioral Sciences, University of Washington, Seattle, WA, (3)Center for Child Health, Behavior and Development, Seattle Children's Research Institute, Seattle, WA, (4)University of California, Los Angeles, Los Angeles, CA, (5)Duke Center for Autism and Brain Development, Department of Psychiatry and Behavioral Sciences, Duke University, Durham, NC, (6)UCLA, Los Angeles, CA, (7)Yale University, New Haven, CT, (8)Department of Psychiatry and Behavioral Sciences, Duke Center for Autism and Brain Development, Durham, NC, (9)Boston Children's Hospital, Boston, MA, (10)Boston Children's Hospital/Harvard Medical School, Boston, MA*

Background: Autism spectrum disorder (ASD) is a highly prevalent neurodevelopmental condition for which there are currently no biomarkers validated for use in clinical trials. The objective of the Autism Biomarkers Consortium for Clinical Trials (ABC-CT) is to investigate the utility of well-evidenced electroencephalography (EEG) and eye-tracking (ET) measures as potential biomarkers for clinical research.

Objectives:

The goals of the ABC-CT are to: (1) evaluate candidate biomarkers in terms of feasibility of implementation, cross-site reliability of data collection, construct validity, discrimination between ASD and typical development (TD), stratification within ASD, developmental stability/sensitivity to change, and predictive value; (2) compare biomarkers to conventional clinician and caregiver assessments; (3) create a public repository spanning genetics, biomarkers, and clinical and behavioral information; and (4) establish an infrastructure optimized for the conduct of future clinical trials.

Methods: The ABC-CT main study commenced in October 2016, with an objective of recruiting 200 rigorously characterized children with ASD (6-11 years; IQ 60-150) and 75 typically developing (TD) control subjects into a longitudinal naturalistic design with three time points (Baseline, 6 weeks, 24 weeks). A biomarker protocol was carried out identically at each timepoint at five sites in accordance with Good Clinical Practice standards. Biomarkers (4 EEG, 5 ET, blood draw) were selected based on strength of existing evidence and relevance to social-communication. Data were collected and analyzed with a high level of methodological rigor, with an explicit pre-specified statistical plan designating a single dependent variable as primary for each biomarker and specifying directional hypotheses of between group effects. A unique study governance brought together diverse expertise spanning academia, government, industry, and collaborating consortia to facilitate progress from discovery to biomarker qualification.

Results: ABC-CT main study data collection was completed in May, 2019. Recruitment milestones were exceeded, and longitudinal attrition was minimal, with 399 children (280 with ASD, 119 TD) enrolling in the study and 374 (260 with ASD, 114 TD) completing the study. Data acquisition procedures were highly successful, with valid data acquisition rates averaging approximately 90% across biomarker data modalities, and 77% of probands contributing genetic samples. In May, 2019, a Letter of Intent for an EEG biomarker, N170 Latency to Upright Human Faces, was accepted into the FDA's Center for Drug Evaluation and Research Biomarker Qualification Program. In November, 2019, a second Letter of Intent was submitted for an ET biomarker, the Oculomotor Index of Orienting to Human Faces. Panels in this symposium will provide report of data from full study sample across time points.

Conclusions: The ABC-CT and similar consortia are advancing the goal of clinically practicable biomarkers by investigating well-evidenced biomarkers in large, well-characterized cohorts in the context of a longitudinal design. Progress is evidenced by engagement with regulatory agencies in developing the first biomarker qualification plans for neurodevelopmental conditions. The use of economical, scalable biomarker technologies holds promise for eventual deployment in a broader range of clinical and research contexts.

202.002 *(Panel)* The Autism Biomarkers Consortium for Clinical Trials: Clinical Characteristics and Evaluation of Clinical Measures Commonly Used in Clinical Trials

S. Faja[1], *M. Sabatos-DeVito*[2], *R. Bernier*[3], *G. Dawson*[4], *K. Chawarska*[5], *S. Jeste*[6], *C. A. Nelson*[7], *S. J. Webb*[3], *F. Shic*[8], *A. Naples*[5], *C. Sugar*[6], *M. Murias*[9], *G. Hellemann*[10], *D. Senturk*[10], *J. Dziura*[11], *C. Brandt*[11] *and J. McPartland*[5], *(1)Boston Children's Hospital, Boston, MA, (2)Psychiatry and Behavioral Sciences, Duke Center for Autism and Brain Development, Durham, NC, (3)Psychiatry and Behavioral Sciences, University of Washington, Seattle, WA, (4)Department of Psychiatry and Behavioral Sciences, Duke Center for Autism and Brain Development, Durham, NC, (5)Child Study Center, Yale University School of Medicine, New Haven, CT, (6)University of California, Los Angeles, Los Angeles, CA, (7)Boston Children's Hospital/Harvard Medical School, Boston, MA, (8)Center for Child Health, Behavior and Development, Seattle Children's Research Institute, Seattle, WA, (9)Duke Center for Autism and Brain Development, Department of Psychiatry and Behavioral Sciences, Duke University, Durham, NC, (10)UCLA, Los Angeles, CA, (11)Yale University, New Haven, CT*

Background: The investigation of interventions for ASD has traditionally relied on clinician rating scales and parent surveys, which are not necessarily sensitive to treatment-related changes and introduce potential for bias when used to measure interventions that are difficult to mask from clinicians and families. The design of the ABC-CT provides an opportunity to directly compare these measures with respect to test-retest reliability, discriminant and convergent validity, and sensitivity to intensity and changes in treatment as usual. The project also provides an opportunity to examine the feasibility of collecting reliable clinical data over three timepoints by a five-site consortium.

Objectives: To examine the characteristics of the final ABC-CT sample as well as the final analyses of the battery of clinical social communication measures and a lab-based measure of face recognition. We report convergent validity, discrimination of diagnostic status, test-retest validity, and sensitivity to naturalistic treatment intensity and changes.

Methods: The final sample included 280 children (65 girls) with ASD and 119 (36 girls) with typical development (TD). Ages ranged from 6 to 11 years over the course of the study with no difference between diagnostic groups, $F(1,397)=0.0$, $p=.85$. Groups were stratified based on age and best estimate of cognitive functioning on the Differential Ability Scales (DAS-2; Elliott, 2007). FSIQ scores ranged from 60-150 for the group with ASD, $M=96.6(18.1)$. Children without ASD had significantly higher IQ, $M=115.1(12.5)$, $F(1,397)=103.4$, $p<.01$. Clinical measures included: CGI-Severity (Guy, 1976), Vineland-3 (Sparrow, Cicchetti, Saulnier, 2017), PDDBI (Cohen et al., 2003), SRS-2 (Constantino, 2012), and AIM (Kanne et al., 2014). A lab-based measure of facial recognition, NEPSY-II Memory for Faces subtest (Korkman, Kirk, & Kemp, 2007), was also administered at each time point. An intervention history measure was developed to evaluate the intensity of interventions received beginning 6 weeks prior to baseline and continuing throughout the 24 week study period.

Results: Clinical measures generally had moderate to strong correlation with one another (rs=.45-.73, ps<.001), suggesting excellent convergent validity within the group with ASD. As expected all measures were also sensitive to group status (Fs>53.3, ps<.001), although the CGI was not administered for TD children. The lab based measure, NEPSY-2 Memory for Faces, also discriminated groups, $F(2,214)=16.50$, $p<.001$, and had small to moderate correlations with clinical measures (rs=.08-.42). Overall, test-retest reliability across a 6-week period was variable across measures and groups (ICCs=.35-.98). Analyses to examine the sensitivity of these clinical measures to treatment as usual are in progress.

Conclusions: ABC-CT provides a direct comparison of standard clinical measures that are commonly utilized in clinical trials for ASD as well as a lab-based social measure of face recognition. This information may be useful in guiding selection of social measures for clinical trials by confirming which traditional measures are feasible in a multisite trial and comparing convergent validity, discrimination of groups, and test-retest reliability. Of particular interest will be the sensitivity of these measures to naturalistic changes in treatment as usual during the school-aged period. The ABC-CT "scorecard" approach may enable better selection of primary outcomes for future studies.

202.003 *(Panel)* The Autism Biomarkers Consortium for Clinical Trials: EEG Biomarker Analyses

S. J. Webb[1], *A. Naples*[2], *A. R. Levin*[3], *G. Hellemann*[4], *C. Sugar*[5], *D. Senturk*[4], *J. T. Benton*[6], *H. M. Borland*[6], *C. Carlos*[2], *T. McAllister*[2], *M. Santhosh*[6], *F. Shic*[6], *M. Murias*[7], *J. Dziura*[8], *C. Brandt*[8], *R. Bernier*[1], *K. Chawarska*[2], *G. Dawson*[9], *S. Faja*[10], *S. Jeste*[5], *C. A. Nelson*[11] *and J. McPartland*[2], *(1)Psychiatry and Behavioral Sciences, University of Washington, Seattle, WA, (2)Child Study Center, Yale University School of Medicine, New Haven, CT, (3)Neurology, Boston Children's Hospital, Boston, MA, (4)UCLA, Los Angeles, CA, (5)University of California, Los Angeles, Los Angeles, CA, (6)Center for Child Health, Behavior and Development, Seattle Children's Research Institute, Seattle, WA, (7)Duke Center for Autism and Brain Development, Department of Psychiatry and Behavioral Sciences, Duke University, Durham, NC, (8)Yale University, New Haven, CT, (9)Department of Psychiatry and Behavioral Sciences, Duke Center for Autism and Brain Development, Durham, NC, (10)Boston Children's Hospital, Boston, MA, (11)Boston Children's Hospital/Harvard Medical School, Boston, MA*

Background: The Autism Biomarkers Consortium for Clinical Trials (ABC-CT) EEG protocol aims to identify social-communicative brain biomarkers relevant to ASD, using measures of signal strength (i.e., modulation of EEG spectral power and event-related potential latency/amplitude). Previously, we reported interim primary dependent variable (DV) results: all DVs demonstrated construct validity and appropriate distributional qualities. The Faces experiment primary DV also showed excellent group discrimination. Test-Retest was acceptable for primary DVs from Resting, Faces, and VEP. Biomotion DVs were less successful. The ABC-CT has now completed the main study acquisition and includes a final sample of 399 participants with ASD (n=280) and TD (n=119).

Objectives:

To report on the final analyses for the ABC-CT EEG battery and the pre-specified primary and secondary DVs. We focus on acquisition validity, discriminant validity, and relation to clinical status at each time point, as well as test-retest reliability.

Methods: EEG was collected during: (A) Resting (or calm viewing), (B) Faces (based on the EU-AIMS face experiment), (C) VEP (checkerboard), and (D) Biological Motion Perception (Biomotion / point light displays of walkers) using standardized EEG equipment, experimental control, and recording parameters (Webb et al., 2019). Valid data was based on completion of 50% of the Resting EEG experiment. Acquisition rates were high with Time 1=97% ASD, 98% TD, Time 2=96% ASD, 91% TD, and Time 3=90% ASD, 96% TD, as manualized (Santhosh et al., 2019). ERP data processing (for Faces, VEP, and Biomotion) were conducted via Matlab, utilizing automated artifact detection and custom programs for component abstraction; EEG data processing used HAPPE (Gabard-Durnam et al., 2018). Our DVs included Resting=slope of the power spectrum, alpha power, and gamma power; Faces=latency of the N170 and P1 to upright faces; VEP=amplitude of the P1; Biomotion=N2 and P300 amplitude to biological motion.

Results: Valid DV rates were between 81-92% for *slope*, 70-97% for *N170 latency to upright faces*, 79%-95% for VEP *P1 amplitude*, and 65%-88% for *N2 amplitude to biological motion*. There was a >20% difference in acquisition rates between the TD and the ASD group for Faces and Biomotion. Focusing on the *N170 latency to upright faces*, our primary outcome variable, we found a significant group difference in latency ($F=11.6$, $p<.01$ AUC=.563), with faster responses in the TD than ASD group. Test-retest was good ($r=.68$, $p<.01$). The *N170* was correlated with age (rs=-.35 to -.49) and was not related to sex (ps=ns).

Conclusions: Through standardized acquisition processes, site training, and timely feedback, we were able to acquire at least one EEG experiment on >90% of children with ASD. We had similar levels of data retention across site and age, but decreased rates in the ADS group for longer ERP experiments. The Faces experiment shows strong promise as a biomarker of social attention. All DVs demonstrated construct validity and appropriate distribution. In our presentation, we will provide parallel analyses for all the EEG DVs as well as an updated "biomarker report card" to guide selection of these DVs for different contexts of use in clinical trials.

202.004 *(Panel)* The Autism Biomarkers Consortium for Clinical Trials: Eye-Tracking Biomarker Analyses

F. Shic[1], *A. Naples*[2], *S. J. Webb*[3], *G. Hellemann*[4], *C. Sugar*[5], *D. Senturk*[4], *M. Murias*[6], *E. Barney*[1], *B. Li*[7], *M. Kim*[8], *K. J. Dommer*[9], *J. Dziura*[10], *R. Bernier*[3], *K. Chawarska*[2], *G. Dawson*[11], *S. Faja*[12], *S. Jeste*[5], *C. A. Nelson*[13] *and J. McPartland*[2], *(1)Center for Child Health, Behavior and Development, Seattle Children's Research Institute, Seattle, WA, (2)Child Study Center, Yale University School of Medicine, New Haven, CT, (3)Psychiatry and Behavioral Sciences, University of Washington, Seattle, WA, (4)UCLA, Los Angeles, CA, (5)University of California, Los Angeles, Los Angeles, CA, (6)Duke Center for Autism and Brain Development, Department of Psychiatry and Behavioral Sciences, Duke University, Durham, NC, (7)Computer Science and Engineering, University of Washington, Seattle, WA, (8)University of Virginia, Charlottesville, VA, (9)Seattle Children's Research Institute, Seattle, WA, (10)Yale University, New Haven, CT, (11)Department of Psychiatry and Behavioral Sciences, Duke Center for Autism and Brain Development, Durham, NC, (12)Boston Children's Hospital, Boston, MA, (13)Boston Children's Hospital/Harvard Medical School, Boston, MA*

Background: The Autism Biomarkers Consortium for Clinical Trials (ABC-CT) eye-tracking (ET) protocol aims to identify oculomotor biomarkers of social-communicative information processing relevant to autism spectrum disorder (ASD) through recording of patterns of eye fixation in multiple task contexts. Eye tracking was collected using an SR Eyelink 1000 Plus eye tracker on both days of the protocol and included the following paradigms: (A) Activity Monitoring, (B) Social Interactive Scenes, (C) Static Images of Social Scenes, (D) Biological Motion Preference (BMP), (E) Pupillary Light Reflex (PLR). (A)-(C) were combined based on principal component analysis from the Feasibility stage of the study into a composite variable, the Oculomotor Index of Orienting to Human Faces (Oculomotor Index), which served as our primary dependent variable (DV) for the ET protocol. Previously (Shic et al., 2017), we reported interim main study primary dependent variable (DV) results demonstrating construct validity and appropriate distributional qualities of dependent variables, as well as excellent group discrimination and test-retest performance.

Objectives:

To report on the final analyses for the ABC-CT experiments in the ET battery and their pre-specified primary and secondary dependent variables. We will report on acquisition validity, discriminant validity, relation to clinical status at each time point (Time 1, Time 2 + 6 weeks, Time 3 +24 weeks), and test-retest reliability.

Methods: Valid trial data was based on 50% valid data acquisition and calibration uncertainty below 2.5 visual degrees, with 25% trial validity required for paradigm validity and 1 paradigm required for participant validity. Rates of acquisition (participant validity) continued to be high with >99% data acquisition at all time points as assessed using manualized quality control procedures (Barney et al., 2018).

Results: The ABC-CT main study includes a final sample of 399 participants with ASD (n=280) and typical development (TD; n=119). Paradigm validity rates were above 97% for all time points for all paradigms excepting PLR (82.6%-98.3%), with slightly less validity in the ASD as compared to TD group. In terms of discriminant validity and test-retest for primary experiment outcome variables, ranked from highest to lowest in Cohen's d: Activity Monitoring (T1=1.04, T2=.96, T3=.95; Test-Retest (TR): .81-.85); Oculomotor Index (.80, .84, .80; .84-.86); Social Interactive (.93, .58, .83; .44-.47); Static Scenes (.53, .53, .39; .59-.69); Biomotion |d|<.22, TR .28-.46; PLR |d|<.31, TR .80-.83. Aggregating across timepoints, correlations within the ASD group with clinical phenotype were modest, maximal rho=-.29 for Activity Monitoring looking at heads to ADOS calibrated severity score.

Conclusions: Valid ET data were obtained on nearly all children. Oculomotor Index and the components of the index continued to show strong promise as a biomarker of social attention in ASD. Markers show significant between group differences and high test-retest reliability. Relationships with phenotypic characteristics in ASD were highly significant but modest in effect size. In our presentation, we will provide parallel analyses for all the ET DVs as well as provide an updated "biomarker report card" to guide selection of these measures (and DVs) for different contexts of use in clinical trials.

ORAL SESSION — BIOMARKERS (MOLECULAR, PHENOTYPIC, NEUROPHYSIOLOGICAL, ETC)
304 - Metabolic and Biochemical Markers in Pregnancy and Early Childhood

304.001 *(Oral)* Attenuation of Sex Differences in Placental Markers during Pregnancy Is Associated with the Development of Autism and Related Traits in Children

A. Tsompanidis[1], *L. Blanken*[2], *E. Steegers*[3], *S. Baron-Cohen*[1] *and H. Tiemeier*[4], *(1)Autism Research Centre, Department of Psychiatry, University of Cambridge, Cambridge, United Kingdom, (2)Department of Psychiatry, Erasmus MC-Sophia Children's Hospital, Rotterdam, Netherlands, (3)Department of Gynaecology, Sophia Children's Hospital, Erasmus Medical Center, Rotterdam, Netherlands, (4)Department of Social and Behavioural Sciences, T.H. Chan School of Public Health, Harvard University, Cambridge, MA*

Background: Males are more likely to be diagnosed with autism, despite greater awareness of under-diagnosis or misdiagnosis of autism in females. Sexual dimorphism in the prenatal endocrine environment may be a significant contributing factor. Sex steroid hormones, including androgens and estrogens, are elevated in the fetal circulation of autistic males and correlate with the development of autistic traits (Baron-Cohen *et al.*, 2019) .Placental function is also sexually dimorphic, with male placentas producing more steroid hormones and having greater risk for complications. Placental regulatory proteins, such as soluble fms-like tyrosine kinase (sFlt-1) and placental growth factor (PGF) are also significantly different when the fetus is male in the 1st trimester (Brown *et al.*, 2014).

Objectives: To investigate in maternal serum:

1. If placental proteins are different between male and female pregnancies in the 2nd-3rd trimester.
2. If levels of these placental proteins correlate with autistic traits.
3. If levels of these placental proteins correlate with autism likelihood.

Methods: First trimester sFlt-1 and PGF concentrations were assessed in maternal serum samples of pregnant women, at 10-12 weeks (1st trimester) and 24-28 weeks (2nd-3rd trimester) of gestation, who consented to take part in the "Generation R" birth cohort, in Rotterdam, the Netherlands. Subsequent assessment of autistic traits in the children at age 6 was based on 18-item abridged version of the Social Responsiveness Scale (SRS). Diagnosis of autism was based on specialist medical records. The final sample consisted of n= 3,767 singleton pregnancies with a completed SRS assessment and n=56 confirmed autism cases in males. Values of SRS and concertation values of hormones were log-transformed and extreme outliers were windorised to reduce skewness. Linear regression analysis was stratified for sex and based on two models, with SRS as the dependent variable: 'Model 1' accounted for the age at the time of SRS testing. 'Model 2' accounted for age of child at SRS testing, age of mother, birth weight (adjusted for gestational age), placental weight, maternal ethnicity & educational attainment.

Results: PGF was significantly higher ($p<0.001$), while sFlt-1 was significantly lower ($p<0.001$) for male pregnancies in the 2nd time-point. Preliminary analysis suggests that PGF levels and the rate of increase for PGF, both correlated to SRS scores in females (Model 1: $p<0.001$, Model 2: $p<0.03$, for both). This finding persisted in analyses restricted to pregnancies without complications, without a diagnosis of autism and with only parents of Caucasian ethnicity. In males, PGF increase was borderline significant in the 1st model ($p=0.021$) but not when all covariates were included in the 2nd model. There was no correlation between sFlt-1 levels and SRS scores. When clinically diagnosed cases were assessed separately, autistic males had significantly lower sFflt-1 levels, when compared to neurotypical controls ($p=0.03$). There was no difference in the levels of PGF between them and male neurotypical controls.

Conclusions: Attenuation of sex differences in the levels of placental markers is associated with later autistic outcomes in children, according to male-like patterns (increased PGF, decreased sFlt-1).

304.002 *(Oral)* Maternal Multiple Metabolic Disorders, Plasma Branched-Chain Amino Acids, and the Risk of Child Autism Spectrum Disorder: Evidence of Sex Difference

A. Panjwani[1], *Y. Ji*[2], *J. Fahey*[3], *A. Palmer*[4], *G. Wang*[2], *X. Hong*[5], *B. Zuckerman*[6] *and X. Wang*[5], *(1)Health and Human Sciences, Purdue University, West Lafayette, IN, (2)The Center on the Early Life Origins of Disease, Johns Hopkins School of Public Health, Baltimore, MD, (3)Johns Hopkins University, Baltimore, MD, (4)Center for Human Nutrition, Johns Hopkins School of Public Health, Baltimore, MD, (5)The Center on the Early Life Origins of Disease, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, (6)Boston University School of Medicine/Boston Medical Center, Boston, MA*

Background: Maternal obesity and diabetes are known risk factors for ASD, and are also associated with branched-chain amino acids (BCAAs). However, the association of maternal multiple metabolic disorders (MMD), alone or in combination with BCAAs, with child ASD has not been well-studied.

Objectives: Bringing several lines of research under a life course framework, we sought to examine joint associations of maternal MMD and BCAAs on child ASD using a prospective birth cohort design.

Methods: We examined 789 mother-infant pairs (89 with ASD), a subset of the Boston Birth Cohort, from a predominantly urban, low-income, minority population. Based on pre-pregnancy overweight or obesity, type 2 or gestational diabetes, high-density lipoprotein cholesterol (HDL<50mg/dl), and hypertensive disorders, mothers were grouped into MMD (score≥3) or no MMD (score<3). Liquid chromatography-tandem mass spectrometry (LC-MS/MS) was used to quantify maternal postpartum plasma BCAAs collected 24-72 hours postpartum. A composite BCAA score was created using factor analysis, and dichotomized at the median. Logistic regression was then used to examine joint associations of maternal MMD and BCAAs on child ASD risk. Differential associations by child's sex were also examined.

Results: The median composite MMD score was 1 (IQR: 0-2). Mothers with an MMD score ≥3 were at a significantly greater risk for having a child with ASD (crude OR: 2.03 95% CI: 1.11-3.71), though this significance was lost upon adjustment with pertinent variables. Maternal high MMD score and above median BCAA concentrations synergistically increased the risk of ASD (adjusted OR: 3.01, 95% CI: 1.44-6.30), and the association was limited to males (crude OR: 5.25, 95% CI: 2.27-12.17; $p_{interaction}$=0.03). ASD risk was highest among children with all three risk factors: male sex, high MMD score, and above-median BCAA score (adjusted OR: 16.09, 95% CI: 6.02-43.04) compared to children without any of these factors (Figure 1). A similar, yet weaker, association was observed among children with other developmental disorders for this comparison (adjusted OR: 4.17, 95% CI: 2.19-7.93). Further, the combination of female sex, high MMD score, and above-median BCAA score was also significant for children with other developmental disorders (adjusted OR: 2.15, 95% CI: 1.20-3.86).

Conclusions: Our findings provide new evidence of joint associations between maternal MMD and BCAA biomarkers on child risk of ASD. They also provide insight on the early life origins of sex differences in ASD. Further studies are warranted to confirm these findings.

304.003 *(Oral)* Serum Biomarker Indicates Higher Maternal Insulin Resistance during Pregnancies of Males, but Not Females, Who Develop Autism

D. A. Bilder[1]*, M. S. Esplin*[2]*, P. Burghardt*[3]*, A. Fraser*[4]*, W. Worsham*[5]*, T. Richins*[5] *and A. V. Bakian*[1]*, (1)Psychiatry, University of Utah, Salt Lake City, UT, (2)Department of Obstetrics and Gynecology, University of Utah, Salt Lake City, UT, (3)Wayne State University, Detroit, MI, (4)Huntsman Cancer Institute, University of Utah, Salt Lake City, UT, (5)University of Utah, Salt Lake City, UT*

Background: Prenatal metabolic syndrome (PNMS) exposure (i.e., diabetes and hypertension during pregnancy) is associated with increased autism spectrum disorder (ASD) risk, which may be attributable to inflammation and steroid dysregulation. Higher PNMS severity precipitates preterm birth. Low maternal sex hormone binding globulin (SHBG) levels indicate insulin resistance and precede clinical manifestations of gestational diabetes and hypertension. Low maternal serum SHBG in early 2nd trimester has been linked to ASD among offspring born at term.

Objectives: Using maternal SHBG levels as a proxy for insulin sensitivity, (1) compare insulin sensitivity during pregnancies that differ by PNMS exposure, offspring ASD status, and pregnancy duration and (2) determine whether insulin sensitivity associated with PNMS exposure, offspring ASD status, and gestational duration are moderated by fetal sex.

Methods: ASD case status were identified among index offspring of Utah's First and Second Trimester Evaluation of Risk (FASTER) study participants who consented to future use of banked early second trimester maternal serum. ASD case status was determine by the Utah Registry of Autism and Developmental Disabilities, which was enriched with cases identified through Utah's participation in CDC's Autism and Developmental Disabilities Monitoring Network. Birth certificate data identified PNMS exposure (i.e., preexisting/gestational diabetes, preexisting/gestational hypertension, and preeclampsia), sex, gestational age, maternal age, pregnancy weight gain, and pre-pregnancy BMI. Maternal serum was stored at -80°C, thawed on wet ice, and aliquoted into pre-cooled tubes. SHBG was measured using RayBiotech (Norcross, GA) ELISA kits. A one-way Analysis of Variance was formulated to quantify the association between a five-level measure of ASD/PNMS exposure: levels 1-4 reflected exposure status in term pregnancies [i.e., ASD-/PNMS- (N = 11), ASD-/PNMS+ (N=8), ASD+/PNMS- (N=28), and ASD+/PNMS+ (N=25)] and the fifth level reflected exposure in preterm pregnancies (pASD+/PNMS+, N=5). Analyses included covariates described above as well as gestational age at serum sampling, and were repeated after stratifying by sex. Post hoc tests used the Scheffé method.

Results: The overall model was significant ($F_{(9,66)}$=4.11, p=0.0003) as was the main effect of ASD/PNMS exposure on serum SHBG concentrations ($F_{(4,66)}$ =7.53, p =<0.0001). A dose-response pattern emerged: increasing ASD/PNMS exposure was associated with decreasing SHBG concentrations. After multiple comparison adjustment, mean SHBG concentrations differed significantly between the ASD-/PNMS- and the pASD+/PNMS+ (mean difference = 154.21, 95% CI = 27.10-281.33, p = 0.009), ASD+/PNMS+ (mean difference = 120.62, 95% CI = 40.07-201.17, p = 0.0006), and ASD+/PNMS- (mean difference = 105.98, 95% CI = 30.76-181.20, p = 0.001) groups. When stratified by sex, similar findings were identified for males; however, the overall model for females was insignificant ($F_{(4,16)}$=0.80, p=0.61) (Figure 1).

Conclusions: Males who develop ASD experienced significantly higher maternal insulin resistance than unaffected males as indicated by lower SHBG levels irrespective of whether clinical manifestations of PNMS emerged. Males with ASD and PNMS exposure born preterm had similar findings. This supports the presence of insulin resistance as a common metabolic milieu in early 2nd trimester among affected males. However, SHBG levels from pregnancies of females were not significantly responsive to ASD or PNMS exposure status.

304.004 *(Oral)* Prediction of Autism Risk Based on Dysregulation of Energy and Amino Acid Metabolism

A. M. Smith[1]*, D. Braas*[1]*, M. Ludwig*[1]*, D. B. Sugden*[1]*, L. Feuling*[1]*, D. Ney*[2]*, E. Donley*[1]*, M. Natowicz*[3]*, D. G. Amaral*[4] *and R. Burrier*[1]*, (1)Stemina Biomarker Discovery, Madison, WI, (2)Nutritional Sciences, University of Wisconsin, Madison, WI, (3)Pathology & Laboratory Medicine Institute, Cleveland Clinic, LL-3, Cleveland, OH, (4)Department of Psychiatry and Behavioral Sciences, The Medical Investigation of Neurodevelopmental Disorders (MIND) Institute, UC Davis School of Medicine, University of California Davis, Sacramento, CA*

Background: Autism spectrum disorder (ASD) is an etiologically heterogeneous disorder with considerable clinical variability among affected individuals. The complexity of the disorder hampers diagnosis, frequently delaying therapeutic interventions. Stratification of a heterogenous ASD population based on metabolic phenotypes (metabotypes) such as altered energy and amino acid metabolism creates an opportunity for the development of diagnostic tests. We previously reported on stratification of 17% of the ASD subjects enrolled in the Children's Autism Metabolome Project (CAMP, ClinicalTrials.gov Identifier: NCT02548442) based on tests for dysregulation of plasma levels of branched chain amino acids. In this work, we extend our approach to develop metabolic tests that stratify ASD based on metabotypes of both altered energy and amino acid metabolism.

Objectives: The study sought to use quantitative plasma metabolite analyses to identify alterations of amino acid and energy metabolism able to stratify ASD subjects into distinct metabotypes that may be clinically actionable.

Methods: Plasma samples from 708 ASD and typically developing (TYP) children, age 18-48 months, were analyzed from CAMP which enrolled 1100 children from 8 centers across the US. The Autism Diagnostic Observation Schedule, Second Edition (ADOS-2) was performed by research reliable clinicians to confirm ASD diagnoses. Thirty-nine metabolites of plasma amino acid and energy metabolism were measured using analytically validated quantitative mass spectrometry-based methods. A discovery set of CAMP subjects (ASD=253, TYP=104) was utilized to set diagnostic thresholds for metabolic tests that identify metabotypes associated with ASD. Tests meeting minimum diagnostic performance criteria (> 5% sensitivity and > 95% specificity) were then evaluated in an independent replication set of CAMP subjects (ASD=246, TYP=105). Tests meeting minimum diagnostic performance in both discovery and replication sets were then optimized into a test battery by removing correlated metabotype tests which identified similar subjects.

Results: In both the discovery and replication studies, 34 metabotype tests associated with increased risk of ASD based on ratios of metabolites were identified. Ratios of metabolites containing: 1) lactate or pyruvate, 2) succinate, 3) α-ketoglutarate, 4) glycine, 5) ornithine, and 6) 4-hydroxyproline in combination with other metabolites were grouped into six clusters based on correlation of ratio measurements. Within these six clusters, ASD subjects were often positive for more than one metabotype. Optimization of the 34 metabotype tests by reducing test redundancy within clusters generated a battery of 14 tests with a diagnostic performance of 50% (CI 45%-54%) sensitivity and 92% (CI 88%-96%) specificity in the CAMP population.

Conclusions: The analysis revealed novel, reproducible metabotypes of ASD. The optimized metabotype test battery can be used as a screening test to identify children at risk for ASD. Combining a metabotype-based modality with a behavioral screening such as M-CHAT/F creates an opportunity to identify those at risk of ASD using both biological and behavioral measures. Utilization of metabotype-based tests further raises the possibility for more precise treatment of ASD based on individual metabolic profiles.

POSTER SESSION — BIOMARKERS (MOLECULAR, PHENOTYPIC, NEUROPHYSIOLOGICAL, ETC)
406 - Biomarkers (molecular, phenotypic, neurophysiological, etc) Posters

406.001 *(Poster)* 2D:4D Ratio and Autism Spectrum Disorder in Brunei

S. H. Lee[1], *S. Aziz*[1,2], *M. Hamid*[3], *Y. Lim*[1], *D. Koh*[1,4,5] *and L. L. Chaw*[1], *(1)PAPRSB Institute of Health Sciences, Universiti Brunei Darussalam, Bandar Seri Begawan, Brunei Darussalam, (2)School of Medicine, University College, Cork, Ireland, (3)Ministry of Health, Bandar Seri Begawan, Brunei Darussalam, (4)NUS Yong Loo Lin School of Medicine, Singapore, Singapore, (5)NUS Saw Swee Hock School of Public Health, Singapore, Singapore*

Background: Despite the global increase in the prevalence of autism spectrum disorders (ASD), relevant research studies are lacking in Brunei Darussalam. Various studies have shown a significant association between a lowered 2D:4D ratio (ratio of second digit/index finger to the fourth digit/ring finger) and ASD, making it one of the potential phenotypic biomarkers for early detection of autism, which is important for early intervention and management.

Objectives: The objective of this study is to explore the association between 2D:4D ratio and ASD in Brunei Darussalam, as a potential phenotypic biomarker to complement early ASD diagnosis.

Methods: We conducted a case-control study comprising 28 ASD and 62 typically developing (TD) children in the case and control group, respectively (age range: 3 to 11 years old; median age: 6 years). Median 2D:4D ratios were measured, compared and analysed between the two groups. Logistic regression models were used to explore potential associations between the median 2D:4D ratio and ASD in respective gender, for both left and right hands, independently.

Results: Our study shows that the median 2D:4D ratio of left hand in ASD males is significantly lower than those in TD males, after adjusting for ethnicity and age [Odds Ratio (OR) = 0.57 (95% Confidence Interval (CI): 0.31 - 0.96); $p = 0.044$]. For females, there is no association of ASD with the median left hand 2D:4D ratio [OR = 3.09 (95% CI: 0.98 - 19.86); $p = 0.144$] or the median right hand 2D:4D ratio [OR = 1.23 (95% CI: 0.42 – 3.88); $p = 0.702$]. Our study also shows a significant positive correlation and/or a reduced asymmetry between the average 2D:4D ratio of left hands and right hands in ASD males (Pearson's correlation (r) = 0.48; 95% CI: 0.076 – 0.75, $p = 0.023$).

Conclusions: There is significant association between a lowered median 2D:4D ratio of the left hand (in males only) and ASD diagnosis. Once validated in a larger sample size, a lowered median 2D:4D ratio on the left hand may be a potential tool to complement ASD diagnosis for males in our study population. There is no association between the median 2D:4D ratio (left or right hands) and ASD in females and this could be due to the small female sample size and/or the possibility of different aetiology for ASD in females. The reduced asymmetry between the average 2D:4D ratio of left and right hands observed in ASD males only (this effect was not observed in ASD females) also suggests the importance of considering gender-specific biomarkers for ASD diagnosis.

406.002 *(Poster)* Clinical, Phenomic and Genomic Effects on Salivary Microtranscriptome and Microbiome Measures in Autism

*S. D. Hicks[1], A. T. Rajan[2], D. Levitskiy[3], R. Ericson[4], S. DeVita[5], R. Uhlig[3], R. Carpenter[5] and **F. A. Middleton**[6], (1)Pediatrics, Penn State Milton S. Hershey Medical Center, Penn State College of Medicine, Hershey, PA, (2)Research & Data Science, Quadrant Biosciences Inc, Syracuse, NY, (3)Quadrant Biosciences Inc, Syracuse, NY, (4)Quadrant Biosciences Inc., Syracuse, NY, (5)Quadrant Biosciences, Syracuse, NY, (6)SUNY Upstate Medical University, Syracuse, NY*

Background: Several clinical, demographic, and ethnogeographic factors are associated with increased risk for autism spectrum disorder (ASD), including birth complications, social adversity, preterm pregnancy, and alterations in BMI, among others. Whether such variables also influence the ability to identify sensitive and specific biomarkers of ASD is an important consideration for developing optimal tools to aid in early diagnosis.

Objectives: We sought to test whether variations in population admixture and mitochondrial haplogroup were associated with more than 36 additional clinical, demographic, and functional outcome factors as well as abundance levels of more than 1100 non-coding human RNA and bacterial taxa and RNA in saliva microtranscriptome data from 692 children age 18 months – 6 years of age with consensus DSM-V diagnoses of ASD (n=383). These data were compared with an age- and gender-matched group of children with non-ASD developmental delay or neurotypical development (n=309).

Methods: Saliva samples and detailed medical, demographic and functional outcome measures were obtained. Medical and demographic features included pregnancy and birth complications, birth stage, BMI, self-reported ethnicity, history of allergies, sinus infections, fever, vision or hearing loss, asthma, eczema, physical or dental problems, history of ADHD, GI problems, sleep problems, family relatives with ASD, Vineland Adaptive Behavior Scale scores, and Autism Diagnostic Observation Scale (ADOS) scores. Saliva DNA exome sequence data, mitochondrial haplogroup data, and microtranscriptome features, including precursor and mature microRNA, Piwi-interacting RNA, small nucleolar RNA, long noncoding RNA, and microbial RNA and taxa were identified using next generation sequencing following by rigorous variant calling, normalization and filtering to identify the most robust genetic and genomic features. Multivariate analysis of variance (ANOVA) was then used to identify variables that were affected by Admixture, Diagnosis, or Admixture x Diagnosis interactions.

Results: 10 different mitochondrial Admixture haplogroups were identified in the subjects, and displayed a robust effect on self-reported ethnicity as well as specific risk factors. For example, significantly higher levels of birth complications were seen in mitochondrial haplogroup L, and significantly higher rates of eczema and lower rates of first degree relatives with ASD were seen in haplogroup L3. No overall effect of Admixture on Diagnosis was detected. However, other features with a significant effect of Admixture included several miRNAs, piRNAs, and Campylobacter, Carnobacterium, and Actinomyces taxa. A total of 169 features showed a significant effect of Diagnosis ($q<0.05$), including several let-7 miRNAs, Micrococcus, Actinomyces, and Rothia taxa, as well as Gender, Pregnancy and Perinatal Complications, Sleep Problems, and Gender. Only 18 features showed a significant interaction of Diagnosis x Admixture. These included 15 piRNA features and 3 microbial RNAs related to Acyl carrier protein, Transketolase, and IMP dehydrogenase.

Conclusions: Our results indicate that several medical and demographic features appear to influence salivary microtranscriptome and microbial data as well as the general risk for ASD. Additional studies are needed to further explore the specific mechanisms that might underlie such interactions.

406.003 *(Poster)* A Multi-Omic Analysis of Peripheral Blood from Children with ASD and Ileocolonic Inflammation

S. J. Walker[1], *B. B. Misra[2,3] and A. Krigsman[4], (1)Wake Forest Institute for Regenerative Medicine, Winston-Salem, NC, (2)Department of Internal Medicine, Wake Forest University Health Sciences, Winston Salem, NC, (3)Department of Internal Medicine, Wake Forest University Health Sciences, Center for Precision Medicine, Winston Salem, NC, (4)Pediatric Gastroenterology Resources of New York and Texas, Austin, TX*

Background: Gastrointestinal (GI) symptoms are a common co-occurring medical issue in children with autism spectrum disorder (ASD). We have previously described unique GI mucosal biomarkers specific for ASD-associated ileocolitis in children. It is not yet known whether unique biomarkers are also present in the blood of these individuals. Identification of a validated blood-based biomarker of ASD-associated ileocolitis would allow for earlier identification of co-morbid GI disease and earlier GI intervention in affected patients. Moreover, it would provide insight into the relevant genes and metabolic pathways in ASD-associated ileocolitis.

Objectives: In an effort to enable a more complete understanding of the biology that underlies GI inflammation in children with ASD, the goal of these studies was to use an integrated omics approach to evaluate blood-based gene expression and serum metabolite relative abundance in GI-symptomatic children with ASD that have a demonstrated histologic ileocolitis.

Methods: The study cohort was comprised of whole blood and serum from 22 children with ASD who were undergoing clinically-indicated ileocolonoscopy for chronic GI symptoms, and 24 non-ASD (typically developing, TD) children undergoing ileocolonoscopy for a variety of GI symptoms. All children with ASD had histologic inflammation of the ileum, colon, or both. The TD controls used for this study were selected based on absence of histologic inflammation anywhere in the GI tract and absence of a neurodevelopmental disorder. Molecular profiling in peripheral blood (transcriptome) and serum (metabolome) from children with ASD (and ileocolitis) and TD children (without ileocolitis) was performed to identify differentially expressed transcripts and metabolite abundance levels that may serve as a proxy for GI inflammation.

Results: Differential gene expression analysis (using whole genome microarray) identified a large number of both up- and downregulated transcripts (**Figure 1A-B**). The significantly upregulated transcripts in ASD were enriched for pathways including ECM-receptor interaction, intestinal immune network, fatty acid biosynthesis, hematopoiesis, serotonin transporter activity, platelet degranulation, platelet activation, signaling and aggregation, and cytokine signaling. The significantly downregulated transcripts in ASD were enriched for pathways such as arachidonic acid metabolism, linoleic acid metabolism, extracellular vesicle-mediated signaling, NOD pathway, aryl hydrocarbon receptor pathways, and oxidative ethanol degradation. From the metabolomics data (**Figure 1C-D**), fatty acid metabolism (acyl carnitines), phenylalanine and tyrosine metabolism were uniquely associated with ASD, whereas steroidal metabolism and xanthine metabolism were uniquely associated with TD controls. Integration of transcript and metabolite data revealed enrichment of caffeine metabolism, purine nucleotide metabolism, and glucose alanine cycle.

Conclusions: On one hand, the gene-expression signatures revealed molecular signaling pathways, while on the other hand the metabolomics data revealed the metabolic biosynthetic and catabolic routes of ASD. Both datasets point to dysregulation of fatty acid and lipid metabolism spanning the two omics layers. Such complementary multi-omics efforts have proven useful to understand the disease mechanisms in greater detail and to facilitate rapid hypothesis generation in the context of ASD.

406.004 *(Poster)* Examining the Relationship between Autonomic Functioning in Preschool-Aged Children with ASD and Social-Emotional Deficits

P. Runyan[1] *and J. F. Scherr*[2]*, (1)Child Development Center, Nationwide Children's Hospital, Westerville, OH, (2)Behavioral Health, Nationwide Children's Hospital, Columbus, OH*

Background: Children diagnosed with Autism Spectrum Disorder (ASD) often experience learning difficulties, produce inappropriate reactions to social cues, and are impulsive. Externalizing and internalizing behaviors, particularly agitation, disruption, and anxiety, can also be exhibited by children with ASD. Autonomic nervous system (ANS) functioning, as measured by heart rate (HR) and respiratory sinus arrhythmia (RSA), has been studied as a biomarker for social-emotional functioning (Neuhaus, Bernier, & Beauchaine, 2014). Higher levels of autonomic dysregulation are related to impaired social-emotional and behavioral regulation in children (Crowell, et. al., 2006), as well as symptoms of overactivity, aggression, and anxiety (Chalmers et al., 2014; Rukmani et al., 2016). However, the relationship between physiological arousal and symptoms of externalizing behaviors and anxiety in children with ASD is not well understood.

Objectives: The present study aims to examine the relationship of ANS functioning in preschool-aged children with and without a diagnosis of ASD with overactive, aggressive, and anxious behaviors directly observed during a play-based assessment.

Methods: Preliminary data were collected from 38 children, aged 2-5 years, who participated in an ongoing study examining physiological arousal and behavioral functioning in preschoolers. Participants were categorized into two groups: children with a clinical diagnoses of ASD (N=21) and typically developing (TD) children (N=17). Baseline physiological data, including average HR and RSA, were collected while the participant watched a preferred 5 minute video. The ADOS-2 comparison score, used to measure ASD symptom severity, and “Other Abnormal Behaviors,” used to measure anxiety, disruptive behavior, and overactivity on a scale of 0-3, were measured across all participants.

Results: Preliminary results indicate that children with ASD demonstrate lower levels of baseline RSA (M = 5.87; SD = 1.26) and higher baseline HR (M = 117.63, SD = 18.34) than TD children (M = 6.57; SD = 1.14 and M= 108.59; SD=15. 04 respectively). The majority (52.4%; N = 11) of children with ASD displayed overactive behaviors during the ADOS-2. Disruptive behavior was observed in 23% (N = 5) of children with ASD and 12% (N = 2) of TD children during the ADOS-2. Anxiety was observed in 14% (N = 3) and 12% (N= 2) of children with and without ASD, respectively. Autism symptom severity was negatively related (r = -.424) to baseline RSA in the ASD group and positively related (r = .404) to overactivity observed in the ADOS-2. Lower levels of baseline RSA were associated with more disruptive behaviors (r = -.349) observed during the ADOS-2 across participants. Higher levels of baseline RSA were associated with more symptoms of anxiety (r =.697) in children with ASD.

Conclusions: Children with ASD are at an increased risk for comorbid symptoms of anxiety, attention deficits, and disruptive behaviors, suggesting that children who display more severe symptoms of ASD have greater behavioral challenges and physiological dysregulation. Children with ASD and co-occurring behavioral challenges are likely to face more social-emotional barriers; therefore, the contribution of physiological functioning in social-emotional behaviors should be considered when developing targeted interventions that focus on the improvement of social-communication skills.

406.005 *(Poster)* A Randomized Controlled Trial of Reading Intervention and the Brain in Children with Autism Spectrum Disorder

R. K. Kana[1]*, J. A. Trapani*[2]*, H. D. Deshpande*[2] *and S. E. O'Kelley*[2]*, (1)University of Alabama, Tuscaloosa, AL, (2)University of Alabama at Birmingham, Birmingham, AL*

Background: Research investigating different profiles of children with reading difficulties have found that children who have adequate decoding abilities but reading comprehension deficits make up a specific subgroup of children with reading disorders (Catts et al., 2005). It is likely that a large number of children with autism spectrum disorder (ASD) fall within this category (Murdaugh et al., 2016; 2017). Reading comprehension problems in ASD children have been addressed in only a handful of studies. While these studies showed improvement in reading comprehension in ASD, they were not based on a model that specifically addresses the primary cognitive and neural issues associated with language comprehension.

Objectives: The primary goal of this randomized controlled functional MRI study is to examine the impact of a visual imagery-based reading intervention in on functional connectivity of the brain’s reading network in ASD children with reading comprehension difficulties.

Methods: Functional MRI data were collected during tasks of word similarities and verbal absurdities from 25 children (age 8-13 years) each at two time points: 1) an experimental group of ASD children who underwent scanning before and after reading intervention (ASD-EXP); and 2) a waitlist control group of ASD children who after the first scan waited out the intervention period before their second scan (ASD-WLC). The children with ASD were identified as having difficulties with reading comprehension as indexed by having average word decoding abilities but poor comprehension (Slosson Oral Reading Test - Revised (SORT-R) reading score of at least 37th percentile and/or a Gray Oral Reading Test – Fourth Edition (GORT-4) accuracy score of at least 25th percentile, a GORT-4 comprehension score below 37th percentile).The intervention consisted of 4-hour sessions, 5 days a week for 10 weeks, adding up to a total of 200-hours of face-to-face instruction. fMRI data were collected on a 3 tesla Siemens MRI scanner.

Results: The ASD-EXP group showed significantly greater improvement in reading comprehension [paired-t(12) = 3.20, p= 0.007] from pre to post-intervention. The ASD-EXP group of children showed significantly greater activity from pre-to-post intervention in the angular gyrus, fusiform, thalamus, precentral, and temporal regions during word similarities task. In verbal absurdities task, the ASD-EXP group showed increased activity in superior parietal and middle frontal areas from pre to post intervention. Increased brain activity in these regions were found to be significantly correlated with improvement in comprehension, as measured by GORT-4.

Conclusions: This study targets neuroplasticity of brain areas underlying reading and tests the impact of intensive imagery-based intervention using instructional procedures based on Dual Coding Theory (Sadoski & Paivio, 2001) to increase language comprehension in children with ASD. These findings provide compelling evidence for the efficacy of a reading intervention in children with ASD that specifically targets an area of intact functioning, visual processing, and uses it to teach compensatory strategies to aid in improving reading comprehension. Data collection for this project is ongoing.

406.006 *(Poster)* Neurophysiological Markers of ASD: Examining the Relationship between Electroencephalography and ADOS Scores in High-Risk Toddlers

N. Shanok[1]*, A. Rouhandeh*[2]*, C. Honsberger*[1]*, E. Brooker Lozott*[1]*, M. Sotelo*[1]*, J. Buxbaum*[3]*, A. Kolevzon*[2]*, S. De Rubeis*[4]*, P. M. Siper*[2] *and J. H. Foss-Feig*[2]*, (1)Els for Autism Foundation, Jupiter, FL, (2)Seaver Autism Center, Department of Psychiatry, Icahn School of Medicine at Mount Sinai Hospital, New York, NY, (3)Department of Psychiatry, Icahn School of Medicine at Mount Sinai, New York, NY, (4)Seaver Autism Center for Research and Treatment, Icahn School of Medicine at Mount Sinai, New York, NY*

Background: Resting-state electroencephalography (EEG) has shown to be a useful tool for studying the relationship between neurophysiological and behavioral functioning in early childhood development. This non-invasive technique is especially advantageous for research on toddlers with autism spectrum disorder (ASD), given the lack of task-specific demands. Preliminary work has shown that in six-month-olds at elevated familial risk for developing ASD, various power and asymmetry measures can be combined to predict autism diagnosis at 18-months on the Autism Diagnostic Observation Schedule (ADOS-2). Hyperactive frontal power, depleted temporal power, and cortical left asymmetry have emerged as the most indicative markers (Bosl et al. 2018; Gabard-Durnam et al., 2015) We sought to expand on this work by examining the association between power and asymmetry measures with ADOS-2 domain sub scores in 18-36-month-olds at high risk for ASD.

Objectives: To explore the extent to which resting-state EEG measures relate to ADOS scores in toddlers at high risk for ASD.

Methods: EEG data was collected using a 128-channel net during the baseline visit as part of a larger caregiver-implemented early intervention study, evaluating the effects of a treatment program on various clinical, eye-tracking, and EEG measures. Here, we examined the associations between power and asymmetry at mid-frontal (F3, F4), lateral frontal (F7-F8), frontoparietal (FP1, FP2), temporal (T7, T8), and parietal (P3, P4) regions with ADOS-2 domain scores (communication, reciprocal social interaction, play, and stereotyped behaviors) using Kendall's rank correlations. Participants (N=5; 40% female) were between the ages of 18 and 36 months (M=28.6 months, SD=7.02) and screened positive on the Modified Checklist for Autism in Toddlers (M-CHAT) prior to being enrolled in the study. EEG measures were examined in theta (4 to 6 Hz), low alpha (6 to 9 Hz), high alpha (9 to 13 Hz), and beta (13 to 30 Hz) frequency bands, and asymmetry scores were calculated by subtracting right hemispheric power from left (i.e. F4-F3).

Results: Results revealed a significant positive relationship between right frontoparietal high alpha power and ADOS-2 reciprocal social interaction scores, τ_b=.800, p=.05 and a moderate negative correlation between right temporal low alpha power and ADOS-2 communication scores, τ_b =-.447, p=.29. Regarding asymmetry, negative correlations were identified between both mid-frontal low alpha asymmetry and mid-frontal beta asymmetry with ADOS-2 reciprocal social interaction scores, τ_b =-.800, p=.05 and τ_b =-.800, p=.05, respectively. There was also a strong negative correlation between frontoparietal theta asymmetry and stereotyped behaviors, τ_b =-.738, p=.077.

Conclusions: These preliminary findings suggest that certain EEG power and asymmetry measures may relate to core ASD social-communication symptoms, as indexed by the ADOS-2. These results are consistent with prior findings linking EEG measures to ASD symptoms in high-risk groups and further support frontal power and asymmetry as useful markers of ASD; this time in 18-month-olds. Future studies should continue to examine the extent that EEG can be utilized as a tool for assessing autism risk and for tracking developmental progression as a function of age or applied interventions.

406.007 *(Poster)* Abnormal Head Growth during Early Fetal Development Is Associated with Autism Spectrum Disorder

O. Regev[1]*, G. Meiri*[2,3]*, I. Dinstein*[3,4,5]*, H. Flusser*[3,6]*, A. Michaelovski*[3,6]*, J. Schuster*[7]*, A. Hadar*[7]*, R. Hershkovitch*[8,9] *and I. Menashe*[1,3]*, (1)Public Health, Ben-Gurion University of the Negev, Beer Sheva, Israel, (2)Preschool Psychiatric Unit, Soroka University Medical Center, Beer Sheva, Israel, (3)National Autism Research Center of Israel, Ben-Gurion University of the Negev, Beer Sheva, Israel, (4)Department of Psychology, Ben-Gurion University of the Negev, Beer Sheva, Israel, (5)Psychology Department, Ben-Gurion University of the Negev, Beer Sheva, Israel, (6)Child Development Center, Soroka University Medical Center, Beer Sheva, Israel, (7)Clalit Health Services, Beer Sheva, Israel, (8)Division of Obstetrics and Gynecology, Soroka University Medical Center, Beer Sheva, Israel, (9)Ben Gurion University, Beer Sheva, Israel*

Background: Current diagnosis of autism spectrum disorder (ASD) is based on the clinical evaluation of abnormalities in social behavior, which are usually not apparent until the second year of life. Nevertheless, emerging evidence suggests that signs of atypical development can be detected in ASD cases before their first birthday and even before birth. Prenatal ultrasonography, which is widely used for screening for fetal anomalies and obstetric complications during pregnancy, could be an excellent tool to discover fetal biomarkers associated with ASD. Nevertheless, only a few studies examined prenatal ultrasonography data in the context of ASD risk, and their findings are limited, controversial, and not specific.

Objectives: The two main objectives of this study are:

1) to identify prenatal ultrasonography biometric measures associated with ASD risk;

2) to determine whether any of these measures are associated with specific cognitive and behavioral phenotypes among children with ASD.

Methods: We conducted a retrospective case-sibling study of children with ASD (cases) from the National Autism Research Center of Israel and their healthy siblings (controls). Ultrasonography biometric measures from the 2nd and 3rd pregnancy trimesters of these sibling pairs (i.e., Head circumference [HC], Bi-Parietal Diameter [BPD], Abdominal Circumference [AC], and Femur Length [FL]) were converted to gestation-matched standardized Z-scores and were compared between cases and controls using paired T-test. Further, conditional logistic regression models were used to assess the independent association of ultrasonography measures with ASD after adjusting to the fetus's gender and mother age. Finally, we examined the correlation between the ultrasonography biometric measures and various cognitive and behavioral phenotypes (e.g., DSM-V severity, ADOS score, IQ, etc.) among children with ASD.

Results: Overall, 153 case-sibling pairs were included in this study. Of these, 64 pairs (42%) had ultrasonography data from both 2nd and 3rd trimesters, while another 46 and 43 pairs had data from either the 2nd or 3rd trimesters respectively. We found that during the 2nd trimester of pregnancy, fetuses later diagnosed with ASD had a significantly larger head compared to their siblings, especially when contrasted to the growth of other body parts (**Table 1**). However, this difference attenuate during the 3rd trimester (**Table 2**). Interestingly, both HC and BPD were mildly but significantly correlated with ASD severity according to DSM-V criteria ($r = 0.23$-0.35; $p<0.05$), but not with their ADOS score or their IQ.

Conclusions: This is the largest study to date and the first case-sibling study that assesses the association of ultrasonography biometric measures with ASD. Our results indicate that fetuses later diagnosed with ASD have abnormal head growth during early fetal development, and this abnormality is associated with a more severe ASD outcome. Integrating these findings with molecular data about brain development in utero may shed light on specific neurological mechanisms underlying ASD outcomes.

406.008 *(Poster)* Validation of Rapid Interactive Screening Test for Autism in Toddlers

***X. Kong**, Radiology, Massachusetts General Hospital, Charlestown, MA*

Background: Autism Spectrum Disorder (ASD) is a group of complex neurodevelopmental disorders, and its incidence has increased rapidly in recent years. More than 70% of individuals with ASD need lifetime care, and the CDC has called it a national healthcare crisis. There is growing evidence that early diagnosis has a significant impact on the prognosis of these individuals who have ASD. The Rapid Interactive screening Test for Autism in Toddlers (RITA-T, 2015) is a recently developed test for early ASD screening on toddlers from 18 to 36 months, which is fast, easy to perform and less expensive. Moreover, its feasibility and variation in sensitivity have never been assessed in an Asian population.

Objectives:

1.To validate the new screening technique, RITA-T, for ASD screening in children 1-6 years old. RITA-T results will be compared with results from ADOS.

2.To use this test in a population of young Asian children to determine its utility among this ethnic group as compared with the general population.

3.To use eye-tracking device on toddlers to determine potential differences in fixation duration for various objects and human faces.

Methods:

Participants: Total n=40 individuals aged 1- 6 years (mean = 3.53 year). These subjects were recruited through clinics and other areas and were identified to be high risk for autism by one or more caretakers.

Collection: RITA-T was administered with the ADOS, which was chosen based on observes during a single visit.

Stats: ROC Curve analysis was performed to validate the effectiveness as well as the cut-off score of RITA-T as a diagnostic screening for ADOS. Linear regression line for ADOS composite score and RITA-T to confirm the feasibility of RITA-T among the Asian population.

Results:

The area under the curve for the ROC curve of RITA-T vs. ADOS on all races is 0.891 (>0.5). RITA-T score of 10 is the optimal cut-off score for ASD screening reference. The PPV for RITA-T score above 13 is 1. Patients with RITA-T score higher than 18 has 100% positive predictive value of diagnosing with ASD.

The linear regression for Asians has a positive correlation as for the linear regression for the overall population, which indicates that RITA-T predicts ADOS among Asians as effective as it also does in the overall population.

ASD toddlers and non-ASD toddlers have different focuses for areas of interest on each screen, which is defined by fixation duration and fixation count.

Conclusions:

RITA-T is an effective ASD screening method to us before the ADOS on Asian and other races.

During patient recruiting, age and sex were not evenly distributed and lacked NT toddlers leads to small group size in each age and sex-matched group for further statistical analysis.

For further research, more age and sex-matched ASD and NT subjects are needed to confirm the ASD diagnostic screening effectiveness of RITA-T; as well as explore the ceiling effects, especially with higher intelligence ASD. Additional toddler subjects are needed to differentiate a cut-off score for ASD screening reference on toddler.

406.009 *(Poster)* Altered Autonomic Functions and Gut Microbiome in Individuals with Autism Spectrum Disorder (ASD): Implications for Assisting ASD Screening and Diagnosis

***X. Kong**, Radiology, Massachusetts General Hospital, Charlestown, MA; Medicine, BIDMC, Boston, MA*

Background: A growing body of literature suggests the presence of autonomic nervous system (ANS) dysfunction in patients with Autism Spectrum Disorder (ASD). As both are parts of the gut-brain axis, gut microbiome factors and the autonomic indices can serve as non-invasive markers indicating the state of the gut-brain axis in ASD. To our knowledge, no previous studies have explored the relationship between ANS and gut microbiome in patients with ASD, nor has the use of combined autonomic indices and gut microbiome factors been used in the context of classifying ASD and neurotypical subjects.

Objectives: To characterize autonomic function among ASD patients in comparison to their paired family controls and explore the ASD gut-brain-axis, we examined the relationship between gut microbiome markers and autonomic indices, as well as the correlation between the gut-brain-axis and clinical presentation of ASD. Moreover, we assessed the predictive capability of gut-brain-axis biomarkers in subtyping ASD cases.

Methods: We recruited 20 patients diagnosed with ASD (7-25 years, 2 of which are siblings) along with 19 first-degree relatives as neurotypical controls. Autonomic indices were measured via Empatica E4 wristband, which determines indices such as IBI, HR, EDA, BVP, and body temperature. Characterization of the gut microbiota was done via high fidelity 16S rRNA amplicon gene sequencing based on collected stool samples of all subjects.

Results: We found that IBI is significantly lower in ASD patients compared to neurotypical controls (paired t-test, $P < 0.004$). Moreover, in the use of combined autonomic-microbiome markers for classification of ASD and neurotypical subjects, a logistic regression model evaluated via ROC curve yielded high sensitivity and specificity for the classification ($AUC = 0.947$).

In examining ASD comorbidities and their relevance to autonomic dysfunction, significant inter-group differences were found in experiencing sleep disturbance among ASD and neurotypical subjects (Fisher's exact test, $P < 0.0005$). Then, we identified autonomic functions that are uniquely altered in ASD subjects with sleep disturbances (Mann-Whitney U test; Temp: $P < 0.1$, BVP: $P < 0.1$).

Conclusions: We hope that the information generated by our research will help to promote the development and validation of more accurate diagnostic tools and effective therapeutic interventions for patients with autism.

406.010 *(Poster)* Association of Brain GABA Concentrations with Anxiety and Other Co-Occurring Psychiatric Symptoms in Adults with Autism Spectrum Disorder

J. P. Giacomantonio[1]*, X. He*[2] *and K. D. Gadow*[3]*, (1)Stony Brook University, Stony Brook, NY, (2)Radiology, Stony Brook University, Stony Brook, NY, (3)Department of Psychiatry, Stony Brook University, Stony Brook, NY*

Background: Individuals with autism spectrum disorder (ASD) are at increased risk for a range of psychiatric anxiety disorders (Gadow *et al*., 2015; Siminoff *et al*., 2008) although their pathogenesis remains poorly understood. Recent studies have implicated GABA in ASD (Brix et al., 2015; Lam, Aman, & Arnold, 2006; Mahdavi et al., 2018; Rojas, 2014), however, research has generally failed to consider the implications of co-occurring psychiatric symptoms, particularly among adults. A recent meta-analysis found evidence supporting lower GABA concentrations (averaged across brain regions) in adults with ASD, MDD, and schizophrenia (Schur et al., 2016), thus raising questions about diagnostic specificity.

Objectives: The aim of the present study was to examine the association of brain GABA concentrations with psychiatric symptom severity among adults with ASD.

Methods: Participants were 16 adult males (18-45 years) with ADOS-defined ASD and IQs ≥80. (1) Single voxel J-editing H-MRS was acquired on Siemens Biograph 3T scanner for the metabolite GABA, which was performed with one voxel ($30\times30\times20$ mm^3) in the anterior cingulate cortex using a TR/TE of 2000/68 ms with a spectral bandwidth of 2 kHz, 384 spectral average and 16 water reference. Prior to the scan, participants completed the Beck Depression Inventory-2 (BDI-2), Adult Self Report Inventory-4 (ASRI-4), the Kaufman Brief Intelligence Test Second Edition (KBIT-2), and the Social Responsiveness Scale-2 (SRS-2).

Results: GABA levels were positively correlated with the severity of self-reported symptoms of generalized anxiety (ASRI-4; r=.629, p=.009), somatization disorder (ASRI-4; r=.510, p=.044), ADHD: Inattention (ASRI-4; r=.532, p=.034), borderline personality disorder (ASRI-4; r=.535, p=.033) and depression (BDI-2; r=.513, p=.042), but were not associated with severity of ASD, as assessed with the ADOS-2 (r=.086, p=.752) or SRS-2 (r=.038, p=.888), or IQ (r=.393, p=.132). After controlling for IQ, GABA levels were correlated with severity of generalized anxiety (ASRI-4; r=.590, p=.021) and somatization disorder (ASRI-4; r=.563, p=.029) subscales.

Conclusions: Research findings suggest that ASD is associated with dysregulation of brain GABA levels, but the results of the present study suggest that it may be premature to rule out the possibility that co-occurring psychiatric symptoms, particularly anxiety, may explain at least in part this association. GABA was not significantly associated with either IQ or ASD severity, possibly because our sample comprised high functioning adults with ASD. Moving forward, additional MRS studies with larger samples, as well as relevant comparison groups, will be necessary to further understand these associations.

406.011 *(Poster)* Atypical Saccadic Velocity in Children with Comorbid ASD and ADHD

S. Major[1]*, E. Tenenbaum*[2]*,* ***J. N. Grapel***[3]*, K. L. Carpenter*[1]*, M. Sabatos-DeVito*[4]*, L. Franz*[1]*, S. N. Compton*[5]*, M. Spanos*[2]*, N. O. Davis*[6]*, R. E. Aiello*[7]*, J. Schechter*[6]*, S. H. Kollins*[6] *and G. Dawson*[7]*, (1)Duke Center for Autism and Brain Development, Department of Psychiatry and Behavioral Sciences, Duke University, Durham, NC, (2)Duke Center for Autism and Brain Development, Durham, NC, (3)Psychology, Duke Center for Autism and Brain Development, Durham, NC, (4)Psychiatry and Behavioral Sciences, Duke Center for Autism and Brain Development, Durham, NC, (5)Psychiatry and Behavioral Sciences, Child/Family Mental Health and Developmental Neuroscience, Duke University Medical Center, Durham, NC, (6)Department of Psychiatry and Behavioral Sciences, Duke ADHD Program, Duke University Medical Center, Durham, NC, (7)Department of Psychiatry and Behavioral Sciences, Duke Center for Autism and Brain Development, Durham, NC*

Background: Saccade velocity requires precise motor control and depends on tonic inhibition of pontine burst cells, which is blocked by the superior colliculus during saccade initiation. Thus, saccade velocity can serve as an indicator of motor dysfunction in neurodevelopmental disorders. Studies investigating saccadic velocity in individuals with autism spectrum disorder (ASD) and attention deficit/hyperactivity disorder (ADHD) have yielded mixed results and have not been studied in children with both ASD and ADHD.

Objectives: We investigated *peak* and *mean* velocity in ASD, ADHD, comorbid ASD+ADHD, and typically developing (TD) children. We hypothesized children with neurodevelopmental disorders would show atypical saccade behaviors compared to TD children. We also hypothesized that saccade velocity would be associated with diagnostic classification and individual differences in behavior as measured by Vineland-3 (VABS) and Aberrant Behavior Checklist-C (ABC).

Methods: The sample included 54 children aged 36-95 months (M=67.62, SD=16.01): ASD (n=13; M IQ=76.46), ADHD (n=9; M=112.44), ASD+ADHD (n=16; M IQ=92.06), and TD (n=16; M IQ=114.81). An eye-tracking task consisted of a 3-minute video which included episodes of an actor using joint attention (JA), making dyadic bids (DB), making a sandwich (SW) and moving toys (MT). The dependent measure was saccadic velocity = pixels moved during an individual saccade/saccade duration in seconds.

Results: T-tests were used to test group effects. The TD group did not significantly differ from the three diagnostic groups. The ASD+ADHD group demonstrated higher *peak* velocity than the ASD-only group (MT, p=0.02) and the ADHD-only group (JA, p=0.02). Linear regression controlling for age and IQ revealed increased *peak* velocity was associated with any ASD diagnosis (JA, p=0.01) and with any ADHD diagnosis (MT, p=0.04) when assessing the entire sample. Among children with ASD, slower *peak* velocity was associated with more impaired motor skills (JA, p=0.02; SW, p=0.05) and communication skills (SW, p=0.03). Slower *mean* velocity was associated with more impaired communication skills (full video, p=0.02; JA, p=0.009) and adaptive behavior (full video, p=0.03). Among children with ADHD, decreased *mean* velocity was associated with increased hyperactivity symptoms (JA, p=0.05).

Conclusions: We found that children with comorbid ASD+ADHD demonstrated faster *peak* velocity in MT than ASD-only and faster *peak* velocity in JA than ADHD-only. Children with ASD tended to exhibit higher *peak* velocity during an episode with high social content (JA), whereas those with ADHD exhibited higher *peak* velocity during an episode with high nonsocial content (MT). Among children with ASD, slower *peak* velocity was associated with communication and motor impairments; slower *mean* velocity was also associated with communication and adaptive behavior impairments. Finally, for children with ADHD, slower *mean* velocity was associated with higher levels of hyperactivity. Saccadic behavior helps us to understand the complex, automatic biological processes that contribute to behavioral outcomes and sensorimotor decision making. This study provides evidence that individuals with comorbid ASD/ADHD have distinct gaze behavior that is present in both social scenes and in nonsocial scenes, providing a potential motor signature that distinguishes them from individuals with ASD alone or ADHD alone.

406.012 *(Poster)* Blood Biomarker Discovery in Autism Spectrum Disorder Using the Somascan Platform

L. Hewitson[1], *M. Devlin*[1], *J. A. Mathews*[2], *J. Lee*[3], *C. Schutte*[1] *and D. German*[4], *(1)The Johnson Center for Child Health and Development, Austin, TX, (2)University of Texas at Dallas, Dallas, TX, (3)Bioinformatics, University of Texas Southwestern, Dallas, TX, (4)Psychiatry, University of Texas Southwestern, Dallas, TX*

Background: Autism spectrum disorder (ASD) is a neurodevelopmental disorder characterized by deficits in social communication and social interaction, and restricted, repetitive patterns of behavior, interests or activities. Although ASD is characterized as a behavioral disorder, research has identified widespread changes in the genome, immune, and endocrine systems of children with ASD at both the systemic and cellular levels. Thus, many putative biological markers are being investigated using multiple approaches, to identify ASD blood biomarkers that may enable earlier detection and aid in the development of therapeutic interventions. Since proteomic analyses have indicated that the levels of many blood proteins are altered in ASD, a panel of proteins may provide a useful blood biomarker.

Objectives: The aim of this study was to perform a proteomic analysis of serum from boys ages 1.5 to 9 years of age, with and without ASD, in order to identify a panel of proteins characteristic of ASD.

Methods: Subjects included 76 boys with ASD (mean age 5.57, SD 1.66 years) and 78 typically developing boys (mean age 5.80, SD 1.99 years). ASD subjects underwent a diagnostic assessment using the ADOS and ADI-R. Clinical diagnosis was made based upon these assessments and overall clinical impression using DSM-IV/DSM-5 criteria. Controls were screened with the Adaptive Behavior Assessment System (ABAS-II) or the Vineland Adaptive Behavior Scales. Fasting blood samples were obtained using routine venipuncture and processed to collect sera following a standardized SOP. Samples were frozen in cryovials at -80^{o}C until analysis. Proteomic analysis was performed using SomaLogic's SOMAScan^{TM} assay 1.3K platform. The measurement data were log10-transformed and normalized across the samples. A machine learning method, Random Forest (RF), was used to identify a protein panel with the highest importance for ASD prediction. For the protein panel, a logistic regression-based prediction model was trained and tested in a 5-fold cross-validation scheme.

Results: A total of 1317 proteins were measured, with 192 excluded from analysis due to calibration insensitivity, leaving 1125 proteins to be analyzed. The mean decrease in Gini (MDG), a measure of variable importance for the RF, was chosen to identify important proteins. With an MDG threshold >0.5, the RF selected 12 proteins of the highest importance resulting in a subset of data consisting of 12 proteins. A logistic regression model was trained and tested after randomly splitting the subset data into training (80%) and test (20%) data for 100 times. A model evaluation metric, area under curve (AUC), was calculated for each model and was as high as 0.813±0.077. Using Gene Ontology (GO), functional enrichments for the selected proteins included cell response to growth factors, cell proliferation, morphogenesis, regeneration, vasculogenesis, signal transduction, and protein signaling.

Conclusions: These data suggest that a panel of serum proteins may be useful as a blood biomarker for ASD. Further analyses by integrative machine learning is on-going to examine whether demographic variables (including age and behavioral/diagnostic sub-scores) will further increase the prediction power measures including AUC, precision and recall. Verification of the protein classifier with independent test sets is warranted.

406.013 *(Poster)* Changes in EEG Coherence in Adolescents and Young Adults after the PEERS Intervention

A. D. Haendel[1], *A. Barrington*[2], *B. Magnus*[3], *A. Arias*[4], *K. Willar*[5], *S. Pleiss*[6], *B. Dolan*[7], *A. J. McVey*[3], *H. K. Schiltz*[3], *R. E. Stanley*[4], *M. Carlson*[8], *E. M. Vogt*[3], *M. Baalbaki*[4], *C. Casnar*[9], *B. Yund*[10], *W. Krueger*[11] *and A. V. Van Hecke*[3], *(1)Speech-Language Pathology, Concordia University Wisconsin, Mequon, WI, (2)Biomedical Engineering, Marquette University, Milwaukee, WI, (3)Psychology, Marquette University, Milwaukee, WI, (4)Marquette University, Milwaukee, WI, (5)Stanford University, Stanford, CA, (6)Great Lakes Neurobehavioral Center, Edina, MN, (7)Medical College of Wisconsin, Milwaukee, WI, (8)Education, Marquette University, Milwaukee, WI, (9)University of Wisconsin-Milwaukee, Milwaukee, WI, (10)Psychology, University of Wisconsin Milwaukee, Milwaukee, WI, (11)Speech Pathology and Audiology, Marquette University, Milwaukee, WI*

Background: ASD is a developmental disorder that affects social communication and behavior. There is consensus that neurological differences present in individuals with ASD. Further, theories emphasize the mixture of hypo- and hyper-connectivity as a neuropathology in ASD, however, there is a paucity of studies specifically testing neurological underpinnings as predictors of success on social skills interventions.

Objectives: The primary aim was to examine whether changes in neural connectivity occurred in young adults who participated in PEERS®, versus a control group of age and gender matched individuals with ASD who did not complete PEERS®.A second aim was to understand whether changes in EEG coherence were related to changes at the behavioral level.

Methods: Thirty young adults (18-27 years, FSIQ > 70) with ASD participated in the 16-week PEERS® intervention program. Electroencephalograms (EEG) were performed in an eyes-open resting state. Prior to as well as upon completion (pre and post) of PEERS®, young adults and social coaches completed self-report surveys: Quality of Socialization Questionnaire (QSQ), Social Responsiveness Scale (SRS), and Test of Yound Adult Social Skills Knowledge (TYASSK). Eight regions of interest, frontal, temporal, parietal, and occipital lobes in each hemisphere, were calculated and averaged (Figure 1). Magnitude Squared Coherence was calculated with the MVDR method for all possible pairings (28) in the alpha band (Pre and Post). Path Analyses were used to allow for correlated outcomes and covariates.

Results: This newly collected data will be compared to previous results obtained by the authors with a sample of adolescents (n = 110). In the adolescents sample, statistically significant differences were found between the ASD EXP and the ASD WL groups at time 2 in OL-TL (β =.202, *p* <.01). Significant effects of Income were found on EEG coherences at time 2 in OR-FR (β = -0.13,*p* <.005), OR-PL (β =-.291, *p* <.01), OR-TL (β =-0.27,*p* <.003), OR-FL (β =-0.14, *p* <.001), and OL-OR (β =-0.30, *p* <.005); ADOS Total score was a predictor of EEG coherences at time 2 in TR-PR (β =-0.27, *p* <.01), OR-TR (β =-0.25, *p* <.009), OL-TL(β = -0.27, *p* < .006). Residualized time 2 score in the FR-PR coherence pair at was significantly related to the Social Skills subtest of the *SSIS* at time 2 (β =.303, *p* <.002). Significant effects of OL-PL residualized coherence(β =.318, *p* < .002), and OR-TR residualized coherence (β =.36, *p* <.008) were found on QSQ-A scores at time 2.

Conclusions: Results from young-adults will be compared to those previously obtained from adolescents, which indicated that individuals exhibiting more severe symptoms of ASD showed less coherence in “short-range” EEG pairings in social brain areas. Adolescents who received PEERS® exhibited changes in an exemplar “short-range” coherence pair that was linked to changes in their social knowledge and behavior; a replication of this finding will be tested for in young adults. The new data is expected to add to the previously found evidence that initial brain differences and risks in ASD are affected by treatment, indicating support of neuroplasticity.

406.014 *(Poster)* Comparison of Blood Heavy Metal Levels and Quantitative EEG Correlates in Children with Autism Spectrum Disorder Aged 3-12 Years and Typically Developing Children :a Cross Sectional Study

S. Gulati[1], *S. Sharma*[2], *A. Gupta*[3], *P. K. Panda*[3], *R. Sharma*[4], *A. Ahmad*[5], *R. Pandey*[6], *R. Sehgal*[2], *A. Srivastav*[7], *J. A. Qadri*[8], *A. Shariff*[7], *S. Khan*[2], *S. Sayeed*[9] *and R. Samanchi*[7], *(1)Center of excellence and advanced research for childhood neurodevelopmental disorders, Child Neurology Division, Department of Pediatrics, All India Institute of Medical Sciences, New Delhi, India, (2)Child Neurology Division, Department of Pediatrics, All India Institute of Medical Sciences, New Delhi, New Delhi, India, (3)Child Neurology Division, Department of Pediatrics, All India Institute of Medical Sciences, New Delhi, India, (4)Department of Physiology, All India Institute of Medical Sciences, New Delhi, India, (5)Department of Physiology, All India Institute of Medical Sciences, New Delhi, New Delhi, India, (6)Department of Biostatistics, All India Institute of Medical Sciences, New Delhi, New Delhi, India, (7)All India Institute of Medical Sciences, New Delhi, New Delhi, India, (8)Anatomy, All India Institute of Medical Sciences, New Delhi, New Delhi, India, (9)Child Neurology Division, Department of Pediatrics, AIIMS, New Delhi, New Delhi, India*

Background: The etiological factors involved in the causation of autism remain elusive and controversial, but both genetic and environmental factors have been considered in the etiology of Autism Spectrum disorder (ASD). Heavy metals are considered as few of the possible environmental agents. The role of heavy metals is biologically plausible because they are known to disrupt enzyme functions, alter cellular signaling processes, and generate oxidative stress leading to apoptosis.

Objectives: The aim of this study was to understand contribution of heavy metal toxicity in development of Autism. Another objective was to determine quantitative EEG correlates of neuronal processing in ASD children, as compared to controls.

Methods: Total 180 children aged 3-12 years with ASD and 117 age and sex matched typically developing (TD) controls were enrolled between June 2016 and December 2018. Each child was subjected to detailed neuropsychological evaluation initially including DSM V criteria for ASD, Childhood Autism Rating Scale (CARS), Autism Behavior Check List (ABC), Child Behavior Check List (CBCL) and Development Quotient determination by Development Profile 3.One ml blood sample was collected in ultrapure Metal-free EDTA coated collection tubes and subjected to elemental analysis for chromium, manganese, lead, arsenic, zinc, iron, copper, selenium, nickel, cadmium and magnesium levels by Inductively Coupled Plasma Mass Spectroscopy.

Quantitative EEG (qEEG) correlates of neuronal processing were also analyzed using neural synchrony and time-frequency analysis, in resting state and using 4 tasks for evaluating executive function: Picture memory, Word memory, Verbal fluency and Digit span forward test. Quantitative EEG could be recorded in 61 children with ASD and 48 controls, during eyes open and eyes closed condition for 10 minutes each using 128 channel hydrocel geodesic sensor net.

Results: 180 children with ASD (153 boys, 85%, age-6.5±1.6 years, CARS-36.59±2.38, Development Quotient-59.94±5.86). ASD subjects were found to have having significantly high level of following metals in blood compared to controls: mercury (35.74±12.11 vs 4.28±2.07, p=0.001), chromium (75.01±20.04 vs 1.0±0.25, p=0.001), manganese (54.13±19.34 vs 10.52±2.99, p=0.001) and lead (128.34±42.09 vs 17.81±6.59, p=0.001). No significant difference was found between blood levels of Arsenic, Iron, Copper, Zinc, Nickel and Selenium between ASD subjects and controls. Similarly, no significant correlation between ASD severity by CARS and any blood heavy metal level could be observed. Only the increased blood lead levels correlated with increased hyperactivity score on CBCL in ASD subjects.

The spectral power of gamma, beta, lower alpha1, theta and coherence of gamma, lower alpha1 during eyes closed condition was significantly ($p < 0.0005$) lower and the spectral power of theta and coherence of lower alpha 1, theta, delta was significantly lower ($p < 0.0005$) during eyes open condition in ASD compared to TD children.

Conclusions: ASD children have different qEEG correlates, as well as, significantly higher blood mercury, chromium, manganese and lead levels as compared to typically developing children. Reduced spectral power and coherence in specific spectral bands could be used as a biomarker in children with Autism Spectrum Disorder.

406.015 *(Poster)* Connecting Brain and Behavior: Understanding GRIN2B Disruptive Mutations

C. M. Hudac[1], *T. DesChamps*[2], *R. K. Earl*[3], *J. Gerdts*[3], *E. E. Eichler*[4], *S. J. Webb*[3] *and R. Bernier*[3], *(1)Psychiatry and Behavioral Sciences, University of Washington, Seattle, AL, (2)Psychology, University of Washington, Seattle, WA, (3)Psychiatry and Behavioral Sciences, University of Washington, Seattle, WA, (4)Department of Genome Sciences, University of Washington, Seattle, WA*

Background: Targeted and effective treatment approaches to improve outcomes and quality of life for individuals with *GRIN2B* are on the horizon, thanks to advances across the fields of genetics, molecular biology, neuroscience, and behavioral science (Stessman, Bernier, & Eichler, 2014). However, efforts to truly achieve precision medicine are thwarted by small sample sizes, as well the lack of objective, sensitive, non-invasive biological measures (e.g., neural biomarkers) that reflect underlying genetic etiology. Clinical and medical features of *GRIN2B* make standardized clinical testing difficult, including severe intellectual disabilities (100%), hypotonia (72%), motor delay (91%), and motor coordination issues (72%) common to carriers of *GRIN2B* mutations (Freunscht et al., 2013). Parent report indicates attention problems are common for children with *GRIN2B* mutations (Freunscht et al., 2013), but little is known about neural attention mechanisms.

Objectives: We sought to link a promising electroencephalography (EEG) based candidate biological indicator ("biomarker") of the attention system to the behavioral profile of children with disruptive *GRIN2B* mutations.

Methods: Participants (N = 159, see Table 1) comprised of the following groups were included in these analyses: GRIN2B (i.e., with a known disruptive *GRIN2B* mutation), No Event ASD (i.e., no known disruptive genetic event), and Typically-Development. A passive auditory oddball EEG experiment (Hudac et al., 2018) measured attention and speed of habituation as reflected by the central N1 (60-140 ms) and P3a (100-350 ms). Linear mixed-effects analyses with random effects [R 3.6, lme() package] tested group differences in condition (i.e., deviant tone/sound vs. repeated tone) and habituation (i.e., the rate of increasing N1 or decreasing P3a amplitude).

Results: Compared to children with ASD but without a known disruptive mutation, we observed even larger amplitude responses when examining children with a disruptive *GRIN2B* mutation, including N1 amplitude, $F(2,146)=13.59$, $p<.0001$, and P3a amplitude, $F(2,144)=6.98$, $p<.01$. Increased N1 and P3a responses were related to lower cognitive abilities, $ps<.0001$, and more attention problems, $ps< .05$. There were no overall habituation differences between groups for the N1, $p>.092$. There was a significant group x condition differences in linear slope of the P3a, $F(2, 20379)=3.99$, $p<.019$, that indicated a unique *GRIN2B* pattern: the increased response to frequent tones habituated rapidly.

Conclusions: The increased N1 and P3a responses in children with *GRIN2B* disruptive mutations is aligned with well-noted attention problems, including hyperactivity, impulsivity, distractibility, and short attention span (Freunscht et al., 2013). These results indicate that both early detection (N1) and later encoding (P3a) stages of the attention system may be affected in *GRIN2B* and may relate to specific behavioral challenges. It may be possible to use this information to generate different management and therapeutic strategies for improving individual outcomes.

406.016 *(Poster)* Context Modulates Attention to Faces in Dynamic Social Scenes in Children and Adults with Autism Spectrum Disorder.

G. J. Pandina[1]*, D. Kaliukhovich*[2]*, N. V. Manyakov*[3]*, A. Bangerter*[4]*, S. Ness*[5]*, A. Skalkin*[6]*, M. Boice*[1] *and F. Shic*[7]*, (1)Janssen Research & Development, Titusville, NJ, (2)Janssen Research & Development, LLC, Beerse, Belgium, (3)Computational Biology, Janssen Research & Development, LLC, Beerse, Belgium, (4)Janssen Research & Development, LLC, Pennington, NJ, (5)Janssen Research & Development, LLC, Titusville, NJ, (6)Janssen Research & Development, LLC, Spring House, PA, (7)Center for Child Health, Behavior and Development, Seattle Children's Research Institute, Seattle, WA*

Background: Compared to typically developing (TD) controls, individuals with autism spectrum disorder (ASD) on average look less at socially informative elements of visual scenes (e.g., people, faces, gestures). Toddlers with ASD were shown to alter the level of allocated visual attention to faces depending on a context (Chawarska et al., 2012). Yet it is uncertain whether the same effects persist in older ASD population.

Objectives: To examine whether context affects allocation of visual attention in dynamic social scenes in children and adults with ASD as compared to TD controls.

Methods: Eye movements of individuals with ASD (n=94; 68 males; mean age [SD]=14.5[7.3] years) and TD controls (n=38; 25 males; age=16.7[13.6] years) were recorded while they viewed two videos presenting an actor in the center and toys in each corner of the screen (total duration=163 seconds) (Plesa-Skwerer et al., 2019). The actor was either (1) silently performing a simple activity, (2) looking at a single moving or (3) stationary toy, or (4) engaged in a viewer-directed speech. For each of the four contexts, mean total looking time normalized by the duration of video display in that context was computed. Additionally, for each context mean percentage of the total looking time (denoted % looking time) spent by participants on looking at five non-overlapping regions of interest (ROIs) in that context was computed. The ROIs included the actor's face, body, hands/activity, toys and the remaining background. Differences in % looking time between the ASD and TD groups in each context were tested using a linear mixed-effects model. Each model included % looking time as a dependent variable, and participant's age, gender, group, ROI and an interaction between the latter two factors as fixed effects. Participant identifier served as the random intercept.

Results: Mean total looking time ranged from 86.5% to 88.3% across contexts and did not differ between the two groups of participants ($p>0.24$). In each context, % looking time varied across ROIs ($p's<10^{-15}$). Although both groups showed similar viewing patterns across ROIs, individuals with ASD looked less at the actor's face when an actor was performing an activity (mean % looking time [SD], ASD vs. TD: 30.7[8.2]% vs. 34.9[5.1]%; Cohen's d=0.56; $p<0.03$) or looking at a moving toy (24.5[13.0]% vs. 33.2[13.8]%; d=0.65; $p<0.001$). Comparisons of % looking time for the core features of faces revealed a consistently lower level of visual attention to the actor's eyes and mouth across contexts in individuals with ASD than in TD controls. In no context was % looking time significantly modulated by age or gender.

Conclusions: Depending on a context, children and adults with ASD view social scenes either in the same or different manner as TD controls. In some contexts, ASD and TD populations differ in allocation of visual attention to faces. Differences in attention to faces observed from toddler years to adulthood suggest that they could be used to discriminate between ASD and TD populations across the lifespan and, thus, could serve as a biomarker of ASD.

406.017 *(Poster)* Development of an Objective Autism Risk Index Using Arabic Remote Eye Tracking Paradigm

F. Alshaban[1] *and I. M. Ghazal*[2]*, (1)Qatar Biomedical Research Institute, Doha, Qatar, (2)Neurological Diseases Research Center, Qatar Biomedical Research Institute, Doha, Qatar*

Background: Deficits in eye gaze are a hallmark feature of autism spectrum disorder (ASD) and are included in gold standard diagnostic instruments. More than a decade of research into abnormalities of eye gaze has confirmed social attention deficits as a key feature of ASD. Across studies, diverse stimulus paradigms have elicited social attention abnormalities, ranging from decreased fixation to others' eyes and social scenes as early as 6 months of age, to gaze abnormalities during dyadic or joint attention bids in preschoolers and older children, to aberrant gaze toward dynamic social stimuli in older high-functioning individuals.

Gaze patterns, particularly those based on dynamic temporal analysis, may be a promising objective risk marker of ASD as well as a quantitative measure of autism symptoms spanning the full continuum of behavior. Developing an Arabic version of eye tracking stimuli paradigm mimic the English ones used by previous studies to be used for Arabic speaking individuals is challenging but promising.

Objectives: The primary aim of the present study was to create an objective, eye tracking-based autism risk index using Arabic version stimuli paradigm.

Methods: Children were recruited for comprehensive multidisciplinary evaluation of ASD and subsequently grouped by clinical consensus diagnosis (ASD n=106, non ASD 100. Remote eye tracking using Arabic version stimuli. Dwell times were recorded to each priori-defined region-of-interest (ROI) and averaged across ROIs to create an autism risk index.

Results: Similar to the previous findings, the autism risk index had high diagnostic accuracy with area under the curve (AUC)= .89 and .84, 95% CIs=.80-.97 and 070-.95, was strongly associated with Autism Diagnostic Observation Schedule-Second Edition severity score.

Conclusions: The autism risk index is a useful quantitative and objective measure of risk for autism in at-risk settings. Using the Arabic remote eye tracking paradigm proved to be as effective as the English version used in previous research projects.Future research in larger samples is needed to cross-validate these findings. If a validated scale for clinical
use, this measure could inform clinical judgment regarding ASD diagnosis and track symptom improvements.

406.018 *(Poster)* Developmental Effects of Serotonin in ASD: Relationship to Core and Associated Symptoms

A. Alcon[1]*, A. San Jose Caceres*[2] *and M. Parellada*[3]*, (1)Hospital Gregorio Marañon, CIBERSAM, IISGM, Madrid, Spain, (2)Child and Adolescent Psychiatry, Fundación para la Investigación Biomédica del Hospital General Universitario Gregorio Marañón, Mardrid, Spain, (3)Fundación Investigación Biomedica Gregorio Marañon, Madrid, Spain*

Background: Compelling evidence points out the plausible association between serotonin and Autism Spectrum Disorder (ASD) (Garbarino, et al., 2018), with around 30% of children with ASD presenting hyperserotonemia (Gabriele, Sacco & Persico, 2014). Furthermore, some studies suggest that pre-pubertal children physiologically show higher levels of serotonin than those past puberty (McBride et al., 1998).

Objectives: The aims of this study are twofold: 1) to explore the relationship between serotonin and ASD symptoms, and 2), using a wide age range sample of individuals with ASD, to study the developmental effect (or lack of) for such relationship.

Methods: One hundred and eight individuals (88,9% male; 92,6% caucasian; ages 3 to 45) were recruited. Thirty-nine individuals were 12 or less years of age, while 69 were older than 12. Socio-demographic data, obstetric history, early developmental milestones, severity of ASD symptoms, associated symptoms, and platelet serotonin levels were assessed in all individuals.

Results: A statistically significant inverse relationship between serotonin and age (r = -0.269; p = 0.005) was observed. Comparing to older individuals, participants under 12 showed, on average, significantly higher serotonin levels (U = 969; p = 0.016). No association between serotonin and severity core or presence of associated symptoms was found in patients under 12 years of age. However, in the older group, hyperserotonemia was related to a delay in motor (r = 0.258; p = 0.038) and language (r = 0.455; p = 0.001) development milestones.

Conclusions: As previously reported, ASD serotonin levels were higher at younger ages. Contrary to what was expected, serotonin levels did not relate to severity of core or presence of associated ASD symptoms. Bigger samples of prepuberal participants will better inform of the relationship between level of serotonin and severity or profile of ASD symptoms. In adults, hyperserotonemia seems to index a global neurodevelopmental delay.

406.019 *(Poster)* Do Motor Abnormalities Constitute an Endophenotype of Autism Spectrum Disorder ?

M. Fabbri-Destro[1]*, G. Scarpini*[2]*, A. Russo*[3]*, E. Scalona*[1]*, C. Marsella*[1]*, M. Pinzino*[1] *and A. Narzisi*[4]*, (1)Istituto di Neuroscienze, Consiglio Nazionale delle Ricerche (CNR), Parma, Italy, (2)Istituto Scienze Neurologiche di Bologna, IRCCS Ospedale Bellaria, Bologna, Italy, (3)Salute Mentale e Dipendenze Patologiche Centro di II livello per i Disturbi dello Spettro Autistico, Azienda Unità Sanitaria Locale di Modena, Modena, Italy, (4)IRCCS Stella Maris Foundation, Pisa (Calambrone), Italy*

Background: It is well established that actions are composed by series of motor acts which are not independent each other, but rather interconnected in a chained organization. For example, in a reach, grasp and place action, the kinematics of the first motor act (and not only of the last one) is influenced by the final goal of the action. This fundamental property of motor organization is deficitary in autism spectrum disorder. Whether siblings of children with autism exhibit the same motor pattern is to date an open point, whose answer could support the existence of a phenotypic link between the genetics of autism and motor abnormalities.

Objectives: The aim of the present study is threefold: first, to verify the existence of an action goal-dependent modulation in typically developing children (TD) since young age (2-5) during the execution of reach-to-grasp and place actions; second, to ascertain that such modulation is absent in children with ASD; third, to investigate the behavior of unaffected siblings (SIB) in the same task.

Methods: Thirty-four children (mean age 3.8 yrs, 10 TD, 11 ASD, 13 SIB) were required to reach and grasp an object, and then place it into a container, which could be either big or small. The upper limb kinematics was recorded via inertial sensors, while the overall movement was videotaped. The duration of each motor act was computed, and submitted to a mixed ANOVA with Group (TD, ASD, SIB) and Size (Big and Small) as factors. Post hoc analysis was Bonferroni corrected.

Results: A significant Group*Size interaction was found for the reaching duration ($F(2, 31)=4.7$, $p=0.01$). Post-hoc comparisons revealed that while TD were significantly faster in reaching when the object had to be placed into the big container (640 vs 710 ms, $p=0.02$), both ASD children and their siblings did not show any modulation (ASD: 584 vs 589ms; SIB: 569 vs 560ms). The same analysis conducted on the placing duration returned a significant main effect of Size ($p<0.001$) but a no significant Group*Size interaction. Both TD and ASD presented a significant modulation for size (TD: 543 vs 753ms, $p=0.009$; ASD: 614 vs 853ms, $p=0.001$). Despite showing a similar pattern (593 vs 671ms) siblings only approached the statistical threshold ($p=0.2$).

Conclusions: Even in simple actions implying different motor intentions, young typically developing children modulate their kinematics throughout the entire actions, i.e. since the initial motor act. Showing this behaviour already in three years old children advocates for the innateness of this property within the human motor system. Children with ASD are not capable of this modulation suggesting a piece-by-piece montage of executed actions. The fact that also siblings present a similar disorganization renders this lacking modulation eligible as an endophenotype of ASD, and reinforces the role of motor deficits in the etiology of autism.

406.020 *(Poster)* Early Evidence of Attentional Biases in Infants at Elevated Likelihood for Autism

A. R. Dallman[1]*, C. Harrop*[1]*, J. Goldblum*[1]*, K. Thompson*[1]*, G. T. Baranek*[2] *and L. R. Watson*[1]*, (1)Department of Allied Health Sciences, University of North Carolina at Chapel Hill, Chapel Hill, NC, (2)Chan Division of Occupational Science and Occupational Therapy, University of Southern California, Los Angeles, CA*

Background: Social and non-social attention differences are hallmarks of autism spectrum disorder (ASD) that have been measured via eye-tracking. However, it is unclear how early in development these differences emerge. Recently, researchers have identified markers of risk in ASD including reduced attention to fearful faces (Wagner, Keehn, Tager-Flusberg, & Nelson, 2019) and reduced left visual field bias (Dundas, Gastgeb, & Strauss, 2012). A notable gap in this literature is the employment of child-directed speech (CDS) videos, which include dynamic social and non-social stimuli that more closely resemble real-life social situations than static pictures.

Objectives: In the present study, we aim to further our understanding of this area by examining attentional biases during three separate CDS conditions.

Methods: Infants (11 to 16 months) were recruited into one of two groups: elevated likelihood of ASD (EL-ASD) based on the dual cut-off criteria of the First Years Inventory Lite (FYI-LITE V3.1b), (Baranek, Watson, Crais, Turner-Brown & Reznick, 2014; n=21) and lower likelihood of ASD (LL-ASD) (n=20). Eye gaze patterns were collected via a Gazepoint GP3 HD eye tracker while infants passively viewed a CDS paradigm that consisted of a baseline video, three CDS videos (a puppet narrative, a book story-telling, and an adult playing with a toy using non-sensical speech), and a second baseline. Areas of interest (AOIs) were mapped for each scene to include social stimuli (i.e., human face, puppet face) and non-social stimuli (i.e., flowers, trees). Social and non-social attention was calculated as a proportion of the total time attending to the screen for each given scene within the CDS paradigm. We examined differences in social and non-social attention, overall attention and number of discrete fixations by AOI using t-tests.

Results: There were no differences in overall attention to the screen (across all scenes) between groups. During the child-directed book reading scene, children in the HL-ASD group spent significantly more time attending to faces ($p = .02$) and had more discrete fixations to the face ($p = .01$) compared to the LL-ASD group. During this same scene, the HL-ASD group spent significant less time attending to the book ($p = .02$) and had fewer fixations to the book ($p = .05$). During the puppet scene, the HL-ASD group fixated on the elephant fewer times (differences approaching significance, $p=0.08$) and spent a significantly greater portion of the time attending at the butterfly ($p=0.02$).

Conclusions: Results suggest that attentional biases may present in infants at HL-ASD. In contrast to previous studies in older children, infants in our HL-ASD group spent significantly greater time looking at faces. This may mean that high-risk infants demonstrate less screen exploration (i.e., scanning the screen visually to explore all the available objects in the field) and instead demonstrate greater attentional inflexibility. This inflexibility may manifest in the later years as attentional inflexibility towards restricted interests. We will further these analyses by examining dyadic gaze (shifting between book and face during the story-telling paradigm) and examine attention to specific facial AOIs (eyes and mouth) to further test this hypothesis.

406.021 *(Poster)* Early Social-Communicative Interventions Affects Event-Related Potentials (ERPs) in Toddlers: A Randomized-Controlled Trial

A. Piatti*, S. Van der Paelt, P. Warreyn and H. Roeyers, Department of Experimental-Clinical and Health Psychology, Ghent University, Ghent, Belgium*

Background: A growing amount of evidence supports the effectiveness of early intervention on the social-communicative skills of children with autism spectrum disorder (ASD).

Objectives: This randomised controlled trial (RCT) tests the effects of Project ImPACT, an early parent-run intervention targeting social-communicative skills, on the behaviour and brain activity of toddlers with Autism Spectrum Disorder (ASD).

Methods: Twenty-five toddlers (3 girls, mean age: 3.1 ±.6) with ASD have participated to date in this RCT and received either Project ImPACT or a treatment which does not focus on social-communicative abilities (TAU). Both treatments are administered at low intensity (90 minutes or less per week) for 18 weeks. Currently, 36 children have completed baseline testing, and outcome data are expected before the INSAR meeting for the entire sample. Outcome measures include ASD symptom severity (ADOS-2, BOSCC), cognitive development (M-SEL), observation of social engagement, and event related potentials (ERPs) in response to standard and deviant voice and non-voice stimuli.

ERP analysis was conducted over the mean voltages in the P1, N2, P3, and N4 time-windows at Fz and Cz sites.

For each time window, a 2(time) X 2 (group) interaction was tested using permutation-based t-test (n=5000) over the difference between baseline and outcome in the mean response to deviant stimuli. For time-windows where this interaction was significant, a comparison with a group of age-matched typically developing children (n = 16, 3 girls) was also carried on. Based on what the literature suggests to be the possible functional meaning of the components affected by treatment, their relationship with the pertinent behavioural measures was also explored.

Results: There was a significant time X group interaction in the P1 (t(1,23) = 1.915, p =.038) and N2 time windows (t(1,23) = 1.950, p =.036). For the ImPACT group, there was a significant effect of time on both components (P1: t(1,14)= 2.443, p =.031; N2: t(1,14) = 2.189, p =.048), whereas this was not the case for the TAU group.

When compared to the TD group at baseline, both groups of children with ASD showed a significantly more negative N2 component (ImPACT: t(1,29) = 1.968, p =.031; TAU: t(1,24) = 1.764, p =.049). At outcome, however, only the TAU group differed significantly from TD (t(1,24) = 2.288, p =.018). As for the P1 component, the two groups of children with ASD did not significantly differ from TD before or after treatment.

Correlation analysis indicates that P1 mean voltages at baseline are related to restricted and repetitive behaviour scores (RRB) observed in the ADOS-2 at the same time-point (r_s =-.621, p =.005), whereas P1 mean voltages at outcome relate to RRB score measured at follow-up, approximately 12 weeks later (r_s =-.563 , p =.012). The P1 gain was also related to a decrease in RRB symptom severity (r_s =-489, p =.034).

Conclusions: Effects of treatment were significant for the ImPACT group on the P1 and N2 components, which typically reflect costs of attentional shift. Consistently with this, the treatment-related increase in P1 mean voltages reflected an attenuation of behavioural rigidity.

406.022 *(Poster)* Event-Related Potential Study of Visual Oddball Test in Children with Autism Spectrum Disorder, ADHD, Comorbid Autism and ADHD, and Neurotypical Children

E. M. Sokhadze[1], *L. Sears*[1], *A. Tasman*[1], *E. L. Casanova*[2], *D. P. Kelly*[3] *and M. Casanova*[4], *(1)University of Louisville, Louisville, KY, (2)University of South Carolina, School of Medicine, Greenville, SC, (3)University of South Carolina School of Medicine Greenville, Greenville, SC, (4)University of South Carolina School of Medicine, Greenville, SC*

Background: Autism spectrum disorder (ASD) and attention deficit/hyperactivity disorder (ADHD) are two of the most commonly diagnosed childhood neurodevelopmental disorders. Although the comorbidity was excluded in DSM IV, DSM-5 does not preclude the concurrent diagnosis of ADHD and ASD (ASD+ADHD). In recent years the prevalence of both ASD and ADHD, as well as comorbid ASD+ADHD, has increased substantially.

Objectives: This study aimed to better understand the distinctions and similarities in manifestations of executive deficits among these conditions. For this purpose we used analysis of behavioral responses such as reaction time (RT)/accuracy and event-related potentials (ERP) during performance on a visual oddball task with illusory figures. Based on our prior data and other reports, we predicted that ASD diagnosis would factor more in such executive function as error monitoring, detection and correction, while those with an ADHD diagnosis would manifest changes in the latency of ERP responses.

Methods: Participants were age-matched children (N=18 per group) with ASD, ADHD, comorbid ASD + ADHD diagnosis and neurotypical controls (CNT). EEG was collected using 128 channel EEG system. The task involved the recognition of a specific illusory shape, in this case a square or triangle, created by three or four inducer disks.

Results: Analysis of data revealed that there were no between group differences in RT to target stimuli, but both ASD and ASD+ADHD groups committed more errors; more specifically, the ASD groups had higher omission error rates than neurotypical children. Post-error RT in ASD and ASD+ADHD groups manifested as a post-error response speeding rather than the corrective RT slowing typical of the controls. The ASD and ASD+ADHD group also demonstrated an attenuated error-related negativity (ERN) component as compared to ADHD and controls. The fronto-central N100 was enhanced and less differentiated in response to target and non-target figures in the ASD and ASD+ADHD groups as compared to CNT children. In addition, several frontal ERP components in response to non-target stimuli had prolonged latencies in the ADHD group as compared to both ASD and CNT groups.

Conclusions: This comparative ERP study confirmed the utility of using electrocortical responses to elucidate differences between ASD and ADHD and their impact in dual ASD+ADHD diagnosis. This information helps define the extent of overlap among these comorbidities both in terms of symptom expression as well as underlying neuropathology.

406.023 *(Poster)* Exploring the Effectiveness of EEG-Based Biomarkers during Facial Emotion Recognition in Classifying Autism in Adulthood

M. H. Black[1,2,3], *T. Tan*[2,3,4], *S. Bolte*[1,2,5,6], *N. T. Chen*[1,2,3,7,8], *O. V. Lipp*[2,7] *and S. J. Girdler*[1,2,3], *(1)School of Occupational Therapy, Social Work and Speech Pathology, Curtin University, Perth, WA, Australia, (2)Cooperative Research Centre for Living with Autism (Autism CRC), Long Pocket, Brisbane, QLD, Australia, (3)Curtin Autism Research Group, Curtin University, Perth, WA, Australia, (4)School of Mechanical Engineering, Curtin University, Perth, WA, Australia, (5)Center of Neurodevelopmental Disorders (KIND), Centre for Psychiatry Research; Department of Women's and Children's Health, Karolinska Institutet, & Stockholm Health Care Services, Region Stockholm, Stockholm, Sweden, (6)Child and Adolescent Psychiatry, Stockholm Health Care Services, Stockholm, Sweden, (7)School of Psychology, Curtin University, Perth, WA, Australia, (8)School of Psychological Sciences, University of Western Australia, Perth, WA, Australia*

Background: Currently evaluating Autism Spectrum Disorders (ASD) is largely based on clinical judgment and behavioral assessment, however there is emerging evidence that electrophysiological biomarkers may support the diagnosis, classification, prognosis, and even treatment of ASD.

Objectives: With the goal of investigating the effectiveness of electroencephalography (EEG) as a potential biomarker for ASD, this study employed a data-driven approach to analysising frequency power as measured during a facial emotion recognition (FER) task in autistic and non-autistic adults.

Methods: Electroencephalogram (EEG) frequency power was collected for 22 autistic adults and 27 non-autistic adults while completing complex, dyamic FER task. This FER tasks involved partcipants viewing 3-7 second long silent video clips of actors expressing positive and negative facial expressions. Following the presentation of each clip, participants were asked to select from four options, which emotion they believed was portrayed in the clip. Machine learning algorithms, including Naïve Bayes, Sequential Minimal Optimization (SMO), Multilayer Perception (MLP), Decision Stump, Random Forest and Random Tree were applied to the data to investigate the accuracy of EEG based biomarkers in classifying ASD in adulthood. Further classifications were conducted based on participants' Social Responsiveness Scale scores -2 (SRS-2) and combining EEG and SRS-2 scores to determine the utility of EEG-based classification compared to a popular screening measure.

Results: Area under the receiving curve (AUC) revealed that classifier accuracy based on EEG alone ranged from 0.62 – 0.88, while accuracy on the SRS-2 ranged from 0.73 – 0.87. Classifications based on EEG and SRS-2 combined ranged from 0.72 – 0.97.

Conclusions: EEG biomarkers collected during FER may provide a prospective means of classifying ASD, offering an accuracy similar to that of the SRS-2 screening measure and similar to current diagnostic assessments. The use of EEG biomarkers and SRS-2 combined resulted in the highest accuracy. The use of EEG-based biomarkers may provide a means of assisting in diagnosis and prognosis through triangulation with traditional behavioral assessment.

406.024 *(Poster)* Habituation As an ASD Biomarker: Capturing Distinct Genetic Profiles in Drosophila and Humans

L. Blok[1], T. DesChamps[2], M. Fenckova[1], I. Erdogan[1], E. E. Eichler[3], S. J. Webb[4], R. Bernier[4], A. Schenck[1] and ***C. M. Hudac***[5,6]*, (1)Department of Human Genetics, Donders Institute for Brain, Cognition and Behaviour, Radboud University Medical Center, Nijmegen, Netherlands, (2)Psychology, University of Washington, Seattle, WA, (3)Department of Genome Sciences, University of Washington, Seattle, WA, (4)Psychiatry and Behavioral Sciences, University of Washington, Seattle, WA, (5)Psychiatry and Behavioral Sciences, University of Washington, Seattle, AL, (6)Department of Psychology; Center for Youth Development and Intervention, The University of Alabama, Tuscaloosa, AL*

Background: Autism spectrum disorder (ASD) and intellectual disability (ID) are highly co-morbid disorders, both associated with sensory information overload and sensory sensitivities (Joosten & Bundy, 2010; Wilson et al., 2019). Habituation is the mechanism by which sensory information is filtered at the neural level, and it represents a fundamental, evolutionarily conserved form of learning. Atypical habituation patterns are reported in ASD (Hudac et al., 2018; Vivanti et al., 2018), and may underlie cognitive and behavior hallmarks of both ASD and ID. Recent work in *Drosophila* has identified >100 orthologs of genes implicated in ID and comorbid ASD to be required for habituation learning (Fenckova et al., 2019). A better understanding of the biological mechanisms at the genetic and neural levels will elucidate the underlying pathophysiology and may help stratify children with similar biological mechanism for filtering sensory information.

Objectives: Our objective is to link gene-specific habituation profiles from *Drosophila* to human children with disruptive mutations to develop habituation as a translational biomarker for preclinical drug screening, objective clinical classification, and stratification of human cohorts.

Methods: Approximately 300 *Drosophila* orthologs were manipulated (gene-specific panneuronal knockdown) and tested in a high-throughput light-off jump habituation assay, in which we recorded the rate by which *Drosophila* continue to respond to a light-off stimulus over successive trials. *Drosophila* models were characterized as habituation deficit (i.e., no or slower decrease in response), or normal habituation. In humans, we targeted a group of children with a known disruptive mutation associated with ASD and/or ID (see Table 1). A passive auditory oddball EEG experiment (Hudac et al., 2018) measured attention and speed of habituation, and here we focus on novelty response of the P3a (100-350 ms). Linear mixed-effects analyses with random effects [R 3.6, lme() package] tested genetic group differences in condition (i.e., rare, deviant sound vs. frequent, repeated tone) and habituation (i.e., the rate of decreasing P3a amplitude).

Results: Genes with deficient habituation in *Drosophila* were in humans predominantly associated with comorbid ASD+ID (as opposed to ID without ASD), p = .001. Based upon these results, we characterized children into either habituation deficit or normal habituation in *Drosophila*. All groups exhibited a P3a novelty response indicated by a larger P3a amplitude for novel relative to frequent sounds, $F(1,3968)=238.4$, $p<.0001$. However, an interaction between habituation, condition, and group, $F(1,3968)=3.85$, $p=.049$, indicated that the habituation deficit group exhibited comparable habituation to both frequent and novel sounds, $p=.08$.

Conclusions: Habituation patterns observed in children within the habituation deficit group were atypical from prior work in TD and other children with ASD (Hudac et al., 2018) and may implicate different biological mechanisms for filtering sensory information. This work provides an argument for the evolutionarily conserved genetic architecture of habituation learning and its relevance to neurodevelopmental disorders. Together, our results raise the exciting possibility that habituation deficits can be used as a widely applicable cross-species biomarker for translational research and may aid in the identification of treatment targets.

406.025 *(Poster)* Higher Lactate Level and Lactate-to-Pyruvate Ratio Might be Potential Biomarkers in Autism Spectrum Disorder

H. Yoo[1]*, M. Oh[2] and S. A. Kim[3], (1)Psychiatry, Seoul National University Bundang Hospital, Seongnam, Korea, Republic of (South), (2)Psychiatry, Kyung Hee University Hospital, Seoul, Korea, Republic of (South), (3)Pharmacology, Eulji University College of Medicine, Daejon, Korea, Republic of (South)*

Background: Mitochondrial dysfunction is considered as one of the pathophysiological mechanisms of autism spectrum disorder (ASD). However, previous studies of biomarkers associated with mitochondrial dysfunction in ASD revealed inconsistent results. Also, as those studies are mainly conducted in Caucasian population, it is necessary to expand those into Asian population.

Objectives: The objective of this research is to evaluate biochemical markers associated with mitochondrial dysfunction in subjects with ASD as compared with their unaffected family members.

Methods: The participants with ASD, both biological parents and their unaffected siblings were recruited through child and adolescent psychiatric clinic at Seoul National University Bundang Hospital. The subjects were ascertained through standardized diagnostic procedures using Korean versions of Autism Diagnostic Interview-Revised (ADI-R), Autism Diagnostic Observation Schedule - 2 (ADOS-2) and social responsiveness scale (SRS). Lactate, pyruvate and lactate-to-pyruvate ratio were examined in the peripheral blood of probands with ASD (Affected Group) and their unaffected family members (biological parents and unaffected siblings, Unaffected Group). Lactate ≥ 22mg/dl, pyruvate ≥ 1.4mg/dl and lactate-to-pyruvate ratio > 25 were defined as abnormal range. The clinical variables were compared in the subjects with higher (>25) and lower (≤25) lactate-to-pyruvate ratio within Affected Group. Independent samples t-tests were used to compare baseline characteristics between two groups. Differences measurement were examined with paired t-tests for both groups. Chi-squared test (χ^2) was performed to determine the ratio of higher level of chemical variables in two groups. Statistical significance was defined as $p < 0.05$.

Results: (1) A total of 58 Affected Group (mean age 99.35 ± 54.01 months, 20.60% female, mean IQ 75.98 ± 20.67) and 137 Unaffected Group (443.43 ± 150.26 months, 51.80% female, mean IQ 103.13 ± 13.88 for siblings) were included in this study. (2) Affected Group showed significantly higher level of lactate and lactate-to-pyruvate ratio compared to Unaffected Group (lactate 19.67 ± 11.40 vs. 13.79 ± 6.17, lactate-to-pyruvate ratio 21.15 ± 18.45 vs. 15.20 ± 9.56, $p < 0.01$). The frequency of subjects with abnormally higher range of lactate level and lactate-to-pyruvate ratio was significantly higher in Affected group (lactate 31.0% vs. 9.5%, ratio 25.9% vs. 7.3%, $p < 0.01$). (3) Clinical variables including domain scores of ADOS-2, ADI-R diagnostic algorithms and total SRS scores did not reveal significant differences in two groups.

Conclusions: These results suggest that the biochemical markers related to mitochondrial dysfunction, especially higher lactate level and lactate-to-pyruvate ratio might be associated with pathophysiology of ASD. Further larger sized study using unrelated individuals is needed for controlling possible effects of age and sex on the chemical biomarkers.

406.026 *(Poster)* Identifying Clusters of Preschoolers with Autism Based on Physiological Responses to Social and Non-Social Videos and Their Relation to Phenotypic Profiles

T. Bazelmans[1]*, T. Charman*[2]*, E. J. Jones*[3] *and S. J. Webb*[4]*, (1)King's College London, Institute of Psychiatry, Psychology and Neuroscience, London, United Kingdom, (2)Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, United Kingdom, (3)Centre for Brain and Cognitive Development, Birkbeck, University of London, London, United Kingdom, (4)Psychiatry and Behavioral Sciences, University of Washington, Seattle, WA*

Background: To understand the emergence of autism symptoms, it is necessary to study mechanisms that may contribute to the compromised development of early social communication skills. Prior research suggests that engagement in social interactions is attenuated early on in autism, which could affect the development of social and language skills. Behavioural attention is, however, not the same as engagement, and studying physiological responses, such as heart rate (HR), to external stimuli can provide additional information about a child's attentional state.

Objectives: We aim to compare HR and heart rate variability (HRV) to social and non-social videos of typically developing (TD) children and children with autism. Besides a case-control approach, clustering techniques are used to look at groups of children with more similar phenotypic and physiological profiles, which are compared using categorical and dimensional analyses.

Methods: Sixty-five TD children and 67 children with autism between 2 and 5-years participated in a study where HR was measured during a screen-based battery of social and non-social videos. The first block of videos included a video of a toy and a man singing English nursery rhymes, the second block was of a woman singing nursery rhymes, once in English and once in Hungarian. Phenotypic profiles were based on the child's non-verbal, language, social and executive function skills as well as autism symptom severity. We conducted four types of analyses: 1) case-control (TD vs. autism) mixed model, 2) mixed model with four identified phenotypic clusters (TD versus ASD with (a) phenotypic scores comparable to TD, (b) mostly difficulties with executive function and social skills, (c) mostly difficulties with language and non-verbal skills, (d) low scores across phenotypic measures), 3) mixed model with three identified physiological clusters (low, medium and high arousal), and 4) principle component analysis (PCA) on the continuous physiological data to find patterns of physiological responses, which were subsequently related to phenotypic data.

Results: Case-control and autism clusters did not reveal any group differences in HR or HRV, however, there was an interaction effect between group and video in the HR models, showing that physiological arousal in children with autism increases more to the social versus non-social videos, especially over time. The physiological clusters were associated with age only and none of the phenotypic measures. This was confirmed by the PCA, which showed that the largest component, related to the child's average HR, correlated with age. The second PCA component showed an increase in HR from the first to the second block of videos; a larger HR increase was associated with poorer language skills. The third PCA component showed a modulation based on video content; children who showed a larger decrease in HR from Toy to Man and from English to Hungarian, had better language and social skills and displayed less autism symptoms.

Conclusions: A variety of techniques showed individual differences in modulation of physiological arousal, which were related to a child's social and communication behaviours. This supports the theory that atypicalities in social engagement could be related to emerging symptoms of ASD.

406.027 *(Poster)* Identifying Neurocognitive Endophenotypes in ASD: A Multi-Method, Family Study of Visual Perception and Attention

K. Nayar[1]*, M. Winston*[1]*, J. Guilfoyle*[2]*, C. J. Stevens*[3]*, F. Shic*[4]*, E. S. Norton*[3] *and M. Losh*[5]*, (1)Feinberg School of Medicine, Department of Psychiatry and Behavioral Sciences, Northwestern University, Evanston, IL, (2)Cincinnati Children's Hospital Medical Center, Cincinnati, OH, (3)Northwestern University, Evanston, IL, (4)Center for Child Health, Behavior and Development, Seattle Children's Research Institute, Seattle, WA, (5)Communication Sciences and Disorders, Northwestern University, Evanston, IL*

Background: Individuals with ASD demonstrate a local visual processing bias (Van der Hallen et al., 2015) and social attention atypicalities (Frazier et al., 2017), which have also been implicated more subtly in parents of individuals with ASD (Nayar et al., 2018; Lee et al., 2019), suggesting a potential genetic influence on visual perception/attention. However, prior studies involving parents do not assess local/global visual processing explicitly nor do they comprehensively examine dynamic looking patterns of social attention. As such, the extent to which visual perception/attention constitute endophenotypes and whether atypicalities are linked to underlying neurobiology, remains unknown.

Objectives: To deeply characterize the behavioral and neural basis of visual perception and attention in individuals with ASD and their first-degree relatives.

Methods: Across tasks, participants included a maximum of 31 individuals with ASD and 34 controls, as well as 62 parents of individuals with ASD and 46 parent controls. To examine bottom-up visual processing, *Global* and *Local* fixation composite scores were generated from two interactive match-two-sample tasks administered on an eye-tracker. Top-down attention was assessed using a suite of analytical methods applied to eye tracking during presentation of a social-emotional scene, characterizing *where* and *how* participants looked. Finally, neural correlates of local/global processing were assessed with event-related potentials (ERPs, i.e., time-locked EEG responses to visual stimuli), including P1, N1, and P3 components. Composite scores of *Local/Global* processing and social attention were generated to discriminate diagnostic groups using receiver operating characteristic curves.

Results: Individuals with ASD demonstrated a greater local than global visual processing style (*Fig.1*) (p<.001), which discriminated the ASD and control groups (area under curve, AUC=.71) with moderate specificity (68%) and fair sensitivity (63%). While parent groups did not differ in *Local/Global* composite scores, ASD parents attended less towards the target match than parent-controls (*Fig.2*). The *Global* composite discriminated ASD- and control- parent groups (AUC=.56) with good specificity (72%), but low sensitivity (39%). The ASD and ASD-parent groups showed reduced social attention over time, with a linear decrease and a dynamic looking pattern (i.e., shifting away earlier and decreasing later) in the ASD (p<.10) and ASD-parent (p<.05) groups, respectively. Both groups also refixated more (repeated fixations on items already explored) toward non-salient, background objects compared to controls (ps<.05), but there were no significant differences in the transitions away from and towards social and non-social information between groups. Finally, in a subgroup with ERP data available (5 ASD/control and 16 parents), atypical N1 and lower P1 amplitudes in the occipital region were found in the ASD and ASD-parent groups, respectively, compared to controls. Occipital N1 peaks were significantly correlated with local visual processing in both ASD and ASD-parent groups only (rs>.7, ps<.05).
Conclusions: Eye-tracking and neural results demonstrated parallel patterns of reduced global perception and social attention between individuals with ASD and, more subtly, parents of individuals with ASD, compared to controls. Findings support the utility of studying social and non-social visual perception and attention to enhance understanding of underlying biological mechanisms contributing to ASD-related traits, potentially reflecting genetic liability to ASD.

406.028 *(Poster)* Increased Mitochondrial Copy Number and Differential DNA Methylation of Mitochondrial Biogenesis and Fusion Genes in a South African ASD Cohort

*S. Bam[1], E. Buchanan[1], **C. Mahony**[1] and C. O'Ryan[2], (1)University of Cape Town, Cape Town, South Africa, (2)Molecular and Cell Biology, University of Cape Town, Cape Town, South Africa*

Background: Mitochondrial dysfunction is implicated in the aetiology of Autistic Spectrum Disorder (ASD) and DNA methylation is known to modify gene expression in ASD. Our group previously reported differential DNA methylation of genes between ASD and controls in a South African cohort. These genes converged on mitochondrial canonical pathways consistent with mitochondrial dysfunction, which was supported by organic acid metabolomics in our cohort. Mitochondrial homeostasis is fundamental to neuronal function, and its perturbations result in a number of compensatory responses, including mitochondrial biogenesis and mitochondrial fusion.
Objectives: The first objective of this study was to quantify mitochondrial copy number and to examine mitochondrial deletions in ASD compared to controls. The second objective was to measure the DNA methylation of PPARGC1A, a transcriptional regulator of mitochondrial biogenesis. The third objective was to examine DNA methylation of STOML2 and MFN1, genes implicated in mitochondrial fusion.
Methods: DNA from 108 South African children (68 ASD and 40 controls) was extracted from buccal cells for mitochondria DNA copy number and mitochondrial DNA deletion quantification. This was done by multiplex quantitative PCR of the mitochondrial genes ND1 and ND4 and the nuclear gene β2-microglobulin. DNA methylation was quantified using targeted Next-Generation Bisulfite Sequencing (tNGBS) of PPARGC1A, STOML2 and MFN1.
Results: There was a significant difference in mitochondrial copy number between ASD and controls. There was an increase in mitochondrial copy number in ASD but this was not accompanied by mitochondrial deletions. PPARGC1A was significantly differentially methylated in ASD, and differential methylation was identified at putative transcription factor binding sites. Together, this is consistent with a mitochondrial stress response where increased mitochondrial copy number is mediated by differential methylation of a transcriptional regulator of mitochondrial biogenesis. Furthermore, differential methylation was also observed in two genes implicated in mitochondrial fusion, another mitochondrial stress response.
Conclusions: This study highlights mitochondrial dysfunction in ASD aetiology in an understudied, African population. We also show that mitochondrial copy number is increased in ASD as a stress response, and could be a biomarker of mitochondrial dysfunction in children with ASD.

406.029 *(Poster)* Magnetic Resonance Imaging Study of Children with Autism Spectrum Disorders with Regression

***X. Ke**, Child Mental Health Research Center for Nanjing Brain Hospital Affilated to Nanjing Medical Universi, Nanjing, China*

Background: ASD is heterogeneous in both etiology and phenotypic expression. Regression is frequently described in ASD. Network anomalies have been shown in ASD. However, limited comprehensive studies have been conducted in patients with ASD with regression， only one about language regression using DTI study.
Objectives: The objective of this study was to analysis the changes of diffusion tensor imaging (DTI) parameters in white matter of ASD children with (ASD-R) and without (ASD-NR) regression using tract-based spatial statistics (TBSS). To explore the network topological properties in ASD children with (ASD-R) and without (ASD-NR) regression.
Methods: In this study, 29 ASD-R (male/female: 21/8; age: 40.24±12.78 months) and 68 ASD-NR (male/female: 60/8; age: 35.65±11.25 months) were recruited. Structural networks were constructed using diffusion tensor imaging and T1-weighted imaging on a 3-T magnetic resonance system. Based on the tract-based spatial statistics analysis of fiber bundle tracing, the FA value of each subject was analyzed, and the merged FA skeleton of the whole group was obtained. Randomize statistics were used to compare the differences of FA skeleton between the two groups. We utilized graph theory to characterize the white matter structure networks. Statistical analyses were performed using IBM SPSS (version 20).
Results: 1. Covariate analysis was performed on the FA values of the two groups of children with total CARS scores. There were still significant differences between the two groups: the bilateral Sagittal stratum (include inferior longitudinal fasciculus and inferior fronto-occipital fasciculus), left anterior corona radiata and left posterior thalamic radiation (include optic radiation), and FA values increased in ASD-R group than in ASD-NR group. 2. There were 10 common hubs based on regional degree and regional efficiency (bilateral insula, hippocampus, caudate nucleus and putamen, left precuneus and right superior frontal gyrus-dorsolateral) in both groups. The hubness of the left superior frontal gyrus-dorsolateral, left middle occipital gyrus and right precuneus were enhanced (by regional degree) and that of the right thalamus was reduced (by regional efficiency) in the ASD-R relative to the ASD-NR group. After controlling for the course of regression, the CARS scores were significantly correlated with the regional efficiency of the right precuneus (r=-0.381, p=0.046) in the ASD-R group.

Conclusions: The FA value of the ASD-R group increased in the bilateral sagittal stratum (include inferior longitudinal fasciculus and inferior fronto-occipital fasciculus), left anterior corona radiata and left posterior thalamic radiation (include optic radiation) than the ASD-NR group.The ASD-R children were different from the ASD-NR children in the distribution of hub regions, although there were no global network property differences between them. In ASD-R children, the right precuneus (PCUN.R) might play an important role and relate to autism symptom severity.

406.030 *(Poster)* Markers of Risk for Autism in Early Infancy: Cry Acoustics and Neurobehavioral Responses at 1-Month of Age Predict Later Autism Diagnoses

S. J. Sheinkopf[1,2], *T. P. Levine*[1,2], *G. Puggioni*[3], *H. Silverman*[4] *and B. M. Lester*[1,2], *(1)Brown Center for the Study of Children at Risk, Women & Infants Hospital, Providence, RI, (2)Department of Psychiatry and Human Behavior, The Warren Alpert Medical School of Brown University, Providence, RI, (3)Department of Computer Science and Statistics, University of Rhode Island, Kingston, RI, (4)School of Engineering, Brown University, Providence, RI*

Background: Autism has prenatal etiology, but diagnostic signs of autism are not readily observable until the second year of life. Identifying precursor signs of autism in early infancy is a high priority for clinical research. Atypical cry characteristics have been reported for infants later diagnosed with autism, and may in part indicate differences in arousal and regulation in infants at risk for autism

Objectives: The goal of this study was to investigate cry acoustics and early neurobehavioral characteristics in relation to later autism diagnoses.

Methods: Participants were drawn from the Maternal Lifestyle Study (MLS), an investigation of 1288 infants with varying pre and postnatal risks followed into adolescence. Autism was identified and confirmed in 12 children (expert clinician judgment using DSM criteria, confirmed by ADOS). Comparison children were matched on the basis of sex, prenatal exposures, and availability of neonatal measures. At 1-month of age the NICU Network Neurobehavioral Scales (NNNS) was administered. The NNNS is a validated observational measure that yields neurobehavioral summary scores in the areas of attention, regulation, stress signs, motor quality, and basic reflexes. Also at 1-month of age, infant cry bouts were elicited, recorded and subjected to acoustic analysis. Acoustic analysis utilized a 2-phase, cepstral-based approach that quantified frequency and time domain characteristics of individual cry utterances grouped within a longer cry bout/episode. Data analyses included binomial logistic regression with presence/absence of autism diagnosis as the outcome. Receiver operating characteristic (ROC) curves were produced using bootstrap resampling in order to estimate the potential signal detection performance of the cry and neurobehavioral features identified from the logistic models.

Results: Using logistic regression with covariates, autism diagnoses were predicted by Cry and NNNS, separately and combined. There were 247 controls for this analysis. Cry acoustic features predicted autism outcomes, in a model with cry ($p = 0.03$) and cry+NNNS ($p = 0.04$). Significant cry features included utterance timing, voicing, frication, and signal amplitude/energy. Significant neurobehavioral features included poor movement quality, elevated stress signs, and disrupted arousal and regulation. Estimated ROC's support the potential for good accuracy of prediction of autism for both models ($AUC_{cry} = 0.95$; $AUC_{cry+NNNS} = 0.96$).

Conclusions: Infants with later diagnoses of autism may differ from non-autism controls on measures of neurobehavior and cry acoustics. These results are too preliminary to discuss in terms of accuracy metrics, but do indicate that signal detection characteristics of the Cry and NNNS variables have the potential of performing well as early predictors of autism. These results suggest that precursor signs of autism may include neurobehavioral measures of arousal and regulation.

406.031 *(Poster)* Measuring Neural Changes with Early Intervention through Electroencephalography

A. H. Dickinson[1], *L. M. Baczewski*[2], *K. Sterrett*[3], *A. Gulsrud*[4], *C. Kasari*[1] *and S. Jeste*[1], *(1)University of California, Los Angeles, Los Angeles, CA, (2)UCLA Semel Institute for Neuroscience and Human Behavior, Los Angeles, CA, (3)University of California Los Angeles, Los Angeles, CA, (4)UCLA Semel Institute for Neuroscience & Human Behavior, Los Angeles, CA*

Background: Early cognitive skills are widely recognized as predictors of long term outcomes for children with autism spectrum disorder (ASD) (Kim et al., 2018; Seltzer et al., 2004). Additionally, higher IQ predicts response to early intervention (Vivanti et al., 2014). Despite the importance of cognitive skills, little is known about the neural underpinnings of cognition among children with ASD, or whether these neural correlates are predictive of cognitive outcomes. A recent EEG study found that school-aged children with ASD exhibit decreased peak alpha frequency (PAF) in comparison to age-matched peers without ASD (Dickinson et al., 2018). PAF was strongly related to verbal cognition among those with ASD, suggesting that PAF may be an objective and quantifiable marker of cognitive function in this population. To the best of our knowledge, no one has examined PAF as a longitudinal marker of cognitive change in ASD. Identifying neural correlates of early cognition in ASD may facilitate the use of these neurobiological markers as measures of response to intervention.

Objectives: In the context of an early intervention clinical trial, (1) does cognitive ability (Mullen DQ) change over the 2-month intervention period, (2) does baseline PAF predict cognitive outcomes, and (3) do changes in peak alpha relate to changes in nonverbal (NVDQ) and verbal cognition (VDQ)?

Methods: Data reported here are from an intervention study of infants at-risk for ASD (ages 12-24 months, mean age at entry = 18 months) at UCLA. Infants were identified as ‘at-risk’ if they exhibited risk signs on the AOSI or ADOS. Parent-child dyads received early behavioral intervention (JASPER or standard-based classrooms) for 4 hours/week for 8 weeks. Cognitive developmental assessments (Mullen Scales of Early Learning) and EEG recording were collected across entry and exit. A planned intent-to-treat analysis by intervention condition is currently in progress. Results presented here include the full sample of infants enrolled in the study with usable EEG and behavioral data at both time points (n= 43).

Results: Linear mixed models were used to investigate change in DQ scores over 2 months. Mullen total DQ and all subdomain t-scores (except gross motor) improved significantly from entry to exit ($p < .05$). Regression analyses revealed that PAF prior to intervention did not predict change in VDQ ($P > .237$) or NVDQ ($P > .6$). However, the change in PAF between the 2 time points was closely associated with change in both VDQ ($R=0.32$; $P=0.03$) and NVDQ ($R=0.54$; $P<.001$). Further inspection revealed that change in PAF in frontal regions was a significant predictor of VDQ change ($R=0.32$; $P=0.03$), whereas frontal ($R=0.47$; $P=0.001$), central ($R=0.34$; $P=0.02$), and occipital ($R=0.43$; $P=0.004$) change in PAF predicted NVDQ change.

Conclusions: High risk infants receiving early intervention showed significant gains in both nonverbal and verbal cognition scores over the brief study period. Additionally, results suggest that change in neurobiological markers such as PAF are related to change in both nonverbal and verbal cognition within this sample, suggesting that PAF may be an objective neural marker of changes in cognition that occur in the context of early behavioral intervention.

406.032 *(Poster)* Parental Autism Traits and Advanced Parental Age at Conception (APA) in Autism Spectrum Disorders (ASD)

A. Alcon[1], *A. San Jose Caceres*[2], *M. J. Penzol Alonso*[3] *and M. Parellada*[4], *(1)Hospital Gregorio Marañon, CIBERSAM, IISGM, Madrid, Spain, (2)Child and Adolescent Psychiatry, Fundación para la Investigación Biomédica del Hospital General Universitario Gregorio Marañón, Mardrid, Spain, (3)HOSPITAL UNIVERSITARIO GREGORIO MARAÑON, MADRID, Spain, (4)Fundación Investigación Biomedica Gregorio Marañon, Madrid, Spain*

Background: Existing literature has described a multifactorial etiology for Autism Spectrum Disorder (ASD), where genetic and environmental factors are likely combined. Amongst potential epidemiological factors, APA has been associated with an increased risk for autism in the offspring (Janecka et al., 2017). These studies have mainly reported that older fathers have an increased risk of having children diagnosed with ASD. Different explanatory models have been proposed, including the possibility of delayed fatherhood in subjects with autistic traits (Gratten et al., 2016).

Objectives: We aim to study whether autistic traits in parents of ASD individuals correlate with parental age (both in mothers and fathers) at time of conception, and to what extent this correlation differs according to the DSM-IV-TR autism subtypes.

Methods: 256 parents of 128 subjects with ASD (almost 90% male and Caucasian) were included in this study. 55% of the probands had received a DSM-IV diagnosis of Autistic Disorder (AUT), 15.6% Asperger Syndrome (AS), and 29% Pervasive Developmental Disorder-Not Otherwise Specified (PDD-NOS). Parental autism traits were evaluated with the Spanish version of the Autism spectrum Quotient for adults (AQ). Bivariate correlation analyses were assessed to investigate the potential association between APA and AQ, also by offspring's ASD subtype.

Results: We found a statistically significant positive relation between parental age at conception and AQ total scores ($\rho = 0.207$, $p = 8.39 \times 10^{-4}$, $n = 256$). Studied separately, this correlation remained significant for mothers ($\rho = 0.233$, $p = 8.23 \times 10^{-3}$, $n = 128$), but not for fathers ($\rho = 0.123$, $p = 0.166$, $n = 128$). Within the different subtypes of ASD, APA and AQ was only positively correlated in parents of participants with AS ($\rho = 0.319$, $p = 0.034$, $n = 44$) when both parents were considered together, but not when split by role (all ps > 0.13).

Conclusions: Contrary to previous literature, our results suggest that mothers – and not fathers - who delay their parenthood tend to present more autistic traits. Regardless of role (i.e. mother or father), parental age seems to relate to an AS profile of symptoms in their probands more so than other ASD subtypes.

406.033 *(Poster)* Preliminary Findings: Hand-Held Pupillometry to Detect an Atypical PLR Threshold

G. T. Lynch[1], *S. M. James*[2], *T. Cardon*[3] *and S. M. McPherson*[4], *(1)Elson S. Floyd College of Medicine, Speech and Hearing Sciences, Washington State University Health Sciences, Spokane, WA, (2)College of Nursing, Sleep & Performance Research Center, Washington State University Health Sciences, Spokane, WA, (3)Applied Behavior Analysis, Chicago School of Psychology, Chicago, IL, (4)Elson S. Floyd College of Medicine, Washington State University Health Sciences, Spokane, WA*

Background: Behavioral tools and parent interview are the primary assessment measures to identify autism spectrum disorder (ASD). However, disparities are documented regarding socioeconomic status and underserved communities, suggesting challenges in current screening practices affecting timely access to treatment. These challenges were recently reported for the M-CHAT-R/F, which identified ASD with less than 40% accuracy based on a cohort of >20,000 children followed from time of screening through age 8. A feasible clinical tool is needed to support screening in the context of routine healthcare which incorporates objective physical measures monitored in relation to ASD risk. The pupillary light reflex (PLR) is a physical marker differentiating ASD from typical development and holds promise for screening within the context of medical exams. Previous studies examining PLR have used static binocular systems which are expensive and require extensive training to operate. Hand-held technology provides objective PLR output metrics and a standard pupillogram which can be monitored over time in relation to neurodevelopment. This exploratory study analyzed PLR parameters obtained using a validated hand-held pupillometry research tool.

Objectives: The purpose was to a) demonstrate sensitivity of the PLR to identify ASD from typical development using gold standard hand-held pupillometry technology and b) identify PLR output metrics to identify a sensitivity threshold to support further clinical studies examining hand-held pupillometry technology. We hypothesized output metrics for ASD obtained using hand-held technology would replicate similar findings documented with static binocular eye-tracking and would significantly differ from typical development based on PLR parameters of return to baseline (RTB T75) and constriction latency.

Methods: PLR measures were obtained from 60 children and adolescents (36 ASD; 24 TD) between ages 6-17 using a Neuroptics PLR-3000 hand-held pupillometer. Replicating prior protocol for PLR analysis, four pupillograms were captured per participant. 238 PLR pupillograms were analyzed for baseline pupil diameter, constriction latency, maximal constriction, and RTB T75. Logistic regression and receiver operating curve analyses (ROC) examined PLR parameters, documenting a latency threshold differentiating groups.

Results: Significant differences were found between groups for RTB (ASD, $M = 2.92$ s; TD, $M = 2.4$ s; $t(211) = -2.105$; $p < .05$ and constriction time (ASD, $M = 0.80$ s; TD, $M = 0.72$ s; $t(232) = -2.146$; $p < .05$. Results of the ROC analysis for RTB T75 identified cases of ASD (n= 240; AUC = 0.586, $p < .05$; 95% CI = 0.512-0.656; $z = 2.29$) with 44% sensitivity (95% CI = 36.2-52.9) and 72.34% specificity (95% CI = 62.2 - 81.1). Thresholds for RTB T75 reveal an ASD specificity criterion of >3.78 s. A threshold of > 5.0 s was identified for 45% of the ASD sample indicating a significant portion of the group did not return to baseline.

Conclusions: PLR parameters captured with hand-held technology replicated previous findings obtained using binocular systems. Increased constriction time and the RTB parameter were significantly different in ASD, representing reduced parasympathetic activity. Further research is needed to examine hand-held pupillometry output metrics, factoring age and sex effects in a younger sample beyond exploratory analysis.

406.034 *(Poster)* Short-Duration Transient Visual Evoked Potentials in Adults with Autism Spectrum Disorder

C. F. Layton[1], *M. A. Rowe*[1], *N. Benrey*[2], *H. Walker*[1], *B. Britvan*[1], *J. George-Jones*[3], *S. M. Lurie*[4] *and P. M. Siper*[1], *(1)Seaver Autism Center, Department of Psychiatry, Icahn School of Medicine at Mount Sinai Hospital, New York, NY, (2)Weill Cornell Med School, New york, NY, (3)Psychology, University of Texas at Austin, Austin, TX, (4)Psychology, Ferkauf Graduate School of Psychology, Yeshiva University, Bronx, NY*

Background: Visual Evoked Potentials (VEPs) offer an objective and non-invasive method to evaluate excitatory and inhibitory postsynaptic activity in the brain. Transient VEPs produce a characteristic waveform in which positive and negative peaks and troughs reflect different cellular events. Our group previously identified weaker VEP amplitudes at two of the earliest VEP components (P_{60}-N_{75}, N_{75}-P_{100}) and weaker gamma wave activity in children with autism spectrum disorder (ASD) relative to typically developing (TD) controls. A short-duration stimulus condition was also validated for use in severely affected pediatric populations.

Objectives: (1) To examine tVEPs in adults with ASD and (2) to assess the reliability of a short-duration tVEP stimulus in an adult sample.

Methods: tVEPs were obtained from 19 adults with ASD (m_{age} = 26.85) and 18 typically developing (TD) controls (m_{age} = 23.20) between the ages of 18-42. Participants viewed two contrast-reversing checkerboard conditions (~100% contrast) to elicit a tVEP response: (1) a traditional 60-s condition ("standard condition") and (2) a short-duration condition (10 2-s EEG epochs with 1-s of adaptation per run). A discrete Fourier transform was applied to the VEP data to extract harmonic frequency components of the response. Amplitudes were measured peak-to-trough and latencies were measured by time-to-peak. Frequency-domain analyses applied magnitude-squared coherence (MSC) statistics to quantify responses in four distinct frequency bands (Band 1, 6-10 Hz, alpha-wave; Band 2, 12-28 Hz, beta-wave; Band 3, 30-36 Hz, gamma-wave; and Band 4, 38-48 Hz, gamma wave). Intraclass correlation coefficients (ICCs) were used to examine the reliability between conditions.

Results: There were no significant differences in P_{60}-N_{75} amplitude for either condition. The ASD group displayed significantly smaller amplitudes compared to controls at N_{75}-P_{100} on both the standard condition (p = .041) and the short-duration condition (p = .045). There were no differences in latency for P_{60} or P_{100}. There was a significant difference in latency at N_{75} in the short-duration condition (p = .006), although this did not reach significance in the standard condition (p = .089). ASD group latencies were approximately 3-4 ms longer than TD latencies for both conditions. MSC multivariate group differences were identified in Band 2 for both the standard (p = .023) and short duration conditions (p = .033). A significant difference was also identified in Band 4 for the short-duration condition (p = .043), but not the standard condition (p = .172). The estimated agreement between conditions for P_{60}-N_{75} amplitude was .843 and for N_{75}-P_{100} amplitude was .923. ICC for latency at N_{75} was .877 and at P_{100} was .87. Agreement among frequency bands was poor for Band 1 (ICC = .456) and strong for Band 2 (ICC = .759), Band 3 (ICC = .783) and Band 4 (ICC = .869).

Conclusions: Results suggest adults with ASD display a pattern of weaker N_{75}-P_{100} amplitudes and weaker beta-wave activity. Standard and short-duration contrast-reversing checkerboard conditions were highly reliable for amplitude, latency, and frequency bands encompassing beta and gamma-wave activity.

406.035 *(Poster)* Signal or Noise? Investigating Discrepancies between Eye-Tracking- and Clinician-Based Assessments of Social Function

S. Sivathasan[1], *C. Klaiman*[2], *S. Richardson*[3], *M. Lambha*[4], *N. Hendrix*[5], *A. Klin*[2] *and W. Jones*[2], *(1)Educational & Counselling Psychology, McGill University, Montreal, QC, Canada, (2)Marcus Autism Center, Children's Healthcare of Atlanta and Emory University School of Medicine, Atlanta, GA, (3)Marcus Autism Center, Atlanta, GA, (4)Marcus Autism Center/Children's Healthcare of Atlanta, Atlanta, GA, (5)Marcus Autism Center, Emory University School of Medicene, Atlanta, GA*

Background: Eighty percent of parents of children with autism spectrum disorder (ASD) report suspecting developmental problems before their child's second birthday. Yet, despite the presence of early concerns, the median age for diagnosis using best practice behavioral measures remains between 4-5 years of age, and later for under-resourced and rural families, hindering crucial access to early intervention. In comparison with this current state, eye-tracking technologies show promise for objectively quantifying biomarkers of atypical social visual engagement–a core component of ASD–and have been shown to reliably detect differences between toddlers with and without ASD. However, better understanding of the discrepancies between eye-tracking and clinical behavioral assessments is needed. Do the differences offer meaningful metrics (clinically-useful signal) or are they merely measurement error (clinically-detrimental noise)?

Objectives: To examine, in a sample of clinically referred patients, cases that are discrepant between eye-tracking-based measures of social disability and clinical gold standard assessments of ASD in children between 16-42 months.

Methods: We focus here on 2 groups of participants in which eye-tracking measures and standardized assessments were at odds, with one set of measures indicating relatively intact social developmental functioning while the other indicated impairment. Participants were recruited through a community clinic and an academic medical center in urban and rural areas of a metropolitan US city. Social visual engagement data were collected via eye-tracking. Doctoral-level psychologists blind to eye-tracking results completed comprehensive developmental assessments, which included the *Mullen Scales of Early Learning*, and the *ADOS-2*. Standard of care was provided in terms of assessment and diagnosis of ASD, and differential diagnoses including other developmental disorders, mental or behavioral disorders, were given.

Results: Among participants whose eye-tracking measures indicated impaired social developmental functioning—but who did not receive an ASD diagnosis and did not have ADOS scores in the impaired range (i.e., false positives, n=30)—~77% instead received a clinical best estimate diagnosis of another diagnosis. Specifically, ~40% had a non-ASD developmental delay (e.g., language disorder, global developmental delay, subthreshold communication disorder) and ~37% were noted to have subthreshold symptoms of ASD. In contrast, participants who received an ASD diagnosis and had impaired or delayed scores—but did not have eye-tracking measures indicating impaired social functioning (i.e., false negatives, n=29)—fell into two sub-groups: one with seemingly-engaged eye-tracking data (that may show signs of relatively improved opportunities for future social engagement), and another in which eye-tracking measures were of poor quality. Additional analyses of individual participant metrics and demographics against standardized assessments and diagnoses given will be presented.

Conclusions: The goal of this ongoing work is to investigate the clinical utility of eye-tracking-based measures of social developmental functioning for identifying ASD in early childhood. Preliminary results indicate that, in cases when eye-tracking-based measures of social disability are discrepant from other clinical assessments, there is meaningful signal that may aid in early identification generally and in identification of complex cases in particular.

406.036 *(Poster)* Similar Respiratory Sinus Arrhythmia and Rsa Reactivity during Sleep in Children with ASD and Typically Developing Peers

E. E. Condy[1]*, A. D'Souza*[1]*, L. Becker*[2]*, A. Buckley*[1] *and A. Thurm*[1]*, (1)National Institute of Mental Health, Bethesda, MD, (2)NIH, Bethesda, MD*

Background: Respiratory sinus arrhythmia (RSA) is a measure of activation of the parasympathetic nervous system (PNS). Higher tonic RSA and greater RSA reactivity (specifically, withdrawal: a decrease in RSA from resting levels after a change in state) is associated with positive behavioral outcomes, such as better self-regulation. For this reason, these measures are relevant in populations with deficits in these areas, such as children with autism spectrum disorder (ASD). Tonic wakeful RSA and RSA reactivity have been measured in individuals with ASD to examine group-level differences between them and typically developing (TD) children, however, results are mixed. One potential reason for this is methodological differences, specifically variations in resting state or state-dependent conditions. Sleep may provide more consistent conditions because specific criteria of sleep staging ensures participants are in a similar brain state. For this reason, slow wave sleep (SWS; N3) and rapid eye movement (REM) sleep have been suggested as potential conditions to examine RSA. Since it has been hypothesized that children with ASD have lower PNS activation during rest and decreased state-dependent withdrawal during wakefulness (Klusek, Roberts, & Losh, 2014), we explored whether children with ASD have lower RSA during both SWS and REM, and blunted RSA withdrawal from SWS to REM compared to TD children.

Objectives: To investigate RSA during sleep in children with ASD compared to TD peers.

Methods: Children with ASD (n=104), developmental delay (DD; n=25) and TD (n=30) underwent polysomnograhic (PSG) recording as well as a behavioral evaluation as part of a longitudinal study at NIMH. Sleep staging from the PSG was used to locate the first and last consecutive 5-minutes of SWS and REM. Electrocardiogram (ECG) data was then processed through Kubios HRV Premium software to derive the root mean square successive difference (RMSSD; an index of RSA) of each child's heartbeats during these four periods. The RMSSD values for each period were log transformed and averaged by stage to create RMSSD[SWS] and RMSSD[REM] composites.

Results: Preliminary analyses from the subset included so far (N=28; 14 ASD, 14 TD), using a 2 (diagnosis) x 2 (stage) mixed repeated measures ANOVA revealed no interaction between diagnosis and sleep stage on RMSSD, nor a main effect of diagnosis; however, there was a main effect of sleep stage ($F(26)=19.24$, $p=0.0002$, $\eta^2=0.094$), such that RMSSD was higher during SWS than REM.

Conclusions: There was no difference in RSA between groups or RSA reactivity in this small sample of children with ASD compared to their TD peers. Furthermore, both groups show similar patterns of PNS activation during sleep, specifically RSA withdrawal during REM. This is consistent with patterns seen in TD adults. However, given the relative REM deficiency seen in children with ASD, further work investigating state-dependent PNS activation patterns during these sleep stage transitions is warranted. In addition, we plan to investigate the relationship between RSA and symptom profiles.

406.037 *(Poster)* Social Attention Profiles Associated with ASD and the Broad Autism Phenotype

M. Winston[1]*, K. Nayar*[1]*, E. Landau*[1]*, N. Maltman*[2,3]*, M. Lee*[4]*, A. L. Hogan*[5] *and M. Losh*[6]*, (1)Feinberg School of Medicine, Department of Psychiatry and Behavioral Sciences, Northwestern University, Evanston, IL, (2)Northwestern University, Evanston, IL, (3)University of Wisconsin, Madison, WI, (4)New York Universiy Langone Health, New York City, NY, (5)Department of Psychology, University of South Carolina, Columbia, SC, (6)Communication Sciences and Disorders, Northwestern University, Evanston, IL*

Background: Atypical visual attention to social stimuli has been well documented in ASD. Evidence also suggests that similar, but more subtle, differences in visual attention may be present in first-degree relatives of individuals with ASD (Pierce et al., 2016; Lee et al., 2019), suggesting atypical attention to social stimuli as a candidate ASD endophenotype related to downstream ASD-related symptomatology. However, there is limited research examining social attention across multiple tasks, or examining the same tasks in ASD and in first-degree relatives, which may be important to elucidate social attention profiles indicative of ASD genetic risk.

Objectives: To investigate social attention (i.e., dwell time and eye movement) across multiple tasks in ASD and in parents to identify profiles indicative of ASD risk.

Methods: Participants included 97 individuals with ASD, 57 ASD controls, 162 ASD parents, and 65 parent controls. Three eye-tracking tasks were examined: 1) A structured narrative task requiring participants to narrate a wordless picture book, 2) An unstructured narrative task requiring participants to tell stories about emotionally ambiguous images, and 3) A passive viewing task of emotional facial expressions. Following Frazier et al. (2016), areas of interest (AOIs) across tasks were analyzed based on effect sizes from t-tests investigating differences in dwell time to produce the ASD and ASD Parent Gaze Profiles. ASD and ASD Parent Index scores were then derived from the profiles of AOIs that best distinguished groups for subsequent analyses. Receiver operator characteristic curves were employed to assess the sensitivity and specificity of the index scores to discriminate groups. Analyses were also conducted to explore group differences in eye movement (i.e., repeated fixations, transitions from one AOI to another) to complement the profiles investigating dwell time. Analyses are currently underway to create an ASD Eye-Movement Profile and an ASD Parent Eye-Movement Profile based on these group differences.

Results: The ASD Gaze Profile was comprised of dwell time towards 58 AOIs across the three tasks, and its index score discriminated the ASD group from the control group (Area Under the Curve (AUC)=.78) with 78% specificity and 63% sensitivity. The ASD Parent Gaze Profile was comprised of only 20 AOIs, and its index score best discriminated the ASD parent group who met criteria for the broad autism phenotype from the parent control group (AUC=.71) with 76% specificity and 57% sensitivity, with slightly lower specificity (75%) and sensitivity (52%; AUC = .67, *Fig. 1*) for the ASD parent group overall. Group differences also emerged in eye-movement data, such that the ASD group exhibited more *repeated fixations* ($p < .05$), whereas the ASD and ASD parent groups demonstrated increased *transitions* towards non-social (rather than social) stimuli (ps<.05).

Conclusions: Findings support and extend prior reports of differences in visual attention towards social stimuli in ASD and first-degree relatives by demonstrating profiles of gaze across multiple tasks that discriminate individuals with ASD and parents from controls. Such specific, data-driven profiles may serve as a marker of ASD genetic risk, and help to inform current understanding of underlying mechanisms contributing to ASD symptomatology.

406.038 *(Poster)* The Influence of Maternal Stress during Pregnancy on Autism Symptoms Severity

A. Alcon[1]*, A. San Jose Caceres*[2]*, A. K. Xavier de Sousa*[3] *and M. Parellada*[4]*, (1)Hospital Gregorio Marañon, CIBERSAM, IISGM, Madrid, Spain, (2)Child and Adolescent Psychiatry, Fundación para la Investigación Biomédica del Hospital General Universitario Gregorio Marañón, Mardrid, Spain, (3)Facultad de Medicina, Universidad de Cantabria, Madrid, Spain, (4)Fundación Investigación Biomedica Gregorio Marañon, Madrid, Spain*

Background: Autism Spectrum Disorders (ASD) involve impediments in social interaction and communication as well as the presence of restricted, repetitive patterns of behavior, interests, or activities (APA, 2013). Compelling evidence supports the effect of environmental factors that may contribute to increased risk of ASD (Emberti Gialloreti et al., 2019). Maternal mental health problems are amongst the most common comorbidities found in pregnancy and postpartum, with up to 25% of women experiencing stress, depression or anxiety during those periods (Cole-Lewis, et al., 2014). In particular, stress during pregnancy has repeatedly shown an increased risk for ASD in the offspring (Chengzhong Wang et al., 2017).

Objectives: Our objective is to study how maternal stress during pregnancy influences symptom severity in the autistic child and the associated symptom early onset sleep disturbances.

Methods: Ninety-nine individuals with a diagnosis of ASD, aged 3 to 39 years, underwent a clinical and sociodemographic evaluation to assess ASD symptom severity. ASD symptomatology was measured with the ADOS, ADI-R, SCQ and RBS. The BEARS questionnaire (Owens et al., 2005) captured retrospective information of sleep disturbances between ages 2 and 5. The total number of obstetrics complications during birth was compiled from the Lewis' scale for obstetric complications (Owen, Lewis, & Murray, 1988) and a shorter, adapted version of the Early Life Exposures Assessment Tool (ELEAT; Schmidt, 2013). Stress during pregnancy was measured with the SRRS questionnaire (Holmes y Rahe, 1967). Bivariate analyses and linear regression were performed to explore the relationship between maternal stress during pregnancy and the ASD severity in the offspring.

Results: Maternal stress during pregnancy related positively to prenatal obstetric complications ($r = 0.200$ $p = 0.048$). Both stress during pregnancy and prenatal obstetric complications were significantly related to stereotyped behaviors ($r = 0.244$ $p = 0.017$ and $r = 0.184$ $p = 0.046$ respectively) but not to other core ASD symptomatology. Higher stress during pregnancy was associated to the presence of sleep disturbance in the child in the early years ($U = 440.5$ $p = 0.012$).

Conclusions: Greater maternal stress during pregnancy seems to be related to a greater number of obstetric complications during birth, and a greater severity of repetitive and stereotyped behaviors in the offspring. Future studies should focus on the direction and mechanisms of the relationship between maternal stress and ASD symptomatology.

406.039 *(Poster)* The Role of the Autonomic Nervous System in Mental Health Disorders Among Mothers of Children with Autism Spectrum Disorder

C. G. Moser[1] *and J. Klusek*[2]*, (1)Communication Sciences & Disorders, University of South Carolina, Columbia, SC, (2)Communication Sciences and Disorders, University of South Carolina, Columbia, SC*

Background: The autonomic nervous system plays an important role in regulating emotional responses (Appelhans & Luecken, 2006). Respiratory sinus arrhythmia (RSA), an index of parasympathetic control, has been implicated as a potential marker of mental health disorders (Nardelli et al., 2015), such that reduced baseline RSA is associated with elevated depression and anxiety symptoms (Hughes & Stoney, 2000). Mothers of children with autism spectrum disorder (ASD) experience higher rates of anxiety and depression than mothers of neurotypical children (Montes & Halterman, 2007). However, the role of RSA in psychiatric vulnerability among mothers of children with ASD is unknown. Studies of individuals with ASD suggest that RSA may be reduced in this population (Klusek, Roberts, & Losh, 2015), yet, little is known about autonomic function in relatives of those with ASD, who are also at increased genetic liability to ASD.

Objectives: The present study aimed to understand the role of RSA in mental health disorders among mothers of children with ASD.

Methods: Participants included 27 mothers of children with ASD (*M* age= 45 years) and 27 control mothers (*M* age= 42 years). The groups did not significantly differ in age (p=.268). Baseline heart rate was collected during a 3-min resting condition. CardioEdit/Batch software (Brain-Body Center, University of Illinois at Chicago) were used to clean the heart rate signal and extract estimates for mean RSA. Mothers completed the Beck Depression Inventory-II (Beck, Steer, & Brown, 1996) and the Beck Anxiety Inventory (Beck & Steer, 1990), which served as indices of current depression and anxiety symptoms. Parenting stress was measured using the Parenting Stress Index-4 (Abidin, 2012) and medication use was indexed by the presence or absence of psychotropic medication use.

Results: A series of general linear models examined group, RSA, and their interactions as predictors of depression and anxiety, controlling for medication use and level of parenting stress. The overall model predicting depression symptoms was significant ($F(5,48)=6.24$ $p<.001$, $R^2=.39$). RSA accounted for significant variance in depression symptoms, with a large effect size (p=.007, η^2_p=.24). Group and its interaction did not account for variance in the model (p's>.809). Lastly, group, RSA, and their interaction were not significant predictors of anxiety symptoms (p's>.118).

Conclusions: Reduced RSA was associated with elevated depressive symptoms across mothers of children with ASD and control mothers. This finding supports reduced RSA as a possible biomarker for depression risk in mothers of children with ASD, mirroring patterns observed in the general population. This finding also has implications for identification and targeted treatment. In the general population, reduced RSA predicts depression severity and treatment response among individuals with mood disorders and is of interest as a biomarker to help stratify subgroups of patients who are most likely to respond to targeted interventions (Rottenberg, Wilhelm, Gross, & Gotlib, 2002; Chambers & Allen, 2002). This study suggests that RSA may play a similar mechanistic role in the presentation of mood disorders in mothers of children with ASD, informing the development of mental health supports for mothers of children with ASD.

406.040 *(Poster)* Use of Empirical Mode Decomposition in ERP Analysis to Classify Familial Risk and Diagnostic Outcomes for Autism Spectrum Disorder

L. Abou-Abbas[1]*, S. van Noordt*[2]*, J. Desjardins*[3] *and M. Elsabbagh*[4]*, (1)Research Institute - McGill University Health Centre, Montreal, QC, Canada, (2)Montreal Neurological Institute, McGill University, Montreal, QC, Canada, (3)SHARCNET, St Catharines, ON, Canada, (4)McGill University, Montreal, QC, Canada*

Background: Atypical brain activity in response to socially relevant stimuli, such as faces and eye gaze, is found in individuals with ASD in early stages of their development and may serve as putative biomarker to supplement behavioral diagnosis

Objectives: We present a novel approach to classification of visual ERPs collected in response to socially relevant stimuli using Intrinsic Mode functions (IMF) derived from Empirical Mode Decomposition (EMD).

Methods: Participants were 104 infants from the British Autism Study of Infant Siblings (BASIS). ERP in response to face and gaze stimuli were collected on 54 infants at risk for autism (HR), by virtue of having an older diagnosed sibling and 50 low risk (LR) when they were 6 to 10 months of age (mean = 7.8 months, SD = 37.2). Seventeen individuals in the HR group were subsequently diagnosed with ASD around three years of age (Three Outcome groups: n=17 HR-ASD, 33 HR-noASD and 44 LR-noASD). EMD was applied to single channels of ERP waveforms to decompose it into IMFs. Initial testing showed that the first three IMFs best characterized the ERP signals. Six features were then extracted for each IMF to give a characterization of the studied input: energy, Shannon entropy, moment, mean, standard deviation and skewness. The maximum values per feature across all channels were selected and used as inputs to two machine learning methods (support vector machines- SVM and k-nearest neighbors- k-NN) for training and testing to classify an unknown input into one of the risk or alternatively the outcome groups.

Results: Different runs were executed for modelling and classification of the participants in the LR and HR groups and classification of diagnosis outcome within the high-risk group: HR-ASD and HR-noASD. The highest accuracy in the classification of familial risk was 89.4%, achieved using an SVM classifier along with the proposed statistical features extracted from temporal IMFs. In contrast, maximum accuracy for classifying infants at risk who go on to develop ASD vs. those who do not was achieved through a k-NN classifier with an accuracy of 76.5% when all six features are used as input, including energy, entropy and statistical features.

Conclusions*:* IMF-based extracted features were highly effective in classifying infants by risk status but less so by diagnostic outcomes. Improvements in performance of machine learning methods are therefore still needed. Small sample size is a limitation to be addressed in future work. Further, analytic approaches that can combine more IMFs features would likely achieve improved performance over single IMF features.

406.041 *(Poster)* Which Perform Best to Identify ASD and TD: Upright Faces, Inverted Faces, or Their Mix?

B. Zhou*, X. He, X. Li, J. Sun, W. Tian, H. Wu, L. Shen and X. Gao, School of Medicine, Tsinghua University, Beijing, China*

Background: Social communication deficit is a key symptom for Autism Spectrum Disorder. Much research has demonstrated that human face is a sensitive biomarker for early detection on Autism Spectrum Disorder (ASD), due to its comprising of rich emotional expressions for a successful social interaction. By applying eye-tracking technology, a variety of different paradigms on faces are proposed with focus on subject's gaze behavior and pupillary change.

However, most efforts of ASD related face studies are on upright faces, fewer of them are on inverted faces. There is the conception that the perception and recognition are better of faces presented upright than that of inverted. But no previous study tells which perform better if they are used to identify ASD and Typical Development(TD) children, upright faces or inverted faces. For future application of face paradigm in early detection on ASD, it's necessary to find out the answer.

Objectives: Comparing three experimental paradigms designed on upright faces, inverted faces, and a mix of above two, find out which paradigm is the best in identifying ASD and TD children.

Methods: 47 ASD and 35 TD children of 3-6 years old were recruited, 23 ASD children provided valid data in the experiments, and 22 TD children as control group are matched by age and gender.

The experiments used SMI desktop eye tracking system with sample frequency 120Hz. The basic paradigm was a series of 12 pictures of same size and luminance on human faces of young people with different gender. In Experiment I, 12 face pictures were all upright. In Experiment II, 12 face pictures were all inverted. In Experiment III, the 2nd,5th, 7th, 10th ,12th pictures were inverted faces, while others were upright.

Subject's Fixation time on Area of Interest (AOI) of eyes, mouth, and faces on each picture were collected, as well as pupillary data. Average Fixation time on above AOIs, plus average and maximum changes of pupil diameter on their amplitude, time, and velocity was extracted as features. Further statistical analysis was done by SPSS and Python.

Results: Three experiments all showed significant difference on features of valid slide numbers and average fixation time on face and eyes, while Experiment II and III showed more on fixation time of mouth and pupil response in maximum diameter change or its changing velocity, referring to attached table.

After correlation analysis and Principal Component Analysis, the predicted probability of the regression modes in three experiments are compared by their AUC (Area Under Curve) of ROC curve. Refer to attached Chart, Experiment II and III showed better result of 88.4% and 89% than that of 83.9% in Experiment I.

Conclusions: Although three face paradigms all showed efficiency in identifying ASD and TD, two experiments with inverted faces perform better than upright faces only. But there's no big difference in result for paradigms with inverted faces only or mixture of both faces. These facts support the finding that inverted face can be a better indicator in identifying ASD and TD.

Biomarkers / Early Development

ORAL SESSION — BIOMARKERS / EARLY DEVELOPMENT
305 - ADHD and Autism: Phenotypic Overlap and Distinction

305.001 *(Oral)* Phase Synchronization Network Study for Attention Deficit/Hyperactivity Disorder Co-Occurrence in Autism Spectrum Disorder Detection

R. Liu[1], *E. Pedapati*[2], *M. Rogers*[2], *K. Cullion*[3], *C. A. Erickson*[2], *L. M. Schmitt*[2], *S. Wu*[3], *J. A. Sweeney*[4] *and D. Gilbert*[3], *(1)Psychiatry, Cincinnati Children's Hospital Medical Center, Cincinnati, OH, (2)Cincinnati Children's Hospital Medical Center, Cincinnati, OH, (3)Cincinnati Childrens Hospital Medical Center, Cincinnati, OH, (4)Psychiatry and Behavioral Neuroscience, University of Cincinnati College of Medicine, Cincinnati, OH*

Background: Attention Deficit/Hyperactivity disorder (ADHD) is a common co-occurring condition in Autism Spectrum Disorder (ASD). ASD with ADHD (ASD+) generally have a higher severity of pathophysiology and reflected in higher rates of hospitalization, medication treatment, and behavioral therapy than ASD alone. The physiological differences between these two groups remains poorly understood, but urgently needed to develop novel diagnostic and therapeutic tools.

Objectives: We hypothesize that phase-based functional connectivity measures may differentiate ASD+, ASD, and typically developing controls (TDC). Specifically, we predict resting EEG phase synchrony would be “over” connected in ASD populations, with ASD+ demonstrating additional phase synchrony than either ASD or TDC groups.

Methods: We recruited children with ASD, ASD+ and TDC. Five minutes of spontaneous scalp EEG recordings were collected with 32-channel electrode nets. After preprocessing and artifact rejection, the remaining dataset contains 39 subjects in the ASD+ group (14.7±3.6 years old), 23 subjects in the ASD group (15.4±3.7 years old), and 26 subjects in the TDC group (16.3±3.5 years old). A phase synchrony measure Debiased Weighted Phase Lag Index (DWPLI) was estimated for each possible pair of electrodes to construct a connectivity network. Local and global significant differences are examined by Network-Based Statistics (NBS) and a network centrality measure (Hubness) with cluster-based permutation tests.

Results: Several functional connectivity networks were detected between groups of interest. DWPLI identified increased gamma frontal-to-occipital interconnectivity of ASD+ over TDC. Hubness measures demonstrate greater gamma network connectivity in ASD+ of left posterior electrodes, whereas gamma connectivity was higher in ASD in the right central electrodes. Greater hubness clusters in the right hemisphere also observed in ASD compared to ASD+ in the theta and beta bands. In addition, ASD+ demonstrated greater variability in connectivity across multiple frequency bands compared to TDC.

Conclusions: As sophistication of rapid brain-based measures such as EEG are readily available, analysis methods such as functional connectivity can quantify dynamic brain states. Currently, in addition to identified networks, we are evaluating what clinical relationships these variables may pose. Such measures could assist in diagnostics as well as play a crucial role in identifying novel physiology-based subgroups for treatment trials and prognosis. This advance analysis methodology serves the discrimination of groups and further will be utilized to track treatment effects. These measures can help quickly and in a cost-effective manner differentiation ADHD features in ASD.

305.002 *(Oral)* Shared and Specific Alterations of Tactile Sensitivity in ASD and ADHD

J. L. He[1,2], *E. L. Wodka*[3,4], *M. Tommerdahl*[5], *M. Mikkelsen*[2,6], *R. A. Edden*[6], *S. H. Mostofsky*[4,7,8] *and N. A. Puts*[6,9], *(1)Russell H. Morgan Department of Radiology and Radiological Science, The Johns Hopkins University School of Medicine, The Johns Hopkins University School of Medicine, Baltimore, MD, (2)F.M. Kirby Research Center for Functional Brain Imaging, Kennedy Krieger Institute, Kennedy Krieger Institute, Baltimore, MD, (3)Kennedy Krieger Institute, Baltimore, MD, (4)Center for Autism and Related Disorder, Kennedy Krieger Institute, Baltimore, MD, (5)Biomedical Enginering, University of North Caroline at Chapel Hill, Chapel Hill, NC, (6)Russell H. Morgan Department of Radiology and Radiological Science, The Johns Hopkins University School of Medicine, Baltimore, MD, (7)Department of Neurology, Johns Hopkins University School of Medicine, Baltimore, MD, (8)Center for Neurodevelopmental and Imaging Research, Kennedy Krieger Institute, Baltimore, MD, (9)F. M. Kirby Research Center for Functional Brain Imaging, Kennedy Krieger Institute, Baltimore, MD*

Background: Recent work has seen an increase in the reporting of tactile abnormalities in ASD and ADHD. Abnormal tactile function may exacerbate social and communicative difficulties, common in ASD and ADHD. Currently, it is unclear the degree to which these reported tactile alterations are disorder-shared and disorder-specific, and how these alterations related social, sensory and disorder-specific clinical symptoms.

Objectives: To investigate whether alterations in tactile sensitivity in ASD, ADHD and ASD + ADHD are disorder-shared and disorder-specific, and whether and how these alterations are related to social and disorder-specific clinical outcomes.

Methods: 103 children with ASD, 108 children with ADHD, 52 children with ASD+ADHD and 210 typically developing children (TDC) between 8-12 years old were included. Vibrotactile detection, discrimination and order judgement were assessed from the left index and middle fingers using a Cortical Metrics stimulator. Diagnosis of ASD was confirmed with the Autism Diagnostic Outcome Scale (ADOS) and Autism Diagnostic Interview – Revised (ADI-R). Diagnosis of ADHD was confirmed with the Conners or Conners-3 when available. Additional information was also acquired with the DuPaul’s ADHD parent-rating scale, the Sensory Processing Measure (SPM) and the Sensory Experience Questionnaire (SEQ).

Results: *Group comparisons:* Static detection thresholds (sDT) were higher (i.e., worse) in children with ASD, ADHD and ASD+ADHD than controls (all $p < .001$). Amplitude discrimination thresholds (aDT), were worse for the ASD and ASD+ADHD groups ($p = .02$ and $p = .01$ respectively), but not ADHD ($p = .16$), when compared to TDC. Temporal order judgement (TOJ) was worse than TDC for ADHD ($p = .05$; TOJ accuracy) and ASD+ADHD ($p = .01$; TOJ thresholds), but not ASD group ($p = .67$; thresholds and p = .37; TOJ accuracy). *Correlational analyses:* sDTs were related to SPM social participation (r(238) = .25, $p < .001$), body awareness ($r(238) = .28$, $p < .001$), SEQ hypo ($r(96) = .34$, $p = .001$) and hypersensitivity ($r(96) = .27$, $p = .006$) across the entire sample. sDT was not related to any ASD-specific clinical outcome in ASD, but was related to hyperactivity on the Conners ($r(31) = .65$, $p < .001$) and DuPaul's ($r(87) = .31$, $p = .011$) parent-rating scales in ADHD. aDT was predictive of ADOS communication problems in ASD ($r(95) = .27$, $p = .008$). TOJ thresholds were related to inattention on both Conners ($r(32) = .44$, $p = .009$) and DuPaul's ($r(86) = .27$, $p = ..032$) parent-rating scales in ADHD.

Conclusions: We show disorder-shared and disorder-specific alterations in tactile sensitivity in atypical neurodevelopment that were related to specific clinical features of the disorder. While elevated sDTs appear to be disorder-shared, elevated aDTs and difficulties with TOJ appear to be specific to ASD and ADHD respectively. Despite being disorder-shared, sDTs differentially related symptoms of ASD and ADHD. Alternatively, aDT and TOJ were disorder-specific and related to disorder-specific impairments.

These findings highlight the clinical relevance of disorder-shared and disorder-specific alterations in tactile sensitivity. The neurophysiological basis (e.g., atypical cortical inhibition) of these alterations might inform future patient-specific interventions.

305.003 *(Oral)* Shared and Distinct Developmental Pathways to ASD and ADHD Phenotypes Among Infants at Familial Risk

M. Miller[1]*, S. Austin*[2]*, A. M. Iosif*[3]*, L. De La Paz*[1]*, A. Chuang*[1]*, B. Hatch*[1] *and S. Ozonoff*[4]*, (1)Psychiatry and Behavioral Sciences, University of California, Davis, MIND Institute, Sacramento, CA, (2)University of California, Davis, Davis, CA, (3)Public Health Sciences, University of California Davis, Davis, CA, (4)Psychiatry and Behavioral Sciences, University of California at Davis, MIND Institute, Sacramento, CA*

Background: Autism spectrum disorder (ASD) and attention-deficit/hyperactivity disorder (ADHD) are believed to share partially overlapping causal mechanisms suggesting that early risk markers during infancy may also overlap (Miller et al., 2019; Stergiakouli et al., 2017).

Objectives: (1) Using person-centered approaches in a sample of infants enriched for ASD and ADHD, how many distinct groups of 3-year-old children emerge based on ADHD and ASD symptomatology?

(2) What infant behaviors uniquely predict ASD- versus ADHD-like profiles, versus serve as shared early predictors?

Methods: Participants included 166 children with a familial risk of ASD (n=89), ADHD (n=38), or low-risk for both (n=39) who were evaluated at 12, 18, 24, and 36 months of age. Latent profile analysis (LPA) was conducted to examine the number of classes that best fit the data based on parent and examiner ratings of ASD (ADOS, SCQ) and ADHD (ADHD-Rating Scale, Behavior Rating Inventory for Children) symptoms. Generalized linear mixed-effects models were used to examine trajectories of infant predictors of latent class membership based on variables independent of those used to define the classes: nonverbal and verbal development; behaviorally-coded negative affect, inattention, activity level, and impulsivity; and examiner-rated social engagement.

Results: ***LPA.*** A three-profile solution was selected based on fit indices and interpretability reflecting a *Typically Developing* Class (low symptoms; n=108), an *ADHD* Class (high ADHD/low ASD symptoms; n=39), and an *ASD* Class (high ASD and ADHD symptoms; n=19).

Predictors of LPA membership. Results are summarized in Tables 1-2 and were generally suggestive of a gradient pattern of differences over the first three years of life among children with ASD- and ADHD-like symptomatology by age 3, with the greatest impairment within the *ASD* Class, followed by the *ADHD* Class.

Conclusions: We did not find a distinct group of children with high ASD symptomatology who did not also have high ADHD symptom ratings, consistent with work conducted in older children/adolescents (Van Der Meer et al., 2012). Elevated ASD symptoms in the preschool period may frequently co-exist with inattention and hyperactivity. Alternatively, high ADHD symptom scores in the *ASD* Class may reflect measurement challenges, since these instruments have not been validated for use in young children with ASD and may measure different constructs than in children at risk for ADHD. Larger samples and measurements of attention/activity level beyond informant reports are required to address this. In this study, we did not focus on categorical diagnostic distinctions but this will be done when our sample enters the age range during which ADHD is typically diagnosed; notably, examiners rarely ascribed secondary clinical outcomes of "ADHD Concerns" for children who had primary diagnoses of ASD despite the presence of elevated parent- and examiner-rated ADHD symptoms.

Findings related to infant predictors of latent class outcomes are mostly suggestive of a gradient pattern of differences over the first three years of life among children with ASD- and ADHD-like symptomatology across measures. These findings suggest a mixture of overlapping and distinct early indicators of 36-month latent class profiles which can be difficult to disentangle early in life.

305.004 *(Oral)* Sustained Visual Attention Is Reduced Among Infants with 36-Month Outcomes of ADHD Concerns but Not in Infants Developing ASD

B. Hatch[1]*, G. S. Young*[2]*, A. Chuang*[1]*, L. De La Paz*[1]*, A. J. Schwichtenberg*[3]*, S. Ozonoff*[2] *and M. Miller*[1]*, (1)Psychiatry and Behavioral Sciences, University of California, Davis, MIND Institute, Sacramento, CA, (2)Psychiatry and Behavioral Sciences, University of California at Davis, MIND Institute, Sacramento, CA, (3)Purdue University, West Lafayette, IN*

Background: Autism spectrum disorder (ASD) and attention-deficit/hyperactivity disorder (ADHD) are thought to partially share developmental pathways (Johnson et al., 2014). One potential shared feature may be difficulties with sustained attention (Wass et. al., 2015; Miller et. al., 2018), although no study has directly compared children with such outcomes on the same measure of sustained attention during infancy.

Objectives: The present study examined sustained visual attention to non-social stimuli in infants at risk for ASD, ADHD, or neither condition. We hypothesized that infants with 36-month outcomes of ADHD Concerns or ASD would show impaired sustained visual attention relative to infants in a comparison group.

Methods: Participants were infants with a family history of ASD (i.e., older diagnosed sibling; *n*=80), family history of ADHD (i.e., older diagnosed sibling or parent; *n*=37), or low familial risk for both conditions (i.e., at least one typically developing older sibling and no family history of ASD or ADHD; *n*=35). At the 36-month visit, participants were categorized into one of three outcome groups: ASD (met DSM-5 criteria; *n*=24), ADHD Concerns (i.e., elevated ADHD symptoms; *n*=16), or a non-ASD, non-ADHD Concerns group (Comparison sample; *n*=112). At 12, 18, 24, and 36-monts of age all were administered a sustained visual attention task, the "Slides" episode from the Laboratory Temperament Assessment Battery (LabTAB; Goldsmith & Rothbart, 1996), adapted for use with an eye-tracker. This task involves the infant being oriented towards a screen where he/she views a series of 5 nature scene image, with no audio track, at increasing time increments (2, 4, 6, 8, 10s). This sequence is repeated three times, totaling 90s. Eye-tracking data was processed using gazepath algorithms (van Renswoude et. al., 2018) to calculate fixation and saccade durations. The primary variable was gaze time percentage. Outcome group differences were analyzed using generalized linear mixed-effects models.

Results: There were significant main effects for outcome ($F(2, 208) = 4.06$, $p = .02$) and visit ($F(1, 283) = 17.96$, $p < .001$), but the outcome by visit interaction was non-significant ($p > .05$). Results are presented in Table 1 and illustrated in Figure 1. Increase in slope of gaze time percentage from 12 to 36 months was not significantly different between outcome groups; however, across visits, the infants with ADHD Concerns outcomes had a lower gaze time percentage than the ASD ($p = .02$) and Comparison groups ($p < .001$). In contrast to our hypothesis, infants with ASD outcomes did not differ significantly from the Comparison group ($p > .05$).

Conclusions: Infants developing ADHD Concerns show impaired sustained visual attention, similar to older children (Corbett et al., 2009) and adults (Marchetta et al., 2008) with ADHD, while infants developing ASD were equivalent to the Comparison group. Disruptions in ability to maintain attention on non-social stimuli during infancy may mark a developmental cascade specific to ADHD rather than general to ADHD and ASD. Further research is needed to investigate early-life patterns of other aspects of attention (e.g., attention shifting, social attention) among infants developing ASD or risk for ADHD.

Cellular Models/Stem Cells

POSTER SESSION — CELLULAR MODELS/STEM CELLS
407 - Cellular models/stem cells Posters

407.001 *(Poster)* Deficiency of Tbck Leads to Deregulation of TBR1, a Gene Associated to Autism Spectrum Disorder .

D. Moreira[1], *A. M. Suzuki*[2], *E. V. Branco*[2], *F. Monfardini*[3], *K. Griesi-Oliveira*[4], *A. L. Sertie*[4] *and M. R. Passos-Bueno*[5], *(1)Centro de Pesquisas sobre o Genoma Humano e Células-tronco (CEGH-CEL), Instituto de Biociências, Uni, São Paulo, Brazil, (2)Universidade de São Paulo, Sao Paulo, Brazil, (3)Universidade de São Paulo, São Paulo, Brazil, (4)Centro de Pesquisa Experimental, Hospital Israelita Albert Einstein, Sao Paulo, Brazil, (5)Department of Genetics and Evolutionary Biology, University Sao Paulo, Biosciences Institute, Sao Paulo, Brazil*

Background: Biallelic pathogenic variants in TBCK have been recently described as the genetic cause of the encephaloneuropathy, infantile hypotonia with psychomotor retardation and characteristic facies 3 (IHPRF3). Whole exome sequencing in 13 familial Brazilian cases of Autism spectrum disorder (ASD), revealed biallelic loss-of-function (LoF) variants in TBCK, a stopgain variant (p.Tyr710*) and a microdeletion (p.Glu687Valfs9*), in two affected sibs, born from healthy parents. Our family adds one additional family to this group of IHPRF3 individuals, for which there are less than 30 families so far reported. Even though not fully characterized, ASD seems to be part of the clinical spectrum of this syndrome, but with unknown penetrance. TBCK, a member of the TBC family of proteins, seems to be related to mTOR signaling and autophagy in non-neural cells.

Objectives: Understand the molecular mechanisms through which deficiency of TBCK underlies the neuronal phenotypes of IHPF3.

Methods: We are conducting cellular and molecular studies in neuroprogenitor cells (NPC) and neurons derived from induced pluripotent stem cells from 2 affected patients and 3 controls. A variety of studies, including imaging, cellular and molecular analysis have been conducted to evaluate cell migration, cell characterization in differentiation neuronal stages, cell cycle, mTOR and other pathways as well as neuron morphological analysis, among others. Statistical analysis to compare control and cases were conducted whenever adequate. The level of significance adopted was <0.05.

Results: Our studies in patients' NPC have shown that deficiency of TBCK leads to decreased mTOR signaling (pRPS6S240/244 protein level; p=0.024). We also observed that patients' NPC migration was dramatically compromised as compared to controls (p< 0.001) and also presented deregulation of cell cycle progression (p<0.01), two processes that are crucial for neurogenesis and cytoarchitecture organization of the brain. Regarding the morphology of patients' neuronal cells, we observed particularly larger cell bodies (about 17.5% larger in patients as compared to controls; p=0.003), and decreased neurite branching as compared to controls. Analysis of mRNA expression through quantitative real time PCR of cellular markers of neuronal development revealed significant dysregulation of TBR1 transcription factor (p<0.001) and important downstream targets implicated in neuronal differentiation and migration.

Conclusions: These preliminary data suggest defects in several neurodevelopmental processes, such as neurogenesis, neuronal differentiation and migration, as the pathophysiological mechanism that may contribute to the autism –like phenotype in patients with biallelic pathogenic variants in TBCK. FAPESP/CEPID, CNPq

407.002 *(Poster)* Human Induced Pluripotent Stem Cell-Derived 3D Organoids Combined with High-Content Screening Reveal Network-Level Phenotypes in Individuals with Idiopathic Autism

M. Durens[1], M. W. Nestor[2], J. E. Nestor[2], M. Williams[3], M. L. Cuccaro[4], H. N. Cukier[4], J. M. Vance[5], A. J. Griswold[4], J. P. Hussman[6], M. A. Pericak-Vance[4] and ***D. Dykxhoorn***[4]*, (1)Hussman Institute For Autism, Baltimore, MD, (2)Hussman Institute for Autism, Baltimore, MD, (3)Rutgers Robert Wood Johnson Medical School, Piscataway, NJ, (4)John P. Hussman Institute for Human Genomics, University of Miami Miller School of Medicine, Miami, FL, (5)Hussman Institute for Human Genomics, University of Miami, Miami, FL, (6)Hussman Institute for Autism, Catonsville, MD*

Background: To date, hundreds of genetic loci have been implicated in ASD risk. Recent studies have shown that genes harboring ASD risk loci are highly enriched in sets of genes expressed during early neocortical development and genes encoding proteins that function in specific biological pathways involving regulation of transcription, chromatin remodeling, cell adhesion, signaling complexes, and synapse function. One of the hypothesized models for the pathogenesis of autism suggests that dysregulation of the balance between excitatory and inhibitory (E/I) neuronal inputs may underlie some phenotypic aspects of ASD. A precise E/I ratio is required to maintain the narrow range of optimal neuronal spiking required for the transfer of information within the brain. Neurodevelopmental deficits in γ-aminobutyric acid (GABA)ergic or glutamatergic neurons may contribute to an imbalance in this E/I ratio. Using human induced pluripotent stem cell (hiPSC)-derived neurons in a 3D model system, we can investigate these potential deficits in an in vitro model system that may more accurately recapitulate human cortical development.

Objectives: The objective of this study was to use 3D serum free embryoid body (SFEB) organoid model to assess for potential differences in the morphology and network-level function that are specific to cortical neurons derived from ASD-specific hiPSCs.

Methods: High throughput approaches were applied to compensate for heterogeneity and variability inherent in iPSC-derived 3D cultures. To model ASD neuronal phenotypes in our ASD cohort, SFEBs were generated from control and ASD individuals (n = 4 lines and 7 lines, respectively). High content screening using the ThermoFisher ArrayScan XTi platform was used to quantify GABA+ and VGLUT+ cells in SFEBs and VGLUT+ neuron morphology. Spontaneous network-level activity was recorded from SFEBs plated onto multi-electrode array (MEA) plates.

Results: High content analysis revealed that SFEBs derived from individuals with autism have fewer GABA+ neurons as compared to controls (N = 288 SFEBs/line, $p<0.001$; Mann-Whitney U). No significant difference in the number of VGLUT+ neurons was seen in individuals with autism compared to controls using the same analysis. A high content screen of the morphology of VGLUT+ neurons showed a decrease in the number of branch points and number of neurites in autism iPSC lines compared to controls (N = 288 SFEBs/line, $p<0.001$; Mann-Whitney). Although not completely uniform, MEA recordings reveal that SFEBs derived from individuals with ASD show increased spontaneous firing (N = 72 SFEBs/line, $p<0.001$; Mann-Whitney).

Conclusions: SFEBs derived from ASD-specific iPSC showed a reduction in the number of GABAergic interneurons compared to control iPSC. Additional alterations in electrophysiological activity were seen in the ASD compared to the control iPSC-derived SFEBs. These findings indicate that potential E/I deficits found in our ASD cohort can be detected using high-content approaches. The results of this study will aid in our understanding of the molecular mechanisms that underlie autism and identify new therapeutic targets.

407.003 *(Poster)* Modeling the Enteric Nervous System in Autism Spectrum Disorder Using iPSC-Derived Innervated Gastrointestinal Organoids

S. J. Walker[1]*, D. Leavitt*[2]*, K. Harrelson*[3] *and D. Mack*[4]*, (1)Wake Forest Institute for Regenerative Medicine, Winston-Salem, NC, (2)Wake Forest University, Winston Salem, NC, (3)Wake Forest University, Winston-Salem, NC, (4)University of Washington, Seattle, WA*

Background: Children with autism spectrum disorder (ASD) are more likely to experience chronic gastrointestinal (GI) symptoms of uncertain etiology than their typically developing peers. Because chronic constiption is a common finding in this population, we hypothesized that in some ASD children an abnormally functioning enteric nervous system (ENS) may underlie colonic hypomotility. We chose to test this hypothesis using a model of Phelan McDermid Syndrome (PMDS) because: (1) ~80% of individuals with PMDS have an ASD diagnosis, (2) >50% of that subset are reported to have chronic GI symptoms and, (3) the hallmark of PMDS is haploinsufficiency of a key neuronal protein, SHANK3. In the central nervous system (CNS), SHANK3 contributes to the formation and maintenance of postsynaptic density of excitatory synapses. The goal of our study using PMDS patient-specific iPSC-derived GI organoids is to determine the role of SHANK3 in the *ENS* and to identify potential therapeutic targets to correct gut hypomotility.

Objectives: To create an *in vitro* model, using iPSCs from PMDS patients, to study ENS function in individuals with ASD and chronic GI symptoms.

Methods: PMDS iPSC lines (proband and non-affected parent) were obtained from the NIMH Repository and Genomics Resource Project. Patient-derived iPSCs were used to create an innervated gut organoid through the combination of individually cultured GI spheroids and neural crest cells (NCCs). After the GI spheroids had been passaged 9 times and NCCs had been cultured for 20 days, the two cell types were mechanically aggregated and co-cultured for 5 days. Immunocytofluorescence was used to characterize the individual components (GI spheroids and NCC) and then the innervated gut organoids following co-culture.

Results: Immunocytofluorescence staining confirmed the presence of Sox9 demonstrating that the patient-derived iPCSs were successfully reprogrammed to GI spheroids (Fig 1A). NCC identity was confirmed by neuronal communication via axonal extensions of nearby NCCs (Fig 1B) and further supported via immunocytofluorescence staining with HNK1 (Fig 1C). Co-culture of mechanically aggregated GI spheroids and NCC for 5 days resulted in evidence of spheroid innervation (Fig 1D).

Conclusions: This pilot study describes the early stages of development of a novel model system to evaluate the contribution of a malfunctioning enteric nervous system in ASD by using iPSCs from a PMDS patient with co-occurring diagnoses of ASD and chronic GI symptoms. Next steps will entail a longer period of co-culture, followed by functional assays.

407.004 *(Poster)* Modelling Early Brain Development in NF1 Autism Using Induced Pluripotent Stem Cells

J. O'Flaherty[1]*, S. Garg*[2] *and S. J. Kimber*[1]*, (1)Division of Regenerative Medicine and Cell Matrix Biology, University of Manchester, Manchester, United Kingdom, (2)University of Manchester, Manchester, United Kingdom of Great Britain and Northern Ireland*

Background: Autism Spectrum Disorder (ASD) is a group of neurodevelopmental disorders thought to arise in early cortical development and have a complex genetic aetiology. However, the critical developmental stages and cell types affected have not been clearly defined. Neural differentiation studies using Human Induced Pluripotent Stem Cells (hiPSC) have suggested that there may be pathological priming during early development which may affect the cortical progenitor stage. Defects at the progenitor stage could affect the function of subsequent mature neurons. Neurofibromatosis 1 is a useful syndromic model of autism due to its monogenic nature and high prevalence of ASD amongst patients (24%). Loss of function mutations in the NF1 gene, results in RAS/MAPK pathway over activity, which causes abnormal cortical neuron development. $Nf1^{+/-}$ animal models suggest that the function of glutamatergic and GABAergic neurons may be affected differently, leading to an inhibition/excitation imbalance, but it is still unclear whether this is also the case in humans.

Objectives: To establish differences in the development of glutamatergic and GABAergic neurons between NF1-ASD and related parental control hiPSCs to determine the major aberrant pathways in early development which may contribute to disease.

Methods: We have generated four transgene-free hiPSC lines from peripheral blood mononuclear cells from two individuals with NF1-ASD and related parental controls, as well as unrelated controls. We are also currently developing isogenic cell lines using CRISPR-Cas9 to correct the NF1 mutations in NF1-ASD cell lines. The hiPSC lines have been differentiated into neuroepithelial, early glutamatergic and GABAergic progenitor cells and immature glutamatergic and GABAergic neurons using established protocols. Differences in their phenotypes throughout development were subsequently explored using qRT-PCR, immunofluorescence and flow cytometry.

Results: The hiPSC lines generated express key pluripotency markers and lack expression of early differentiation markers throughout several passages (p10-p20). We observed differences in the early development of cortical glutamatergic and GABAergic neurons. Furthermore, NF1-ASD hiPSCs appeared to have changes in the cell cycle throughout neuronal development.

Conclusions: Our results demonstrate that there are early differences between healthy and NF1 mutant lines in the development of excitatory and inhibitory neurons, suggesting that mutations in the NF1 gene may affect cortical neuronal development in ASD. As NF1 is a key protein in the RAS/MAPK pathway, which is also affected in other models of autism, these findings may prove useful more widely in understanding autism.

407.005 *(Poster)* Multiple RNA Sequencing Platforms Reveal Complex Impact of Air Pollution Exposure on Cerebral Organoid Development

S. M. Bilinovich[1], *K. L. Uhl*[1], *K. C. Lewis*[1], *D. Vogt*[1], *J. W. Prokop*[1] *and D. B. Campbell*[2], *(1)Pediatrics and Human Development, College of Human Medicine, Michigan State University, Grand Rapids, MI, (2)Department of Pediatrics and Human Development, Michigan State University, Grand Rapids, MI*

Background: Air pollution exposure has been established as a risk for development of autism spectrum disorders (ASD). Genetic variants in key genes can account for some cases of ASD, but cannot explain the majority cases. Environmental factors causing epigenetic changes may account for ASD not explained by genetic variants. While two-dimensional cellular models can be used for preliminary examination of the effect of environmental pollutants, it lacks the ability to model the three-dimensional development of the complex human brain and the symbiotic relationship between different cell populations during cortical development.

Objectives: To understand how diesel particulate matter (DPM), a key component of urban air pollution, exposure during cerebral cortex development affects different cell populations in the complex brain development using cerebral organoids and how it correlates to ASD.

Methods: Cerebral organoids were generated from commercially available human induced pluripotent stem cells (hIPSC). After 30 days of maturation, cerebral organoids were exposed to 30µg/mL of DPM for 7 days. Gene expression of the organoids was then evaluated with three distinct transcriptome-wide methods: Illumina paired end RNAseq, long read direct RNAseq using Nanopore, and single-cell RNA-seq (scRNA-seq) using the 10x Genomics platform.

Results: RNA-seq of the cerebral organoids shows that we have 117 upregulated genes and 24 downregulated genes with a log2FC greater than 1 or less than -1 with a q-val of <0.05. Analysis of scRNA-seq shows 18 distinct cell clusters in the cerebral organoids. We identified several cell types including intermediate progenitor cells, radial glia, choroid plexus, and neurons. DPM alters several of the cell populations resulting in decreased cell numbers. A closer analysis of ASD susceptibility genes and genes linked to intellectual disability shows certain cell populations enriched for genes, with multiple ASD-associated genes altered by DPM exposure.

Conclusions: Cerebral organoids are an ideal cellular model for examining the complexity of brain development. Our project shows that the combination of several RNAseq platforms and cerebral organoids can give unique insights into how different cell types in the developing brain can be affected by environmental factors.

407.006 *(Poster)* Utilizing Forebrain-like Organoids to Characterize the Impact of TBR1 De Novo Mutations on Regulation of Deep Layer Cortical Development at a Single-Cell Resolution

B. A. DeRosa[1], *R. M. Mulqueen*[1], *A. Nishida*[1], *C. A. Thornton*[1], *K. A. Torkenczy*[1], *A. J. Fields*[1], *M. Co*[1], *K. M. Wright*[2], *F. J. Steemers*[3], *A. C. Adey*[4] *and B. J. O'Roak*[1], *(1)Molecular & Medical Genetics, Oregon Health & Science University, Portland, OR, (2)Vollum Institute, Oregon Health & Science University, Portland, OR, (3)Illumina, Inc., San Diego, CA, (4)Knight Cardiovascular Institute, Oregon Health & Science University, Portland, OR*

Background: The *in vitro* differentiation of 3D cortical organoids from induced pluripotent stem cells (iPSCs) has been shown to recapitulate neurobiological processes that occur during *in vivo* midfetal cortical development. Prior studies have identified this midfetal period as a potential critical window when many autism risk genes begin to function as a network, especially in deep layer neurons. However, our understanding of how specific *de novo* mutations (DNMs) impact network characteristics during brain development is limited. Here, we perform an intensive genomic characterization of these cortical organoid models and utilize this system to understand the effects of DNMs in *TBR1,* a key transcriptional regulator of deep layer neuronal fate.

Objectives: To characterize molecularly distinct changes in cortical organoids at a single-cell resolution and alterations induced by *TBR1* DNMs.

Methods: Forebrain-like organoids were differentiated from two unedited control iPSC lines, in addition to, isogenic pairs of a control iPSC line edited to contain DNMs in the autism risk gene *TBR1*. Multiple individual organoids from two differentiation experiments were sampled at culture days 30, 60, and 90. Dynamic changes in epigenetic state during organoid differentiation were assessed using an optimized single-cell combinatorial indexing (sci) ATAC-seq (Mulqueen et al. 2019). Single-cell profiles were collapsed into groups using cisTopic then analyzed for enrichment of specific transcription factor binding motifs. Pseudotemporal analysis was performed to uncover the succession of putative transcription factor activity. In parallel, a subset of organoids were also evaluated using 10x Genomics single-cell RNA-seq.

Results: We previously reported chromatin accessibility profiles from a single control iPSC line and *in vitro* differentiation that we assessed for protocol optimization (three time points, over 12,076 single-cells). Here, we generated additional data on six organoids from this same differentiation experiment (~12,000 additional single cells) and ~2,500 single cell 3' RNA profiles for each of three organoids (paired at each time point). In addition, we generated data on a differentiation replicate as well as a second control line (two organoids per line per timepoint, ~25,500 single cells). Organoids generated from the original line used for optimization are morphologically the same across experiments showing similar numbers of cortical rosettes and patterning of markers recapitulating human corticogenesis *in vivo*. While organoids generated from the second control iPSC line are smaller than those produced from the first control, the regional patterning of cortical markers is similar. Using CRISPR-Cas9, we successfully generated isogenic pairs of our control line with and without an ASD-associated *TBR1* mutation for which we are currently generating additional organoids and genomic data.

Conclusions: Our data support cortical organoids as viable models of fetal brain development, which can be characterized at single cell resolution. Our initial assay of a control iPSC line revealed a progression of chromatin and development of cell types similar to the stereotyped progression in human cortical development. Characterization of organoids with *TBR1* DNMs will address important gaps in knowledge to better understand the role of *TBR1* and its regulated pathways in the development of ASD.

Cellular Neuroscience

POSTER SESSION — **CELLULAR NEUROSCIENCE**
408 - Cellular Neuroscience Posters

408.001 *(Poster)* Altered Expression of Cadherins Suggests Their Potential Roles in Dendrite Development and Autism

***J. A. Frei**, R. F. Niescier, J. E. Nestor, M. W. Nestor, G. J. Blatt and Y. C. Lin, Hussman Institute for Autism, Baltimore, MD*

Background: Multiple members of the cadherin superfamily have been strongly implicated in autism. The cadherin superfamily contains more than one hundred cell adhesion molecules. A genome wide association study identified the classical type II cadherins CDH8 and CDH11 and the protocadherin PCDH9 as candidate risk genes. We hypothesize that cadherin signaling pathways could be disrupted in autism and may exhibit increased vulnerability of altered neuronal structure and stability in neurons.

Objectives: We first determined the expression of autism risk cadherins CDH8, CDH11 and PCDH9 in iPSC-derived neural precursor cells (NPCs) from control and autism individuals to evaluate whether cadherin levels are commonly altered in autism. We then investigated the expression patterns of cadherins in developing mouse brains and in primary neurons at the subcellular level. Cdh11 knockout mice were used to examine functional effects on dendrite arborization and calcium signaling. This study provides novel insights into common and distinct functions of different cadherins in neural circuit formation and the implication in autism.

Methods: Western blot analyses were performed to evaluate the protein expression of CDH8, CDH11 and PCDH9 in iPSC-derived NPCs, the developing mouse tissues and primary neurons. Subcellular localization as well as enrichment of cadherins in synaptic plasma membrane and postsynaptic densities were further analyzed using a synaptic fractionation assay and immunocytochemical labeling with neuronal markers PSD95, synapsin1 and GAT1. By co-immunoprecipitation, binding partners of cadherins were identified. Morphometric analysis was performed to measure the effect of Cdh11 knockout on the complexity of dendritic arbors. Calcium activity was measured in Cdh11 knockout and wildtype cultures using calcium indicators in the IncuCyte S3 Live-Cell Analysis System.

Results: We found altered cadherin expression levels in iPSC-derived NPCs from autism individuals with an increase of CDH8 and a decrease of CDH11. Temporal expression analysis in the developing mouse brains revealed increased expression of cadherins in the time frame of dendritogenesis and synaptogenesis. Cdh8 was preferentially expressed in excitatory synapses and interacted with neuroligin-1. *Cdh11* knockout mice showed a similar increase of cadherin-8 protein as in iPSC-derived NPCs along with elevated expression of neuroligin-1 and PSD95. The Cdh11 knockout hippocampal neurons exhibited an increase in dendritic complexity and altered neuronal activity.

Conclusions: The present study suggests altered expression profiles of cadherins in autism brains, thus strengthening the hypothesis of a central role of cadherins in autism. The findings highlight that cadherins of different subfamilies are expressed in a developmental time window implicated in autism. The results of this study further provide evidence that Cdh8 and Cdh11 are involved in regulating the development of neuronal circuitry and indicate a potential mechanism by which they may be involved in the etiology of autism.

408.002 *(Poster)* Ankyrin-B Deficiencies Cause Defects in Axonal Development, Synapse Formation, and Cortical Connectivity.

***D. N. Lorenzo**[1], B. A. Creighton[1], D. Viswanathan[1], K. A. Breau[1], J. C. Bay[2] and S. Afriyie[1], (1)Cell Biology and Physiology, University of North Carolina at Chapel Hill, Chapel Hill, NC, (2)Cell Biology and Physiology, UNC-Chapel Hill, Chapel Hill, NC*

Background: Ankyrin-B (AnkB) is an integral component of the membrane-associated cytoskeleton, where it binds the spectrin meshwork to organize specialized membrane domains. AnkB also couples motor proteins to organelles to promotes axonal transport and growth. Two major AnkB isoforms are expressed in the brain, ubiquitously expressed 220kDa (AnkB220) and neuron-specific 440kDa (AnkB440) AnkB. *ANK2,* which encodes AnkB, is a high confidence autism spectrum disorder (ASD) gene. Loss of both AnkB isoforms in mouse brains results in absence of long cortical axonal projections and overall reduction in axonal length, confirming that AnkB serves important roles in neuronal development in both humans and mice. In contrast, specific AnkB440 loss increases axonal branching in cultured cortical neurons and *in vivo*. Here we examine the independently and combined molecular mechanisms driven by AnkB isoforms that underlie their effects on cortical neuronal connectivity and function.

Objectives: To dissect the AnkB isoform-specific molecular mechanisms underlying AnkB's role in neuronal cortical connectivity and synaptic function.

Methods: To determine the isoform-specific functions of AnkB during axonal development and synaptogenesis, and their role in ASD, we developed mice lacking either AnkB440 or AnkB220 in neural progenitors. We combined histology, high resolution microscopy, biochemistry, and rescue experiments in neuronal cultures and *in vivo* to define the potential pathogenic effects of ASD-linked mutations.

Results: We identified AnkB isoform-specific effects on axon growth, morphology, cue response during axonal guidance, and synaptogenesis. For example, AnkB440 is required for proper signal transduction downstream of guidance receptors to promote actin cytoskeleton remodeling during axon development. On the other hand, loss of AnkB220 leads to specific deficits in cortical lamination and corpus callosum formation. Additionally, combined loss of both isoforms results in dendritic morphology and spine defects. Selected ASD-linked AnkB mutations failed to rescue these cellular defects.

Conclusions: AnkB isoforms have critical and distinct cell-autonomous roles in the growth and guidance of long cortical axons, dendritic morphology, and synapse formation and function. We will describe the molecular mechanisms underlying these AnkB functions and how they are affected by AnkB-linked ASD variants. Our findings suggest that both AnkB isoforms contribute to neuronal development and function through independent mechanisms that may have a combined effect on cortical connectivity and give rise to functional deficits in ASD patients.

408.003 *(Poster)* Cytoplasmic-Predominant Pten Increases Microglial Activation and Synaptic Pruning in a Murine Model with Autism-like Phenotype

N. B. Sarn[1,2], *R. Jaini*[2,3,4], *S. T. Thacker*[5], *H. Lee*[2], *R. Dutta*[4,6] *and C. Eng*[7], *(1)Department of Genetics and Genome Sciences, Case Western University, Cleveland, OH, (2)Genomic Medicine Institute, Lerner Research Institute, Cleveland, OH, (3)Comprehensive Cancer Center, Case Western Reserve University School of Medicine, Cleveland, OH, (4)Cleveland Clinic Lerner College of Medicine, Cleveland, OH, (5)Genomic Medicine Institute, Lerner Research Institute of Cleveland Clinic, Cleveland, OH, (6)Neuroscience, Lerner Research Institute, Cleveland, OH, (7)Genomic Medicine, Cleveland Clinic, Cleveland, OH*

Background: Germline mutations in the gene encoding Phosphatase and Tensin homolog deleted on chromosome TEN (*PTEN*) account for ~10% of all cases of autism spectrum disorder (ASD) with coincident macrocephaly. To explore the importance of nuclear PTEN in the development of ASD and macrocephaly, we generated a mouse model with predominantly cytoplasmic localization of Pten ($Pten^{m3m4/m3m4}$ model). Cytoplasmic predominant Pten expression leads to a phenotype of extreme macrocephaly and behavior reminiscent of high-functioning ASD.

Objectives: The primary objective of this study was to determine if constitutive Pten dysfunction predisposes microglia to aberrant activation, leading to increases in synaptic pruning during neurodevelopment.

Methods: Using IPA, we analyzed our $Pten^{m3m4/m3m4}$ neural transcriptome, and were able to bring our observed pathway-based predictions to *in vitro* and *in vivo* validation. Initially, we utilized a series of co-culture experiments with microglia and neurons from $Pten^{WT/WT}$ and $Pten^{m3m4/m3m4}$ genotypes to investigate Pten localization, synaptic pruning, phagocytosis, and C1q expression. To further validate our *in vitro* findings we used $Pten^{m3m4/m3m}$ mice to determine at what age microgliosis occurs in this model, as well as quantify cortical and hippocampal expression of Pten, Synaptophysin, Psd-95, C1q, and Iba1 thought the course of neurodevelopment.

Results: Transcriptomic analysis of the $Pten^{m3m4/m3m4}$ cortex revealed upregulated gene pathways related to myeloid cell activation, myeloid cell migration, and phagocytosis. Interestingly, a contrasting downregulation of gene pathways related to synaptic transmission was observed. Follow up of the transcriptomic data, *in vitro* revealed a 25-fold increase in C1q expression ($p = 0.0002$) in mutant microglia compared to wild-type a. In addition, we assessed phagocytic ability and efficiency of $Pten^{m3m4/m3m4}$ microglia. We found 20 % increase in the number of phagocytic $Pten^{m3m4/m3m4}$ microglia compared to $Pten^{WT/WT}$ ($p = .001$). We also found $Pten^{m3m4/m3m4}$ phagocytic microglia were ~2 times more efficient in their phagocytic ability compared to $Pten^{WT/WT}$ microglia ($p = 0.004$). To assess impact on synaptic pruning, we co-cultured combinations of wild-type and mutant microglia with neurons and found that $Pten^{m3m4/m3m4}$ microglia co-cultured with $Pten^{m3m4/m3m4}$ neurons resulted in a 2-fold increase in pruning compared to when no microglia were present ($p= 0.0001$). These *in vitro* findings on over pruning of neuronal synapses via a potential neuron-microglia cross talk in a $Pten^{m3m4/m3m4}$ system, were consistent with *in vivo* observations in our murine model. At 3 weeks of age significant increase in microglial cell area was observed in the cortex of mice with $Pten^{m3m4/m3m4}$ mutations compared to that of the $Pten^{WT/WT}$ cortex ($p = <0.0001$). This microgliosis was concurrent with drop in *Pten* expression levels to below 50% of wild-type levels in the cortex ($p = <0.001$). The decline in Pten expression and concurrent increase in microgliosis was strongly associated with decreased expression of synaptic markers in the cortices of $Pten^{m3m4/m3m4}$ mice.

Conclusions: These findings provide direct causal evidence that dysregulated Pten in microglia has an etiological role in microglial activation, phagocytosis, and synaptic pruning. Collectively, our data suggest altered PTEN activity in microglia could serve as a key regulator of synaptopathy phenotypes in PTEN-ASD patients.

408.004 *(Poster)* Interneuron-Specific Knockout of Semaphorin 3F Induces Neuroinflammation and Endothelial Injury with Disruption of the Blood Brain Barrier

R. Jagadapillai[1], *Z. Li*[2], *E. Gozal*[3] *and G. Barnes*[4], *(1)Departments of Pediatrics, PRI, University of Louisville, Louisville, KY, (2)Neurology, Vanderbilt University, Nashville, TN, (3)Pediatrics, PRI, University of Louisville, Louisville, KY, (4)Neurology, University of Louisville School of Medicine, Louisville, KY*

Background: Semaphorin is a well-known neurovascular molecule which impacts both neurogenesis and vasculogenesis. Both cell and neurite motility of the neurons and endothelial cells are regulated by semaphorin 3F-Neuropilin 2 (Sema 3F-NRP2) signaling. The immune system and glia also express neuropilins and semaphorins but their function in these cell types is much less clear. Recent evidence suggests that Neuropilin 2 signaling regulates inflammation and the loss of Sema 3F-NRP2 signaling has also been shown to increase vascular permeability and inflammation. Autism spectrum disorder (ASD) is a disorder with some evidence for neuroinflammation but little is known about vascular involvement and blood brain barrier function. We aimed to determine whether neuroinflammation we previously described in knockouts for Sema 3F-NRP2 signaling, a murine model of autism and epilepsy, also involved platelet-endothelial activation and injury.

Objectives: In the present study, we aim to examine neuroinflammatory markers in our GABAergic neurons-specific Sema3F KO mouse model of ASD that may parallel human neuroinflammation characteristics identified in ASD patients. We will examine whether these neuroinflammation processes lead to platelet activation and endothelial injury and to possible disruption of blood brain barrier (BBB) integrity.

Methods: Using a genetic model of ASD and epilepsy, Semaphorin 3F knockout mice (CRE+FF) and control mice (Cre−FF, Cre+WT, Cre−WT) expressing Semaphorin 3F, we examined physical (brain weight) and electrophysiological (EEG) changes and the expression and distribution of markers of inflammation (iba1 and iNOS) and of oxidative stress (3-nitrotyrosine) in the hippocampus, cortex and amygdala brain regions. In addition, we stained these brain regions for platelets (CD61) and platelet activation (p-selectin and serotonin) markers and for albumin leakage as an indicator of blood brain barrier integrity.

Results: Sema 3F deletion in interneurons results in brain weight loss and EEG changes and induces signs of neuroinflammation including activation of microglia, iNOS induction, and increased 3-nitrotyrosine. Signs of platelet deposition, activation, and release of serotonin occur in multiple brain regions important in ASD. Finally, along with platelet products, albumin leakage and uptake and outlining of neurons in these regions suggest possible BBB deficits mediated by inflammation.

Conclusions: In summary, disruption of neurovascular signaling molecules, such as Sema3F-NRP2, may mediate causative pathophysiology in some subgroups with ASD via neuroinflammation, oxidative stress, and compromised BBB integrity.

408.005 *(Poster)* Preliminary Cellular Evidence of Demyelination in Temporal Lobe White Matter As People with ASD Age into Adulthood

K. D. Murray[1], ***A. E. Carr***[2], *A. Z. Davis*[3], *S. Taylor*[4] *and C. M. Schumann*[2], *(1)Psychiatry and Behavioral Sciences, UC Davis School of Medicine, Sacramento, CA, (2)MIND Institute, UC Davis, Sacramento, CA, (3)UC Davis MIND Institute, Davis, CA, (4)Public Health Sciences, University of California, Davis, Sacramento, CA*

Background: Extensive literature links autism spectrum disorder (ASD) symptomatology to impairments in neuronal connectivity and communication. Postmortem human brain tissue provides an invaluable opportunity to evaluate the cellular underpinnings of altered neuronal connectivity in ASD. Utilizing electron microscopy techniques, we and others have identified alterations in axon density in ASD brains. In addition, our own studies indicate a significant decrease of myelin thickness in multiple white matter regions of the temporal lobe in adults with ASD. This difference is not present in younger cases, suggesting possible demyelination as people with ASD age into adulthood. However, the underlying trajectory and potential pathology of oligodendrocytes, the cells that form myelin in the brain, across age remains unknown. We hypothesize that, in white matter regions of the temporal lobe where thinning of myelin was identified, there will be an age-related decrease in oligodendrocyte density in people with ASD.

Objectives: To measure oligodendrocyte density in superficial white matter dorsal to the superior temporal gyrus (STG) of postmortem human brain tissue from a wide age range of neurotypical and ASD individuals.

Methods: We collected postmortem human brain samples from 24 male cases (11 ASD, 13 neurotypical controls) ranging from 2-44 years of age. Tissue blocks containing the temporal lobe were cut with a sliding microtome at 100µm thickness and Nissl stained for cell bodies using our standard histological protocols. A total of eight sections were selected per case (1000µm apart) spanning the STG rostral to caudal. White matter regions were identified by the cytoarchitecture of the surrounding cortex and hand traced at 2.5x magnification. A 500µm x 500µm grid was superimposed over the tissue to ensure a maximum counting field depth of 500µm. Stereological measures (utilizing StereoInvestigator optical fractionator software from MBF Bioscience) were applied to count oligodendrocyte populations specifically in the superficial white matter (SWM) dorsal to the superior temporal gyrus (STG) at 100x under brightfield microscopy. All stereological quantification was performed with a 5µm guard zone and 15µm optical dissector height. Oligodendrocytes were identified based on their unique cellular morphology: 2.5µm -6µm diameter, dark nuclear boundary and spherical shape.

Results: The density of oligodendrocytes decreases with age in ASD superficial white matter dorsal to STG (correlation = 0.42). This age-related decrease in oligodendrocyte density seen in ASD does not occur in neurotypical individuals, and in fact density increases with age. There is no significant difference in oligodendrocyte density in younger cases (2-14 years) ($p<0.23$). In contrast, oligodendrocyte density is significantly decreased in adolescents and adults (15-44 years) ($p<0.02$). These age dependent trends align with previously found changes in the trajectory of myelin thickness with age in both groups.

Conclusions: The significant decrease in oligodendrocyte density with age in ASD is consistent with previous findings of decreased myelin thickness in white matter regions of the temporal lobe. A decrease in myelin thickness, axon density, and oligodendrocyte density with age suggests an overall degenerative pattern and disrupted neuronal connectivity in ASD that does not occur in neurotypical individuals.

408.006 *(Poster)* Testing the Link between Cell Cycle Disruption and ASD: Impacts of Chd8 Mutation on Cell Proliferation Dynamics in Embryonic and Postnatal Brain.

C. P. Canales[1], *S. Frank*[2,3], *J. Bennett*[4], *A. A. Wade*[5], *H. Mir*[6], *P. Beauregard*[7], *D. G. Amaral*[8] *and A. S. Nord*[5], *(1)Center for Neuroscience | MIND Institute, Department of Psychiatry and Behavioral Sciences, University of California Davis, Davis, CA, (2)MIND Institute, UC Davis, Davis, CA, (3)Department of Molecular Biology, Princeton University, Princeton, NJ, (4)UC Davis, Davis, CA, (5)Center for Neuroscience, Department of Neurobiology, Physiology, & Behavior, University of California, Davis, Davis, CA, (6)Center for Neuroscience, University of California Davis, Davis, CA, (7)Center for Neuroscience, UC Davis, Davis, CA, (8)Department of Psychiatry and Behavioral Sciences, The Medical Investigation of Neurodevelopmental Disorders (MIND) Institute, UC Davis School of Medicine, University of California Davis, Sacramento, CA*

Background: *De novo* mutations in the chromatin-remodeling factor *CHD8* (Chromodomain-Helicase DNA-binding protein 8) are strongly associated with autism spectrum disorder (ASD) and more generally with neurodevelopmental disorders (NDDs). Most *CHD8* mutations are expected to lead to a loss of functions and carrier patients display, among other manifestations, ASD-like behavior, intellectual disability, and macrocephaly. We previously reported that *Chd8* regulates the transcription of cell cycle genes and via paired transcriptomic and neuroanatomy analyses that *Chd8* plays a crucial role during early neurodevelopment. However, proliferation in the brain occurs throughout the lifespan at specific times and in specific brain regions. Thus, modeling the proliferative changes pathological mechanisms linking cellular proliferation and *Chd8* haploinsufficiency from the molecular to system level at different developmental and post-natal stages is critical.

Objectives: : Here, we hypothesized that *Chd8*-associated neuropathology is not limited to early neurodevelopment and/or to aberrations in a single cell type or region of the brain. Therefore, we aim to address major questions regarding the disrupted genomic control of neuronal proliferation dynamics in cortex, hippocampus and cerebellum, all three brain regions that exhibit anatomical size differences identified by MRI analysis in the *Chd8* haploinsufficient mice.

Methods: Using mice that harbor a heterozygous *Chd8* mutations and present behavioral deficits relevant to ASD and Intellectual Disability (ID), we performed 1) unbiased stereology to further characterize and investigate the causal roots of the cortical expansion previously described, 2) paired transcriptomic profiling (RNA-Seq) with neuroanatomical and functional studies (Immunohistochemistry and Edu pulse and chase assays) to investigate perturbations in cell cycle and neuronal progenitors dynamics during development and postnatally in cortex, hippocampus and cerebellum.

Results: Our unbiased stereological analysis validated the previously reported macrocephaly phenotype associated with *Chd8* haploinsufficiency with increased cortical volume but found no change in neuronal cell counts or cell body volume. Transcriptional signatures reflect observed changes in neuroanatomy and synaptic transmission and postnatal studies in hippocampus and cerebellum proliferative dynamics provide functional evidence of the impact of *Chd8* haploinsufficiency on proliferative and neurogenic processes.

Conclusions: Our current data, combined with our previous reported findings provide mechanistic insights into the proliferative and neuroanatomical pathology of ASD. These findings contribute to the critical knowledge on how chromatin remodeling factor haploinsufficiency contribute to ASD-relevant brain overgrowth, postnatal processes and adult neurogenesis, aspects that are often overlooked in ASD and NDDs.

408.007 *(Poster)* The Relationship between Parvalbumin Expression and Neuronal Function May Provide a Mechanistic Explanation for Autism

R. F. Niescier*, M. Kilander and Y. C. Lin, Hussman Institute for Autism, Baltimore, MD*

Background: Differences in Excitation/Inhibition (E/I) balance in the brain have been linked to a variety of neurological conditions. In particular, mouse models and individuals with autism spectrum disorder (ASD) have exhibited differences in E/I balance through downregulation of parvalbumin (PV)-positive interneurons (PVIs), a class of neurons characterized through the presence of PV protein, as well as their fast-spiking capabilities. These neurons are found throughout the brain, and form local inhibitory synapses on either excitatory cell bodies or axon initial segments. PV itself is a calcium chelating protein that is thought to buffer the excess cytoplasmic calcium that occurs during neuronal spiking, and downregulation of this protein is associated with excess cytoplasmic calcium, and resulting disruptions in synaptic activity.

Objectives: While PVIs' involvement in ASD has been well-characterized in mice, the nature of how downregulation of PV affects PVIs, and whether this would result in excitotoxicity, is still not understood. Further, there is controversy concerning the fate of PVIs when PV is downregulated; whether the PVIs can survive without PV, or whether actual PVI numbers are reduced, is not fully understood. In this study, we examined the role of PV in PVIs. We hypothesize that the expression of PV correlates with neuronal morphology and synaptic activity, and knockdown of this protein will lead to abnormal dendritic arborization and disrupted synaptic activity.

Methods: We employed a mouse model that expresses the fluorescent protein tdTomato under the PV expression regulatory elements (PV-tdTomato), independent of the endogenous PV transcript. Using a primary cell culture approach, we examined PV levels in PVIs transcriptionally by Fluorescent *in-situ* Hybridization (FISH) analysis and translationally by immunocytochemistry. We further performed morphometric analysis and calcium imaging to determine the neuronal morphology and spontaneous calcium activity in PVIs. We have also used both a lentiviral and AAV approach to reduce the levels of PV using shRNA.

Results: Using our PV-tdTomato cultures, we have found that protein levels of PV show a broad variation in protein expression levels, and do not follow a normal distribution. PV also does not correlate with tdTomato expression, although some PV is typically found in tdTomato labeled PVIs. FISH analysis revealed that while PV protein and mRNA levels correlate, they do not show an association with tdTomato signal. PV levels correlate with the expression of CaMKIV, calcium/calmodulin-dependent protein kinase type IV, and inversely correlate with dendritic arborization. Additionally, the mean amplitude of spontaneous Ca^{2+} signaling peaks, as measured by the calcium indicator G-CaMP6, was increased in PVIs with low PV expression. Moreover, L-glutamate-mediated excitation of PVIs elicits, in parallel with a transient activation of ERK1/2, a fast upregulation of PV protein levels.

Conclusions: We show that variability of PV levels in PVIs have direct consequences on cellular morphology and neuronal activity. With the reduced levels of PV seen in ASD, our results suggest a putative mechanism for the cellular differences observed in this condition.

Clinical Genetics

POSTER SESSION — CLINICAL GENETICS
409 - Clinical Genetics Posters

409.001 *(Poster)* AutDB2020: A Resource for Autism Research

***E. Larsen**, S. Spring-Pearson, A. Sarkar, M. Estevez and S. Banerjee-Basu, MindSpec Inc., McLean, VA*

Background: Since its public launch in 2007, the autism genetic database AutDB (http://autism.mindspec.org/autdb/Welcome.do) has evolved into a multi-modular platform consisting of curated ASD-related genetic and functional evidence that has become a widely cited resource by the ASD research community. Ongoing curation of ASD-associated genetic and functional evidence has resulted in enormous growth across the modules of AutDB. In particular, the Human Gene Module has seen a significant increase in the number of ASD candidate genes following the application of next generation sequencing (NGS) technologies in large ASD cohorts.

Objectives: The objective of AutDB is to continue to provide a publicly available web-portal for the ongoing collection, manual annotation, assessment and visualization of genes linked to ASD.

Methods: The current modules of AutDB include the original Human Gene Module, which annotates all ASD-linked genes and their associated variants; the Animal Model module, which catalogs behavioral, anatomical and physiological data from rodent models of ASD; the Protein Interaction (PIN) module, which builds interactomes from direct relationships of protein products of ASD genes; and the Copy Number Variant (CNV) Module, which catalogs deletions and duplications of chromosomal loci identified in ASD. All data in AutDB is manually curated from peer-reviewed, published scientific literature.

Results: The number of ASD candidate genes in AutDB has increased from 328 to 1117 since 2012. Many of the newly added genes were curated based on their identification in genome-wide studies of large ASD cohorts. The latest release of AutDB (September 2019) includes 14,258 rare variants in ASD-linked genes extracted from 1448 publications. Based on multiple lines of variant evidence, we have identified over 100 important ASD genes in which rare, likely pathogenic variants have been identified in ASD cases across published studies. Furthermore, many of these genes have subsequently been shown to be responsible for ASD-associated neurodevelopmental syndromes in which affected individuals frequently present with developmental delay/intellectual disability, seizures, dysmorphic features, and/or other congenital anomalies, in addition to ASD. Included in this resource are animal models derived from many high confidence genes that recapitulate a number of core and other ASD-related phenotypes observed in human patients, lending further evidence to the importance of these genes in ASD pathogenesis. Together, we provide a curated catalog of ASD genes encompassing coding and non-coding variants, as well as ASD-associated copy number variants.

Conclusions: AutDB is the most comprehensive resource for exploring genetic variation in ASD. The modular architecture of AutDB allows us to integrate genetic and functional evidence in order to better access the potential importance of a given candidate gene in ASD pathogenesis, while our quarterly release schedule of newly annotated data ensures that AutDB is an up-to-date resource highlighting the most recent advances in ASD research for usage by the scientific community.

409.002 *(Poster)* Autism High-Risk Genes and New Genetic Subtypes

***H. Guo**[1,2], H. Wu[1], T. Wang[1,2], Y. Quan[1], M. Chen[1], M. He[1], B. Du[1], E. E. Eichler[2] and X. Kun[1], (1)Center for Medical Genetics, School of Life Sciences, Central South University, Changsha, China, (2)Department of Genome Sciences, University of Washington, Seattle, WA*

Background: Autism spectrum disorder (ASD) is a group of neurodevelopmental disorders with considerable genetic and clinical heterogeneity. Genetic studies have implicated hundreds of susceptibility genes and *de novo* variants in more than 100 genes confer increased risk for ASD. Even so, these genes account for only a small fraction of patients, suggesting that a large number of genes with extremely rare variants await discovery as study sample sizes increase.

Objectives: In an effort to better understand the genetic architecture, identify new risk genes, and define new genetic subtypes of autism spectrum disorders.

Methods: We targeted ~200 autism candidate genes originally implicated in cohorts of European descent for sequencing in 5256 families from the Autism Clinical and Genetic Resources in China cohort over the last five years using a modified single-molecule molecular inversion probes method.

Results: We validated recurrent *de novo* likely gene-disruptive mutations in 26 genes and identified multiple novel ASD high-risk genes. During this analysis, we identified transmission of private gene-disruptive mutations in genes predominantly associated with *de novo* mutations (DNMs) and showed that clinical revaluation of carrier parents revealed mild neurodevelopmental or related endophenotypes. We also identified families with DNMs in two or more candidate genes. Combining available exome sequencing data, we show that such oligogenic cases occur more frequently in probands associated with more severe phenotypes, including social impairments and seizure burden. By followed large-scale international collaboration, we and our collaborators defined new genetic subtypes (including *CSDE1*, *TANC2*, *GRIA2*, *ZNF292* and *TNRC6B*) of autism and related neurodevelopmental disorders by genotype-phenotype correlation studies.

Conclusions: We identify new risk genes and transmission of deleterious mutations in genes primarily associated with DNMs. Genotype-phenotype correlation analysis by large-scale international collaboration will not only lead to a causal diagnosis for patients but also be important for a better understanding of genotype–phenotype associations, definition of new ASD subtypes and in guiding precision medicine.

409.003 *(Poster)* Bringing Whole Genome Sequencing to the Clinic: The Itarget Autism Initiative (Individualized Treatments for Autism Recovery using Genetic-Environment Targets)

K. Calli[1], *Y. Qiao*[1], *S. Martell*[1], *H. MacRitchie*[1], *J. Howe*[2], *A. Sorkhou*[3], *M. Gallad*[3], *S. Jones*[1,4], *S. W. Scherer*[2], *E. Rajcan-Separovic*[5] *and M. S. Lewis*[1], *(1)Medical Genetics, University of British Columbia, Vancouver, BC, Canada, (2)The Hospital for Sick Children, Toronto, ON, Canada, (3)Illumina Canada, Inc, Vancouver, BC, Canada, (4)Canada's Michael Smith Genome Sciences Centre, Vancouver, BC, Canada, (5)Pathology, University of British Columbia, Vancouver, BC, Canada*

Background: Genetic testing for autism spectrum disorder (ASD) routinely includes chromosome microarray (CMA) to detect genome copy number variants (CNVs); whereas whole exome/genome sequencing (WES/WGS) is rapidly emerging to identify single nucleotide variants (SNVs) and insertions/deletions (indels). In Canada, WES may be covered by provincial health insurance (PHI) if the patient qualifies; otherwise families are left untested, or pay privately.

iTARGET-Autism (www.itargetautism.ca) joined together with Illumina Canada and MSSNG (www.mss.ng) to increase access to community, clinic-based WGS for individuals with confirmed ASD to identify causes informative to personalized counselling and care.

Objectives: 1. Translate gold standard WGS and genetic counselling to the clinic. 2. Identify phenome/genome autism subtypes (VarSeq; Golden Helix). 3. Negate complementary CMA/CNV analysis, while optimizing accurate and informative diagnoses.

Methods: We tested 100 autistic patients referred to the Autism Integrated Medical Services (AIMS) clinic who did not meet PHI criteria for funded WES. WGS performed at TCAG (SickKids, Toronto) via MSSNG and hospital-based CMA identified SNVs, Indels, and CNVs in families with idiopathic ASD.

Results: The first 48/100 genomes already show results impacting autism management and personalized counselling by identifying gene variants closely fitting "whole-person phenotypes" using a Clinical Geneticist lens (see Table 1). 100% of clinically reported CNVs identified by CMA were also identified by WGS, including novel CNVs and SNVs pertinent to each individual's specific autism and co-morbidities. Key results thusfar are:

1. WGS data from 48/100 individuals include 18 ASD affected children and 30 parents from 15 families (12 trio/3 quad families).
2. ~40% of families showed pathogenic and/or likely pathogenic autism-related SNVs/indels and/or CNVs across multiplex and simplex families +/- positive family history respectively (42% of trio/33% of quad families). Among 18 affecteds, 6 (33%) were found to have pathogenic and/or likely pathogenic SNVs/Indels and/or CNVs .
3. One child showed both a pathogenic SNV related to autism and secondary compound-heterozygous SNVs for Alport Syndrome.
4. 17/18 affecteds had hospital-based diagnostic CMA. 6/17 of these affecteds had pathogenic, likely pathogenic, and/or CNV variants of unknown significance (VUS; 8 non-redundant unique CNVs total). All 8 CNVs (from 260 Kb-1.56 Mb in size, including 2 de novo pathogenic CNVs) were detected by WGS using VarSeq software. This suggests that the WGS-VarSeq algorithm can reliably replace CMA for CNV detection, despite our small cohort

The WGS-VarSeq algorithm detected one VUS CNV not reported by CMA; a 100Kb, maternally-inherited duplication involving a single gene, *TSPAN7,* associated with speech delay/seizures. The patient has mild speech delay without seizures, with a maternal family history of idiopathic epilepsy and learning difficulties/ADHD.

Conclusions: We are confident that analysis of the remaining 52 genomes will further validate the translational potential of this small pilot study and the larger iTARGET project objectives to optimize early autism diagnosis to stratify more precise and personalized "best-fit" treatments.

409.004 *(Poster)* Determining the Pathogenicity of a Variant in MEF2C in an Individual with Autism Spectrum Disorder Identified through a Targeted Childhood Epilepsy Panel

M. Jun[1,2], *Y. Qiao*[2], *K. Calli*[2], *C. Chijiwa*[3], *E. Rajcan-Separovic*[1], *K. Haas*[3], *S. X. Bamji*[3] *and M. S. Lewis*[2], *(1)Pathology, University of British Columbia, Vancouver, BC, Canada, (2)Medical Genetics, University of British Columbia, Vancouver, BC, Canada, (3)University of British Columbia, Vancouver, BC, Canada*

Background: Many genes have been found to cause a pathogenic effect on Autism Spectrum Disorder (ASD), with most genetic etiologies of ASD to include chromosomal copy number variants (CNVs), highly penetrant single nucleotide variants (SNVs) and insertion/deletions (indels). The gene for Myocyte-Specific Enhancer Factor 2C (*MEF2C*) has been rarely associated with ASD and is essential for myogenesis and the development of the anterior heart, neural crest, and plays a role in craniofacial development. MEF2C haploinsufficiency syndrome, via mutation of the gene, typically involves a genomic micro-deletion at chromosome 5q14.3. Individuals with this mutation show a variety of symptoms, with the common features being intellectual disability (ID), global developmental delay (GDD), epilepsy, stereotypic movements, hypotonia, and cerebral malformation.

As part of the iTARGET Autism project (http://www.itargetautism.ca/), we investigated the functionality and pathogenicity of a novel SNV in the MEF2C gene identified in a young girl with ASD and the following features:

- Generalized neuromotor delay due to hypotonia, just starting to walk at age 3 years
- Atypical febrile seizures requiring anticonvulsant prophylaxis
- Completely nonverbal, and only started to use simple nonverbal tools to show her wants and feelings
- Limited eye contact, stereotypic arm and hand movements
- Moderate to severe ID
- Minor craniofacial dysmorphism
- A small muscular cardiac ventriculoseptal defect (VSD) which spontaneously closed, without any family history of cardiac structural defects
- Negative relevant family history

Objectives: To neuro-functionally analyze the pathogenicity of a novel variant in MEF2C identified in a patient with ASD.

Methods: As a clinical CNV microarray was negative, a targeted clinical sequencing panel available through GeneDx Inc, including 50 targeted epilepsy-related genes was used to evaluate a genetic association with the proband's condition. Variant functionality testing was performed with use of rat hippocampal cells transfected with GFP. Three different types of neurons were used to visualize changes in length, density, and excitatory/inhibitory synapses: control, wild-type, N231k variant.

Results: *Childhood Epilepsy Panel:* Proband was found to have a de novo heterozygous point mutation in the C-terminal transactivation region (c.693 C>G, p.Asn231Lys). This point mutation results in a missense mutation, in exon 7 of MEF2C gene]. This mutation occurs in a position that is conserved in mammals andis predicted to have damaging effect by multiple computational pathogenicity predicting tools including. Furthermore, it is absent from the normal control population databases of GnomAD exomes and genomes.

Variant Characterization: A loss of function of excitatory synapses in N231k variant neurons was identified, suggesting the variant alters a change in normal function and is thus likely pathogenic. A decrease in % mushroom spines of the N231k variant suggest a decrease in excitatory synapses, which is further proved by the decrease in PSD-95 density in N231k variant neurons (see Figures 1 and 2).

Conclusions: Variant functionalization is essential for understanding the genetic etiology of an individual's ASD. This novel variant in MEF2C has been shown to affect one of the two known functions of this essential gene, suggesting that this is a pathogenic variant that may be contributing to the etiology of this individual's ASD.

409.005 *(Poster)* Differential Effects of Deletions and Duplications on Autism Risk across the Genome

E. A. Douard[1]*, A. Zeribi*[1]*, C. Schramm*[1]*, P. Tamer*[1]*, S. Nowak*[1]*, M. A. Loum*[1]*, M. P. Poulin-Lord*[2]*, B. Rodríguez-Herreros*[3]*, E. Loth*[4]*, G. Schumann*[5]*, T. Bourgeron*[6]*, A. Labbe*[7]*, T. Paus*[8]*, L. Mottron, M.D.*[9]*, C. Greenwood*[10]*, G. Huguet*[1] *and S. Jacquemont*[1]*, (1)UHC Sainte-Justine Research Center, University of Montreal, Montreal, QC, Canada, (2)Département de neurosciences, Université de Montréal, Montréal, QC, Canada, (3)Université de Montréal, Montréal, QC, Canada, (4)Department of Forensic and Neurodevelopmental Sciences, Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, United Kingdom, (5)King's College London, London, United Kingdom, (6)Human Genetics and Cognitive Functions, Institut Pasteur, Paris, France, (7)Département de Sciences de la Décision, HEC Montreal, Montreal, QC, Canada, (8)Departments of Psychology and Psychiatry, University of Toronto, Toronto, ON, Canada, (9)Autism Research Group, CIUSSS du Nord-de-l 'Île-de-Montréal, Montréal, QC, Canada, (10)Lady Davis Institute for Medical Research, Jewish General Hospital, Montreal, QC, Canada*

Background: Deleterious deletions and duplications (copy number variations, CNVs) are identified in up to 11% of individuals with autism. However, only 12 CNVs have been formally associated with autism because the majority are too rare to perform individual association studies.

Objectives: We recently developed models to estimate the effect-size of undocumented CNVs on IQ and sought to extend this approach to autism susceptibility and multiple cognitive domains.

Methods: We identified CNVs in an autism sample from the Simons Simplex Collection and MSSNG, first degree relatives, and individuals from two unselected populations. Statistical models integrating scores of genes encompassed in CNVs were used to explain their effect on autism susceptibility and multiple cognitive domains.

Results: Deletions decrease IQ by 2.6 points per unit of "probability-of-being loss-of-function intolerant" (pLI). The effect of duplications on IQ is three-fold smaller. The autism susceptibility increases when deleting or duplicating any unit of pLI. Results are unchanged after removing de novo and neuropsychiatric CNVs. Once CNV effects on IQ are accounted for, autism susceptibility remains unchanged for duplications but is only borderline significant for deletions. Deletions and duplications differentially affect social communication, behavior, and phonology, whereas both equally affect motor skills. Model estimates for autism risk overlap with previously published observations.

Conclusions: Autism . Our model, trained on CNVs encompassing >4,500 genes, suggests highly polygenic properties of CNVs with respect to autism risk. These models will help interpreting CNVs identified in the clinic.

409.006 *(Poster)* Genetic Diagnostic Yield of Chromosome Microarray Analysis and Trio-Based Whole Exome Sequencing Among Chinese Children with Autism Spectrum Disorder

F. Li*, Xinhua Hospital Affiliated to Shanghai Jiao Tong University School of Medicine, Shanghai, China*

Background: Chromosome microarray analysis (CMA) is recommended as the first-tier diagnostic test for patients with autism spectrum disorder (ASD) by the American College of Medical Genetics and Genomics (ACMG) in 2011. And it has been widely applied to the cohort of patients with ASD in Shanghai Jiao Tong University School of Medicine affiliated Xinhua Hospital in recent years. Furthermore, the advent of decreasing cost combined with superior efficiency of WES enables an additional 10%–15% identification of causes of ASD. Not until recently, the work by Tammimies *et al.* published in *JAMA* showed that the combined diagnostic yield of CMA and WES was higher among children with ASD co-occurring more complex morphological phenotypes. However, WES started relatively late in China.

Objectives: To determine the diagnostic yield of CMA and WES and the impact of the molecular diagnosis on clinical management in China

Methods: In Xinhua cohort of ASD, 968 Chinese children were diagnosed as ASD, more than 80% of whom were tested by CMA in recent years. And 431 unrelated children with ASD were tested by CMA from August 2016 to December 2017 as soon as whole exome sequencing (WES) was applied to patients with ASD in clinical practice in Xinhua Hospital. High resolution CMA was utilized to investigate rare CNVs among 401 patients (including 177 mildly/moderately and 224 severely affected individuals), together with an ancestry-matched control cohort (n = 197).

Results: Diagnostic yield was about 4.2%, with 17 clinically significant CNVs identified in ASD individuals, of which 12 CNVs overlapped with recurrent autism risk loci or genes. Autosomal rare CNV burden analysis showed an overrepresentation of rare loss events in ASD cohort, whereas the rate of rare gain events correlated with the phenotypic severity. Further analysis showed rare losses disrupting genes highly intolerant of loss-of-function variants were enriched in the ASD cohort. Among these highly constrained genes disrupted by rare losses, *RIMS2* is a promising candidate contributing to ASD risk. Given a high suspicion of genetic etiology and/or reproductive planning of the parents, 65 probands with negative findings of copy number variants (CNVs) were further analyzed by trio-based WES. A total of 23 children received a molecular diagnosis: 3.9% (17/431) from CMA and 9.2% (6/65) from WES, corresponding to a total diagnostic yield of 12.7%. Among patients with ASD analyzed by WES, 45 of 65 patients were co-occurring with developmental disability or intellectual delay (DD/ID), while the rest were without DD/ID. Data showed that all of the presumed causative genes (*CHD8*, *AFF2*, *ADNP*, *POGZ*, *SHANK3* and *IL1RAPL1*) highly related to ASD were identified in patients with ASD &DD/ID. Notwithstanding, no disease-related genes and variations were detected among patients without DD/ID

Conclusions: In spite of the negative findings of CMA, WES remains an efficient diagnostic tool for ASD. And children with negative findings of CNVs and co-occurring DD/ID are more likely benefit from the dual testing strategy (CMA combined with WES) in clinical practice, thus contributing to the corresponding change of clinical management and prenatal genetic counselling.

409.007 *(Poster)* Genetic Investigation in Autism Spectrum Disorder CASES

C. Ludvig Goncalves[1]*, J. Lin*[1]*, M. de Aguiar da Costa*[2]*, B. De Moraes*[2]*, L. Do Nascimento Alves*[3]*, G. R. Souza-Lin*[4]*, G. D. Farias*[4]*, P. G. Ambrosio*[5]*, K. Madeira*[5]*, L. B. Wessler*[6] *and E. L. Streck*[6]*, (1)Laboratory of Autism and Neurodevelopmental Research, Universidade do Extremo Sul Catarinense, Criciúma, Brazil, (2)UNIVERSIDADE DO EXTREMO SUL CATARINENSE, CRICIUMA, Brazil, (3)UNIVERSIDADE DO EXTREMO SUL CATARINENSE, CRICIÚMA, Brazil, (4)Universidade do Sul de Santa Catarina, Tubarão, Brazil, (5)Laboratório de Pesquisa Aplicada em Computação e Métodos Quantitativos (LACOM), Universidade do Extremo Sul Catarinense, Criciúma, Brazil, (6)Laboratório de Pesquisa de Doenças Neurometabólicas (Labneuromet), Universidade do Extremo Sul Catarinense, Criciúma, Brazil*

Background: Autism Spectrum Disorder (ASD) is a complex and heterogeneous neurodevelopmental disorder where the etiological diagnosis and genetic counseling have been a challenge to the families, especially in underdeveloped countries. In the last years, with greater knowledge about the genetic and molecular mechanisms it is possible identify the etiological causes in up to 25% of autism cases in genetics centers.

Objectives: Thus, the aim of this study was to investigate genetic patterns in a sample of ASD patients who attended a public care outpatient clinic.

Methods: The study was performed in the neurogenetic research outpatient clinic of the University of Southern Santa Catarina, SC, Brazil, between 2010 and 2018. Data were obtained from data review of medical records. From a total of 417 patients diagnosed with ASD, 145 children were submitted to Polymerase chain reaction (PCR) karyotype for fragile X syndrome and 32 children were qualified for further investigation by for Chromosomal Genomic Hybridization - Array (CGH-Array).

Results: The average age of the patients was 6.8 ± 5.7 years old. PCR karyotype for fragile X syndrome was performed in 145 (34.8%) of the patients, of whom 22 (15%) had some change in karyotype and 3 (2%) in PCR for fragile X. Chromosomal Genomic Hybridization - Array (CGH-Array) were performed in 32 (7.7%) patients, of whom 22 (68.7%) showed some alteration.

Conclusions: The karyotype analysis allows the identification of numerical and structural chromosomal alterations and, even in the face of the development of complex genetic tests, is still considered the main genetic screening test. In our study, karyotype examination and investigation of the fragile X gene was able to generate a response at a rate higher than that found in the literature, which is around 10% and 1.6%, respectively. The CGH array offers greater sensitivity by allowing the identification of submicroscopic genetic variations. In our study, the method was able to detect changes at a rate higher than that found in the literature, which is 9 to 15%. Among the alterations found in the CGH- ray, microdeletion, microduplication and gain of genetic material were more frequent. Five patients presented 47 XY +21, four patients presented 46 XY - 9qh+, two patients presented 46 XY - 16qh+ and more two 46 XY 1qh+, the others presented individual alterations. Despite the small sample size, it can be concluded that genetic evaluation is an important etiological investigation method in ASD cases, being the CGH-Array so far the most effective tool. The search for a cause for autism is fundamental allowing the adequate family genetic counseling and the indication of more specific treatments.

409.008 *(Poster)* Genotype-Phenotype Correlation and Functional Analysis of ASD High-Risk Gene KMT5B

G. Chen[1]*, H. Lin*[2]*, X. Jia*[1]*, H. Wu*[1]*, Y. Quan*[1]*, Q. Zhang*[1]*, Y. Bin*[2]*, X. Kun*[1] *and H. Guo*[1]*, (1)Center for Medical Genetics, School of Life Sciences, Central South University, Changsha, China, (2)Central South University, Changsha, China*

Background: KMT5B is a histone methyltransferase that involves in the regulation of histone H4K20 methylation, gene transcription and DNA repair process. *KMT5B* is highly expressed in embryonic brain, while it gradually decreases and eventually tend to be stable after birth. *KMT5B* knockout mice are embryonic lethal. Recent studies has shown that *KMT5B* variants cause autism spectrum disorder (ASD) and related neurodevelpmental disorders.

Objectives: To determine the phenotype spectrum caused by *KMT5B* mutations and to explore whether and how *KMT5B* involves in neurodevelopment.

Methods: Single-molecule molecular inversion probes methods was used to targeted sequence ASD high-risk genes including KMT5B in a large Chinese ASD cohort. Immunostaining on in vitro cultured mouse neurons and mouse in utero electroporation was used to investigate the phenotypes resulted from disruption of KMT5B.

Results: We identified two transmitted likely gene-disrupting(LGD) mutations (c.978-1G>A and c.1205_1206insGCGTAAAA:p.K403Sfs*11) and one *de novo* missense mutation (c.788T>C:p.L263P) in three ASD patients. To explore genotype–phenotype correlations, we curated and analyzed the new identified and reported clinical information from 20 patients with KMT5B mutations (10 *de novo* LGD, 2 transmitted LGD, *8 de novo* missense). We observed that patients with *KMT5B* pathogenic mutations are mainly associated with ASD, intellectual disability (ID), languages development delay and developmental regression. Knockdown of *KMT5B* expression in cultured primary cortical neurons lead to a decrease in neuronal dendritic complexity and an increase in dendritic spine density. Knockdown of endogenous *KMT5B* expression in the mouse embryonic cerebral cortex by in utero electroporation resulted in decreased proliferation and accelerated migration of neural precursor cells which were rescued by overexpression of human *KMT5B*. While two *de novo* missense mutations (c.788T>C:p.L263P, c.791G>C:p.W264S) located in the SET domain failed rescue the phenotypes indicationg a loss-of-function effect.

Conclusions: These findings suggest that histone methyltransferase KMT5B plays important roles in neurodevelopment. Loss of function mutations in *KMT5B* cause a neurodevelopmental disorder with main features of ASD, ID and language developmental delay.

409.009 *(Poster)* Precision Medicine in Autism Spectrum Disorders: Insights from a Cross-Sectional Study of Clinical Chromosomal Microarray Testing, Outcomes & Medically Actionable Diagnoses

K. Wigby[1,2], *M. M. Clark*[2], *L. Curley*[2], *A. C. Richardson*[3], *I. Reyes*[2], *M. Feddock*[2], *L. Brookman-Frazee*[4,5,6], *C. Hobbs*[2], *J. Friedman*[2,7], *S. F. Kingsmore*[2] *and J. G. Gleeson*[7], *(1)Pediatrics, University of California San Diego, San Diego, CA, (2)Rady Children's Institute for Genomic Medicine, San Diego, CA, (3)Research, Rady Children's Hospital-San Diego, San Diego, CA, (4)Psychiatry, University of California, San Diego, La Jolla, CA, (5)Child and Adolescent Services Research Center, San Diego, CA, (6)Autism Discovery Institute, Rady Children's Hospital-San Diego, San Diego, CA, (7)Neuroscience, University of California San Diego, San Diego, CA*

Background: Chromosomal microarray (CMA) is recommended as a first-tier genetic test in the medical evaluation of autism spectrum disorders (ASD). However, there may be substantial variability in clinical genetic testing practices despite available guidelines. Understanding current genetic testing practices and its associated factors can facilitate the identification of care improvement targets and the utilization of genomic precision medicine.

Objectives: Characterize CMA ordering practices and outcomes among providers treating children with ASD in a regional pediatric healthcare organization (Rady Children's Hospital-San Diego (RCHSD)). Investigate the association of CMA ordering practices with phenotype, clinical services utilization, and demographic factors.

Methods: Data on 1832 children meeting the following criteria were extracted from the electronic medical record: (1) ASD listed on the child's "problem list," a clinician validated list of features and diagnoses; (2) had at least one encounter at RCHSD (including primary and specialty care) between January 2015 and August 2018; (3) born after January 1st 2012. Children were a mean age of 5.5 years (range 2.3-7.3 years), 79% male and 39.4% Latinx. Data on phenotypic features, clinical services, and demographic information were abstracted. Socioeconomic status was estimated by median household income by zip code. Descriptive statistics were used to characterize practice patterns and multi-variate regression analyses were used to examine factors associated with practice patterns.

Results: Follow-up data after ASD diagnosis was available for 77. 1% (median 0.5 years, range 0.1-3.6 years). At least 1 CMA was ordered by a RCHSD affiliated clinician for 387 children (21%); an additional 41 children had a CMA ordered by an outside provider. Higher clinical service use and sub-specialist evaluation was associated with the likelihood of CMA order ($p<0.001$). This included evaluation in multiple departments (OR 1.12, 95% CI 1.05-1.18), neurology consult (OR 13.75, 95% CI 9.93-19.18) or genetics consult (OR 6.75, 95% CI 4.31-10.64). While global developmental delay was also associated ($p=0.01$) with CMA order (OR 1.46, 95% CI 1.09-1.97), 655 of the 899 children with global developmental delay did not have a CMA order. Of the 234 CMA orders with available results, a pathogenic or likely pathogenic copy number variant was reported in 10 (4.3%) including 3 medically actionable findings (47, XXY, 17q11.2 deletion syndrome, 17p11.2 deletion syndrome). There was substantial variability in the use of other diagnostic studies including biochemical testing, other genetic testing, brain imaging and EEG.

Conclusions: The amount and type of clinical services a child received was associated with the likelihood of CMA order. These findings provide direction for care improvement targets. Specifically, implementation strategies aimed to improve access to genetic counseling and testing should include and explicitly target children not being evaluated in neurology or clinical genetics. As many genomic etiologies of ASD would not be detected by CMA, utilization of more comprehensive testing such as whole genome sequencing (WGS) would likely improve diagnostic yield, optimize potential for medically actionable results, and reduce variability of further testing practices.

409.010 *(Poster)* The Family History Interview of Neurodevelopmental and Neuropsychiatric Conditions: Comparing First and Second Degree Family Members of Autistic and Typically Developing Individuals

E. Loth[1], *B. Oakley*[2], *D. V. Crawley*[2], *H. L. Hayward*[2], *J. Ahmad*[2], *T. Charman*[3], *J. K. Buitelaar*[4], *D. G. Murphy*[2] *and E. Simonoff*[5], *(1)Department of Forensic and Neurodevelopmental Sciences, Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, United Kingdom, (2)Forensic and Neurodevelopmental Sciences, Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, United Kingdom, (3)Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, United Kingdom, (4)Karakter Child and Adolescent Psychiatry University Centre, Nijmegen, Netherlands, (5)King's College London, Institute of Psychiatry, Psychology and Neuroscience, London, United Kingdom*

Background: Clinical and genetic evidence suggests that Autism Spectrum Conditions (ASC) frequently co-occur with other neurodevelopmental and neuropsychiatric conditions (NDC/ NPC), both in individuals [1] and families [2, 3]. However, previous studies examining family history in autism either focused solely on autism symptoms, assessed NDC/ NPCs in first-degree relatives only, and/ or only included individuals with established clinical diagnoses. The latter may have resulted in underestimating clinical features in older generations (due to lack of access to diagnosis) or individuals with sub-clinical traits. Moreover, the relationship between familial neurodevelopmental/neuropsychiatric liability and clinical symptom profiles in autistic individuals remains relatively unexplored.

Objectives: We developed a new semi-structured Family History Interview to assess a range of NDC/ NPCs in first and second-degree relatives in the EU-AIMS Longitudinal European Autism Project. We compared 1) frequency of overall NDC/ NPCs, as well as individual disorders between family members of autistic vs TD/ ID probands, and 2) examined the relationship between the proband's and familial severity of NDC/NPC features.

Methods: The FHI was conducted with 349 informants (mother, father, both biological parents, or adult proband) reporting on family members of 219 probands with ASD, and 120 controls (113 with typical development, and 17 with Intellectual Disability without ASD.) Before the interview, informants were sent a short description of nineteen NDC/ NPCs, and were encouraged to discuss them with family members. To begin the interview, a family tree was created to obtain demographic information on family members. For each family member, four entry questions were asked about formal diagnosis, special support at school, referrals to psychiatrist/ psychologist, and treatments. Then, for each condition, 'screening' and, where applicable, 'symptom' questions were asked. Responses were scored as no/ unlikely, possible/ suspected, or probable/ definite. 'Don't know' responses were coded as 'no'. Informants gave confidence ratings about their knowledge of each family member (which was very high in the majority of 1st degree relatives, and moderate-to-very high in 2nd degree relatives).

Results: All first-degree relatives of the ASC group had a significantly higher number of autism and total NDC features than first-degree relatives of the TD/ ID group, and this remained significant once ASD itself was excluded (all $p< 1x\ 10^{-8)}$. First degree-relatives of the ASC group also had significantly more NPC features than those of the TD group, with the highest symptom load in mothers. Brothers had on average the overall highest number of NDC/ NPD features ($p= 2x\ 10^{-16}$). Both maternal grandparents of the ASC group had more NDC (and maternal grandmothers more NPC features) than TD grandparents (p<.001).

Further, in both ASD and control groups, probands' overall number of NDC/ NPC features was significantly related to the total familial NDC/ NPC feature load (ASD: r=.47, p<.001; TD r=.41 <.001) but in the ASD group, this association was higher in females (r=.62, p<.0001) than in males (r=.4, p<.001).

Conclusions: Findings indicate that NDC and NPC features were consistently more elevated in relatives of autistic than non-autistic probands, and familial liability was associated with probands' clinical symptom profile.

409.011 *(Poster)* The Paris Study: A Resource to Identify Subgroups of Individuals with Autism By Integrating Clinical, Brain Imaging and Genetics Data

*F. Cliquet[1], **C. Leblond**[2], A. Mathieu[1], J. Fumey[3], F. Campana[1], S. Malesys[4], A. Vaysse[3], T. Rolland[1], G. Dumas[5], R. Toro[1], N. Traut[1], N. Lemiere[1], A. Lefebvre[1], A. Maruani[6], F. Amsellem[7], A. Beggiato[8], A. Boland[9], J. F. Deleuze[10], M. Leboyer[11], R. Delorme[8,12] and T. Bourgeron[13], (1)Institut Pasteur, Paris, France, (2)Institut PASTEUR, Paris, France, (3)Human genetics and cognitive functions, Institut Pasteur, Paris, France, (4)Neurosciences, Institut Pasteur, Paris, France, (5)Human Genetics and Cognitive Functions Unit, Institut Pasteur, Paris, France, (6)hopital robert debre, paris, FRANCE, (7)Pasteur, Paris, France, (8)Pasteur Institute, Human Genetic and cognitive function, Paris, France, (9)Centre National de Recherche en Génomique Humaine, Evry, France, (10)Labex GENMED, Centre National de Génotypage-IG-CEA, Paris, France, (11)INSERM U955, AP-HP, Université Paris-Est Créteil, Créteil, France, (12)Excellence centre for Autism and Neurodevelopmental disorders, Paris, France, (13)Human Genetics and Cognitive Functions, Institut Pasteur, Paris, France*

Background: Autism is characterized by deficits in social communication and restricted pattern of interest and stereotypies. But beyond this unifying classification, lies a very heterogeneous group of individuals with different clinical symptoms. This heterogeneity hampers the development of targeted clinical trials on homogeneous subgroups of patients sharing similar causes of autism.

Objectives: Our multidisciplinary team made of clinicians, psychologists, neuroscientists and geneticists has collected and analyzed a large dataset of clinical, brain and genetics data on a large group of patients with autism collected through the PARIS cohort. This resource can be used to identify new genetic pathways and mechanisms for autism, but also to develop new clinical classifications.

Methods: The PARIS study consists of a deep-phenotyped cohort of 4,503 individuals including 1,102 probands with autism, 2,745 relatives and 656 controls. For all the patients and most of the first-degree relatives, we have clinical data and DNA. We have SNP data for 2,815 participants (1,085 patients, 1,089 relatives and 641 controls), whole exome/genome sequencing (WES/WGS) data for 1,938 participants (481 patients, 1,018 relatives and 439 controls) and methylation data for 316 participants (72 patients, 148 relatives and 96 controls). At the brain level, we have collected Magnetic Resonance Imaging (MRI) and Electroencephalographic (EEG) data on more than 800 individuals. MRI data are acquired at 1-3T, and include structural T1W data, functional MRI data, and diffusion weighted MRI. Our EEG protocol includes resting states (eyes opened, eyes closed), classical tasks for induced (e.g. action execution and observation) and evoked (e.g. MisMatch Negativity) activity, but also a new paradigm of real-time social interaction with a virtual partner.

Results: Using the resource, we characterized the genotype-phenotype relationship of autism-associated genes such as *SHANK1*, *SHANK2*, *SHANK3*, *CNTN5*, *CNTN6* and others that will be presented. We also studied multiplex families with at least two members with autism and showed that patients can share risk factors, but also carry different risk variants suggesting a multiple hits inheritance in some families. Finally, the contribution of the common variants in the susceptibility is estimated by computing the polygenic scores of the patients, their relatives and controls.

Conclusions: There is a need for research on complex conditions such as autism to have access to large dataset with deep clinical, brain and genetic profiles. The effort of the PARIS study is also aligned with other initiatives such as the European EU-AIMS/AIMS2-trials project, the Simons Simplex Collection, the SPARK and the MSSNG projects. These collaborative initiatives must be extended to additional projects focused on epilepsy and intellectual disability in order to identify the shared and specific factors associated with these complex conditions.

409.012 *(Poster)* Whole Exome Sequencing Identifies Novel De Novo Variants Related with NF-Kb Signaling Pathway in Autism Spectrum Disorders

H. Yoo[1], *N. Kim*[2,3], *K. H. Kim*[2,4], *W. J. Lim*[4,5], *J. Kim*[6] *and S. A. Kim*[7], *(1)Seoul National University Bundang Hospital, Seongnam, Korea, Republic of (South), (2)Genome Editing Research Center, Korea Research Institute of Bioscience and Biotechnology, Deajon, Korea, Republic of (South), (3)Bioinformatics, KRIBB School of Bioscience, Korea University of Science and Technology, Deajon, Korea, Republic of (South), (4)Bioinformatics, KRIBB School of Bioscience, Korea University of Science and Technology, Daejon, Korea, Republic of (South), (5)Genome Editing Research Center, Korea Research Institute of Bioscience and Biotechnology, Daejon, Korea, Republic of (South), (6)Clinical Sciences, University of Texas Southwestern Medical Center, Dallas, TX, (7)Pharmacology, Eulji University College of Medicine, Daejon, Korea, Republic of (South)*

Background: Autism spectrum disorder (ASD) is highly genetically heritable condition and it is considered to be caused by a combination of environmental and genetic factors such as *de novo* and inherited variants as well as rare or common variants in hundreds of related genes. Previous genome-wide association studies have identified some susceptibility genes, but many genes associated to ASD is still undiscovered.

Objectives: The objectives of this study is to examine rare *de novo* variants to identify risk genetic factors of ASD using whole exome sequencing (WES), functional characterization and genetic network analyses of identified variants in Korean family data .

Methods: Subjects with ASD, their biological parents and unaffected siblings were recruited. The clinical best estimate diagnosis of ASD was made for probands and siblings by board-certified child psychiatrists according to the Diagnostic and Statistical Manual of Mental Disorders (DSM-5) by using comprehensive diagnostic instruments including Korean versions of Autism Diagnostic Interview-Revised and Autism Diagnostic Observation Schedule. For variants discovery and filtering, GATK best practice was used for bioinformatics analysis and was mapped and annotated to GRCh37 (hg19) reference genome assembly using dbSNP 137/138 build databases. For *in silico* prediction, we used dbSNP, 1000 genomes, ESP6500, ExAc, GME, HRCR, and Kaviar. The genetic network of the identified *de novo* variants were constructed by closely interacting gene neighbors using “Variant effect” core analysis in Ingenuity Pathway Analysis software (IPA, Qiagen).

Results: A total 151 individuals from 51 families were participated in this study (probands' mean age 70.16 [SD 27.35] months, 4 females, IQ mean 56.74 [SD 22.35). We identified *de novo* variants in 36 *de novo* variants (28 missense, 1 nonsense, 2 silent, 1 5’UTR, 1 exonic, 1 intronic, and 2 deletion) as potential significant contributors of ASD. In genetic network analyses, we identified 6 networks having functional relationship. Among the interactions between the *de novo* variants in this study, NF-κB signaling-related genes, which have strong relation to neurological functions, were commonly observed at 2 networks (ANKRD27, TMEM8A and TTC21A genes and ADCY7, ATXN1, IWS1, KCTD9, MT-ND2, NFKB1 and PPP1R16B genes) in IPA assay.

Conclusions: We identified novel variants that might underlie the genetic cause of ASD using WES and genetic network analyses on Korean families with ASD. The functional characterization of novel variants provides insight that might contribute to complex neurodevelopmental disorders, particularly related to functional genetic network including NF-κB signaling pathway.

Clinical Trial Design

POSTER SESSION — **CLINICAL TRIAL DESIGN**
410 - Clinical trial design Posters

410.001 *(Poster)* Multicentre, Randomized Controlled Trial of the Frankfurt Early Intervention Program for Toddlers and Preschool Children with Autism Spectrum Disorder – a-Ffip

Z. Kim[1], *J. Kitzerow*[2], *K. Teufel*[1] *and C. M. Freitag*[3], *(1)Department of Child and Adolescent Psychiatry, Psychosomatics and Psychotherapy, University Hospital Frankfurt, Goethe University, Frankfurt am Main, Germany, (2)Department of Child and Adolescent Psychiatry, Psychosomatics and Psychotherapy, Autism Research and, Frankfurt am Main, Germany, (3)Autism Research and Intervention Center of Excellence Frankfurt, University Hospital Frankfurt, Frankfurt am Main, Germany*

Background: Naturalistic developmental behavioral interventions (NDBI) have been shown to improve autism specific symptoms in toddlers and preschool aged children with ASD. Studies on early and longitudinal development in children with ASD point to many impaired core domains, which need to be targeted by complex, individualized NDBI approaches focusing on the child’s individual strengths and weaknesses. Cost-effective interventions which can easily be implemented in the local health care / social welfare system are necessary. A-FFIP is such a complex, low-intensity, manualized approach. It has shown medium effects in a small clinically controlled study on autism symptom improvement measured by the ADOS severity score after one year (Kitzerow, J., Teufel, K., Jensen, K., Wilker, C., & Freitag, C. M., 2019). Therefore, an adequately powered, randomized-controlled, multi-centre efficacy study is currently performed. Here, we present essentials of the study design of the multicentre, randomized-controlled A-FFIP trial.

Objectives: (1)To establish one-year efficacy of the low intensity, manualized early intervention program A-FFIP in toddlers and preschool children aged 2;0 to 5;6 years old with ASD compared to early intervention as usual (EIAU). It is hypothesized that A-FFIP will result in improved autism specific symptoms compared to EIAU; (2) To assess A-FFIP effects on the child’s cognition, language and behavior; on parent’s competences, anxiety, depression and stress, and family quality of life; (3) To study the child’s and parents’ characteristics as predictors and moderators of outcome; (4) To explore treatment mechanisms (mediators) related to parents’ and child’s competences.

Methods: The trial is designed as a confirmatory phase III, prospective, randomized, multi-centre, controlled, parallel-group study with two treatment groups (134 subjects, i.e. 67 subjects per treatment group) and six measurement time points. Study participants are recruited at four study centres in Germany. Experimental intervention is the manualized Frankfurt Early Intervention program for children with Autism Spectrum Disorder (A-FFIP; Teufel, K., Wilker, C., Valerian, J., & Freitag, C. M., 2017). Two hours of intervention/week with two therapists working with the child are provided. Control intervention is early intervention as usual (EIAU). For EIAU, individual or group therapy intensity of 1-10 hours/week as well as waiting time prior to intervention onset is allowed.

Results: The data collection is currently in process (descriptive data of the current sample will be presented at the conference). The primary endpoint is the absolute change in the total score of the Brief Observation of Social Communication Change (BOSCC-AT) between baseline and 12 months after the first intervention session. The secondary endpoints include measures on the child's and parent's characteristics and competences. See also figure 2.

Conclusions: If efficacy of A-FFIP is established, the current study will change clinical practice strongly towards implementation of evidence based methods in ASD early intervention in Germany. Additional positive effects by the trial will be: (1) Improvement of care including diagnosis as well as treatment in underserved areas in Germany; (2) Alerting many different professionals working in early intervention to effective methods; (3) Establishing an effective method and setting of training professionals to high treatment fidelity of evidence based early intervention.

410.002 *(Poster)* Preliminary Findings of the Pre-Pilot of the World Health Organization Caregivers Skills Training in Hong Kong

H. Fok[1]*, P. Wong*[2] *and J. S. Lau*[1]*, (1)Faculty of Social Sciences, The University of Hong Kong, Hong Kong SAR, Hong Kong, (2)University of Hong Kong, Pokfulam, Hong Kong*

Background: It was estimated that the incidence of autism spectrum disorders was 5.49 per 10,000 and the prevalence rate was 16.1 per 10,000 for children less than 15 years old in Hong Kong[1]. The figure is likely an underestimation because a rigorous epidemiological study on children and youth mental disorders is yet-to-be conducted in Hong Kong to detect the undiagnosed individuals[2]. The Jockey Club Autism Support Network (JC A-Connect) and The University of Hong Kong sought and collated the understandings and experiences of caregivers and experts. Consequently, the adaptation and localisation of the World Health Organization Caregivers Skills Training (WHO-CST) to the Hong Kong context took place in 2018.

Objectives: This study aimed to examine the perceived benefits, feasibility, and acceptability of the WHO-CST in Hong Kong adopting the implementation science approach[3].

Methods: A sequential mixed-methods design was used. Caregivers of children with ASD or developmental delays were invited to participate in the pre-pilot stage of the study. Their pre-post changes in mental health and confidence in caregiving were measured. They also joined the post-intervention focus group interviews. Repeated measure analyses and pattern coding analysis[4] were conducted.

Results: 19 female caregivers of 15 male and 4 female children completed the pre-post questionnaires (Table 1). The quantitative analyses showed a statistically significant positive trend in changes of mental health ($F(2, 22) = 3.92$, $p < .05$), but not confidence in caregiving ($F(2, 20) = .054$). Four patterns emerged from the qualitative data: 1) *Perceived benefits*. The participants stated that their parent-child relationship and emotional well-being improved and the caregivers' conflict within the families and challenging behaviours in children reduced; 2) *Useful elements*. Participants felt that four caregiving skills, i.e., 'offering choices', 'problem-solving and self-care', 'mood thermometer', and' engagement with children through play' were useful; 3) *Cultural barrier in implementation*. Some participants mentioned that although home-visitation was perceived as a hesitation for participation due to the cultural belief that "family shames must not be spread abroad" at the beginning, after being visited, they regarded home-visits as the uniqueness of the WHO-CST programme because it provides tailored-made support to them; and 4) *Major challenges and proposed solutions*. The participants mentioned that competing daily activities for both the employed and housewives was a major challenge for them although almost all of them appreciated very much of the programme. Another challenge was related to the influences of other caregivers in the families to fully implement the learned skills at homes. Fathers or grandparents of the children who did not understand nor appreciate the rationale of engaging and teaching children through play could negatively impact the efficacies of the strategies learned. Hence, some participants suggested that the arrangements for child-care and make-up classes may help to tackle the former challenge. Blended teaching and learning, i.e., including e-learning materials, can be used to educate caregivers in the families who cannot physically attend the WHO-CST.

Conclusions: The preliminary findings provide important implementation process evaluation data for our large pilot study of the locally adapted WHO-CST in Hong Kong.

410.003 *(Poster)* SPARK Research Match: A National Registry for Clinical Trial Recruitment

J. Toroney[1]*, J. K. Law*[1,2]*, C. W. Lehman*[3]*, B. Vernoia*[3]*, S. Xiao*[3]*, P. Feliciano*[4] *and W. K. Chung*[3,5]*, (1)Kennedy Krieger Institute, Baltimore, MD, (2)Johns Hopkins School of Medicine, Baltimore, MD, (3)Simons Foundation, New York, NY, (4)SFARI, Simons Foundation, New York, NY, (5)Department of Pediatrics, Columbia University, New York, NY*

Background:

The Simons Foundation Powering Autism Research for Knowledge (SPARK) is a collaborative, online study that enrolls individuals with a professional diagnosis of autism and their family members into an autism research cohort. All participants consent to be contacted about future autism research studies. To date over 200,000 participants, including over 85,000 with ASD, have enrolled. A core feature of SPARK, called research match (RM), facilitates study recruitment for researchers – a major challenge in clinical trials. RM services are available to researchers at no cost. In return, researchers agree to share their study data with SPARK to strengthen its core dataset.

Objectives: 1) Describe the research match process for clinical trials

2) Report recruitment metrics for research match-assisted studies

Methods: Access to the SPARK cohort is available to approved investigators. Applications are submitted online (https://base.sfari.org/) and reviewed by the SPARK participant access committee. Studies are approved to recruit for one year with the possibility of renewal. Eligible participants are identified based on study inclusion/exclusion criteria and geographic location. Participants are notified via email and actively indicate "interested" (or "not interested") in the study. Interested participants provide authorization for SPARK to share contact information with the study team. Investigators must agree to bi-directional data sharing and are required to track participant enrollment. Participant and researcher feedback are captured upon study completion.

Results: As of October 2019, SPARK approved 10 applications for interventional studies registered on ClinicalTrials.gov. For 8 recruiting studies (5 completed, 3 active), the number of potentially eligible SPARK participants ranged from 56 to 1,051 (median=214). Participants indicating initial interest in each study ranged from 17 to 104, with per study response rates between 8%-37%. Study enrollment ranged from 0 to 21 participants, with one study reaching 42% of their recruitment goal. Additionally, feedback data from researchers and participants will be shared.

Conclusions: SPARK research match is an effective platform for supporting clinical trial recruitment.

410.004 *(Poster)* Using Naturalistic Interactions in Clinical Trial Design for Minimally Verbal Autism: Lessons from a Motor Communication Skills Intervention

A. McKinney[1], *K. Hotson*[1], *E. J. Weisblatt*[2,3], *J. Foster*[4], *C. M. Dias*[2], *S. Murphy*[5], *S. Villar*[6], *D. ben Shalom*[7] *and M. Belmonte*[8], *(1)Division of Psychology, Nottingham Trent University, Nottingham, United Kingdom, (2)Peterborough Neurodevelopmental Service, Cambridgeshire and Peterborough NHS Foundation Trust, Peterborough, United Kingdom, (3)Department of Psychology, University of Cambridge, Cambridge, United Kingdom, (4)Institute of Psychiatry, Psychology, and Neuroscience, King's College London, London, United Kingdom, (5)Institute for Health Research, University of Bedfordshire, Luton, United Kingdom, (6)MRC Biostatistics Unit, University of Cambridge, Cambridge, United Kingdom, (7)Department of Foreign Literatures and Linguistics, Ben-Gurion University, Beer Sheva, Israel, (8)Com DEALL Trust, Bangalore, India*

Background: Assessment of candidate therapies for severe autism poses challenges including autism's heterogenous presentation, suitability and acceptability of outcome measures, and barriers to recruitment and retention. We are addressing these obstacles in a randomised controlled trial (ISRCTN 12808402) of Point OutWords (http://PointOutWords.online/), a caregiver-delivered, iPad-assisted intervention targeting motor and cognitive skills prerequisite to non-spoken communication in nonverbal and minimally verbal children with autism, a group largely excluded from research.

Objectives: Primary aims of this feasibility trial are to 1) establish recruitment/completion rates, 2) assess whether quantitative measures at baseline match clinicians' decisions on inclusion criteria, and 3) assay suitability of outcome measures.

Methods: Our parallel-groups randomised controlled design aims to recruit 46 children aged 3–15 years, diagnosed with autism and speaking fewer than 100 words functionally. Clinicians are asked to recruit children with motor impairment and greater receptive than expressive language. The intervention group uses Point OutWords half an hour 5 times a week over 8 weeks. Controls have equal caregiver/iPad contact time using other iPad apps. Communication, motor, and daily living skills are tested at baseline and post-intervention; assessments include the Mullen Scales of Early Learning (MSEL), Vineland Adaptive Behavior Scales (VABS-2), Verbal Motor Production Assessment for Children (VMPAC) British Picture Vocabulary Scale (BPVS), and measures of movement efficiency during interactions with the iPad itself. Parents keep diaries and take part in focus groups.

Results: Of 300 children with an autism diagnosis accessing the Peterborough Children's Neurodevelopmental Service, 55 (18%) were deemed by clinicians to meet inclusion criteria, 45 of whom were contactable, 22 of whom (49%) were recruited. 18/22 children completed the MSEL whereas only 13/22 completed the BPVS. 8/13 children fully tested thus far had significantly better VABS-2 Receptive than Expressive language, and these same children showed superior Gross to Fine motor skills ($r = 0.65$, $p < 0.016$, Figure 1). Age-equivalent MSEL scores showed an uneven profile, consistent at a group level with VABS-2, in which Fine Motor and Receptive Language exceeded Expressive Language age equivalents (Figure 2, $F(2, 24)=8.77$, $p =0.0013$, *post hoc* FM-EL p=0.0149, RL-EL p=0.0086). 11/13 children had severe deficits in VMPAC Global Motor Control, Focal Oromotor Control, and Sequencing. Consistent with these measures, baseline variance of speed and direction of finger movements across the iPad touchscreen was heightened in contrast to a typically developing reference sample.

Conclusions: This study has successfully recruited a somewhat more homogeneous, motor-impaired population in whom receptive outpaces expressive language. Initial findings demonstrate feasibility of recruiting and testing these severely affected autistic children using a combination of parent reports, observational assessments of parent and child play, play-based assessments (*e.g.,* MSEL), and motor interactions with the iPad itself, all of which glean information from naturalistic, ecologically valid interactions rather than real-time responses to instructions (*e.g.,* BPVS). Some parents expressed surprise at skills manifested, but also observed the high burden of so many tests. Insights from this trial will refine ecologically valid assessment procedures not only for the current motor skills intervention but also in autism clinical trials more broadly.

Clinical Trial Endpoints

ORAL SESSION — CLINICAL TRIAL ENDPOINTS
306 - Social and Non-Social Behaviours in Assessment and Treatment

306.001 *(Oral)* Performance of Clinical Scales Measuring Restricted and Repetitive Behaviors (RRBs) in a 12-Week Observational Study in Individuals with ASD

J. F. Hipp[1], *T. Ciobanu*[1], *P. Schoenenberger*[1], *E. Eule*[1], *D. Volz*[2], *F. Bolognani*[3], *L. Murtagh*[1] *and D. Umbricht*[1], *(1)Neuroscience and Rare Diseases (NRD), Roche Pharma Research and Early Development, Roche Innovation Center, Basel, Switzerland, (2)Department of Biometrics, F. Hoffmann-La Roche AG, Basel, Switzerland, (3)VectivBio Holding AG, Basel, Switzerland, Basel, Switzerland*

Background: Restricted and repetitive behaviors (RRBs), including stereotyped or repetitive motor movements, insistence on sameness, and highly restricted interests, are one of the two core symptom domains in autism spectrum disorder (ASD). There is a high need for accurate and reliable assessments of RRBs for the use in clinical trials. Several clinical scales measure the frequency or severity of RRB symptoms including the Repetitive Behavior Scale–Revised (RBS-R), Repetitive Behavior Questionnaire (RBQ-2/2A) and Children/Adult Routine Inventories (CRI-R/ARI). However, there is no consensus in the field on which ones of these scales, if any, would be appropriate for the use in clinical trials, and they have not been compared head to head to date.

Objectives: To compare the psychometric properties, stability, and ability to separate individuals with and without ASD of different RRB scales over a 12-week period.

Methods: We conducted an observational multi-center study (ongoing). Individuals with ASD (n = 68, target: 90) stratified into three age groups (children: 5-12, adolescents: 13 – 17, adults: ≥18) and two levels of functioning (IQ ≥ 50 & < 70, IQ ≥ 70) completed a battery of assessments (including RRB scales RBS-R, RBQ-2/2A and CRI-R/ARI) at three clinic visits (baseline, week 2, week 12). The main inclusion criteria were a confirmed ADOS-2 diagnosis of ASD and a CYBOCS-ASD score of ≥12 assessed at the screening visit. We tested the stability of scales over the 12 weeks using ANOVA/ANCOVA. We compared RRB scores from the study sample (ASD) to historical scores from typically developing (TD) and individuals with ASD from different data sources (EU-AIMS, NDAR, SSC, Roche studies).

Results: Psychometric properties (internal consistency, test-retest reliability) and convergent/divergent validity were good across RRB scales. RRB severity in the study sample was higher compared to values for historical ASD samples likely reflecting the effectiveness of the enrolment criterion (CYBOCS-ASD score of ≥12). For instance, RBS-R score was 0.54 higher (standardized mean score) as compared to the score of reference data sets, and clearly separated from typical developing controls (1.43 standard deviations). Surprisingly, the caregiver- and self-reported forms of CRI-R/ARI and RBQ-2/RBQ-2A scales were not correlated raising important questions regarding the use of self-reported vs. caregiver-reported scales in clinical trials. The stability analyses revealed that over the whole study population mean scores were fairly stable over the 12-week observation period, but the variance of the score changes was larger over the entire 12-week period compared to the two weeks from baseline to week 2 (i.e. test-retest) suggesting that the score changes may reflect true changes in symptom severity.

Conclusions: Our results show comparable psychometrics across RRB scales and reveal their sensitivity to clinical factors. Scales are sensitive to enrolment criteria, differentiate between ASD and TD participants, and pick up spontaneous fluctuations in RRB symptoms over the course of a 3-month observational period.

306.002 *(Oral)* Increases in Parent Responsiveness Mediate the Relationship between Treatment Group and Improvements in Social Communication Symptoms.

P. H. Davis[1], *H. Elsayed*[2], *E. Crais*[3], *L. R. Watson*[3] *and* ***R. Grzadzinski***[4], *(1)University of North Carolina, Chapel Hill, NC, (2)Allied Health sciences, University of North Carolina, Chapel Hill, NC, (3)Department of Allied Health Sciences, University of North Carolina at Chapel Hill, Chapel Hill, NC, (4)Carolina Institute for Developmental Disabilities, University of North Carolina, Chapel Hill, NC*

Background: Early interventions for children at elevated likelihood of developing Autism Spectrum Disorder (EL-ASD) are often delivered through parent-mediated models. An area of current exploration is whether changes in parent behaviors, e.g. parent responsiveness, are a mechanism through which to improve and track child behaviors in these interventions. In addition, research highlights the association between parent responsiveness and the development of toddler social-communicative skills (Watson et al., 2017; Yoder et al., 2015), highlighting that this relationship needs further exploration.

Objectives: This study examines the mediating effect of changes in parent verbal responsiveness (PVR) between treatment group and changes in social communication behaviors. We hypothesize that changes in PVR will significantly mediate the relationship between treatment group and changes in child social communication behaviors (SC) such that increases in PVR will be associated with larger improvements in child SC in the treatment group compared to the control group.

Methods: This study used extant data from toddlers at EL-ASD who participated in a randomized controlled trial of a parent-mediated early intervention (see Watson et al., 2017). Children were seen for assessments at age 14 months (Time 1; n=87; 60 males) and 22 months (Time 2; n=83). Children were randomly assigned to either a treatment group (Adapted Responsive Teaching; ART; n=45) or Referral to Early Intervention and Monitoring (REIM; n=42); referred to as Group in analyses. The Brief Observation of Social Communication Change (BOSCC; Grzadzinski et al., 2016), a treatment response measure that quantifies changes in ASD symptoms, was applied to parent-child free-play videos using standard coding procedures at Times 1 and 2 to examine changes in child SC behaviors. These videos were also coded using the Parent Verbal Responsiveness (PVR) coding scheme adapted from Yoder et al. (2015). Changes in BOSCC (BOSCC-SC) and PVR (PVR Change) from Time 1 to Time 2 were calculated. Mediation analyses were conducted, controlling for PVR at Time 1 and BOSCC SC at Time 1, using Process v3.1 (http://www.afhayes.com) in SPSS.

Results: To date, videos for 74 dyads have been coded using the BOSCC. Analyses revealed that the relationship between Group and changes in BOSCC-SC was significantly mediated by PVR Change, such that improvements in PVR (increases) were associated with improvements in BOSCC-SC (decreases) for the ART group but not the REIM group. See Figure 1. Coding on all available dyads will be completed and the analyses will be re-run prior to the conference.

Conclusions: These results provide evidence that parent responsiveness may be a mechanism through which to improve and monitor child behaviors during early intervention. Understanding whether there is an association between changes observed in the child and changes observed in the parent has implications for the identification of treatment mechanisms and may lead to novel intervention programs for young children at risk for ASD.

306.003 *(Oral)* Toward a Fully Automated Computer Vision Approach for Measuring Facial Affect in ASD

C. J. Zampella[1]*, L. Cordero*[1]*, E. F. Ferguson*[2]*, M. L. Cola*[1]*, V. Petrulla*[1]*, A. Riiff*[1]*, J. Pandey*[1]*, R. T. Schultz*[1]*, J. Parish-Morris*[1] *and J. D. Herrington*[3]*, (1)Center for Autism Research, Children's Hospital of Philadelphia, Philadelphia, PA, (2)University of California Santa Barbara, Santa Barbara, CA, (3)Perelman School of Medicine, University of Pennsylvania, Philadelphia, PA*

Background: Atypical emotional expressiveness has long been associated with ASD, but there is increasing evidence that facial expression differences in ASD are nuanced and context-dependent. For example, people with ASD may express emotions more frequently and intensely in solitary (versus social) contexts. Automated facial analysis using computer vision has vast potential for elucidating individual and situational variability in facial affect by providing efficient, fine-grained, and objective measurement of naturally-occurring expressions.

Objectives: 1) Evaluate whether individuals with ASD produce context-appropriate positive affect, and 2) validate a fully automated computer vision approach for measuring facial affect in ASD and neurotypical samples.

Methods: 40 youth and young adults with ASD (mean age=13.2, 13 female) and 41 typically developing controls (TDC; mean age=12.2, 17 female) were recorded during a computerized battery designed to elicit language and facial expressions. ASD and TDC groups were matched on age, sex, and general intelligence (ASD/TDC FSIQ=104/107). The battery included two humorous videos lasting 23 and 28 seconds, respectively, to elicit spontaneous positive affect. Camera footage of participants' faces during each video was extracted and analyzed using the open-source program OpenFace and an in-house facial analysis software suite. Each segment was also manually coded for the presence or absence of smiling. Key dependent variables included frequency of smiling in each group (manually coded), and intensity of facial activity corresponding to smiling (measured through automated computer digitization of Action Units 6 and 12 of the Facial Action Coding System, based on machine learning algorithms). Summary statistics of smiling intensity included frame-by-frame averages of Action Units 6 and 12, and area under the curve (AOC) as a function of time.

Results: The majority of participants smiled at the videos, with no overall differences in smiling rates between ASD and TDC groups (74% of the ASD sample smiled, 77% TDC sample, χ^2=.18, p=.67). Across diagnostic groups, participants who were coded as having smiled showed significantly higher AOC values than those who did not (Mann-Whitney U=1479, p<.001) – a validation of our computer vision technique. See the Figure for time series plots of smiling magnitude in participants who smiled versus those who did not, separately by diagnostic group and video. No diagnostic group differences in AOC values (i.e., smiling intensity) were identified for either video, though one video approached trend level (U=361, p=.48 and U=389, p=.10 [ASD>TDC]; see Figure).

Conclusions: Participants with ASD and neurotypical peers demonstrated similar frequency and intensity of smiling in response to humorous videos. These results join other literature suggesting that emotional expression may be less atypical in ASD when the measurement context carries low social demands. This study expands on prior research by providing validation for an automated facial analysis system, capable of measuring spontaneous facial affect with higher spatial and temporal granularity than human annotation. Accordingly, further analyses using graph theory to study the *quality* of expressions are underway in this dataset, and will incorporate more detailed information about how affect unfolds across multiple components of the face (i.e., additional action units) and over time.

306.004 *(Oral)* What Lies Beyond the Autism Diagnosis? a Transdiagnostic Approach to Modeling Distinct Autism Symptom Dimensions in Relation to Comorbid Psychopathology

C. G. McDonnell[1]*, E. A. DeLucia*[1]*, E. Anagnostou*[2]*, E. Kelley*[3]*, S. Georgiades*[4]*, R. Nicolson*[5]*, X. Liu*[6] *and R. A. Stevenson*[7]*, (1)Department of Psychology, Virginia Polytechnic Institute and State University, Blacksburg, VA, (2)Holland Bloorview Kids Rehabilitation Hospital, Toronto, ON, Canada, (3)Queen's University, Kingston, ON, Canada, (4)McMaster University, Hamilton, ON, Canada, (5)University of Western Ontario, London, ON, Canada, (6)Genomics, Queen's Genomics Lab at Ongwanada, Kingston, ON, Canada, (7)Western University, London, ON, Canada*

Background: Autism spectrum disorder (ASD) is a heterogeneous disorder comprised of a range of social difficulties and restricted, repetitive behaviors (RRBs). Despite the diverse symptom content defining ASD, overall diagnostic classifications and composite total scores are most often used for evaluating how ASD relates to other types of psychopathology. Much less is known regarding how *distinct* ASD symptom dimensions relate to internalizing and externalizing behavioral problems, leaving a significant gap in our understanding of which aspects of ASD most strongly relate to comorbidity that impedes our ability to support the mental health of autistic individuals. Moreover, little research has considered whether patterns of comorbidity are similar in ASD relative to other disorders. Comparative cross-disorder research is necessary to advance comorbidity research by examining whether the same comorbidity patterns are observed in ASD and other related disorder contexts, such as Attention Deficit/Hyperactivity Disorder (ADHD).

Objectives: The first objective was to examine the structure of autism symptoms in a large, province-wide dataset (N = 1,359) of youth with ASD or ADHD, and to evaluate whether the emergent structure was similar across groups. The second objective was to examine relations among emergent autism symptom dimensions with a broad range of internalizing (e.g., depression, anxiety) and externalizing (e.g., attention problems, oppositionality) psychopathology factors. We were particularly interested in the extent to which autism symptom dimensions explained additional variance in comorbid psychopathology beyond diagnostic group status (ASD versus ADHD).

Methods: Participants included 1,359 youth ages 6-18 (ASD group n=758, 20% female; ADHD group n=601, 30% female) who participated in the Province of Ontario Neurodevelopmental Disorders (POND) Network. Caregivers reported on autism symptoms using the Social Communication Questionnaire (SCQ) and broader types of psychopathology using the Child Behavior Checklist (CBCL), including affective, anxiety, somatic, ADHD, ODD, and conduct problems.

Results: To model symptom dimensions, item-level factor analyses of the SCQ were conducted across groups. Results demonstrated that a three-factor solution comprising Social Problems, Repetitive Verbal and Motor Behavior, and Gesture domains provided the best fit to the data and was highly congruent across ASD and ADHD. Second, correlation analyses between primary study variables demonstrated differential patterns of associations between autism dimensions and psychopathology (see Table 1). Third, regression analyses were used to examine how these emergent symptom dimensions related to psychopathology (see Table 2). Across both disorders, Repetitive Behavior was transdiagnostically associated with all CBCL scales, whereas Socialization was uniquely associated with Affective Problems. Moreover, autism dimensions explained significantly (between two and eight times) more variance in psychopathology outcomes than diagnosis.

Conclusions: Overall, results demonstrate that autism symptoms can be broken down into discrete dimensions broadly tapping the social and RRB domains that differentially relate to comorbid psychopathology. These autism symptom dimensions showed robust incremental predictive power beyond diagnostic group status in predicting comorbidity, such that RRBs were transdiagnostically associated with all psychopathology outcomes. Implications for transdiagnostic ASD research and clinical work will be discussed.

POSTER SESSION — CLINICAL TRIAL ENDPOINTS
411 - Clinical trial endpoints Posters

411.001 *(Poster)* Orbiting - an Observational Study to Evaluate and Explore Scales for Restricted and Repetitive Behaviors and Digital Biomarkers in Children, Adolescents and Adults with Autism Spectrum Disorder (ASD)

*J. F. Hipp[1], **E. Eule**[1], P. Schoenenberger[1], T. Ciobanu[1], T. Kilchenmann[2], D. Nobbs[2], M. Lindemann[2], M. del Valle Rubido[1], D. Volz[3], F. Bolognani[4], L. Murtagh[1] and D. Umbricht[1], (1)Neuroscience and Rare Diseases (NRD), Roche Pharma Research and Early Development, Roche Innovation Center, Basel, Switzerland, (2)Roche Pharma Research and Early Development. Roche Innovation Center Basel, Hoffmann-La Roche, Basel, Switzerland, (3)Department of Biometrics, F. Hoffmann-La Roche AG, Basel, Switzerland, (4)VectivBio Holding AG, Basel, Switzerland, Basel, Switzerland*

Background: Restricted and repetitive behaviors (RRBs) are core features of ASD according to DSM-5. RRBs constitute a broad range of behaviors, including simple motor stereotypies as well as more complex ritualized and rigid behaviors, compulsions, and restricted interests that vary in frequency, intensity, and duration. A number of clinical scales to measure RRBs exist, however, they have not been designed to measure change and their utility for use in clinical trials remains largely unknown (Scahill et al 2015). Furthermore, some scales are available only for pediatrics and others only for adults. Generally, availability of caregiver-reported scales is very limited for adults. There is a need for a systematic investigation using longitudinal data to compare different RRB scales across age and IQ in ASD.

Objectives: oRBiting (ClinicalTrials.gov Identifier: NCT03611075) is a non-drug observational study that seeks to characterize different scales to measure RRBs across age and IQ in ASD longitudinally and in addition to explore the use of digital biomarkers to complement traditional clinical assessment and scales. The results from this study will inform the planning and setup of future drug interventional studies in programs aimed at treating RRBs in ASD.

Methods: At screening consenting participants were assessed for the following key eligibility criteria: ASD diagnosis (DSM-5 criteria) confirmed by ADOS-2, ABIQ (SB5) ≥ 50, CGI-S ≥ 4, CYBOCS-ASD total score ≥ 12, 5 to 45 years, males and females. The study (ongoing) aims to enroll 90 participants with ASD and 45 typical developing controls (TD) grouped into nine cohorts with ~15 participants each based on age (children 5-12 years; adolescents 13-17 years, and adults 18-45 years), diagnosis (ASD, TD) and ABIQ for participants with ASD (SB5 ≥ 70 versus participants with 50 ≤ SB5 < 70). Eligible participants visit the clinic at baseline, week 2 and week 12 and complete a battery of clinical outcome assessments testing RRB symptoms: Children's Yale-Brown Obsessive Compulsive Scale for ASD (CYBOCS-ASD), Montefiori Einstein Rigidity Scale Revised (MERS-R), Repetitive Behavior Scale Revised (RBS-R), Repetitive Behavior Questionaire-2 (RBQ-2 and RBQ-2A, Routine inventories (CRI-R and ARI). Additional clinical scales include: Global Clinical Impressions, Vineland^{TM}-II (survey), Executive functioning (BRIEF/A), Short Sensory Profile (SSP), Sleep questionnaires (CSQI/PTQI), Anxiety questionnaires (PRAS-ASD/HAM-A/BAI), Quality of Life (PedsQL) and Reading the Mind in the Eyes Test (RMET). For adult and adolescent participants we collect both the self-reported and caregiver-reported scale versions if available (e.g. RBQ-2A and RBQ-2, ARI and CRI-R) to enable direct comparison of the respective scales versions in same individuals. Furthermore, digital biomarker data are collected from all participants in their homes using wearable devices.

Results: In early November 2019 enrollment into this study was ongoing (N=119/135 enrolled) and is planned to be completed end of December 2019.

Conclusions: This poster details the trial design and conduct. Initial study results are presented on companion posters.

411.002 *(Poster)* Preliminary Validation of the Behavioral Inflexibility Scale-Clinical Interview

B. A. Boyd[1]*, J. W. Bodfish*[2]*, C. Harrop*[3] *and L. Lecavalier*[4]*, (1)Juniper Gardens Children's Project, University of Kansas, Kansas City, KS, (2)Vanderbilt Kennedy Center, Vanderbilt University, Nashville, TN, (3)Department of Allied Health Sciences, University of North Carolina at Chapel Hill, Chapel Hill, NC, (4)Ohio State University, Columbus, OH*

Background: Current outcome measures are not adept at detecting the incremental changes seen in individuals with autism spectrum and related disorders, have not been consistently validated with these populations, and often fail to measure functional or clinically-relevant outcomes. In addition, many of the existing outcome measures solely rely on parent or caregiver report, making them more prone to placebo effects and more difficult to include as blinded outcome measures in clinical trials. Repetitive and inflexible behaviors are among the most common forms of aberrant behavior that occur in the context of neurodevelopmental disorders; however, existing repetitive behavior measures also heavily rely on parent report. It then becomes essential to develop tools that use other measurement formats to move the field towards more objective assessment of the functional impact of these behaviors. Our team developed a clinical interview version of the Behavioral Inflexibility Scale (BIS-CI) to meet this objective.

Objectives: The primary objective is to examine the reliability and validity of the BIS-CI.

Methods: The BIS-CI is a structed clinical interview version of the parent reported BIS. The BIS-CI consists of two sections (a) a 25 item symptom checklist (scored as present / absent), and (2) a set of seven questions designed to provide a multidimensional assessment of the functional impact of the items endorsed on the symptom checklist portion. The interview questions are scored using a 5-point Likert severity rating scale based on the caregiver's response to the question. The BIS-CI derives a total score ranging from 0 (no impairment) to a maximum score of 28 (maximum impairment). To understand the psychometric properties of the BIS-CI, n=144 children with ASD, ages 3 – 17 years, and their families completed a number of clinic-based measures to assess validity and reliability. Trained clinicians conducted interviews with parents as part of the clinic-based assessment battery.

Results: Child demographic data: 80% of children were male, 71% were white, the mean age was 9 years old (SD= 7.0), and a substantial majority had at least one co-occurring condition. Validity data: Factor analysis suggested a 1 factor solution with factor loadings ranging from 0.50 to 0.74 and acceptable fit indices (RMSEA = 0.09, CLI = 0.961, TLI = 0.927). The BIS-CI was correlated with the parent BIS at 0.65. Correlations with the Repetitive Behavior Scales-Revised (RBS-R), as a form of convergent validity, ranged from 0.38 – 0.58. The correlation with the Social Communication Questionnaire (SCQ), as a form of discriminant validity, was 0.26. Additional measures further demonstrating convergent and discriminant validity will be presented. The BIS-CI was not significantly related to child IQ ($p > .90$). Reliability data: Test-retest reliability was 0.87 and Cronbach's alpha was 0.80.

Conclusions: The BIS-CI is a potentially valid and reliable measure that can be used to assess the functional impact of the repetitive and inflexible behaviors of children with ASD. The brevity of the measure also suggests it could be feasible to include in clinical trials. Future work will be needed to examine the measure's sensitivity to change over time.

411.003 *(Poster)* Symptom Improvement in Children with Autism Spectrum Disorder Following Bumetanide Administration Is Associated with Decreased GABA/Glutamate Ratios

F. Li*, Xinhua Hospital Affiliated to Shanghai Jiao Tong University School of Medicine, Shanghai, China*

Background: Bumetanide has been reported to alter synaptic excitation–inhibition (E-I) balance by potentiating the action of γ-aminobutyric acid (GABA), thereby attenuating the severity of autism spectrum disorder (ASD) in animal models. However, clinical evidence of its efficacy in young patients with ASD is limited.

Objectives: The objective of this study was to evaluate the efficacy and safety of bumetanide treatment and examine the effect on neurotransmitter levels in the brain and the association between the latter and changes in ASD symptoms.

Methods: This was investigated in the present clinical trial of 83 patients, randomised to the bumetanide group (bumetanide treatment, 0.5mg twice daily) or the control group (no bumetanide treatment). Primary [Children Autism Rating Scale (CARS)], secondary [Clinical Global Impressions (CGI)], and exploratory [inhibitory (γ-aminobutyric acid, GABA) and excitatory (glutamate, Glx) neurotransmitter concentrations measured in the insular cortex (IC) and visual cortex (VC) by magnetic resonance spectroscopy (MRS)] outcome measures were evaluated at baseline and at the 3-month follow-up. Side effects were monitored throughout the treatment course.

Results: Compared with the control group, the bumetanide group showed significant reduction in symptom severity, as indicated by both total CARS score and number of items assigned a score ≥3. The improvement in clinical symptoms was confirmed by CGI. GABA/glutamate ratio in both the IC and VC decreased more rapidly over the 3-month period in the bumetanide group than that in the control group. This decrease in the IC was associated with the symptom improvement in the bumetanide group.

Conclusions: Our study confirmed the clinical efficacy of bumetanide on alleviating the core symptoms of ASD in young children and it is the first demonstration that the improvement is associated with reduction in GABA/glutamate ratios. This study suggests that the GABA/glutamate ratio measured by MRS may provide a neuroimaging biomarker for assessing treatment efficacy for bumetanide.

411.004 *(Poster)* The Effectiveness of the Dutch Version of PEERS® for Adolescents with Autism Spectrum Disorder; Results from a Randomised Controlled Trail with Active Control Condition

B. van Pelt[1,2], *S. Idris*[1], *G. Jagersma*[2], *A. Maras*[2], *J. Duvekot*[3], *J. van der Ende*[1], *N. E. M. van Haren*[1], *M. H. J. Hillegers*[1] *and K. Greaves-Lord*[1], *(1)Child- and Adolescent Psychiatry/Psychology, Erasmus MC, Rotterdam, Netherlands, (2)Academy, Yulius, Dordrecht, Netherlands, (3)Erasmus MC - Sophia Children's Hospital, Rotterdam, Netherlands*

Background: Limited social skills are a major challenge for adolescents with Autism Spectrum Disorder (ASD), as social skills become crucial for peer acceptance. Adolescents with ASD often have few friends, and experience increased peer rejection, resulting in greater functional impairment and poorer quality of life. Consequently, they are frequently referred to social skills training. Yet, evidence-based social skills interventions for adolescents with ASD are available in few cultures. The Program for the Education and Enrichment of Relational Skills (PEERS®) has shown to be effective for autistic adolescents in randomized control trials (RTCs) in several cultures. However, validation of PEERS® in other cultural settings is needed, given the sensitivity to cultural conventions of the particular content of social skills trainings.

Objectives: The current preliminary study examines the effectiveness of the Dutch version of PEERS®, utilizing an RCT with an active control condition, and observational, self-, parent- and teacher reported measures of social competence at pre- (T1), intermediate (T2), post (T3) intervention and follow-up (T4). Secondly, we examine client satisfaction.

Methods: Adolescents were randomly assigned to one of two conditions: the experimental condition (PEERS®) or an active control condition; ROAD (Regulation, Organization and Autonomy Didactics; psycho-education on adolescent socio-emotional developmental issues). The Dutch version of PEERS® consists of 14 weekly, 90 minute adolescent sessions and parallel parent sessions. ROAD also consists of 14 weekly, 90 minute adolescent sessions, with parent-involvement through e-mail. In the current study, social skills were assessed using parent-reports on the Social Responsiveness Scale-2 (SRS-2). Other relevant measures, such as behavioral observation utilizing the Contextual Assessment of Social Skills (CASS), were also obtained, but are not yet presented. Clients satisfaction was rated by providing grades from 1 (low satisfaction) - 10 (high satisfaction).

Results: We included 106 adolescents with ASD (73 males; n=54 PEERS, n=52 ROAD), ranging from 12-18 years old (M=14.57), with a mean total IQ of 102.66 (SD=17.18).

Preliminary analyses (T1: n=105, T3: n=82) show that at T1, mean total SRS-2 scores in the PEERS (88.90, SD 27.01) versus ROAD (86.20, SD 22.01) condition do not differ significantly $F(1,103) = .311$, $p = .578$. At T3, scores also do not differ between PEERS (69.09, SD 27.15) and ROAD (72.76, SD 26.18), $F(1,80) = .386$, $p = .536$.

Both conditions show significant improvement regarding SRS-2 mean scores from pre- to post assessment (PEERS $t(54)=-3.713$, $p < .01$, ROAD $t(53)=-4.035$, $p < .01$).

The difference amongst conditions regarding Δ SRS-2 scores from pre- to post assessment (PEERS: 19.81 vs. ROAD: 13.44) reached marginal significance $F(1,80) = .392$, $p = .051$, indicating a trend towards a superior effect in the PEERS condition. As for clients satisfaction (total n=81); in the PEERS condition, adolescents average satisfaction grade was 7.5, parents 8.2. In the ROAD condition, adolescents average satisfaction grade was 7.3, parents 7.5.

Conclusions: These preliminary findings suggest that the Dutch version of PEERS® treatment is effective in improving the social skills of autistic adolescents. Moreover, clients satisfaction is high. Results on other outcome measures will be presented at the conference.

411.005 *(Poster)* The Relationship between Core Symptoms and Associated Symptoms in ASD

J. F. Hipp[1], ***T. Ciobanu***[1], *P. Schoenenberger*[1], *E. Eule*[1], *D. Volz*[2], *F. Bolognani*[3], *L. Murtagh*[1] *and D. Umbricht*[1], *(1)Neuroscience and Rare Diseases (NRD), Roche Pharma Research and Early Development, Roche Innovation Center, Basel, Switzerland, (2)Department of Biometrics, F. Hoffmann-La Roche AG, Basel, Switzerland, (3)VectivBio Holding AG, Basel, Switzerland, Basel, Switzerland*

Background: Autism spectrum disorder (ASD) is characterized by the two core symptom domains of social communication deficits and restricted and repetitive behaviors. In addition, there are a number of associated symptoms including anxiety, executive control dysfuntioning, sensory hyper-/hyposensitivity, sleep impairment, and intellectual disability. The correlation between the two core symptom domains and specific associated symptoms is poorly understood.

Objectives: To investigate systematically the relationship between the two core (RRB, SCD) and associated symptoms (anxiety, executive control dysfunction, hyper/hyposensitivity, sleep) within a single cohort of individuals with ASD.

Methods: We conducted an observational multi-center study (ongoing). Individuals with ASD (n = 68, target: 90) stratified into three age groups (children: 5-12, adolescents: ≥12 – 18, adults: ≥18) and two levels of functioning (IQ >50 & ≤70; IQ > 70) completed a battery of assessments measuring (1) RRBs: Repetitive Behavior Scale–Revised (RBS-R), Repetitive Behavior Questionnaire (RBQ-2/2A), and Children/Adult Routine Inventories (CRI-R/ARI); (2) SCD: The Vineland Adaptive Behavior Scale (VABS-II); and (3) associated symptoms: anxiety: Parent-Rated Anxiety Scale (PRAS-ASD) in children and adolescent, Hamilton Anxiety Rating Scale (Ham-A) in adults; Cognitive abilities and executive control: Behavior Rating Inventory of Executive Functions (BRIEF/BRIEF-A), sensory abnormalities: Short Sensory Profile (SSP), IQ: Stanford-Binet Intelligence Scale-Fifth Edition (SB5). The main inclusion criteria were a confirmed diagnosis of ASD (ADOS-2) and a CYBOCS-ASD score of ≥12 assessed at the screening visit.

Results: In pediatrics (5-18 years), we found medium to high correlations between RRBs and anxiety (r = 0.58 to 0.75), and RRBs and executive control (working memory: r = 0.36 to 0.43, inhibition: r = 0.54 to 0.57, attentional shift: r = 0.57 to 0.70). Correlations of the same associated symptoms with SCDs were not significant. However, we found low to medium correlations between IQ and SCDs (communication and socialization domains: r = 0.39 to 0.41). Generally, in adults, correlations with associated symptoms were much weaker and only executive control was significantly correlated with RRB and SCD symptoms.

Conclusions: Our results suggest that associated symptoms have differentiated associations with the two core symptom domains of RRB and SCD, and that the strength of the associations generally decline with age. E.g., anxiety and executive function deficits seem to be linked to RRBs, while overall IQ is linked to SCDs. While more work is needed to understand the nature of the relation between core and associated symptoms this work sheds some light on the relational structure.

411.006 *(Poster)* Understanding Meaningful Changes in Autism Spectrum Disorder Clinical Trial Outcomes Using an Exit Interview Methodology

T. Willgoss[1]*, C. Burbridge*[2] *and J. Smith*[1]*, (1)Roche Products Limited, Welwyn Garden City, United Kingdom, (2)Clinical Outcomes Solutions Ltd, Folkstone, United Kingdom*

Background: Recent FDA guidelines highlight the importance of patient-focused drug development. Reliable and valid measures of social communication challenges that reflect meaningful changes in a real-world setting are thus critical for assessing the efficacy of new behavioral and pharmaceutical interventions in autism spectrum disorder (ASD). The Vineland™-II Adaptive Behavior Scales – Second Edition (Vineland™-II) is one of six measures of social communication impairment recommended by an expert panel to assess measures for their utility in ASD clinical trials. Vineland™-II has been used in multiple clinical trials, including those evaluating balovaptan (VANILLA [NCT01793441], V1ADUCT [NCT03504917], and AV1ATION [NCT02901431]). It is therefore important to assess the impact of changes in Vineland™-II in a real world-setting.

Objectives: Exit interviews are being conducted as part of the AV1ATION and V1ADUCT trials to gain an understanding of the perception of meaningful change in elements of ASD captured by Vineland™-II (socialization, communication, and daily living skills) and health-related quality of life (HRQoL). Here, we describe the methodology of these exit interviews.

Methods: Exit interviews, each consisting of an in-depth, 60-minute, telephone-based conversation in the native language, are being conducted with study partners of trial subjects who have recently completed the Week 24 visit of the AV1ATION and V1ADUCT trials. Experienced interviewers ask open-ended questions to gain insights into the impact of ASD on the lives of individuals and their families followed by focused discussion on the meaning of any changes experienced over the course of the trial. Questions focus on the domains captured by Vineland-II™: socialization, communication, and daily living skills, with some discussion on changes in HRQoL. All interview data are audio-recorded, transcribed and analyzed using thematic analysis to understand meaning and real-world impact of any changes. Additionally, quantitative ratings of change from baseline, overall and per domain (based on 7-point scales), are provided by study partners during the interview. Experienced, independent clinician reviewers are also rating the changes, using the same rating scales, for a number of transcripts (n=20). Inter-rater reliability will be assessed for clinician reviewers if the sample size permits. These data, alongside blinded descriptive data from selected outcome variables in the clinical trials, will inform anchor-based analyses exploring the interpretation of meaningful change on Vineland-II™.

Results: This novel approach will provide improved understanding of meaningful change in individuals with ASD in a real-world setting, supported by quantitative estimates of meaningful change on the Vineland™-II scale. Studies are ongoing and initial data support this approach. The rich qualitative accounts of observed changes and their meaning provide impactful evidence to support the relevance of numerical changes observed on Vineland™-II.

Conclusions: Exit interviews conducted after clinical trials will provide a rich source of both qualitative and quantitative data that provide a detailed account of what constitutes a meaningful change in ASD outcomes. This methodology will also provide a valuable way to assess the clinical meaningfulness of additional outcome measures in future ASD trials.

Cognition: Attention, Learning, Memory

POSTER SESSION — COGNITION: ATTENTION, LEARNING, MEMORY
412 - Cognition: Attention, Learning, Memory Posters

412.001 *(Poster)* ASD, but Not ADHD, May Have Deficit in Visuospatial Working Memory

Q. Chen*, Y. Jin and Z. Wang, Sun Yat-sen University, Guangzhou, China*

Background: Both as neurodevelopmental disorders emerged from early childhood, Autism Spectrum Disorder (ASD) and Attention Deficit/Hyperactivity Disorder (ADHD) may have overlap but distinct neurocognitive basis, such as executive function (EF). Visuospatial working memory (VSWM), a core component of EF, was thought to be correlated with learning, behavior regulation, metacognition and the core symptoms of ASD and ADHD. However, it hasn't met agreement on whether ASD and ADHD children would have deficits on VSWM, especially on the different periods of encoding and retrieving.

Objectives: The study aimed to identify whether VSWM were impaired in children with ASD and those with ADHD, and further to explore the concrete characteristics of memory encoding and retrieving.

Methods: 21 boys with ASD, 16 boys with ADHD and 15 boys with typical development (TD) aged 6-12 years old were recruited in present study. The Chinese edition of Wechsler Intelligence Scale for Children (C-WISC), Child Autism Rating Scale (CARS), Social Response Scale (SRS) and Swanson, Nolan, Pelham-IV rating scales (SNAP-IV) were applied to assess participants' cognition ability and the core symptoms of ASD and ADHD respectively. Meanwhile, the paradigm of face encoding and retrieving were arranged to evaluate the specific aspect of VSWM. We conducted one-way analysis of (co)variance to compare the characteristic differences (age, IQ, VSWM) among the three groups, and additional post hoc Bonferroni procedures were used for multiple comparisons. Furthermore, Pearson correlation analysis was employed to explore the relationship between VSWM and core symptoms of ASD and ADHD.

Results: The three groups were matched on age and FIQ, while there existed differences on verbal comprehensive index (VCI) and process speed index (PSI). Children with ADHD showed severer inattention, hyperactivity and social dysfunction than TD, and participants with ASD manifested more social problems than ADHD and TD. The results of behavioral task implied the deficits of VSWM were obviously in ASD but not ADHD during both encoding and retrieving periods. After controlling for PSI, the results remained that ASD boys responded slower than TD in encoding task (RT_{-ASD}=1542±296ms, RT_{-ADHD}=1369±248ms, RT_{-TD}=1210±264ms, F=6.594, P=0.008), while made more errors in retrieving task (ACC_{-ASD}=0.60±0.16, ACC_{-ADHD}=0.79±0.14, ACC_{-TD}=0.80±0.17, F=10.024, P=0.001). What's more, the social deficits of ASD were correlated with performance on VSWM: the worse of social cognition they had, the more errors they made (r=-0.566, P=0.007).

Conclusions: Our findings suggest that children with ASD but not ADHD may possess deficits in VSWM, and they showed different abnormal formats during encoding and retrieving period. Meanwhile, it may be related with social difficulties. Our study has shed lights on the underlying behavioral mechanism to discriminate ASD and ADHD.

412.002 *(Poster)* An Examination of the Relationship between Fine Motor Ability and Executive Functions in Toddlers with and without ASD

*D. Solomon[1], **A. K. Platner**[1,2], S. R. Edmunds[1] and S. Faja[1], (1)Boston Children's Hospital, Boston, MA, (2)Franciscan Children's, Brighton, MA*

Background: Despite literature supporting a relationship between motor skills and executive functions (EF) as well as their impact on academic readiness and achievement in school-aged children, little research has investigated these abilities in young children with ASD compared to their neurotypical peers (Cameron et al., 2012, & Rigoli, Piek, Kane, & Oosterlaan, 2012). One recent study (St. John et al., 2016), noting a lack of clarity on the emergence of EF challenges in children with ASD under three years old, examined EF and motor skills in young children at high and low risk for ASD. Their work suggested that motor skill development might be a key factor in atypical EF development for high-risk children. A more nuanced understanding of these possible relations and how they differ between children with and without ASD will result in improved early detection of delays and more targeted intervention and support.

Objectives: To assess the degree to which fine motor ability (FM) is related to everyday executive functioning in young children with ASD and their typically developing peers (TD).

Methods: Toddlers with ASD (n = 13) and TD (n = 16) completed a battery of tasks as part of a larger study describing the trajectory of executive functioning abilities as related to diagnostic status. Toddlers completed the Mullen Scales of Early Learning (MSEL) to assess FM and the Behavior Rating Inventory of Executive Function (BRIEF) at 2 years of age. Fine Motor T-score, controlling for verbal ability (MSEL Verbal DQ), was entered as a predictor of BRIEF Shift, Executive Control, Working Memory, and composite scores. Differences by diagnostic group were explored. Data collection is ongoing.

Results: Toddlers with ASD had significantly lower fine motor ability, shifting, executive control, working memory, and overall BRIEF scores compared to TD toddlers. Across all toddlers, and controlling for their verbal ability, children with better FM were rated as having less difficulty with shifting between tasks (β= -.66, p=.01), working memory (β= -.45, p=.03), executive control (β=-.52, p=.04), and total executive functioning (β= -.48, p=.04). Preliminary analyses suggest that some relations may be different for TD vs. ASD children such that the relation between FM and shifting or working memory components of executive functioning might be stronger for TD children than for children with ASD.

Conclusions: This study indicates that FM and EF abilities are generally lower in children with ASD as compared to their TD peers. Furthermore, it supports the current literature suggesting that in general, FM is related to EF in children; possibly implying that interventions seeking to increase EF should emphasize FM development in tandem. However, preliminary results of this study suggest that the strength of the relationship between FM and EF might differ across diagnostic groups. These findings highlight the importance of examining and comparing developmental profiles of children with and without ASD in order to learn more about the emergence of skill deficits and relationships and to inform early and effective intervention. Data collection and analysis is ongoing.

412.003 *(Poster)* Attention Processes across Sensory Domains: Characterization from EEG and Eye Tracking

***C. M. Nelson**[1], M. M. Mahony[2], T. DesChamps[3], R. Bernier[4], F. Shic[5], S. J. Webb[4], L. Morett[1] and C. M. Hudac[6], (1)University of Alabama, Tuscaloosa, AL, (2)Bernier Lab, Psychiatry and Behavioral Sciences, University of Washington, Seattle, WA, (3)Psychology, University of Washington, Seattle, WA, (4)Psychiatry and Behavioral Sciences, University of Washington, Seattle, WA, (5)Center for Child Health, Behavior and Development, Seattle Children's Research Institute, Seattle, WA, (6)Psychiatry and Behavioral Sciences, University of Washington, Seattle, AL*

Background: Attention is a cognitive process that plays a significant role in directing a person's purposeful and reflexive thoughts and actions. Attention in individuals with ASD is a particularly intriguing area of research with inconsistent findings (Travers, Klinger & Klinger, 2011). Given sensory sensitivities in ASD, it is important to understand attention processes across different domains (e.g., auditory, visual). Current research has implicated attention as an underlying process in modulating sensory sensitivities. For instance, individuals with ASD demonstrate early detection of sound frequency deviation, but habituate to novel sounds slowly (Hudac et al., 2018). Eye-tracking paradigms have indicated attention as a key player in social activity monitoring in ASD. For example, toddlers with ASD have shown decreased attention to the activities of others compared to typically developing peers (Shic et al., under review). However, the relationship of attention between each of these sensory domains has yet to be examined.

Objectives: We aimed to examine the relationship between auditory and visual attention by examining relationships across modes of measurement (EEG and ET) in a sample of typically developing participants and participants with ASD.

Methods: Preliminary data from children with ASD (n = 6) and typically developing children (n = 42) who completed an ongoing study were included in these analyses. An auditory odd-ball EEG task (Hudac et al., 2018) measured the N1 amplitude to infrequent and frequent tones and the P3a amplitude to frequent tones and novel sounds. An eye-tracking paradigm measured gaze patterns within areas of interest (AOIs: Background, Shared Activity, Head and Body) during a scene depicting two actors engaged in a shared social activity. Here, we focus on AOI percentages calculated for the head and shared activity across conditions in which the actors were looking at each other (i.e., mutual gaze) and looking at the shared activity (i.e., activity directed gaze). Pearson correlation analyses focused on examining relationships between ERP (N1/P3a) and the eye-tracking (%AOI) attention responses by condition.

Results: Results across all participants indicated that increased looking to the activity was associated with increased auditory attention responses, including P3a frequent amplitude (r = +0.374, p = 0.009), P3a novel amplitude (r = +0.361, p = 0.012), and N1 infrequent amplitude (r = -0.351, p = 0.014) in the mutual gaze condition. No significant correlations were found in the activity directed gaze condition. Children with ASD that had smaller auditory attention responses (N1/P3a to frequent) exhibited more visual attention to the head, but only in the activity directed gaze condition (See Table 1). However, TD participants with smaller auditory attention responses corresponded with more visual attention to the head and activity but only in the mutual gaze condition (See Table 1).

Conclusions: This preliminary analysis suggests that there are significant relationships between attention processes across these two domains.

412.004 *(Poster)* Atypical Perception in Autism: Characterizing Inference in Basic Perceptual Processing

***B. S. Hadad**, University of Haifa, Haifa, Israel*

Background: Perceptual atypicalities are a widely acknowledged but poorly understood feature of autism.Prevailing models, formulized in Bayesian terms, suggest that reduced top-down influences underlie atypicalities in perception. Within this framework, changes in bottom-up factors, if they exist at all, are considered *quantitative*, mostly involving changes in noise levels. Consequently, testing has little consideration of potential underlying constraints of basic sensory-perceptual processing.

Objectives: We have recently demonstrated violation of Weber's law in autism, in the visual and tactic modalities, suggesting a modality-independent mechanism of abnormal stimulus encoding. Specifically, JNDs in individuals with ASD are not scaled with intensities, indicating deficits in the low-level calibration mechanism. Here, we examined whether this modulated mechanism of stimulus encoding is associated with the reduced effects of priors (e.g., anchoring, range effects). We hypothesized that the typical pattern of increased biases for noisier measurements may not be evident in autism, where scalar variability (Weber ratio) does not seem to hold.

Methods: A set of experiments was designed to examine the relationship between the precision of the sensory input and the utilization of perceptual priors. In Experiment 1, we extended our recent findings by demonstrating the violation of Weber's law in autism also in the auditory domain, while manipulating the effect of perceptual anchoring. We examined discrimination thresholds for empty tones intervals using three standards durations. JNDs were compared across the different durations and between two conditions: (1) blocked presentation in which strong anchoring is established for each standard (2) random presentation in which anchoring is weaker. Experiment 2 utilized the height-width illusion to manipulate perceptual bias (i.e., longer rectangles are perceived narrower than shorter ones), while blurring the vertical contours composing the rectangles by imposing a Gaussian filter varying in its standard deviations (i.e., precision of the measurement). Increased biases were expected in neurotypicals for noisier measurements.

Results: In Experiment 1, 17/17 of our TD showed the expected increase in JNDs with increasing durations, as well as the expected effect of anchoring, indicated by higher JNDs for the random presentation. Interestingly, 7/10 of our ASD did not show any scaling of JNDs with durations but a sub-group of 3/10 showed adherence to Weber's law. Perceptual anchoring was smaller in ASD and remained constant across intensities (presumably because Weber's law does not hold). Experiment 2 demonstrated substantial increase in the amount of the height-width illusion as a function of blurriness for TD, while for ASD, JNDs did not scaled with the increased blurriness to the same extent, and the bias magnitude remained fairly constant across the different noise levels.

Conclusions: The typical pattern of increased effects of biases for noisier measurements is *not* evident in autism, demonstrating modulations in the relative weights of perceptual biases and incoming sensory input. The results suggest that the qualitative changes (the violation of the constant Weber ratio) in the underlying constraints of basic sensory-perceptual processing may account, at least in part, for the often reported modulated perceptual inference in ASD.

412.005 *(Poster)* Auditory Attention Switching Difficulty in Young Adults with Autism Spectrum Disorder

***K. A. Emmons**[1], B. K. Lau[1], E. Larson[1], S. R. Dager[2], A. Estes[1] and A. K. K. Lee[1], (1)Speech and Hearing Sciences, University of Washington, Seattle, WA, (2)Radiology, University of Washington, Seattle, WA*

Background: Communication in everyday life depends crucially on the ability to dynamically switch attention between competing auditory streams. Many of us do so effortlessly, such as switching attention between different speakers at a party. Sensory processing difficulties, particularly in the auditory domain, are commonly reported by individuals with autism spectrum disorder (ASD). Past studies have shown various auditory processing deficits in ASD, including difficulty listening under noisy conditions and impaired cross-modal attention switching; however, few studies have looked specifically at auditory attention deployment in ASD.

Objectives: This study investigates individual differences in the ability to switch auditory attention in young adults with ASD and age- and sex-matched controls. We hypothesize that individuals with ASD will demonstrate difficulty switching auditory attention.

Methods: Twenty-two participants aged 21 to 22 years (ASD n=11; TD n=11) were recruited from a larger longitudinal study conducted at the University of Washington Autism Center. All participants passed an audiometric screen of <= 20 dB hearing level at octave frequencies between 250 and 8000 Hz for inclusion in the study. The study paradigm consisted of presenting participants with two simultaneous auditory streams, each consisting of two compound words. On Switch Attention trials, participants were instructed to attend to the first speaker for the first word, then switch attention to the second speaker for the second word. On Hold Attention trials, participants were instructed to attend to the first speaker for both the first and second words. In each trial, the speakers were either both male, both female, or a male/female pair. Speakers' sex was manipulated to make the task harder (male/male or female/female) or easier (male/female). Additionally, speakers were either co-located (both from the left or both from the right) or spatially separated (one from the left and one from the right). There were 8 blocks, each consisting of 24 trials, for a total of 192 trials per participant. The entire task lasted approximately 30 minutes and was performed while the participant was undergoing magnetoencephalography recording.

Results: A two-way mixed ANOVA was conducted to investigate the effect of group and condition on task performance. There was a significant main effect of group, $F(1,20) = 15.45$, $p = 0.001$, with the TD group performing better than the ASD group. One-way ANOVAs were conducted to investigate the effect of group on performance and showed a TD advantage across all conditions. The ASD group performed above chance on Maintain Attention trials, and on Switch Attention trials where speakers were a male/female pair and spatially separated. However, on Switch Attention trials where speakers were male/male or female/female or where their voices were co-located, the ASD group did not perform above chance.

Conclusions: These results suggest that young adults with ASD can switch attention from one auditory stream to the other when speakers' voices are a male/female pair and spatially separated, although less accurately than TD individuals. The ASD group showed greater difficulty switching attention from one stream to the other when speakers' voices were both male or both female or were co-located.

412.006 *(Poster)* Characterizing the Metrics and Timing of Saccadic Eye Movements in Children and Adolescents with ASD

L. Chukoskie[1]*, D. Vong*[1]*, S. Rengarajan*[1]*, B. Keehn*[2] *and J. Townsend*[1]*, (1)University of California San Diego, La Jolla, CA, (2)Speech, Language, and Hearing Sciences, Purdue University, West Lafayette, IN*

Background: Fast and accurate orienting movements, such as eye saccadic movements play an important role in obtaining information available in dynamic social environments. Individuals with autism spectrum disorder (ASD) have difficulty executing fast shifts of visual attention (Townsend, et al.,1996) and accurate saccades to targets (Miller, et al., 2014). ASD individuals frequently have trouble redirecting gaze behavior appropriately, which has been highlighted as one of the earliest signs of ASD (Zwaigenbaum, et al. 2005). Although others have studied saccadic movements in ASD individuals using a range of techniques and ages, here we quantify the metrics and timing of saccades using a high-accuracy video-based eye tracking system in a sample of children and adolescents.

Objectives: We measured gaze behavior during baseline, gap and overlap saccade paradigms to assess expected differences between individuals with ASD and typically developing (TD) individuals, particularly with respect to number of saccades, saccade accuracy, and saccade latency.

Methods: Thirty-six ASD and eighteen TD children and adolescents were calibrated and assessed using the Gap-Overlap paradigm on the EyeLink 1000 video-based eye tracking system. A central fixation target was surrounded by possible target locations arranged in two concentric circles located approximately 5° and 10° from the central fixation target for a total of 16 total peripheral target locations. The central fixation target either 1) extinguished as the target appeared (baseline condition) 2) extinguished 400 ms before the peripheral target appeared (gap condition), or 3) extinguished 400 ms after the peripheral target appeared (overlap condition). Each trial began with the participant focused on the central fixation target. And subjects were instructed to move their eyes to the peripheral target "as quickly as possible." Two trials of each condition were presented at each of the 16 peripheral target locations for a total of 96 trials. Data from each trial was manually inspected using a custom MATLAB script. All trials in which we observed blinks, unsteady fixation in the 200 ms prior to target onset, or indications of drowsiness were excluded from further analysis. This data cleaning step allowed us to gain better clarity over the saccade metrics and timing results which were quite variable in the ASD group.

Results: The most consistent finding was that individuals with ASD required more saccades to get on target in all three task conditions. There was a trend toward significant differences in accuracy of the first saccade in the baseline and overlap conditions. Standard deviation of latency (ie. variability in the time to launch a saccade) was itself very variable across ASD participants.

Conclusions: Our analysis suggests that a one should consider differences in basic orienting behaviors in attempting to understanding an individual's response in dynamic situations. The additional time needed to orient correctly can result in missed information and/or opportunities in dynamic scenarios.

412.007 *(Poster)* Child Temperament and Parental Responsivity during Play: A Window into Heterogeneity Among Children with ASD

J. T. Mattson[1]*, H. Mikus*[2]*, N. Stagnone*[2] *and* ***S. T. Kover***[3]*, (1)Seattle Children's Hospital, Seattle, WA, (2)University of Washington, Seattle, WA, (3)Speech and Hearing Sciences, University of Washington, Seattle, WA*

Background: Chetcuti, Uljarevic, and Hudry (2019; *JCPP*) named temperament as a critical construct for understanding individual differences among children with ASD. In particular, Chetcuti et al. suggested that the relationship between temperament and aspects of the environment relevant to developmental outcomes, such as parental behaviors, could illuminate mechanistic bases of ASD heterogeneity. Indeed, differences between children with ASD and typical development have been identified for both temperament–especially effortful control–and parental behaviors, including responsivity and directiveness (Konstantareas & Stewart, 2006; Ku, Stinson, & Macdonald, 2019). In typical development and other disabilities, individual differences in effortful control are related to parental responsivity and directiveness (Eisenberg et al., 2015; Song et al., 2018). The current study extends previous research to a heterogeneous sample of children with ASD using a context critical for development: parent-child play.

Objectives: In children with ASD, we investigate within-group individual differences in parent-rated temperament, with a focus on effortful-control (attention-focusing, inhibitory-control), in relation to parental behavior (responsivity and directiveness) during play.

Methods: Participants with ASD (*n*=22, 6 female) were ages 3-11 years (*M*=7.4 years; *SD*=2.5 years). See Table 1. Based on child's age, child temperament was assessed by parental report using the Children's Behavior Questionnaire (CBQ, 3-7 years; Rothbart et al. 2001), Temperament in Middle Childhood Questionnaire (7-10 years), or Early Adolescent Temperament Questionnaire (>10 years; Rothbart et al. 1992/2007). Two effortful control indices overlapped across questionnaires and were the focus of analysis: attention-focusing and inhibitory control. Parent-child dyads were video-recorded during an unstructured, 10-18 minute free-play session; parental behavior was coded using Behavioral Observation Research Interactive Software (http://www.boris.unito.it). Toys were constant across dyads and appropriate for object-focused and symbolic play (e.g., blocks, firetruck, marble-run, picnic basket, farm animals). Twelve behaviors were coded with an adaptation of the Maternal Behavior Rating Scale (Van Keer at al., 2017); those relating to responsivity and directiveness were the focus of analysis (sensitivity to child's interest, responsivity, effectiveness, directiveness, and pace). Each parental behavior was scored in two-minute intervals on a 1-5 Likert scale and averaged across the minimum of five time epochs. Calculated for 10% of videos, inter-rater agreement within one scale-point was 96% (Van keer et al., 2017). Pearson correlations were tested between parent-rated temperament and observer-rated parental behavior scores.

Results: Attention-focusing was negatively correlated with parental directiveness (i.e., higher attention-focusing was associated with lower directiveness), *r(19)*=0.47, *p*=0.030. Inhibitory-control was positively correlated with parental effectiveness, *r(20)*=0.44, *p*=.041, and negatively correlated with parental pace, *r(20)*=0.55, *p*=0.008. See Figure 1.

Conclusions: Parental responsivity and directiveness during parent-child play can be predicted by effortful control aspects of child temperament (attention-focusing, inhibitory-control) in children with ASD. Specifically, children with higher levels of parent-rated effortful control experienced lower levels of observer-rated parental directiveness and pace. These findings have implications for understanding heterogeneity in outcomes for children with ASD and for potential parental interventions. Further research is needed to determine how parental behaviors differ according to temperament over time and how those behaviors moderate effects of temperament on long-term developmental outcomes (Chetcuti et al., 2019).

412.008 *(Poster)* Cluster Analysis of Extremely High Ability Autism Reveals Heterogeneity in Cognitive Performance and Behavioral Phenotypes in a Gifted/Talented Clinical Cohort

L. G. Casten[1]*, T. C. Kalmus*[1]*, J. Michaelson*[2]*, S. Assouline*[3]*, T. Nickl-Jockschat*[3] *and T. Abel*[4]*, (1)Psychiatry, The University of Iowa, Iowa City, IA, (2)Division of Computational and Molecular Psychiatry, Iowa City, IA, (3)The University of Iowa, Iowa City, IA, (4)University of Pennsylvania, Philadelphia, PA*

Background: Although the extreme heterogeneity of autism is well-appreciated, current research is dominated by findings that relate chiefly to autism at low to average IQ. Comparatively little is known about the clinical features of autism in a population with high IQ. Exploration of this phenotype can provide insight into the symptomatology autism without the confounds of intellectual disability, and may have implications for effective clinical diagnosis and intervention across the spectrum.

Objectives: Using a one-of-a-kind sample from a major gifted and talented assessment center in the midwestern United States, we aimed to use psychoeducational data to cluster individuals with autism into distinct subgroups. Clusters were then recapitulated in a supervised learning framework to determine if differences between groups were robust and interpretable.

Methods: In a sample of over 1,300 individuals seen at a gifted/talented assessment and counseling clinic, we filtered to those who received an ASD diagnosis and an IQ-matched control group (final sample size of 353: 68 autism cases, 285 controls) who had Wechsler IQ and Behavioral Assessment System for Children (BASC) scores. Mean age of the sample was 10, there were 236 males and 112 females. The analysis presented here is a first look at this data. Hierarchical clustering was done on individuals with an autism diagnosis using scaled IQ and BASC data. We then developed a classifier to predict cluster status to examine whether the differences between clusters was robust enough to accurately predict cluster membership. ANOVA was then conducted to assess the significance of feature-level differences between clusters, and Tukey's Honest Significant Difference tests to find where the differences were.

Results: Cluster analysis revealed 3 distinct clusters.There were no significant differences in full-scale IQ scores between the clusters. Cluster 1, had a significantly higher verbal comprehension index score than the other clusters ($F=9.1$, $p<0.001$) and a lower processing speed. This group had a very similar behavioral profile to Cluster 2, but Cluster 2 had a less extreme IQ profile. Cluster 3 had a unique behavioral profile, with significantly less problematic scores on BASC measures. Behavioral measure differences that survived Bonferroni multiple test correction were: **adaptability** ($F=42.8$, $p<0.0001$), **functional communication** ($F=41.2$, $p<0.0001$), **leadership** ($F=16.27$, $p<0.0001$), **conduct problems** ($F=13.6$, $p<0.0001$), **social skills** ($F=11.25$, $p<0.0001$), and **attention problems** ($F=8.9$, $p<0.01$).

We then developed a classifier using linear discriminant analysis predicting cluster membership. We were able to accurately classify 90% of unseen test cases into the correct cluster.

Conclusions: Our results show that extreme heterogeneity is found across all levels of intellectual ability in autism. Interventions and educational plans tailored towards high ability autism should be individualized and can likely be informed by what cluster these individuals fall into. Using cluster analysis, we can effectively distinguish profiles found in high ability autism and better understand their phenotype using IQ and behavioral measures. Further research is underway to define the genetic and neuroimaging correlates of these clusters.

412.009 *(Poster)* Cognitive Flexibility Moderates the Association between Life Events and Emerging Psychopathology in Youth with ASD

N. J. Wright[1]*, V. Carter Leno*[2]*, R. Bedford*[3]*, T. Bennett*[4]*, E. Duku*[5]*, S. Georgiades*[5]*, P. Mirenda*[6]*, I. M. Smith*[7]*, T. Vaillancourt*[8]*, C. Waddell*[9]*, A. Zaidman-Zait*[10]*, L. Zwaigenbaum*[11]*, A. Pickles*[2]*, P. Szatmari*[12] *and M. Elsabbagh*[13]*, (1)Biostatistics & Health Informatics, Kings College London, London, United Kingdom, (2)King's College London, Institute of Psychiatry, Psychology and Neuroscience, London, United Kingdom, (3)Kings College London, London, United Kingdom, (4)Offord Centre for Child Studies, McMaster University, Hamilton, ON, CANADA, (5)McMaster University, Hamilton, ON, Canada, (6)University of British Columbia, Vancouver, BC, Canada, (7)Dalhousie University / IWK Health Centre, Halifax, NS, CANADA, (8)University of Ottawa, Ottawa, ON, Canada, (9)Simon Fraser University, Vancouver, BC, Canada, (10)Tel-Aviv University, Tel-Aviv, Israel, (11)University of Alberta, Edmonton, AB, Canada, (12)The Hospital for Sick Children, Toronto, ON, Canada, (13)McGill University, Montreal, QC, Canada*

Background: In typically developing individuals, experiencing stressful life events (SLE's) is related to mental health problems. Youth with ASD are more likely to experience SLE's (Green, McGinnity, Ford, & Goodman, 2004) and experience higher rates of mental health problems (Siminoff et al., 2008). In addition, aspects of cognitive functioning associated with ASD may increase the chance of developing mental health problems following SLE exposure (Kerns, Newschaffer, & Berkowitz, 2015). Specifically, cognitive inflexibility may moderate the association between SLE and psychopathology, such that individuals with ASD have difficulty disengaging from distressing memories or in flexibly adapting to unexpected events.

Objectives: The current study aimed to test whether cognitive flexibility moderates the association between SLE exposure and emerging psychopathology in youth with ASD.

Methods: Participants came from the "Pathways to Better Outcomes" longitudinal study of children with ASD (n = 260). Around 7 years of age, SLE's were assessed as the total number of events in the preceding 12 months from the parent-report Family Inventory of Life Events and Changes and cognitive flexibility was assessed using the teacher-report Cognitive Shifting subscale of the Behaviour Rating Inventory of Executive Functioning. Mental health outcomes were assessed at age 10 using the Total, Externalizing and Internalizing problems scales from the parent-report Child Behavior Checklist (CBCL). To test whether cognitive flexibility moderates the association between SLE exposure and emerging mental health outcomes, main effects and the interaction term of SLE's and Cognitive Shifting were included in the models as predictors of later CBCL scores.

Six-year parent-report CBCL (to account for mental health problems prior to SLE exposure, family income (to account for sociodemographic risk), and study site were included as covariates. As a secondary step, autism symptom severity (assessed using 6-year ADOS) and IQ (assessed using 6-year full-scale IQ from the WPPSI) were added to test whether the results were specific to executive function. Path analysis models were fitted using the sem command with maximum likelihood estimation in Stata v14.

Results: The models showed excellent fit to the data (CFI > .99). There was a significant interaction between Cognitive Shifting and SLEs in the prediction of CBCL Total Problems ($p < .05$). This was driven primarily by the Externalizing subscale (interaction term $p < .05$) - the association between SLE's and Externalizing problems was significant only for children with low levels of Cognitive Shifting ($p<0.05$ at 1 standard deviation (SD) below the mean) but no association was found for those with strong Cognitive Shifting abilities. The results were unchanged after the addition of ADOS severity and IQ.

Conclusions: Consistent with the hypothesis, analyses showed that cognitive flexibility moderated the impact of SLE's on mental health outcomes later in childhood, whilst adjusting for mental health problems prior to SLE exposure and relevant sociodemographic factors. Cognitive flexibility may increase resilience by allowing youth with ASD to compensate or adapt more easily to environmental risk for psychopathology. Results suggest that interventions targeting cognitive shifting ability may be important for reducing the negative impact of SLE's in children with ASD.

412.010 *(Poster)* Cognitive Flexibility and Behavioral Inflexibility Differentiate Autism Spectrum Disorder and Attention Deficit Hyperactivity Disorder in Children

C. M. Perry[1]*, A. R. Dallman*[1]*, E. McQueen*[1]*, B. A. Boyd*[2] *and C. Harrop*[1]*, (1)Department of Allied Health Sciences, University of North Carolina at Chapel Hill, Chapel Hill, NC, (2)Juniper Gardens Children's Project, University of Kansas, Kansas City, KS*

Background: Two neurodevelopmental disorders (NDDs) with a high degree of comorbidity and phenotypic overlap are attention deficit/hyperactivity disorder (ADHD) and autism spectrum disorder (ASD). Executive functioning (EF) and cognitive and behavioral inflexibility (BI) are constructs that both overlap and dissociate these disorders (Martel, Nikolas, & Nigg, 2007), and can contribute to our understanding of shared and distinct variance between ASD and ADHD.

Objectives: The aims of the study are: (1) identify profiles of EF across NDDs using the NIH Toolbox Cognition Battery (NIH-TCB), (2) test the hypothesis that executive function deficits (EFd) and BI differentiate our ASD, ADHD, ASD+ADHD, and typically developing (TD) groups, and (3) recognize areas of BI that are most problematic in the ADHD population.

Methods: 70 children, ages 3-17, participated in the study; 19 ADHD, 17 ASD, 17 ASD+ADHD and 17 TD. ASD and TD subjects were matched to the ADHD sample based on sex, age, and IQ from a previous study (total sample 76 ASD, 93 TD, 51 ASD+ADHD). A larger matched sample (~120) is anticipated by May 2020, with 40 ADHD participants. Subjects completed the Stanford-Binet (SB-5) abbreviated intelligence quotient (ABIQ) and four tasks from the NIH-TCB [Flanker Inhibitory Control and Attention (Flanker; inhibition), Dimensional Change Card Sort (DCCS; cognitive flexibility), Pattern Comparison Processing Speed (PCPS; processing speed), and Picture Sequence Memory Test (PSMT; episodic memory)]. Caregivers completed a basic demographic form, questionnaires regarding ASD symptomatology, and the Behavioral Inflexibility Scale (BIS; Boyd, Bodfish, Lecavalier, & Harrop, 2018); a 38-item parent report measure of behavioral inflexibility in children with ASD rated on a scale from 0 to 5. To test for differences between groups, we used a series of independent samples t-tests.

Results: Children with ASD demonstrated greater cognitive inflexibility, as measured through the DCCS, than TD children (approaching significance $p=0.07$). There were no significant differences on inhibitory control between ADHD, ASD and TD children ($p>0.05$), but ASD subjects performed significantly better than the ASD+ADHD group ($p=0.03$). No significant differences were found on episodic memory or processing speed tasks between groups ($p>0.05$). There were significant differences on ratings of BI between some of our groups(ASD > ADHD > TD, $p<0.01$), but not others (ASD = ASD+ADHD, $p>0.05$). To identify areas of BI that are problematic,

Conclusions: This modest-sized study confirmed our hypothesis that EFd, explicitly cognitive flexibility, and BI play a significant role in differentiating ASD and ADHD. This important finding suggests EFd remain a meaningful target for cross-diagnostic intervention approaches. These findings should be interpreted cautiously given this preliminary sample. However, we find it promising that BI differentiates three of the four groups, suggesting that while BI may be a common feature between ADHD and ASD, the magnitude of it is what differentiates these NDDs.

412.011 *(Poster)* Continued-Influence Effects in Autism Spectrum Disorder

A. J. Gordon[1] *and M. Solomon*[2]*, (1)Psychiatry & Behavioral Sciences, University of California, Davis, M.I.N.D. Institute, Sacramento, CA, (2)Department of Psychiatry and Behavioral Sciences, The Medical Investigation of Neurodevelopmental Disorders (MIND) Institute, UC Davis School of Medicine, University of California Davis, Sacramento, CA*

Background: Decades of research has provided compelling evidence that misinformation – false or inaccurate information – continues to influence judgement and decision making despite subsequent correction, a phenomenon known as the continued influence effect (CIE; Lewandowsky et al., 2012). However, no research has investigated the CIE in autism spectrum disorder (ASD). Relative to those with typical development (TD), individuals with ASD exhibit specific deficits in cognitive flexibility (Fujino et al., 2019) and episodic memory (Cooper et al. 2017), meaning that they may be more susceptible to the effects of misinformation either through inefficient memory-updating following a correction or deficient recall of correct information.

Objectives:

1. To investigate whether ASD individuals are more susceptible to the CIE than those with TD.
2. To examine whether the CIE is specifically related to poorer cognitive flexibility and episodic memory in ASD.

Methods: 79 IQ-matched participants (44 ASD; 35 TD) read a series of brief news reports that contained confirmations or corrections of prior information. Following each report, participants were presented with two pictorial memory probes and asked to choose the image that matched the reports' *correct* facts. Importantly, the *incorrect* image either matched the initial *misinformation* (interference condition) or did not match *any* prior information (no-interference condition), resulting in three conditions: confirmation (CON), correction/interference (CORR_INT), and correction/no-interference (CORR_N_INT). Our dependent variable was drift rate, a combination of accuracy and reaction time that quantifies the rate of information processing and accounts for a potential speed-accuracy trade-off.

Results: There was a significant effect of condition on participants' drift rates ($F(2,154)=4.449$, $p=.013$), highlighting that *all* participants had a slower drift rate when a correction was followed by an interfering probe (CORR_N_INT; demonstrating the presence of the CIE). There was also a significant effect of diagnosis ($F(1,77)=5.257$, $p=.025$), with ASD participants drift rate being less than for TD. However, there was no significant interaction between the factors suggesting that ASD participants did not display a uniquely greater CIE than those with TD ($F(2,154)=0.583$, $p=.559$; Fig. 1). Further analyses examined whether participants' drift rate was related to measures of cognitive flexibility (from the Dimensional Card Change Sort task; DCCS) or episodic memory (from the Picture Sequence Memory task; PSM) from the NIH toolbox (Gershon et al., 2013). These analyses revealed that drift rate in all conditions was positively associated with measures of cognitive flexibility uniquely for ASD participants (Fig. 2). However, scores did not relate to episodic memory for either diagnosis group.

Conclusions: Our data revealed that overall individuals with ASD performed more poorly on the task than those with TD, however, evidence for a specifically larger CIE in this group was not found. Instead, the data suggested that flexible cognition closer to the level observed in TD is key for ASD individuals to overcome the effects of previously learned misinformation more efficiently. These findings therefore provide preliminary evidence that strategies to improve cognitive flexibility may be critical to aid individuals with ASD to function in a world in which misinformation is an ever-increasing concern.

412.012 *(Poster)* Decision-Making Impairments in Adolescents and Young Adults with Autism Spectrum Disorder

M. K. Krug[1]*, C. C. Coleman*[2]*, A. J. Gordon*[3] *and M. Solomon*[4]*, (1)Department of Psychiatry & Behavioral Sciences, UC Davis MIND Institute, Sacramento, CA, (2)Department of Psychiatry & Behavioral Sciences, The Medical Investigation of Neurodevelopmental Disorders (MIND) Institute, University of California, Davis, Sacramento, CA, (3)Psychiatry & Behavioral Sciences, University of California, Davis, M.I.N.D. Institute, Sacramento, CA, (4)Department of Psychiatry and Behavioral Sciences, The Medical Investigation of Neurodevelopmental Disorders (MIND) Institute, UC Davis School of Medicine, University of California Davis, Sacramento, CA*

Background: Individuals with Autism Spectrum Disorder (ASD) may show impaired (Mussey et al., 2015; Zhang et al., 2015) or even enhanced (South et al., 2014) performance on the Iowa Gambling Task (IGT), which measures decision-making under ambiguity. A modified version of the IGT (mIGT), which eliminates the potential confound of differences in exploratory behavior and allows for separation of approach (choosing to "play" a good deck) and avoidance (choosing to "pass" on a bad deck) behavior, has been developed but has not yet been used in ASD (Cauffman et al., 2010). Decision-making under risk can be assessed using the Game of Dice Task (GDT), where outcomes are unambiguous and explicit. Zhang et al. (2015) found impaired performance and suboptimal use of trial feedback in ASD.

Objectives:

1. Investigate decision-making under risk in ASD using the GDT. 2. Examine decision-making under ambiguity in ASD using the new mIGT.
3. Characterize decision-making performance across both tasks using cluster analysis.

Methods: 84 participants with ASD (Age = 17.45[3.16]; FSIQ = 100.52[14.91]) and 88 participants with typical development (TD) (Age = 17.35[3.15]; FSIQ = 109.16[12.35]) performed the GDT and mIGT.

In the GDT a bet is placed on 1, 2, 3 or 4 sides of the die. A selection of 1 or 2 sides is considered "risky," while selection of 3 or 4 sides is considered "safe." For each mIGT trial one of four decks is pre-selected and can be "played" or "passed." Two decks are profitable (good decks) and two decks are not (bad decks).

Results: GDT:

Mean net score (#safe choices – #risky choices) was significantly higher for those with TD (11.58[9.00]) versus ASD (7.69[8.99]), U=2592.000, p=.001. TD was more likely to place a safe bet following a "safe" win trial (U=2517.000, p=.003) compared to ASD, indicating better use of positive feedback (Fig.1).

mIGT:

Participants with TD showed better avoidance of bad decks compared to ASD (U=3041.000, p=.043) and had a greater net score at the end of the task compared to ASD (U=3053.500, p=.046) (Fig.2).

Cluster Analysis:

K-means clustering analysis was performed on GDT Net Score, mIGT Net Score for bad decks and mIGT Net score for good decks for all participants (ASD and TD). Three clusters were produced: Cluster 1 was characterized by risky performance on GDT and no learning on mIGT; Cluster 2 was characterized by good performance on GDT and learning to avoid bad decks; Cluster 3 was characterized by good performance on GDT and learning to approach good decks. A Chi Square analysis indicated a significantly different distribution of individuals across the clusters by diagnosis (X^2=8.686, p=.014), with greater than expected individuals with ASD in Cluster 1 (p=.015) and fewer than expected in Cluster 2 (p=.017).

Conclusions: Participants with ASD show impairments in decision making under risk and under ambiguity, where they are specifically impaired at avoiding bad decks. Longitudinal data collection is ongoing, and future analyses will assess development of decision-making processes throughout adolescence and young adulthood as well as associations with comorbid psychopathology and adaptive functioning.

412.013 *(Poster)* Delayed Sleep Onset Is Associated with Emerging Behavioral Regulation Difficulties in Youth with Autism

R. Tesfaye[1], *N. J. Wright*[2], *R. Bedford*[3], *A. Zaidman-Zait*[4], *T. Bennett*[5], *E. Duku*[6], *S. Georgiades*[6], *P. Mirenda*[7], *I. M. Smith*[8], *W. J. Ungar*[9], *T. Vaillancourt*[10], *C. Waddell*[11], *L. Zwaigenbaum*[12], *A. Pickles*[13], *P. Szatmari*[14] *and M. Elsabbagh*[15], *(1)Neuroscience, McGill University, Montreal, QC, Canada, (2)Biostatistics & Health Informatics, Kings College London, London, United Kingdom, (3)King's College London, London, United Kingdom, (4)Tel-Aviv University, Tel-Aviv, Israel, (5)Offord Centre for Child Studies, McMaster University, Hamilton, ON, CANADA, (6)McMaster University, Hamilton, ON, Canada, (7)University of British Columbia, Vancouver, BC, Canada, (8)Dalhousie University / IWK Health Centre, Halifax, NS, CANADA, (9)University of Toronto / The Hospital for Sick Children, Toronto, ON, Canada, (10)University of Ottawa, Ottawa, ON, Canada, (11)Simon Fraser University, Vancouver, BC, Canada, (12)University of Alberta, Edmonton, AB, Canada, (13)King's College London, Institute of Psychiatry, Psychology and Neuroscience, London, United Kingdom, (14)The Hospital for Sick Children, Toronto, ON, Canada, (15)McGill University, Montreal, QC, Canada*

Background: Sleep is disturbed in up to 80% of children with autism spectrum disorder (ASD). Observational and experimental studies have found poor sleep impairs executive functioning (EF) performance, which includes skills like cognitive flexibility and inhibition, in typically developing youth and youth with other developmental disorders. EF is a well-documented lifelong difficulty in individuals with ASD. Accumulating biological evidence and developmental accounts suggest that EF deficits in ASD may be exacerbated by poor sleep affecting neural pathways responsible for EF development. To date, the impact of childhood sleep disturbances on EF development in ASD are unknown.

Objectives: To examine if sleep problems in school-age children with ASD are associated with emerging EF difficulties. Specifically, we hypothesized that frequent night awakenings, longer sleep onset and shorter sleep duration at 6 years of age would be associated with lower teacher-reported EF performance at 7 years.

Methods: Data were drawn from an ongoing Canadian longitudinal study *Pathways to better outcomes*. Items on the *Children's Sleep Habits Questionnaire* were used to capture sleep quantity and quality for 113 children (mean age = 6.6 years, SD = 3.7). A binary coding approach was used to categorize night awakenings and sleep onset (0 = never, 1= sometime or always), and average sleep duration per weeknight was in hours. Raw scores on the Metacognition (MCI) and Behavioral Regulation (BRI) indices on the teacher *Behavior Rating Inventory of Executive Functioning* were used to measure EF approximately one year later (mean age = 7.7 years, SD = 3.1).

Two separate linear regression models, for MCI and BRI, were used to examine associations between sleep and EF, controlling for study site, age, and household income. As a secondary step, additional regression models were run accounting for IQ and ASD symptom severity with the ADOS calibrated severity score, to test the specificity of associations between sleep and EF.

Results: Delayed sleep onset predicted higher BRI (i.e., poorer behavioral regulation), accounting for all covariates (ß = 0.23, p = 0.02). Night awakenings (ß = -0.14, p = 0.21) and sleep duration (ß = 0.17, p = 0.10), did not significantly predict BRI. In contrast, no sleep variable predicted MCI: sleep onset (ß = 0.14, p = 0.15), night awakenings (ß = 0.08, p = 0.50), nor sleep duration (ß = 0.15, p = 0.17).

Conclusions: Delayed sleep onset is a robust predictor of behavioral regulation problems in school-age children with ASD, controlling for covariates of IQ and ASD symptom severity. Delayed sleep onset often leads to daytime sleepiness and is a core symptom of insomnia, the most frequently reported sleep disturbance in ASD. Difficulties initiating sleep could indicate internal dysregulation due to circadian rhythm disturbances (that control sleep timing), which have been documented in ASD. Such disturbances are strongly linked to behavioral problems in youth, including impaired inhibition and cognitive shifting, functions included in the BRI. Follow-up investigations will include examining the relationship between sleep disturbance and specific EF behavioral subscales, controlling for daytime sleepiness, which can impair daily regulatory abilities.

412.014 *(Poster)* Distinguishing between Implicit and Explicit Measures of Metacognition in Autism

S. E. Lind[1], *T. Nicholson*[2], *D. M. Williams*[3], *P. Carruthers*[4] *and C. Grainger*[5], *(1)City, University of London, London, United Kingdom, (2)University of Kent, Canterbury, England, United Kingdom, (3)University of Kent, Canterbury, United Kingdom, (4)University of Maryland, College Park, MD, (5)University of Stirling, Stirling, United Kingdom*

Background: Metacognitive monitoring (awareness of one's own mental states/cognition) is a key component of self-awareness and plays an important role in learning. The few existing studies of metacognitive monitoring in autism have required participants to make explicit judgements about their knowledge. The closer the correspondence between *judgements* of one's knowledge and one's *actual, objectively measured* knowledge, the more accurate one's metacognitive monitoring is. Previous findings using such tasks have been mixed.

Objectives: We aimed to resolve discrepancies in previous findings by employing not only a standard, explicit test of metacognitive monitoring, but also a "gambling" paradigm adapted from comparative psychology to assess metacognitive monitoring non-verbally/implicitly.

Methods: Twenty-five children/adolescents with ASD and 25 age- and IQ-matched typically developing comparison children/adolescents took part. The implicit and explicit tasks are illustrated in Figures 2 and 3, respectively. Each involved a visual discrimination "object level" task; either choosing the most densely pixelated or lightest blue of two arrays. In the implicit task, after each discrimination trial, participants chose between a circle and a triangle, which appeared on screen. Points were awarded/taken away depending on whether discriminations were correct or incorrect, and whether the circle or triangle was selected, as follows:

- correct + triangle -> win 30 points;
- correct + circle -> win 10 points;
- incorrect + triangle -> lose 30 points;
- incorrect + circle -> lose 10 points.

Accurate implicit metacognitive monitoring was indicated by a greater tendency to choose the triangle (high risk) more on correct than incorrect discrimination trials, and to choose the circle (low risk) more on incorrect than correct trials.

In a second session, participants completed the explicit task (using different visual discrimination stimuli for the object level task). This time, after each discrimination trial, participants chose between the options, "confident" or "not confident", rather than triangle or circle. The points structure was equivalent to the one in the implicit task. Accurate explicit metacognitive monitoring was indicated by a greater tendency to choose "confident" on correct than incorrect discrimination trials and, to choose "not confident" more on incorrect than correct trials.

Results: On the implicit task, gamma scores (the measure of metacognitive accuracy) were slightly and non-significantly lower among participants with ASD than comparison participants in the implicit task (Bayes factor supported the null hypothesis; ASD: M = .37, SD = 32; comparison: M = .45, SD = .28), $t(49) = 0.95$, p = .25 d = 0.27, but on the explicit task, they were moderately and significantly lower (Bayes factor supported the alternative hypothesis; ASD: M = .35, SD = .28; comparison: M = .51 SD = .26), $t(49) = 1.98$, p = .02, d = 0.59. Correlations between metacognitive monitoring, theory of mind, and autism traits were also analysed.

Conclusions: These results provide further evidence for explicit metacognitive monitoring difficulties in autism. More importantly, as the first study of non-verbal/implicit metacognitive monitoring in autism, the results extend the field significantly; indicating a strength for autistic individuals in this domain. Implications for theory and clinical practice will be discussed.

412.015 *(Poster)* Episodic Memory Dysfunction in ASD – Is It Real?

M. A. Alkan[1]*, A. Easton*[1]*, D. M. Riby*[2] *and T. V. Smulders*[3]*, (1)Psychology, Durham University, Durham, United Kingdom, (2)Department of Psychology, Durham University, Durham, United Kingdom, (3)Bioscience Institute, Newcastle University, Newcastle upon Tyne, United Kingdom*

Background: Episodic memory (EM) is memory for past events in specific spatial-temporal contexts ('what-where-when' memory) (Tulving, 1972). In typical development, EM emerges around 4-5 years of age (Tulving, 2003, 2005). Existing research suggests that individuals with autism spectrum disorder (ASD) display significantly poorer memory when recalling episodic events, compared to neurotypical controls (NT) - which might derive from diminished autonoetic (self-knowing) consciousness and impaired binding processes. However, often tests of EM use verbal material to be recalled which can be problematic for young NT children and children with ASD. Moreover, it is still not well understood how EM develops. Language delays and language impairments are documented in ASD. Therefore, complying with the demands of traditional EM tasks which rely on the language capacity of the child may underestimate their EM ability. Here, we report the first experiments exploring EM in ASD using a behavioural and nonverbal measure of EM which allows us to identify the integration and binding of different associations within an episodic representation – enabling children to show us rather than tell us about the contents of their memories.

Objectives: The aim of this study was to provide the first insights into EM in ASD using a behavioural and non-verbal measure of memory that allows us to disambiguate events in spatiotemporal context, with information about What happened, Where and in Which occasion.

Methods: We developed a hide-and-seek task combining elements of the "What-Where-When" memory test by Holland and Smulders (2011) and the "What-Where-Which" memory test by Eacott & Norman (2004). At this stage 5 children with ASD (mean age = 7.8 years; SD = 1.58 [5 Male]) and 49 NT children (mean age = 5.2 years; SD = 0.9 [30 Male; 19 Female) participated. Children completed two sessions to hide six coloured pens (what) at specific locations (where) in two different contexts (which). At retrieval, children retrieved 6 pens across two sessions yielding two trials each of What-where, What-Which and What-Where-Which. Cognitive functioning was assessed using Wechsler Intelligence Scale (WPPSI-IV and WAIS-IV) and will be used to match the groups (ASD and NT) on mental age.

Results: A GZLM was performed on binary data using group as the dependent variable, and trial type as the predictor to see if there was an effect of group on performance in the episodic task. Results showed no effect of group on accuracy in the WWWhich episodic task: Main effects of Group: Wald $X^2 = 5.229$, p=. 0.265. Comparisons to chance revealed that NT children are performing well over chance (p<0.05) and a similar pattern is observed in a slightly older group of ASD children (p=0.08, d=1.04).

Conclusions: Initial findings suggest that contrary to existing research reporting poorer episodic skills among children with ASD, children with ASD demonstrate a pattern of performance similar to TD children. The study provides a preliminary suggestion that when language is removed from a WWWhich task autistic children show a relatively typical pattern of performance, certainly no clear evidence of atypicality.

412.016 *(Poster)* Examination of Behavior Problems in Children with Autism Spectrum Disorder: Influence of Executive Functions

M. T. Chen[1]*, C. H. Chiang*[2] *and Y. A. Lin*[3]*, (1)Psychology, National Chengchi University in Taiwan, Taipei City, NC, Taiwan, (2)Department of Psychology, National Chengchi University, Taipei City, Taiwan, (3)Tri-Service General Hospital, Taipei, Taiwan*

Background: the literature has established the interconnections between autism spectrum disorder (ASD) and individual weak executive functions (EFs), as well as the relationship between ASD symptoms and problem behaviors. However, only a few studies have investigated how EFs affect children with ASD on their behavior problems, and if the influence of EFs work the same way among typically development (TD) children.

Objectives: the goal of the current study is to investigate if EFs produce different degrees of influence on behavior problems between the TD and the ASD group.

Methods: the present ASD sample includes 29 children who was formally diagnosed with ASD by a team including psychiatrists and clinical psychologists and met the ASD cut-off by Autism Diagnostic Observation Schedule (ADOS) and the Autism Diagnostic Interview-Revised (ADI-R). All 25 children of the TD sample did not demonstrate ASD characteristics while using social communication questionnaire. The ASD and the TD group were comparable in age (grand M = 105.79 months, SD = 1.95), sex (88.89% male), and the intelligence quotient (IQ). We assessed all participants' EFs and problem behaviors, using the behavior rating inventory of executive function (BRIEF) and the child behavior checklist (CBCL) respectively.

Results: trending in the expected direction, the results showed that the ASD group demonstrated significantly more problem behaviors than did the TD group ($p < .001$). Critically, the difference was fully mediated by the weaker EFs of the ASD group (EFs $p < .001$; after controlling for EFs, ASD status $p = .103$) and a marginally significant interaction between EFs and ASD status that buffered the detrimental effect of EFs on PB for the ASD group ($p = .063$). Because of the small sample size and that BRIEF consists of a behavior regulation index (BRI) and metacognition index (MI) aspect of EFs, we further explored the effects of these two types of EFs on problem behaviors separately. The results replicated and strengthened the former findings on composite EFs for BRI, in that now ASD status significantly buffered the negative effect of weak BRI on problem behaviors for the ASD group (interaction $p = .009$). The same moderation, however, disappeared for MI: weaker MI predicted more problem behaviors regardless of ASD status (interaction $p = .259$).

Conclusions: the current research indicates that even though weak EFs may contribute to children's problem behaviors in the ASD group, change in EFs might actually impact their problem behaviors less than for children in the TD group. This finding is especially pronounced when one focuses on BRI, and it disappears for MI. Overall, the results imply that more basic components of EFs such as MI compared to BRI should be treated first to reduce problem behaviors.

412.017 *(Poster)* Executive Functions in High School Students Graduating with a Regular Diploma: Associations with the Ability to Self-Manage Daily Life Tasks and Internalizing and Externalizing Behaviors

***G. I. Orsmond**, E. G. Munsell and W. J. Coster, Department of Occupational Therapy, Boston University, Boston, MA*

Background: Executive functions (EF) may play a prominent role in the transition to adulthood as youth assume new responsibilities, especially for high school students on the autism spectrum who plan to continue to college or competitive employment. We examined EF profiles in high school students on the autism spectrum who were in their last year of school and preparing to graduate with a regular high school diploma. We then examined whether EF predicted key outcomes (the ability to self-manage daily life tasks; internalizing and externalizing behaviors).

Objectives: The objectives were to: (1) describe the EF profiles of diploma-track high school students on the autism spectrum; and (2) examine the associations among executive functions, the ability to self-manage daily life tasks, and internalizing and externalizing behaviors.

Methods: Participants were 33 parents and 32 youth on the autism spectrum who were in their last year of high school and expecting to graduate with a regular high school diploma. Youth ranged in age from 17 – 20 years old and 25 were male (78%). All youth had a parent-report diagnosis of autism spectrum disorder (ASD), received special education services or accommodations for ASD, and had a score of 15 or higher on the Social Communication Questionnaire (SCQ-L; Rutter et al., 2003). Parents and youth separately completed the Behavior Rating Inventory of Executive Function – Adult Version (BRIEF-A; Roth et al., 2005). Parents completed the Adult Behavior Checklist (ABCL; Achenbach & Rescorla, 2003) and a measure of the youth's ability to self-manage daily life tasks (PEDI-CAT-ASD Responsibility domain; Haley et al., 2012). The BRIEF-A includes an overall Composite score (GEC), Behavioral Regulation Index (BRI; subscales Inhibit, Shift, Emotional Control, and Self-Monitor) and Metacognition Index (MCI; subscales Initiate, Working Memory, Plan/Organize, Task Monitor, and Organization of Materials).

Results: Repeated measures MANOVA indicated that parents reported that the youth had more EF challenges than the youth reported themselves (BRIEF-A GEC, BRI, MCI, and all subscales). Parents reported that youth had clinically significant levels of EF difficulties on the Shift, Initiate, Working Memory, Plan/Organize, Task Monitor and Organization of Materials subscales. Youth did not report clinically significant difficulties on any of the subscales. Regression analyses using parent-report data showed that MCI significantly predicted greater difficulty in self-managing daily life tasks ($B = -.361$, $p < .001$), whereas BRI significantly predicted greater internalizing ($B = .391$, $p < .05$) and externalizing behaviors ($B = .673$, $p < .000$).

Conclusions: Diploma-track high school students on the autism spectrum showed variable EF profiles with elevated impairments in shifting attention, initiation, working memory, planning and organizing, and monitoring tasks. Parents consistently reported that the youth had more EF impairments than did the youth, a pattern observed in other self- versus proxy-reports of behaviors and skills of youth on the autism spectrum. Metacognitive impairments were associated with difficulty self-managing daily life tasks while behavioral regulation impairments were associated with internalizing and externalizing behaviors. The findings suggest important directions for services, supports, and interventions for diploma-track high school students on the autism spectrum.

412.018 *(Poster)* Exploring Mediating Effects of Executive Functions to Explain Relationships between Psychopathology and Social Adaptive Functioning in a Mixed Clinical Sample, Including Autism Spectrum Disorder

***K. Schauder**[1], X. You[2], S. Li[3], C. Jeppsen[4], K. Flaharty[5], M. F. Skapek[6], R. Clinton[7], A. Verbalis[4], C. E. Pugliese[4], C. Vaidya[8] and L. Kenworthy[4], (1)Center for Autism Spectrum Disorders, Children's National Hospital, Rockville, MD, (2)Center for Neuroscience, Children's National Hospital, Washington DC, DC, (3)Georgetown University, Washington DC, DC, (4)Center for Autism Spectrum Disorders, Children's National Hospital, Washington, DC, (5)Georgetown Unviersity, Washington DC, DC, (6)Psychological Sciences, University of Connecticut, Storrs, CT, (7)Children's National Health System, Washington, DC, (8)Psychology, Georgetown University, Washington, DC*

Background: It has long been established that the presence and extent of psychopathology predicts adaptive functioning, with higher internalizing and externalizing symptoms leading to poorer adaptive outcomes. Executive function (EF) is related to both psychopathology and adaptive functioning and is disrupted across several clinical disorders, leading to the idea that EF may be a shared mechanism to explain links between psychopathology and adaptive functioning. Specifically, EF is an important precursor to social skills, and executive dysfunction predicts poorer social outcomes in individuals with ASD.

Objectives: To explore components of EF as possible mediating mechanisms in the relationship between psychopathology and social adaptive functioning.

Methods: Within the Research Domain Criteria (RDoC) framework, 133 children (ages 8-13) participated in an ongoing study examining profiles of EF and their underlying functional neural circuitry across clinical disorders, including ASD, attention-deficit/hyperactivity disorder, and generalized anxiety disorder. Internalizing and externalizing psychopathology was rated by parents on the Child Behavior Checklist (CBCL) and social adaptive functioning was assessed with the Social Domain of the Vineland Adaptive Behavior Scales, Third Edition. Three dimensions of EF -- shift/flexibility, inhibition, and working memory -- were assessed using both the Behavior Rating Inventory of Executive Function (BRIEF-2; parent report) and tasks tapping these specific EF dimensions that were completed during an fMRI scan. Correlations between measures of psychopathology, social adaptive behavior, and EF were explored, and mediation models were further tested to establish which components of EF mediate the relationship between psychopathology and social adaptive behavior.

Results: Increased psychopathology was associated with decreased social adaptive functioning (internalizing: $r(131) = -.35$, $p < .001$); externalizing: $r(131) = .38$, $p < .001$). All parent-report measures of EF were significantly positively correlated with measures of psychopathology (r's: .23 to .65) and significantly negatively correlated with social adaptive functioning (r's: -.18 to -.43). Task-based measures were not significantly correlated with their corresponding parent-report index of EF, nor with measures of psychopathology or social adaptive functioning. Mediation analyses revealed that the relationship between psychopathology (internalizing and externalizing symptoms) and social adaptive functioning is mediated by parent-reported executive functions of shifting (Internalizing: CI = -.41 to -.11; Externalizing: CI = -.35 to -.09) and inhibition (Internalizing: CI = -.27 to -.04; Externalizing: CI = -.52 to -.07), but not working memory (Internalizing: CI = -.14 to .04; Externalizing: CI = -.13 to .03).

Conclusions: The relationship between psychopathology and social adaptive functioning is mediated by parent-reported executive functions of shifting and inhibition, but not working memory. This suggests that one's ability to flexibly respond and inhibit impulses may explain how the presence of psychopathology manifests into real-world adaptive difficulties, at least in the social domain. Future directions include investigating other domains of adaptive functioning and more specific aspects of psychopathology (e.g., anxiety, aggression). Additionally, it will be important to understand how task-based behavioral measures of EF and functional neural networks relate to parent-reported EF and to measures of psychopathology and adaptive functioning. Finally, establishing shared and unique mechanisms across disorders will support targeted treatment and intervention.

412.019 *(Poster)* Inefficient Information Sampling Under Explicit Costs in Children with ASD

H. Lu[1,2], *L. Yi*[3] *and H. Zhang*[2,4,5], *(1)Academy for Advanced Interdisciplinary Studies, Peking University, Beijing, China, (2)Peking-Tsinghua Center for Life Sciences, Peking University, Beijing, China, (3)School of Psychological and Cognitive Sciences and Beijing Key Laboratory of Behavior and Mental Health, Peking University, Beijing, China, (4)School of Psychological and Cognitive Sciences, Peking University, Beijing, China, (5)PKU-IDG/McGovern Institute for Brain Research, Peking University, Beijing, China*

Background: Information from the environment is generally beneficial but can also be costly to gather. Balancing the costs and benefits of information sampling and sampling optimally is thus central to human survival. One of the core symptoms of autism spectrum disorders (ASD), repetitive behaviors, may be interpreted as a failure to take into account the cost of information sampling; that is, spending too much time and energy to gather information that is redundant and helps little to reduce uncertainty (Palmer, Lawson, & Hohwy, 2017). How people with ASD trade-off the costs and benefits of information sampling, however, has received little research yet. By introducing explicit monetary costs into an information-sampling game, one recent study (Lu, Yi, & Zhang, 2019) found that adults with high autistic traits have a lower efficiency of winning rewards when the cost is high and the evidence is ambiguous.

Objectives: The present study aims to understand whether ASD influences the optimality of information sampling in children, specifically when additional information is beneficial for future decisions but incurs explicit costs.

Methods: Fourteen children with ASD and 21 typically developing (TD) children played a computer-based information-sampling game adopted from Lu et al. (2019). In each trial, children were faced with two islands: one island had a dog-to-cat ratio of 80%:20% or 60%:40%, and the other had the opposite ratio. They were told one island was secretly selected and could sample up to 20 animals sequentially with replacement from the selected island to infer which had been selected. However, each sample would cost 0, 0.1, or 0.4 points from 10 points that children could gain at most for each correct inference. The experiment consisted of 96 trials, with 3 cost blocks counterbalanced between children and two ratio blocks in a random order nested in each cost block.

Results: In all analyses, we regressed out the effects of age and IQ to control the group differences. To quantify the optimality of sampling, we used sampling efficiency – the expected gain for children's sampling numbers divided by the maximum expected gain. We found that the efficiency of the ASD group was lower than the TD group (Fig. 1a), specifically in the high-cost condition (i.e., 0.4 points). Further analyses showed that the absolute deviation from the ideal sampling numbers of children with ASD was significantly larger than TD in the high-cost condition (Fig. 1b). However, both groups showed a similar bias towards oversampling overall in the high-cost conditions (Fig. 1c). Results showed that children with ASD had a higher variation of sampling numbers across trials overall, particularly in the low-cost condition (i.e. 0.1 points) and also an evident trend in the high-cost condition (Fig. 1d).

Conclusions: In sum, we found that sampling choices of children with ASD were less optimal compared to TD children particularly when information gathering was highly costly, even after statistically controlling age and IQ differences. Together with Lu et al. (2019), ASD or high autistic traits suggest lower efficiency in sampling behaviors, but only under high sampling costs.

412.020 *(Poster)* Judgements of Auditory Visual Synchrony and Their Association with Reported Anxiety.

J. M. Bebko[1], *A. Porthukaran*[2], *A. Ledenko*[1], *M. Ferland*[3], *M. Segers*[1] *and B. L. Ncube*[2], *(1)York University, Toronto, ON, Canada, (2)Psychology, York University, Toronto, ON, Canada, (3)York University, Toronto, ON, CANADA*

Background: Auditory and visual information is often processed as one seamless experience even when there are slight temporal differences in the perception of this information. The degree of acceptance of asynchrony, for example in auditory-visual information, is what defines the temporal binding window (TBW). People with ASD have larger TBWs, which, in principle, means that other unrelated stimuli have a greater probability of interference with information that should be bound. While there is an emerging body of evidence on the TBW in ASD, the practical consequences of a difficulty binding information that should be related needs further clarification.

Objectives: We examined whether less accuracy of temporal binding could be associated with increased difficulties in other areas, such as anxiety in social situations where visual and auditory information must be processed quickly, or more generalized anxiety. We also examined potential links among IQ, autism symptoms, anxiety and the size of the TBW.

Methods: Samples were: Twenty children with ASD, ages 7-17 years (Mean=12.58, SD=2.88), 74% males, mean IQ=105.53 (SD=11.92); and thirty typically developing children, ages 7-18 years (Mean=11.90, SD=3.05), 32% males, mean IQ=103.34 (SD=9.67).

Synchrony Judgement Task: Participants decided whether the auditory and visual information in a brief stimulus was synchronous or not, the timing varying randomly across trials. The dependent variable was the number of errors in synchrony judgement. The stimuli consisted of a woman who expressed emotions (crying or laughing), social linguistic stimuli (SL; sharing a brief story), social non-linguistic stimuli (SNL; making non-word oral sounds) or stimuli that were non-social and non-linguistic (NSNL; a finger playing notes on a piano). Participants were also given a brief measure of IQ (Weschler Abbreviated Scale of Intelligence (WASI-2)), and parents completed measures looking at anxiety (Spence Children's Anxiety Scale) and autism symptoms (Sensory Profile 2 and the Social Responsiveness Scale).

Results: There were no significant correlations among measures of autism symptoms and the behavioural task. However, in the ASD sample, children who made more errors in synchrony judgements on the SL and SNL stimuli had lower scores on the WASI (verbal, non-verbal, as well as total; all r ranging from -0.52 to -0.63, $p < 0.05$). In addition, for children with ASD, there were significant correlations between reports of anxiety and their performance on synchrony judgement tasks. For example, children whose parents reported lower social anxiety made fewer synchrony judgement errors in the social conditions (i.e. SL and SNL; r = - 0.47, -0.65, respectively), while children with higher reported levels of social anxiety made more synchrony judgement errors in the NSNL condition.

Conclusions: Social interactions involve the rapid integration of auditory and visual information in interpersonal situations. Errors in identifying which components of an interaction should be bound together would make understanding social events chaotic, leading to increased anxiety, as components may be serendipitously or associatively bound that are quite unrelated. The current findings indicate that in ASD, the inability to make accurate synchrony judgements is related both to intelligence and reported social and general anxiety.

412.021 *(Poster)* Lack of Agreement between Self, Parent, and Clinician Reports of ADHD Symptoms in Adolescents with ASD

K. King[1]*, M. K. Krug*[2] *and M. Solomon*[3]*, (1)Psychiatry and Behavioral Sciences, MIND Institute, Sacramento, CA, (2)Department of Psychiatry & Behavioral Sciences, UC Davis MIND Institute, Sacramento, CA, (3)Department of Psychiatry and Behavioral Sciences, The Medical Investigation of Neurodevelopmental Disorders (MIND) Institute, UC Davis School of Medicine, University of California Davis, Sacramento, CA*

Background: It can be difficult to diagnose attention deficit hyperactivity disorder (ADHD) in individuals with autism spectrum disorder (ASD) due to the atypical and idiosyncratic attention patterns they often display (Dawson & Lewy, 1989). Reports about rates of ADHD in ASD vary from 29% to 73% (Ovsanna T. Leyfer & Susan E. Folstein, 2006). Two potential causes of this discrepancy include diagnostic overshadowing (Miodovnik, Harstad, Sideridis, & Huntington, 2015) and differences in sensitivity, and or validity of the measures used to assess ADHD symptoms. While the Achenbach System of Empirically Based Assessment (ASEBA) (Achenbach & Rescorla, 2001; 2003),The Conners' Rating Scale (Conners, 1973; Fee, Matson, & Benavidez, 1994), and the Kiddie Schedule for Affective Disorders (K-SADS) (Masi, Favilla, & Mucci, 2000; Masi, Mucci, Favilla, & Poli, 1999) have been used in ASD they have not yet been tested for reliability and validity in autism in a single comprehensive study (Leyfer, 2006).

Objectives: Investigate inter-rater agreement between clinicians (K-SADS (adolescents); The Structured Clinical Interview for DSM V (SCID) (American Psychiatric Association, 2015) and self and parent report for adolescent and young adult participants (CONNERS 3 (Conners, 2008); Conners Adult ADHD Rating Scales (CAARS) (Christiansen, Hirsch, Abdel-Hamid, & Kis, 2014); ASEBA) when rating ADHD symptoms.

Methods: 47 adolescents (Mean Age= 14.9; Mean FSIQ = 101.4) and 41 young adults with ASD (Mean Age = 20.3; FSIQ = 99.4) participated. Each participant met criteria for ASD on The Autism Diagnostic Observation Schedule (ADOS) (Lord et al., 2000) and Social Communication Questionnaire (SCQ) (Rutter, Bailey, & Lord, 2003). The SCID and K-SADS were administered to both adolescent and adult participants separately by trained raters. ADHD symptoms were assessed with the ASEBA parent and self-report questionnaires. The CONNERS 3 self and parent report were completed for adolescent participants and the self and parent report CAARS questionnaires were completed for adult participants.

Results: 40.4% of the ASD sample met diagnostic criteria for ADHD on the K-SADS (Table 1) and 17% met diagnostic criteria on the SCID (Table 2). The Inattention domain on the CONNERS 3 and CAARS parent reports best matched the ADHD rates found in the clinical interviews (χ^2 = .090, p=.764 and χ^2 =.00, p=1.0 respectively). ASEBA parent and self-report underrepresented the ADHD rates found in the clinical interviews for adolescents, but the ASEBA Attention Problems scale fell close to the clinical interview rate in adult participants (χ^2 =.57, p=.450 for parent report and χ^2 =.91, p=.34 for self-report).

Conclusions: The CONNERS 3 and CAARS best coincide with ADHD rates found in the clinical interview (SCID/K-SADS). The ASEBA does not capture ADHD rates in the ASD population as well when looking at individuals under 18. With age, both parent and self-report on the ASEBA are more in alignment with clinical interview rates. It is essential in clinical practice to understand which measures most accurately assess ADHD in ASD for optimal treatment outcomes.

412.022 *(Poster)* Long-Term Melodic Memory Among Children with Autism Spectrum Disorder.

S. T. S. Wong*, S. Stanutz, S. Sivathasan, E. Stubbert, J. Burack and E. M. Quintin, Educational & Counselling Psychology, McGill University, Montreal, QC, Canada*

Background: Short and long-term memory for individual tones and melody are enhanced among some musically untrained persons with autism spectrum disorder (ASD) (Bonnel et al., 2003; Stanutz, Wapnick, & Burack, 2014). Particularly, absolute pitch (AP), the ability to identify pitch of a tone without a reference pitch, is enhanced among musical savants with autism (Hermelin, 2001). As the abilities to identify and distinguish pitches are not as outstanding in typically developing (TD) children (Cooper, 1995; Fancourt, Dick & Stewart, 2013), AP may offer a potential framework for understanding the musical memory strengths of persons with ASD.

As visual-spatial skills have been linked to musical learning among both TD persons (Rauscher & Zupanee, 2000) and musical savants with ASD (Heaton 2012), they may be a potential mechanism for the enhanced musical memory among persons with ASD.

Objectives: Investigate the potential roles of pitch memory and visual-spatial skills in performance on a melodic memory task among high functioning children with ASD.

Methods: High functioning children with ASD aged 8-12 years and TD children matched on chronological (and mental) age learned 4 melodies and completed a melodic memory task one week later. In the first session, the participants learned melodies in a specific key that were each matched to a specific animal. One week later, the participants were presented each of the four melodies in the original key and two other transposed keys. They were then asked to identify 1) the key in which they originally learned each melody; and 2) the animal with which each melody was paired. The Wechsler Abbreviated Scale of Intelligence, 2nd edition (WASI-II), Digit Span of the Wechsler Intelligence Scale for Children, 5th edition (WISC-V, DS), Salk and McGill Music Inventory (SAMMI, Levitin et al. 2004), and Music Training and Experience Questionnaire (MTEQ, Quintin et al., 2011) were administered to account for intelligence and musical experience. The children with ASD were assessed with the Autism Diagnostic Observation Schedule, 2nd edition (ADOS-2) to confirm their diagnosis. One parent of each child completed the Social Responsiveness Scale, 2nd edition (SRS-2) and the Social Communications Questionnaire Lifetime version (SCQ-L) to ascertain autism symptomatology among the participants with ASD and to ensure that the TD children did not present with signs of ASD.

Results: In preliminary analyses, 7 children with ASD showed more accurate long-term melodic memory ($p < .05$) than 16 TD children after accounting for intelligence and auditory working memory (measured with WISC-V, DS), but no group difference were found in distinguishing the target melody from the transposed version of the melody ($p > .05$) (Figure 1). Correlational analyses revealed a positive relationship between accuracy in pitch memory task and all of the cognitive measures among the participants with ASD, but not among the TD participants (Table 1).

Conclusions: These tentative findings suggest that previously documented strengths in musical memory among children with ASD are attributable to melodic memory rather than pitch memory. They also suggest the potential cognitive overlap between visuo-spatial skills and pitch memory within children with ASD.

412.023 *(Poster)* Motor Ability As a Predictor of Language Ability in Older Children in Autism Spectrum Disorder

T. Sanjeevan[1]*, D. Zhang*[2] *and E. Anagnostou*[3]*, (1)Autism Research Centre, Holland Bloorview Kids Rehabilitation Hospital, Toronto, ON, Canada, (2)Medicine, University of Toronto, Toronto, ON, Canada, (3)Holland Bloorview Kids Rehabilitation Hospital, Toronto, ON, Canada*

Background: Procedural memory, a system involved with sequence-specific learning across motor and cognitive skills, has been argued to underlie language learning. Recent literature has suggested that deficits in procedural learning may, therefore, contribute to language and motor deficits across children with neurodevelopmental disorders including Autism Spectrum Disorder (ASD), a proportion of whom experience both motor and language impairment. Previous studies have reported that fine motor abilities, but not gross motor abilities, predict receptive and expressive language abilities in infants with ASD. Given that language and motor skills are still developing during infancy and early childhood, we may find differences in these associations in older children with and without ASD. Understanding these relationships at different ages can inform service development and ensure that services are tailored to meet the needs of children with ASD across age groups.

Objectives: This study is currently evaluating the language and motor abilities of school-aged children with and without ASD to determine which areas (fine motor, gross motor and balance) of motor ability predict receptive and expressive language abilities.

Methods: Eighteen children have participated in the study thus far. Five children with ASD were age (9-13 years) and IQ-matched with thirteen typically developing (TD) children. Participants completed (1) the Perceptual Reasoning subscale of the Wechsler Abbreviated Scale of Intelligence – Second Edition (WASI-2) as a standardized measure of non-verbal intelligence; (2) the Bruininks-Oseretsky Test of Motor Proficiency – Second Edition (BOT-2) as a standardized measure of fine and gross motor ability and balance; and (3) The Oral and Written Language Scales – Second Edition (OWLS-2) as a standardized measure of receptive and expressive language abilities. We conducted two hierarchical regressions: one with listening comprehension standard scores (receptive language) as the dependent variable and the other with oral expression standard scores (expressive language) as the dependent variable. We entered nonverbal IQ and diagnosis to control for confounding effects and six subscale standard scores of the BOT-2: Fine Motor Precision, Fine Motor integration, Manual Dexterity, Upper-limb Coordination, Bilateral Coordination and Balance.

Results: Our preliminary results are promising. The Fine Motor Precision standard scores were a significant predictor of receptive language scores, accounting for 24.8% of variance in scores across ASD and TD groups beyond non-verbal IQ and diagnosis, $F(1,14) = 6.320$, $p = 0.025$. Additionally, the Balance subscale appears to be trending towards significance, accounting for 16.1% of variance in scores beyond non-verbal IQ and diagnosis, $F(1,14) = 3.552$, $p = 0.058$. For expressive language scores, none of the BOT-2 subscales were significant predictors.

Conclusions: The initial results of this ongoing study indicate that in addition to fine motor abilities, balance may potentially be associated with language abilities in older children with and without ASD. These findings suggest that the relationship between motor and learning abilities may not be limited to sequencing.

412.024 *(Poster)* Print Vs. Pictures: Are Eye-Gaze Differences in Children with and without ASD during Shared Book Reading Associated with Emergent Literacy Skill Performance?

R. T. Wicks[1]*, J. M. Paynter*[2]*, M. Stainer*[2] *and M. F. Westerveld*[1]*, (1)School of Allied Health Sciences, Griffith University, Gold Coast, QLD, Australia, (2)School of Applied Psychology, Griffith University, Gold Coast, QLD, Australia*

Background: Significant challenges in becoming proficient readers are found in 30-50% of school-age children with autism spectrum disorder (ASD; Arciuli et al., 2013). Shared book reading during the preschool years facilitates language and emergent literacy learning in typically developing children, including important predictor skills of later reading ability (e.g., alphabet and vocabulary knowledge; NELP, 2008). Yet despite experiencing similar exposure to shared book reading as their peers without ASD, children with ASD often show differences in emergent literacy development. These consistently include relative strengths in print skills (e.g., alphabet knowledge) and challenges in meaning-related skills (e.g., vocabulary, comprehension; Westerveld et al., 2016). Such differences may reflect the detail-focused style observed in ASD which may lead to a greater focus on print versus pictures during shared book reading. Visual attention to print and pictures during shared book reading has been shown to differentially facilitate alphabet knowledge and vocabulary learning in preschoolers without ASD (Evans and Saint-Aubin., 2009; Justice et al., 2008), yet research investigating visual attention during shared book reading and association with emergent literacy performance for preschoolers with ASD is limited.

Objectives: We aimed to investigate differences between preschoolers with and without ASD in attention to print versus pictures during experimental shared book reading tasks. We used eye tracking technology to explore between-group differences in eye gaze to areas of interest (print vs. picture) and links to alphabet and vocabulary knowledge performance.

Methods: Participants included 60 3-5 year-old children (ASD: n = 37; M age = 54.27; SD = 8.88; without ASD: n = 23; M age = 47.43; SD = 8.12) recruited via autism-specific early intervention centres and mainstream childcare centres, local allied health professionals, and social media platforms. Experimental versions of two storybooks were created for viewing on a screen with narration. Children's eye movements were measured using a Tobii X2-30 binocular eye-tracker while each storybook was viewed on a computer screen. To assess children's emergent literacy skills, alphabet knowledge tasks and a vocabulary task (Peabody Picture Vocabulary Test; PPVT-4) were administered.

Results: Linear mixed-effect modelling (LMM) will be used to analyze the eye movement data collected. Models will be fit using the *lme4* package in *R*. The fit of each model will then be evaluated with R^2 using the MuMIn package in *R*. Between group differences in proportions of fixations, latency to first fixation and gaze fixation duration on each area of interest (print vs. pictures) will be analyzed. Fixed effects in the full model will include group (ASD vs. without ASD) and area of interest (print vs. picture); random effects will include subject and item (page of the book).

Conclusions: Findings will contribute to an enhanced understanding of the links between visual attention during shared book reading for preschoolers with ASD and their emergent literacy skills. Results will inform future shared book reading intervention research aimed at providing individualised support to promote emergent literacy and facilitate later reading success for children with ASD.

412.025 *(Poster)* Puzzling It out: Using a Novel Measure to Explore Metacognitive Abilities in Autism

K. Craig[1], *D. Hale*[1], *C. Grainger*[2], *I. Argyropoulos*[3] *and M. E. Stewart*[4], *(1)Heriot-Watt University, Edinburgh, United Kingdom, (2)University of Stirling, Stirling, United Kingdom, (3)Heriot-Watt University, EDINBURGH, United Kingdom, (4)Heriot-Watt University, Edinburgh, United Kingdom of Great Britain and Northern Ireland*

Background: Metacognition, or the understanding of one's own thought processes, is known to improve academic achievement, serves as the basis of therapeutic treatment for mental health conditions, and has been positively linked to social skills in autism. Current metacognitive research in autism has garnered equivocal results. To date there are no tasks which measure multiple metacognitive skills, the ones currently available only evaluate a small subset of skills and often involve language.

Objectives: With the guidance of an autistic mentor, this study looked to develop, explore, and validate a novel task measuring multiple metacognitive skills in order to better understand metacognitive differences in autism.

Methods: Basing the task on the concept of the block design test, a known strength for autistic individuals that lacks the need for language, we aimed to remove confounding effects of task demands on metacognitive processes. Skills evaluated were chosen by their ability to cover the entire metacognitive process that happens before, during and after completing a task. Therefore, the task evaluates planning (study time allocation, planning time), monitoring and control (increased accuracy of study time allocation as task progresses) and reflection (confidence judgments).

Study1

The task was built in PsychoPy and given to participants on a desktop computer. A third of the participants completed the task on their own computers via a link. Seventy-seven participants aged 18-25 took part in the study.

Study 2

Both autistic and neurotypical participants ages 10 to 18 are currently completing the Puzzle Task as part of a battery of assessments. Research is taking place within school-based computer suites.

Results: Study 1

After 39 participants, results indicated ceiling effects in that 15 of the puzzles had 81% or better accuracy rates. Puzzles were made more challenging and 38 additional participants recruited. Due to skew caused by ceiling effects, spearman's correlations were run. All three areas of metacognition (planning, r = 0.26, p = 0.02; monitoring and control r = -0.36, p = 0.002; evaluating r = 0.25, p = 0.03) significantly correlate with achievement as measured by puzzle accuracy. Components of metacognition also significantly correlate with each other (r's from -0.58 to 0.24).

Study 2

Results will be available for the conference.

Conclusions: Study 1

The Puzzle Task is a good task for measuring all aspects of metacognition, allowing the relationship between specific metacognitive skills and behavior to be evaluated in future research. Additionally, the data suggests a strong link between metacognitive abilities and puzzle accuracy, in that participants with longer planning times and better prediction and judgment accuracy complete more puzzles correctly.

Study 2

We expect to find patterns of strengths and weaknesses in autistic metacognitive abilities. This information will inform interventions aimed at improving academic achievement, access to mental health therapy, and/or social interactions in autism.

Note: I can show video of myself demonstrating each part of the task. No participants or sound are included. It is a screen shot capture only.

412.026 *(Poster)* Rhythm Perception: A Preserved Musical Ability of Children with Autism Spectrum Disorder

H. Dahary[1]*, M. Kaedbey*[2]*, C. Rimmer*[1]*, S. Sivathasan*[3] *and E. M. Quintin*[3]*, (1)McGill University, Montreal, QC, Canada, (2)McGill Unversity, Montreal, ON, Canada, (3)Educational & Counselling Psychology, McGill University, Montreal, QC, Canada*

Background: There is growing evidence showing musical ability as a strength of people with autism spectrum disorder (ASD). Many studies demonstrate intact or superior musical pitch, melody, and memory perception in ASD (Heaton, 2009), but only a few studies explore musical rhythm perception abilities. The preliminary research on rhythm perception suggests that people with ASD can process and produce simple and complex rhythms and that these musical skills are positively linked to cognitive visual-spatial skills in adolescence (DePape et al., 2012). Therefore, it is possible that rhythmic patterns in music can be used as temporal cues for synchronizing social interactions and facilitating impulse control in children and adolescents with ASD (Pellitteri, 2000). However, more research on the developmental trajectory of rhythm perception and its association with cognitive skills is necessary for future intervention planning.

Objectives: The purpose of this research is to 1) compare rhythm perception in typically developing (TD) children and children with ASD, as well as 2) compare rhythm perception and 3) its association with cognitive skills in younger and older children with ASD.

Methods: Eighteen TD children and 29 children with ASD (6-12 years of age) were recruited to examine objective #1. Nineteen older children with ASD (13-17 years of age) were also recruited to examine objective #2-3. All the participants completed a cognitive test (WISC-V/ WASI) and a rhythm perception task, which was an adapted version of the Beat Alignment Test (Iverson & Patel, 2008). The participants listened to short musical excerpts with overlaid beeps (on or off the musical beat) and identified whether the beeps matched the musical beat.

Results: One-sample t-tests revealed that TD children and children with ASD performed above chance level (two choices: 50%) on the rhythm perception task ($p < .05$); however, further inspection revealed that children with ASD with cognitive difficulties (full scale IQ < 70) could not complete the task above chance level, ($p > .05$) and thus, were removed from the sample ($n = 8$). An independent t-test revealed no group differences in task performance ($p > .05$). #2: There was also no difference in task performance between younger and older children with ASD ($p < .05$). Pearson correlations was used to confirm that there was no significant relationship between task performance and the age of participants ($p > .05$). #3: There was a strong positive correlation between visual-spatial abilities and rhythmic perception in older children with ASD ($r = .52$, $p < .05$) but not in younger children with ASD ($p > .05$).

Conclusions: Findings are consistent with previous research showing preserved rhythm perception for children with ASD across development, though this may not extend to children with ASD with cognitive difficulties. In harmony with the literature, we also found that rhythmic perception abilities are associated with visual-spatial abilities in adolescence. Findings could help guide the development of musical training programs that leverage preserved rhythm perception in ASD by using rhythmic patterns in music to facilitate behavioural (social skills, impulse control) and cognitive (visual-spatial abilities) functioning.

412.027 *(Poster)* Self-Regulation in Preschoolers with Autism Spectrum Disorder: Links to Autism Symptoms, School Performance, and Behavioral Regulation Strategies

Y. Chen *and L. B. Jahromi, Teachers College, Columbia University, New York, NY*

Background: Self-regulation development in early childhood has a long-lasting impact on children's school success and psychosocial wellbeing. Delays in self-regulation development are often reported in children with autism spectrum disorder (ASD). There is a need for research investigating how self-regulation of children with ASD is linked to their school performance and the factors that are related to children's self-regulation development.

Objectives: This study examined two essential self-regulatory skills, executive function (EF) and effortful control (EC), and their relations to the symptom severity and school performance of preschoolers with ASD.

Methods: A total of 32 preschoolers with ASD (M=52.64 months, SD= 6.70) from two private schools in the greater New York City area participated in this study. All participants had a clinical diagnosis of autism that was confirmed with an Autism Diagnostic Observation Schedule-Second Edition (Lord et al., 2012). Participants' EF skills were assessed directly through the NIH Toolbox Early Childhood Cognition Battery (Gershon et al., 2013), and their levels of EC were measured through a parental report, the Child Behavior Questionnaire-Short Form (Putnam & Rothbart, 2006). Participants' school performance was assessed using two teachers' measures, the Teacher Rating Scale of School Adjustment (Birch & Ladd, 1997) and the School Liking and Avoidance Questionnaire (Ladd & Price, 1987). Three behavioral measures were designed to assess participants' behavioral regulation strategies under frustrating situations: delayed delivery of tokens, edibles, and delayed turn-taking with an adult.

Results: Children with more severe ASD symptoms demonstrated significantly lower EF skills (see Table1 for all correlations) and lower behavioral school engagement as reported by teachers of children with ASD. Thus, children with more ASD symptoms demonstrated more difficulties in cooperating with others in school. In contrast, participants with higher levels of EC demonstrated greater school liking and better behavioral participation in school activities.

Participants' EF skills and levels of EC were positively associated with their maximum wait time during a delayed turn-taking task, such that children with better EF skills and higher levels of EC waited significantly longer for the teacher to finish her turn in playing without any disruptions or aggressions in an interactive turn-taking task.

Participants who used language to help regulate behaviors during tasks of delayed delivery of tokens and edibles were able to wait significantly longer than those who did not use language. Similarly, participants who used language more frequently during a turn-taking task with an adult were able to wait significantly longer than those who used less language.

Further analysis showed that participants with better joint attention skills on the ADOS-2 tended to use more language to help regulate their behaviors under frustrating situations. Female participants also tended to use more language than males during an interactive turn-taking task with an adult to facilitate their regulation.

Conclusions: Self-regulation plays a crucial role in the school performance of children with ASD. The severity of ASD adversely impacts the development of self-regulation in this atypical population. Language appeared to be the only behavioral regulation strategy that was related to children's longer waiting in all three delayed tasks.

412.028 *(Poster)* Sticky or Slippery Attention: How Do Symptoms of ASD and ADHD Affect Children's Attention Disengagement?

J. Wang[1], *Q. Wang*[2], *Y. Zhang*[3], *T. Yin*[4], *X. Gong*[5], *X. Li*[5], *J. Liu*[5] *and L. Yi*[6], *(1)School of Psychology and Cognitive Sciences, Perking University, Beijing, China, (2)Peking University, Beijing, China, (3)Peking University, beijing, China, (4)Peking University Sixth Hospital, Peking University Sixth Hospital, National Clinical Research Centerfor Mental Disorders, Beijing, China, (5)Peking University Sixth Hospital, National Clinical Research Center for Mental Disorders, Beijing, China, (6)School of Psychological and Cognitive Sciences and Beijing Key Laboratory of Behavior and Mental Health, Peking University, Beijing, China*

Background: Some studies reported that people with autism spectrum disorder (ASD) had "sticky attention", for example, they could display longer disengaging latency (Elsabbagh et al., 2009, 2013). However, some evidences demonstrated comparable disengaging latency in people with ASD and typically-developing (TD) people (Fischer et al., 2014, 2015). On the other hand, Attention Deficit Hyperactivity Disorder (ADHD) was embodied with general distractibility that they distract their focused attention to the on-going task unrelated stimuli (Aboitiz, Ossandon, Zamorano, Palma & Carrasco, 2014; Cheung et al., 2015). Considering that ADHD is one of the most common co-occurring mental disorder in ASD, it is intriguing to examine the attentional disengagement in children with ASD and ADHD, compared with children with these disorders alone.

Objectives: In current study, we examined (a) the impact of comorbidity with ADHD on attentional disengagement of ASD. and (b) how symptoms of ASD and ADHD influence children's attentional disengagement. We hypothesized that different effect of ASD and ADHD symptoms on children's attentional disengagement: specifically, the autistic trait would lengthen the disengaging latency while hyperactivity trait would shorten the disengaging latency.

Methods: A group of children with ASD ($N = 33$, $M_{age} = 8$, $M_{IQ} = 104$), a group of children with ASD with comorbid ADHD ([ASD-ADHD], $N = 18$, $M_{age} = 6.17$, $M_{IQ} = 82.78$), a group of children with ADHD ($N = 31$, $M_{age} = 7.16$, $M_{IQ} = 109$) and a group of TD children ($N = 28$, $M_{age} = 7.68$, $M_{IQ} = 110$) completed the attentional disengagement task. Participants' disengaging latency from central stimuli to simultaneous or subsequent onset of peripheral stimuli was measured by eye- tracking technology. The setting of two condition enables us to prob both ability of disengaging attention from a fixed target (Disengage Condition) and shifting attention to another location with the hint of prior cue (Shift Condition). We compared disengaging latency of four groups in both Disengage Condition and Shift Condition.

ASD group, ADHD group and ASD-ADHD group were categorized into atypical development (AT) group; typical development (TD) group and AT group were combined into an independent factor of Group to predict the disengaging latency along with autistic traits and hyperactivity traits. Children's autistic traits and hyperactivity traits were measured by Autism Spectrum Screening Questionnaire (ASSQ) and ADHD Rating Scale.

Results: We found that (a) disengaging latency in condition of Disengage was longer than that in Shift condition for all groups; (b) disengaging latency in condition of Disengage for the ASD-ADHD group was significantly longer than ASD, and ADHD groups. Disengaging latency of the ADHD group was significantly shorter than the TD group in Disengage condition; (c) more severe repetitive behavior and less severe hyperactivity were correlated with longer disengaging latency; (d) symptom of repetitive behavior had larger effect on disengaging latency in the TD group than AT group.

Conclusions: Our findings suggested that the comorbidity of ASD and ADHD would deteriorate the attentional disengagement of ASD group, and autistic trait prolonged disengaging latency while hyperactivity trait acts on it adversely.

412.029 *(Poster)* The Impact of Activities and Speech on Scene Scanning Patterns in School-Age Children with ASD

M. M. Çelebi[1], *M. M. Mahony*[2], *M. C. Aubertine*[3], *K. J. Dommer*[4], *E. Barney*[5], *M. Kim*[4], *S. Corrigan*[4], *A. Atyabi*[6] *and F. Shic*[5], *(1)Acibadem University, Istanbul, Turkey, (2)Bernier Lab, Psychiatry and Behavioral Sciences, University of Washington, Seattle, WA, (3)Seattle Children's Hospital and Research Institute, Seattle, WA, (4)Seattle Children's Research Institute, Seattle, WA, (5)Center for Child Health, Behavior and Development, Seattle Children's Research Institute, Seattle, WA, (6)Seattle Children's Research institute University of Washington, Seattle, WA*

Background: Previous work has shown that toddlers with ASD look less at activities and heads than typically-developing (TD) toddlers when presented with dyadic interactive play scenes (Shic et al., 2011). Less is known about how school-age children with ASD visually process scenes with dyadic interactive play, and even less is known about how components, such as the presence or absence of activities or speech, underlie this process.

Objectives: To examine how speech and activities modulate differences in face scanning and activity monitoring between school-age children with and without ASD.

Methods: Participants were 30 children with ASD (Mean Age=7.84 years, SD=2.77) and 22 TD children (Mean Age=7.93 years, SD=2.40). Stimuli were presented as three 20-second activity monitoring video clips depicting two actresses interacting naturalistically over a shared activity. Clips were broken into sections by the presence of Speech (no speaker/one speaker) and Activity (no activity/activity). For each possible combination of conditions, dependent variables were based on the proportions of time spent examining the regions-of-interest (ROIs): (a)%Activity and (b)%Head. When Speech was present, we also examined looking at (c)%Speaker Head and (d)%Non-Speaker Head. Statistical analyses used linear mixed model approach to examine group and condition effects; associations with ADOS autism severity in ASD group were measured using Pearson's correlation.

Results: For %Activity, ANOVA revealed a group main effect (F(1,48.6)=5.91, p=.019) and no group interaction, with ASD looking more at activities than TD children (ASD M=45.2%; TD M=33.4%; d=.74). For %Heads, a group main effect (F(1,48.9)=6.65, p=.013) and a 3-way-interaction (group x activities x speakers, F(1,138.1)=6.94, p=.009) were observed. ASD group generally looked less at heads (ASD M=25.9%; TD M=38.1%; d=-.76); this was driven primarily by the condition with no activities and one speaker (ASD M=35.2%; TD M=56.2%; d=-1.32, p<.001) and, to a lesser extent, activities with no speaker (ASD M=9.8%; TD M=21.5%; d=-.73, p=.035). When a speaker was present, between-group differences did not exist in %Speaker Head(p's>.270); however for %Non-Speaker Head a group main effect (F(1,43.9)=12.6, p<.001) and a group x activities (F(1,44.9)=12.4, p<.001) interaction were observed. This interaction indicated between-group differences only when no activity was present (no Activities: d=-1.75, p<.001; with Activities: d=-.70, p=.070). Interestingly, correlations between looking patterns and severity of autism symptoms were correlated to %Speaker Head (r(28)=-.42-.60, p<.05).

Conclusions: As expected, children with ASD looked less at heads than TD children. Contrary to expectations, they looked more at activities. Between-group differences in face scanning were heightened when no activities and one speaker were present. This effect was driven by diminished looking at non-speaking, compared to speaking heads, suggesting children with ASD are making fewer predictions regarding the interactive nature of dialogue. This may be due to diminished ability to use scene cues (e.g. people talking or engaging in activities) to infer the importance of agents or to split their attention accordingly as TD children do. Interestingly while between-group differences in looking at heads seemed driven by attention to non-speaker's head, relationships with phenotype within ASD strongly associated with looking at the speaker's head, suggesting a potential separation between discriminative and stratification markers.

412.030 *(Poster)* The Impact of Auditory Distractors on Visual Search and Classroom Performance in College Students with ASD

C. King[1]*, C. Lory*[1]*, S. Kang*[2]*, S. Bergmann*[3]*, R. A. Mason*[4] *and B. Keehn*[3]*, (1)Purdue University, West Lafayette, IN, (2)Purdue University, West Lafayette, IN, (3)Speech, Language, and Hearing Sciences, Purdue University, West Lafayette, IN, (4)Educational Studies, Purdue University, West Lafayette, IN*

Background: Individuals with autism spectrum disorder (ASD) are enrolling in post-secondary education in increasing numbers; however, students with ASD are less likely to complete a degree than students with other disabilities. Successful classroom performance relies on the ability to focus selectively on relevant course-related information, while filtering out irrelevant distractions. These attentional functions – selecting and filtering - are associated with academic achievement. However, individuals with ASD exhibit pervasive impairments in filtering irrelevant visual and auditory information. Yet, it is unclear how this may affect in-class performance. The present study used visual search (VS), a task in which individuals with ASD excel, to investigate filtering of irrelevant auditory information and its association with off-task classroom behaviors in college students with ASD.

Objectives: To investigate the impact of filtering of irrelevant social and non-social noise on VS performance in college students with ASD, and to examine the association between filtering abilities and classroom behavior in students with ASD.

Methods: To date, participants are 5 college-aged students with ASD and 14 age- and IQ-matched typically developing (TD) students (projected n = 20 ASD, 20 TD). Participants completed a VS paradigm and three classroom observations. Participants' task was to indicate the presence or absence of a target "T" embedded within arrays of distractor "Ls," which were rotated in 1 of 4 cardinal orientations in set sizes of 18, 27, and 36. The task was divided into 3 conditions: quiet (no auditory stimuli), social (a stereo-monotract of two continuous overlapping voices of equal amplitude reading stories) and non-social (speech-shaped pink noise matching the amplitude and intensity of the social condition). The conditions were counterbalanced across participants. For the classroom observations, each participant was observed for 3, 30-minute sessions. The instructor, participant, and peer behavior (e.g., engagement/off-task, attentional shifts on/off-task, response to instructor/peer) were coded online.

Results: In the VS task, groups did not differ for overall response time (RT) or accuracy. As expected, participants were faster with smaller set sizes and when the target was present ($p< 0.05$); RT did not vary across noise conditions. To examine the cost of filtering, difference scores were calculated by subtracting noise conditions from the quiet condition (quiet – social; quiet - non-social). Students with ASD showed a greater filtering costs to social (M = -131ms) and non-social (M = -156ms) conditions, whereas TD students exhibited an RT benefit to social (TD = 97ms) and non-social (M = 91ms) noise conditions; however, group differences were not statistically significant ($ps = 0.19$). For both groups combined, there was a significant correlation between social difference score and off-task attentional shifts ($p< 0.05$), indicating that poorer filtering during VS was associated with more frequent off-task attentional shifts in the classroom.

Conclusions: Although preliminary, our results suggest that college students with ASD may have difficulty filtering irrelevant social and non-social auditory information. Further, the association between difficulties filtering in the VS task and increased off-task attentional shifts in the classroom data suggest that problems filtering may contribute to more off-task classroom behaviors.

412.031 *(Poster)* The Impact of Bilingualism on the Executive Function Skills of Arabic-English Children with Autism and Their Typically Developing Peers

S. Sharaan[1]*, S. Fletcher-Watson*[2] *and S. E. MacPherson*[3]*, (1)University of Edinburgh, Edinburgh, United Kingdom, (2)Division of Psychiatry, University of Edinburgh, Edinburgh, United Kingdom, (3)Department of Psychology, Human Cognitive Neuroscience, Edinburgh, United Kingdom*

Background: there is evidence to suggest that certain executive function (EF) skills are impaired in children with autism, underlying several of autism's key characteristics. There is also evidence to suggest that the regular use of two languages has the potential to extend EF capacities. Most of the findings to date have focused on non-clinical populations, and are characterized by a substantial amount of conflicting evidence. Much remains unknown about the impact of bilingualism on the EF abilities of children with autism, with less than five studies published to date.

Objectives: to investigate the impact of bilingualism on the EF performance of Arabic-English children with autism and their typically developing (TD) peers, thus contributing to the evidence-base surrounding bilingual children with autism.

Methods: a battery of EF tests tapping into flexible switching (dimensional change card sorting task), sustained attention (psychomotor vigilant task), working memory (self-ordered pointing task) and interference control (simon task) was administered to 132 child participants from 10+ nationalities (mainly from the Middle East and North Africa region) based in the United Arab Emirates. The participants' ages ranged 5-12 years (mean age of 8.75 and SD of 1.73) and made up 4 groups; 33 TD Arabic-English bilinguals, 33 Autistic Arabic-English bilinguals, 33 TD Arabic/English monolinguals, and 33 Arabic/English Autistic monolinguals. Participants were matched on age, non-verbal IQ, and socioeconomic status. The distribution of gender groups was more balanced in the TD group (approximately 45% male and 55% female) versus the autistic group (approximately 60% male and 40% female). We hypothesize that bilingual groups (both TD and autistic) will outperform monolingual groups on interference control, flexible switching, sustained attention, and working memory.

Results: findings indicate a bilingual advantage for children with autism in sustained attention, a monolingual advantage for children with autism and their TD peers in interference control, and equivalent performances between bilingual and monolingual participants for children with autism and their TD peers in working memory and flexible switching. Findings suggest that bilingualism in autism can have differential influences in executive function depending on the task and outcome variables.

Conclusions: the reality is, parents, therapists, and educators around the world lack sufficient evidence to support their language decisions and choices for children with autism. These choices hold consequences for the treatment, education and formation of ethnic identities for children with autism. We can infer from the results that bilingualism does not negatively impact EF skills in children with autism, and can actually show an advantage in specific outcome variables of EF tests. We will also report on data from ratings-based measures of EF (using the Comprehensive Executive Function Inventory – CEFI) which assess the EF abilities of the same participants but across a wider time span, in school and home environments, from the perspective of teachers and parents respectively. Finally, we will report on the relationship between EF performance on direct tasks and autism symptoms (as measured by the Social Responsiveness Scale – 2 and rated by teachers), highlighting individual differences in EF performance in children with autism. **Background:** there is evidence to suggest that certain executive function (EF) skills are impaired in children with autism, underlying several of autism's key characteristics. There is also evidence to suggest that the regular use of two languages has the potential to extend EF capacities. Most of the findings to date have focused on non-clinical populations, and are characterized by a substantial amount of conflicting evidence. 412.032 *(Poster)* The Relationship between Cognitive Processes and Social Responsiveness: Investigating Executive Function Patterns in Autism Spectrum Disorders

J. E. Blume[1] *and A. Mastergeorge*[2]*, (1)Department of Human Development and Family Studies, Texas Tech University, Lubbock, TX, (2)Texas Tech University, Lubbock, TX*

Background: A strong relationship exists between executive function and social competencies in youth with ASD (Gilloty et al., 2010; Kouklari et al., 2018). The influences of both executive function and social skills for youth with ASD have been evaluated in regard to quality of life, theory of mind, and adaptive behavior; however few studies have assessed the role of executive function skills in contributing to social skill variability (Berenguer et al., 2018; de Vries & Geurts, 2015; Tsermentseli et al., 2018). As impairments in executive function skills increase from childhood to adolescence for individuals with ASD, exploring the underlying role of specific executive function skills in explaining social behavior patterns warrants further investigation (Pugliese et al., 2015; Rosenthal et al., 2013; Gardiner & Iarocci, 2018). Based on these limited studies, observed relationships between executive function and social functioning in this population are specific to metacognition rather than behavior regulation (Leung et al., 2016; Torske et al., 2018). However, these studies have been limited by small ASD sample sizes (n=70, n=86, respectively), and the only study that examined this relationship with a larger sample size focused on evaluating gender differences while exclusively including metacognitive executive function factors (Chouinard et al., 2019). Therefore, the detailed relationship between executive function skills and social functioning remains unclear.

Objectives: This study extends limited previous published evidence utilizing a larger sample size to investigate the unique roles of executive function elements (see Table 1). These study objectives will examine variability in social responsiveness factors including social awareness, social cognition, social communication, and social motivation to inform the potential role of underlying cognitive processes in social behavior patterns observed in ASD.

Methods: This investigation utilized a subset of secondary data originally collected through the Autism Brain Imaging Database Exchange II (ABIDE, *N*=171, 138 male, mean age=11.24 years, SD=2.49). The ABIDE database promotes brain connectome and phenotypic characterization of autism by aggregating de-identified neuroimaging and phenotypic data from 19 sites. We performed linear regression analyses, using scores on the *Behavior Rating Inventory of Executive Function* (BRIEF; Gioia, Isquith, Guy, & Kenworthy, 2000) Clinical Scales as a predictor of scores on the *Social Responsiveness Scale* (SRS; Constantino & Gruber, 2005) Treatment Subscales.

Results: Reported executive function clinical scale scores were found to significantly account for 4.5-10% of variability in social functioning measures, with the greatest variability for social motivation followed by social awareness, social cognition, and social communication (see Tables 2-5). Models only indicated organization of materials and planning/organizing to be significantly associated with social functioning when controlling for other executive function skills and was not consistent across all models.

Conclusions: These findings support previous studies' claims that metacognitive executive functions are more strongly associated with social functioning compared to behavior regulation factors. In contrast to previous findings, the model including individual elements of both metacognition and behavior regulation significantly accounted for variability in social motivation (Torske et al., 2018). Next analytic steps include discerning differences in executive function and social functioning relationship associations specific to IQ and gender.

412.033 *(Poster)* The Relationship between Performance on a Musical Working Memory Task and Parent Reports of Working Memory: A Comparison between Typically Developing Children and Children with ASD.

G. Philibert-Lignieres[1]*, C. Rimmer*[1]*, B. Tillmann*[2]*, A. Bertone*[1]*, G. Iarocci*[3]*, T. Q. Boucher*[3] *and E. M. Quintin*[4]*, (1)McGill University, Montreal, QC, Canada, (2)Université Claude-Bernard Lyon1, Lyon, France, (3)Psychology, Simon Fraser University, Burnaby, BC, Canada, (4)Educational & Counselling Psychology, McGill University, Montreal, QC, Canada*

Background: Autism Spectrum Disorder (ASD) is often associated with strengths in music perception, which requires auditory working memory, although parent reports often suggest difficulty with working memory in daily life.

Objectives: We thus aim to **1)** compare the performance of typically developing (TD) children and children with ASD on a musical working memory task and **2)** investigate the relationship between the performance on a musical working memory task and (non-musical) day-to-day working memory skills.

Methods: Eighteen children with ASD (age= 6-12) and eighteen TD children (age= 7-11) participated in this study. To assess musical working memory, sequences of 3, 4, and 5 pitches were presented in pairs and participants were asked to identify whether sequence-pairs were similar or different. The 4 and 5 pitch sequences included two conditions: 1) the different sequence-pairs introduced a new pitch, or 2) the different sequence-pairs used already introduced pitch but inversed their position in the sequence. The goal of creating these two conditions (e.g., 4 pitch vs. 4 pitch with inversion) was to increase the task's complexity. Total performance was calculated as Hits minus False Alarms. The Working Memory Scale of the Behavior Rating Inventory of Executive Functions-2 (BRIEF-2) parent questionnaire was used as a potential correlate of the participants' task performance.

Results: 1) Independent sample t-tests revealed that total performance on the musical working memory task did not differ between the ASD and TD groups, nor did it differ on the 3- 4- 5-pitch and 4- 5-pitch with inversion conditions (all *p*-values >.05). However, when comparing the performance within groups, the TD group performed significantly lower on the 4-pitch with inversion vs. the 4-pitch condition (p=.001), while the ASD group's performance did not differ between conditions (p=.110). Both ASD and TD groups performed significantly lower on the 5-pitch with inversion vs 5-pitch condition (p=.01) **2)** Independent sample t-test revealed that there was significantly lower BRIEF-2 working memory skills in the ASD compared to TD group (p=.01). However, BRIEF-2 working memory skills were not related to musical working memory task performance for either group.

Conclusions: Our findings reveal that children with ASD performed equally well on the musical working memory task in comparison to TD children. While the 5-pitch sequences were more difficult for both groups, the ASD group's performance on the 4-pitch sequences with and without inversion revealed that they were not as impacted by the complexity and difficulty of the task in comparison to TD children. This finding is in line with documented strengths of people with ASD in musical perception. Furthermore, parent reports of working memory were not related to task performance for either group. Results provide preliminary evidence for the use of music as a strength-based modality to assess the working memory abilities of children with ASD to complement traditional tests and questionnaires.

412.034 *(Poster)* The Role of Executive Functioning, Language Ability, and Theory of Mind in Autistic Adults' Interview Performance

J. E. Norris[1] *and K. L. Maras*[2]*, (1)Centre for Applied Autism Research, University of Bath, Bath, United Kingdom, (2)Psychology, Centre for Applied Autism Research, University of Bath, Bath, United Kingdom*

Background: Formal social interactions such as police interviews, healthcare consultations, and job interviews are complex, often ambiguous, social situations that provide a microcosm of the problems experienced by autistic people in everyday life. Producing appropriately detailed, accurate, relevant, and coherent responses to questions requires monitoring of one's cognitions, generating and planning an appropriate response, holding in mind various reporting options, inhibiting reporting of details deemed to be irrelevant or inaccurate, and selecting an optimal level of detail whilst switching between one's own and the interviewer's perspective. These are all areas of difficulty for autistic people, and are particularly exacerbated under open questions.

Objectives: To examine the role of executive functioning (EF), Theory of Mind (ToM) and language ability on autistic adults' interview performance under different levels of support and question types, using data collected across two separate interview studies.

Methods: Tests of EF, ToM, and language were measured in two studies (reported elsewhere) investigating adaptations to interview questions: 1) a study of autobiographical memories in police, employment, and healthcare contexts, with 30 autistic adults and 30 typically developing (TD) comparisons interviewed both with and without question support; and 2) a study adapting employment interview questions based on employer ratings of answer quality, with 25 autistic and 25 TD comparisons, again interviewed both with and without question support. Tests included inhibition, working memory, ERRNI mean length of utterances (MLU), ERRNI forgetting index, Adult-Theory of Mind (A-ToM), and the Tower test.

Results: For study 1, multiple linear regression predicting specificity in the 'no support' condition was conducted, with group (autistic or TD) as the predictor in step 1, and all measures as above in step 2. Both models were significant (p = .048 and p = .015). Group was no longer a significant predictor at step 2, p = .366, with working memory (forward span) the only predictor, p = .004. Models were non-significant when predicting residual specificity difference between the 'no support' and 'support' conditions, ps > .323.

For study 2, a regression was conducted predicting answer quality ratings at Phase 1 (no support), with group as predictor in step 1, and all additional measures in step 2. Both models were significant (p = .002 and p = .010). At step 2, group remained significant, p = .016, as well as working memory (forward) p = .012, and ToM, p = .027. Models were non-significant when predicting residual difference between answer quality ratings for the supportive and non-supportive questions, ps > .654.

Conclusions: When open, unsupportive questions are asked, recall quality is related to working memory and ToM abilities in an employment interview context. However, when questions are sufficiently supportive, EFs and ToM do not predict recall. Under open questioning, respondents may rely on working memory to hold the question in mind. During employment interviews, ToM skills may be additionally required to determine the most appropriate response to a question. These findings provide insight into which EFs may be scaffolded in order to effectively support autistic people's recall in interviews.

412.035 *(Poster)* Towards a Model of Neurodevelopmental Continuum for ASD, ADHD and Schizophrenia

D. Canu[1]*, C. Ioannou*[1]*, M. Biscaldi*[1]*, C. Fleischhaker*[1]*, N. Smyrnis*[2] *and C. Klein*[1]*, (1)Department of Child and Adolescent Psychiatry, University of Freiburg, Freiburg, Germany, (2)National and Kapodistrian University of Athens, Athens, Greece*

Background: According to the Neurodevelopmental continuum hypothesis, neurodevelopmental disorders, including ADHD, Autism and Schizophrenia, should be reconceptualised as lying on an aetiological and neurodevelopmental continuum, with the individual disorders reflecting various degrees of abnormal brain development and resulting functional abnormalities. The model stands on recent findings of shared genetic risk factors, as well as overlapping pathogenic mechanisms.

Objectives: Genetic predisposition is expressed by different degrees of cognitive impairment and persistence of functional impairment. Coherently, our primary goal is to explore commonalities and diagnostic specificities among the three conditions in various cognitive subdomains.

Methods: Four groups of young adults were included: 26 with Autism Spectrum Disorder (ASD, 19.7±1.9, 25 males), 28 with Attention-Deficit/Hyperactivity Disorder (ADHD, 19.9±1.4, 15 males), 21 with Early-Onset Schizophrenia (SCZ, 19.7±1.7, 15 males), 29 typically developing participants (TD, 19.8±1.6, 12 males). Participants were matched on age and full-scale IQ. Eye movements were recorded binocularly at 1000 Hz using the Eye Link 1000+ system, while four basic ocular-motor tasks (prosaccade (PRO), antisaccade (ANT), memory-guided saccade (MEM), fixation (FIX)) were administered in counterbalanced order.

Results: With respect to saccadic RT, ASD and ADHD did not differ from TD in the measure of intra-subject variability (ISV) for PRO, ANTI, MEM. Conversely, SCZ were significantly more variable than TD in all tasks, than ASD in PRO, but not compared to ADHD, while being significantly slower than TD and ASD for PRO and ANT, marginally compared to ADHD for ANT. Increased percentage of anticipatory saccades in ASD and ADHD, in comparison to TD, was found for MEM, only marginally for PRO in ASD versus TD, again for all tasks in SCZ versus TD, but also compared to ASD and ADHD in ANT. A significantly higher percentage of direction errors during ANT aggregated all clinical groups, increased frequency of intrusive saccades during FIX gathered SCZ and ASD, marginally ADHD, compared to TD. As for microsaccades, SCZ and ASD showed a higher frequency of microsaccades for FIX (condition without distractors) and PRO (preceding correct saccades), only SCZ for ANT (both preceding correct saccades and direction errors), compared to TD.

Conclusions: Results suggest preserved sensory-motor control in ASD and ADHD, as compared to SCZ. Conversely, increased anticipatory saccades and direction errors support the presence of inhibition deficits across groups, suggesting a common (pre-)frontal functional impairment. Of note, mean RT discriminates the clinical groups better than ISV, thus emerging as a trans-diagnostic process to the three conditions and, uniquely for SCZ, a rather general deficit, independent of the specific task. Finally, atypical microsaccadic frequency might suggest common abnormalities in motor response preparation in SCZ and ASD. Across all tasks, participants with Schizophrenia appear more impaired than those with ADHD and ASD, which often did not significantly differ from each other, which might be related to the idea of a continuum of impairment.

412.036 *(Poster)* Understanding Attentional Strengths and Weaknesses in Autism Spectrum Disorder

B. Keehn[1]*, G. Kadlaskar*[1]*, S. Bergmann*[1] *and R. McNally Keehn*[2]*, (1)Speech, Language, and Hearing Sciences, Purdue University, West Lafayette, IN, (2)Indiana University School of Medicine, Indianapolis, IN*

Background: Infants at elevated risk for autism spectrum disorder (ASD), as well as children, adolescents, and adults diagnosed with ASD excel at visual search compared to their typically developing (TD) peers. Paradoxically, slowed attentional disengagement has also been found across the lifespan in those at risk for, or diagnosed with, ASD. However, how these two paradoxical states co-exist within the same individuals and their underlying neurofunctional mechanisms remain to be determined.

Objectives: To 1) examine the relationship between enhanced visual search and impaired disengagement, and 2) assess the role that the locus coeruleus – norepinephrine (LC-NE) system, as indexed by pupil diameter, plays in the manifestation of atypical attentional processes in the same cohort of children with ASD.

Methods: Participants were 26 children with ASD and 26 age- and non-verbal IQ-matched TD children. The study consisted of separate visual search, gap-overlap, and resting eye-tracking paradigms. For the visual search paradigm, participants were instructed to find the target (vertical line) embedded within an array of tilted (10°) distractor lines. The target was present on 50% of trials, and displayed within set sizes of 18, 24, and 36 items. In the gap-overlap task, participants were instructed to fixate on a central crosshair and then move their eyes to a peripheral target once it appeared. Each trial began with a crosshair presented alone for a random duration. Next, a target could appear with either the crosshair remaining on the screen (overlap condition) or 200ms after the crosshair disappeared (gap condition). For the resting eye-tracking paradigm, a black central crosshair was presented on a grey background, and participants were instructed to relax, remain still, and to look at the crosshair. Saccadic latency and pupil diameter were monitored using an EyeLink 1000 Plus remote eye-tracking system.

Results: For the visual search paradigm, groups did not differ significantly for RT or accuracy; although children with ASD showed faster search efficiency (ASD: 26ms/item; TD: 35ms/item), these did not differ significantly. For the gap-overlap paradigm, groups did not differ on overall saccadic RT. Saccadic RT difference scores (overlap – gap, i.e., gap effect) were larger for children with ASD (ASD = 66ms; TD = 39ms), however, these did not differ significantly. Pupil diameter was significantly larger in the ASD group ($p < .05$). Correlations between gap effect and search efficiency measures showed that for the ASD group (but not the TD group), slower disengagement was associated with better search efficiency ($p < .05$). Across both groups, larger pupil size was related to slower disengagement and more efficient visual search ($ps < .05$).

Conclusions: Between-group differences were not present for visual search and disengagement measures. However, for the ASD group, greater search efficiency was associated with slower attentional disengagement. For both groups, increased tonic activation of the LC-NE system (i.e., larger pupil size) was associated with increased search efficiency and poorer attentional disengagement. The present findings suggest attentional strengths and weaknesses are associated in individuals with ASD, and may be linked to atypical activation of the LC-NE system.

412.037 *(Poster)* Visual Attention and Proactive Inhibition in a Social and Non-Social Cueing Task in Autism Spectrum Disorder

*A. Thillay[1], S. Morel-Kohlmeyer[1,2], E. Houy-Durand[1,2], F. Bonnet-Brilhault[1,2], M. Latinus[2] and **C. Wardak**[2], (1)CHRU Tours, Tours, France, (2)UMR 1253, iBrain, Université de Tours, Inserm, Tours, France*

Background: Spatial attention allows to select and process relevant information in the environment. It is classically studied with a cued detection task, in which a visual cue is presented at the future location of the target in order to facilitate its detection. In some trials, the cue is presented at the incorrect location (invalid vs valid trials), leading to longer reaction times (RTs) due to the incorrect orientation of attention. This very-well known paradigm has recently been reexamined in typically developing (TD) subjects, showing that RTs were susceptible not only to attentional factors but also to executive ones like proactive inhibition, preventing inappropriate reactions to events (i.e. the cue in a cueing paradigm).

Autism spectrum disorder (ASD) has been associated with dysfunctions in spatial attention. Previous studies using a cueing paradigm in ASD subjects have found various results. One source of variability is the nature of the cue used to orient attention: central (endogenous) or peripheral (exogenous), and social (e.g. orientation of the eyes) or non-social (e.g. arrow or object). Another source of variability could be the proactive inhibition process, which has never been evaluated in a cueing paradigm in ASD.

Objectives: Our objective was to assess the reaction times in a cued detection task in ASD and evaluate both the influence of the nature of the cue (social or non-social) and of the context (more or less proactive inhibition).

Methods: Twelve ASD (20-37 years old, 3 females) and twelve TD (matched with ASD) adults were included in our protocol. The subjects performed three blocks of peripheral cueing tasks. In the first one, the subjects had to fixate a central cross and to press a button when a target (star) appeared on the left or the right side of the screen. In the two other blocks, trials with only the target (star) were mixed with trials in which the target was preceded by a cue presented on the same side (valid) or on the other side (invalid) of the screen (75% validity). The cue could either be social (a face) or non-social (a butterfly), and was presented at three possible timings before the target. The fixation was controlled thanks to eye-tracking.

Results: Performance and RTs were recorded. Two of the 12 ASD subjects were impaired in cued trials (low performance). In the remaining 10 ASD subjects, RTs were faster in cued than in non-cued trials, a validity effect was observed (valid trials faster than invalid ones), with no difference between social and non-social cues. These results were not significantly different from those of TD subjects. However, the RTs for the first block, allowing to measure the proactive inhibition, showed an impairment in ASD subjects compared to TD subjects.

Conclusions: Exogenous spatial attention does not seem to be atypical in ASD participants, even for social cues. However, proactive inhibition in ASD participants seems very variable and is not comparable with TD subjects. The relationship between this proactive inhibition, spatial attention and clinical measures needs to be explored in further details.

412.038 *(Poster)* Visual Search: A Direct Comparison between Young Adults with ASD, ADHD, Schizophrenia and Healthy Controls

***D. Canu**[1], C. Ioannou[1], M. Biscaldi[1], C. Fleischhaker[1], N. Smyrnis[2] and C. Klein[1], (1)Department of Child and Adolescent Psychiatry, University of Freiburg, Freiburg, Germany, (2)National and Kapodistrian University of Athens, Athens, Greece*

Background: Superior visual search is a replicated finding in the literature on Autism Spectrum Disorder (ASD). Conversely, results from the literature on Attention-Deficit/Hyperactivity Disorder (ADHD) are more mixed, with some studies showing typical performance and others pointing out less efficient serial search in ADHD. Finally, most studies on visual search in Schizophrenia highlighted deficits in focal attentional processing. However, similarities between attentional impairments in the three clinical groups have also been reported.

Objectives: The primary goal of our study is to determine the diagnostic specificity of search deficits. To our knowledge, the literature systematically comparing the visual search performance in patients with ADHD and Schizophrenia is limited to one study, while no study has so far included an ASD group in the comparison.

Methods: A visual search task was presented to four groups of young adults, namely typically developing (TD; 19.8±1.6, 41% males), ASD (19.7±1.9, 96% males), ADHD (19.9±1.4, 54% males) and Early-Onset Schizophrenia (SCZ; 19.7±1.7, 71% males), while eye movements were recorded with the Eye Link 1000+ system. Participants were matched on age and full-scale IQ.

Results: Initiation of search – latency of the first saccade on the search grid – was typical in all participants except those with SCZ, who had significant higher intra-subject variability (ISV) than both TD and ADHD, but not compared to ASD. Within search, ASD manifested significantly reduced mean and ISV of total search duration – between the first saccade on the grid and the last fixation on target – and of the first part of search – between the first saccade on the grid and the first fixation on target – in comparison with all other groups, including TD. Conversely, both ASD and SCZ showed significantly longer mean duration than ADHD and were more variable than TD and ADHD regarding first fixation on target. Additionally, ASD needed a significant lower frequency of fixations on target than SCZ, but not compared to ADHD or TD. In the post-search phase – between the onset of the last fixation on target and the button press on the keyboard – SCZ were the slowest and most variable group, followed by ASD and ADHD. The overall search performance – between trial onset and button press – resulted in typical manual mean RT in ASD and ADHD, versus TD, while being abnormally long in SCZ, compared to all other groups. ISV was typical in ADHD, below typical in ASD, above typical in SCZ.

Conclusions: Results suggest that the ability to extract individual targets is intact in ASD and ADHD. However, ASD only show a bias toward local information, as indicated by longer first fixation duration, despite intact global processing. Differently, lower search efficiency in SCZ might be explained by both (a) abnormal global processing, due to impairment in the guidance mechanisms that affect the time until the first fixation on target, and (b) a deficit in central discrimination, with resulting difficulties in extracting critical features of the target.

412.039 *(Poster)* Weighting of Perceptual Beliefs and Sensory Evidence: Prediction in Autism Spectrum Disorder

S. B. Guillory[1]*, Y. Zhang*[1]*, C. McLaughlin*[1]*, H. Grosman*[1]*, M. Amezcua*[1]*, E. Isenstein*[2]*, P. M. Siper*[1]*, D. Halpern*[1]*, D. H. Mathalon*[3]*, A. R. Powers*[4] *and J. Foss-Feig*[5]*, (1)Seaver Autism Center, Department of Psychiatry, Icahn School of Medicine at Mount Sinai Hospital, New York, NY, (2)University of Rochester, Rochester, NY, (3)Psychiatry, University of California, San Francisco, San Francisco, CA, (4)Yale University School of Medicine, New Haven, CT, (5)Psychiatry, Icahn School of Medicine at Mount Sinai, New York, NY*

Background: Autism spectrum disorder (ASD) is characterized by deficits in social communication and interaction, restricted interests and behaviors, and sensory abnormalities. A growing body of work suggests that alterations in predictive processes may contribute to these symptoms, where fundamental differences in the weighting of sensory evidence over prior knowledge can influence the way individuals with ASD approach their surroundings and navigate social situations.

Objectives: Here we assessed the integrity of predictive processes in adults with ASD. To this end, we manipulated stimulus presentation probabilities and measured neural activity with scalp electroencephalography (EEG) and behavioral responses in two separate experiments.

Methods: In one experiment, adults with ASD (n=14, mean age=22.1±7.1 years) and neurotypical controls (NTC; n=14, mean age=22.4±3.7 years) passively participated in an auditory mismatch negativity (MMN) paradigm that comprised of a standard stimulus presented on 85% of the trials and three deviant stimuli each representing 5% of the total trials. Deviant stimuli differed from the standard along the dimensions of duration, frequency, and duration+frequency. Here, participants were conditioned to expect the standard stimulus; the MMN reflects the mismatch in expectations from priors versus the actual auditory stimuli when presented with a deviant tone. We predicted that a bias towards sensory evidence would result in attenuated MMN signal in ASD.

In a second experiment using a Pavlovian learning task, we tested the relative weighting of sensory evidence and prior beliefs (ASD: n=9, mean age=25.2±5.7 years; NTC: n=9, mean age=21.6±3.1 years). We first induced an association between an at-threshold tone (75% likelihood detection) and a visual stimulus through frequent, concurrent presentations. Next, we tested the strength of perceptual beliefs by systematically lowering the proportion of trials with a perceivable tone to subthreshold (50% and 25% likelihood detection levels) or absent, measuring tone detection. Here, a bias towards prior beliefs occurs when participants report hearing tones on trials when none was presented. We posited that ASD participants would report the tone on no-tone trials less frequently than NTCs, again reflecting a bias towards sensory evidence.

Results: Results from the first experiment revealed no significant main effects of deviant type ($F(2,52)=1.80$, $p=0.18$, $\eta_p^2=0.07$) or group ($F(1,26)=0.32$, $p=0.58$, $\eta_p^2=0.01$), and no interaction ($F(2,52)=0.35$, $p=0.71$, $\eta_p^2=0.01$). These results indicate that expectations of deviant tones did not differ between groups.

In the second experiment, there was no significant difference between groups in reports of hearing a tone on tone absent trials ($t(16)=0.09$,$p = 0.93$,Cohen's $d=0.045$). Together, both groups responded to hearing a tone greater than chance on tone absent trials (ASD: $p=0.009$, NTC: $p=0.002$), suggesting greater weighting of prior beliefs. Examining the neural response, we found a significant interaction between threshold level and group, $F(3,48)=4.48$, $p=0.007$, $\eta_p^2=0.22$, such that ASD participants showed comparable neural response across threshold levels whereas NTC participants demonstrated attenuated neural response at the lowest threshold levels (25% likelihood detection and tone absent).

Conclusions: In two sperate experiments, we found no evidence of compromised prediction processing in ASD in the context of beliefs about the occurrence of low-level auditory sensory input.

Cognitive Neuroscience

PANEL SESSION — **COGNITIVE NEUROSCIENCE**

203 - Examining Neural Dynamics of Social and Nonsocial Cognitive Control in ASD: Converging Evidence from EEG and MEG

Panel Chair: So Hyun Kim, *Psychiatry, Center for Autism and the Developing Brain, White Plains, NY*

Executive function (EF) difficulties are one of the core cognitive deficits in ASD. However, there is still limited evidence for the neural mechanisms underlying the cognitive control deficits in individuals with ASD. Using cutting-edge, advanced electroencephalogram (EEG) and magnetoencephalography (MEG) methods, we will capture spatial and temporal dynamics of both social and non-social cognitive control in individuals with ASD across a wide age range (2-19 years). The first (Arthur et al.) and second presentations (Thomas et al.) use the EEG analyses of theta oscillations to examine distinctive EF-related neural profiles in children with ASD and their unique patterns of associations with an early infant brain function (Arthur et al.) or to concurrent functional outcomes at school-entry (Thomas et al.). The third presentation (Cremone-Caira et al.) aims to unpack the individual and group heterogeneity in EF using both resting EEG and ERPs among school-age children with ASD, ADHD, or typical controls. Finally, the fourth presentation (Vandewouw et al.) is focused on temporal and spatial neural correlates of response inhibition and emotional regulation in those with and without ASD using an emotional go/no-go task using MEG recordings.

203.001 *(Panel)* Mapping Cognitive Flexibility from 8 Months to 7 Years in a Longitudinal Sample of Infants with Older Siblings with ASD

R. Arthur[1,2], *T. Bazelmans*[3], *R. Haartsen*[4], *E. J. Jones*[4], *M. H. Johnson*[4] *and T. Charman*[5], *(1)Kings College London, London, United Kingdom, (2)Centre for Brain & Cognitive Development, London, United Kingdom, (3)King's College London, Institute of Psychiatry, Psychology and Neuroscience, London, United Kingdom, (4)Centre for Brain and Cognitive Development, Birkbeck, University of London, London, United Kingdom, (5)Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, United Kingdom*

Background: Autism Spectrum Disorder (ASD) is known to strongly overlap with other developmental conditions such as Attention Deficit Hyperactivity Disorder (ADHD). Both ASD and ADHD have been linked to differences in executive function and cognitive flexibility which can have mild to severe impacts on an individual's daily living. In the present study, we explored the brain mechanisms that may underpin cognitive control in a longitudinal cohort enriched for later ASD and ADHD outcomes.

Objectives: Our overarching goals are to map the common and distinct profiles of difficulties with cognitive control/executive functioning in children with and without ASD and ADHD symptoms. Further, we will examine whether profiles of cognitive control in mid childhood are associated with common roots in early infant brain function. We focus on fronto-central theta, a neural signature associated with the implementation of cognitive control.

Methods: We recruited 7- to 10-year-old children from an ongoing longitudinal study who were at an elevated familial likelihood of developing ASD (EL, current $n = 17$; projected $n = 50$), or had a typical likelihood (TL, current $n = 10$; projected $n = 30$). Executive function domains of inhibition control and flexibility were assessed with a battery including a computerised Go / No-Go task where children were asked to respond to a cat and not to a dog in the first block, before switching the response/stimulus mapping in the second block. We examined differences by likelihood group, and how individual differences in mid-childhood cognitive control associated with EEG theta (4-5 Hz) power and connectivity (debiased weighted phase lag index) measured at 14 months while infants passively viewed social and non-social videos.

Results: Preliminary analyses on the Go/No-Go task revealed that the task showed the expected modulation by condition. When the children were asked to switch their response to a different stimulus, children displayed a longer reaction time to Go compared to No-Go trials ($F(1,25) = 632.70$, $p < .0001$, $\eta_p^2 = .567$), but this difference was stronger in the EL group than the TL group (interaction effect between Condition and Group: ($F(1,25) = 6.07$, $p = .021$, $\eta_p^2 = .195$). Furthermore, children who displayed shorter reaction times on the Go trials also tended to exhibit more frontal theta power and increased levels of EEG connectivity (4-5 Hz) during infancy (Power $r_{Spearman} = -.62$, $p = .102$; and EEG connectivity $r_{Spearman} = -.68$, $p = .071$, $N = 8$). Further analyses will focus on associations with ASD and ADHD symptomatology measured via parent report.

Conclusions: Our work suggests that we can detect emerging profiles of difficulties with executive functioning in children with an older sibling with ASD relative to controls, but these difficulties are subtle. However, individual differences in executive functioning were associated with variation in infant brain activity during passive viewing. Further analyses will test whether this could reflect an early-emerging system that could buffer developmental trajectories towards or away from ASD and ADHD symptoms.

203.002 *(Panel)* Neural and Behavioral Impairments in Cognitive Control in Kindergarteners with ASD: EEG Analyses of Theta Oscillations

H. R. Thomas[1], *G. Buzzell*[2], *Y. B. Choi*[3], *C. B. Klein*[1], *N. Fox*[2] *and* ***S. H. Kim***[1], *(1)Psychiatry, Center for Autism and the Developing Brain, White Plains, NY, (2)University of Maryland, College Park, MD, (3)Psychiatry, Weill Cornell Medical College, White Plains, NY*

Background: Children with ASD demonstrate impairments in cognitive control compared to their typically developing (TD) peers (Happé et al., 2006). At the neural level, cognitive control is known to rely on theta oscillations, arising from the mediofrontal cortex (MFC; Cavanagh & Frank, 2014). MFC theta increases following error responses and predict behavioral adaptations in youth (Buzzell et al., 2019) and adults (Cavanagh et. al., 2011). Preliminary work in young children with ASD show similar error-related changes in MFC theta (Kim et al., 2019); however, direct comparisons of MFC theta in ASD and TD controls are lacking.

Objectives: Examine whether ASD and TD children differ in both behavioral and neural correlates of cognitive control.

Methods: Fourth-four cognitively-able children with ASD (11 females; M_{age}=63.1 months, SD=4.3) and 24 TD children (10 females; M_{age}=63.4 months, SD=4.9) at kindergarten-entry performed a child-friendly go/no-go task ("Zoo Game"). At the behavioral level, overall accuracy was assessed; regression analyses were conducted to examine behavioral differences between the groups. Time-frequency approaches were employed to extract response-locked theta power from two theta band (4-7 Hz) ROIs: 1) an "early theta" ROI from 0-200 ms post-response; 2) a "late theta" ROI from 200-400 ms post-response. A pair of two-way repeated measures ANOVAs (accuracy [correct vs. error-trials] by diagnosis [ASD vs. TD]) examined whether error-related theta differed across diagnostic groups. Pearson's correlations assessed relations between error-related theta and zoo game performance. Partial correlations explored associations between theta and academic outcomes (Woodcock-Johnson III tests of achievement [WJ]; Woodcock et al., 2001).

Results: Children with ASD were significantly less accurate on the Zoo game compared to the TD group, even after controlling for NVIQ, age, and gender (b=0.63, p=0.001). At the neural level, only the late theta ROI yielded a significant interaction between accuracy and diagnosis (F=4.70, p=0.034), such that TD children exhibited a larger error (vs. correct) increase in theta relative to children with ASD (Figure 1). Partial correlations revealed that error-related differences in late theta were significantly correlated with a WJ math subtest (Applied Problems), above and beyond NVIQ and zoo game performance (r=0.39, p=0.011)

Conclusions: Children with ASD demonstrated behavioral and neural deficits in cognitive control, compared to their TD peers. Notably, deficits in error-related theta for the ASD group were most pronounced in a later (200-400 ms) time window. Cognitive control is thought to involve a cascade of processing whereby the need for control is first detected, followed later by recruitment of top-down control to bias behavior favorably. The later theta time window observed in our sample may more closely map onto neural processes associated with the recruitment of top down control, and this second stage of cognitive control could be particularly impaired in ASD. Consistent with such an interpretation, late theta was correlated with high-level cognitive functioning, specifically academic achievement. Ongoing analyses will seek to directly test whether those with ASD exhibit deficits in the recruitment of top-down control by investigating: 1) theta-band connectivity between medial and lateral frontal sites; 2) whether post-error behavior is impacted.

203.003 *(Panel)* An Examination of Event-Related Potentials and Resting EEG Correlates of Executive Function Among School-Aged Children with ASD, ADHD and Typical Development

A. M. Cremone-Caira[1]*, J. I. Nikolaeva*[2]*, V. E. Sanchez*[3]*, R. Gilbert*[4] *and S. Faja*[4]*, (1)Boston Children's Hospital Labs of Cognitive Neuroscience, Boston, MA, (2)Communication Sciences and Disorders, Northwestern University, Evanston, IL, (3)Division of Developmental Medicine, Boston Children's Hospital, Boston, MA, (4)Boston Children's Hospital, Boston, MA*

Background: Executive function (EF) is often impaired among individuals with ASD, even in the absence of generalized cognitive difficulties. EF involves distinct skills including inhibition, working memory, and set-shifting. Understanding the neural profile underlying EF in children with ASD is particularly critical because EF has been linked to academic and social functioning. However, the neural correlates of EF remain poorly understood in ASD, particularly compared to clinical conditions that share EF challenges such as ADHD.

Objectives: To examine group differences in event-related potentials (ERPs) during a Go/Nogo task and resting EEG, and relations between these neural correlates and EF outcomes measured via objective behavioral tasks.

Methods: To date, 21 children with ASD, 24 with ADHD, and 22 with typical development (TD) provided usable ERP data during the Go/Nogo task. Group differences in mean amplitude and latency for the N2, P3, and ERN ERP components were examined for the 'go' and 'nogo' conditions of this task. Resting EEG was also available for 24 children with ASD, 25 with ADHD, and 24 with TD. Relative EEG power was extracted over a cluster of frontal electrodes (F3, F1, Fz, F2, F4) at the theta, alpha, beta, and low gamma ranges. Participants were between 7-11 years, had full-scale IQs of 84 or above, and were not taking stimulant medications during study visits. IQ differed by group and was controlled for in subsequent analyses. Children in the ASD group with elevated symptoms of ADHD (CBCL>65) were excluded. A battery of EF tasks was administered including the Change, Stroop, Digit Span, and Hungry Donkey Task, which indexed behavioral inhibition, interference suppression, working memory, and strategic long-term decision making, respectively.

Results: A significant group (ASD/ADHD/TD) by condition (Go/Nogo) interaction was detected via repeated measures ANOVA for N2 mean amplitude, F(2,63)=4.38, p=.02. No other significant effects were detected for ERPs. Relative EEG power differed by frequency band (theta/alpha/beta/low gamma) for the three groups, F(6,207)=3.88, $p\leq$.01. Across groups, children who required longer warning durations to inhibit a dominant response on the Change Task had lower relative beta power, r(70)= -.283, p=.02. Stroop performance (i.e., suppressing interfering information) related to relative power in the low gamma range, r(68)=.309, p=.01, with children who had larger differences between congruent and incongruent Stroop trials having higher gamma power. Larger P3 amplitude related to better performance on the Digit Span, r(64)=.268, p=.03. Children with more advantageous selections in the final two blocks of the Hungry Donkey Task exhibited the greatest theta power, r(68)=.358, $p\leq$.01, and highest theta-beta ratios, r(68)=.362, $p\leq$.01.

Conclusions: ERPs and resting EEG related to different aspects of EF, suggesting the need for more nuanced examination of neural correlates of EF during early development. Examination across clinical populations provides a way to improve specificity of neural biomarkers as tools for classification versus stratification within group.

203.004 *(Panel)* Understanding Emotional Inhibition in Children and Adolescents with ASD: A Pond Imaging Study

M. M. Vandewouw[1]*, K. Safar*[2]*, J. Sato*[3]*, J. P. Lerch*[4]*, E. Anagnostou*[5] *and M. J. Taylor*[3]*, (1)Neuroscience & Mental Health Program, The Hospital for Sick Children Research Institute, Toronto, ON, Canada, (2)Diagnostic Imaging, Hospital for Sick Children, Toronto, ON, Canada, (3)The Hospital for Sick Children, Toronto, ON, Canada, (4)Wellcome Centre for Integrative Neuroimaging (WIN), University of Oxford, Oxford, ON, United Kingdom, (5)Holland Bloorview Kids Rehabilitation Hospital, Toronto, ON, Canada*

Background: Emotion regulation is an important aspect of social interactions, and relies on the ability to inhibit responses to emotional stimuli. Autism spectrum disorder (ASD) is classically associated with poor emotional face processing skills, and individuals with ASD also show difficulties in executive functions, particularly in inhibitory control. The underlying spatial and temporal neural dynamics of emotional inhibition has rarely been studied in children and adolescents with ASD.

Objectives: The purpose of this study was to understand the neural underpinnings of response inhibition and emotional regulation in those with and without ASD using an emotional go/no-go task using magnetoencephalography (MEG) functional imaging.

Methods: MEG data were obtained at the Hospital for Sick Children from 127 ASD and typically developing (TD) youth (included in final analyses, out of an initial sample of 206 participants), children aged 7-10yrs (ASD: N=26, TD: N=27) and adolescents, aged 11-19yrs (ASD: N=40, TD: N=34). Blue or purple frames containing emotional distractors (happy or angry faces) were presented, and participants responded rapidly to a target colour in vigilance (25% go trials) and inhibition (75% go trials) conditions. Functional images were generated for each emotion in both conditions for the no-go trials by applying beamformer weights on 100ms sliding windows (25ms overlap, 50–500ms) using SPM12. A factorial design model with task and emotion as within-subject factors and group (TD/ASD) as a between-subject factor was used to test for between-group differences ($p<0.05$, corrected) in inhibition (inhibition/vigilance across emotion), emotion (happy/angry in the vigilance condition), and the interaction of inhibition and emotion.

Results: Comparing the inhibition and vigilance tasks (inhibition>vigilance) across emotion, the TD children showed prolonged increased activation (175–500ms) of the left insula compared to ASD, while this effect reversed in the adolescents at an early time window (ASD>TD, 50–200ms). Comparing emotional faces found that angry faces elicited greater activation of the left inferior frontal gyrus (IFG) in the ASDs compared to the TDs in the children (275–500ms) and adolescents (50–225ms). The interaction of inhibition and emotion in the children showed increased activation of the right inferior temporal gyrus (175–275ms) in TDs, while the ASDs demonstrated increases in the left temporal gyri (100–300ms). The adolescent TDs showed increased activation in the IFG (225–475ms) and right middle temporal gyrus (300–475ms).

Conclusions: In inhibition, differences between TD and ASD children and adolescents in the insula, a region which has been implicated in salience and inhibitory control, shows that while the TD children demonstrated typical increases in processing speed with development, the ASD group only demonstrated some catch up by adolescence. Increased left IFG activation to angry faces in ASDs in the vigilance condition could reflect an increased reliance on an area important in processing angry faces to compensate for known difficulties in understanding this emotion by those with ASD. The IFG is also involved in successfully inhibiting motor responses; the observed interaction in the adolescents demonstrates, however, that this region is not being recruited appropriately during inhibition.

PANEL SESSION — COGNITIVE NEUROSCIENCE
204 - Eye Tracking and the Brain

Panel Chair: Frederick Shic, *Center for Child Health, Behavior and Development, Seattle Children's Research Institute, Seattle, WA*

Discussant: Shafali Jeste, *University of California, Los Angeles, Los Angeles, CA*

This panel examines how eye tracking and neuroscience techniques are working in concert to provide new perspectives on ASD. The panel brings together researchers from both Europe and the United States, with panelists drawn from a wide diversity of backgrounds and seniority in the field, showcasing a range of neuroimaging techniques including functional MRI, electroencephalography, and functional near infrared spectroscopy, as they relate to eye-tracking data. The first presentation highlights how eye movements may index specific subgroups within the autism spectrum associated with distinct neural architecture; the second highlights the interplay between eye tracking and fundamental disturbances in joint attention behaviors in toddlers and children; the third examines within-individual consistency of EEG and eye tracking across repeat visits, homing in on a facet of biomarker development that is both methodologically critical and innovative as a biomarker in of itself; and finally, the fourth study highlights how neuroscience techniques and behavioral biomarkers from eye tracking may provide distinct and complementary information that may, in unison, provide even more predictive power. This work highlights the deepening trend towards multi-modal, interdisciplinary science that is becoming a critical component of our advancing efforts to understand the foundational mechanisms of ASD.

204.001 *(Panel)* The Search for Biomarkers and Phenotypically Meaningful Subtypes of ASD Based on Eye Tracking, Clinical, and Brain Imaging Data

K. Pierce[1], *M. V. Lombardo*[2], *V. Gazestani*[3], *A. Cheng*[4], *S. Nalabolu*[4], *T. H. Wen*[1], *C. Barnes*[5] *and E. Courchesne*[1], *(1)Autism Center of Excellence, Neurosciences, University of California, San Diego, La Jolla, CA, (2)Center for Neuroscience and Cognitive Systems, Laboratory for Autism and Neurodevelopmental Disorders, Istituto Italiano di Tecnologia, Rovereto, Italy, (3)Neurosciences, Univeristy of California, San Diego, La Jolla, CA, (4)Neurosciences, University of California, San Diego, La Jolla, CA, (5)University of California, San Diego, La Jolla, CA*

Background: Markers that define ASD subtypes are extremely valuable because of their potential implications about causes, mechanisms, prognosis, and treatments. However, discovering such subtypes requires not only large sample sizes[3], but also deep clinical and neural phenotyping. We previously published two studies[4,5] totaling 444 subjects, using an eye tracking paradigm, the "Geo Pref Test" that examined the degree to which a toddler preferred to visually fixate on geometric, rather than social, images. Results indicated that ~20% of toddlers with ASD spend very high levels of time visually fixating on geometric rather than social images, a profile not often seen in non-ASD contrast groups. Here we have collected data on an independent sample of 1,180 toddlers that has not yet been published. Presumably, if experience dependent mechanisms play a role in growth and development, hypotheses could be tested that examine relationships between visual attention, behavioral symptoms and brain functional connectivity patterns.

Objectives: Goals were to examine: (1) validation statistics (e.g., specificity) in the overall cumulative sample using the 69% fixation geometric as the critical cut off; (2) correlations with clinical phenotype; (3) neural functional connectivity patterns in a subset of toddlers who participated in both eye tracking and brain imaging. We hypothesized that toddlers that preferred geometric images, or "GeoPref ASD" toddlers, would show a disruption in connectivity between brain regions that support social and visual processing.

Methods: An overall total of 1,624 toddlers participated in eye tracking using the GeoPref Test (age range 12-48 months, N=607 ASD and N=1,017 non-ASD). Fixation duration within each area of interest (i.e., geometric or social) was recorded, and validation statistics examined using standard formulas. Toddlers also participated in clinical tests including the ADOS, Mullen, and Vineland. A subset of toddlers participated in resting state sleep fMRI (N=195). Within this cohort, functional connectivity between networks, including between the Default Mode (DMN) and Occipito-Temporal Cortex (OTC), was examined. **Figure 2A.**

Results: Toddlers with ASD fixated more on geometric images than any other diagnostic group ($F=44.06$, $p<.0001$), and sensitivity and specificity (i.e., 18% and 98%) was similar to previous studies when the 69% cut off was used. **Figure 1.** Significant correlations between percent geometric fixation and clinical phenotype, including overall ADOS ($r=.44$), receptive ($r=-.34$), and expressive language ($r=-.35$) was found (all $ps<.0001$). Examination of resting state data revealed functional hypoconnectivity between "social brain" circuitry including the DMN and OTC in toddlers with ASD when all ASD toddlers were combined regardless of eye tracking, and compared to Non-ASD contrast groups. For example, effect sizes, Cohen's d, illustrating the magnitude of difference between ASD vs TD was $d=.66$, **Figure 2B,** but increased to 1.28 when a subtype model was used and functional connectivity between the GeoPref ASD subtype was specifically compared to TD toddlers. **Figure 2 C.**

Conclusions: Early deviances in brain development may be related to abnormal visual attention in a specific ASD subtype. This in turn may contribute to challenges with language and social interactions during early life, placing such "GeoPref ASD" toddlers at a disadvantage.

204.002 *(Panel)* Eye Gaze and Neural Correlates of Joint Attention in Autism Spectrum Disorders

L. Billeci[1]*, V. Costanzo*[2]*, S. Calderoni*[3]*, F. Apicella*[2]*, A. Narzisi*[4] *and F. Muratori*[3]*, (1)Consiglio Nazionale delle Ricerche (CNR), Pisa, Italy, (2)IRCCS Fondazione Stella Maris, Calambrone (Pisa), Italy, (3)Department of Clinical and Experimental Medicine, University of Pisa, Pisa, Italy, (4)IRCCS Stella Maris Foundation, Pisa (Calambrone), Italy*

Background: Joint attention (JA) is described as the ability to coordinate visual attention with another person and then shift the gaze toward a shared object or event. Deficits in JA are known to be one of the prominent features of Autism Spectrum Disorders (ASD), and have been correlated not only with social and communicative problems, but also with deficits in language development.

Literature reports on two main components of JA: the response to JA and the initiation of JA. Eye-tracking has recently been used during JA tasks in ASD, focusing in particular on RJA and gaze accuracy. Literature has also suggested a correlation between JA abilities and specific neural circuitry, which can be studied by various brain imaging techniques.

Objectives: In this presentation, we will present our research on visual and neural correlates of joint attention in ASD.

Methods: We first review our study describing visual patterns of toddlers with ASD (N=17) and TD (N=15) during RJA and IJA tasks in an eye-tracking scenario. We then present a pilot study in which, using a similar paradigm, we applied an integrated EEG/eye-tracking approach to investigate gaze and neural correlates of RJA and IJA in high-functioning children with ASD (N=11). In this study, we also evaluated changes in brain function and visual pattern after six months of rehabilitative treatment. Finally, we present novel results related to the study of JA processing in younger sibling of children with ASD (N=19).

Results: We found no difference in the RJA task between toddlers with ASD and TD toddlers ($p>.10$), whereas different gaze patterns emerged in IJA tasks ($p=.02$). We hypothesized these differences were due to ASD-related impairments in visual disengagement from faces, in global scanning of the scene, and in the ability to anticipate object action. Our pilot work subsequently showed IJA and RJA subtend both overlapping and specialized neural circuitries. In addition, in a subgroup of subjects, we observed trends of changes in both brain activity and connectivity after rehabilitative treatment in both the two tasks, which were correlated with modifications in gaze measures ($r=.0.80$). Finally, in our study of younger siblings, we applied our previously implemented RJA/IJA eye-tracking paradigm and found an intermediate pattern of visual processing between ASD and TD, with some features similar to that of TD children and some similar to ASD children. As an exploratory study, we also investigated correlations ($r=0.70$, $p=0.03$) between gaze response to JA of these siblings and functional activation of their brain (i.e. asymmetry, coherence) as measured during rest by using high-density EEG.

Conclusions: Overall, our results suggest that the assessment of JA, and in particular of IJA, with eye-tracking can give new insights regarding the atypical development of JA in the very early stages of ASD. In particular, by applying this kind of protocol in younger siblings of children with ASD, it could be possible to identify some biomarkers of the disorder. In addition, by using a multimodal approach, it is possible to characterize JA-related brain circuitries correlating with visual pattern in ASD.

204.003 *(Panel)* Exploring Consistency between Brain Activity and Consistency of Social Viewing in ASD

A. Naples[1]*, A. R. Levin*[2]*, F. Shic*[3]*, D. Senturk*[4]*, R. Bernier*[5]*, G. Dawson*[6]*, S. Jeste*[7]*, K. Chawarska*[1]*, C. Sugar*[7]*, M. Murias*[8]*, J. Dziura*[9]*, C. Brandt*[9] *and J. McPartland*[1]*, (1)Child Study Center, Yale University School of Medicine, New Haven, CT, (2)Neurology, Boston Children's Hospital, Boston, MA, (3)Center for Child Health, Behavior and Development, Seattle Children's Research Institute, Seattle, WA, (4)UCLA, Los Angeles, CA, (5)Psychiatry and Behavioral Sciences, University of Washington, Seattle, WA, (6)Department of Psychiatry and Behavioral Sciences, Duke Center for Autism and Brain Development, Durham, NC, (7)University of California, Los Angeles, Los Angeles, CA, (8)Duke Center for Autism and Brain Development, Department of Psychiatry and Behavioral Sciences, Duke University, Durham, NC, (9)Yale University, New Haven, CT*

Background: Both electroencephalography (EEG) and eye-tracking (ET) are promising biomarker acquisition tools in ASD. Recent research has highlighted that, within an individual over time, the shape of the EEG power spectral density (PSD) exhibits high levels of test-retest reliability. Similarly, in eye-tracking research, monozygotic in contrast to dizygotic twins exhibit striking levels of similarity in eye-tracking scan paths. Together, these findings suggest that both EEG and ET are under high-levels of biological control that manifest "trait-like" stability. However not all individuals exhibit these high levels of consistency. Rather, there is a wide range of within person consistency, which may represent a meaningful biomarker unto itself.

Objectives: Using EEG and ET data collected from 225 individuals with ASD and 75 typically developing controls at 3 timepoints spanning 6 months, we evaluated: (1) within-person consistency in EEG activity, (2) within-person consistency in ET scan-paths, and (3) whether individual consistency in EEG associated with consistency in ET.

Methods: Data were collected from 225 individuals with ASD and 75 TD controls between the ages of 6 and 11 across five sites as part of the Autism Biomarkers Consortium for Clinical Trials (ABC-CT). EEG was recorded during one quiet, eyes-open resting session at each time point, and ET was collected across 2 sessions at each time point to displays of static and dynamic social stimuli. Individual similarity in EEG was calculated as the correlation of detrended EEG power spectra across frequency bands. Similarity between ET sessions was calculated as the correlation of binned gaze coordinates for identical stimuli and the difference of Shannon entropy between sessions as an index of exploratory gaze behavior.

Results: Analyses of the full sample are ongoing. Our preliminary results show (1): From 49 participants collected during the feasibility portion of the study across two days, on average, the correlation of PSD within individuals was r = .76 and between individuals was .54, ranging from r = 0 to r = .99. Preliminary results from ET from 100 individuals across six weeks revealed: (1) average within person correlations ranged from r = .34 for social movies to .37 for static images. However, within participant correlations ranged from .-.4 to .99 indicating substantial variability across individuals. Diagnostic groups differed in within-person consistency in only 1 of 5 stimulus categories (videos containing high levels of movement) in which TD controls exhibited greater consistency of looking across 6 weeks (p <.001, Figure 1).

Conclusions: Our data reveal that the within person consistency of EEG PSD and ET vary substantially across individuals, with some individuals exhibiting high levels of variability across time points and others almost identical EEG power spectra and ET scan paths. Ongoing analyses explore within person consistency across a span of six months and the relationships between EEG activity and eye-tracking and their relationships with clinical characteristics. Nevertheless, current results demonstrate that within-individual consistency can differentiate diagnostic groups and exploring the sources of within-individual variability offers a novel approach towards refining our use of ET and EEG as biomarker tools in ASD.

204.004 *(Panel)* Biological Motion Perception in ASD: A Combined Functional Near Infrared Spectroscopy and Eye-Tracking Study

F. Shic[1], *M. Kim*[2], *B. Li*[3], *Y. A. Ahn*[4], *E. Barney*[1], *K. J. Dommer*[5], *M. C. Aubertine*[6], *S. Corrigan*[5], *E. Neuhaus*[7], *N. M. McDonald*[8], *K. A. Pelphrey*[2] *and A. Atyabi*[9], *(1)Center for Child Health, Behavior and Development, Seattle Children's Research Institute, Seattle, WA, (2)University of Virginia, Charlottesville, VA, (3)Computer Science and Engineering, University of Washington, Seattle, WA, (4)Psychology, University of Miami, Miami, FL, (5)Seattle Children's Research Institute, Seattle, WA, (6)Seattle Children's Hospital and Research Institute, Seattle, WA, (7)Seattle Children's Hospital, Seattle, WA, (8)UCLA Center for Autism Research and Treatment, Los Angeles, CA, (9)Seattle Children's Research institute University of Washington, Seattle, WA*

Background: Previous work using functional MRI have found atypical activation of the right superior temporal sulcus and prefrontal cortex in response to biological motion in individuals with ASD. However, these effects have not been replicated using functional near infrared spectroscopy, and little is known about how these brain changes relate to visual attention patterns.

Objectives: To examine bilateral PFC and superior temporal sulcus (STS) modulation by emotional biological motion (biomotion) in participants with ASD compared to typically developing (TD) participants, focused on hemodynamic response as observed from oxygenated hemoglobin (HbO), and to explore relationships among brain activity in ASD, phenotypic characteristics, and eye movement data.

Methods: Children (ASD n=30; TD n=30; Table 1) watched emotional biomotion clips (fear, anger, joy, neutral) interleaved with rotating control point light displays (PLDs) in 40 trials over 12 minutes while wearing a Gowerlabs NTS fNIRS cap covering prefrontal cortex (PFC) and superior temporal sulcus (STS) areas and eye movements tracked with an SR Eyelink 1000 Plus. Changes in oxygenated hemoglobin (HbO) were preprocessed with motion artefact removal involving PCA filtering, channel-wise artefact removal, stimuli/trial rejection, and spline interpolation followed by band pass filtering (0.00hz-0.50hz) and baseline correction using the 2s prior interval of each trial. Results were analyzed with linear mixed effects models and FDR control for 38 channel comparisons. Interpretation compared channel results with brain atlas-registered locations. Examination of relationships between brain activity and phenotype and eye tracking in ASD used Spearman's correlation.

Results: TD participants demonstrated widespread cortical responses to biomotion-rotation, with increased HbO to biomotion in 9 of 38 brain areas. In ASD no channels were significantly activated. ASD-TD comparisons suggested hypoactivation in ASD in response to biomotion in left inferior frontal and left inferior temporal gyri. In ASD, diminished right superior temporal responses to biomotion was associated with increased autism severity (r=-.56, p=.026), whereas increased activation in left frontal inferior orbital and ventrolateral prefrontal cortices were associated with lower IQ and higher autism severity (r=-.62, p=.013; r=.51, p=.040, respectively). Eye tracking analyses revealed group and condition main effects and no interaction, with children with ASD having less trackable data (p<.001), more fixations (p=.049), and more blinks (p<.001) per unit time than TD. Higher blinks/second were associated with higher autism severity (r=.59, p=.014) in ASD. Despite overlap in phenotypic relationships, no eye tracking-fNIRS relationships survived control for multiple comparisons. However, combining strongest fNIRS and eye-tracking associations in predicting autism severity indicated non-overlapping improvements in model fits (r=.65, p<.025) (AIC: 98.3 (fNIRS), 96.1 (ET), 92.3 (combined)).

Conclusions: These results highlight atypical neural response of children with ASD to biological motion as well as disturbed elementary visual exploratory behaviors. Despite strong relationships from both eye tracking and fNIRS to autism severity, there were few relationships between eye tracking and fNIRS. These results suggest that these two outcome modalities, in this study, may be disassociable. Improved model fits in predicting autism severity by combining variables from both modalities may suggest potential advantages of multimodal biomarkers that increase precision by leveraging non-overlapping constructs.

POSTER SESSION — **COGNITIVE NEUROSCIENCE**

413 - Cognitive Neuroscience Posters

413.001 *(Poster)* A Pilot Study of High-Definition Transcranial Direct Current Stimulation (HD-tDCS) to Right Ventrolateral Prefrontal Cortex (vlPFC) in Autism Spectrum Disorder

***D. B. Parmar**, N. Albein-Urios, A. Ware, M. Barham, J. Lum, E. Sciberras and P. G. Enticott, Faculty of Health, School of Psychology, Deakin University, Burwood, VIC, Australia*

Background: Cognitive inflexibility and repetitive behaviours are hallmark features of autism spectrum disorder (ASD) that can significantly impair daily functioning. Cognitive flexibility has been linked to the ventrolateral prefrontal cortex (vlPFC), while reduced activity in the vlPFC in ASD is related to both cognitive inflexibility and restrictive and repetitive behaviours (RRB) patterns. Non-invasive brain stimulation techniques, including high-definition transcranial direct current stimulation (HD-tDCS), can be used to modulate cortical activity with a view to therapeutic outcomes.

Objectives: In a pilot study, we investigated whether anodal HD-tDCS to right vlPFC can improve cognitive and behavioural flexibility in young people with ASD.

Methods: Using a randomized, double-blinded, crossover study design, anodal HD-tDCS was delivered for 20 minutes over the right vlPFC for four consecutive days. Twelve participants (7 Males, mean age = 25 years) underwent both the HD-tDCS active and sham condition, with a one-month interval between conditions. Cognitive Flexibility was assessed before and after HD-tDCS across three domains: cognitive, behavioural, and neurophysiological. The corresponding outcomes assessed in this study were the Behaviour Rating Inventory of Executive Functioning (BRIEF; *shift subscale*), the Probabilistic Reversal Learning Task (PRLT; providing a direct approach to examining flexible choice behaviour), and electroencephalography (EEG; specifically, feedback related negativity).

Results: Generalised linear mixed model analyses were used to examine whether anodal HD-tDCS had an effect on the BRIEF shift scale, PRLT and feedback related negativity, with treatment condition (active versus sham) and time (pre-post) as the independent variables. The analysis yielded no significant differences between HD-tDCS active and sham conditions or between pre-post sessions on the BRIEF shift scale, PRLT and Feedback Related Negativity. In terms of tolerability and feasibility, there were no serious side effects or adverse events reported across conditions.

Conclusions: While the current pilot study supports the feasibility of tolerability of HD-tDCS in ASD, it does not provide support for efficacy of stimulation of right vlPFC when targeting cognitive and behavioural flexibility in ASD. We discuss limitations of our approach, particularly concerning sample size, individualised stimulation parameters, and the heterogeneity of ASD.

413.002 *(Poster)* Action Mindreading in Autism

***C. Becchio**[1], C. Ansuini[1], F. Battaglia[1,2], D. Albergo[1,3], J. Podda[1,4], A. Cavallo[1,5], J. F. Patri[1], M. Valente[3], L. Nobili[2] and S. Panzeri[6], (1)Cognition, Motion and Neuroscience, Istituto Italiano di Tecnologia, Genova, Italy, (2)IRCCS Istituto Giannina Gaslini, Ospedale Pediatrico, Genova, Italy, (3)Neural Computation Laboratory, Istituto Italiano di Tecnologia, Rovereto, Italy, (4)Scientific Research Area, Italian Multiple Sclerosis Foundation, Genova, Italy, (5)Department of Psychology, University of Turin, TORINO, Italy, (6)Neural Computation Laboratory, Istituto Italiano di Tecnologia, Rovereto and Genova, Italy*

Background: The ability to “mindread” the actions of others is crucial to interpret and anticipate their behavior. Children with autism spectrum conditions (ASC) have been proposed to be delayed in the development of this ability, with knock-on on consequences on social interaction across lifespan. However, the exact nature of atypicalities in action mindreading associated with autism remains unknown. Here we report on a study combining motion tracking, psychophysics and computational modelling to compare single-trial computations underlying action mindreading in typically developing (TD) children and children with ASC.

Objectives: To analyze how intention encoding – the mapping of intention to movement kinematics – and intention readout – the mapping of kinematics to ascription of intention – intersect at a single-trial level in TD children and children with ASC.

Methods: Eight- to eleven-year old TD children (n=35) and children with ASC without accompanying intellectual impairment (n=35) watched a hand reaching for a bottle, either to pour or to drink, and decided on the intention of the observed grasp. In a within-subjects counterbalanced order, participants observed grasping acts performed by either TD children or children with ASC (see Fig. 1a). We developed a quantitative framework, employing logistic regression, to analyze single-trial computations involved in extracting intention-related information from the observation of typical and autistic movement kinematics.

Results: TD children performed well above chance on intention discrimination from the observation of both typical and autistic kinematics. Children with ASC instead performed near chance. Single-trial analysis results indicated that the poor performance of ASC children did not reflect a lack of sensitivity of intention readout to movement kinematics. Children in both groups used variations in kinematics to judge intention. The ability to correctly link these variations to the correct intention, however, was significantly reduced in ASC children compared to TD children (see Fig. 1b).

Conclusions: Children with ASC “see” variations in movement kinematics, but are unable to link such variations to the correct intention. These findings contradict the hypothesis that children with autism are “blind” to subtle differences in movement kinematics and suggest that ASC-related difficulties in action mindreading originate at the intersection between intention encoding and readout.

413.003 *(Poster)* Basic Oculomotor Characteristics Are Similar between Young ASD Children and Matched Controls

I. Avni[1,2], *A. Bar-Sinai*[2,3], *D. Reboh*[2,4], *I. Menashe*[2,5], *G. Meiri*[2,6], *L. Shmuelof*[1] *and I. Dinstein*[2,4,7], *(1)Cognitive and Brain Sciences, Ben-Gurion University of the Negev, Beer Sheva, Israel, (2)National Autism Research Center of Israel, Ben-Gurion University of the Negev, Beer Sheva, Israel, (3)Department of Psychology, Ben-Gurion University of the Negev, Beer Sheba, Israel, (4)Department of Psychology, Ben-Gurion University of the Negev, Beer Sheva, Israel, (5)Public Health, Ben-Gurion University of the Negev, Beer Sheva, Israel, (6)Preschool Psychiatric Unit, Soroka University Medical Center, Beer Sheva, Israel, (7)Psychology Department, Ben-Gurion University of the Negev, Beer Sheva, Israel*

Background: A variety of eye tracking studies have reported that children with autism view images and movies of social interactions differently than typically developing children. It is commonly assumed that these differences in gaze behavior are generated by different stimulus preferences such that children with autism choose to fixate on different locations in the presented images/movie as compared with controls. An alternative explanation is that differences may be caused by basic oculomotor characteristics (e.g., saccade frequency or kinematics) that may differ across groups. To test this, we analyzed oculomotor characteristics of toddlers with autism and controls as they watched animated movies and also during presentation of salient targets that elicited saccades.

Objectives: To compare basic oculomotor characteristics between children with autism and controls during presentation of movies and salient targets that elicit saccades.

Methods: A total of 85 children (56 with autism and 29 controls), 2-8-years-old, were recruited by the National Autism Research Center of Israel at Ben Gurion University (www.autismisrael.org). All children participated in an eye tracking study where they viewed two animated movies (each 1.5 minutes long) and 50 trials containing a salient visual stimulus that was presented in different locations on the screen. Segments of the movies where the child was not observing the screen and trials where the child was not fixating during stimulus presentation were excluded. We used the remaining data to compute the frequency of saccades during each of the movies as well as their basic kinematic features including peak velocity, extent, and duration. For trials with salient targets we also computed first saccade latency as well as its accuracy in terms of angle and extent. These characteristics were compared across groups using t-tests and correlated with ADOS and cognitive scores for the autism group.

Results: There were no significant differences between children with autism and controls in all analyses of all measures. There were no significant differences in the frequency of saccades during either movie, nor in their peak velocity, extent, or duration. Saccade latency and accuracy did not differ across groups on trials containing salient visual stimuli. Furthermore, children in both groups exhibited similar velocity by distance scaling in agreement with the isochrony principle. There were no significant correlations between any of the oculomotor measures and ADOS or cognitive scores.

Conclusions: The results demonstrate that basic oculomotor characteristics of children with autism and controls are statistically indistinguishable. This indicates that previously reported differences in gaze behavior are indeed due to differences in visual preferences rather than potential differences in basic oculomotor control. These findings are encouraging from a therapeutic perspective, because they suggest that basic oculomotor function is intact in the majority of cases.

413.004 *(Poster)* Differences in Activity of the Brain's Executive Network in Autism Spectrum Disorder

K. E. May *and R. K. Kana, University of Alabama, Tuscaloosa, AL*

Background: Autism spectrum disorder (ASD) is characterized by impairments in executive function (EF) (Hill, 2004; Hughes et al., 1994), suggested to reflect an overreliance of the prefrontal cortex (PFC) when completing EF tasks. This is contrasted by research pointing to poor recruitment of the PFC in individuals with ASD (Gilbert et al., 2008; Minshew & Keller, 2010). Despite the EF dysfunction being a compelling cognitive model of ASD, there has been inconsistencies in findings, particularly in PFC response to EF tasks.

Objectives: In order to assess the emerging consensus across neuroimaging studies of EF in ASD, the current study used coordinate-based anatomical likelihood estimation (ALE) analysis of 18 functional magnetic resonance imaging (MRI) studies.

Methods: EF tasks included Tower of London, Go/NoGo, Flanker Task, False-Belief, N-back, Random Response Generation, etc. This resulted in a meta-analysis of 900 participants (408 ASD, 492 typically developing (TD) individuals). Participants ranged from 7 to 52 years of age and were of average IQ. All studies matched ASD and TD participants by age and IQ, and the majority of the ASD participants were high-functioning.

Results: Within-group analysis (EF task vs. Control Task) revealed that both TD and ASD participants had significant activity in the prefrontal regions. Analysis of group differences indicated greater activation in ASD, relative to TD participants, in the right middle frontal gyrus (MFG) and the anterior cingulate cortex (ACC), and lesser activation in the bilateral middle frontal, left inferior frontal gyrus (LIFG), right inferior parietal lobule (RIPL), and precuneus. Although the prefrontal cortex activation in ASD and TD participants seems relatively similar, the wider network for EF regions including IPL are recruited differentially in ASD participants with distinctly different foci of PFC cortex activation (p = .001; k=50). The reduced parietal activation in ASD participants may reflect a potential lack of interaction between frontoparietal networks with other regions during EF tasks as is seen in TD adults (Lynch et al., 2017). These results support the executive dysfunction hypothesis of ASD and suggests that the differential of activation within frontoparietal circuits may be related to some of the EF difficulties individuals with ASD experience. It is possible that this effect may be determined primarily by inhibitory control (IC) tasks, as out of the 18 fMRI tasks examined in our study, 11 assessed IC using a variety of tasks.

Conclusions: The findings of this study underscore neurobiological differences in EF network recruitment, which in turn may contribute to the development of an executive dysfunction profile for ASD. Examining connectivity profiles of networks like EF may provide more information about the synchronization of core and extended EF regions in accomplishing higher cognitive tasks in ASD.

413.005 *(Poster)* Dynamics of E/I Activity Predict Social and Sensory Symptoms Transdiagnostically

A. Naples[1]*, J. Wolf*[1]*, C. Carlos*[1]*, J. H. Foss-Feig*[2]*, A. Anticevic*[3]*, S. Kala*[1]*, A. Bagdasarov*[1]*, E. Cummings*[1]*, V. Srihari*[3] *and J. McPartland*[1]*, (1)Child Study Center, Yale University School of Medicine, New Haven, CT, (2)Seaver Autism Center, Department of Psychiatry, Icahn School of Medicine at Mount Sinai Hospital, New York, NY, (3)Division of Neurocognition, Neurocomputation, and Neurogenetics (N3), Yale University School of Medicine, New Haven, CT*

Background: An imbalance of excitatory and inhibitory (E/I) brain activity has been posited as a mechanism driving symptomatology in autism spectrum disorder (ASD) and other psychiatric conditions, such as schizophrenia spectrum disorders (SZ). However, experimental findings linking E/I measures and symptoms are inconsistent. The slope, or aperiodic component of the EEG power spectrum, is a noninvasive measure of E/I activity that changes in response to task demands, variations in behavioral state, and pharmacological manipulation. Here we explore the hypothesis that dynamic E/I balance over time may provide insight into ASD and SZ symptomology, above and beyond commonly used metrics of E/I that are averaged over time.

Objectives: To explore whether the dynamics of E/I ratio within an individual reflects meaningful variability in symptoms across and between groups.

Methods: In 38 adults with ASD, 57 adults with typical development (TD), and 39 adults with SZ, we collected 4 minutes of resting EEG data. Using a 2s sliding window multitaper Fourier transform, we estimated the power spectral density of the EEG and the slope of activity between 2 and 55hz. We then calculated two measures of variability to capture the dynamics of this activity: (1) Entropy, reflecting the complexity of the signal; and (2) the Hurst exponent, describing the tendency of the slope to exhibit self-similarity in time around its mean.

Results: Consistent with prior research, all individuals in the sample demonstrated a negative slope, indicating that the EEG approximated a power-law distribution; there were no group differences in mean slope. Individuals with ASD exhibited greater entropy (p = .011) than those with TD, and individuals with SZ showed marginally greater entropy (p = .058) than TD controls. Across all participants, increased entropy was associated with greater Autism Diagnostic Observation Schedule (ADOS) severity scores (r = .21, p = .039) and reduced facial recognition performance (r = -.30, p = .002). Across groups, the Hurst exponent correlated strongly with auditory hypersensitivity (Glasgow Sensory Questionnaire, r = .29, p = .007), and overall difficulties with filtering sensory input (Sensory Gating Inventory, r = .29, p = .048), indicating that reduced predictability of E/I ratios over time associated with greater sensory symptomology.

Conclusions: Variability of E/I activity differentiated groups and was associated with symptoms across groups. Our results suggest that intra-individual variability provides useful information about brain activity relevant to transdiagnostic symptom expression. While global differences in E/I balance may drive symptoms, unpredictable shifts in this balance may further exacerbate symptoms. If an individual is unable to predict the severity of their own symptoms, from moment to moment, the impact of these symptoms will invariably be greater. These data suggest that, in addition to characterizing the mechanisms of global E/I balance, it is critical to understand dynamic changes in balance within an individual in the absence of external manipulation. Our findings provide a first step towards characterizing this variability at the individual level within ASD.

413.006 *(Poster)* EEG-Based Brain-Computer Interface (BCI) for Distress Identification for Individuals with ASD

B. T. Susam[1]*, S. Eldeeb*[1]*, C. M. Conner*[2]*, J. Golt*[3]*, S. A. Porton*[2]*, M. Akcakaya*[1]*, S. W. White*[4] *and C. A. Mazefsky*[2]*, (1)Electrical and Computer Engineering, University of Pittsburgh, Pittsburgh, PA, (2)Department of Psychiatry, University of Pittsburgh School of Medicine, Pittsburgh, PA, (3)The University of Alabama, Tuscaloosa, AL, (4)Psychology, The University of Alabama, Tuscaloosa, AL*

Background: Individuals with autism spectrum disorder (ASD) often have impaired emotion regulation (ER). There is growing interest in complementing psychosocial therapeutic approaches for ER with technology-based tools to improve therapy efficacy. Our long-term goal is to develop a novel electroencephalography (EEG)-based brain-computer interface (BCI) that will monitor brain activity in adolescents and adults with ASD in order to help cultivate emotional self-awareness, support generalization of ER skills, and provide options for self-learning outside of the therapy session. Here, we provide initial proof of concept for the use of brain activity to support ER studies by using EEG to distinguish between distressed and non-distressed conditions.

Objectives: The present study sought to investigate the effect of distress on the brain activity of individuals with ASD via an EEG-based BCI. We applied machine learning (ML) to recorded EEG data from the Affective Posner Task to classify distressed and non-distressed conditions represented by the LOSE and WIN conditions of the Posner task, respectively.

Methods: Twelve individuals with ASD (9 male; age= 12-19 years) participated. EEG data were collected using a Wearable Sensing DSI-24 system. We identified patterns of brain activity associated with distress during the Affective Posner task, described in Figure 1. Only data from the first game involving deception (randomly generated cues that responses were incorrect, making the $50 contingent reward seem less likely) were utilized in the ML analyses. After pre-processing, 3 seconds of EEG data time-locked to the feedback (wrong, correct or too slow) for each trial were extracted. A total of 15 temporal and spectral features were calculated from the extracted EEG to be used in the classification between WIN and LOSE conditions [1-8]. Radial Basis Function Support Vector Machine (RBF SVM) was used as the classifier. Feature selection was applied to optimize the classification performance[9]. Five-fold cross validation was used to avoid overfitting[10]

Results: Classification performance results are summarized in Table 1 (average accuracy of 83.83% 8.41; specificity of 74.20% ±9.311; sensitivity of 83.34% ±8.97). The most important EEG features for distinguishing distress conditions were the total power of EEG in the frontal cortex, especially in F3, F4 and Fz channels (according to 10-20 international system), and the mean of EEG signal calculated over these 3 channels.

Conclusions: We built an EEG-based BCI to support the study of ER in individuals with ASD, and applied machine learning to demonstrate promising preliminary evidence that EEG-based BCI can be used to distinguish distressed and non-distressed conditions. The most informative features were obtained from the frontal cortex, which have also been identified as important to ER in the broader affective neuroscience literature. Our future work will include a study to investigate the generalization of distressed vs non-distressed condition classification across individuals. Ultimately, once refined, this EEG-based BCI will be utilized to support increasing emotional awareness and generalization of skills learned in the Emotion Awareness and Skills Enhancement (EASE) program, which is an individual therapy designed to improve one's ability to manage intense negative emotions[11].

413.007 *(Poster)* Early Sensory Perception Is Less Influenced By Initial Models in Autism Spectrum Disorder

J. Goris[1,2], *S. Braem*[1,2,3], *S. Van Herck*[4], *E. Deschrijver*[1,2], *J. R. Wiersema*[2,5], *B. Paton*[6], *J. Todd*[6] *and M. Brass*[1,2], *(1)Department of Experimental Psychology, Ghent University, Ghent, Belgium, (2)Research group EXPLORA, Ghent University, Ghent, Belgium, (3)Department of Psychology, Vrije Universiteit Brussel, Brussels, Belgium, (4)Department of Neurosciences, KU Leuven, Leuven, Belgium, (5)Department of Experimental-Clinical and Health Psychology, Ghent University, Ghent, Belgium, (6)Functional Neuroimaging Laboratory, University of Newcastle, Callaghan, NSW, Australia*

Background: Recent theories of autism spectrum disorder (ASD) attempt to explain both social and sensory symptoms of ASD by using the predictive coding framework. Central to these accounts is the hypothesis of a core deficit in the context-sensitive adjustment of predictions, meaning that individuals with ASD have difficulties with estimating in which contexts an event is more surprising and in which it is not. In a recently published study we indeed showed that prediction errors are less modulated by context in ASD on an early sensory level (Goris et al., 2018). Interestingly, however, this decreased context-sensitivity could be caused by either an overestimation of volatility in ASD (i.e., being too fast to update one's model of the world) as proposed by predictive coding theories, or by underestimating volatility (i.e., being slower or "more reluctant" to update one's initial model).

Objectives: In the current study, we aimed to differentiate between the hypotheses of faster versus slower model updating in ASD by investigating how predictions are weighted in relation to the first acoustic context participants were presented with (i.e., their initial model), and to what extent predictions are updated when this context changes. To this end, we used electroencephalography (EEG) to look at the mismatch negativity (MMN) component, reflecting early sensory prediction error processing.

Methods: A group of 27 adults diagnosed with ASD was compared to a gender-, age- and IQ-matched group of 27 neurotypical adults on the well-validated multi-timescale MMN paradigm. In this task, participants were presented with tones that were either standard (presented with a high frequency) or deviant (low frequency) in a block, and these roles reversed every block. The length of the blocks was also manipulated, resulting in slow changing and fast changing alternations. A well-replicated observation in this paradigm is that predictions are shaped by the initial acoustic context: for the initial deviant tone predictions are updated slower (resulting in a larger MMN in slow changing than in fast changing blocks), in comparison to the second deviant tone. If ASD is characterized by faster model updating, we hypothesized the ASD group would be less influenced by the initial context, and thus show a weaker interaction between tone history and block length. If individuals with ASD tend to update models slower, their responses should be shaped more by the initial context, resulting in a stronger interaction.

Results: The ASD group was less influenced by the initial acoustic context, as their MMN responses to the initial deviant sound were less influenced by block length compared to the second deviant. In fact, the MMN modulation by block length was stronger for the second deviant than the initial deviant tone in the ASD group. This interaction effect also correlated with total scores on the ADOS-2, assessing ASD symptoms.

Conclusions: These results suggest that individuals with ASD are less influenced by initial contexts, and update predictions more when contexts change. This is consistent with the idea that people with ASD overestimate the volatility of the environment, as proposed by predictive coding theories.

413.008 *(Poster)* Effect of Reduced Gabaergic Signaling on Temporal Order Judgment in Mice

T. Atsumi[1,2], *M. Chakrabarty*[2], *R. Fukatsu*[2], *S. Miyachi*[3], *Y. Terao*[1] *and M. Ide*[2], *(1)Department of Medical Physiology, Faculty of Medicine, Kyorin University, Mitaka, Tokyo, Japan, (2)Department of Rehabilitation for Brain Functions, Research Institute of National Rehabilitation Center for Persons with Disabilities, Tokorozawa, Saitama, Japan, (3)Cognitive Neuroscience Section, Primate Research Institute of Kyoto University, Inuyama, Aichi, Japan*

Background: Individuals with autism spectrum disorder (ASD) often show sensory abnormalities and an altered γ-aminobutyric acid (GABA)-mediated signaling in brain. We found increased sensory hyper-responsiveness in ASD associates with greater temporal resolution of stimulus order judgment (Ide et al., 2019, *Journal of Autism and Developmental Disorders*). Previously, we reported that GABA concentration in the autistic brain negatively correlated with severity of sensory hyper-reactivity measured by self-report questionnaire (Atsumi et al., 2019, INSAR). However, the role of GABAergic neural signaling in task performance during temporal order judgment (TOJ) is unknown.

Objectives: We hypothesized that lower GABAergic signaling heightens temporal resolution of stimuli. The present translational study examined whether blocking GABA-A receptor improves stimulus temporal resolution of tactile-TOJ.

Methods: We used three mice as animal model and trained them to perform the TOJ task (Wada et al., 2005). In one trial, the animal was delivered air-puff stimulations successively to its left and right whiskers. If the subject correctly nose-poked the side stimulated latter, a liquid reward was delivered, otherwise a 5 ~ 14 sec time-out trial was delivered as punishment. We trained the animals with ±300 ms of stimulus onset asynchronies (SOA). During testing, we added eight new SOAs (±5 ~ 240 ms) to the conventional sets (baseline) and de-livered them randomly. Temporal resolution was calculated by fitting cumulative Gaussian function to the response data in each SOA. We administered a GABA-A antagonist, (+)-Bicuculline (1 mg/kg: BIC) and its vehicle (saline with DMSO: CON) intraperitoneally on different days, prior to the sessions. Either drug/vehicle was injected every second day, and the response data from three days were pooled.

Results: The mice needed 28 ~ 34 days to acquire the task. Pharmacological test revealed all the three mice showed better temporal resolution with BIC (64, 6, and 92 ms, respectively) than CON (234, 11, and 105 ms, respectively; Figure 1). We performed generalized linear mixed model (GLMM) analysis to examine the effect of dose on task performance, by setting subjects and sessions as random factor (Aarts et al., 2014). An analysis of variance revealed the main effect of dose, indicating better performance in BIC than in control ($p < 0.05$).

Conclusions: The preliminary result suggests that administration of GABA-A blocker may improve TOJ performance in mice. There is a possibility that GABAergic neural dysfunction in ASD brain may induce greater neural response to temporal processing of external stimuli, resulting in their heightened perceptual intensity. Future studies should aim to reveal the mouse brain areas analogous to humans that relate to temporal resolution of stimuli, and examine whether the GABAergic signaling in that area associates with sensory hyper-responsiveness.

413.009 *(Poster)* Emotion Cues Improve Visual Temporal Resolution in Individuals with Autism Spectrum Disorders

M. Ide[1], *T. Atsumi*[1,2], *R. Fukatsu*[1] *and M. Chakrabarty*[1], *(1)Department of Rehabilitation for Brain Functions, Research Institute of National Rehabilitation Center for Persons with Disabilities, Tokorozawa, Saitama, Japan, (2)Department of Medical Physiology, Faculty of Medicine, Kyorin University, Mitaka, Tokyo, Japan*

Background: Atypical sensory profiles across a variety of sensory modalities are well known in autism spectrum disorders (ASD). Sensory hyper-responsivity is a diagnostic characteristic derived from these sensory abnormalities. We earlier reported that tactile temporal resolution to judge the orders of two successive vibrotactile stimuli associates with the symptomatic severity of ASD (Ide et al., 2019, *Journal of Autism and Developmental Disorders*). A study in typically developed (TD) individuals previously demonstrated that anxiety modulates the effect of emotions on low-level visual processing (Ferneyhough et al., 2013). Considering the reports of high prevalence of co-morbid anxiety disorders (20 %～40 %) in ASD, we hypothesized that anxiety also affects emotion induced change in higher-order visual processing in ASD.

Objectives: We investigated if sudden presentation of facial emotion cues (Disgust vs. Neutral) change the visual temporal resolution in individuals with ASD compared to TD individuals. We then examined whether individual anxiety level associates with magnitude of the change.

Methods: ASD (N = 14) and typically-developed individuals (N = 15) participated in the current study. Participants reported the laterality of the last of two sequential, brief Gaussian blob flashes (Fig1). The key manipulation was presentation of an irrelevant picture prime for a duration of 100 ms, randomly 300～500 ms before the Gaussian blobs. The trials in two separate blocks contained Disgust and Neutral facial emotions randomly intermixed with scrambled images as baseline. Temporal resolution was calculated for each participant by fitting cumulative Gaussian function to the response data. Comparisons were done after adjusting the temporal resolution in each type of facial emotion trials to their respective baseline and thereafter subtracting values of Neutral trials from those of Disgust. Individual anxiety levels were estimated by using self-report questionnaire of State-Trait Anxiety Inventory (STAI: Spielberger et al., 1983).

Results: Tests of within-group difference of means from the reference value zero (= no effect of emotion signals) revealed a significant improvement of visual temporal resolution with Disgust>Neutral facial cue in ASD (mean ± sem = -12.50 ± 4.47; t (13) = -2.79, p = 0.01) but not TD (1.78 ± 3.68; t (13) = 0.48, p = 0.63) (Fig2). Additionally, the extent of improvement in ASD was significantly better than TD (t (27) = -2.48, p = 0.02). The magnitude of the change in temporal resolution with Disgust>Neutral associated positively with subjective state-anxiety scores (r = 0.46, p = 0.04) only in ASD.

Conclusions: We found that Disgust emotion cues markedly enhanced the temporal resolution in ASD compared to TD. Furthermore, individual state-anxiety scores significantly modulated the temporal resolution change in ASD. In contrast, there was neither an apparent emotion-induced effect on temporal resolution nor any modulatory trend of the same by state-anxiety in TD. Collectively, the findings reveal that task-irrelevant visual affective signals interact with individual state-anxiety levels to predominantly alter the higher-order, temporal processing of visual information in ASD.

413.010 *(Poster)* Examining the Links between Language Ability and Working Memory Impairments in Preschoolers with Autism

C. F. Colman[1], *P. E. Vidal*[2], *S. R. Edmunds*[3] *and S. Faja*[3], *(1)Division of Developmental Medicine - LCN, Boston Children's Hospital, Boston, MA, (2)Boston Children's Hospital: Labs of Cognitive Neuroscience, Boston, MA, (3)Boston Children's Hospital, Boston, MA*

Background: There is evidence of executive function impairments in autism spectrum disorder (ASD). Investigations have yielded inconsistent findings regarding impairments in working memory, although visual-spatial working memory is more consistently disrupted (WM) (Kenworthy et al., 2008). Although it has been theorized that executive dysfunction can be mediated by language deficits, specifically a failure to use language for self-regulation (Joseph et al., 2005), relatively little is known about how language ability underlies executive functioning in preschoolers with ASD.

Objectives: The present study aims to test the internal and external language processes that may support WM performance in young children with ASD.

Methods: As part of a larger study charting the trajectory of executive control in ASD, preschoolers with ASD (n=37) and typical development (n=46) were assessed at 2 and 4 years. All analyses controlled for nonverbal IQ (Mullen Scales of Early Learning [MSEL] visual reception T-score) because diagnostic groups differed on nonverbal IQ. Internal language capacity was operationalized as the MSEL verbal developmental quotient (verbal DQ). External verbal behavior was operationalized as percentage of trials in which a child used verbal strategies (i.e., self-speech) during the Self-Ordered Pointing (SOP) task (Hongwanishkul et al., 2005). Working memory was measured with a composite of two behavioral WM tasks administered based on participant age. All children completed an adapted version of the PEFB Hide & Seek Task (Garon et al., 2014). In addition, children in the 2-year-old cohort completed a 3- and 6-box-stationery & scrambled Boxes Task (Griffith et al.,1999), and children in the 4-year-old cohort completed the SOP Task.

Results: After controlling for VR T-scores, TD children had higher correct search scores in Hide & Seek, F(1, 79)=7.93, p=.006, and completed larger spans in the SOP, F(1, 41)=4.13, p=.049. Groups did not differ in Boxes performance or use of verbal strategies. Within the ASD group, WM measures correlated and were combined to create a WM composite score (2-year-olds: Boxes and Hide & Seek, r(21)= .547, p=.010; 4-year-olds: SOP and Hide & Seek, r(16)= .657, p= .006). Verbal strategies and Verbal DQ were not significantly correlated, r(15)= -.29, p=.30. Further, while verbal DQ scores positively predicted WM performance (β=.36, p=.03), verbal strategies negatively predicted WM performance (β= -.49, p=.06) among children with ASD.

Conclusions: WM performance was reduced on the SOP and Hide & Seek among preschoolers with ASD relative to controls when nonverbal IQ was controlled. For the ASD group, use of verbal strategies and verbal IQ predict WM performance independently such that children with higher verbal DQ scores performed better on WM tasks and four-year-olds who used verbal strategies during SOP tended to have worse WM performance. This suggests that, although language level is related to WM performance, children with ASD who employ verbal mediation may not be successful in overcoming challenges related to spatial WM. Results also revealed verbal strategies and verbal DQ were not related, suggesting that verbal strategies may be used regardless of underlying language ability.

413.011 *(Poster)* Neural Corelates of Schema-Dependent Encoding in Children with Autism Spectrum Disorders: The Role of Behavioral Flexibility

K. M. Cook[1], *J. Cherry*[2], *X. You*[3], *J. Merchant*[4], *M. F. Skapek*[5], *M. D. Powers*[6], *C. E. Pugliese*[6], *L. Kenworthy*[6] *and C. Vaidya*[7], *(1)Interdisciplinary Program in Neuroscience, Georgetown University, Washington, DC, (2)Georgetown University, Washington, DC, (3)Center for Neuroscience, Children's National Hospital, Washington DC, DC, (4)University of Marland, College Park, MD, (5)Psychological Sciences, University of Connecticut, Storrs, CT, (6)Center for Autism Spectrum Disorders, Children's National Hospital, Washington, DC, (7)Psychology, Georgetown University, Washington, DC*

Background: Children with autism spectrum disorder (ASD) exhibit behavioral rigidity and difficulties adapting to novel situations. Schemas are frameworks of real-world knowledge that support superior memory and generalization to novel contexts, which is important for flexible adaptive behavior. Neuroimaging studies with adults show that medial prefrontal cortex (mPFC) supports memory formation of schema-congruent information whereas the medial temporal lobe (MTL) supports memory formation of schema-incongruent information. Whether this pattern of neural engagement is observed in typically developing (TD) or autistic children is unknown. Further, whether these neural correlates relate to behavioral flexibility has not been examined. Due to known atypicalities in MTL and mPFC in ASD, we hypothesized that the neural correlates of schema-dependent memory will differ between TD and ASD and vary by behavioral flexibility.

Objectives: Assess differences in MTL and mPFC activation supporting schema-memory between ASD and TD children and examine associations with behavioral flexibility.

Methods: Children aged 8-16 years with confirmed diagnosis of ASD (N=12,Males=3,FSIQ=114) and TD (N=19,Males=5,IQ=122) performed an associative encoding task on object-scene image pairs that varied in schema-congruency (Congruent=snorkel-reef; Intermediate=flowers-playroom; Incongruent=cabinet-canyon) during functional magnetic resonance imaging at 3T. They were tested for recognition memory for objects and their associated scene 20 minutes later outside the scanner. Encoding-related activation for subsequently remembered vs forgotten object-scene pairs was examined for congruency differences with separate one-way ANOVAs in anatomical masks for MTL and mPFC, and for each group (ps<0.05 corrected). Parents completed the Flexibility Scale (Strang et al., 2017, Autism Dev Disord, 47) assessing their child's behavioral flexibility. These scores were used to examine the association with activation in ASD.

Results: In a GroupxCongruency ANOVA, groups did not differ in object recognition or associative memory, which was higher for schema-congruent pairs relative to intermediate and incongruent pairs $F(2,57)=12.8$,$p<0.001$. In TD children, a main effect of congruency emerged in one cluster in mPFC and one in left MTL; follow-up 2X3 ANOVA on beta values showed greater mPFC and reduced MTL activation for intermediate pairs and the opposite pattern for congruent pairs $F(2,57)=15.9$,$p<0.001$. ASD children exhibited no significant clusters responsive to congruency. For direct group comparison, we applied TD clusters as region-of-interest to ASD data and compared extracted beta values with two-sample t-tests – mPFC activation was reduced in ASD for intermediate pairs $t(29)=2.34$,$p=0.02$ and in the MTL for congruent pairs $t(29)=2.87$,$p=0.005$. Intermediate-pair mPFC activation was significantly higher in children with ASD with better behavioral flexibility $r=-0.61$,$p=0.03$. Further, whole-brain correlational analysis revealed a significant cluster in left dorsolateral prefrontal (BA9/44/46) where higher activation was associated with better flexibility in ASD.

Conclusions: Neural correlates supporting schema-dependent memory encoding differed in TD children relative to published adult findings, such that intermediate, rather than congruent, level of schema-congruency engaged the mPFC most and MTL least. Only in ASD, mPFC engagement for intermediate pairs depended upon behavioral flexibility such that inflexible children exhibited minimal sensitivity to congruency. Further work is needed to disentangle the direction of causality between schema-dependent memory processing and behavioral flexibility.

413.012 *(Poster)* Neural Processing of Formant-Exaggerated Speech and Nonspeech in School-Age Children with and without Autism Spectrum Disorders

F. Chen[1], *Y. Zhang*[2], *H. Zhang*[3] *and G. Peng*[1], *(1)Research Centre for Language, Cognition, and Neuroscience & Department of Chinese and Bilingual Studies, The Hong Kong Polytechnic University, Hong Kong, Hong Kong, (2)Department of Speech-Language-Hearing Sciences, University of Minnesota, Minneapolis, MN, (3)Speech-Language-Hearing Centre, Shanghai Jiao Tong University, Shanghai, China*

Background: Previous studies have provided evidence for atypical auditory processing of infant-directed speech (IDS) in autism spectrum disorders (ASD). But the underlying neural mechanisms of processing multiple attributes of IDS remain unclear. Apart from the prominent pitch exaggeration, formant exaggeration in IDS can lead to significant enhancement in neural activation in 6- to 12-month-old healthy infants (Zhang et al., 2011).

Objectives: The present event-related potentials (ERP) study examined neural coding of formant exaggeration in school-age children with and without ASD. The stimuli included both speech and nonspeech to tease apart 'phonetic' versus 'acoustic' processing. There were three research questions. First, did the school-age typically-developing (TD) children also show neural enhancement towards the formant exaggeration in IDS? Second, did children with ASD show a similar neural processing pattern towards formant-exaggerated IDS? Third, did the two groups differ when processing the pure acoustic changes of formants embedded in nonspeech sounds?

Methods: Seventeen high-functioning children with ASD (all boys, age mean = 8.6 years, range 6.1~11.6 years) and 17 TD children (all boys, age mean = 8.4 years, range 6.4~10.8 years) participated in this study. These two groups did not differ in terms of age, non-verbal IQ, and working memory. Compared with adult-directed (AD) speech sounds, the IDS had lower F1 and higher F2, while holding F0, F3 and F4 constant (Zhang et al., 2011). The corresponding AD and ID nonspeech sounds shared exactly the same F1, F2 and F3 as the speech while removing other frequencies. There were two conditions: speech and nonspeech, and two alternating blocks: ID and AD blocks, which were counterbalanced among subjects. Duration and intensity of the stimuli were normalized. Each type of sounds was repeated 200 times, with a total of 800 trials.

Results: Based on the grand mean data, three ERP components were analyzed: N1, N250, and late negative response (LNR) (Fig. 1). In the speech condition, both ASD and TD children showed no sensitivity to formant exaggeration in all three components (Fig. 2D, 2E, 2F). In the nonspeech condition, there were significant effect of stimulus type (AD vs. ID) on mean amplitude in all three components of N1, N250, and LNR for ASD group, and in two components of N1 and LNR for TD group (Fig.2A, 2B, 2C). Furthermore, TD group exhibited stronger neural responses to speech sounds in right recording sites than the ASD group (Fig. 1B).

Conclusions: These findings suggest that both school-age TD and ASD children did not show neural enhancement to the formant exaggeration in IDS, which reflected a declined discrimination of within-category variations in their native speech sounds as children age. However, they were still sensitive to such subtle formant changes in nonspeech sounds, which reflected a deviated pattern between acoustic and phonetic processing. Moreover, children with ASD were more sensitive to acoustic formant changes embedded in nonspeech, which corroborated the view of enhanced spectral processing capacity beyond pitch processing in ASD.

413.013 *(Poster)* Phenotypic Factors That Interfere with the Severity of Autistic Spectrum Disorder.

***J. Portolese**, Clinical Hospital, Sao Paulo, Brazil*

Background: Autistic Spectrum Disorder (ASD) is a neurodevelopmental disorder that develops in the early years of life. Behavioral observation forms the basis of the diagnosis, with criteria focused on social disabilities and restricted and repetitive patterns of behavior, interests or activities. However, there is great heterogeneity in clinical presentation. Studies support the existence of subtypes in ASD, but it is not yet clear whether specific subtypes with characteristic symptom profiles are considered or as part of a continuum of severity.

Several works to explore underlying TEA structures have contributed to a more dimensional view proposed in the DSM-5 for the diagnosis of TEA. In this sense, most studies using factor analysis or PCA and cluster analysis used as input characteristics measures of sociability, stereotyped and repetitive movements, measures related to communication and IQ.

The relationship between the main symptoms of ASD, IQ and severity of clinical presentation is well established in the literature, however, we cannot say the same, including temperament measures. Studies that seek continuous severity in critically ill patients are scarce. In addition to the symptomatology of ASD, this study found a continuum of children aged 6 to 7 years with ASD in a sample composed only of patients with IQ <75.

Objectives: To find out if the inclusion of measures that can provide us with temperament and functionality variables, as well as the central symptoms variables of ASD and IQ, can contribute to better explain phenotypic variability in a sample of ASD patients with IQ <75.

Specific Objectives: 1) Is it possible to separate stable groups of patients by phenotypic composition? 2) Test association between severity of clinical presentation, as measured by the Childhood Autism Rating Scale (CARS) and phenotypic composition.

Methods: 60 patients diagnosed with ASD and aged between 6 and 7 years.

Assessment tools: Autism Diagnostic Interview - Revista-ADI-R; IQ assessment using the SON-R 2½-7 instrument; Vineland Adaptive Behavior Scale (VABS), Child Behavioral Checklist (CBCL) and CARS.

Descriptive statistical analysis and comparison of scales were performed using the R Studio software, and Principal Component Analysis was performed to assess the contribution of different behavioral assessment scales to explain the variation of patients' phenotypic construct and regression analyzes were performed. to predict the severity of the presentation as measured by CARS.

Results: The analysis suggests that, in general, there are components that contribute to the phenotypic variability related to the cognition / functionality of the patient, a second related to the presence of behavioral problems associated with emotional regulation and two, with different contributions that are communication and behaviors. stereotyped and repetitive forms of ADD. Analyzes suggest greater functionality variability, changes in sociability, cognition, and greater presence of emotional behaviors, stereotyped and repetitive behaviors, and communication. Through multiple regression analysis, no significant causal correlations were found between the components and the variables age and CARS.

Conclusions: The inclusion of temperament measures increased the explanation of the clinical presentation variability; However, different phenotypic compositions were not related to severity in clinical presentation.

413.014 *(Poster)* Reduced GABA Concentration in the Supplementary Motor Area Underlying Difficulty in Inter-Limb Coordinated Movements in Individuals with Autism Spectrum Disorder

***Y. Umesawa**[1], K. Matsushima[2], T. Atsumi[1,3], T. Kato[4], R. Fukatsu[1] and M. Ide[1], (1)Department of Rehabilitation for Brain Functions, Research Institute of National Rehabilitation Center for Persons with Disabilities, Tokorozawa, Saitama, Japan, (2)Kansai Medical University, Hirakata, Osaka, Japan, (3)Department of Medical Physiology, Faculty of Medicine, Kyorin University, Mitaka, Tokyo, Japan, (4)Department of Human Health Science, Graduate School of Medicine and Faculty of Medicine, Kyoto University, Kyoto, Japan*

Background:

Coordinated movements between bilateral hands and feet are needed in various situation of daily life (e.g., riding a bicycle), and most of individuals with autism spectrum disorders (ASD) show difficulties in those movements. Generally, rhythmic hand-foot coordinated movements in the ipsilateral side of body (e.g., left hand and left food) are more difficult when the person moves the limbs in the opposite direction than in the same direction (directional constraint: Baldissera et al., 1982). In considering that difficulties of coordinated movements are prominent in ASD, we assumed that excitability/inhibitory imbalance known as a remarkable feature of ASD brain possibly contributes deficits of the movements. We hypothesized that decreased inhibitory metabolite, such as gamma-aminobutyric acid (GABA) level in the brain motor areas results in stronger directional constraint in ASD than typically developed (TD) individuals.

Objectives:

We investigated whether stronger d irectional constraint during inter-limb coordinated movements are obvious in individuals with ASD. Then, we addressed whether decreased GABA concentration in the brain motor areas (i.e., primary motor area [M1] and supplementary motor area [SMA]) links to severer difficulty of the movements.

Methods:
Nineteen ASD (mean age: 19.0 ± 1.3 years, 6 females) and 20 TD (mean age: 19.0 ± 2.7 years, 6 females) participants whose IQs were above 75 participated the study. The participants performed ipsilateral hand-foot rhythmic movements (i) in the same direction and (ii) in the opposite direction, which were measured as a part of Bruininks-Oseretsky Test of Motor Proficiency, Second Edition (BOT-2) (i.e., Tapping feet and fingers). GABA concentration in M1 and SMA were measured by using 1H-magnetic resonance spectroscopy (1H-MRS). The GABA concentration was quantified relative to creatine by using Gannet 2.0 (Harris et al., 2015).

Results:
The numbers of successful rhythmic movements in ASD group in the opposite directional condition were less than those of TD ($t(37) = -2.92$, $p = 0.005$; Figure 1). There was no group difference in the same directional condition. In addition, we found that the numbers of successful rhythmic movements in the opposite directional condition were positively correlated with GABA levels in SMA only in ASD group ($r = 0.54$, $p = 0.018$; Figure 2).
Conclusions:
Reduced GABA levels in SMA associated with stronger directional constraint during ipsilateral hand-foot coordinated movements in ASD. One previous study found strong neural activation in SMA when directional constraint of hand-foot movements was observed (Nakagawa et al., 2016). Our findings suggested that disinhibition derived from reduced GABA concentration in SMA may be underlying strong directional constraint in ASD. Impairments in modulating neural activation in the brain motor areas by inhibitory metabolites may link to difficulties of coordinated movements observed generally in individuals with ASD.

413.015 *(Poster)* Social Attribution in ASD: fMRI Task Data from the Pond Network

M. M. Vandewouw[1]*, C. Hammill*[2]*, J. P. Lerch*[3]*, E. Anagnostou*[4] *and M. J. Taylor*[2]*, (1)Neuroscience & Mental Health Program, The Hospital for Sick Children Research Institute, Toronto, ON, Canada, (2)The Hospital for Sick Children, Toronto, ON, Canada, (3)Wellcome Centre for Integrative Neuroimaging (WIN), University of Oxford, Oxford, ON, United Kingdom, (4)Holland Bloorview Kids Rehabilitation Hospital, Toronto, ON, Canada*

Background: Theory of Mind (ToM) is the ability to think about mental states and understand that others can have a different mental state from one's own. ToM skills enable the explanation and prediction of other individual's behaviours, strongly influencing the quality of social interactions. A defining characteristic of autism spectrum disorder (ASD) is difficulty in social interactions, which is thought to be driven by poor social cognition and a lack of ToM skills. The social attribution task (SAT), consisting of videos of geometrical shapes performing complex social (both positive and negative interactions) or random movement, prompts recruitment of ToM skills, and has been shown to activate ToM brain regions.
Objectives: The purpose of this study was to examine the neural underpinnings of ToM using the SAT during fMRI, in a large cohort of children and adolescents with and without ASD.
Methods: fMRI data (3T Siemens PrismaFIT scanner) were acquired during the SAT (3 runs of 8 pseudorandomized blocks of positive social interactions, negative interactions, and random interactions) in 60 ASD and 47 TD participants aged 5 to 19 years at the Hospital for Sick Children. Data were slice-time and motion corrected, censored of high-motion volumes, smoothed, intensity normalized, cleaned of nuisance signals, bandpass filtered, and ICA de-noised. Within-run time-series analysis was performed using FSL's FILM, with task conditions (positive social, negative social, and random) as explanatory variables and examining their pairwise contrasts. Contrasts were averaged over runs within each subject, and group-level analysis was performed using t-tests to examine group differences with FSL's FLAME. Gaussian Random Field theory was used for cluster-level multiple comparisons correction ($Z>2.3$; $p<0.05$, corrected).
Results: While watching both the social compared to random interactions, both the TD and ASD participants showed increased activation in classic ToM areas including the bilateral temporal parietal junctions, superior frontal gyri and right temporal regions. The random interactions elucidated increased response in primary visual regions and default mode network in both groups. There was a significant between-group difference in the left orbital inferior frontal gyrus, with the TDs deactivating this region to social interactions compared to baseline and the ASDs showing little difference. Compared to the ASDs, the TDs also activated the right superior temporal pole significantly more to both the positive and negative interactions. Breaking down the social interactions, the TDs activated the left medial superior and inferior frontal gyri, right frontal operculum cortex, and right orbital middle frontal gyrus significantly more than the ASDs. In the physical compared to negative social interactions, the TDs activated the bilateral anterior cingulate cortex, middle frontal gyrus, and right temporal pole significantly more than the ASDs.
Conclusions: Both the ASD and TD participants recruited classic ToM regions during the SAT, supporting the usefulness of this complex task to examine social cognition. Increased activation to the random interactions in the TD compared to ASD participants may indicate that reduced "switching-off" in those with ASD.

413.016 *(Poster)* Where to Draw the Line: Evaluating Visuospatial and Attentional Processing in Individuals with Autism Spectrum Disorders

A. J. Steigerwald[1]*, A. K. Donehower*[2]*, J. C. Barnett*[3]*, B. J. Ferguson*[4]*, R. Zamzow*[5]*, K. M. Heilman*[6] *and D. Q. Beversdorf*[7]*, (1)Department of Biological Sciences, Portland State University, Portland, OR, (2)Department of Human Development and Family Science, University of Missouri, Columbia, Columbia, MO, (3)Columbia Public Schools, Columbia, MO, (4)Health Psychology, Radiology, & Thompson Center for Autism & Neurodevelopmental Disorders, University of Missouri, Columbia, MO, (5)MU Interdisciplinary Neuroscience Program, Columbia, MO, (6)Department of Neurology, University of Florida College of Medicine, Gainesville, FL, (7)Department of Radiology, Neurology, and Psychological Sciences, University of Missouri, Columbia, Columbia, MO*

Background: Autism spectrum disorders (ASD) are neurodevelopmental disorders that are characterized by repetitive behavioral patterns and difficulty with social interaction and communication. These difficulties include impaired emotional facial recognition that usually involves attending more to another's mouth, while neurotypical individuals focus more on another's eyes during social interactions. Previous studies have shown that when performing a vertical line bisection task, neurotypical individuals exhibit a top-end bias.

Objectives: This study aims to elucidate whether the downward bias in facial recognition in individuals with ASD will correspond with a downward bias during vertical line bisection and quadrisection tasks. Evaluating how individuals with ASD attend to visual space is important for understanding the cognitive mechanisms behind such biases, as it will help identify whether facial fixation points are correlated with performance on an objective spatial reasoning task.

Methods: To answer this question, this study looked at 20 participants with ASD and 20 age, IQ, and sex-matched control participants between the ages of 6 and 23. The participants were asked to bisect, quadrisect from the top, and quadrisect from the bottom vertical lines placed in their left, center, and right visual spaces using both their left and right hands. Each participant completed 6 trials in each of the 18 conditions for a total of 108 bisection and quadrisection attempts. Distance from the true midpoint and quadripoint were calculated for each trial and compared between the two groups.

Results: There was no significant difference between the ASD and control groups for vertical line bisections or bottom quadrisections. One participant with ASD did not appear to understand the quadrisection instructions. However, for those who did comprehend the task, there was a significant difference for top quadrisections, with ASD participants having a greater deviation above the true top quadripoint than control participants ($t(37)=1.74$, $p=0.045$).

Conclusions: From this evidence, it does not appear that the preference for attending to the mouth over attending to the eyes in ASD has a correlation to spatial representation, since this would have been reflected in a downward bias on the bisection and quadrisection tasks. In fact, for the top quadrisections there appears to be an upward bias in the ASD group. This may be due to the more focal attentional demands of the quadrisection task. Future studies will need to confirm this finding and additionally evaluate the role of focal vs global and allocentric vs egocentric attentional demands in this upward top quadrisection bias.

413.017 *(Poster)* Granular Informatics for Understanding ASD: Categorial Granularities in Brains and Cognition

***H. Kozima**, Graduate School of Education, Tohoku University, Sendai, Japan*

Background: ASD people have, according to its diagnostic criteria, impairments of social communication and restricted interest. A number of researchers have tried to find a unified model behind the phenotypical diversity; however, any plausible model that well-explains the diversity has not yet been proposed.

A neuro-anatomical research (Casanova 2006) on ASD brains reported that mini-columns in ASD brains have higher density than that of TD. Higher density of mini-columns in ASD suggests that an ASD brain employs a larger number of mini-columns in information processing. It also suggests that ASD brains process information in less integrated way because the smaller mini-columns reduce long-distance connection between them. (Fig.1)

Objectives: We show that “cognitive granularity” function as endophenotype of ASD. Cognitive granularity represents the size of the basic elements that are operable in one’s cognitive system. In other words, it represents the size of semantic units (schema, basic level categories, etc.) to articulate and recognize the environment. Cognitive granularity also represents the level of abstraction at which one can efficiently predict and control the physical and social world.

We assume that the granular characteristics of the brain structure determines the cognitive granularity, which in turn determines information processing styles of ASD and TD populations. Since it is measurable by psychological experiments, cognitive granularity can function as an endophenotype of ASD, which should explain the relationship between the two qualitatively different behavioral criteria for ASD diagnosis and also the diverse and sometimes enigmatic symptoms of ASD.

Methods: We conduct a series of psychological experiments to determine the size of perceptual, linguistic, and mentalizing categories, as an indicator of cognitive granularity. (Fig.2)

(Perception) The subjects discriminate colors, geometrical shapes, facial expressions (real and computer generated). We evaluate the discriminating thresholds and category sizes.

(Language) The subjects name a set of objects (in photos), sort the objects into groups. We identify the prototypes and their semantic extent.

(Mentalization) The subjects predict behavior of animated or robotic agents, which show a variety of goal-directed behavior. We measure how effectively they predict the behavior, from which we estimate the level of abstraction from the individual cases.

Results: Our preliminary experiments showed that ASD people have smaller perceptual and linguistic categories compared to TD. This suggests the finer cognitive granularity in ASD. We also observed the way ASD people are good at memorizing individual samples of the agents’ behavior. However, for a set of behavior that share the same goal, they tend to fail to find the sameness and so fail to predict the behavior. This suggests that ASD people have difficulty in mentalizing the agents’ behavior in terms of goals or intentions.

Conclusions: We showed the relationship between the anatomical granularity in brains and the cognitive granularity in categorial abstraction. Also, we showed that the cognitive granularity is psychologically measurable. Although the research is still in a preliminary stage, we are proceeding toward constructing a unified model of ASD based on the cognitive granularity.

Communication and Language

ORAL SESSION — COMMUNICATION AND LANGUAGE
307 - Speech and Communication Development and Individual Differences

307.001 *(Oral)* Distinct Speech Progression Following an Early Speech Regression in Autism: A Retrospective Study on 2047 Children

D. Gagnon[1,2]*, A. Zeribi*[3]*, E. A. Douard*[3]*, V. Courchesne*[2]*, B. Rodríguez-Herreros*[4]*, S. Jacquemont*[3]*, G. Huguet*[3]*, M. A. Loum*[3] *and L. Mottron, M.D.*[2]*, (1)Département de psychiatrie, Université de Montréal, Montréal, QC, Canada, (2)Autism Research Group, CIUSSS du Nord-de-l 'Île-de-Montréal, Montréal, QC, Canada, (3)UHC Sainte-Justine Research Center, University of Montreal, Montreal, QC, Canada, (4)Université de Montréal, Montréal, QC, Canada*

Background: Approximately 25% of autistic children show an early speech regression (ESR) of previously acquired words within their first three years of life, a particularity rarely encountered in non-autistic children. Whether regression represents a core autistic symptom associated with higher prototypicality, an extreme of a continuum of loss in autism, a subcategory of autism, or even a distinct condition is uncertain. Progress in this language phenotype may advance the issue of autism heterogeneity, increasing our capacity to build a mechanistic model of autism.

Objectives: Specify and quantify the effect of ESR and associated communicative atypicalities on autistic speech development and phenotypic features up to 18 years.

Methods: Retrospective data from 2047 unrelated autistic children were extracted from the Simons Simplex Collection. The language progression pattern of children classified according to ESR were presented by Kaplan-Meir plots and tested for differences by Cox proportionate hazards models (ages in months). We modeled the probability of being a fluid speaker depending on ESR, age and intellectual disability (non-verbal IQ<70), using multiple logistic regression. Stepwise variables selection based on a logistic regression model was used to select atypical communicative features associated with ESR; their relative pattern in the autistic population was evaluated using multiple correspondence analysis (MCA) and their association with communicative and behavioral outcomes was computed using linear regression analysis. All results are shown with 95% confidence intervals.

Results: First words emerged earlier in children who experienced ESR (HR=3.4 [95% CI, 2.7-4.2]; p=1.6e-26), so did first phrases if ESR happened after (HR=5.1 [4.1-6.3]; p=1.0e-45), and first phrases emerged later if ESR happened before (HR=0.59 [95% CI, 0.5-0.7]; p= 1.7e-10). Distributions of speech milestones achievement age are shown in figure 1a,b,c. Speech fluency was delayed in children with ESR (figure 1d). However, over 97% autistic children without intellectual disability, with or without ESR, will reach fluid speech by 18years (ESR: 0.98 [95% CI, 0.97-0.99] ; No-ESR: 0.99 [0.989-0.996]), and over 70% of those with intellectual disability (ESR: 0.73 [0.64-0.81] ; No-ESR: 0.87 [0.82-0.91]). Once fluid speech was reached their level of communication was not affected by ESR. The best selection of atypical communicative features associated with ESR highlighted a combination of three features: no nodding at age 4-5 (OR=2.08; [1.4-3.1]; p=2.3e-04), having had a persistent confusion with pronouns (OR=1.9; [1.3-2.8]; p=9.4e-04) and limited comprehension of simple language at age 4-5 (OR=1.9; [1.3-2.8]; p=2.38e-03). These features present a similar pattern in the entire autistic population when computed in the MCA. Presenting all three features increased the chance of having had an ESR by 7.2-folds ([3.8-13.8]; p=1.4e-09). The combination of those features was significantly associated with higher severity of autistic traits, independently of IQ.

Conclusions: Autistic children with ESR show a distinct pattern of language acquisition marked by early typical speech development, a regression/plateau followed by a catch-up with their peers. This catch-up is associated with a group of autistic communicative features that might be representative of a core language development profile in autism whose properties may not be extended to the entire spectrum.

307.002 *(Oral)* An Exploratory Population Study of Social Communication Disorder (SCD) Relative to Autism Spectrum Disorder (ASD)

S. Ellis-Weismer[1]*, E. Rubenstein*[2]*, M. S. Durkin*[3] *and L. Wiggins*[4]*, (1)University of Wisconsin-Madison, Madison, WI, (2)Waisman Center at UW Madison, Madison, WI, (3)Population Health Sciences, University of Wisconsin School of Medicine and Public Health, Madison, WI, (4)Centers for Disease Control and Prevention, Atlanta, GA*

Background: There is considerable debate about how to conceptualize and assess Social Communication Disorder (SCD) versus autism spectrum disorder (ASD). Children who meet DSM-5 diagnostic criteria for SCD have persistent difficulties in social uses of verbal and nonverbal communication but do not have restricted interests and repetitive behaviors (RRB) seen in children with ASD. The onset of SCD may begin early in development but cannot be diagnosed until at least 4 years of age when abilities in and expectations for social communication increase. SCD can co-occur with language disorder but not with ASD, intellectual disability (ID), or global developmental delay (GDD).

Objectives: We compared social communication functioning and RRB in children with Probable SCD to children with non-SCD developmental delay and children with ASD.

Methods: We used data from the Study to Explore Early Development (SEED) Phase-1 (2007-2011) and Phase-2 (2012-2016). SEED is a multi-site case-control study designed to examine risk factors for ASD. Our sample consisted of children ≥ 4 years (mean age 5) who had past diagnoses of developmental delay (DD) or screened positive for ASD symptoms (N=1,502) and were seen for a comprehensive in-person evaluation. Children were classified as having ASD based on results of the Autism Diagnostic Observation Schedule – Second Edition (ADOS-2) and Autism Diagnostic Interview - Revised (ADI-R). Based on Foley-Nicpon et al. (2017), we assessed SCD symptoms among children not classified as having ASD, ID or GDD using a subset of items from the ADI-R that reflect diagnostic criteria for SCD. Potential SCD groups were determined by creating tertiles of total score for SCD-related items. Probable SCD cases were children with total ADI-R item scores in the highest tertile, Possible the second tertile, and No SCD first tertile. ID was defined as deficits in nonverbal cognition on the Mullen Scales of Early Learning (MSEL) and adaptive function on the Vineland Adaptive Behavior Scales, and GDD as deficits in all domains on the MSEL.

Results: Five groups of children were analyzed in this study: ASD+ID (N=388), ASD-No ID (N=642), DD Probable SCD (N=163), DD Possible SCD (N=173), and DD No SCD (N=136). ADOS-2 social affect and RRB algorithm scores were significantly higher for children with ASD (with and without ID) than the Probable SCD group (p values<.00001). Mean ADOS-2 scores for the Probable SCD group tended to be higher than for the No SCD group but were not significantly different (p values between 0.1702 and 0.2028). The ADI-R revealed a consistent pattern in which both ASD groups had significantly higher scores than the Probable SCD group which in turn had significantly higher scores than the No SCD group across Social, Communication, and RRB domains (p values <.0001).

Conclusions: Some children who have social communication delays but do not meet criteria for ASD may qualify for a diagnosis of SCD. Our results suggest that SCD may fall along a continuum involving elevated deficits (relative to DD with No SCD) in social communication and presence of RRBs that do not reach the clinical threshold for ASD.

307.003 *(Oral)* Relative Importance of Prosody Versus Voice Quality for Clinician Assessments of Speech in ASD

E. Weed[1]*, R. Fusaroli*[1]*, J. Mayo*[2] *and I. M. Eigsti*[3]*, (1)Aarhus University, Aarhus, Denmark, (2)University of Connecticut, West Hartford, CT, (3)Psychological Sciences, University of Connecticut, Storrs, CT*

Background: Trained clinicians (Nadig and Shaw, 2012) and untrained peers (Grossman, 2015) are able to distinguish speakers with ASD from NT speakers on the basis of short samples of speech. However, they are not always aware of which acoustic features or combination of features they are responding to (Nadig and Shaw, 2012; Redford et al., 2018). Prosody and voice quality both contribute to the overall impression of a speaker, but a recent meta-analysis (Fusaroli et al, 2017) found almost no studies of voice quality in ASD.

Objectives: To assess whether trained clinicians' classification of adolescent speakers as either ASD or NT on the basis of speech alone is based primarily on acoustic features supporting prosody or voice quality.

Methods: We analyzed speech data (8 scripted sentences per participant) from 15 adolescents diagnosed with ASD (mean age = 14.4 years, SD = 1.48) with IQ scores in the typical range, and 15 adolescents with typical development (TD; mean age = 14.1 years, SD = 1.91); groups did not differ on chronological age or full-scale IQ. Participants in both ASD and the NT groups demonstrated average to high average performance on standardized language measures (see Mayo, 2015, for details).

Using acoustic features selected on the basis of previous literature (Fusaroli et al, 2017; McCann & Peppé 2003), we constructed two Bayesian logistic regression models. Model 1 predicted clinicians' classifications on the basis of *prosody measures*: standard deviation of the fundamental frequency, utterance duration, and articulation rate. Model 2 added measures of *voice quality* (creak, jitter, shimmer, and H1H2) to the prosody measures of Model 1.

Results: Model 1 (*prosodic measures only*) had an accuracy of 0.74 (CI: 0.72 - 0.76), sensitivity of 0.66 (CI: 0.62 - 0.70), and specificity of 0.82 (CI: 0.78 - 0.85). Model 2 (*prosodic plus voice measures*) had an accuracy of 0.72 (CI: 0.69 - 0.75), sensitivity of 0.68 (CI: 0.63 - 0.73) and specificity of 0.76 (CI: 0.72 - 0.80). Thus, there was no gain in adding measures of voice quality when predicting clinical rater intuitions.

Conclusions: Judgements based on clinical intuition display high sensitivity (0.86) and specificity of (0.86) in classifying these samples (Eigsti, Mayo and Simmons, INSAR 2016). Although the literature suggests that the speech of people with ASD may be atypical in terms of both prosody and voice quality, these data suggest that clinicians may base their assessment primarily on prosodic features supporting pitch and rhythm.

307.004 *(Oral)* Backchanneling Frequency of Older Children with and without ASD

H. Matthewman[1,2]*, E. Zane*[3] *and R. Grossman*[4]*, (1)University of Bath, Bath, United Kingdom, (2)FACE Lab at Emerson College, Boston, MA, (3)SUNY Fredonia, Fredonia, NY, (4)CSD, Emerson College, Boston, MA*

Background: Research on conversational skills of people with ASD have mostly focused on the individual's contribution to communication as a *speaker*, but not as a *listener*. But listener behaviors are arguably as important for maintaining smooth and successful conversation as speaker behaviors are: Listeners provide verbal and nonverbal responses called "backchannels" (e.g., saying "*uh-huh"* or nodding one's head), which serve to signal interest, comprehension, and turn taking behavior. Lacking or inadequate listener backchanneling distresses the speaker (Rosenfeld, 1967) and their speech becomes more disorganized and harder to understand (e.g., Bavelas et al., 2000; Kraut et al., 1982). Further, listeners who backchannel less, are perceived as generally less desirable social partners (Vinciarelli et al., 2012), leading to negative social interactions and poor communication outcomes.

Objectives: In spite of its importance for successful communication, hardly anything is known about backchanneling behavior in ASD. The current study compares the frequency of backchanneling signals between children with and without ASD during a conversation with a researcher.

Methods: Forty-three older children participated (ASD N = 20; TD N = 23). Participant groups did not significantly differ on age (ASD *M* = 13.8, TD *M* = 13.4; *p* = 0.553), sex (ASD 16m:4f, TD 14m:9f, *p* = 0.17), language (ASD *M* = 110, TD *M* = 113; *p* = 0.52), or IQ scores (ASD *M* = 116, TD *M* = 112; *p* = 0.37). All participants were video-recorded while engaging in a "Double Interview" with a researcher (Garcia-Winner, 2002). First, the researcher asks the participant questions about family, holidays, hobbies, and school. Then, the roles are reversed, and the participant asks the researcher similar questions. The second half of the interview – when participants acted as interviewers – were coded for verbal and nonverbal backchanneling. We focused on the second half of the Interview because the researcher produced longer turns in their responses, resulting in more time that the participants were in the listener role.

Results: Participants with ASD produced significantly fewer backchannels per minute than their TD peers (ASD *M* = 3.45, TD *M* = 6.56; F(1,41) = 14.03, *p* = 0.001). Both participant groups backchanneled more during times of mutual eyecontact between conversation partners (*F*(1, 41) = 5.89, *p* = .020); there was not a significant interaction between gaze and group on backchanneling frequency (*F*(1, 41) = 2.60, *p* = .15). See Figure 1. Backchanneling frequency significantly correlated with scores on the Social Communication Questionnaire. See Figure 2.

Conclusions: Older children with ASD backchannel less frequently than TD controls, regardless of whether they are sustaining eye contact with their conversation partner. Because backchanneling is crucial to conversational success, reduced backchanneling by individuals with ASD likely negatively affects their social interactions with others. Consequently, developing interventions targeting appropriate and effective use of listener behavior, including backchanneling, could be of critical importance for improving social outcomes in ASD.

POSTER SESSION — COMMUNICATION AND LANGUAGE
414 - Communication and Language Posters

414.001 *(Poster)* A Dimensional Exploration of Social Communication (pragmatic) Abilities Using an Interactive Assessment Protocol

Y. Brukner[1,2]*, A. Bakalash*[1]*, D. Klein*[1]*, N. Laor*[2,3] *and O. Golan*[1,2]*, (1)Department of Psychology, Bar-Ilan University, Ramat-Gan, Israel, (2)Association for Children at Risk, Givat Shmuel, Israel, (3)Sackler School of Medicine, Tel-Aviv University, Tel-Aviv, Israel*

Background: Social communication (SC) or pragmatics, is a key diagnostic criterion of ASD, and the characterizing feature of social communication disorder (SCD). The study of autistic traits in sub-clinical and neurotypical populations offered a broader scope of SC. Nevertheless, this broader examination has mostly relied on self, parent, or teacher reports, rather than on ecologically valid assessments that could characterize subtle variations in SC.

Objectives: To evaluate an ecologically valid SC assessment protocol with a sample of children representing clinical, sub-clinical, and normative levels of SC.

Methods: Participants were 120 children (48 females), aged 8-13 (M=10.08; S.D.=1.26), with normative intelligence. Eleven children had ASD, 17 had SCD, 12 had subclinical communication difficulties, and 80 were neurotypical. Children participated in a semi-structured interaction with an examiner, comprising (1.) ten minutes of free-chat, (2.) a favorite book/movie description, (3.)+(4.) personal stories of positive and negative social experiences, and (5.) telling a story from a picture book. Participants were videotaped and coded by reliable raters, who were blind to the child's condition, on context-appropriate structural-verbal (e.g. balanced narrative, initiation and response) and non-verbal (e.g., facial expressions, intonation) components of SC. In addition, proportions of mental and physical verbs used in children's narratives (parts 2.-5.) were calculated. Children self-reported on the Emotion Awareness Questionnaire (EAQ, Rieffe et al., 2008) and parents filled out the Social-Responsiveness Scale (SRS-2; Constantino & Gruber, 2012) as external validators.

Results: Exploratory factor analysis of the 20 free-chat activity scorings yielded a general factor which explained 38.56% of the variance, with internal consistency of .91. These items were summed as a single free-chat score.

Internal consistency of codings for narrative activities (2.-5.) ranged between .60-.93. Hence, scores were summed over and above activity. Exploratory factor analysis of the 16 narrative scorings yielded a general factor which explained 46.50% of the variance, with internal consistency of .90. These items were summed as a single narrative score.

Proportion of physical and mental verb use in participants' narratives were averaged over and above narrative activities into single 'physical' and 'mental' content scores.

Correlation analysis revealed the free-chat and narrative scores were positively correlated (r=.83, p<.001). Physical verb use was negatively correlated with both free-chat (r=-.33) and narrative (r=-.26) factors (p<.01 for both). Mental verb use was only marginally correlated to the free-chat factor (r=.16, p<.1), and not correlated to the narrative factor.

Both free-chat and narrative factors correlated with the SRS-2 Social Communication Index (SCI; r=-.65, and -.51, respectively, p<.001 for both). Only the free-chat factor was correlated with the EAQ general score (r=.34, p<.001). Physical verb use was correlated with SRS-2 SCI score (r=.18, p<.05) and marginally correlated with the EAQ score (r=.17, p<.1). Mental verb use showed no significant correlation with either EAQ or SRS-2.

Conclusions: The current study demonstrated an ecologically valid protocol, dimensionally characterizing SC abilities across a clinical, sub-clinical and neurotypical sample, which correlates well with existing measures. Our results highlight the centrality of context dependent verbal and non-verbal behaviors in the assessment of SC.

414.002 *(Poster)* ASQ: A Questionnaire for the Assessment of Communication, Language and Speech of Young Children with ASD

H. Copty-Diab[1] *and E. Dromi*[2]*, (1)Constantiner School of Education, Tel Aviv Univesity, Tel Aviv, Israel, (2)Constantiner School of Education, Tel Aviv University, Tel Aviv, Israel*

Background: Each child diagnosed with autism spectrum disorder (ASD) has the right for an early intervention program tailored to his overall clinical profile (Dromi, 2018). The selection of specific targets for intervention requires a detailed and reliable evaluation of the clinical profile of each child. The goal of the present study was to develop an instrument for speech-language pathologists (SLPs) that would enhance their selection of intervention goals for young children diagnosed with ASD. The Autism Spectrum Questionnaire (ASQ) was designed for this purpose.

Objectives: To construct a questionnaire to be used by SLPs and to examine its internal consistency, reliability, and discriminant validity.

Methods: The ASQ consists of 53 items that are classified into six sub-domains: Emotional Engagement, Communication, Symbolic Representation, Language Comprehension, Motor Planning / Sensory Regulation, and Speech Production. Responses in each item range from 1 (never) to 5 (always). Scores are calculated separately for each domain, and a total score is provided from the sum of all items. Twenty-five SLPs participated in this study. All of them had at least four years of experience working with children with ASD. Each SLP filled in the ASQ twice: Once on a child with ASD between the ages of 3-6 years, and in the second time on a child with typical development (TD) between the ages of 2-5 years. All the children with ASD had previously undergone thorough developmental assessments by a neurologist and a psychologist utilizing the ADOS-2 or the ADI; all had Developmental Quotient (DQ) scores noted in their medical records. All children with ASD were receiving language therapy for at least 3 months prior to the beginning of this study.

Results: The ASQ clearly differentiated between the two groups of children (ASD and TD). The distribution of the total score of each group were compared by the Wilcoxon Two Sample test. ROC analyses were performed to assess the ASQ's discriminant validity and revealed the scale's high ability to distinguish children with ASD against TD children (AUC= 0.98 -1.00). Positive high correlations were found between the ADOS-2 and the ASQ total scores [$r(25)=-0.7$, $p<.0003$]. Correlations between the scores in each of the six domains of ASQ and the ADOS-2 total score varied. The ASQ scores and the DQ scores were highly correlated with each other [$r(25)=0.61$, $p<.05$] (Table 1).

Conclusions: The ASQ was used successfully by SLPs and provided a clear direction for selecting intervention goals for children with ASD. Further research is needed in order to attempt a full standardization of the ASQ measurement, as well as for testing its applicability for children with other neurodevelopmental disorders.

414.003 *(Poster)* Acoustic-Perceptual Analysis of Oral Narratives in Individuals with Autism

M. V. Andrianopoulos *and C. E. Gargan, Department of Communication Disorders, University of Massachusetts, Amherst, MA*

Background: Acoustic differences in the speech, voice and prosody of individuals with autism include increased pitch variability, atypical/shallow vocal quality, fast or slow rate, exaggerated/decreased pitch, and inappropriate phrasing, stress and resonance. Research supports that human listeners can perceive speech differences under controlled conditions that distinguish children with ASD from typically developing (TD) peers. For example, human listeners distinguished children with autism from TD controls as sounding significantly “different” on the basis of story sequencing, articulation, fluency, and emotional language (Andrianopoulos et al., 2015); using more words per utterance during elicited story telling tasks (Dahlgren, 2018); and speech intelligibility (Redford et al., 2018). There is limited consensus regarding which acoustic features contribute to the perception of prosodic differences in autism. The clinical usefulness of perceptual ratings of prosody remains limited. Continued empirical research investigating the ability of trained listeners to identify individuals with autism on the basis of speech, voice and prosody could contribute to the development of an objective definitions of “atypical prosody” to be used across clinical, diagnostic, and research settings.

Objectives: The following research questions were addressed: Do individuals with autism have acoustic differences in their speech, voice, and prosody during oral narrative productions compared to controls?; Are speakers with autism described by trained human listeners as sounding “different” with respect to perceptual correlates of prosody; Are speakers with autism identified by trained human listeners based on their speech, voice, and prosody?

Methods: A between-group study was conducted to investigate acoustic-perceptual features of the voice during an oral narrative re-telling task in individuals with autism (n=15; 12 males, 3 females) compared to TD controls (n=15;) matched for age, gender and language. Participants were monolingual speakers of English, between 7;10 to 15;1 years of age. Testing took place in a 1:1 setting in a sound-treated, double-walled chamber with an ambient noise level of 25 dBA. Participants’ produced an oral narrative using controlled picture stimuli, which was audio recorded for analysis. The duration of each story (seconds), average fundamental frequency (f0), f0 range, standard deviation of f0, rate, and intensity was measured per participant using the Multi-Dimensional Voice Program and compared between groups. Trained listeners used a novel perceptual rating tool consisting of Likert scales to describe the oral narratives with respect to pitch, intonation, rate, fluency, timbre, loudness, and group membership (ASD vs. TD).

Results: The acoustic-perceptual analysis of 18 participants’ oral narratives has been completed. The group means for duration and fundamental frequency during an elicited storytelling task are presented in Table 1. Data collection and analysis will be complete by December 2019. Planned statistical analysis includes one-way analysis of variance, t-tests, Fisher’s Exact, Cohen’s d, and Cohen’s kappa for intra- and inter-rater reliability of perceptual judgments.

Conclusions: Published empirical **r**esearch findings are contradictory. The results of this study support differences in duration during elicited spontaneous storytelling tasks (Dahlgren et al., 2018; Redford et al., 2018). Clinical implications and directions for future research require reliable operational metrics to assess prosody in autism.

414.004 *(Poster)* Aspects of Language Divergently Map Onto Motor Deficits, Dyspraxia and Symptom Severity in Children with Autism

B. Tuncgenc[1]*, C. A. Koch*[2]*, M. J. Stabile*[3]*, S. H. Mostofsky*[4] *and I. M. Eigsti*[3]*, (1)Psychology, University of Nottingham, Nottingham, MD, United Kingdom, (2)Center for Neurodevelopmental and Imaging Research, Kennedy Krieger Institute, Baltimore, MD, (3)Psychological Sciences, University of Connecticut, Storrs, CT, (4)Center for Autism and Related Disorder, Kennedy Krieger Institute, Baltimore, MD*

Background: Language deficits commonly observed in the autism spectrum conditions (ASC) span a wide range, including impairments in pragmatics (i.e., social-contextual aspects of language), word choice differences, and poorer use of grammatical structures. In storytelling, which is a critical skill for school performance and social interactions, narratives of children with ASC have a shorter and less coherent structure as compared to those of typically-developing (TD) children (see meta-analysis by Baixauli et al., 2016). Children with ASC also use fewer mental-state terms (e.g., "know", "think") to express others' perspectives, and have more difficulty comprehending social-emotional words (Tager-Flusberg et al., 2006). Certain grammatical structures, such as first-person quoted speech, may also be indicative of perspective-taking abilities (Brunye et al., 2009), but whether first-person speech use is impaired in ASC requires further investigation. A recent longitudinal study (Bal et al., 2019) reported that early motor skills strongly predicted language skills at age 19, indicating the importance of examining relations between language and motor skills in ASC.

Objectives: This study examined (a) whether narrative structure and first-person speech usage is impaired in children with ASC, and (b) how each linguistic variable is linked with other autism-associated impairments, namely: autistic trait severity (Social Responsiveness Scale-2: SRS-2), dyspraxia (child-modified version of Florida Apraxia Battery: FAB-child), and impaired basic motor control (Physical and Neurological Examination of Subtle Signs: PANESS).

Methods: Fifty-five 8- to 12-year-old children (29 ASD, 26 TD) participated in a storytelling game, during which they watched a narrator tell a story, and then retold this story. Key story elements were identified a priori; the proportion of key elements included in retellings was the measure of narrative structure. The proportion of first-person speech usage to utterances was calculated.

Results: Narrative structure and first-person speech were significantly correlated (r= .57, p< .0001). Further, children with ASC produced significantly shorter narrations ($F(2,52)$= 10.358, p = .02) and fewer first-person speech utterances compared to peers with TD ($\chi^2(55)$= 5.45, p= 0.02; Table 1). Impaired narrative structure was associated with increased ASD severity (SRS-2: r= -.33, p= .02) and poorer motor ability (PANESS: r= -.49, p= .001), but not with praxis performance (Figure 1). Decreased first-person speech production was associated with poorer praxis (FAB-child: r= -.37, p=.05), but not with motor ability or autistic trait severity (Figure 1).

Conclusions: Children with ASC showed reduced command of two language variables, narrative structure and first-person speech usage, during story retellings. Importantly, the two variables showed divergent patterns in their relationship with other autism-associated impairments. Strong associations of narrative structure with motor ability and ASC severity support previous research that narrative structure is a core social-communicative impairment in ASC. First-person speech being uniquely associated with dyspraxia may reflect the perspective-taking demand that is common in both measures. These findings provide insight into how different aspects of language use can map onto the highly heterogeneous autism phenotype.

414.005 *(Poster)* Autistic Adults Show More Lexically-Guided Perceptual Learning

T. Karaminis[1]*, R. Wallwork*[2] *and L. Lawrence*[3]*, (1)Department of Psychology, Edge Hill University, Ormskirk, United Kingdom, (2)Edge Hill University, Ormskirk, United Kingdom, (3)Psychology, Edge Hill University, Ormskirk, United Kingdom*

Background: In our social interactions, we continuously tune into individual speakers, who pronounce words differently, depending on their accent, dialect, gender, age or other factors. This tuning is supported by a type of learning referred to as lexically-guided perceptual learning: When hearing ambiguous speech sounds, we use our lexical and phonotactic knowledge to infer which sounds we have heard. Subsequently, we adjust our phonetic categories (broadly speaking: our expectations for how different phonemes ought to sound) to include such ambiguous sounds. The continuous adjustment of phonological categories, driven by lexical knowledge and recent speech input, enables us to process ambiguous speech more efficiently.

Many theoretical accounts of autistic perception have suggested that autistic people present difficulties in calibrating their perceptual systems to current environments by using knowledge accrued from their recent sensory experiences. Such difficulties have been shown mainly in non-linguistic domains. In this study, we hypothesise that similar difficulties are also present in speech perception and affect lexically-guided perceptual learning. If so, autistic people should present less pronounced lexically-driven perceptual learning compared to neurotypical individuals.

Objectives: We sought to test this prediction by examining lexically-guided perceptual learning in autistic and neurotypical adults.

Methods: We tested 13 autistic adults aged between 19 and 46 (M = 33.80; SD = 11.71). We also tested 14 neurotypical adults of comparable age, and verbal and reasoning abilities.

Participants were tested on a lexically-guided perceptual learning paradigm (Drozdova et al., 2015), which had an 'Exposure-Test' design. In the Exposure phase, participants listened to a short story which contained an ambiguous sound selected from the [l/r] continuum (based on pretesting). Each participant heard one of two versions of the story ('learning conditions') in which the ambiguous sound replaced either all [r] sounds or all [l] sounds in the story.

In the Test phase, participants completed a phonetic-categorisation task on ambiguous sounds from the continuum between [l] and [r] sounds.

We analysed the responses in the phonetic-categorisation task with statistical modelling, using the number of responses that were consistent with the learning condition as the dependent variable. The statistical model included effects of group and of the level within the continuum of ambiguous sounds.

Results: Our analyses showed that both autistic and neurotypical participants presented reliable lexically-driven perceptual learning effects. Contrary to our prediction, lexically-driven perceptual learning was more pronounced in autistic participants compared to neurotypical participants.

Conclusions: Our results suggest that the difficulties of autistic people in calibrating their perceptual systems to current environments do not generalise to lexically-driven perceptual learning. By contrast, autistic people presents enhanced abilities to use lexical or phonotactic knowledge to adjust their phonetic categories to recently speech input.

These findings are consistent with accounts suggesting that autistic people present enhanced perceptual abilities, including enhanced speech perception abilities. These findings are also consistent with our earlier findings that neurotypical individuals with higher levels of autism traits present more lexically-driven perceptual learning. Our current work involves examining these differences developmentally.

414.006 *(Poster)* Autistic Children Show a Preference for Subtle Averted Gaze Versus Direct Gaze

***P. Maes**, E. Clin, F. Stercq and M. Kissine, ACTE — Center of research in Linguistics — ULB Neuroscience Institute, Université libre de Bruxelles, Brussels, Belgium*

Background: Atypical eye contact is often quoted among the socio-communicative deficits that define Autism Spectrum Disorder (ASD). Sensitivity to eye gaze and the ability to make eye contact are necessary to engage in joint attention, which plays an important role in language development. Both impairments in joint attention and delays in language acquisition characterize the developmental path of autistic children. Additionally, deficits in visual social attention are largely reported in ASD. However, there is currently no robust eye-tracking evidence that autistic children systematically display abnormally low attention to the eye region. Interestingly, at least one study found that infants at high risk for ASD show a preference for static images of faces with an averted versus direct gaze.

Objectives: Building on this finding and on the idea that sensitivity to direct gaze is a precursor of joint attention, and therefore of language, we explore the preference for direct versus averted gaze in 3- to 5-year-old typically-developing (N=55) and verbal and non-verbal autistic (N=29) children. The aim is to investigate whether they (1) can differentiate direct from averted gaze, and (2) show a preference for direct or averted gaze.

Methods: Stimuli were two identical videos of a person uttering a sentence with neutral emotion, displayed on each side of a screen equipped with a mobile eye-tracker. In one video, the speaker's gaze fixated the camera, while the other was manipulated so that the gaze was averted. There were two conditions of averted gaze. Original gaze was either modified slightly resulting in a subtle averted gaze or more strongly resulting in an obvious averted gaze. Following the stimuli presentation, videos with direct gaze were always rewarded with an animation after a short anticipation window (see Figure 1).

Results: There was a significant main effect of stimulus type (χ^2 (1) = 124.4272, $p<0.001$), with more fixations on the video with direct gaze than with either averted gaze. There was also a significant interaction between stimulus type and group (χ^2 (1) = 48.6249, $p<0.001$). Overall, typically-developing children made more fixations on the video with direct gaze than with either averted gaze. There was no significant difference between the two stimulus types for autistic children. Finally, there was a significant interaction between stimulus type, group and intensity of averted gaze (χ^2 (1) = 70.0481, $p<0.001$) (see Figure 2). Both groups made more fixations on the video with direct gaze when the averted gaze was obvious. However, when the averted gaze was subtle, typically-developing children made more fixations on the video with direct gaze, and autistic children on the video with averted gaze.

Conclusions: Preliminary results suggest that typically-developing children show a preference for direct gaze regardless of intensity of averted gaze. Autistic children show the same preferential pattern when the averted gaze is obvious. However, they show a preference for averted gaze when the gaze is averted more subtly. In the future, analyses of the anticipation phase will be conducted, as well as analyses including ASD symptomatology severity and level of language.

414.007 *(Poster)* Bilingualism in School-Aged Children with and without ASD: A Multi-Case Study

***M. L. Beauchamp**, Research Institute- McGill University Health Centre Montreal, Montreal, QC, Canada*

Background: Worldwide, bilingualism is common (Tucker, 1998). Many families of children with autism are told to refrain from using their minority language with their child for fear that it will exacerbate language deficits (Yu 2013). Such recommendations are not evidence-based and may lead to reduced participation in conversations, diminished abilities to communication with certain family members and limited access to their cultural community (Kremer-Sadlik, 2005; Yu 2013). Moreover, preschool-aged bilingual children with autism (B-ASD) can develop similar language abilities to those of their monolingual children with autism (M-ASD; Hambly & Fombonne, 2012; Ohashi et al., 2012). However, little is known about their linguistic abilities when language demands change during the school years and how BC-ASD compare to neurotypically developing bilingual (B-ND) children in one or both of their languages.

Objectives: The following study aims to shed light on this subject. Specifically, we asked: Are there differences in the performances of B-ASD on French language tasks of receptive vocabulary, receptive language and expressive language skills, when compared to (a) French M-ASD, (b) to their B-ND peers, and (c) to French M-ND peers? And if so, how do B-ASD differ from these peers?

We predicted that B-ASD will overall have similar performances to their monolingual peers with autism. We expected that both B-ASD and M-ASD may have stronger vocabularies relative to their overall receptive language abilities (Kjelgaard & Tager-Flusberg, 2001), a pattern which we did not expect in ND children. We also expected that B-ND would present an expressive-receptive gap (Gibson et al., 2012), which we did not expect in B-ASD, as some children with autism are reported to have better performances on expressive versus receptive language tasks (Eigsti & Bennetto, 2009).

Methods: A multiple-case study was conducted focusing on three French-English B-ASD and two French M-ASD, as well as 19 French-English B-ND and 12 French M-ND children. All children were recruited from the Greater Montréal Region and Greater Ottawa Region, had NVIQs >70, no speech or language disorders, and were six to nine years of age. Autism diagnosis was confirmed through the *Social Communication Questionnaire*. Bilingual children's expressive and receptive language abilities were assessed using the *Clinical Evaluation of Language Fundamentals* in French and in English and receptive vocabularies through the *Peabody Picture Vocabulary Test* and the *Évaluation en images Peabody*. Monolingual children were assessed only in French.

Given the small sample size of children with autism, we opted to complete two different *k-means cluster analyses*: the first analysis examined how the four groups clustered on French-language measures and the second one the performances of the two bilingual groups on French and English-language measures

Results: We found that B-ASD showed similar performances on language measures to those of M-ASD and of B-ND and M-ND children. Additionally, we did not find an ASD language pattern for either of our language groups.

Conclusions: Results from this small-scale study indicate that these B-ASD seem to develop similar language abilities to those of M-ASD, and of their ND peers, be they monolingual or bilingual.

414.008 *(Poster)* Children with Minimal Verbal Skills and Autism Use of Communicative Functions and Communication Partner across Naturalistic Setting

S. Suswaram[1]*, N. Brady*[2] *and K. K. Fleming*[3]*, (1)Speech Language Hearing: Sciences and Disorders, University of Kansas, Lawrence, KS, (2)University of Kansas, Lawrence, KS, (3)Life Span Institute, University of Kansas, Lawrence, KS*

Background:

- Communication necessities and demands differ based on context, environment and the communication partners. For children with minimal verbal abilities and Autism, information of their communication skills in a naturalist setting can provide necessary information for planning intervention.
- In the current study, we assess children's communicative functions in relation to the naturalistic setting to understand the probable pattern of responses using Communication Complexity Scale (CCS, Brady et al. 2012)

Objectives:

- Similarities and differences in the functions of communication based on naturalistic setting
- The effect of context and communication partner on communicative function

Methods:

- Thirty children (22 Male, 8 Female) between the ages of 3 and 15 years, with minimal verbal skills and autism were observed in three different naturalistic contexts within their schools.
- Observations were coded for 10-minutes in three different settings. We used time sampling procedures, with30 seconds of observation followed by 10 second coding intervals, generating 16 observation intervals. The three contexts are as follows:
    - Structured (e.g. group circle time, art)
    - Unstructured (e.g. snack, free play)
    - Structured One-on-One (e.g. goal work, speech therapy)
- The CCS was used to assign scores to the most complex communication act observed during each observation interval for the naturalistic contexts.
- For the current analysis, the CCS scores of 6 or above, that associated with communicative functions directed towards a communication partner (Adult or Peer) was used:
    - Behavior regulation (BR) - requests and protests
    - Joint attention (JA) - social comments
    - Response to question (RQ) - responses to the communication partner's questions
    - Prompted, imitation, reading (PIR) - prompted communications, imitates based on the communication partners, and readings activities that produces communication acts
- Reliability of the CCS scores was examined for 33% of the naturally occurring contexts. Average percent agreement was 73.02% for function and score combined.

Results: Context and Communicative Function

- The frequencies of communication acts with functions of JA, BR, RQ, and PIR varied somewhat according to the setting. Chi-square test indicates a significant difference between the communicative functions across settings, χ^2 (6, N =483) = 75.046, p <.0001.
- PIR was the most common function in the One-on-One and Structured settings, while BR and JA occurred with approximately equal frequencies across settings.
- Table 1 shows the distribution of functions across setting

Communicative Partner and Function

- Significant differences in the communicative function (only scores 6 and above) were found for communication used with adults or peer communication partners, χ^2 (3, N =244) = 11.934, p = .008.
- Overall, communication was directed more towards adult (96%) than peers (4%).

Conclusions:

- Differences across communicative functions between contexts may reflect differences in expectations and support in different classroom contexts. This information may help in setting goals for student progress.
- Regardless of the settings, students communicated more with adults than their peers. Student communication directed towards peers fostered relatively more JA and RQ. However, communication directed towards adults produced more PIR and BR. Therefore, goals focused on increasing peer communication and JA functions might benefit from activities designed around unstructured settings.

414.009 *(Poster)* Comparing Standardized Assessment Scores to Parental Report in Communication

C. Gelep*, A. Kniola, K. Tuohy and S. Char, Mailman Segal Center for Human Development, Nova Southeastern University, Ft. Lauderdale, FL*

Background: Previous research completed on an earlier version of a community-based developmental assessment clinic database produced no correlation between the *Differential Ability Scales, Second Edition, Early Years' (DAS-II)* Verbal Skills scale and the Communication domain on the *Vineland Adaptive Behavior Scales, Second Edition, Parent/Caregiver Rating Form (Vineland-II)*. This previous finding suggested that parents may be inflating their child's communication deficits. However, other research conducted suggests that parents are generally reliable reporters regarding their child's language capabilities (Miller, Perkins, Dai, & Fein, 2017).

Objectives: This study aims to add to the previous research conducted on this database with the inclusion of new data and hypothesizes that children who score higher on the Verbal Skills scale of the cognitive functioning assessment called the *Differential Ability Scales, Second Edition, Early Years and School-Age Battery (DAS-II)*, will also yield higher scores on the Communication domain as measured by the *Vineland Adaptive Behavior Scales, Second or Third Edition, Parent/Caregiver Rating Form (Vineland-II, 3)*.

Methods: Participants included 110 children (Males n = 87, Females n = 23) evaluated at a community-based developmental assessment clinic, over the span of three years. Ages of participants ranged from 30 to 214 months (μ= 78.18 months) and they were assessed using the *Vineland-II* or *Vineland-3*. The sample consisted of 34.5% Caucasian, 23.6% African American, 22.7% Latinx, 10.9% biracial, and 1.8% Asian Americans participants. It is important to note that 0.9% selected 'other' in relation to ethnicity. All participants were at-risk for autism spectrum disorder (ASD), as determined by a phone screening method prior to the evaluation. However, not all participants were ultimately diagnosed with ASD.

Results: As hypothesized, there was a significant positive correlation ($r = .513$, $p < .01$) found between the subjects on the *DAS-II's* Verbal Skills scale and the *Vineland's* Communication domain.

Conclusions: These results suggest that the higher the scores on the *DAS-II's* Verbal Skills Scale, the higher the scores on the *Vineland's* Communication domain. Contrary to previous research utilizing an earlier version of the database, parents/caregiver report on the adaptive measure is aligned with the results of the cognitive assessment.

414.010 *(Poster)* Comparing Treatment Gains in Joint Attention in Structured and Unstructured Contexts

N. Libster[1]*, J. Panganiban*[2] *and C. Kasari*[3]*, (1)UCLA Center for Autism Research and Treatment, Los Angeles, CA, (2)Semel Institute, University of California Los Angeles, Los Angeles, CA, (3)University of California, Los Angeles, Los Angeles, CA*

Background: Several studies have demonstrated the effectiveness of interventions aimed at improving joint attention skills in children with Autism Spectrum Disorder (ASD; Kasari et al., 2006; Kasari et al., 2014). In a randomized control study by Kasari et al. (2014), parents of children with ASD were either actively trained by interventionists to prompt for joint attention during everyday activities (CMM group) or they were educated on ways to teach their children social communication skills (CEM group). The researchers found that both groups showed improvements in initiating joint attention (IJA), and the CMM group displayed significantly more IJA skills than the CEM group. The researchers measured IJA using the Early Social Communication Scales (ESCS; Mundy et al., 2003), a structured assessment designed to elicit joint attention skills. It is unknown whether the acquired joint attention skills that children exhibited on the ESCS could be generalized to less structured play assessments, which are not designed to elicit joint attention. It is important to understand whether interventions are effective at increasing IJA in more naturalistic contexts.

Objectives: Compare IJA skills exhibited on a structured assessment versus a play assessment among a subset of participants from Kasari et al. (2014).

Methods: This secondary data analysis consisted of a subset of children (n= 28) between 2 and 5 years of age with ASD who participated at the UCLA site of a larger multi-site study (Kasari et al., 2014). Children received the ESCS and the Structured Play Assessment (SPA) at entry, exit, and follow-up. During the SPA, the child plays with five sets of toys independently without being prompted for social communication. The ESCS and SPA were coded for coordinated looks, alternate gazes, points, gives, shows, and language at all three time points. IJA frequencies were then calculated. For each assessment, a generalized linear mixed effect model with a random intercept was conducted, holding chronological and mental age constant.

Results: On the ESCS, children displayed 47% more IJA skills at exit ($p = 0.04$) and 64% more IJA skills at follow-up ($p < 0.01$) compared to entry. On the SPA, children displayed 38% more IJA skills at exit ($p = 0.06$) and 67% more IJA skills at follow-up ($p < 0.01$) compared to entry. Comparing the two assessments, children displayed 19% more IJA skills on the SPA than on the ESCS ($p = 0.05$).

Conclusions: These findings indicate that interventions aimed at improving joint attention are effective at improving IJA skills in structured assessments as well as in naturalistic play settings. In fact, children exhibited higher rates of IJA during play than on the ESCS. One limitation of our study was the sample size – due to limited power, we were unable to explore differences in IJA between treatment groups. Our next steps will be to compare IJA in the ESCS and SPA across time and treatment for all 112 participants.

414.011 *(Poster)* Comparison of Communication Level Based on Ethnicity for Children at Risk for Autism Spectrum Disorder

K. Tuohy*, A. Kniola, C. Gelep and S. Char, Mailman Segal Center for Human Development, Nova Southeastern University, Ft. Lauderdale, FL*

Background: Research has shown different prevalence rates for autism spectrum disorder (ASD) among different ethnicities. ASD has been shown to be diagnosed more often in White children compared to Latinx and Black children (Durkin, 2017). There are multiple areas of functioning that are taken into account when diagnosing ASD that can impact these ethnic disparities, such as overall communication. Previous research suggests that White children score significantly higher on the domain of understanding communication compared to Latinx and Black children with ASD (Stronach & Wetherby, 2017). However, these researchers also found no significant difference between the different ethnicities based on their use of communication (Stronach & Wetherby, 2017). Therefore, differences in communication level based on ethnicity may vary by specific communication domain for children with ASD.

Objectives: This study aims to add to this body of research and to determine whether communication level differs based on ethnicity for children with ASD. Based on the above findings, it is hypothesized that White children will score significantly higher on the Communication domain of the *Vineland Adaptive Behavior Scale, Second or Third edition, Parent/Caregiver Rating Form (Vineland-II, 3)*, which incorporates different domains of communication.

Methods: Participants consisted of 184 children who completed a comprehensive developmental assessment at a community-based developmental assessment clinic over the span of three years. Out of the 184 participants, 119 participants (64.7%) were diagnosed with ASD. A majority of the participants were male (77.2%) and ages ranged from 19 to 253 months (μ= 68.78). There were 39.7% participants who identified as White, 35.3% identified as Latinx, and 25% identified as Black. Seven participants were excluded due to missing data. The participants completed a comprehensive developmental assessment that included the *Vineland-II, 3*, as part of a testing battery(Sparrow, Cicchetti, & Balla, 2005; Sparrow, Cicchetti, & Saulnier, 2016).

Results: A series of independent samples *t*-tests were utilized for analysis. The results revealed a significant difference for communication level between White children (M = 80.59, SD = 18.08) and Latinx children (M = 71.92, SD = 18.44) who were diagnosed with or at risk for ASD; $t(132) = 2.74$, $p = .007$. No significant difference in communication level was found for White and Black children (M = 75.47, SD = 18.75; $t[111] = 1.44$, $p = .152$) or for Latinx and Black children ($t[105] = -.968$, $p = .335$) who were diagnosed with or at risk for ASD.

Conclusions: The results partially supported the hypothesis because White children who were evaluated for ASD had significantly higher communication scores on the Vineland compared to Latinx children. These results may be due to cultural differences in how language is understood and expressed between White and Latinx cultures.

414.012 *(Poster)* Comparison of Language Characteristics Associated with Autism Spectrum Disorder, Intellectual Disability, and Co-Morbidity in a Diverse Clinical Sample

B. Rennie[1]*, C. H. Qi*[2] *and C. Burnette*[3]*, (1)University of New Mexico, Center for Development and Disability, Albuquerque, NM, (2)Special Education, University of New Mexico, Albuquerque, NM, (3)Integrated Center for Autism Spectrum Disorders, University of Nebraska Medical Center Munroe-Meyer Instittute, Omaha, NE*

Background: Children with autism spectrum disorder (ASD), global developmental delay (DD), and intellectual disability (ID) are at increased risk for severe language difficulties. Some research has suggested unique language profiles for children with ASD, with stronger expressive than receptive language scores. However, little is known about language profiles of individuals with ASD and DD/ID in diverse samples. Given the importance of language skills for independent functioning for those with ASD and those with DD/ID, it is critical to understand language profiles associated with ASD and ID to assist in developing tailored, individualized interventions.

Objectives: The purpose of this study was to compare language profiles associated with children diagnosed with ASD, DD/ID, comorbid ASD and DD/ID, and those without either diagnosis on measures of language in a clinical sample of predominantly Hispanic children and adolescents in the southwestern United States.

Methods: Participants included 337 children and adolescents (73.8% male; *M*age = 6.70, *SD* = 4.27) age 3-21 years who were evaluated between January 2015 and October 2017. All participants were referred for evaluation of possible ASD. Clinical diagnoses were made based on results of interviews, *Autism Diagnostic Observation Schedule, Second Edition* (*ADOS-2*), cognitive, language, and adaptive behavior assessments. Four groups were formed: children with ASD but no DD/ID (38%), DD/ID but no ASD (7.7), both ASD and DD/ID (19%), and no ASD or DD/ID diagnosis (35.3%). Inclusion criteria were (a) aged between 3 and 21, and (b) spoke English as their primary language.

Measures: The *ADOS-2* and clinical interview were used to assess ASD symptoms. Cognitive abilities were measured by the *Differential Ability Scales, Second Edition*. Adaptive behavior was measured using the *Vineland Adaptive Behavior Scales, Third Edition* or the *Adaptive Behavior Assessment System, Third Edition*. Receptive and expressive language skills were assessed with the *Oral and Written Language Scale*-2 or the *Preschool Language Scale-5*.

Results: Significant differences were found in percentages of children who had language impairment (standard score of 70 or below on a language test) among the four groups by chi-squared proportion test, $X2(3, 331) = 94.37$, $p = 0.000$. More children with DD/ID and comorbid ASD and DD/ID had language impairment compared with children with ASD only and those without either diagnosis (see Table 1).

For children with ASD only, receptive language scores ($M = 77.90$, $SD = 19.55$) were significantly higher than expressive scores ($M = 73.05$ $SD = 18.62$), $t(127) = 5.175$, $p < .000$, CI [2.996-6.707]. For children with DD/ID only and those with combined ASD and DD/ID, receptive language scores were not significantly different from expressive scores (see Table 2).

Conclusions: Regarding overall language performance, scores indicate Neither Diagnosis > ASD > DD/ID > ASD and DD/ID, suggesting an additive effect of diagnosis. Unlike previous research demonstrating relatively more impaired receptive than expressive language in children with ASD, a pattern of significantly stronger receptive language ability was only found in children without either diagnosis or in children with only ASD, further suggesting unique language profiles.

414.013 *(Poster)* Comparisons of Steps in Theory-of-Mind Development between Autistic and Typically Developing Children in Hong Kong and Mainland China

C. C. H. Cheung[1]*, Y. Rong*[1]*, Y. Xiong*[1] *and T. P. Y. Tang*[2]*, (1)Research Centre for Language, Cognition, and Neuroscience, Department of Chinese and Bilingual Studies, The Hong Kong Polytechnic University, Hong Kong, Hong Kong, (2)Speech Therapy Unit, Department of Chinese and Bilingual Studies, The Hong Kong Polytechnic University, Hong Kong, Hong Kong*

Background: While a meta-analysis has shown that false belief (FB) understanding of typically developing (TD) children in Hong Kong (HK) develops much later than that of children in mainland China (Liu et al., 2008), whether the former also acquire other theory-of-mind (ToM) skills later than the latter remains unclear. Moreover, no study has compared ToM skills of HK autistic children with those of mainland Chinese autistic children. Wellman and Liu (2004) have devised a ToM scale to investigate the developmental sequence of five ToM skills: diverse desires (DD), knowledge access (KA), diverse beliefs (DB), contents FB (CFB), and hidden emotion (HE). Given Liu et al.'s finding, we hypothesize that both autistic and TD children in HK will perform worse than their mainland China counterparts in CFB. Furthermore, given Zhang et al.'s (2016) finding that the developmental sequence of the five ToM skills in mainland Chinese autistic children deviated from that in TD children, we hypothesize that the same will be observed in HK autistic and TD children.

Objectives: To examine HK autistic and TD children's performance on Wellman and Liu's (2004) ToM scale, and to compare the results with those from mainland Chinese autistic and TD children reported by Zhang et al.

Methods: 47 ASD ($M = 6.16$; range: 3.5–9.58) and 93 TD children in HK ($M = 5.10$; range: 3.33–6.83) participated. They were matched with Zhang et al.'s autistic and TD groups on age. To compare the developmental sequence of ToM between HK autistic and TD children, another TD group ($N = 137$; $M = 5.61$) matched with ASD group on language ability was formed. The tasks used by Zhang et al. (translated into Cantonese) assessed understanding of the five ToM skills.

Results: Among the five ToM tasks, chi-square analyses showed that HK TD children's passing rates were significantly lower than mainland Chinese TD children on KA and HE (see Table 1). In contrast, HK autistic children significantly outperformed mainland Chinese autistic children on KA, DB, and CFB (see Table 1). Like Zhang et al., we found that HK autistic children's developmental sequence of the five ToM skills (i.e., KA < DD < DB < CFB < HE) deviated from that of HK TD children (i.e., DD < KA < DB < CFB < HE) (see Table 2). Moreover, the developmental sequence of the five ToM skills in HK autistic children differed from that of mainland Chinese autistic children, which was DD < DB < KA < CFB < HE (see Table 2).

Conclusions: This study partially confirmed our hypothesis: the developmental sequence of the five ToM skills in HK autistic children deviated from that of HK TD children. However, contrary to our hypothesis, neither TD nor autistic children in HK performed worse than their mainland Chinese counterparts on CFB. Our finding that the developmental sequence of the five ToM skills in HK autistic children differed from that of mainland Chinese autistic children supports the idea that the developmental sequence of ToM is subject to cross-cultural/regional variations.

414.014 *(Poster)* Comprehension of Presupposition Trigger Ye 'also' By Mandarin-Speaking Children with Autism Spectrum Disorders

***S. An**, Guangdong University of Foreign Studies, Guangzhou, China*

Background: Pragmatic deficits have been reported to be a hallmark in individuals with Autism Spectrum Disorders (ASD) (Tager-Flusberg, 1999). However, little research has been done to investigate understanding of presuppositions, especially the comprehension of specific presupposition triggers, in ASD population.

Previous research (Bergsma, 2006; Höhle, Berger, Müller, Schmitz, & Weissenborn, 2009; Hüttner, Drenhaus, van de Vijver, & Weissenborn, 2004; Lee, 2002; Liu, Pan & Hu, 2011; Matsuoka, Miyoshi, Hoshi, Ueda, Yabu, & Hirata, 2006; Müller, Höhle, Schmitz, & Weissenborn, 2009; Nederstigt, 2003) revealed that TD children were able to produce 'also' as early as one and half years old across different languages, but they could not demonstrate adult-like interpretation until late seven years old (for relevant reviews, see Berger and Höhle, 2012). Note that the test stimuli in the above-mentioned comprehension work are isolated sentences. The stimuli are inappropriate when there is no discussion of others maintaining the same activity, or some other activities conducted by the same individual/s under discussion (Höhle et al., 2009; Stalnaker, 1974, 2002), which might contribute to preschool children's failure to comprehend 'also' in an adult-like manner.

Different from the large amount of research done with TD children, no study has been conducted to extend the investigation of comprehension of presuppositions to individuals with ASD. Cheung (2019) reported that Cantonese-speaking children were selectively impaired in comprehending different types of presupposition triggers, namely, definite description, factive predicates, change-of-state verbs, implicative verbs, iteratives and counterfactual conditionals and temporal clauses. The study did not include the counterpart of 'also' in Cantonese as a stimuli. In another word, no data with respect to the comprehension of presupposition trigger 'also' in ASD population has been reported before.

Objectives: The present study tried to advance the current understanding of pragmatic deficits in ASD individuals by investigating the comprehension of presupposition trigger *ye* 'also' in Mandarin-speaking preschoolers with ASD and their typically developing (TD) controls. Moreover, we were interested to investigate whether preschool Mandarin-speaking children are capable of interpreting presupposition trigger *ye* 'also' in an adult-manner when presupposed parts are introduced with proper context.

Methods: Picture Selection Task was adopted. Participants were instructed to select correct pictures after they hear the stimuli. Stimuli are compound clauses, which are comprised of two simple clauses, for instance, *the boy is running, the girl is also running*. The verb phrases of the first clauses were replaced by sounds of 'cars passing by'. In this way, the stimuli provide felicitous context for presupposition trigger 'also'.

Results: Children with ASD and TD children were matched on age, language ability and cognitive ability as well as executive function. We found that 22 Mandarin-speaking ASD children (4-5yrs) performed significantly worse than their matched 29 TD peers, who interpreted *ye* 'also' in an adult-like manner.

Conclusions: Preschool TD children do have the knowledge of 'also'; children with ASD are impaired in presuppositions of 'also', which is another area of pragmatic inferences.

414.015 *(Poster)* Computational Assessment of Verbal Entrainment in Individuals with Autism Spectrum Disorder and First-Degree Relatives

***S. P. Patel**[1], G. Dillman[1], G. E. Martin[2] and M. Losh[1], (1)Communication Sciences and Disorders, Northwestern University, Evanston, IL, (2)Communication Sciences and Disorders, St. John's University, Staten Island, NY*

Background: Difficulties in prosody (e.g., intonation, volume, rate), turn-taking, and overly formal speech constitute common social communication deficits in autism spectrum disorder (ASD), which can significantly hinder social interactions (Paul et al., 2009). Subtle, parallel differences in social communication have also been noted in parents of individuals with ASD (Landa et al., 1992). In typically developing (TD) individuals, social interactions are supported by entrainment, or the unconscious tendency to become more similar to one's communicative partner. Verbal entrainment is evidenced across lexical, semantic, syntactic, and prosodic domains. However, objective characterization of how deficits in these areas, specifically prosody, impact broader social communication in ASD remains a challenge in research and clinical contexts. Given the clinical and etiologic heterogeneity of ASD, assessment of verbal entrainment in parents may inform understanding of traits linked to genetic liability of ASD. Therefore, this study implemented a comprehensive, computational investigation of lexical, semantic, syntactic, and prosodic entrainment in individuals with ASD and their parents.

Objectives: To objectively measure verbal entrainment in individuals with ASD and their parents.

Methods: Individuals with ASD (n=26), their parents (n=53), and respective control groups (n=26 ASD controls; n=30 parent controls) participated in a 10-minute interactive game with an examiner. The pair conversed to determine if the silhouettes they were independently viewing matched. Lexical entrainment was based on lemmatized words, semantic entrainment on Word2Vec representations of the corpus and using word embeddings (Goodkind et al., 2018), and syntactic entrainment on 2-grams of part-of-speech-tags (Duran et al., 2019). Prosodic entrainment was measured using the contour-based, parametric, and superpositional intonation stylization toolkit (Reichel, 2011). Measures of cognitive ability, ASD symptom severity, and ratings of pragmatic language ability were examined in relation to entrainment within each domain.

Results: Analysis of the full sample is ongoing. In a preliminary sample of 12 individuals with ASD and 12 TD controls, individuals with ASD exhibited reduced lexical (p=.03) and syntactic entrainment (p=.09). In a sample of 22 parents of individuals with ASD and 19 parent controls, parents of individuals with ASD demonstrated significantly reduced semantic entrainment (p=.02). Lower full-scale IQ was marginally associated with poorer lexical entrainment in ASD (p=.08). Increased ASD severity in the social affect (p=.01) and restricted interests and repetitive behaviors (p=.03) domains was associated with poorer lexical entrainment in individuals with ASD. Across individuals with ASD and TD, decreased lexical entrainment was associated with greater pragmatic language violations in a separate conversational context (p=.01). In parents of individuals with ASD, reduced lexical entrainment was associated with a socially reticent personality style (p=.02).

Conclusions: Reduced entrainment detected in individuals with ASD and their parents highlights verbal entrainment as a potential mechanism underlying social communication impairments in ASD and more subtle differences in parents, potentially marking genetic liability to ASD. Findings that objective, computational measurements of entrainment are highly associated with ASD symptom severity and ratings of pragmatic language, as well as personality styles consistent with the broad autism phenotype in parents, highlight the promise of such computational tools in research and intervention studies.

414.016 *(Poster)* Contextual Differences in Joint Attention Behaviors Among Children with Autism

A. Dakopolos *and L. B. Jahromi, Teachers College, Columbia University, New York, NY*

Background: Children with autism spectrum disorder (ASD) often exhibit deficits in joint attention compared to their typically developing peers. The fluidity of naturalistic social interactions requires children to constantly assess and reassess the context of their environment while making judgements about themselves, their social partner, and objects or events of interest (Mundy & Jarrold, 2010). It is likely that children's social behaviors are influenced by different task demands, and therefore it is important to understand how contextual differences and task demands may be related to joint attention behaviors of children with ASD.

Objectives: The purpose of the present study is to examine joint attention behaviors of children with ASD in three contexts including *competing demands*, *teaching*, and *free play* in order to gain insights into aspects of social contexts that may promote or discourage joint attention.

Methods: Participants included 44 children with ASD (35 males) between the ages of 30 and 66 months (*Mage*= 49.33, *SD*= 10.01 months). Children with ASD and their mothers participated in a series of interactions including *competing demands, teaching* and *free play,* each of which lasted 5 minutes. An adapted version of the Early Social Communication Scales (Mundy et al. 2003) was administered to capture children's initiations of joint attention (IJA), and response to mother's bids for joint attention (RJA). Coding was completed by two research assistants, and measures of reliability were conducted by an independent coder (IJA ICC = 0.74-0.85; RJA ICC = 0.72-1.0).

Results: To test whether IJA and RJA differed as a function of context, mixed models were fitted with context as a fixed factor and participant as a random factor. Children's expressive and receptive language were controlled, and post-hoc pairwise contrasts using Bonferroni corrections were analyzed. For IJA, the model revealed a significant difference between the competing demands task and teaching task, t (86) = 6.82, $p < .001$, and the competing demands task and free play task, $t(86) = 5.77$, $p < .001$, while the difference was non-significant between the teaching task and free play task, t (86) = -1.04, $p = .55$. For RJA, the model indicated a significant difference between the competing demands task and teaching task, t (86) = -3.15, $p = .006$, and the competing demands task and free play task, t (86) = -3.54, $p = .002$, however the difference was non-significant between the teaching task and free play task, t (86) = -0.39, $p = .92$.

Conclusions: The rate of children's joint attention differed depending on the context of their interaction. Children exhibited greater frequency of IJA during the competing demands task, and greater frequency of RJA during the free play and teaching tasks. The utility of assessing child and parent behaviors in different contexts may relate to *functions* of the demands inherent in the tasks. The competing demands task may tap into children's social motivation, whereas the teaching task may relate to their attention more broadly - each task exerting unique pressures on the social interaction.

414.017 *(Poster)* Developmental Relationships between Joint Engagement and Child Vocabulary

K. Bottema-Beutel[1]*, S. Y. Kim*[1]*, S. Crowley*[2] *and P. Yoder*[3]*, (1)Lynch School of Education, Boston College, Chestnut Hill, MA, (2)Boston College, Chestnut Hill, MA, (3)Department of Special Education, Vanderbilt University, Nashville, TN*

Background: Higher-order supported joint engagement (HSJE), wherein caregivers and children reciprocally engage with toys, is longitudinally associated with autistic children's language (Bottema-Beutel et al., 2014). Follow-in utterances refer to parent talk that is semantically related to children's focus of attention. This type of talk, when embedded within HSJE (HSJE + FI), is also longitudinally associated with autistic children's language (Bottema-Beutel et al., 2014). At present, the direction of effect is not clear- do early HSJE and HSJE + FI influence later vocabulary, or does the pathway work in the reverse direction? Cross-lagged panel analysis is one way to answer this question.

Objectives: To determine if there were superior cross-lagged effects for:

(a) Early HSJE + FI and later expressive vocabulary vs. early expressive vocabulary and later HSJE + FI

(b) Early HSJE + FI and later receptive vocabulary vs. early receptive vocabulary and later HSJE + FI

(c) Early HSJE and later expressive vocabulary vs. early expressive vocabulary and later HSJE

(d) Early HSJE and later receptive vocabulary vs. early receptive vocabulary and later HSJE

Methods: This project is a secondary analysis of data collected on 91 autistic children who were 3-4 years old at study entry. Video recordings of caregiver-child interactions at Time 1 and 8 months later were coded for duration of HSJE and HSJE + FI at each timepoint. The MCDI was also collected at both timepoints to measure children's expressive and receptive vocabulary. Structural equation modeling (SEM) was used to calculate standardized coefficients and *p*-values for cross-lagged associations, while accounting for all other concurrent and longitudinal associations between variables. Coefficients for relevant cross-lagged associations were compared via linear combinations to identify a superior pathway, which allows for inferring a direction of effect.

Results: See Figures 1 and 2 for SEM results. Analyses indicated:

1. Effects of early HSJE + FI on later expressive vocabulary were significant while effects of early expressive vocabulary on HSJE + FI were not.
2. Effects of early HSJE+FI on later receptive vocabulary were significant while effects of early receptive vocabulary on later HSJE + FI were not.
3. Effects of early HSJE on later expressive vocabulary were significant while the effects of early expressive vocabulary on later HSJE were not.
4. Effects of early HSJE on later receptive vocabulary were significant, while the effects of early receptive vocabulary on later HSJE were not.

However, none of the coefficients within the pairs of crossed lagged coefficients listed in a-d were significantly different from each other (all *p*'s > .05).

Conclusions: While statistically superior pathways were not found for any of the 4 sets of cross-lagged panels, it is notable that all cross-lagged associations between early joint engagement and later vocabulary were significant, while none of the cross-lagged associations between early vocabulary and later joint engagement were significant. This provides some evidence that HSJE and HSJE + FI are useful starting points for promoting autistic children's vocabulary development in early intervention contexts, as compared to considering vocabulary a prerequisite for advancing developmentally important forms of joint engagement.

414.018 *(Poster)* Divergent Associations of Emotional Prosody Perception, Executive Function and Advanced Theory of Mind in School-Aged Children with High-Functioning Autism

F. M. Tsao[1]*, Y. H. Luo*[1]*, L. Y. Chang*[1] *and H. M. Liu*[2]*, (1)Psychology, National Taiwan University, Taipei, Taiwan, (2)Special Education, National Taiwan Normal University, Taipei, Taiwan*

Background:Impairment in theory of mind (ToM) and executive dysfunction have been proposed to explain social-communication deficits of autistic spectrum disorder (ASD). Inhibition and planning of executive function (EF) were related to first-order false-belief task in school-aged children with ASD (Joseph & Tager-Flusberg, 2004). The typically-developing (TD) school-aged children continue to master their higher-order ToM ability, and inhibitory control was associated with recognizing transgressions of social norms (in the faux pas task) and social reasoning (in the eyes tasks) (Osterhaus, Koerber, & Sodian, 2016). Children with high-functioning autism (HFA) performed less accurate to judge emotions of speech prosody (Wang and Tsao, 2015).

Objectives: The goal of this study was to evaluate the ToM deficit hypothesis in school-aged HFA children through exploring development of emotional prosody perception, EF and ToM, as well as investigating subcomponents of EF skills for developing higher-order ToM.

Methods: *Participants.* HFA (*n*=53, mean age=10.08 years) or TD children (*n*=60, mean age=9.93 years) in Taiwan. Inclusion criteria of HFA group: CAST (Childhood Asperger Syndrome Test) score≧5 and FSIQ of WISC-IV>85. **Table 1** lists tasks of emotional prosody perception, lower-order ToM, advanced ToM and EF.

Results: (a). ***developmental trends.*** Children were divided into middle (n=76, mean age = 9.31 years) and late (n=37, mean age = 11.42 years) childhood groups. Results of AgeXGroup 2-way ANOVAs showed that HFA group performed poor than TD group in lower-order ($p<.001$) and advanced ToM (eyes task, $p=.017$, faux pas task, $p=.013$). The Age effect was significant in all ToM tasks. AgeXGroup interaction effect was only significant in the lower-order ToM ($p=.040$). On emotional prosody perception, the Age effect was significant (p=.007), but neither Group nor AgeXGroup effect was significant. The Age effect was significant in each task of EF, except Wisconsin card sorting task (WCST). The Group and AgeXGroup effects were not significant in EF tasks.

(b). developmental associations. For HFA group, results of partial correlation (control for Age) revealed that eyes task was associated with faux pas ($r=.288$), emotional prosody ($r=.342$), and WCST (shifting, $r=.376$). The faux pas task was associated with ToL (moves, $r=-.363$) and WCST (errors, $r=-.437$). Emotional prosody was associated with WCST (shifting, $r=.520$, and errors, $r=-.437$). For TD group, the eyes task was associated with emotional prosody ($r=.397$), but faux pas task was not significantly associated with other tasks.

For HFA group, the path analysis ($\chi^2(1)=.824$, $p=.364$, RMSEA=0.000 and GFI=.992) showed that shifting directly related to recognize emotions from pictures and voices (**Figure 1a**). Additionally, planning directly relate to detect faux pas. In contrast, the path analysis (**Figure 1b**) for TD group ($\chi^2(1)=.659$, $p=.417$, RMSEA=0.000 and GFI=.993) revealed that eyes task directly link to emotional prosody but indirectly link to planning.

Conclusions: The HFA group exhibit impairments in recognizing complex emotions and detecting social transgressions of higher-order ToM. Results of path analysis for HFA children highlight the importance of shifting to identify mental states but the involvement of planning to detect violations in social context.

414.019 *(Poster)* Do High- Vs. Low-Risk Toddlers Differ in Production of Functional Acts in Early Adult-Child Interactions?

N. M. Hendrix[1]*, C. Roberts*[2]*, S. Ozcaliskan*[3]*, J. Moses*[4] *and M. Kyle*[5]*, (1)Marcus Autism Center, Emory University School of Medicine, Atlanta, GA, (2)Emory University, Atlanta, GA, (3)Georgia State University, Atlanta, GA, (4)Weill Cornell Medicine, Center for Autism and the Developing Brain, White Plains, NY, (5)Columbia University Medical Center, New York, NY*

Background: Infants at high risk for autism spectrum disorder (ASD) demonstrate reduced gesture usage as young as 12 months of age (Choi et al., 2019). Toddlers with ASD, for example, demonstrate weaknesses in deictic gesture production (e.g., pointing toward items; Manwaring et al., 2018; Özçalışkan et al., 2016). As such, previous work has largely targeted exposure to and use of deictic gestures in this population. In contrast, less work has examined functional acts (e.g., twisting a jar open or giving a bottle to one's mother), which emerge in typical development around 8-to 10-months of age (Capone & McGregor, 2004). Functional acts involve action upon items and thus are often excluded from gesture analyses (Özçalışkan & Goldin-Meadow, 2005). However, they constitute a key nonverbal communication strategy commonly considered in diagnostic evaluations (Lord et al., 2012) and are also observed less frequently in children with ASD (e.g., Wetherby et al., 2007). Closer consideration of functional acts may offer a more comprehensive view of nonverbal communicative development in typical and atypical development.

Objectives: We examined child use of functional acts in the context of play interactions with a clinician and a primary caregiver during a structured social communicative play assessment (Wetherby & Prizant, 2003). We examined whether differences emerged in use of functional acts between children who were identified as high-risk *vs*. those identified as low-risk, a subset of whom later received a diagnoses of ASD (n = 13 high-risk infants, n = 1 low-risk infant).

Methods: A sample of 35 24-month-old toddlers (20 male, 15 female; 82.9% Caucasian) has been drawn from a larger prospective, longitudinal study examining the development of ASD symptoms in high-risk infant siblings of children with ASD (n = 15) as compared to low-risk infants (n = 20). Video recordings of the children engaged in a structured 15- to 20-minute assessment of initiations and responses to clinician communicative bids were coded following earlier gesture work (Özçalışkan et al., 2017). Specifically, the team used a coding protocol that classified gestures by type and function as well as functional acts. Moreover, the team coded whether gestures and functional acts occurred in isolation or with speech or eye contact.

Results: Preliminary findings (n = 35) indicate that children later diagnosed with ASD tended to engage in fewer functional acts directed toward an adult (M = 10.29, SD = 5.95) as opposed to children without a diagnosis (M = 15.48, SD = 8.52; $t(33) = 1.975$, $p = .057$). However, frequency of functional acts did not significantly differ based upon risk status ($p = .123$).

Conclusions: Early gesture predicts language outcomes in typical and atypical development (e.g., Choi et al., 2019; Sauer et al., 2010; Özçalışkan et al., 2017). Given the relatively lower production of gestures in children with ASD, exploration of nonverbal communicative strategies other than gestures, such as functional acts, can inform early diagnosis of ASD and consequently, more positive language learning outcomes in this population.

414.020 *(Poster)* Does Multilingual Exposure Have an Effect on the Severity of Autistic Traits?

S. Crockford[1]*, O. Ozturk*[1]*, J. L. Gibson*[1] *and N. Katsos*[2]*, (1)University of Cambridge, Cambridge, United Kingdom, (2)Theoretical and Applied Linguistics, University of Cambridge, Cambridge, United Kingdom*

Background: Current research suggests multilingualism may have a significant impact on various aspects of autism. Recent evidence shows that multilingual autistic individuals demonstrate improved executive function and communicative competence.[1,2,3,4] All of the mentioned abilities are abilities that are also found to be impaired in autism.[5,6,7] If multilingualism affects a number of autistic deficits, it is possible that it could interact with the way in which autistic traits are expressed.

Objectives: This study investigates the relationship between multilingualism and the prevalence of autistic symptomatology, as measured by the Social-Responsiveness Scale (SRS-II).

Methods: Data from the children in this sample were taken from two separate research projects conducted at the University of Cambridge and UCL's Institute of Education. In total, 22 monolingual and 30 multilingual autistic children (mean age = 12.9 years, sd ± 11.05) were tested as at UCL's Institute of Education and at the University of Cambridge. Parents of these children completed an extensive language background questionnaire, where they reported on the number of languages spoken, proficiency and frequency of use in each language. Parents of children were additionally asked to complete the SRS-II, a questionnaire aimed at identifying autistic traits.

Results: Firstly, we ran an independent t-test to assess whether the average SRS-II scores differed between the monolingual and bilingual groups, where the bilingual group was defined as any child who was reported as being exposed to more than one language. The independent t-test showed no significant difference between the average total SRS scores for bilinguals (mean score = 78.772) and monolinguals (mean score = 81.125) (t(38.334) = -0.793, p-value = 0.4328). Finally, we looked at whether proficiency and frequency of use in multiple languages among the bilingual group predicted differences in SRS scores in the second cohort. The regression models revealed that overall level of multilingualism, measured as a combination of proficiency and frequency of use, significantly predicted differences in total SRS-II scores. We found that higher levels of bilingual proficiency and frequency of use predicted overall lower SRS-II scores ($F(1, 30) = 2.415$, $p = 0.004$, > 0.01; $r^2 = 0.22$).

Conclusions: Our results showed a tendency towards lower SRS scores in the children growing up in multilingual environments, with bilingual proficiency predicting lower presentations of autistic traits. The findings from this project will help inform our knowledge of autism and how strong environmental factors, such as multilingualism, may influence its aetiology.

414.021 *(Poster)* Emergent Literacy Skills in Children with and without Autism Spectrum Disorders

I. Misiunaite[1]*, D. Davidson*[2] *and S. Vanegas*[3]*, (1)Loyola University Chicago, Chicago, IL, (2)Psychology, Loyola University Chicago, Chicago, IL, (3)School of Social Work, Texas State University, San Marcos, TX*

Background: Emergent literacy is the stage, usually occurring during the preschool period, during which the skills, knowledge, and attitudes that are precursors to reading and writing start to develop (Whitehurst & Lonigan, 1998). Children with Autism Spectrum Disorder (ASD) are at risk for poor literacy skills because characteristics of ASD can produce limited engagement in the typical learning experiences that encourage emergent literacy skills development (Travers et al., 2011). However, few studies have been conducted with children with ASD who are in this early literacy stage (e.g., Lanter etal., 2012; Westerveld et al., 2017).

Objectives: Emergent literacy skills include code-related and meaning related emergent skills. Code-related skills include letter knowledge, print concepts, early name writing, and phonological awareness. Meaning-related skills include vocabulary, and oral narrative retelling and comprehension (NICHD, 2005). The primary objectives of this study were to explore the strengths and weaknesses of code-related and meaning-related emergent literacy skills in children with and without ASD.

Methods: Thirty-seven children participated, 17 children with ASD and 20 neurotypical (NT) children (see Table 1 for demographic information). All children were recruited through schools and other community organizations that serve children with and without ASD. Following informed consent procedures, measures assessing code-related emergent literacy skills (letter knowledge, print concepts, early name writing, phonological awareness), meaning-related emergent literacy skills (receptive vocabulary, oral narrative recall, oral narrative comprehension), theory of mind (ToM) and joint attention (JA) were administered.

Results: On code-related emergent literacy skills, children with ASD did not differ from NT children in letter knowledge or phonological awareness. However, group differences were found for print conventions and name writing, $t(35) = 2.22\text{-}2.81$, $p > 0.003$, d = 0.72 - 0.91, respectively. Children with ASD scored significantly lower on both tasks than NT children (see Table 2). For meaning-related emergent literacy skills, children with and without ASD did not differ on receptive vocabulary, $t(35) = 1.92$, $p = 0.06$, $d = 0.63$. However, the quality of the oral narratives produced by children with ASD was significantly lower, $t(35) = 4.99$, $p = 0.0001$, $d = 1.64$. Moreover, their oral narrative comprehension was significantly lower than that of the NT children, $t(35) = 5.2$, $p = 0.0001$, $d = 1.73$. Regression analysis showed that JA but not ToM predicted the results for children with ASD.

Conclusions: Children with ASD were able to name letters and letter sounds as well as NT children, but had more difficulty than their NT peers with print conventions and name writing. For example, while 75% of NT children earned full points on the name writing task, only 18% of the children with ASD were able to do so. In terms of meaning-related emergent literacy skills, children with ASD were less likely than NT children to answer questions about a story they heard correctly, and they were less likely to include the necessary details when retelling the same story. Results also showed that joint attention may play an important role in emergent literacy skills development in children with ASD.

414.022 *(Poster)* Evidence for the Dimensional and Categorical Accounts of Language Development in Children with Autism Spectrum Disorder

*E. Jiménez[1], **E. Haebig**[2] and T. T. Hills[1], (1)Psychology, University of Warwick, Coventry, United Kingdom, (2)Communication Sciences and Disorders, Louisiana State University, Baton Rouge, LA*

Background: Children with ASD have significant delays in early language acquisition, but unlike neurotypical late talking children, the language development in children with ASD is accompanied by restricted interests, repetitive behaviors and social communication deficits. Might the language delay and the core deficits of ASD be related? This question highlights one of the central theoretical controversies surrounding lexical development in children with ASD. That is, are the language delays associated with ASD merely adjustments along a continuum of development, where differences are primarily quantitative and along a single dimension (*dimensional account*)? Or are the delays the result of a categorical difference in the way children with ASD learn language, giving rise to distinct language profiles that are not simply delayed versions of typical development (*categorical account*)?

Objectives: We investigated evidence for the dimensional and categorical accounts of lexical development among children with ASD by conducting a large-scale comparison of early lexical profiles (syntactic class and semantic categories) with typically developing (TD) toddlers and late talkers. We also examined whether the verbs that children with ASD produce differ in their social characteristics, relative to verbs produced by typically developing toddlers.

Methods: We compared the lexical composition of 216 children with ASD, aged 11 to 173 months, with 7,287 TD toddlers with and without language delay, aged 8 to 30 months, who were matched on expressive vocabulary. Expressive vocabulary was measured using the Communicative Development Inventory (CDI; Fenson et al., 2006). The data from children with ASD were obtained from the National Database for Autism Research (Payakachat et al., 2016) and TD data came from the Wordbank database (Frank et al., 2017). Children who did not have an ASD diagnosis were subclassified as either typical talkers (TTs) or late talkers (LTs). Late talking toddlers where those who scored at or below the 10th percentile on the CDI. We examined the syntactic composition of the children's lexicons using the syntactic classifications specified by Bates et al. (1994) and semantic composition using the categories specified on the CDI. To assess our second aim, we collected social ratings of the verbs on the CDI from a sample of 54 adults.

Results: Children with ASD and LTs produced a lower proportion of nouns and a higher proportion of predicates than TTs (Figure 1). All groups demonstrated a noun bias (producing more nouns than predicates); however, children with ASD had a reduced noun bias relative to TTs and LTs ($ps < .001$). Additionally, the ASD group produced a higher proportion of action words than either TTs or LTs, a lower proportion of sound effects than TTs, and a higher proportion of places than TTs. Also, children with ASD produced fewer high-social verbs ($H(1) = 11.16$, $p < .001$; Figure 2). All differences were found for children who produced fewer than 75 words, except for places (>300 words).

Conclusions: The group differences across syntactic classes, semantic categories, and social features of verbs highlight unique features of early vocabulary development in children with ASD and provide partial support for the categorical account.

414.023 *(Poster)* Executive Functions in Bilingual and Monolingual Children with Low and High Levels of Autistic-like Traits

***D. Kascelan**[1], J. L. Gibson[2] and N. Katsos[3], (1)University of Leeds, leeds, United Kingdom, (2)University of Cambridge, Cambridge, United Kingdom, (3)Theoretical and Applied Linguistics, University of Cambridge, Cambridge, United Kingdom*

Background: Research on bilingualism has shown cognitive advantages in executive functions, such as in attentional control (Adesope et al., 2010) and working memory (Carlson & Meltzoff, 2008). Alternatively, the same areas are often impaired in autism (Schuh & Eigisti, 2012). Therefore, studying bilingualism and autism offers an avenue for investigating interaction between contrasting cognitive profiles. However, diagnosing autism may be more complex and qualitatively different in bilinguals than in monolinguals. Specifically, the same levels of autistic traits tend to be acknowledged to a significantly different degree across various cultures (Burke et al., 2015). As bilinguals are often bicultural, investigating potential interactions of bilingualism and autism only in diagnosed samples suffers a risk of leaving out a large part of the spectrum caused by the cultural bias in the diagnosis.

Objectives: The study investigates the interaction of bilingualism and autistic-like traits (ALTs) in a general sample of children in relation to their cognitive skills. By looking at children with low or high levels of ALTs from a general population sample, without requiring a clinical diagnosis of autism, we eschew any disparities that might arise between monolinguals and bilinguals caused by the diagnostic bias. The following questions are addressed: (1) do bilinguals and monolinguals differ in their executive function skills? (2) does the level of ALTs affect children's executive function skills? (3) does bilingualism have ameliorating effects on cognitive skills in children with high ALTs?

Methods: The sample included 19 bilinguals with high ALTs, 25 bilinguals with low ALTs, 21 monolinguals with high ALTs, and 28 monolinguals with low ALTs, matched on age (*M* = 9;1, *SD* = 1;7) and the socioeconomic status. Monolinguals spoke English, and bilinguals spoke English and another language. Low ALTs indicated virtually no impairment in social communication/interaction and in restricted interests/repetitive behaviour (³ -1SD from the population mean on the ALTs measure). High ALTs indicated difficulties in the same areas (³ +1SD from the population mean on the ALTs measure). ALTs were measured with the Social Skills Improvement System-Rating Scales (Gresham & Elliott, 2008) and the Social Communication Questionnaire (Rutter et al., 2003). Demographics were collected through a caregivers' questionnaire. The dependent variables were measured with three executive function tasks.

Results: We identify three patterns of findings. On the inhibition measures, bilinguals showed a trend towards advantage, with no difference between children with low and high ALTs. On the switching and the visual working memory measures, there were no differences between the groups no matter the language status (bilingual vs. monolingual) or the level of ALTs (low vs. high). Finally, on the audio-visual working memory measure, monolinguals with low ALTs outperformed bilinguals with high ALTs.

Conclusions: These findings make a unitary account of executive functions and bilingualism unlikely. We suggest that investigating sociolinguistic variables, such as the community norms of how languages are used could help solve this predicament. Considering ALTs, the majority of tasks do not show negative effects of ALTs on executive functions. Nevertheless, children with higher levels of ALTs might experience executive function difficulties.

414.024 *(Poster)* Exploring Examiner Responsiveness during the ADOS with Minimally Verbal Individuals with ASD

C. G. La Valle[1]*, F. Frimpong*[2]*, S. Reddy*[2] *and H. Tager-Flusberg*[1]*, (1)Department of Psychological and Brain Sciences, Boston University, Boston, MA, (2)Boston University, Boston, MA*

Background: Previous research studies have examined how children's gestures affect how their caregivers respond to gestures (Choi et al., 2019; Dimitrova et al., 2016; Leezenbaum et al., 2014). Caregiver responsiveness, specifically contingent responses (semantically relevant) in turn, shape children's language development (Goldin-Meadow et al., 2007; Tamis-LeMonda et al., 2014). However, less is known about whether *different* communication modalities (speech, speech/gesture, gesture, sign) and the *quality* of pragmatic communication (e.g., precise gestural forms vs approximations) produced by MV individuals with ASD may influence responding by an *unfamiliar* conversational partner.

Objectives: To examine how the conversational partner (examiner) responds based on the communication modality and quality of form used by MV individuals with ASD.

Methods: Forty-four MV individuals with ASD (33 males; *M*age: 12.22 years, *SD* = 4.17) were administered the ADOS (Module 1). Transcripts of the ADOS were coded for each occurrence of the participants' requests. The requests were coded for modality (speech, gesture, speech/gesture, or sign), and quality of form (precise/clear or approximate/modified). Following each request, the response of the examiner was coded as contingent or non-contingent. Contingent was defined as a verbal or nonverbal examiner response that is semantically related to the participant's request and produced within one utterance. Non-contingent was defined as a verbal or nonverbal examiner response that is not semantically related to the participant's pragmatic communication or a failure to respond. 1) A logistic regression was used to determine if modality (speech, gesture, etc.), age, and gender could explain variance of examiner responding; 2) A second logistic regression model included quality of form, age, and gender on examiner responding.

Results: 1) In the first model, speech (p = .002) resulted in more contingent responding by the conversational partner compared to non-speech modalities (Fig. 1). Specifically, there was a 75% chance that the examiner would respond contingently to a speech-based request compared to a 53% chance if the participant did not use speech. Neither age nor gender were significant. 2) In the second model, quality, age, and gender had no statistically significant effect on explaining examiner responding (Fig. 2).

Conclusions: The use of speech plays an important role in responding by the conversational partner in contrast to the lack of influence based on quality of form for MV individuals with ASD. These findings suggest that interventions should target the expansion of pragmatic functions (e.g., commenting) without the need to focus on sharpening the quality of form. The study findings can allow for appropriate alterations in language and communication intervention techniques to incorporate a multidimensional view of social communication which considers the influential role of the conversational partner and interactional context on the pragmatic communication abilities of MV individuals with ASD.

414.025 *(Poster)* Exploring the Relationship between Prosodic Control and Social Competence in Children with and without Autism Spectrum Disorder

N. E. Scheerer[1,2]*, T. Q. Boucher*[1]*, J. A. Jones*[3] *and G. Iarocci*[1]*, (1)Psychology, Simon Fraser University, Burnaby, BC, Canada, (2)Psychology, Western University, London, ON, Canada, (3)Psychology, Wilfrid Laurier University, Waterloo, ON, Canada*

Background: The ability to communicate thoughts, ideas, and emotions is integral to social development. We know this in part because of conditions such as autism spectrum disorders (ASDs), where early social communicative deficits (e.g., joint attention) are predictive of later language deficits. As children develop, speech becomes the dominant form of social communication, as it allows complex ideas and emotions to be conveyed between individuals. Social aspects of speech production, such as prosody (e.g., vocal pitch), must be carefully regulated to accurately express information about the emotionality, excitability, and intent of the speaker. Thus, a child may acquire fluent, even excellent speech articulation, but their social communication may be compromised due to poor prosodic control.

One way to investigate the prosodic control of speech is by utilizing the frequency altered feedback paradigm. Previous research has demonstrated that when the fundamental frequency of a speaker's auditory feedback is briefly altered, a manipulation that is perceived as a change in vocal pitch, the speaker produces a compensatory response in the direction opposite to the manipulation. The size and timing of these responses to frequency altered feedback have allowed researchers to gain valuable insight into how auditory feedback is used to regulate vocal pitch.

Objectives: The objective of this research is to gain a better understanding of how auditory information is used to regulate the prosodic aspects of speech in children with and without ASD. Furthermore, this research aims to explore the relationship between the prosodic control of speech, or more specifically the control of vocal pitch, and social communication abilities.

Methods: Seventy-five children between the ages of 3 and 13 years, with and without ASD, produced vocalizations while being exposed to unaltered and frequency altered auditory feedback. The parent-report multidimensional social competence scale (MSCS) and the autism quotient (AQ) were also used to assess social functioning and autism characteristics, respectively.

Results: MM-ANOVAs were conducted to compare the effect of experimental condition and diagnosis on vocal response magnitudes and latencies. While a main effect of experimental condition indicated that all children produced compensatory responses to the frequency altered auditory feedback, $F(2, 146) = 499.946$, $p < .001$, $np2 = .873$, vocal response magnitudes were similar across children with and without ASD, $F(1, 73) = .182$, $p = .671$, $np2 = .182$. However, children with ASD produced faster responses to the auditory feedback manipulation, $F(1, 73) = 8.042$, $p = .006$, $np2 = .099$. Hierarchical multiple regressions indicated that these faster responses were associated with poorer parent-rated social competence, MSCS $R2 = .236$, $F(3, 48) = 4.935$, $p = .005$, and higher autism symptom scores, AQ ($R2 = .150$, $F(3, 51) = 3.002$, $p = .039$.

Conclusions: These findings suggest that basic speech production differences are present in at least a subgroup of children with ASD. These results represent a key step in understanding how atypicalities in the mechanisms supporting speech production may manifest in social-communication deficits, as well as broader social competence, and vice versa.

414.026 *(Poster)* Expressive and Receptive Vocabulary Impairments in Primary-School-Aged Children with Autism Spectrum Disorder: A Pilot Study in Russian

V. Arutiunian[1]*, A. Minnigulova*[2]*, A. Sorokin*[3,4]*, E. Davydova*[3]*, D. Pereverzeva*[3]*, S. Tyushkevich*[3]*, U. Mamokhina*[3]*, K. Danilina*[3]* and A. Lopukhina*[1]*, (1)Center for Language and Brain, National Research University Higher School of Economics, Moscow, Russian Federation, (2)Faculty of Humanities, National Research University Higher School of Economics, Nizhny Novgorod, Russian Federation, (3)Federal Resource Center for ASD, Moscow State University of Psychology and Education, Moscow, Russian Federation, (4)Haskins Laboratories, New Haven, CT*

Background: Children with Autism Spectrum Disorder (ASD) usually have comorbid language impairments even at the single-word level, failing in expressive and receptive vocabulary assessment tests (Kjelgaard & Tager-Flusberg, 2001). Importantly, previous studies disagree on the difference between receptive and expressive domains in autism: there is an evidence of more impaired expressive vocabulary (Jarrold et al., 1997), more impaired receptive vocabulary (Seol et al., 2014), and no difference in expressive-receptive domains (Kjelgaard & Tager-Flusberg, 2001). These inconsistencies can come out due to high heterogeneity of autistic groups as well as criteria for including children into studies, e.g., age or non-verbal IQ.

Objectives: The goal of the present study is to clarify whether primary-school-aged Russian children with ASD have difficulties at the single-word level et either expressive and receptive vocabulary.

Methods: 30 children participated in the study: 15 children with ASD ($M_{age} = 8.69$, $SD = 0.99$), varying in non-verbal IQ (range 40 – 110), and a control group of 15 typically developing children, TD ($M_{age} = 8.58$, $SD = 0.94$). All children with ASD had a clinical diagnosis within the autism spectrum (F84.0, F84.1 or F84.5) according to ICD-10 and were assessed by licensed psychiatrist with Autism Diagnosis Observation Schedule (Lord et al., 2000).Expressive and receptive vocabulary has been scored by the Test for assessment of language development in Russian *KORABLIK* (Lopukhina et al., 2019). For expressive vocabulary assessment, we used picture naming ($N = 48$), and for receptive vocabulary assessment, we used word-to-picture-matching paradigm ($N = 48$) in which each visual set consisted of four pictures – target, phonological distractor, semantic distractor, and unrelated picture. All stimuli were taken from the Verbs and Nouns Stimuli Database for Russian (Akinina et al., 2014, 2015, 2016) and were counterbalanced.

Results: We showed that children with ASD have impairments in both word production, 87% vs. 96%, $Est. = 1.45$, $SE = 0.38$, $z = 3.73$ $p = 0.0001$, and word comprehension, 91% vs. 97%, $Est. = 1.64$, $SE = 0.50$, $z = 3.25$ $p = 0.001$. Importantly, children with ASD displayed a difference in expressive and receptive vocabulary: production was more impaired then comprehension, 87% vs. 91%, $Est. = 0.66$, $SE = 0.19$, $z = 3.45$ $p = 0.0005$. Finally, in ASD group, for both word production and comprehension we found a correlation between accuracy and non-verbal IQ (for production, $r = 0.55$, $p = 0.03$, for comprehension, $r = 0.57$ $p = 0.02$), but there was no a correlation with age.

Conclusions: Similarly to the previous studies, we showed that children with ASD had impairments at the single-word level, and accuracy both in production and comprehension correlated with non-verbal IQ (Kjelgaard & Tager-Flusberg, 2001). Crucially, our results demonstrated that expressive vocabulary is more impaired than receptive. However, we acknowledge that this is a pilot results with a relatively small group size. Data from a larger group would provide much precise information on expressive-receptive abilities of Russian children with ASD.

414.027 *(Poster)* Frequency of Household Book Reading May Explain SES Disparities in Expressive Language – Findings from a Nationally-Representative Sample of Children with ASD

M. G. Pecukonis*, M. Barokova, C. G. La Valle and H. Tager-Flusberg, Department of Psychological and Brain Sciences, Boston University, Boston, MA*

Background: While most studies have focused on identifying the neurobiological bases of language impairments in ASD (Groen et al.,2008), few have explored how the environment shapes language development in this population. One study found that children with ASD from higher socioeconomic status (SES) families had greater language abilities (Grandgeorge et al.,2009), which may be explained by differences in language learning experiences, such as book reading. Book reading has a positive impact on language development for children with and without ASD (Boyle et al.,2019; Hoff,2013), but it occurs less frequently in low SES households (Yarosz & Barnett,2010). Previous research on typically-developing children has demonstrated that book reading mediates the relation between SES and language (Farrant & Zubrick,2011), yet no studies have explored this relation in ASD.

Objectives: The current study used data from the 2018 U.S. National Survey of Children's Health to investigate whether expressive language (EL) in children with ASD differs based on family SES and frequency of household book reading, and to determine whether book reading mediates the relation between SES and EL.

Methods: The sample included $N = 95$ children with ASD (15 females), ages 2–5 years, whose parents completed all survey items of interest. On 3 items, parents reported whether or not their child was able to use 1, 2, and 3 word sentences; yes/no responses from each item were converted (1=yes/0=no) and summed to form an EL composite score. SES was operationalized as the highest education level attained by parents, and book reading frequency as the number of days during the past week that someone at home read to the child.

Results: The Mann-Whitney U test showed that EL was higher for children whose parents completed a higher education level (U=485.00,p=.025;Figure 1.a.). The Kruskal-Wallis H test showed that EL was higher for children who were read to more frequently ($\chi^2(3)$=11.698,p=.008;Figure 1.b.); the only comparison to survive post-hoc Bonferroni correction was 1–3 days versus 7 days (p=.009). Results of the mediation analysis (Hayes,2017) revealed that parent education was indirectly related to child EL through its effect on book reading frequency (Figure 2). Children whose parents completed more than high school were read to more frequently than children whose parents completed high school (B=.610,p=.017). Also, children who were read to more frequently had higher EL than children who were read to less frequently (B=.314,p=.005). The relation between parent education and child EL became non-significant when controlling for book reading frequency (B=.450,p=.101), demonstrating full mediation. This effect remained significant even when child age was included as a covariate (B=.186;95% CI=.008–.459), although ~80% of the variance in child EL was not accounted for in this model.

Conclusions: Results suggest that book reading may play a significant, although small, role in language development for children with ASD. Future studies should use qualitative methods to understand why parents from low SES families are reading less frequently to their children, so that these aspects of the proximal environment can be targeted in interventions that improve language abilities in children with ASD.

414.028 *(Poster)* Growth in Morphological Awareness of Children with ASD and Typical Development: Associations with Age, Verbal Ability, and Reading Comprehension

N. S. McIntyre[1]*, J. R. Steinbrenner*[1]*, M. C. Zajic*[2] *and P. Mundy*[3]*, (1)Frank Porter Graham Child Development Institute, University of North Carolina at Chapel Hill, Chapel Hill, NC, (2)University of Virginia, Charlottesville, VA, (3)University of California at Davis, Sacramento, CA*

Background: Morphemes are the smallest units of meaning within words and Morphological Awareness (MA) refers to the awareness of and ability to manipulate morphemes in words. The development of MA relies on additional verbal abilities (e.g. semantics) and has been shown to improve over the school-aged years (Carlisle et al.,2010); extant research indicates that many children with ASD demonstrate deficits in MA (Eigsti et al.,2011). These language skills support proficient reading comprehension (RC) in typically developing (TD) children (Carlisle et al.,2010). The development of reading comprehension (RC) is a significant challenge for many children with ASD (McIntyre et al., 2017) and little is known about their MA development or how it relates to their RC outcomes. This study was designed to examine the relations between MA, RC, verbal abilities, and age in a sample of children with ASD and no ID as compared to those with TD.

Objectives: 1) To examine the development of MA over a 30-month period in school-aged children with ASD or TD using latent growth curve modeling, 2) To test the hypothesis that age and verbal abilities are significantly related to MA development among these children, and 3) To examine the hypothesis that MA development predicts reading comprehension outcomes in both samples.

Methods: Participants included eighty-five 8- to 18-year-old children with ASD and forty-four with TD (Full-scale IQ ≥ 70). Data were collected at 3 timepoints (TP) across 30 months. ASD symptoms confirmed with ADOS-2. Verbal ability (VIQ) was measured by WASI-2. MA was measured with the Test of Derivational Morphology (Carlisle, 2000). Reading comprehension (RC) was measured with the Gray Oral Reading Test-5 (GORT-5).

Results: The final growth model fit the data adequately, CFI=.98, SRMR=.08. 1) ASD group scored lower than TD on MA across all TPs and growth was best represented by nonlinear model: greater growth TP1-2 than TP2-3 (Figure 1). 2)TD and ASD TP1 age and VIQ significantly and positively predicted variation in intercepts of MA growth curves and slopes of MA for TD. For ASD, only TP1 age predicted MA slope, with younger children demonstrating greater growth. 3) In both groups TP3 RC was significantly associated with both intercept and the slope of MA growth curves.

Conclusions: Both groups improved in their morphological awareness skills with similar 30-month growth rates regardless of initial scores, but the ASD group scored lower on average and did not catch up with the TD group. Being older and having higher VIQ was significantly associated with better initial MA performance and both factors impacted growth rates in TD while only age predicted growth for ASD, with younger children demonstrating greater growth. In both groups, initial MA and growth in MA were significantly and positively associated with reading comprehension at TP3. These data provide unique details about the language development of school-aged children with ASD as compared to TD and raise the possibility that morphological awareness is an important intervention target to improve reading comprehension in both groups of children.

414.029 *(Poster)* Higher Autism Spectrum Quotient Scores Predict Higher Permissiveness of Pragmatic and Semantic Impairments

M. Oi[1] *and R. Mizutani*[2]*, (1)Kanazawa University, United Graduate School of Child Dev., Kanazawa, Japan, (2)United Graduate School of Child Development, Kanazawa University, Kanazawa, Japan*

Background: Based on a previous finding that individuals with autism spectrum disorder (ASD) show empathy toward autistic characteristics we reported that the higher the maternal autism spectrum quotient (AQ) score, the lower the tendency to perceive pragmatic impairments as problematic. In the present study, we investigated whether these results could be replicated for adult males and semantic impairments.

Objectives: The purposes of the present study were to clarify 1) whether higher AQ scores would predict increased permissiveness of pragmatic impairments when using the Communication Checklist - Adult (CC-A) with both males and females included as raters, 2) whether higher AQ scores would predict higher permissiveness of semantic impairments, and 3) whether higher AQ scores would predict higher permissiveness of language impairments.

Methods: The AQ was administered on all study participants (124 adults [60 males, 64 females]; mean age ± standard definition [SD], 35.04 ± 8.01 years). All participants rated 21 pragmatic, six social engagement, and seven language impairment subitems from the CC-A on a five-point scale. Additionally, they rated 25 collocation errors produced by 12 individuals with ASD on a five-point scale. Correlation coefficients were calculated between AQ scores and age, the mean scores for 27 pragmatic and social engagement impairment subitems, and the mean scores for seven language impairment subitems. Covariance structure analysis (CAS) was then applied to these variables and path diagrams were produced.

Results: The mean ± SD AQ score was 17.94 ± 7.47. Four adults whose AQ scores were higher than the cut-off 33 were not excluded from the analysis. Significant correlations were found between AQ scores and the mean scores of the 27 pragmatic and social engagement impairment subitems ($r=.185$, $p<.05$), and between AQ scores and the mean scores of the 25 collocation errors ($r=.235$, $p<.01$); however, no significant correlation was found between AQ scores and the mean scores of the seven language impairment subitems. In addition, no significant correlations were found between any of the variables and age. However, differences were seen between males and females in terms of correlations relating to the mean scores of the 25 collocation errors. A significant correlation was found between AQ scores and the mean scores of the 25 collocation errors in females ($r=.262$, $p<.05$), but not in males. A significant correlation was seen between age and the mean scores of the 25 collocation errors in males ($r=.348$, $p<.01$), but not in females. Additionally, the mean scores of the 25 collocation errors were significantly lower in females than in males ($F=6.054$, $p<.05$).

Conclusions: Higher AQ scores predicted higher permissiveness of pragmatic impairments when males were included as raters of the pragmatic and social engagement impairment subitems on the CC-A. Higher AQ predicted higher permissiveness of semantic impairments when combining males and females. However, higher AQ did not predict higher permissiveness of language impairment subitems on the CC-A. These findings suggest that females are less permissive toward semantic impairments than males, who seem to become more permissive of these impairments with age. Further investigation is needed in this regard.

414.030 *(Poster)* How Do Autistic Adults Use Syntactic and Prosodic Cues to Manage Spoken Discourse? Exploring Discourse Strategies with Basic Discourse Units

P. Geelhand[1]*, F. Papastamou*[2] *and M. Kissine*[1]*, (1)ACTE — Center of research in Linguistics — ULB Neuroscience Institute, Université libre de Bruxelles, Brussels, Belgium, (2)Université Libre de Bruxelles, Bruxelles, Belgium*

Background: Within the framework of discourse analysis, segmentation units are crucial to explore how spoken discourse is realized and organized. To date, most segmentation units are delineated either by syntactic cues or by prosodic cues. However, while syntax and prosody can be considered as two distinct levels of surface segmentation, they are also interdependent and come together at a discrete organizational level. In the framework of Basic Discourse Units (BDUs; Degand & Simon, 2008, 2009a, 2009b), segmentation units surface at this latter level when there is a match between the boundary of a syntactic and of a prosodic unit. More interestingly, these two types of boundaries can coincide in different ways, yielding distinct BDUs which reflect different strategies of discourse management and processing. Considering the known prosodic impairments in Autism Spectrum Disorder (ASD), it is important to incorporate prosodic information when representing speech of autistic individuals, as communication difficulties might not only surface in the syntactic organization of the discourse content, but also in prosodic strategies to deliver speech.

Objectives: This study aims at providing novel insight into the communication difficulties in ASD by segmenting a corpus of spoken discourse into BDUs. We hypothesize that autistic adults will display more atypical strategies to convey speech than neurotypical adults, reflecting more difficulties to manage the on-going discourse than neurotypicals.

Methods: The transcriptions of six Experimenter-Autistic Speaker dyads and six Experimenter-Neurotypical Speaker dyads, time-aligned to the audio were segmented into BDUs in two independent phases, viz. a syntactic and a prosodic one. Syntactic units were classified in two categories: 1) dependency clauses and 2) discourse-structuring devices (e.g., because, of course, well). Prosodic units were determined according to silent pauses (> 200 milliseconds). In a third phase, the boundaries of these two types of units were mapped onto each other, following four mapping types, viz. one-to-one mapping (one dependency clause-one prosodic unit; congruent BDU), many-to-one mapping (several dependency clauses-one prosodic unit; silent-bound BDU), one-to-many mapping (one dependency clause-several prosodic units, syntax-bound BDU), discourse-structuring device-one prosodic unit (regulatory BDU) and mismatch mapping (no coincidence between boundaries; mixed BDU).

Results: There was a significant group difference in total number of BDU produced, $\chi^2(1) = 7.2084$, $p = 0.007$. Overall, autistic participants produced significantly more BDUs than neurotypical participants. When looking at types of BDUs separately, and controlling for total number of BDU, results partially corroborated our hypotheses as autistic adults did not produce more discourse units associated with didactic/pedantic strategies and/or processing difficulties (syntax-bound BDUs); $z = -1.727$, $p = 0.08$. Furthermore, they produced more units associated with 'information-packaging' (silent-bound BDUs); $z = 2.625$, $p = 0.008$. However, autistic adults did produce less units associated with strategies of interactional/meta-discursive regulation (regulatory BDUs), $z = -1.957$, $p = 0.05$.

Conclusions: Taken together, the present study provides evidence that multidimensional linguistic units such as BDUs can distinguish the speech delivery strategies of autistic adults from those of their neurotypical peers, even based on simple prosodic cues like silent pauses. Crucially, neurotypical adults used more BDUs reflecting discourse management strategies than autistic adults.

414.031 *(Poster)* How Do Caregivers Design Their Talk to Accommodate Young Children with Limited Spoken Language?

S. Crowley[1]*, K. Bottema-Beutel*[2] *and S. Y. Kim*[2]*, (1)Boston College, Chestnut Hill, MA, (2)Lynch School of Education, Boston College, Chestnut Hill, MA*

Background: Much research has examined caregiver talk in interactions with young autistic children (e.g., Meirsschaut, Warreyn, & Roeyers, 2011). Longitudinal studies have shown different types of caregiver talk influence children's language development, marking the importance of this research (e.g., McDuffie & Yoder, 2010). While there is some research examining how caregiver talk influences children's moment-to-moment joint engagement (Bottema-Beutel, Lloyd, Watson, & Yoder, 2017), most research takes a one-sided view of language, and examines only the caregiver's contribution to the interaction. Given that interventions have been developed that attempt to influence how caregiver's design their talk in interactions with their children (Venker et al., 2012), it is critical to understand how caregiver talk structures particular interaction formats, that in turn serve as a vehicle for the development of language and interactional competence. Of particular interest is understanding how different caregiver utterance types build upon children's ongoing activities, and project and constrain children's subsequent interactive moves (Schegloff, 1982), especially in interactions with autistic children who have limited language.

Objectives: The purpose of this study is to explore (1) the ways that caregivers design their turns at talk within play interactions with young autistic children who have limited spoken language, and (2) the interactive sequences that unfold following caregiver talk.

Methods: Data are comprised of 15-minute caregiver-child free play sessions of 3-5 year old autistic children that were video recorded for a larger project. All children spoke fewer than 5 words at study entry; the current study uses videos collected 8 months later. Five videos were randomly selected from each of three child-language levels (low, medium, and high; total $n = 15$) based on MCDI scores. Caregiver's and children's talk and actions were transcribed using conversation analysis (CA) conventions (Jefferson, 2004; Mondada, 2018). Transcripts were analyzed using CA, a micro-analytic, qualitative method used to examine the sequence organization of interactions. According to this framework, interactions are often comprised of sequences of 'first pair parts' (FPPs) and 'second pair parts' (SPPs), whereby an FPP requires the listener to provide an SPP at the earliest opportunity (e.g., summons-response, question-answer) (Schegloff, 2007). We focused our analysis on caregiver FPPs, and how they were designed to accommodate children who did not yet have the linguistic or interactional competence to provide SPPs.

Results: Our analysis revealed five caregiver strategies. Table 1 provides descriptions and transcript extracts that illustrate each strategy, and the interactional sequence in which they were embedded. First, caregivers formatted their FPP's so that either their own or their child's in-progress actions could be taken as an SPP. Caregivers also provided SPPs after their own FPPs, and attempted to repair 'dangling' FPP's through repetition or reformulation of the original FPP. Lastly, if the child provided a seemingly irrelevant SPP (e.g., the response was not 'type-fitted') the caregiver reframed the FPP so that the child's SPP could be taken as completing the sequence.

Conclusions: Our findings suggest particular caregiver interactional moves create opportunities for children to complete interactional sequences, regardless of their language level or interactional competence.

414.032 *(Poster)* Incremental Validity of Automated and Human-Coded Vocalization Measures for Predicting Expressive Language Skills of Infant Siblings of Children with Autism Spectrum Disorder

J. McDaniel[1], *S. R. Edmunds*[2,3], *W. L. Stone*[4] *and P. Yoder*[5], *(1)Life Span Institute, University of Kansas, Lawrence, KS, (2)Boston Children's Hospital, Boston, MA, (3)Harvard Medical School, Boston, MA, (4)Psychology, University of Washington, Seattle, WA, (5)Department of Special Education, Vanderbilt University, Nashville, TN*

Background: Siblings of children with autism spectrum disorder (ASD) are at elevated risk for communication disorders relative to children with siblings without ASD. Fourteen percent of infant siblings are diagnosed with a language delay and an additional 19% are diagnosed with ASD. Predicting expressive language skills based on early vocalizations, which precede spoken words, could provide key information for monitoring the development of infant siblings of children with ASD and for making intervention decisions. When deciding among specific vocalization variable predictors, incremental validity is arguably among the most rigorous methods to demonstrate whether a variable is worth the time and expense. Human-coded measure of vocal complexity and automated measure of volubility (number of vocalizations) exhibited strong construct validity evidence in children with ASD for predicting expressive language. Because validity evidence is population-specific, validity evidence is needed for using these measures with infant siblings of children with ASD.

Objectives: Do volubility and vocal complexity each exhibit incremental validity for predicting later expressive language skills in infant siblings of children with ASD?

Methods: Twenty-two siblings (14 male, 8 female) of children with ASD participated. See Table 1 for participant characteristics at entry into the study. Sixteen participants were reported to be white, 3 to be more than one race, 1 to be Asian, and 1 to be African American. The vocal variables include an automated variable and human-coded vocal variables collected from video-recorded structured procedures (Table 2). Expressive language variables were collected 3 months later. Twenty percent of video recordings were coded for reliability. The primary coder was blinded to which recordings would be coded for reliability. Multiple component measures were aggregated for vocal complexity and expressive language constructs to increase stability (components correlated $r \geq .4$).

Results: For reliability of the vocal communication variables, a two-way random model using absolute agreement indicated an intraclass correlation coefficient of .95, which is very good. In a multiple regression model, both volubility (B=4.26 x 10^4, *SE*=1.84 x 10^4, p=.03, ΔR^2=.12) and vocal complexity (B=2.035, *SE*=.57, p<.01, ΔR^2=27) were significant predictors of later expressive language and exhibited incremental validity. Vocal complexity exhibited a large effect size. The full model with both predictors accounted for 59% of the variance in expressive language skills.

Conclusions: Human-coded vocal complexity exhibited incremental validity above and beyond volubility for predicting expressive language with a large effect size. Automated volubility also accounted for unique variance in later expressive language; however, the effect size was moderate. Findings support the complementary use of automated and human-coded variables, considering their strengths, weaknesses, and costs. Automated analyses require a large initial financial investment with lower maintenance costs. In contrast, human coding costs remain high, but human-coded vocal complexity exhibited a larger effect size for incremental validity than volubility. Different research laboratories, as well as clinical service providers, may differentially weight the expense of automated variables depending on their current access to equipment and software. Future analyses will combine vocal variables from automated and human-coded procedures to potentially optimize predictive power and utility.

414.033 *(Poster)* Indexing Autistic Identities

J. Cuda[1] *and K. Bottema-Beutel*[2]*, (1)Boston College, Chestnut Hill, MA, (2)Lynch School of Education, Boston College, Chestnut Hill, MA*

Background: There is limited literature centering autistic perspectives regarding their high school experience. Adolescence and early adulthood are formative years, as autistic individuals begin to cultivate their identity. This may include understanding their neurodivergence within neurotypical contexts, all while simultaneously facing biological, physical, and socioemotional transitions (Gobbo & Shmulsky, 2016; Hedges et al., 2014). Narrative analysis can be used to reveal the ways in which individuals understand their experiences to accomplish and perform certain functions. One such function is constructing identities (Van de Mieroop, 2015). Identity is conceptualized as a performance that is constructed and can be transformed through interaction (De Fina, 2015; Depperman, 2015). Because autism is considered a cultural identity and social group (Clary-Lemon, 2010; Parsloe, 2015), and the performance of autistic identities is not widely explored, examining autistic narratives in this way can further contribute to the field.

Objectives: The purpose of this study is to examine how autistic youth index their autistic identity through recounted narratives about their high school experience.

Methods: This micro-analytic study uses narrative analysis (Riessman, 2003) to examine the stories of participants regarding their experiences with peers, family, and school professionals in high school. Using narrative analysis is optimal for this purpose because through storytelling, autistic narrators situate themselves in past settings and describe events that highlight action and/or change (Ochs & Capps, 2001, 2004; Georgakopoulou, 2006; De Fina, 2015). As participants expand on their cognitive and emotional stance, language they use within stories positions them in various ways, performing their autistic identities (Depperman, 2015).

The five autistic participants in this study were not directly asked to tell stories from high school, though four did so in their responses to general interview questions about their high school experiences. Table 1 provides the semi-structured interview protocol. First, narrative episodes were culled from the transcribed dataset. Subsequent passes through identified narrative segments looked for recurring discursive phenomena related to identity construction.

Results: Analysis of narratives reveals how participants use the discursive phenomena of (1) agency, (2) membership, and (3) paradoxical language to index their autistic identities. Narrators vacillated between showing active and passive agency in stories about service provision and self-advocacy. When referencing relationships with other peers or their diagnosis label more explicitly, narratives suggested varying levels of distance from “autism” as an affiliative group. Paradoxical language was evident in participant narratives indicating tenuous relationships with their neurodivergence. Table 2 provides descriptions and examples.

Conclusions: How autistic youth index their identities through stories told about high school can better inform stakeholders, and support other autistic individuals who may share similar experiences. Participant shifts between active and passive agentic roles in narratives about service provision, suggest that autistic youth have difficulties in articulating their goals, strengths, and needs. This emphasizes the importance of developing meaningful support services for building self-determination skills as students prepare to transition out of secondary settings. Findings also suggest how school-based counseling services addressing stigma can help autistic youth who struggle socially with their diagnosis and the choice to disclose.

414.034 *(Poster)* Influences of Language on Emotional Behavior Problems and Sleep Difficulties in Preschoolers with ASD

N. Reyes[1]*, V. H. Bal*[2]*, N. Jones*[3] *and T. Katz*[4]*, (1)JFK Partners, University of Colorado Anschutz Medical Campus, Aurora, CO, (2)Graduate School of Applied and Professional Psychology, Rutgers University-New Brunswick, Piscataway, NJ, (3)Neuren Pharmaceuticals, Birmingham, United Kingdom of Great Britain and Northern Ireland, (4)Department of Pediatrics, University of Colorado School of Medicine, Aurora, CO*

Background: Previous research suggests that children with Autism Spectrum Disorder (ASD) tend to experience behavior, emotional, and sleep problems. However, currently, there is limited evidence for whether having limited verbal skills put younger children at greater risk for having those problems.

Objectives: The aim of this study was to examine whether *preverbal* children with ASD are more likely to experience behavior, emotional, and sleep problems than *verbal* children with ASD.

Methods: Preschool children who completed the Autism Diagnostic Observation Schedule (ADOS), and Mullen Scales of Early Learning (MSEL) from the Autism Treatment Network (ATN) dataset were included. This study included 1375 children an average age of 3.90 years (range=1.51 to 6 years). Using the MSEL, *preverbal* term was used to describe children who were classified as having no words or few vocalizations; and the *verbal* term was also used to describe children who were described as having some words and/or phrases. Modules 1 and 2 of the ADOS were administered to all the children to assess for an ASD diagnosis. Parents also completed the Child Behavioral Checklist (CBCL) to gauge information about their children’s behavior, emotional, and sleep problems; and they reported on the number of hours of intervention that children were currently receiving.

Results: Based on the MSEL classification of preverbal and verbal, 336 children (24.44%) were included in the preverbal group and 1,039 (75.56%) in verbal group. Differences between preverbal and verbal groups were assessed using odds ratios in logistic regression analysis while controlling for autism severity (ADOS), chronological age, and total hours of intervention/week. Regarding internalizing problems, children in the preverbal group were described as being at about 1.7 times the odds of having internalizing problems t-score at or above 60 when compared to children in the verbal group (OR=1.71, 95% CI=1.24-2.37, p=0.0011). With respect to externalizing or sleep problems, no differences were found between the preverbal and verbal groups.

Conclusions: Findings from this study suggest that young children with ASD with limited language abilities are more likely to be described by their caregivers as experiencing internalizing difficulties. Clinically, these results suggest that clinicians may need to screen and further assess these problems and to provide appropriate referral and services for these children as needed.

414.035 *(Poster)* Initiation of Joint Attention at 12 Months and Speech-like Vocalizations at 24 Months in Infants at High and Low Risk of ASD

N. Yacoub[1], *V. Petrulla*[2], *L. D. Yankowitz*[2], *M. L. Cola*[2], *F. Syed*[1], *I. Fathali*[1], *O. Fawibe*[1], *A. S. Russell*[1], *M. Swanson*[3], *N. Marrus*[4], *S. S. Meera*[5], *A. Estes*[6], *W. Guthrie*[2], *B. Tunc*[2], *J. Pandey*[2], *S. Paterson*[2], *J. Pruett*[7], *H. C. Hazlett*[8], *S. R. Dager*[9], *L. Zwaigenbaum*[10], *T. St. John*[11], *J. Piven*[12], *R. T. Schultz*[2], *J. Parish-Morris*[2] *and .. The IBIS Network*[8], *(1)Center for Autism Research, Philadelphia, PA, (2)Center for Autism Research, Children's Hospital of Philadelphia, Philadelphia, PA, (3)University of Texas at Dallas, Richardson, TX, (4)Washington University School of Medicine, St. Louis, MO, (5)National Institute of Mental Health and Neurosciences, Bangalore, India, (6)Speech and Hearing Sciences, University of Washington, Seattle, WA, (7)*Co-senior author, **For the IBIS Network, Washington University School of Medicine, St. Louis, MO, (8)University of North Carolina, Chapel Hill, NC, (9)Radiology, University of Washington, Seattle, WA, (10)University of Alberta, Edmonton, AB, Canada, (11)University of Washington, Seattle, WA, (12)*Co-senior author, University of North Carolina, Chapel Hill, NC*

Background: Autism Spectrum Disorder (ASD) is characterized by deficits in social communication and the presence of repetitive behaviors (American Psychiatric Association, 2013). Joint attention refers to shared focus on an object between two individuals, and typically develops within the first 24 months of life (Lee, et al., 2018; Miller & Markovitch, 2015). Initiating joint attention (IJA) creates a positive social feedback loop between child and parent, promoting social development and language acquisition (Nyström, Thorup, Bölte, & Falck-Ytter, 2019; Morales et al., 2000). Understanding the link between IJA – which is atypical in ASD (Bruinsma et al. 2004) – and infant vocalizations gathered during relatively brief developmental evaluations could help define the overlap between social development and vocalization metrics in infants at high and low familial risk for ASD.

Objectives: In this study, we assess the link between IJA in 12-month-old infants at high and low risk of ASD and vocalization behavior in those same infants at 24 months.

Methods: 171 infant siblings of children with ASD (high risk: HR) or without ASD (low risk: LR) were administered the CSBS (Wetherby & Prizant, 2002) as part of the longitudinal Infant Brain Imaging Study (IBIS) at 12 and 24 months. Assessments were audio/video recorded. At 24 months, infants underwent gold standard assessments to determine diagnostic status: LR, HR without ASD (HR-), and HR with ASD (HR+, Table 1). Infant vocalizations during the CSBS were coded as speech-like or non-speech-like by a reliable team of student raters using ELAN software (ELAN, 2018), and speech-like vocalization count was extracted using in-house R scripts. Generalized linear models (Bates, 2008) used the interaction of diagnostic group and CSBS IJA raw scores at 12 months to predict the number of speech-like vocalizations produced at 24 months after controlling for site, sex, maternal education, recording duration, and 12-month speech-like vocalization rates.

Results: There was a negative relationship between IJA bids at 12 months and speech-like vocalizing at 24 months in the HR+ group compared to the LR group (Estimate: -.15, SE: .02, z=-7.99, p<.001) and the HR- group (Estimate: -.15, SE: .02, z=-8.63, p<.001). In contrast, the relationship between IJA at 12 months and speech-like vocalizing at 24 months did not differ in LR and HR- groups (Estimate: -.001, SE: .01, z=.12, p=.91; Figure 1).

Conclusions: IJA is an early predictor of later language ability as measured by standardized tests (Mundy et al., 2007). This study showed that IJA at 12 months is differentially related to speech-like vocalizations at 24 months in infants that do and do not develop ASD. Whereas IJA at 12 months did not add significant predictive variance to brief vocalization samples at 24 months in HR- and LR infants (after accounting for a variety of relevant variables), the HR+ group demonstrated an atypical trajectory, with greater IJA at 12 months associated with reduced speech-like vocalizing at 24 months.

414.036 *(Poster)* Interpersonal Synchrony and Phonological Memory: Predictors of Vocabulary Size in Children with ASD

E. A. Choi *and S. T. Kover, Speech and Hearing Sciences, University of Washington, Seattle, WA*

Background: Arunachalam and Luyster (2016) suggest that lexical acquisition is altered in children with ASD due to disrupted intake of linguistic input; yet, the factors that reduce intake of input are not well understood. Because social communication difficulties–by definition–are prevalent in ASD, impaired interpersonal synchrony (e.g., turn-taking) could contribute to reduced input intake, via overlapping speech (Choi & Lee, 2013; Northrup & Iverson, 2015). That is, a child who vocalizes over a conversation partner's utterances may experience impoverished access to those utterances, thereby limiting opportunities for vocabulary acquisition. At the same time, the child's ability to hold linguistic information in mind (i.e., phonological memory) contributes to lexical abilities in children with other sources of language delay, although findings on this relationship for children with ASD have been mixed (Eberhardt & Nadig, 2018; Norbury et al., 2010).

Objectives: This study simultaneously tested the association of overlapping speech and phonological memory with receptive and expressive vocabulary size in children with ASD.

Methods: Participants with ASD (*N*=24) were 3- to 11-year-olds with nonverbal IQs ranging from 34 to 133 (Leiter-3; Roid et al., 2013). See Table 1. Peabody Picture Vocabulary Test (PPVT-4; Dunn & Dunn, 2007) and Expressive Vocabulary Test (EVT-2; Williams, 2007) standard scores indexed receptive and expressive vocabulary size. Overlapping speech and phonological memory were assessed during a nonword repetition task (Eaton et al., 2015), in which the participant was prompted to repeat nonwords of increasing length (e.g., "*This is a kog. Can you say kog*?"). The rate of overlapping speech was defined as the count of participant vocalizations during examiner prompts divided by the total number of examiner prompts. Phonological memory was defined as the proportion of nonword consonants correctly repeated. Linear regressions tested overlapping speech and phonological memory as unique predictors of vocabulary standard scores, controlling for nonverbal IQ, separately for the PPVT-4 (*n*=24) and for the subset of participants who completed the EVT-2 (*n*=18).

Results: Overlapping speech and phonological memory were, respectively, negatively and positively correlated with receptive, $r(22)=-0.67$, $p < 0.001$, $r(22)=0.78$, $p < 0.001$ and expressive, $r(16)=-0.72$, $p=0.001$, $r(16)=0.87$, $p < 0.001$, vocabulary size. See Figure 1. Using regression, nonverbal IQ significantly predicted both receptive and expressive vocabulary. For receptive vocabulary, overlapping speech, $b=-8.04$, $SE=3.61$, $t(20)=-2.23$, $p=0.038$, and phonological memory, $b=11.48$, $SE=4.01$, $t(20)=2.86$, $p=0.010$, were unique predictors. For expressive vocabulary, phonological memory was the only significant predictor besides nonverbal IQ, $b=15.04$, $SE=4.48$, $t(14)=3.36$, $p=0.005$.

Conclusions: Phonological memory positively predicted receptive and expressive vocabulary size in children with ASD, parallel to research on children with language delays (Ellis Weismer et al., 2000). Overlapping speech, a measure of interpersonal asynchrony, was negatively correlated with both receptive and expressive vocabulary size and remained a significant predictor for receptive vocabulary when controlling phonological memory and nonverbal cognition. With social interaction being a hallmark weakness for ASD, further investigation into how interpersonal asynchrony disrupts intake of linguistic input for vocabulary acquisition is warranted.

414.037 *(Poster)* Investigation of Linguistic Pitch and Time Processing in High-Functioning Adolescents with Autism Spectrum Disorders

F. Chen[1]*, C. C. H. Cheung*[2]*, Y. Zhang*[3]*, J. Yan*[4] *and G. Peng*[1]*, (1)Research Centre for Language, Cognition, and Neuroscience & Department of Chinese and Bilingual Studies, The Hong Kong Polytechnic University, Hong Kong, Hong Kong, (2)Research Centre for Language, Cognition, and Neuroscience, Department of Chinese and Bilingual Studies, The Hong Kong Polytechnic University, Hong Kong, Hong Kong, (3)Department of Speech-Language-Hearing Sciences, University of Minnesota, Minneapolis, MN, (4)Cangzhou Research Centre for Child Language Rehabilitation, Cangzhou Normal University, Cangzhou, China*

Background: Previous studies have shown enhanced pitch perception (e.g. Heaton, 2005) and impaired time processing (e.g. Maister & Plaisted-Grant, 2011) in individuals with autism spectrum disorders (ASD). However, it remains unclear whether such deviated patterns of auditory processing in ASD would transfer to higher-level linguistic pitch and time processing. In this study, we focus on two prominent phonological features in Mandarin Chinese, lexical tones and voice onset time (VOT), which utilize pitch and time changes respectively to convey phonemic contrasts.

Objectives: The present study aimed to address two main questions, (i) whether high-functioning Mandarin-speaking adolescents with ASD can perceive two speech continua varying in lexical tone and VOT in a categorical manner, and (ii) whether performance in categorical perception (CP) of speech could index language ability as well as working memory.

Methods: 23 high-functioning Mandarin-speaking adolescents with ASD and 20 age-matched typically developing controls (TDC) participated in this study. For the lexical tone condition, a 7-step continuum ranging from Tone 1 (ba, 'eight') to Tone 2 (ba, 'to pull') was generated (Fig. 1A). For the VOT condition, a 7-step time continuum ranging from ba (unaspirated stop, 'eight') to pa (aspirated stop, 'to lie') was synthesized (Fig. 1B). In addition to the identification and discrimination tasks to test CP performance for the two speech continua, all the participants also took the *Test of Language Ability* (Ning, 2013) and working memory tests (including forward digital span test and nonword repetition test). Table 1 shows the participants' characteristics and scores of language ability, digital span, and nonword repetition.

Results: To avoid inclusion of individuals who had problems in perceiving synthetic speech sounds, a minimum accuracy score of 80% in the identification of two ending stimuli in each continuum was required for the analyses of CP data. All the 20 TDC met the accuracy criterion for both lexical tone and VOT conditions. Of the 23 subjects with ASD, 20 and 15 ASD subjects met the criterion for lexical tone condition and VOT condition respectively. The results indicated that high-functioning adolescents with ASD showed intact CP of lexical tones, as reflected by measures of the identification function and discrimination function similar to those found in TDC. In contrast, ASD participants showed an impaired CP for the VOT continuum, as reflected by much wider boundary width and lower discrimination peakedness compared with TDC. Moreover, the degree of CP of lexical tones correlated with overall language ability and digital span in ASD participants, while no such correlations were detected in the VOT condition.

Conclusions: These findings suggest that the unbalanced acoustic processing capacities for pitch and time can be generalized to higher-level linguistic processing in ASD. Specifically, for the high-functioning Mandarin-speaking adolescents with ASD, the CP of native lexical tones was largely intact, whereas in stark contrast the CP of native aspirated vs. unaspirated stops was severely compromised. Furthermore, the higher degree of CP of lexical tones correlated with better language ability in Mandarin-speaking individuals with ASD.

414.038 *(Poster)* Language Skills and Their Cognitive Correlates in Adults with Autism Spectrum Disorder

M. Nadeau[1]*, J. Crutcher*[2]*, K. D. Csumitta*[2]*, L. Kenworthy*[3]*, A. Martin*[2] *and G. L. Wallace*[1]*, (1)The George Washington University, Washington, DC, (2)NIMH, Bethesda, MD, (3)Center for Autism Spectrum Disorders, Children's National Hospital, Washington, DC*

Background: Language impairment is commonly associated with Autism Spectrum Disorder (ASD) (Whitehouse et al., 2010). One approach to bifurcating language ability is separating language structure and pragmatic language (Bishop, Whitehouse, & Sharp, 2009). Current research on cognitive correlates of language difficulties in ASD (Weismer et al., 2018; Volden et al., 2009) mainly focuses on children. Executive function (EF) is a set of skills related to an individual's cognitive control. Understanding how EF relates to language skills may help us to gain a more complete picture of language challenges in ASD and the cognitive profile of autistic people. This study aims to analyze the relationship between executive function skills and language ability in adults with ASD.

Objectives: Analyze the association between EF and language ability in autistic adults.

Methods: Participants were young adults with ASD (n=41; M age=25.60+/-10.28; M IQ=113.49+/-13.86; 32 males) who completed several self-report measures. The Behavior Rating Inventory of Executive Function, Adult Self-Report (BRIEF-A; Roth et al., 2013) was used to assess several components (nine subscales and two indices) of EF. Furthermore, the Communication Checklist Self-Report (Bishop et al., 2009) was used to quantify language skills in two areas: structural and pragmatic language. Correlation analyses were performed relating EF to language skills. Four multiple linear regressions were completed controlling for age, sex, and IQ in step one. Two different sets of variables were used for step two of these analyses: (1) the variables found to have significant correlations with language skills and (2) two indexing variables compiled from the BRIEF-A, the metacognition index and the behavior regulation index.

Results: Lower structural language ability in adults with ASD was correlated with several areas of EF challenge including: inhibition, shifting, self-monitoring, initiation, working memory, planning and organizing, organization of materials, and task monitoring. Moreover, lower pragmatic language ability was correlated with EF difficulties in the areas of: inhibition, shifting, self-monitoring, initiation, working memory, planning and organizing, and task monitoring. Regression models indicate that EF (above and beyond age, sex, and IQ) predicts both structural ($F=5.082$; $p=.002$) and pragmatic ($F=5.608$; $p<.001$) language skills. For structural language this effect can be explained by the metacognition index ($t=-2.860$; $p=.008$). Whereas, within pragmatic language the prediction is driven by self-monitoring ($t=-2.603$; $p=.017$).

Conclusions: EF is positively correlated with language skills in the areas of structural and pragmatic language. After controlling for age, sex, and IQ, we found pragmatic language can be predicted by self-monitoring and structural language can be predicted by the metacognition index. These findings establish a link between executive function and language skills in adults with ASD that has not been previously established. Language impairment is an important target for intervention in individuals with ASD. These findings suggest that improving EF, particularly metacognition, might also cascade to improve language skills (and vice versa). Future intervention studies are needed to examine these possibilities.

414.039 *(Poster)* Lexical Alignment Contributes to Communicative Success during Social Problem Solving

***M. J. Stabile**, R. M. Weissenberg and I. M. Eigsti, Psychological Sciences, University of Connecticut, Storrs, CT*

Background: Typical speakers tend to adopt words used by their conversational partners. This "lexical alignment" enhances communication by reducing ambiguity and promoting a shared understanding of the topic under discussion (Reitter & Moore, 2014). Pragmatic language impairments are central to autism spectrum disorder (ASD), but lexical alignment has been little studied to date; further, it has been studied primarily via structured laboratory tasks that may overestimate performance (Branigan et al, 2016). The current study utilized a task eliciting extended spontaneous discourse to explore lexical alignment and its associations with task performance.

Objectives: Previous work from our team found that task performance (operationalized as a correct interpretation of described routes; see below) was associated with executive functions and ASD symptoms. Here, findings are extended to an examination of *linguistic* features associated with task performance. We hypothesized that adolescents with ASD would exhibit reduced lexical alignment during social communication, and explored associations between lexical alignment and task performance.

Methods: Twenty-nine adolescents (n=15 TD, 14 ASD) completed a social communication Maps Task in which participants collaborated with an undergraduate research assistant (RA; naive to study hypotheses) to navigate a series of maps. Participants alternated between "Tourist" and "Guide" roles, completing six maps. "Guide" maps (Figure 1a) contained a route drawn from a starting point through a series of landmarks to a finish point; the corresponding "Tourist" map contained similar landmarks, without the route, which the Tourist was asked to draw with a pencil. Routes were digitized for analysis (Figure 1b). ***Path Deviation*** was operationalized as the number of pixels contained within the area formed by the spatial difference between correct and drawn routes (Figure 1c). ***Lexical alignment*** was operationalized as the proportion of shared vocabulary produced by Guides on successive maps.

Results: Path Deviation was higher for ASD+RA pairs, F=8.61, p=.007, suggesting less efficient or accurate route-drawing. Group differences held whether the participant or RA was drawing the route, indicating that group differences were not only due to motor differences. With the participant as Guide, repeated-measures ANOVA revealed a significant group difference, F=4.507, p=.04, with reduced alignment in the ASD group (Figure 2). There was no effect of trial and no interaction between group and trial, p's>.18. When the RA was the Guide, alignment did not differ for the ASD and TD pairs, F=.36, p=.55, and there was again no main effect of trial and no interaction, p's>.25. For Participant Guides, lexical alignment was associated with Path Deviation, $r(25)$=-.55, p=.005; this relationship was not significant for RA Guides, $r(25)$=-.08, p=.70. Finally, alignment tended to increase across trials for the TD pairs, and decrease for ASD pairs.

Conclusions: Adolescents with ASD had greater difficulty describing navigational routes to a study-naïve RA, yielding routes that were less accurate. Decreased lexical alignment, i.e., a tendency to share vocabulary in describing routes, appears to contribute to communicative difficulties in ASD. These findings raise the possibility that explicit guidance to use shared vocabulary may be a useful intervention to support better communication.

414.040 *(Poster)* Lexical Semantic Abilities of Hebrew-Speaking Children with ASD

***N. Sukenik**[1], N. Friedmann[2] and L. Tuller[3], (1)Bar Ilan University, Ramat Gan, Israel, (2)Brain and Language Lab, Tel Aviv University, Tel Aviv, Israel, (3)UMR iBrain 1253, Inserm, University of Tours, Tours, France*

Background: Previous studies yielded contradicting findings regarding whether the semantic component is intact in individuals with ASD. Most studies have assessed semantic abilities by using tests such as picture naming and semantic priming (Minshew&Goldstien, 1993; Kamio et al., 2007). In many cases, High-functioning children with autism performed at par to their age-level groups (Eigsti et al., 2011; Tager-Flusberg et al., 1990). However, other studies found the semantic-component to be impaired (Lord, Shulman &DiLavore, 2004; Paynter& Peterson, 2010).

Objectives: The aim of the current study is to test the semantic lexicon and the lexical semantic abilities of children with ASD using the widely accepted model of Lexical Retrieval (Nickels, 1997) and systematically assess each of its components.

Methods: Participants were 38 Hebrew-speaking children with ASD, 34 boys and 4 girls, ranging in age from 8;5 to 17;9 (mean age = 11;4, SD = 2;2).

Three background measures were obtained for each of the participants to serve as baseline measures; nonverbal IQ (Raven's progressive matrices), pragmatic abilities (CCC), and reading ability (TILTAN).

16 tasks were chosen for their ability to differentiate the different parts of the model. Tasks included conceptual-tasks (odd-one-out, picture-association), lexical retrieval tasks (picture-naming, word-definition), reading tasks (TILTAN screening test, written-word-picture matching) and sentence comprehension tasks (sentence-picture matching, sentence-comprehension). Group scores were analysed and compared to an age-matched group of typically developing children. Next, individual profiles were build based on each individual's performance on each of the 16 tasks with the aim of pin-pointing the locus of impairment, if one exists.

Results: As a group, the ASD group performed significantly below TD age-peers on 3 out of 5 tasks directly evaluating the semantic lexicon; the proportion of children scoring significantly below age expectations varied widely. Lexical-semantic scores, although age-correlated for most tasks, were generally not related to level of pragmatic deficit, or to NVIQ. Inspection of individual results gave rise to two different lexical semantic/language profiles: children with ASD with an impairment in the semantic lexicon (n = 12) or impairment in access to the semantic lexicon (n = 4) from reading, and children with ASD having an intact semantic lexicon (n = 22).

Conclusions: The majority of children with ASD in this group have intact lexical semantic abilities and if these are impaired they are part of a wider linguistic deficit. A small group of children with ASD was found to have a deficit in accessing the semantic lexicon through reading, a fact that has profound implications for teaching and intervention methods. Our results highlight the importance of testing a wide range of linguistic abilities in children with ASD as well as performing in-depth error analyses of their performance. Some participants were able to compensate for their deficits in tasks with pictures / written words and their deficits were evident only on very specific tasks and in some cases only when error analysis was made.

414.041 *(Poster)* Longitudinal Analyses of Expressive Language Development in Mandarin-Exposed Preschool Children with ASD

Q. Xie[1]*, H. Yao*[2] *and Y. E. Su*[3]*, (1)School of Foreign Languages, Central South University, Changsha, Hunan, China, (2)Karolinska Institute, Stockholm, Sweden, (3)Childa Language Lab, School of Foreign Languages, Central South University, Changsha, Hunan, China*

Background: Longitudinal studies among preschool children with ASD learning Indo-European languages have highlighted the huge heterogeneity in their expressive language development (Tek et al. 2014); moreover, various factors such as early (pre)linguistic skills, joint attention, autism severity, etc. may predict their expressive language growth (Venassa et al. 2019). However, longitudinal studies in children learning typologically different language are needed to track early expressive language development and its influential factors in children with ASD across countries.

Objectives: This study attempts to delineate expressive language development in preschoolers with ASD exposed to Mandarin Chinese. Moreover, we investigate whether children's general language skills and autism severity may predict their expressive language development.

Methods: Using the *Putonghua Communicative Development Inventory: Words and Sentences* (PCDI) and the *Autism Behavior Checklist* (ABC), we assessed 61 preschoolers with ASD on their vocabulary, grammar and the decontextualized uses of language (i.e., the uses of language beyond the 'here and now' context), as well as their autism severity over one year's span. Parents completed these scales at two time points (children's mean ages were 47.26±11.59 months at time 1 and 59.39±11.58 months at time 2). To explore the group heterogeneity, we divided the whole sample into two groups based on their vocabulary production level at time 1: the Low Verbal group (LV, N=30, MA=42.10±9.79 months, *M*(vocabulary)=16.17±23.82 words, *M*(ABC)=66.82±24.07), and the High Verbal group (HV, N=31, MA=52.26±11.12 months, *M*(vocabulary)=335.00±161.62 words, *M*(ABC)=71.00±27.48.

Results: (1) Independent T-tests revealed that both the LV and HV groups showed significant increases in most of the 24 vocabulary items (LV: ps<0.05 for 20/24 comparisons; HV: ps<0.05 for 21/24 comparisons), and most of the 4 grammatical items, word combination, MLU, and sentence complexity (LV: ps<0.05 for 6/7 comparisons; HV: ps<0.05 for 5/7 comparisons). However, both groups showed no significant gains for most of the 5 items in the uses of decontextualized language (LV: ps<0.01 for 1/5 comparisons; HV: ps<0.05 for 1/5 comparisons). (2) Hierarchical regression analyses showed that for both groups, when setting age for control variable, the core language (vocabulary and grammar) didn't predict the growth of decontextualized language over time (ps>0.05), but the latter was a significant predictor for both the vocabulary and grammar development (ps<0.05). The ABC scores didn't predict the expressive language growth in either subgroup (ps>0.05).

Conclusions: In general, both the LV and HV subgroups of Mandarin-exposed children with ASD demonstrated similar patterns of an 'uneven' expressive language development, i.e., language growth was more apparent for core language skills (vocabulary, grammar), compared to the uses of decontextualized language. Furthermore, core language skills have limited effect in predicting children's growth of decontextualized language (Miniscalco et al. 2014). Instead, the latter may play a pivotal role in the subsequent development of core language skills in young children with ASD, warranting early intervention in increasing the uses of decontextualized language in children with ASD across countries (Leech et al. 2017; Su et al. 2018).

414.042 *(Poster)* Maternal Education Level Is Related to Expressive Language Abilities in Children with ASD

M. G. Pecukonis[1]*, J. Levinson*[2]*, A. Chu*[2]*, S. broder-Fingert*[3,4] *and E. Feinberg*[2,4]*, (1)Department of Psychological and Brain Sciences, Boston University, Boston, MA, (2)Boston University School of Public Health, Boston, MA, (3)Boston Medical Center, Boston, MA, (4)Boston University School of Medicine, Boston, MA*

Background: Several studies have demonstrated a significant relation between maternal education level and language abilities in typically-developing children (see Hoff, 2006 for review). This relation however has remained understudied in children with autism spectrum disorder (ASD). One study used retrospective parent-report data to explore this relation in a sample of French children with ASD (Grandgeorge et al., 2009); they found that mothers who completed more schooling reported that their children spoke their first words earlier than mothers who completed less schooling. Another study used a more objective, standardized measure of language and found that higher maternal education level predicted greater change in language abilities in Israeli children with ASD (Itzchak & Zachor, 2011). While findings from these studies suggest that maternal education level is related to language abilities in children with ASD, no studies have explored this relation in a racially diverse sample of American children with ASD. Furthermore, no studies have tested whether maternal education level is differentially related to expressive versus receptive language in children with ASD.

Objectives: The current study aimed to investigate the relation between maternal education level and child expressive and receptive language abilities in a racially diverse sample of children with ASD.

Methods: Secondary analyses were conducted using data from a multisite community-based intervention study (Project EARLY, NCT02359084). The final sample was comprised of 81 racially diverse children diagnosed with ASD, the majority of whom received public insurance (Table 1). At baseline, maternal education level was collected via parent-report. Two groups were formed based on maternal education level – children whose mothers obtained a high school education or below (*N*= 40; less than high school, high school degree, or GED), and children whose mothers obtained an education beyond high school (*N*= 41; some college, associate's degree, bachelor's degree, some graduate school, or graduate degree). 12-months after baseline, children (2.42–4.04 years) completed the expressive and receptive language subscales of the Mullen Scales of Early Learning (Mullen, 1995).

Results: Results of the Mann-Whitney U Tests showed that expressive language t-scores were higher for children whose mothers obtained an education beyond high school compared to children whose mothers obtained a high school education or below (Figure 1.a.; *U*=1030.00, *p*=.038). There were no significant differences in child receptive language t-scores between maternal education level groups (Figure 1.b.; *U*=1692.00,*p*=.903).

Conclusions: Results demonstrated that higher maternal education level is associated with better expressive language abilities, but not receptive language abilities, in children with ASD. Future studies should identify which variables within the child's proximal environment (e.g., quantity and quality of household language input; Hoff-Ginsberg, 1998) mediate the relation between maternal education level and expressive language abilities in children with ASD so that these variables can be targeted in intervention.

414.043 *(Poster)* Maternal Mediation Strategies during Interaction with Toddlers- a Comparison of Dyads with Autism Spectrum Disorder (ASD) and Dyads with Typical Development (TD)

A. Bloch[1,2], *A. Oren*[3], *Y. Bloch*[2,4] *and E. Dromi*[3], *(1)Child Development Center, Loewenstein Hospital, Ra'anana, Israel, (2)Sackler Medical School, Tel Aviv University, Tel Aviv, Israel, (3)Constantiner School of Education, Tel Aviv University, Tel Aviv, Israel, (4)Pediatric Psychiatric Outpatient Clinic, Shalvata Mental Health Hospital, Hod Hasharon, Israel*

Background: During interactions with toddlers, mothers use various mediation strategies to construct mutual play and support learning. Such mediation skills play an important role in the development of toddlers' communicative skills, and tend to evolve as the toddler develops. Autism Spectrum Disorder (ASD) introduces challenges to the ongoing mother- toddler's dyadic interaction and natural strategies intuitively applied by mothers may be thus altered. Acknowledging the mothers' roles in the development of toddlers' communicative skills, a close inspection of such strategies is highly desirable.

Objectives:

1. To study the use of different maternal strategies during interaction with toddlers, at early lexical levels
2. To compare the strategies used by mothers in the two groups at similar lexical levels

Methods: 24 mother-toddler dyads participated in the study: In nine dyads, the toddlers had been previously diagnosed with ASD; In fifteen dyads, the toddlers were typically developing (TD). Toddlers in the two groups were matched by lexical levels at study entry. The mean age in the ASD group was 31.5 months and in the TD - 17 months. Each dyad was video recorded three times, at home, during naturalistic interaction. The first recording took place when toddlers reached a productive lexicon of 40-70 different words. Two additional recordings took place in intervals of two months.

Mothers' verbal mediation strategies were divided into five main categories: requests for information, descriptions, encouragements, shifting attention and directing toddler's behavior. The frequency of each strategy was calculated in order to characterize both within- group developmental changes and differences between the two groups.

Results: 1. Mothers from both groups used verbal encouragement in a similar fashion and frequency. The frequency of one specific type of encouragement, exact repetition of the child's production, significantly increased at a similar rate in both groups across the three visits ($f(2,44)=3.77$, $p< 0.05$).

2. Significant differences were found between the two groups of mothers regarding strategies associated with control of the interaction. Specifically, mothers of toddlers with ASD made more frequent attempts to redirect their child's attention ($F(1,22)= 74.56$, $p<0.01$) and used more prohibiting utterances ($F(1,22)= 8.14$, $p<0.01$).

3. Significant group differences were also found regarding three indices. Mothers of ASD toddlers had higher indices of both maternal overall talkativeness ($F(1,22)= 5.43$, $p<0.05$), the use of nonverbal means to support the child's action($F(1,22)= 9,51$, $p<0.01$) and the simultaneous use of different means of communication ($F(1,22)=19.8$, $p<0.01$).

4. Of all the maternal mediation strategies, requests for information were the most prevalent antecedents for the toddlers' productions. While common in the ASD mothers' group, shifting toddlers' attention seldom resulted in a toddler's verbal production.

Conclusions: Results highlight that in many respects, maternal mediation strategies reflect the lexical level of their child. However, our main finding is a distinct interaction style of ASD mother that is expressed in a rather elevated use of verbal and nonverbal mediation strategies in hope of maintaining continuous interaction that could not be otherwise achieved due to their toddlers' difficulties.

414.044 *(Poster)* Measuring Sensitivity to Audio-Visual Synchrony, a Potential Mechanism Underlying Language Impairments in ASD, Using Respiratory Sinus Arrhythmia (RSA)

E. Tenenbaum[1], *G. Righi*[2], *C. E. McCormick*[3], *H. Tokadjian*[4] *and S. J. Sheinkopf*[5], *(1)Duke Center for Autism and Brain Development, Durham, NC, (2)Department of Psychiatry and Human Behavior, The Warren Alpert Medical School of Brown University, Providence, RI, (3)Human Development and Family Studies, Purdue University, West Lafayette, IN, (4)Rhode Island Consortium for Autism Research and Treatment (RI-CART), East Providence, RI, (5)Brown Center for the Study of Children at Risk, Women & Infants Hospital, Providence, RI*

Background: Differences in visual attention in children with ASD are theorized to impact language development by altering the alignment between linguistic input and the visual environment (Venker, Bean, & Kover, 2018). One basis for this perspective is evidence of differential sensitivity to audio-visual synchrony. Previous work demonstrated that children with ASD fail to show a preference for synchronous relative to asynchronous audio-visual stimuli while watching a woman producing child-directed speech. Further, preference for synchrony was positively associated with language abilities. This work used a preferential looking paradigm and left unclear whether diminished attention to synchronous stimuli reflects a lack of *recognition* of synchrony, or simply a lack of preference. To clarify this, we measured heart rate variability in response to asynchrony.

Objectives: (1) To elucidate potential mechanisms underlying connections between sensitivity to audio-visual synchrony and language by evaluating whether children with ASD show different physiological responses to synchronous and asynchronous stimuli. (2) To explore whether these responses are stimulus (social vs. nonsocial) dependent and related to language ability.

Methods: In a 2 x 2 within-subject design, we acquired electrocardiogram (sampled at 1kHz) during four counter-balanced stimuli blocks of 75 seconds: audio-visual synchronous and asynchronous social (i.e., a woman speaking) and nonsocial (i.e., noise-making toys) stimuli. In the asynchronous condition, the video precedes the audio track by 1 second. The dependent measure is respiratory sinus arrhythmia (RSA), a measure of heart rate variability in the frequency range of respiration. Higher baseline RSA reflects better capacity for attention and engagement. Decreases in RSA during a task can be used as an index of attention to/engagement with stimuli. Effects of synchrony and stimulus type were assessed with analysis of variance. Relations between RSA, language ability (Preschool Language Scale), and ASD symptomatology (Autism Diagnostic Observation Schedule-2) were assessed using Pearson correlations.

Results: With 11 participants with ASD tested (M=4.12 years, SD=1.23), no significant differences in RSA have been identified based on synchrony or stimulus type. No significant correlations emerged for RSA and language ability. Preliminary data suggest a correlation between RSA difference scores for the synchronous and asynchronous social stimuli with restricted, repetitive behaviors on the ADOS-2. Larger decreases in RSA for asynchronous stimuli (i.e., greater sensitivity to asynchrony) is associated with lower rates of restricted, repetitive behaviors, $r(11) = -.75$, $p < .01$ (see Figure 1).

Conclusions: Our previous work showed that children with ASD differ from language-matched typically developing children in attention to audio-visual synchrony and that this attention pattern is related to language. That work supports the notion that atypical processing of audio-visual synchrony may be one mechanism underlying language impairments in ASD. The current results leave open the possibility that children with ASD lack a *recognition* of audio-visual synchrony. With implications for aspects of development and behavior beyond language, preliminary findings suggest a relation between insensitivity to asynchrony and restricted, repetitive behaviors. Data collection is ongoing. This work highlights ways in which the study of in-the-moment attention to auditory and visual stimuli can advance our understanding of development in ASD.

414.045 *(Poster)* Meta-Representation and Complex Syntax in Children with ASC and TD

K. F. Schroeder[1]*, S. Durrleman*[2] *and W. Hinzen*[1]*, (1)Department of Translation and Language Sciences, Universitat Pompeu Fabra, Barcelona, Spain, (2)Department of Linguistics, Université de Genève, Geneva, Switzerland*

Background: Recent evidence supports the emergence, at around 4-5 years of age, of meta-representational cognitive capacities involved in reasoning both about false-beliefs (FB) and about the same objects under different descriptions ("intensionality"). Further evidence from children both with typical development (TD) and with autism spectrum conditions (ASC) supports a strong relation between the development of FB reasoning and embedded clause understanding. This suggests a potential common cognitive substrate between intensionality, FB, and embedded clauses.

Objectives: The objective of this study was to assess how complex syntax and meta-representational capacities involved in intensionality and false belief reasoning relate to one another in children with ASC.

Methods: 25 children with ASC (mean age 9;4) and 25 TD children (mean age 9;1) matched on on both chronological and verbal mental age (VMA) participated in the study. In a picture-matching task presented via touch-screen, participants were assessed on FB, intensionality and embedded clause performance (including relative clauses and three complement clause tasks, 'says that', 'sees that' and 'seems that', the latter manipulating the appearance-reality distinction).

Results: Results showed that the ASC groups performed significantly lower than matched TDs in embedding overall ($p \geq .0001$) and in particular the tasks assessing complement clauses ($p \geq .002$), with most difficulty on 'says that' ($p \geq .004$). Correlational analysis suggested that intensionality, complement clauses and FB all correlated with each other in the ASC group only ($p \leq .001$). In the TD group, no such correlations were identified.

Conclusions: These findings suggest a relation between certain meta-representational cognitive capacities and the maturation of the syntax of complementation among children with ASC.

414.046 *(Poster)* More Evidence That Frequency Counts Are Insufficient for Understanding Nonverbal Communication Differences in ASD: Autistic Adults Use Head Gestures at the Same Rate As Controls

A. de Marchena[1]*, S. Watson*[1]*, A. Bagdasarov*[2]*, E. S. Kim*[3]*, A. Riiff*[3] *and R. T. Schultz*[3]*, (1)University of the Sciences, Philadelphia, PA, (2)Child Study Center, Yale University School of Medicine, New Haven, CT, (3)Center for Autism Research, Children's Hospital of Philadelphia, Philadelphia, PA*

Background: Weaknesses in nonverbal communication are required for a diagnosis of ASD, yet remain poorly understood in verbally fluent speakers, especially adults. Many nonverbals are deployed during speech and provide critical information that supplements language. Nonverbal cues are also deployed during *listening;* speakers pick up on these cues and modify communication accordingly. Most research on nonverbal communication in ASD has employed narrative tasks, in which participants engage in a speaking, but not a listening, role, making it impossible to explore nonverbal features of listening in this population. *Head gestures* (e.g., affirmation, negation, uncertainty) are a common nonverbal cue used extensively during listening. In this study we used a naturalistic conversation task to study communicative head gestures in ASD, during both speaking and listening.

Objectives: To evaluate the frequency of head gestures produced by adults with and without autism during back-and-forth conversation, in both listener and speaker roles. We hypothesized that autistic adults would make a similar number of head gestures while speaking, consistent with most narrative research, but may provide fewer "backchannel" head gestures when listening.

Methods: 12 autistic adults and 12 age- and IQ-matched neurotypical adults (see Table) completed a collaborative referential communication task designed to elicit spontaneous back-and-forth conversation with a confederate in a controlled setting. One interlocutor was shown a grid of eight abstract figures and tasked with describing the figures to the other with the goal of ordering them correctly (see Figure). Participants completed this task under two conditions: (1) *Director* condition, in which participants had the completed grid, and (2) *Matcher* condition, in which confederates had the completed grid. Although both interlocutors spoke and listened in each condition, generally the director talked more and the matcher listened more. All head gestures produced by the participants were coded by the first author. Data on 18 additional participants will be available by INSAR2020.

Results: A mixed ANOVA was conducted with Group (autistic, neurotypical) as a between-subjects factor, Role (Director, Matcher) as a within-subjects factor, and head gesture count as the dependent variable. There was a significant main effect of Role, (p=0.01, η^2=.28), with head gestures far more common in the Director role. There was no main effect of Group (p=0.40, η^2=.03); the interaction between Role and Group was also not significant (p=0.92, η^2<.001).

Conclusions: All participants in this study used more head gestures when in a speaking role than in a listening role, consistent with other nonverbal communication behaviors. Adults in both groups used head gestures at a strikingly similar rate, consistent with a growing body of evidence demonstrating that the rate of spontaneously produced *hand* gestures is similar in ASD, even though autistic adolescents and adults may prioritize different communicative functions with their gestures, and may produce gestures that are harder to understand. Simple quantitative measures such as frequency may be insufficient to characterize nonverbal communication production in ASD; we plan to further explore our own dataset by examining: (1) the *function* of each head gesture, and (2) the *clarity* of function for each movement.

414.047 *(Poster)* Morphosyntax in Minority Adolescents and Young Adults with Autism

T. M. Girolamo[1]*, M. L. Rice*[1] *and S. F. Warren*[2]*, (1)Child Language Doctoral Program, University of Kansas, Lawrence, KS, (2)Speech-Language-Hearing: Sciences and Disorders, University of Kansas, Lawrence, KS*

Background: Despite the importance of language abilities and evidence that individuals with autism may also have language impairment (LI; e.g., Kjelgaard & Tager-Flusberg, 2001; Modyanova, Perovic, & Wexler, 2017; Roberts, Rice, & Tager-Flusberg, 2004), little is known about the morphosyntactic abilities of adolescents and young adults with autism. Even less is known about such abilities in racial/ethnic minority adolescents and young adults with autism. These gaps limit the ability to accurately diagnose and provide treatment suitable to diverse communities.

Objectives: Taking what is known on tense-marking and morphosyntax in children with autism, this study asked:

1. What is the accuracy of the sample on tense-marking elicitation tasks in a sample of racial/ethnic minority adolescents and young adults with autism and special education needs?
2. What error patterns are prevalent in the sample?

Methods: The New York City Board of Education & University of Kansas Institutional Review Boards approved this study. Participants were 10 male racial/ethnic minority adolescents and young adults with autism (N=10). All attended a specialized public school for students with autism, received their education in self-contained settings with small class sizes, qualified for free/reduced meals, and were exempt from state standardized testing due to their special education needs. Participants completed the phonological probe, 3s, and past tense probes of the Test of Early Grammatical Impairment (TEGI). As part of the broader research program, participants also completed the Clinical Evaluation of Language Fundamentals-3 ($M_{total\ language}$=52.89, SD=6.72) and the Wechsler Scales of Intelligence-Third Edition Digit Span (M=4.8, SD=3.23).

Following the TEGI Manual (Rice & Wexler, 2001), responses were counted as correct (i.e., finite), incorrect (i.e., nonfinite), unscorable (i.e., unelicited responses, such as progressive *-ing*), or no response. Error analysis further categorized incorrect and unscorable responses (Modyanova et al., 2017). If the examiner prompted and received multiple responses, all responses were included in this analysis.

Results: All participants passed the phonological probe and had an average screener score (i.e., an average of finite to nonfinite responses on the 3s and past-tense probes) of 58%, SD=36%. As Figure 1 displays, 50% of the sample had adult-like or near adult-like performance on the 3s probe & 40% on the past-tense probe. Table 1 shows the frequency and percentages of response types, as well as the number of participants who gave a given response type. Overall, about 50% of responses were finite, 20% either present or past progressive (i.e., auxiliary + *-ing*), and 10% nonfinite (i.e., a bare stem).

Conclusions: This study adds to what is known on morphosyntax in an understudied community in research. Specifically, here some individuals with autism who might be characterized as having low language based on standardized age-referenced measures had adult-like morphosyntactic abilities. Further, given that the most prevalent error was present progressive on the 3s probe and past progressive on the past-tense probe (while most responses were finite), it may be that administering standardized assessments – even highly structured ones such as the TEGI – to individuals with autism merits special considerations.

414.048 *(Poster)* Naturalistic Joint Attention and Theory of Mind in Children with ASD and TD Peers

V. Tecoulesco *and L. R. Naigles, Psychological Sciences, University of Connecticut, Storrs, CT*

Background: Individuals with autism spectrum disorder (ASD) often show differences in theory of mind (ToM; the ability to take the perspective of another person), an integral skill for interpersonal interactions. Joint attention (JA) or the ability to coordinate with a person during communication has also been found to be a meaningful precursor to ToM ability in both children with ASD (Mundy et al., 1986) and typically developing (TD) peers (Charman et al., 2000; Nelson et al., 2008) as understanding of attentional state may underlie an understanding of mental state (Baron-Cohen, 1989). Research on JA to date has primarily focused on testing specific skills in constrained situations designed specifically to elicit JA and testing ToM in younger children.

Objectives: Here we examine how parent-toddler engagement in JA during free-play, which captures how child and caregiver purposefully switch attention between each other and an object in more natural situations, relates to ToM performance 3 years later.

Methods: Forty-two parent-toddler dyads (ASD:n=20; TD:n=22) participated in three, thirty-minute, semi-structured play sessions separated by four months as part of a longitudinal study of early language. The groups were matched on receptive language (t(40)=.03,p=.97) at visit 1 (Mage ASD=32monts;Mage TD=20 months). Sessions were recorded and coded for joint attention type (IJA, in which the child initiates; RJA, in which the child responds to the parent's initiation; and passive attention (PA) in which parent and child are focused on the same object but the engagement lacks referential looks at each other). ToM was assessed approximately 3 years later (Mage ASD=6.4 years; Mage TD=5.5years); children were given both an unexpected change of contents and unexpected change of location task, which were summed for one composite score.

Results: The TD group's (89% correct) performance was significantly higher on ToM than the ASD group (48% correct) (t(40)=4.42,p<.001). When controlling for cognitive ability at Visit 1, JA performance at the initial visit did not relate to later ToM. RJA at Visit 2 was positively related to ToM for the ASD group (r=.484, p=.036) and just missed significance for the TD (r=.449,p=.054). IJA engagement at visit 3 was related to subsequent ToM for both groups (ASD: r=.504,p=.028;TD: r=.546, p=.016). When the entire sample was included in a regression of ToM performance on visit 1 IQ, visit 1 receptive language, visit 2 RJA, visit 3 IJA and group, early IQ did not predict a significant amount of variance (.2%), early language predicted 14 % of variance, RJA 18%, IJA an additional 15%, and group an additional 9% of variance.

Conclusions: When more naturalistic parent child encounters are analyzed, early JA performance relates to later ToM in both children with ASD and TD peers, indicating that JA is equally important for both groups in ToM development. Measuring ToM at this age left less variability in the TD group, many performed at ceiling, while the older ASD group still included children who performed at floor; however meaningful relationships still emerged. Early joint attention skills contribute to ToM performance above and beyond individual language ability.

414.049 *(Poster)* Observational and Reported Measures of Language and Pragmatics in Young People with Autism: A Comparison of Respondent Data and Gender Profiles.

***A. Sturrock**, Human Communication, Hearing and Development, The University of Manchester, Manchester, United Kingdom*

Background: Females who meet criteria for autism spectrum disorder (ASD) are at much greater risk than males of going undiagnosed (Dworzynski, et al. 2012), or being diagnosed with other conditions (Giarelli, et al. 2010). It is estimated that females represent a quarter of the total diagnosed population (Loomes, et al. 2017) but may be particularly underrepresented in higher IQ groups (70+; Nicholas, et al. 2008). A contributing factor in this discrepancy seems to be the poorly understood presentation of surface behaviours associated with a female phenotype of ASD (Kreiser and White, 2014). However, data in this area are complex, with differences between findings often appearing to be influenced by the person reporting on behaviours (clinicians, parents, teachers or the individual themselves), which may, in turn, be affected by the setting in which the child is being observed (e.g. at home or school; Mandy et al., 2012; Szatmari, et al., 1994).

Objectives: (1) Identify pragmatic, language and social behaviours of FwASD compared with MwASD and matched TDs as observed using a clinical checklist and as reported by parents, children and teachers.

(2) Compare clinical observation measures with parent- and child–report measures.

(3) Compare parent and teacher ratings of social behaviours.

(4) Compare functional measures with direct assessments.

Methods: Female children with autism spectrum disorder (FwASD) and performance intelligence quotient (PIQ) over 70 were compared with male children with ASD (MwASD) and typically developing (TD) controls (age 8-11 years) using a range of language and pragmatic measures. Functional ability was assessed using clinical observations and parent, teacher and self-reports. Results were compared between measures, and with direct assessments of language and pragmatics, in order to identify potential biases.

Results: This study found that FwASD performed better than MwASD but worse than TD controls on clinical observations of pragmatic ability. FwASD also performed worst overall on a parental measure of emotions. There were also a number of clear differences in the assessment results of children with ASD associated with the person reporting on the behaviours (clinicians, parents, teachers or the individual themselves). There were also discrepancies between results from observation measures and direct assessments. This was largely in line with the wider literature, but provides novel data, particularly on the assessment of language and communication, and potential biases impacting on the assessment of FwASD.

Conclusions: This research will contribute to our understanding of the female phenotype of ASD which could improve recognition, referral and accurate diagnosis of this group. By providing gender-normative data, we show the relative strengths and weakness experienced by FwASD in comparison to TD peers, which could lead to targeted therapy for this group. Additionally, this paper draws wider conclusions about the use of observational, report and direct assessment. It considers their relative use in developing a profile of abilities, and demonstrates potential biases. With all assessment methods showing some limitations, it is the recommendation of this paper that researchers and clinicians should provide holistic assessment; including a range of informants and be aware of potential biases.

414.050 *(Poster)* Parent-Reported Temperament and Child Vocalization Behaviors in 6- and 12-Month-Old Infants at High- and Low- Familial Risk of ASD

***R. Serruya**[1], V. Petrulla[2], L. D. Yankowitz[2], S. Paterson[2], M. L. Cola[2], S. Plate[2], S. Gregory[1], S. Chen[1], T. N. Stevens-Allen[1], M. Nally[1], S. S. Meera[3], M. Swanson[4], N. Marrus[5], A. Estes[6], J. Pandey[2], J. Pruett[7], H. C. Hazlett[8], S. R. Dager[9], L. Zwaigenbaum[10], T. St. John[11], J. Piven[12], R. T. Schultz[2], J. Parish-Morris[2] and .. The IBIS Network[8], (1)Center for Autism Research, Philadelphia, PA, (2)Center for Autism Research, Children's Hospital of Philadelphia, Philadelphia, PA, (3)National Institute of Mental Health and Neurosciences, Bangalore, India, (4)University of Texas at Dallas, Richardson, TX, (5)Washington University School of Medicine, St. Louis, MO, (6)Speech and Hearing Sciences, University of Washington, Seattle, WA, (7)*Co-senior author, **For the IBIS Network, Washington University School of Medicine, St. Louis, MO, (8)University of North Carolina, Chapel Hill, NC, (9)Radiology, University of Washington, Seattle, WA, (10)University of Alberta, Edmonton, AB, Canada, (11)University of Washington, Seattle, WA, (12)*Co-senior author, University of North Carolina, Chapel Hill, NC*

Background: Autism Spectrum Disorder (ASD) is characterized by deficits in social communication and the presence of repetitive behaviors (American Psychiatric Association, 2013). Temperament plays a key role in cognition and learning (Rothbart and Putnam 2002), and has been found to differ between infants who develop ASD and those who do not (Paterson et al. 2019). Two major factors of temperament include surgency and negative affect. The former captures a tendency to approach novel people and situations, while the latter embodies constructs such as fear and sadness. These temperament constructs are captured in the parent-report Infant Behavior Questionnaire-Revised (IBQ-R). Naturalistic vocalization sampling holds promise as a method to achieve fine-grained phenotyping of infant behavior (Warren et al. 1996), but it is currently unknown whether brief infant vocalization samples (including delight and distress vocalizations) correlate with parent ratings of temperament (Ozonoff et al. 2010).

Objectives: In this study, we investigate the link between naturalistic samples of (1) distress vocalizing (crying) and (2) delight vocalizing (laughter) and parent-reported temperament subscores in high- and low-risk infants at 6 and 12 months of age.

Methods: Infant siblings of children with ASD (high-risk; HR) and without ASD (low-risk; LR) were administered the AOSI at 6 months and the AOSI and CSBS at 12 months (Table 1). At 24 months, participants underwent gold-standard testing to determine diagnostic category: high-risk with ASD (HR+), high-risk without ASD (HR-), or low risk. Assessments were audio/video recorded. Delight and distress vocalizations were timestamped and categorized by reliable undergraduate coders using ELAN (ELAN, 2018), counted, and normalized per 10 minutes of recording time. Parents completed the IBQ-R at all timepoints. Linear models predicted IBQ-R subscores from the interaction between diagnostic group and vocalization metrics, after accounting for site (lme4 in R, Bates, 2008).

Results: At 6 months, the relationship between distress vocalizing and fear scores was stronger in the LR group than the HR+ group (Estimate: -.07, SE: .20, t=2.85, p=.005; Table 2) and the HR- group (Estimate: -.05, SE: .03, t=-1.87, p=.06; Table 2). There were no significant differences in the relationship between distress vocalizing and fear scores for the HR+ and HR- groups, nor relationships between distress vocalizing and other negative affect subscales in any groups. At 12 months, the relationship between distress vocalizing and sadness scores was stronger in the HR+ group than the LR group (Estimate: .06, SE: .03, t=2.07, p=.04; Table 2). Mean and standard deviation No other group differences emerged in the relationship between distress vocalizing and negative affect subscores, and no group by delight interactions emerged in any surgency subscales at either time point.

Conclusions: In this exploratory study, we investigated relationships between brief vocalization samples (distress and delight) and parent reported temperament in a large sample of HR+, HR-, and LR infants. Differential group by vocalization relationships did not emerge for surgency subscores, while significant differences emerged for distress vocalizing. This suggests that parent report of temperament correlates modestly with naturalistic samples of vocalization behavior, primarily in the domain of negative affect.

414.051 *(Poster)* Partner Matters: Linguistic Accommodation in Children and Teens with ASD Vs. Typical Controls during Experimentally-Manipulated Conversations

M. L. Cola[1]*, L. D. Yankowitz*[1]*, V. Petrulla*[1]*, A. Riiff*[1]*, S. Plate*[1]*, E. F. Ferguson*[2]*, A. Pomykacz*[1]*, K. Bassanello*[1]*, J. Pandey*[1]*, R. T. Schultz*[1] *and J. Parish-Morris*[1]*, (1)Center for Autism Research, Children's Hospital of Philadelphia, Philadelphia, PA, (2)The Center for Autism Research/CHOP, Philadelphia, PA*

Background: Successful communication demands that speakers to do more than merely produce and perceive speech; they must also read a partner's social cues and respond by dynamically adjusting their own linguistic contributions. These adjustments during conversation – which often result in convergence on the complimentary processes that define "good" conversation (e.g., smooth turn-taking) – are known as linguistic accommodation (Gregory, Dagan, & Webster, 1997) or conversational entrainment (Pickering & Garrod, 2004). Sensitive and socially-responsive conversational behaviors play a significant role in successful communication, and research suggests that entrainment is associated with improved rapport, empathy, and perceived connection between social partners (Manson et al., 2013). Disruptions in this phenomenon may yield significant consequences. For example, difficulty reading and responding to a peer's social cues during conversation (and failure to adjust one's own contribution accordingly) will negatively impact an individual's ability to make and retain friends. A small body of research suggests that conversational entrainment is a challenge for individuals with autism spectrum disorder (ASD; Wynn et al., 2018), which may contribute to conversational breakdowns and social difficulties. Here, we examine language behavior in children with ASD and typically developing (TD) peers during experimentally manipulated conversations.

Objectives: Assess whether children with and without ASD modulate their conversational contributions (as measured by the number of words produced per minute) during 3-minute interactions with partners who act interested or bored.

Methods: Verbally fluent school-aged individuals with ASD (N=59) and TD (N=58; Table) completed the Contextual Assessment of Social Skills (CASS; Ratto et al., 2011) with two novel conversation partners naïve to diagnosis. The first person acted interested in the participant (Interested condition; talked more), while the second acted bored (Bored condition; talked less). Language was transcribed and words per minute (WPM) was calculated. Contributions of diagnostic group, age, sex, and full-scale IQ to WPM were assessed using a generalized linear mixed effects model with a Poisson distribution to account for repeated non-normally distributed count data. Tukey-corrected comparisons of estimated marginal means assessed the directionality of effects.

Results: There was a significant interaction between diagnosis and condition on WPM (estimate=.09, z=2.98, p=.003), after accounting for age and full-scale IQ. This interaction was driven by TD participants, who produced significantly more words during the Interested condition than the Bored condition (estimate=1.09, z=3.8, p<.001), demonstrating successful entrainment with their conversational partner (Figure). The ASD group maintained consistent language behavior across conditions (Table).

Conclusions: Subtle features of a conversation can influence whether social communication is successful, and this study highlighted a potential driver of communication challenges in ASD: reduced linguistic accommodation. While TD participants modulated their behavior in response to social cues emitted by their conversational partner, the ASD group did not. Reduced entrainment during conversations could contribute to significant social challenges experienced by individuals with ASD. Our findings have implications for understanding the effect of conversational partner behavior on social communication, and may be valuable for clinicians interested in improving conversational competence in verbally fluent individuals on the autism spectrum.

414.052 *(Poster)* Peer Language Input and Social Interaction in Monolingual and Bilingual Preschoolers with ASD

L. K. Perry[1]*, R. M. Fasano*[1]*, S. Custode*[1]*, S. G. Mitsven*[1]*, A. Adams*[1]*, L. Vitale*[1] *and D. S. Messinger*[2]*, (1)Psychology, University of Miami, Coral Gables, FL, (2)University of Miami, Coral Gables, FL*

Background: Autism spectrum disorder (ASD) is often associated with language delays. Although bilingualism is increasing in the United States, and is the norm worldwide, very little research has been done to understand bilingual development in children with ASD. Of the studies that have examined bilingual children with ASD, many find levels of language proficiency similar to monolingual children with ASD, despite a theoretical increased risk of delay. Critically, however, the field lacks a rigorous quantitative understanding of the language environments of bilingual learners, particularly those with ASD. Recent advances in automated measurement allow for efficient collection of objective measures of the simultaneous interactions and language use in inclusive preschool classrooms—an important language environment for many children with ASD.

Objectives: Here we utilize automated objective measures of language and movement to quantify the language experiences of monolingual and bilingual preschoolers in ASD inclusion classrooms, asking how peer input affects children's language development.

Methods: Thirty-nine 3-5 year olds, 12 with ASD (8 bilingual), 12 typically developing (TD; 6 bilingual), and 15 with developmental delays (DD; 4 bilingual) from 4 inclusion classrooms, participated. During observations every 2-4 weeks, children wore lightweight vests equipped with Language ENvironment Analysis (LENA) recorders to measure vocalizations and two Ubisense radio frequency identification tags to proximity/orientation. Ubisense measures of proximity/orientation were used to determine instances of social contact (children < 2 m apart and oriented towards one another) and synchronized with LENA data to assess when each child produced/received vocalizations to/from each of their peers. Using linear mixed effects regression models, we predicted each child's vocalizations while in social contact to each peer from their previous vocalizations to that peer (language output), that peer's previous vocalizations to them (language input), their diagnosis, their language background (bilingual, monolingual), and interactions between language background and peer input and between language background and diagnosis.

Results: As can be seen in Figure 1, we found a main effect of peer input such that children who received more language input from their peers at time t were more likely to produce language output to those same peers at time t+1, $X^2(1)=30.58$, $p<.00001$. We also found an interaction between language input and language background such that monolinguals had a greater effect of peer input on language output than bilinguals, $X^2(1)=22.23$, $p<.00001$. Finally, as can be seen in the figure, the difference between monolingual and bilingual children was driven by those with ASD and DD, as these groups showed a greater effect of language background on the relationship between language input and output.

Conclusions: Overall, the language input children received from their peers increases their subsequent language output to those peers—even while controlling for their own previous levels of talking. However, the effect of peer input was greater for monolingual than bilingual children, especially for children with ASD or DD, suggesting that social interaction and language exchange with peers is a potential target for intervention to support language development in these at-risk groups.

414.053 *(Poster)* Phonological Awareness and Language Development in Preschoolers with ASD with and without Hyperlexia

D. Macdonald[1]*, E. M. Quintin*[1]*, G. Luk*[1] *and B. Mercadante*[2]*, (1)Educational & Counselling Psychology, McGill University, Montreal, QC, Canada, (2)Department of Psychology, McGill University, Montreal, QC, Canada*

Background: Preschoolers with autism spectrum disorder (ASD) are known to have a special interest in written material, with a portion of preschoolers with ASD possessing an early ability to read words, referred to as hyperlexia (HPL). It is unclear what skills underly this precocious reading ability. When comparing children with ASD to children with typical development (TD), studies have found mixed results in phonological awareness, verbal comprehension and reading profiles. To date, however, no study has compared these skills among TD, ASD with (+HPL) and without (-HPL) during the preschool period prior to formal reading instruction.

Objectives: To compare phonological awareness, verbal comprehension and reading profiles among preschoolers with ASD+HPL and ASD-HPL, to preschoolers with TD, as well as to examine the interrelations of these constructs within each group.

Methods: Preschoolers (N=30) aged 3-5 years with ASD+HPL (n=8), ASD-HPL (n=7) and TD (n=15) participated in the study. Children with ASD+HPL were defined by an exceptional strength in word reading, but impairments in cognitive, linguistic and reading comprehension abilities. All children completed Verbal Comprehension Index (VCI) subtests of the WPPSI-IV; the NEPSY-II Phonological Processing subtest, and the Letter-Word Identification and Passage Comprehension subtests of the Woodcock-Johnson IV Test of Achievement as measures of word reading and reading comprehension respectively.

Results: The ASD+HPL group outperformed the TD group (p=.001) and the ASD-HPL group (p=.002) on the word reading task, while the TD group outperformed the ASD+HPL group in VCI (p=.001). There were no significant differences in VCI between the TD and ASD-HPL groups (p=.48). Similarly, there were no significant differences among ASD+HPL, ASD-HPL and TD groups on phonological awareness or reading comprehension, although mean group performance of the ASD groups was below average on the NEPSY-II. Interestingly, the ASD+HPL group showed the larger discrepancy between word reading and overall language skills (phonological awareness and VCI). Phonological awareness and VCI were significantly correlated in the TD group (r=.73, p=.002) and in the ASD-HPL group (r=.79, p=.03), but not in the ASD+HPL group (r=.15, p=.72). Only the ASD-HPL group showed a significant correlation between VCI and word reading (r=.83, p<.05). Phonological awareness did not significantly correlate with word reading in the TD or ASD groups combined or in ASD+/-HPL subgroups.

Conclusions: Results suggest that TD and ASD-HPL groups are similar in their VCI, phonological awareness and reading profiles. ASD+HPL showed a different pattern. Despite the strongest reading skills, VCI and phonological awareness were weaker in the ASD+HPL group. These findings suggest that, for ASD+HPL, neither phonological awareness nor verbal comprehension skills are required for word reading, possibly implying a non-phonological route to word reading despite advanced word reading skills. These findings suggest a potentially unique underlying process used for reading in preschoolers with ASD, especially those with early word reading abilities. Interventions should use this strength in basic reading skills to improve language and reading comprehension in the ASD+HPL group from an early age.

414.054 *(Poster)* Phonological Awareness and Visual Spatial Abilities in School-Age Children with Autism

C. Rimmer[1]*, G. Philibert-Lignieres*[1]*, T. Q. Boucher*[2]*, G. Iarocci*[2] *and E. M. Quintin*[3]*, (1)McGill University, Montreal, QC, Canada, (2)Psychology, Simon Fraser University, Burnaby, BC, Canada, (3)Educational & Counselling Psychology, McGill University, Montreal, QC, Canada*

Background: Phonological awareness is an essential precursor to reading acquisition and refers to the awareness of sound structures in language and the ability to manipulate (i.e., blend, segment, and delete) sounds at both the syllable and individual phoneme levels. Phonological awareness development may be vulnerable in children with autism spectrum disorder (ASD) given that many children with ASD demonstrate delays in language and communication. The current literature yields mixed findings showing that preschool children with ASD demonstrate difficulties with phonological awareness, while some studies indicate phonological awareness as a relative strength within this population. Children with ASD present with heterogenous language and cognitive profiles, yet, an important overlap between oral language skills and nonverbal cognitive abilities has been identified.

Objectives: The current study aimed to investigate the phonological awareness skills of school-age children with ASD compared to children with typical development (TD), while exploring the role of individual differences in IQ and ASD symptom severity on phonological awareness abilities.

Methods: Eighteen children with ASD (age= 6-12, *M*=9, *SD*=1.71, male *n*=16) and seventeen TD children (age= 6-11, *M*=9, *SD*=1.53, male *n*=8) participated in this study. Phonological awareness was measured using the *NEPSY-II Phonological Processing* subtest, ASD symptomology using the Social Responsiveness Scale-2 (SRS-2, and cognitive abilities, including verbal and visual spatial abilities, were measured using the Wechsler Abbreviated Scale of Intelligence - 2nd Edition (WASI-II).

Results: MANOVAs revealed that the ASD and TD groups did not differ in their score on the NEPSY-II Phonological processing subtest ($p > .05$) and the WASI-II ($p > .05$), demonstrating similar phonological awareness and cognitive abilities. Within the ASD group, a regression analysis revealed that visual spatial, but not verbal cognitive abilities, predicted phonological awareness scores ($p < .05$) and that autism symptoms did not predict scores in phonological awareness skills ($p > .05$). Regression coefficients indicated that within the ASD group, participants with a higher visual spatial score obtained a higher score in phonological awareness skills compared to those with a lower visual spatial score. Within the TD group, a regression analysis showed that visual spatial abilities, verbal abilities, and autism symptoms did not predict scores in phonological awareness skills ($p > .05$).

Conclusions: Results contribute to the literature in examining phonological awareness skills in school-age children with ASD, demonstrating that it is a relative strength within this population and is not related to autism symptom severity. Additionally, our findings support previous research showing a relationship between phonological awareness skills and nonverbal cognitive abilities in children with ASD. Given the increase in attention to the academic achievements within this population, findings add to our understanding of phonological awareness skills of children with ASD compared to aged-matched peers and can help inform instructional interventions aiming to increase reading success.

414.055 *(Poster)* Pragmatic Language Competence of School-Aged Children with Autism Who Achieve and Do Not Achieve Optimal Outcome in Peer Conversations

Y. Li[1], *H. Zhu*[1], *Y. Zou*[1], *W. Cao*[2], *Y. Ji*[1], *Y. Wang*[1], *Y. Zhang*[1] *and X. Zou*[1], *(1)Child Development and Behavior Center, Third Affiliated Hospital of SUN YAT-SEN University, Guangzhou, China, (2)South China Academy of Advanced Optoelectronics, South China Normal University, Guangzhou, China*

Background: These years more and more children with autism spectrum disorders (ASD) are able to adapt into mainstream education and develop peer relationships. Some of them even obtain remarkable progress and achieve what is called optimal outcome (OO). Researches show that these school-aged high-functioning ASD (HFA) children may still present some residual deficits, pragmatic language competence being one of them. However, little is known about these subtle difference from a quantitative and detailed aspect. Most of the standard tests of pragmatic language are designed as parent/teacher report scales or checklists and structured evaluation. Since some pragmatic impairments are only present in real-life social interactions, we set up a natural environment and explore children's pragmatic language competence during peer conversations, which provides a new perspective in detecting and evaluating pragmatic language ability.

Objectives: This study aims to compare communication acts with social elements, conversational skills and autistic-specific speech acts of mandarin-speaking OO, HFA and TD children during peer talk.

Methods: 6 OO (mean age:9.69±1.88, IQ: 102.67±11.98), 16 HFA (mean age 9.17±1.45, IQ: 97.50±12.02) and 22 age-matched and IQ-matched TD children participated in this study. We used a strategic card game to induce peer talk between children with ASD(OO or HFA) and his/her TD peer（age difference less than 2 years). Then we coded and analyzed the 10 minute conversation using the CHILDES (Child Language Data Exchange System). We developed a new coding system to assess communication acts combined with social elements, which is based on 35 social-communicative skills: (①self-expressing: dissatisfied, show off, joy, etc.②self-peer social and emotional attunement: modest, perspective-taking, admiring, negotiating, etc.③executive function: turn-taking, disagree, agree, suggesting, etc.). The coding aspects of conversation skills include turn-taking, initiation, continuation (reply and expand), discontinuity and repair. Furthermore, we defined the special autistic-style speech into five types according to the ASD linguistic symptoms. The ANOVA and non-parameter test were used to test the significance of the difference.

Results: The results suggested that compared to OO group and TD peer, HFA children showed significantly less amount and types of communication acts (amount: OO>HFA, p=0.005, HFA<TD, p=0.001, HFA:23.75±10.87, OO:44.67±10.11, TD:40.82±13.72; types: OO>HFA, p=0.001,HFA<TD, p=0.035, HFA:9.75±3.61,OO:16.16±2.32,TD:12.91±3.16), and less amount of conversation continuation (OO>HFA, p=0.022, HFA<TD, p=0.030, HFA:31.00±14.16, OO: 31.00±14.16, TD:44.91±17.76). Compared to their own TD peer, HFA children showed less ratio and amount of expansion in his/her turn (ratio: HFA:0.24±0.09, TD:0.32±0.09, p=0.036; amount: HFA:15.06±7.97, TD:24.68±10.14, p=0.015), more autistic-style speech (sum: p=0.000, type: p=0.003) and more discontinuity(p=0.032). The difference in conversational initiation and repair was not significant.

Conclusions: The results of this study gave new evidence about the pragmatic language competence of high-functioning ASD children and those who achieve OO. HFA children have troubles in conversational continuation of a certain topic, clarifying messages and adding more related information in their own speech turns, while OO group perform better pragmatic competence by expressing and communicating with more social elements. These findings shed light on the future directions of intervention and support for school-aged children with ASD.

414.056 *(Poster)* Preschool Children with Autism Showed Impairment in Recognizing Emblems but Not Iconic Gestures

Y. Huang[1], *C. H. E. Cheng*[2] *and S. Chee*[1], *(1)Educational Psychology, The Chinese University of Hong Kong, Hong Kong, Hong Kong, (2)The Chinese University of Hong Kong, Hong Kong, Hong Kong*

Background: In comparison to their typically developing (TD) peers, children with autism spectrum disorder (ASD) have deficits in understanding and producing gestures (Colgan et al., 2006). However, findings on the types of gestures (e.g., iconic gestures, emblems) in deficit are inconsistent in the literature.

Objectives: The present study aimed to investigate the impairment in gestural production and recognition skills of different types of gestures in children with ASD compared to TD children.

Methods: Thirty-seven preschool children aged 4 to 6 years participated in the current study (TD n=15, ASD n=22). There was no significant difference between participants with ASD and those with typical development, in chronological age (U = 146, p = .567) and language developmental age (U = 120, p = .168). The participants' gestural skills were measured by gestural recognition and production tasks (So et al., 2017; So et al., 2016). Twenty iconic gestures (e.g., DRIVE) or emblems (e.g., GREETING), which are commonly used in daily life, were tested. For the gestural recognition task, we videotaped an experimenter producing the 20 target gestures. Each time, the child was shown a gesture and was asked to point to one of three written options that best identified its meaning or to orally name the gesture. In the gestural production task, the experimenter asked the child to produce the target gestures one at a time. A gesture was considered appropriate if it conveyed the target meaning. Generalized linear mixed effect model was conducted with language developmental age and group (ASD or TD) as fixed effects while child and gesture as random effects.

Results: Compared to the TD group, children with ASD showed delay in producing both emblems (p < .001) and iconic gestures (p = .019), as well as recognizing emblems (p = .012). However, impairment in recognizing iconic gestures was not found (p = .925). Results also showed that children with ASD recognized iconic gestures better than emblems (p = .030).

Conclusions: Iconicity may benefit gestural recognition in children with ASD. One common iconic strategy is a handling strategy, where the hands show holding or grasping an imagined object in action; another is an instrument strategy, where the hands represent the shape or a dimension of the object in a typical action. These strategies provide a perceived similarity between a gesture form and its real-world referent (Perniss, Thompson, & Vigliocco, 2010). Children with ASD may guess the meaning with the perceived similarity, which made them recognize the iconic gestures as well as their TD peers. However, the impairment in producing iconic gestures indicated that children with ASD may not be aware of these strategies when producing gestures. Therefore, explicit descriptions of the iconic strategies may be crucial in teaching gestural skills to children with ASD. Besides, since the iconic strategies are not available in other types of gestures including emblems, teaching these gestures in a real scene (e.g., role-play games) may help children with ASD build up the relationship between the form of a gesture and its meaning.

414.057 *(Poster)* Providing Visual Supports Via a Smartwatch to Improve Directive Following for Children with Autism Spectrum Disorder

A. M. O'Brien[1], *H. C. Shane*[2], *R. W. Schlosser*[3], *C. Yu*[2], *A. A. Allen*[4], *J. Cullen*[5], *A. Benz*[5] *and L. O'Neill*[5], *(1)Speech and Hearing Bioscience and Technology, Harvard University, Boston, MA, (2)Boston Children's Hospital, Waltham, MA, (3)Northeastern University, Boston, MA, (4)Boston Children's Hospital, Boston, MA, (5)Fayettville-Manlius Central School District, Fayetteville, NY*

Background: Children with autism spectrum disorder (ASD) with limited functional speech often demonstrate difficulties with directive-following (Schlosser et al., 2013). While there is limited research investigating receptive language for this population (Sevcik, 2006), visual supports augment directive following for many of these children (Schlosser et al., 2013). Delivering visual supports to a smartwatch may increase the naturalness of directive prompting. Preliminary case series design studies have suggested that directive following can be improved for children with ASD by providing visual supports on an Apple Watch™ held in front of the child in a "just-in-time" (JIT) manner (O'Brien et al., 2016; Schlosser et al., 2017). Given these promising feasibility studies, this investigation used an experimental design to explore the relationship between providing visual supports on a smartwatch and directive-following outcomes.

Objectives: The following questions were addressed: (1) Will the participant attend to, and follow, directives sent via text message to her smartwatch? and (2) is it is possible to gradually increase the distance between the mentor and the learner during prompt delivery?

Methods: A 9-year-old female with ASD with limited functional speech participated in this study. A single case, multiple probe, experimental design was used across three settings, over 16 days, in an elementary school. A mentor texted three written directives, per setting, to the participant's Apple Watch™ in a JIT manner. Introduction of the intervention was staggered across settings. The mentor systematically increased her distance from the participant.

Results: Based on visual analysis of graphed data, use of the smartwatch intervention improved the participant's directive following, and increased the mentor's distance from the learner, across all three settings. In later sessions, the participant also began to demonstrate "anticipatory responses" of upcoming directives. Video examples of the intervention will be shown.

Conclusions: Overall, this study suggests the effectiveness of using an Apple Watch™ to provide visual supports to a learner with ASD. This intervention allows for increased distance between the mentor and learner allowing for a more naturalistic academic environment. This intervention may have positive implications for perceived independence or actual independence through anticipatory response learning.

414.058 *(Poster)* Qualitative and Quantitative Operational Differences in the Intersection of Bilingualism and ASD: A Systematic Review

R. Hantman[1]*, A. B. Choi*[2] *and G. Luk*[3]*, (1)Boston University, Boston, MA, (2)Boston Children's Hospital, Boston, MA, (3)Educational & Counselling Psychology, McGill University, Montreal, QC, Canada*

Background: Bilingualism's growing prevalence leads to an increasing clinical and practical need to understand how bilingualism manifests in cognitive and language outcomes in individuals with ASD. Limited research has shown findings on bilingualism's impact on ASD (e.g., Gonzalez-Barrero & Nadig, 2017; Petersen et al., 2012), but they have been constrained by small samples, inconsistent comparison groups, and heterogeneous operational definitions of bilingualism. To date, no review has synthesized the literature on the intersection of bilingualism and ASD both qualitatively and quantitatively.

Objectives: We systematically examined the literature's intersection of bilingualism and ASD, emphasizing their operationalization. Specifically:

1. How is bilingualism defined?
2. How is ASD described?
3. What research has examined the influence of bilingualism and ASD on each other?
4. Are language outcomes different in monolingual and bilingual children with ASD?

Methods: We examined six databases (e.g., ERIC, PsycINFO), yielding 319 articles (Figure 1). 173 articles from a pilot search were included, generating 290 unique articles. We screened titles, abstracts, and keywords and included 98 eligible studies based on three inclusion criteria:

1. Participants were stakeholders within the ASD field
2. One or more participant groups spoke two or more languages
3. Published in English, peer-reviewed, and empirical

55 papers were included; each were coded for 113 variables about terminology, "bilingualism", diagnosis, methodology, and goals. The first two authors double-coded 25% of the papers, with an inter-rater reliability of 93%. Having reported standardized language outcomes, seven studies were included in a meta-analysis.

Results:

1. Bilingualism was labeled 134 times across 50 unique labels. "Bilingualism" accounted for 28% of labeling, while 42% of labeling instances fell in the "Other" category (e.g., "limited English abilities"). Bilingual participants spoke between two (68%) and six (4%) languages. 35% of the studies had bilingual participants with a range of first languages (L1; e.g., English or French), followed by Spanish (22%) and English (15%). English was the most common second language (L2) at 50%, followed by a range of L2s (29%; e.g., Yoruba, Croatian). Testing language did not necessarily align with the participants' L1.
2. ASD was operationalized 119 times across 13 unique labels. "Autism" accounted for 35% of labeling, "ASD" for 28%, and "autistic" for 8%. 47% of the studies did not use any assessments to verify/diagnose participants and, surprisingly, 80% did not use the ADOS.
3. There were geographic differences as well: 64% were conducted in North America, 16% in Asia, and 9% in Europe. 49% were quantitative, 45% qualitative, and 5% mixed (Figure 2A). 51% of papers compared language and clinical groups and 49% did not include a comparison group (Figure 2B). 35% of studies aimed to study language skills, followed by perspectives (25%) and intervention practices (24%).
4. Using a meta-analytic method, we found bilingual and monolingual children with ASD did not differ in language skills.

Conclusions: There are substantial variations in labels of bilingualism and ASD, leading to inconsistent operationalization and obscuring the understanding of how bilingualism and ASD interact, posing a challenge to best support this growing population.

414.059 *(Poster)* Rate of Communication and Gesture Use in Toddlers with and without Autism Spectrum Disorder across Everyday Activities at Home

A. Delehanty[1]*, M. Hoehl*[1] *and A. Wetherby*[2]*, (1)Speech-Language Pathology, Duquesne University, Pittsburgh, PA, (2)Florida State University Autism Institute, Tallahassee, FL*

Background: In a review of the evidence for intervention practices for children with autism spectrum disorder (ASD) under the age of three, Zwaigenbaum and colleagues (2015) emphasized the importance of building the capacity of caregivers to provide learning opportunities in the natural environment. Rate of communication, gesture use, and initiation of joint attention are important predictors of developmental outcomes in children with and without ASD. To date, the communicative acts of young children in the context of different activities in the home environment have not been examined.

Objectives: To examine rate of communication and relative frequency of communicative functions expressed by young children with and without ASD across everyday activities at home.

Methods: Participants were 211 toddlers diagnosed at age 3 with ASD (n=121), developmental delay (n=46), and typical development (n=44) recruited through screening in primary care from the archival database of the FIRST WORDS Project. Children completed a video-recorded home observation at a M_{age} of 20.01 months (SD=1.70). Parents were asked to interact with their child during a variety of activities, including play with toys, play with people, mealtime, caregiving, family chores, and book sharing. Activity types and child communicative acts were coded using Noldus Pro Observer XT.

Results: Children with TD communicated at higher rates during book sharing than other activities (Figure 1). Children with ASD communicated at higher rates during play with people, when they were not required to shift their attention between objects and others. Children with ASD used a significantly higher rate of deictic gestures during book sharing compared to overall deictic gesture use (M=1.15, SD=1.46) with a small effect size (d=0.24). They produced a higher rate of representational gestures during snack time (M=.30 SD=.85) and play with people (M=.21 SD=.42), again with small effect sizes (d= 0.26 and 0.21, respectively). Across groups, relatively low rates of communication were observed during family chores and gross motor play with "props."

Communicative Functions: High relative frequencies of acts for joint attention were observed during book sharing, as children tapped or labeled pictures (Figure 2). Acts for behavior regulation were common during mealtime and caregiving (e.g., requesting and protesting). High relative frequencies of acts for social interaction occurred during play with people, when social exchanges were being shared between the adult and child and objects were not present.

Conclusions: On average, families spent the majority of their home observations engaged in play with toys (35-40%); however, children communicated across activities. Book sharing appeared to foster both deictic gesture use and joint attention. These findings support the notion that early intervention can, and should, incorporate more than just toy play. Strategies to increase active engagement can be used to scaffold communication during daily, necessary activities like caregiving, chores, and mealtime so that parents can implement intervention throughout the day. Finally, when conducting ASD screening or a communication evaluation in the home, it may be important to examine rate of communication during activities that do and do not require the child to engage in triadic coordination of attention.

414.060 *(Poster)* Relations between Factivity Semantics of Mental Terms and the Five-Step Theory-of-Mind Scale in Cantonese-Speaking Children with and without Autism Spectrum Disorders

C. C. H. Cheung[1]*, Y. Rong*[1]*, Y. Xiong*[1] *and T. P. Y. Tang*[2]*, (1)Research Centre for Language, Cognition, and Neuroscience, Department of Chinese and Bilingual Studies, The Hong Kong Polytechnic University, Hong Kong, Hong Kong, (2)Speech Therapy Unit, Department of Chinese and Bilingual Studies, The Hong Kong Polytechnic University, Hong Kong, Hong Kong*

Background: While considerable research has examined false belief (FB) understanding in children with autism spectrum disorders (ASD), little is known about their other theory-of-mind (ToM) skills. Wellman and Liu (2004) have devised a ToM battery to examine the developmental steps of five ToM skills, including diverse desires (DD), knowledge access (KA), diverse beliefs (DB), contents FB (CFB), and hidden emotion (HE). Based on the finding that strong non-factive mental terms predicted FB understanding in typically developing (TD) children (Cheung et al., 2009), we hypothesize that different mental terms will predict different ToM skills in Cantonese-speaking children with and without ASD. Specifically, we expect that (a) strong non-factive mental terms such as *ji5wai4* ("falsely think") will predict CFB understanding; (b) factive mental terms such as *zi1dou6* ("know") will predict KA; and (c) mental terms that denote emotions, such as *hou2hoi1sam1* ("happy"), will predict HE.

Objectives: To examine whether knowledge of the factivity semantics of six mental terms, including three factive ones (*hou2hoi1sam1* ("happy"), *zi1dou6* ("know"), and *ng4gei3dak1* ("forget")) and three strong non-factive ones (*ji5wai4* ("falsely think"), *ng6wui6* ("mistakenly think"), and *waan6soeng2* ("imagine")), predict the five ToM skills in Wellman and Liu (2004) in Cantonese-speaking children with and without ASD.

Methods: 40 Cantonese-speaking children with ASD (mean age = 6.91, *SD* = 1.47) and 60 TD children matched on language ability (mean age = 6.22, *SD* = 0.94) participated in this study. A Cantonese version of Wellman and Liu's (2004) five ToM tasks was used to assess participants' understanding of the five ToM skills. Knowledge of the factivity semantics of mental terms was evaluated on the basis of participants' ability to judge the truth/falsity of the complement clauses following factive and strong non-factive mental terms. Participants' language ability and nonverbal intelligence were measured using the Test of Hong Kong Cantonese Grammar (T'sou et al., 2006) and the Primary Test of Nonverbal Intelligence (Ehrler & McGhee, 2008), respectively. All participants' scores for language ability and nonverbal intelligence were within the normal range.

Results: Hierarchical multiple regressions were conducted to examine the unique contribution of the factivity semantics of mental terms to the five ToM skills. After the effects of age, language ability, and nonverbal intelligence were controlled for, the results showed that autistic children's understanding of *zi1dou6* ("know") significantly predicted DD and KA, and their understanding of the three strong non-factive mental terms significantly predicted CFB. In TD children, *ng4gei3dak1* ("forget") was found to predict DD and CFB, and *hou2hoi1sam1* ("happy") was found to predict HE.

Conclusions: The present study partially confirmed our hypotheses: (a) *zi1dou6* ("know") significantly predicted KA; (b) the three strong non-factive mental terms significantly predicted CFB in children with ASD; and (c) *hou2hoi1sam1* ("happy") significantly predicted HE in TD children. However, contrary to our hypothesis, *ng4gei3dak1* ("forget") significantly predicted CFB in TD children. These findings suggest that children with ASD rely on knowledge of strong non-factive mental terms for CFB understanding, whereas TD children rely on knowledge of the factive mental term *ng4gei3dak1* ("forget") for CFB understanding.

414.061 *(Poster)* Relationship between Parental Education and Communication Levels for Children at Risk for Autism Spectrum Disorder

K. Tuohy*, C. Gelep, A. Kniola and S. Char, Mailman Segal Center for Human Development, Nova Southeastern University, Ft. Lauderdale, FL*

Background: Previous research consistently found a link between socioeconomic status (SES) and autism spectrum disorder (ASD; Bhasin & Schendel, 2007; Durkin et al., 2017). Parental education is one factor that is closely related to SES that may play a role in the diagnosis and presentation of ASD. Past research has mainly focused on maternal education and showed that more than 16 years of maternal education was related to an increased risk for ASD by more than twofold (Bhasin & Schendel, 2007). However, social communication has shown to be lower among those with lower maternal education in children with and without ASD (Rosenberg et al., 2018).

Objectives: This study aims to add to this body of research and to determine whether parental education is associated with communication level for children at risk for and diagnosed with ASD. Based on the above findings it is hypothesized that both maternal and paternal education will be positively correlated with the Communication domain of the *Vineland Adaptive Behavior Scale, Second or Third edition, Parent/Caregiver Rating Form* (*Vineland-II, 3*).

Methods: Participants included 239 children who completed a comprehensive developmental assessment at a community-based developmental assessment clinic over the span of three years. Out of the 239 participants, 158 participants were diagnosed with ASD (66.1%) after completing a comprehensive developmental assessment. 75.7% of the participants were male and the mean age was approximately 68.54 months (SD = 43.68). The sample consisted of 30.5% White children, 27.2% Latinx children, 19.2% Black children, 11.3% Biracial children, 2.5% Asian children, 2.1% other, and there was about 7.1% missing information on ethnicity. Twenty participants were excluded from the maternal education correlation due to missing information while 47 participants were excluded from the paternal education correlation. The participants completed a developmental assessment that included the *Vineland-II, 3*as part of the testing battery (Sparrow, Cicchetti, & Balla, 2005; Sparrow, Cicchetti, & Saulnier, 2016).

Results: There was a significant positive correlation between maternal education and the Vineland's Communication domain (r = .228, p = .001). However, paternal education and the Vineland's Communication domain were not significantly correlated (r = .384, p = .064).

Conclusions: The hypothesis was partially supported because these results revealed that higher maternal education is linked to better communication for children at risk for or diagnosed with ASD. These results support previous findings and may be explained by the idea that mothers with higher education use more expressive communication and gestures with their children, which may increase the child's understanding and use of communication.

414.062 *(Poster)* Sensory Processing Behaviors Relate to Listening Comprehension and Oral Expression in ASD

K. M. Parks[1]*, E. Anagnostou*[2]*, E. Kelley*[3]*, R. Nicolson*[4]*, S. Georgiades*[5]*, X. Liu*[6] *and R. A. Stevenson*[7]*, (1)The University of Western Ontario, London, ON, Canada, (2)Holland Bloorview Kids Rehabilitation Hospital, Toronto, ON, Canada, (3)Queen's University, Kingston, ON, Canada, (4)University of Western Ontario, London, ON, Canada, (5)McMaster University, Hamilton, ON, Canada, (6)Genomics, Queen's Genomics Lab at Ongwanada, Kingston, ON, Canada, (7)Western University, London, ON, Canada*

Background: Issues related to sensory processing are a defining feature of autism spectrum disorder (ASD). Sensory processing issues occur in several modalities including vision, audition, and touch, and can impact how a child modulates and interprets incoming sensory information from the environment. Additionally, language and communication issues are core diagnostic features in ASD. Difficulties related to language and communication can include restricted expressive and receptive language, limited comprehension of verbal and non-verbal cues, and reduced vocabulary. Importantly, communication and language development are reliant upon successful sensory perception. Despite this, little attention has been devoted to examining whether increased issues in sensory function relate to reduced comprehension and expression in ASD.

Objectives: We aimed to test whether sensory issues relate to reduced listening comprehension and oral expression in autistic children.

Methods: Participants (N=442) included autistic (*n*=280, *mean age*=11.05±4.19) and typically-developed children (TD; *n*=162, *mean age*=11.41±4.55). The Oral and Written Language Scales (OWLS-II) was administered to children to assess listening comprehension and oral expression. Parents completed a well-established questionnaire assessing sensory processing (Short Sensory Profile; SSP). Linear regressions were performed for the autistic and TD children to assess if the seven sensory domains on the SSP (*Tactile, Taste/Smell, Movement, Sensory Seeking, Auditory Filtering, Low Energy*, and *Visual/Auditory*) predicted listening comprehension and oral expression.

Results: The SSP significantly predicted listening comprehension in autistic ($F(7,255)=4.31$, $p<.001$), but not TD children ($F(7,153)=.29$, $p=.959$). With autistic children, the subscales *Movement, Sensory Seeking, Auditory Filtering,* and *Low Energy* were all individually predictive. Increased *Movement* and *Sensory Seeking* subscales were related to increased language scores for autistic children whereas *Auditory Filtering* and *Low Energy* were related to *decreased* language scores. The SSP also significantly predicted oral expression in autistic children $F(7,246)=2.72$, $p=.010$, with the subscales *Tactile, Movement,* and *Sensory Seeking* being individually predictive. Interestingly, the SSP also predicted oral expression in TD children $F(7,153)=2.19$, $p=.038$, but only the *Auditory Filtering* subscale was individually predictive (see Table for statistics).

Conclusions: Our findings indicate that atypical sensory processing significantly relates to the comprehension and use of language in autistic children. In particular, *Auditory Filtering* and *Low Energy* were negatively related to listening comprehension, but not oral expression in autistic children. Surprisingly, the two subscales reflecting increased sensory input (*Sensory Seeking* and *Movement*), were positively related to listening comprehension *and* oral expression in autistic children. This pattern indicates that sensory processing has a unique impact on autistic children that is not apparent in TD children. To our knowledge, this is the first data to show that sensory behaviors related to increased language abilities in autistic children are reflective of the quantity of incoming sensory information as oppose to the manner in which it is processed, and that sensory behaviors related to decreased listening comprehension, in particular, are reflective of decreased sensory engagement in autistic children. Overall, our findings demonstrate the importance of sensory processing in language outcomes in autistic children as well as the importance of sensory processing in language abilities more broadly across development.

414.063 *(Poster)* Service Utilization of Minimally Verbal Individuals with Autism

S. C. Brandjord[1] *and A. N. Esler*[2]*, (1)Educational Psychology, University of Minnesota, Minneapolis, MN, (2)University of Minnesota, Minneapolis, MN*

Background: While outcomes are improving, about 20-30% of people with autism remain minimally verbal (Tager-Flusberg & Kasari, 2013), defined as using single words or less (Thurm et al., 2015). Families of minimally verbal individuals typically face high care-related costs, as their children have higher rates of co-occurring health conditions, including gastrointestinal disorders, neurological conditions, feeding difficulties, and sleep disorders (Carr & Owen-DeSchryver, 2007), as well as challenging behaviors (Goodwin et al., 2018) compared to individuals with ASD and functional language. The minimally verbal end of the spectrum is traditionally understudied in autism research and underserved clinically (Siegel, 2018), and an important area of investigation is how families access services and supports for their children (Becerra et al., 2017).

Objectives: To understand the medical, intervention service, financial support, and family systems needs of families of minimally verbal individuals with autism.

Methods: An online survey was developed and disseminated to identify services families currently are receiving, their perceived efficacy, and the services they would like to receive but are currently unable to access. Parents/caregivers also were asked about barriers to obtaining services. Participants were recruited from the Simons Powering Autism Research for Knowledge (SPARK) genetics study.

Results: A total of 608 caregivers completed the survey. The individuals they reported on ranged in age from 4 to 52 (M = 10.78), with 83 age 18 and up, and were predominantly male (80%) and white (71%), with 99% of individuals having been professionally diagnosed with ASD. Only 21% of respondents felt there were no treatment services or supports needed for their child at this time. Medical services identified as most needed by families were: biomedical (23%), dietary intervention (22%), and genetics (17%). Most needed interventions were social skills training (41%), in-home supports (33%), applied behavior analysis (32%), and leisure opportunities (25%). The most frequently rated barriers to obtaining desired services included insufficient financial resources (58%), resources unavailable within the community (56%), being unable to find resources (47%), and a waitlist that is too long (42%).

Conclusions: Results confirmed that families of minimally verbal children are not accessing a variety of services they feel are needed. Provider shortage and service cost were persistent barriers, highlighting the need for policies and resource allocation that improve financial supports for families, as well as expand training, recruitment, and retention of professionals and support workers.

414.064 *(Poster)* Speech Prosody Predicts Social Competence in Children without but Not Those with ASD

A. T. DeBoice[1], *N. E. Scheerer*[2,3], *E. K. McClay*[1], *M. Gurm*[2], *T. Q. Boucher*[2], *H. Yeung*[1] *and G. Iarocci*[2], *(1)Simon Fraser University, Burnaby, BC, Canada, (2)Psychology, Simon Fraser University, Burnaby, BC, Canada, (3)Psychology, Western University, London, ON, Canada*

Background: In communication, speakers vary their speech prosody to convey changing emotional states. Abnormal speech prosody, such as atypical intonation, rate, and rhythm of speech are common characteristics seen with individuals diagnosed with Autism Spectrum Disorder (ASD). These atypicalities can be indicative of the child's ASD severity and are associated with how others perceive their social competence, which may consequently impede typical social development. More recently, it has also been shown that these speech characteristics can influence how others communicate with individuals with ASD.

Objectives: The objective of the current study was to: (1) examine whether a child's social competence may be predicted from their prosodic speech features and (2) to explore how prosodic properties of parent's speech may be indicative of their child's autism characteristics and/or social competence.

Methods: Twenty children with and twenty without ASD participated in this study, along with their parents. Participants were matched by diagnostic group, and did not significantly differ in age ($t(38)$=-.53, p=.60) or IQ ($t(38)$=1.53, p=.14). Participants were excluded if they had an IQ<70; one TD child was excluded as their IQ data was more than 2 SD from the group. Parents completed the Multidimensional Social Competence Scale (MSCS) to measure their child's social competence. Children and parents were asked to build a Lego object. Mean fundamental frequency (F0), pitch range, pitch variability, and spontaneous speech were extracted from recordings of the dialogue between the parent and child as they completed this task.

Results: A hierarchical regression indicated that age and sex did not predict MSCS scores for children with or without ASD. When the children's mean F0, pitch range, pitch variability, and spontaneous speech scores were added to the model, these speech characteristics increased the significance of the model for the children without (R^2=.777, F(6,12)=6.981, p=.002), but not the children with, ASD (R^2=.025, p=.999). A significant proportion of the variance in the MSCS scores of the children without ASD was accounted for by mean F0 (p<.05), and pitch range (p<.01).

To assess the relationship between parent's speech characteristics and their child's social competence, a hierarchical regression was conducted to see whether, the parent's speech characteristics could predict their child's social competence (after controlling for the parent's age). Age alone was not a significant predictor, but when the speech characteristics were added to the model, significant variance in MSCS scores of children with, but not without, ASD was accounted for (R^2=.653, F(5,14)=5.267, p=.006). Specifically, the amount of spontaneous speech produced by the parents accounted for significant variance in their child's social competence (p<.05).

Conclusions: The results indicate that among children without ASD, there is a relationship between the development of speech characteristics and social competence. This pattern was not found for autistic children suggesting that the development of their speech communication skills is separate from their social skill development. The speech of parents of children with, but not without, ASD was found to predict their child's social competence; this may reflect an attempt by these parents to scaffold their child's speech communication.

414.065 *(Poster)* Spontaneous Linguistic Alignment Is Reduced and Less Flexible in Children with ASD

R. Fusaroli[1], *E. Weed*[1], *D. A. Fein*[2] *and L. R. Naigles*[2], *(1)Aarhus University, Aarhus, Denmark, (2)Psychological Sciences, University of Connecticut, Storrs, CT*

Background: Social impairment in ASD has been associated with an impaired ability and propensity to imitate others. However, the extent and form of impairment in imitation in ASD is still unclear. Here we focus on linguistic alignment: the tendency to re-use an interlocutor's words ("mommy, give me the *giraffe*", "is that a *giraffe*?"), and syntax ("the giraffe *has fallen*", "yes and the elephant *has gone* to help her"). Previous studies indicated typical alignment in (low support needs) participants with ASD involved highly structured, task-oriented conversations. Given the centrality of alignment in establishing common ground and rapport in social interactions, we need to assess whether alignment is typical also in everyday unscripted conversations.

Objectives: We investigated i) the developmental trajectory of linguistic alignment in children with ASD and typically developing children during spontaneous parent-child interactions; ii) whether the trajectory is affected by the clinical and cognitive features of the child.

Methods: We analyzed spontaneous speech in 67 parent-child dyads from a longitudinal corpus (30 minutes of play activities, 6 visits over 2 years). We included 32 children diagnosed with ASD and 35 linguistically matched TD children (mean age at recruitment respectively 32.76 and 20.27 months). Alignment was calculated using the ALIGN Python library (Duran et al., 2019). We first contrasted child alignment in actual conversations with that in surrogate pairs formed by a parent and a child from two different dyads. We used Bayesian multilevel zero-and-one-inflated beta regression models. This accounts for the propensity of children to align at all (rate), the number of linguistic forms aligned on average when the children actually align (level[a]), and exact repetitions, as a function of diagnostic group, visit, Vineland Socialization (VS), Mullen Expressive Language (MEL) and Visual Reception (MVR).

Results: See table for details. Children in both groups consistently align their lexical and syntactic choices to their parents beyond the surrogate-pair baseline. The number of utterances with any form of alignment increases with age in both groups, albeit less so for children with ASD. Further, the actual number of linguistic forms aligned in those utterances decreases with age and more so in the TD children. This indicates that as they grow, children might engage more in their parents' linguistic production by reusing their words and syntax, but they do so more flexibly and employ them in slightly different constructions (thus reducing the level of alignment).

Verbal skills were positively related to alignment rate in both groups, but negatively to alignment level (for both groups on syntactic levels and only the ASD group for lexical levels). Socialization skills were positively related to lexical alignment rate for both groups, and to the increase in syntactic alignment rates for both groups. They were also strongly negatively related to syntactic alignment levels. No relation was found with MVR.

Conclusions: While the ability to align might be intact, we observe fewer and more rigid instances of spontaneous alignment in ASD modulated by both verbal and socialization skills.

414.066 *(Poster)* Subgroup Identification of Speakers with and without ASD Using Network Models of Acoustic Features of Prosody and Voice

E. Weed[1]*, R. Fusaroli*[1]*, J. Mayo*[2] *and I. M. Eigsti*[3]*, (1)Aarhus University, Aarhus, Denmark, (2)University of Connecticut, West Hartford, CT, (3)Psychological Sciences, University of Connecticut, Storrs, CT*

Background: Untrained peers can recognize an atypical quality to the speech of some people with ASD (Grossman, 2015; Redford et al., 2018). Although certain acoustic features such as pitch range (Nadig & Shaw, 2012) have been shown to be important groupwise factors for distinguishing between ASD and TD speech, no clear pattern of features associated with the speech of people with ASD has yet been shown, and the speech of people with ASD has been described confusingly as e.g. both "monotonous" and "variable," "stilted" and "exaggerated" (Fusaroli et al., 2017). This raises the intriguing possibility that while autistic speech may sound atypical, this atypicality may manifest in different ways in different individuals. Because speech quality is defined by a complex set of interrelated acoustic variables, we used network models to explore the multivariate space describing the speech qualities to which raters respond.

Objectives: Study goals were (1) to identify potential sub-groups of typical and atypical speakers, using acoustic features of prosody and voice, and (2) to describe the vocal and prosodic qualities characteristic of these subgroups.

Methods: We analyzed speech data (8 scripted sentences per participant) from 15 adolescents diagnosed with ASD (mean age = 14.4 years, SD = 1.48) with IQ scores in the typical range, and 15 adolescents with typical development (TD; mean age = 14.1 years, SD = 1.91); groups did not differ on chronological age or full-scale IQ. Participants in both the ASD and the NT groups demonstrated average to high average performance on standardized language measures (see Mayo, 2015, for details). These recording were categorized by 15 naive raters as "typical," "somewhat unusual," or "definitely atypical." Acoustic features extracted from the participants' speech were used to build a network of speakers, using positive and negative partial correlations between acoustic variables to define the strength and direction of the connections. A community-detection algorithm (Reichardt & Bornholt, 2006) was used to identify acoustic profiles of speakers.

Results: When speakers were modeled as nodes in a network, they clustered roughly in correspondence to their classification as "typical" or "atypical" by naive raters. The community detection algorithm identified four acoustic profiles among the speakers. One profile contained primarily speakers characterized as "typical," while the other three showed distinct patterns of acoustic quantities. Atypical speakers were distinguished from typical speakers by slower speech rate, but atypical speakers were also distinguished from each other primarily by different patterns and degrees of breathiness and nasality.

Conclusions: These results suggest that while the acoustic patterns of typical speakers tend to resemble one another, there may exist identifiable subgroups of atypical speakers. Although the community detection algorithm was free to identify up to ten different groups, it identified only four meaningfully different clusters of speakers, suggesting that similarities between atypical speakers within each subgroup were stronger than their differences. These data point toward the possibility of moving beyond broad descriptions such as "monotonous" toward a more nuanced understanding of the different types of atypical prosody and voice quality in ASD.

414.067 *(Poster)* Talking More and Pausing Less: Girls with ASD Behave Differently during Brief Natural Conversations

S. Cho[1]*, M. Liberman*[1]*, C. Cieri*[1]*, N. Ryant*[1]*, M. L. Cola*[2]*, V. Petrulla*[2]*, L. D. Yankowitz*[2]*, J. Pandey*[2]*, R. T. Schultz*[2] *and J. Parish-Morris*[2]*, (1)Linguistic Data Consortium, University of Pennsylvania, Philadelphia, PA, (2)Center for Autism Research, Children's Hospital of Philadelphia, Philadelphia, PA*

Background: Autism spectrum disorder (ASD) is primarily diagnosed in boys (4:1; Baio et al., 2018), with greater male:female ratios in higher IQ ranges (10:1; Lord & Schopler, 1985). However, a recent meta-analysis suggests that ASD girls have been underdiagnosed and thus excluded from many studies (Loomes et al., 2017), rendering it urgent to understand this subgroup. Previous studies demonstrate atypical conversational behaviors in children with ASD relative to typically developing (TD) peers (Capps, Kehres, & Sigman, 1998), but few studies have included sufficient numbers of girls to assess sex differences, and even fewer have explicitly compared autistic girls to typical girls. This study begins to fill that gap by analyzing speech/pause duration in a large sample of boys and girls with and without ASD.

Objectives: Measure effects of sex and diagnosis on quantitatively derived speech/pause patterns in girls and boys with and without ASD during natural conversations.

Methods: Ninety-two ASD (n=45, 16 girls, mean age=11.46) or TD (n=47, 24 girls, mean age=10.06) children, matched on IQ and sex ratio but not on age (p=0.02; included as a covariate in all analyses; Table), completed 5-minute "get-to-know-you" conversations with a young adult confederate (n=25, 22 females). Trained annotators transcribed and time-stamped audio recordings. An in-house GMM-HMM based Speech Activity Detector automatically time- segmented audio files into speech/silence segments. We automatically diarized speakers using Python, and manually reviewed diarization. Silence segments were coded as within-turn or between-turn silence. Between-turn silences were further coded as Confederate-to-Participant or Participant-to-Confederate, depending on the direction of the turn change. The number and duration of segments with overlapping speech did not differ by group, and were excluded from analyses. We measured duration and rate (per minute) of speech/silence segments and total speech time for each participant. Features were compared by group and related to clinical measures to understand individual differences in ASD participants. Total duration of conversations did not vary by group (p=0.63), but was covaried in all analyses.

Results: ASD girls spoke the longest (vs. TD girls: p=0.017; vs. ASD boys: p=0.014; vs. TD boys: p=0.012; Fig.1A) and produced more speech segments than other subgroups (vs. ASD boys: p=0.014; vs. TD girls: p=0.018; vs. TD boys: p=0.011; Fig.1B). ASD girls' mean speech segment duration was longer than TD girls (p=0.031; Fig.1C), and ASD girls produced more within-turn pauses than ASD boys (p=0.042) and TD boys (p=0.018; Fig.1D). ASD girls' between-turn (Confederate-to-Participant) silence (i.e., latency to respond) was shorter than ASD boys (p=0.01; Fig1.E) and less frequent than TD girls (p=0.012) and ASD boys (p<0.001; Fig.1F). Frequent within-turn pauses predicted higher adaptive behavior scores and improved social responsiveness scores for ASD girls – but not boys (Table 1).

Conclusions: ASD girls speak differently than ASD boys, but may differ from TD girls and boys as well. Conversational behaviors that conflict with a male-referenced conceptualization of ASD (e.g., greater volubility and faster conversational responding in girls) may interact with clinical biases to place girls at particular risk of under-diagnosis, thus reducing access to ASD-specific supports.

414.068 *(Poster)* Temporal Associations between Child Joint Attention and Mother Attention for Children with Autism during Naturalistic Social Interactions

A. Dakopolos *and L. B. Jahromi, Teachers College, Columbia University, New York, NY*

Background: During early development, an infant's maintenance of joint attention depends on their partner's skillful support (Adamson & Russell, 1999). Joint attention development is of particular importance for children with autism spectrum disorder (ASD), as they often demonstrate deficits in joint attention skills compared to their peers. Understanding the contingent relations between parental behaviors and their child's social communication behaviors during a social exchange may provide a clearer picture of contextual elements and behaviors of the social partner that may support joint attention in children with ASD.

Objectives: The purpose of the present study is to assess whether joint attention behaviors of children with ASD and their mother's social attention are temporally related during a social interaction.

Methods: Participants included 44 children with ASD (35 males; *Mage*= 49.33, *SD*= 10.01 months) and their mothers (*Mage*= 36.62, *SD* = 4.10 years). Two groups were created for subsequent analyses. The minimally-verbal group (n = 20) consisted of children who were administered ADOS-2 module 1, and the verbal group (n = 21) consisted of children who were administered either ADOS-2 module 2 or module 3. An adapted version of the Early Social Communication Scales (Mundy et al. 2003) was administered to capture children's initiations of joint attention (IJA; ICC = 0.74-0.89), and response to their mother's bids for joint attention (RJA, ICC = 0.72-1.0). Mother attention was measured using *dyadic orienting* (Leekam et al., 2006). An independent observer coded dyadic orienting as instances in which the child successfully made a *visual* (ICC = .85), *auditory* (ICC = .97), or *multisensory* (ICC = .87) bid for their mother's attention. Mother and child behaviors were coded in 15-second intervals. Contingency analysis identified lag-1 associations between child joint attention and subsequent mother dyadic orienting. A Yule's Q (odds ratio) was calculated, indicating the strength of contingency between child and parent behaviors (Bakeman & Gottman, 1997).

Results: Findings revealed that following intervals in which the child initiated joint attention, mothers were more attentive to their child's attentional bids in subsequent intervals (t (31) = 3.77, p < .001). Additionally, for intervals in which mothers attended to their child's bid for attention, children were more likely to initiate joint attention in the subsequent interval (t (28) = 3.96, p < .001). While child IJA and subsequent mother attention were contingently related, this relation was moderated by children's expressive (F (1, 24) = 4.25, p = .050) and receptive (F (1, 24) = 7.83, p = .009) language, and interacted differently for the verbal group compared to the minimally verbal group, such that language ability promoted the contingent relation for the minimally verbal group, but discouraged the contingent relation for the verbal group.

Conclusions: Mother attention promoted subsequent child IJA, and child IJA promoted subsequent mother attention. Children's language ability emerged as an important moderator of the contingency between child IJA and mother attention. Mothers may hold expectations or assumptions about their child's communicative abilities that inform how they attend or respond to them socially.

414.069 *(Poster)* Test-Retest Reliability of Linguistic Variables Derived from Short Semi-Structured Conversations in Individuals with and without ASD

V. Petrulla[1]*, M. L. Cola*[1]*, L. D. Yankowitz*[1]*, A. Riiff*[1]*, S. Plate*[1]*, K. Bassanello*[1]*, A. Pomykacz*[1]*, J. Pandey*[1]*, E. S. Brodkin*[2]*, R. T. Schultz*[1] *and J. Parish-Morris*[1]*, (1)Center for Autism Research, Children's Hospital of Philadelphia, Philadelphia, PA, (2)Department of Psychiatry, University of Pennsylvania, Philadelphia, PA*

Background: Social communication is a core challenge in autism spectrum disorder (ASD), but has proven difficult to reliably measure, especially in natural contexts that generalize well to everyday function. The Contextual Assessment of Social Skills (CASS; Ratto, Turner-Brown, Rupp, Mesibov, & Penn, 2011) is a short, semi-structured conversation used to measure social skills in individuals with ASD. Analyzing linguistic behavior during the course of a short conversation can shed light on a person's vocal-motor phenotype, personality, volubility, as well as their internal thoughts, feelings, and interests (Tausczik & Pennebaker, 2010). Even something as simple as how talkative a person is when meeting someone new can serve as a marker of social and conversational skill (Ratto, et al., 2011). Despite the potential for using natural language processing to analyze conversational behavior as a fine-grained phenotypic outcome measure in social communication treatment research, few conversation tasks have established (1) test-retest reliability between administrations and (2) applicability across a range of ages and cognitive ability levels.

Objectives: In this study, we assess the test-retest reliability of linguistic behaviors produced during short, semi-structured conversations from individuals of different ages and cognitive ability levels.

Methods: Thirty-two participants aged 6-24 with ASD and of typical development (TD, Table 1) participated in two sets of two 3-minute CASS conversations with four novel confederates. The first confederate in each set acted interested in the participant (Interested condition), while the second acted bored (Bored condition). Trained undergraduate raters orthographically transcribed audio recordings of both sets of conversations. R packages for text-mining, LIWC (Tausczik & Pennebaker, 2010), and in-house scripts were used to extract participant word count and percentage of time spent talking from the transcribed conversations. Test-retest reliability of separate linguistic variables was compared by condition, between administrations, using two-way absolute agreement intraclass correlations (irr in R, Gamer et al., 2019).

Results: Intraclass correlations revealed good (Interested condition; ASD ICC=0.73, TD ICC=0.6, Fig. 1) and excellent (Bored condition; ASD ICC=0.88, TD ICC=0.78, Fig. 1) correlations between conversation administrations in participant word count (Cicchetti, 1994). Talking percentage indicated a similar pattern (Interested condition: ASD ICC=0.63, TD ICC=0.73; Bored: ASD ICC=0.83, TD ICC=0.80), demonstrating the CASS conversation's ability to capture consistent information between administrations among individuals across a wide range of ages and with significantly different cognitive levels.

Conclusions: A snapshot of an individual's social communication phenotype in a natural setting can provide useful information for screening, diagnosis, prediction, and treatment planning. Using word count and talking percentage, we determined that in both the Interested and Bored conditions, the CASS demonstrates good and excellent test-retest reliability, respectively. This was true for both the ASD and TD groups. Importantly, test-retest reliability remained high despite significant variance in the cognitive levels and ages of both ASD and TD participants. Data collection for this project is ongoing. We anticipate that our sample will double by April of 2020, which will allow us to analyze a larger range of linguistic variables and assess potential moderators of test-retest reliability (e.g., sex, IQ, and symptom severity).

414.070 *(Poster)* Testing the Reliability of the Autism Classification System of Functioning: Social Communication – Integrated for Children and Youth Ages 2 to 18 Years

B. Di Rezze[1], *P. Rosenbaum*[2], *M. J. C. Hidecker*[3], *L. Zwaigenbaum*[4], *C. Roncadin*[5], *E. Duku*[1], *S. J. Gentles*[1], *S. Georgiades*[1], *H. Viveiros*[6] *and H. Fang*[1], *(1)McMaster University, Hamilton, ON, Canada, (2)CanChild Centre, McMaster University, Hamilton, ON, Canada, (3)Communication Disorders, University of Wyoming, Laramie, WY, (4)University of Alberta, Edmonton, AB, Canada, (5)Autism Spectrum Disorder Service, McMaster Children's Hospital - Hamilton Health Sciences, Hamilton, ON, Canada, (6)Pediatrics, McMaster University, Hamilton, ON, Canada*

Background: The Autism Classification System of Functioning: Social Communication (ACSF:SC) is a 5-level classification system that operationalizes 'levels' of social communication functioning in ASD, providing a common language and basis to stratify children according to ability within a clinical setting, and in research. The ACSF:SC can be used by parents and professionals use the same levels to complete two ratings based on a child's observed social communication – the child's best capacity and their typical performance. It was first developed for preschool children with ASD (ages 3 to <6 years) among whom its psychometric properties have been established. Recently, the ACSF:SC has been revised through content validity testing to both toddler (ages 2 to <3 years) and school-aged children (6-21 years) creating the ACSF:SC-Integrated. With this expanded age-range, reliability testing is a necessary next step to be tested with parents and professionals to ensure consistency in reporting for the population of children/youth with ASD.

Objectives: To test the intra- and inter-rater reliability of the ACSF:SC-Integrated in children and youth with ASD ages 2 to 18 years.

Methods: Using recruitment methods ranging from direct in-clinic contact to online outreach, we approached families of 227 children/youth with ASD (across 3 Ontario sites, 2 Alberta sites, and families engaged in previous ACSF:SC studies). One parent and two professionals completed the ACSF:SC -Integrated for each child with ASD twice, approximately 4-6 weeks apart. Intra- and interrater reliability of the ACSF:SC-Integrated was assessed using weighted Cohen's kappa (κ_w) with quadratic weights.

Results: At the time of first classification using ACSF:SC-Integrated by parents, 78 children/youth were classified. Children characteristics included 62 males, mean age 6.5±3.5 years, and mean age range 2.1-15.6 years, respectively. For age breakdown of sample, 12 aged 2 to <3 (10 males, age 2.5±0.2 years), 29 aged 3 to <6, 36 (21 male, age 4.3±0.9 years), 35 aged 6 to 16 (31 males, age 9.6±2.6 years). Professionals had a range of backgrounds, including teachers/educational assistants (n=7), early childhood educators (n=2), ABA therapists (n=5), Speech-Language Pathologists (n=5), physicians (n=2), occupational therapists (n=1), and others (n=7). Intra-rater agreement results were as follows for best capacity and typical performance, respectively: for parents (n=49) κ_w= 0.66 (95% CI=.40-.92) and (n=50) κ_w= 0.76(95% CI=.52-1.00; for professional ratings (n=12) κ_w= 0.97 (95% CI=.92-1.00) and (n=11) κ_w= 0.92 (95% CI=.82-1.00). The inter-rater agreement between parents and clinicians were (n=28) κ_w= 0.64 (95% CI=.37-.92) and κ_w= 0.74 (95% CI=.58-.90), for best capacity and typical performance, respectively. Inter-rater reliability between the first and second professional will be analyzed when the sample-size increases as data continues to be collected, which will be updated for the conference presentation, in addition to existing analyses presented here.

Conclusions: Findings demonstrate reasonable consistency in rater agreement when parents and/or professional are completing the ACSF:SC-Integrated for children ages 2 to 16 years old. ACSF:SC-Integrated has similar or better intra and inter-rater agreement results than the previous ACSF:SC preschool version. Intra-rater agreements for parents and professionals were similar and at times exceeded agreement expectations.

414.071 *(Poster)* The Effects of Augmentative and Alternative Communication Interventions on Speech Production in Autism Spectrum Disorder: A Systematic Review and Meta-Analysis

O. Wendt[1]*, R. W. Schlosser*[2] *and M. Moeyaert*[3]*, (1)Communication Sciences and Disorders, University of Central Florida, Orlando, FL, (2)Northeastern University, Boston, MA, (3)Educational and Counseling Psychology, University at Albany, State University of New York, Albany, NY*

Background: Approximately 25-35% of individuals with autism spectrum disorder (ASD) present with little or no functional speech and are candidates for augmentative and alternative communication (AAC). Despite documented effectiveness of AAC interventions, the autism field continues to face fears from stakeholders that the adoption or the continued use of AAC modalities may hinder the acquisition of natural speech. If left unanswered, this may lead families to postpone, or worse, reject AAC modalities altogether leaving their children less likely to reach their full potential.

Objectives: This project uses meta-analytic methods to aggregate and evaluate intervention literature with respect to:

1. What are the effects of AAC interventions on speech production?
2. Are included AAC interventions effective in terms of AAC outcomes?
3. Do some types of AAC interventions (e.g., PECS, manual signs, electronic devices, multimodal AAC) yield more effective speech outcomes?
4. Is there a relation between the effectiveness of AAC outcomes and speech?
5. Are the gains in speech greater when the speech measure is related to the vocabulary of the AAC modality as opposed to generalized speech measures?
6. Do published studies yield more effective speech compared to unpublished work?
7. Are pre-intervention vocal imitation skills a predictor of speech gains?
8. Are the gains in speech greater with speech output from devices/applications relative to without speech output (e.g., communication boards)?

Methods: A multi-faceted search strategy will include: (a) several general-purpose databases; (b) publisher databases (e.g., ScienceDirect, Sci-Hub, Scopus); (c) six trial registers for unpublished trials; (d) reference lists of included studies; (e) forward citation searches of included studies; and (f) contacting authors of included studies. To aid data extraction we will prepare a coding form and manual to code each study in terms of: (a) Participant characteristics; (b) AAC approach; (c) treatment intensity; (d) intervention design; (e) speech production design; (f) generalization design; (g) maintenance design; (h) type of speech; (i) speech measurement technique; (j) IOA, % of sessions, observer status; (k) treatment integrity, measure, % of sessions, and observer status; (l) outcomes (speech & AAC outcomes); (m) magnitude of effects: implementation of latest effect size metrics for individual study analysis as well as aggregation of group and single-case designs; and (n) risk-of-bias assessment using the PEDro scale for group experimental designs, the Single-Case Experimental Design Scale, and the EVIDAAC Single-Subject Scale. Reliability of study inclusion and coding will be established.

Results: This project will update and extend an earlier review by Schlosser and Wendt (2008). At the time, nine SCED studies (27 participants) and two group studies (98 participants) were included, providing evidence that AAC interventions do not impede speech production. More detailed analyses found that observed gains varied across individuals and were rather modest.

Conclusions: Conclusions of the previous review will be revised consistent with the updated data set and analyses; refined intervention protocols and innovations in AAC technologies over the last decade may have led to improved outcomes. Advances in clinical AAC research may also allow to identify potential predictors of speech acquisition. Presenters will draw implications for clinical practice and future research.

414.072 *(Poster)* The Emotional Valences of Negative Passive Sentences in Japanese By Adults with ASD Tendencies

K. Yorozuya[1]*, J. Adachi*[2]*, M. Saito*[3] *and R. Yorozuya*[4]*, (1)Educaiton, Hokkaido University, sapporo, Japan, (2)Graduate School of Education, Hokkaido University, Sapporo, Japan, (3)Department of Special Education, Hokkaido University of Education, Sapporo, Sapporo, Japan, (4)Department of English Language Education, Hokkaido University of Education, Sapporo, Sapporo, Japan*

Background: As Lartseva, Dijkstra, and Buitelaar (2015) point out, although people with ASD are able to correctly classify emotional language stimuli as emotionally positive or negative, there is still a need to investigate ASD people's difficulty in processing subtle meanings of emotional language.

In the Japanese language, there are two types of passive, namely "direct passive" sentences with clearly stated subjects and "indirect passive" sentences with implied subjects.

In order to expand the scope of this research field, this study investigates ASD people's capacity to judge subtle emotional valences of passive sentences in Japanese.

Objectives: The purpose of this study is to verify the hypothesis that ASD people tend to have difficulties in understanding the subtle negative connotations of indirect passive sentences with implied subjects. By studying such difficulties of people with ASD tendencies, we can gain insights into the characteristics of ASD people's interpretation of linguistic stimuli.

Methods: Twelve adults with ASD tendencies judged the emotional valences of fifteen direct and fifteen indirect passive sentences, both types depicting various degrees of negative emotional valences . The subjects responded by indicating the degree of emotional valences on a continuum of a line ranging from negative to positive, a measurement instrument called a Visual Analogue Scale (VAS). The distances (millimetres) of their slash marks were measured from the zero point in the middle of a line between the negative and the positive extremes on each end. Their response data are compared with those of a Control group of a hundred and six adults (university students) without ASD tendencies. The ages of the adults with ASD tendencies ranged from 18 to 25, and those of adults without ASD tendencies ranged from 19 to 22.

Results: Both of the Control group and the ASD group showed a significant difference between indirect and direct passive sentences（$P < .001$, $d = 0.98$; $P = 0.003$, $d = 0.93$).

For the direct and indirect passive sentences there were no differences between the ASD group and the Control group. However, whereas the Control group judged ALL the indirect passive sentences as having negative emotional valences, the judgments of the adults with ASD tendencies fluctuated and some of them even judged some indirect passive sentences as having neutral or positive emotional valences.

Conclusions: Based upon the above results, it can be said that some people with ASD tendencies have difficulties in interpreting the subtle meanings of indirect passive sentences which lack clear subjects. The implication of this study relates to the need for caretakers and teachers to be aware of such difficulties that people with ASD face in daily communication in the Japanese language, and pay due considerations to support their well-being in the society.

414.073 *(Poster)* The IQ Discrepancy Differentiates the Language Delay in ASD Children

*S. W. Hsu[1], F. P. Kung[2], C. J. Fang[3], K. L. Chen[4] and **T. Y. Yu**[5], (1)Department of Urology, Antai Medical Care Corporation Antai Tian-Sheng Memorial Hospital, Pingtung, Taiwan, (2)Renton School District, Renton, WA, (3)Department of Occupational Therapy, San José State University, San Jose, CA, (4)Department of Occupational Therapy, College of Medicine, National Cheng Kung University, Tainan, Taiwan, (5)Department of Occupational Therapy, College of Medicine, I-Shou University, Kaohsiung City, Taiwan*

Background: IQ discrepancy (IQD) refers to the discrepancy between verbal and nonverbal intellectual abilities, indicating an atypical pattern of verbal-performance IQ differences (i.e., the distance between measured verbal [VIQ] and performance intelligence [PIQ] quotients). IQD appears to be related to several aspects of child development, but no studies have examined the association between IQD and language delay in children with autism spectrum disorders (ASD).

Objectives: The aims of the study were to establish whether 1) a group difference existed in the language delay among ASD children with different levels of IQD; 2) an association existed between IQD and language delay.

Methods: A total of 507 children with ASD were divided into three groups according to the size of the IQD: EVEN IQ (n=469; IQD within 1 SD), discrepantly higher VIQ (n=64; VIQ > PIQ above 1SD [≥ 15 points]), and discrepantly higher PIQ (n=74; PIQ > VIQ above 1SD [≥ 15 points]). Children with ASD were assessed with the Language Disorder Scale of Preschoolers (LDS) and Wechsler Preschool and Primary Scale of Intelligence™ – Fourth Edition (WPPSI™-IV) respectively to measure their language disability and determine their IQD. The LDS contains three subtests: overall language ability, listening comprehension, and oral expression. Each subtest could differentiate three groups: normal, borderline, and delayed. Chi-square tests were used to examine the relationships between IQD and language delay.

Results: The results indicated significant differences among the three subgroups ($p < 0.05$) in the LDS. The results of the LDS show that 313 children had language delay in overall language ability (61.7%); 224 children, in listening comprehension (44.2%); and 278 children, in oral expression (54.8%). The FIQ, VIQ, PIQ, and IQD in the WPPSI-IV were 76.20 (SD = 11.02), 77.61 (SD = 13.88), 78.28 (SD = 15.28), and 10.69 (SD = 7.99) respectively, all of which were below the FIQ of 100 in the psychometric curve. Chi-square tests showed that IQD was related to children's overall language ability, listening comprehension, and oral expression ($X^2 = 17.68$, df = 4, $p = .003$; $X^2 = 19.88$, df = 4, $p = .001$; $X^2 = 16.03$, df = 4, $p = .002$). Children with even IQD showed better language ability than did children with discrepantly higher VIQ or PIQ. Moreover, children with discrepantly higher VIQ were associated with better language ability than were children with discrepantly higher PIQ, and vice versa.

Conclusions: The results of this study showed that IQD was significantly associated with language delay in children with ASD. The results of this study could encourage clinicians, educators, and therapists to consider IQD when measuring children's language function and to analyze the patterns of language disability in preschool children with ASD. Possible language problems of children with ASD may be detected early based on routine evaluation of cognitive profiles. Furthermore, the language delay could be explained in terms of IQD. Professionals should pay attention to children's language problems when they have IQD.

414.074 *(Poster)* The Importance of Speech Sounds for Learning New Words

***N. Brady**[1], L. Williams[2] and C. Kosirog[2], (1)University of Kansas, Lawrence, KS, (2)Life Span Institute, University of Kansas, Lawrence, KS*

Background: Children with autism and minimal verbal skills differ according to the amount and types of speech sounds (phonemes) they produce. However, little attention has been given to how these differences may relate to progress in learning to speak (Biller & Johnson, 2019; (Brady et al., 2015)

Objectives: The purpose of this study is to examine how speech sound production relates to language measures including word productions measured concurrently, and 6 months later.

Methods: 26 Children (18 males and 8 females) between the ages of 60 and 100 months with autism and minimal verbal skills participated. The following measures were collected from each child at time 1: number of different consonants produced during a recorded sample at school; number of speech sounds and oral motor gestures imitated during an assessment; and phonemic scores derived from elicited speech attempts (Chenausky, Norton, Tager-Flusberg, & Schlaug, 2018; L. Williams, Pitt, Fleming, Becker, & Brady, 2018). The phonemic scoring provided differential weighting for accuracy of each phoneme in comparison to target production. The following word production measures were obtained at time 1 and 6 months later at time 2: # different words produced during production probes, scores from the Expressive Vocabulary Test (K. T. Williams, 2007), and Communication Complexity Scores (CCS Brady et al., 2018). CCS scores describe expressive communication during a naturalistic probe, with higher scores assigned to word productions. We ran simple correlations to determine relationships between speech sound production measures and word production measures.

Results: Significant moderate-large correlations were found between speech sound measures and the word production outcomes, as shown in Table 1.

Table 1. Correlations between speech sound and word production variables

	oral/verbal imitation	*# different consonants*	*Phonemic Scores*	*EVT Raw Score 1*	*EVT Raw Score 2*	*CCS Optimal*
oral/verbal	1.000					

imitation						
Total # of consonants	0.519	1.000				
Phonemic Scores	0.553	0.516	1.000			
EVT Raw Score 1	0.629	0.345	0.741	1.000		
EVT Raw Score 2	0.486	0.568	0.735	0.733	1.000	
CCS Optimal	0.334	0.428	0.405	0.443	0.516	1.000
Total # of Words	0.448	0.490	0.657	0.426	0.656	0.396

Of note, word production outcomes (EVT, and Total # words) were more strongly correlated to phonemic scores than oral/verbal imitation or number of different consonants.

Conclusions: These results indicate a strong relationship between children's speech sound production skills and their concurrent and future word productions. The phonemic scoring system provided a weighted score in which productions were given points for how closely they approximated target productions. Approximations of consonants and vowels were described with this scoring system. Our results provide further support for carefully assessing and treating speech sound productions as part of an overall communication program for children with autism.

414.075 *(Poster)* The Interrelationship of Speech Motor Control, Language and Prosody in Autism

C. E. Gargan *and M. V. Andrianopoulos, Department of Communication Disorders, University of Massachusetts, Amherst, MA*

Background: Research supports that differences exist in the acoustic-perceptual features of prosody in autism. The underlying mechanisms that contribute to prosodic differences are not well understood. Several hypotheses exist to explain prosodic impairment in autism, ranging from a lack of one's ability to 'tune in' to the speech environment and 'tune up' speech behaviors (Shriberg et al., 2011) to differences in language (Lyons, Simmons, & Paul, 2014), auditory processing (Bonneh, 2011), executive functioning (Filipe, 2018), and speech motor control (Velleman, Andrianopoulos, et al., 2010). It is important to investigate sensorimotor and cognitive linguistic processes and the impact they have on receptive and expressive prosody. The outcomes of such research can lead to a better understanding regarding the nature of prosodic differences in some individuals with autism, how to effectively assess prosody, and the development of evidence-based interventions.

Objectives: This research addressed the following questions: 1) Do individuals with autism perform with significantly less accuracy on structured receptive and expressive prosody tasks in comparison to Typically Developing (TD) controls; 2) Is performance on Alternate Motion Rate (AMR) and Sequential Motor Rate (SMR) tasks positively correlated with expressive prosody scores?; and 3) Are standardized receptive vocabulary scores positively correlated with expressive and receptive prosody scores?

Methods: A between-group study was conducted to investigate prosodic ability, as well as the degree of relationship between prosody, speech motor control, and language abilities in individuals with autism (n=17; 11 males, 6 females) in comparison to TD controls (n=17) matched for age, gender, and language. Participants were monolingual speakers of English, between 7;10 to 19;0 years of age. Experimental tasks included standardized receptive and expressive vocabulary testing, structured expressive and receptive prosody tasks, AMRs and SMRs. Testing was completed in a sound-treated, double-walled chamber with an ambient noise level of 25 dBA. Performance on the prosody tasks resulted in a composite receptive/expressive prosody score per participant. The AMR/SMR tasks were audio recorded using the Tascam multi-track digital recorder for each participant to determine the number of syllables produced per second, per task, using the Multi-Dimensional Voice Program. Between-group differences were studied using t-tests and/or Welch-Aspen t-test to control for unequal variances between groups. Pearson's correlation analyses were conducted to examine the degree of relationship between prosody, speech motor control and language.

Results: The individuals with autism performed with significantly less accuracy on receptive (p=.000) and expressive (p=.000) prosody tests compared to controls. Correlation coefficients between expressive prosody and AMR/SMR tasks are *very weak* to *weak* as follows: p^(r=.116); t^(r=.115); k^(r=.237); and p^t^k^(r=.04). There was a *moderately strong* correlation between receptive vocabulary and expressive prosody (r=.597) and a *strong* correlation between receptive vocabulary and receptive prosody (r=.7).

Conclusions: The outcomes show that some individuals with autism have impaired receptive and expressive prosody. Consistent with previous literature, the results demonstrate a strong connection between language and prosody. A weak positive relationship was revealed between speech motor control and prosody. Implications for future research will be discussed.

414.076 *(Poster)* The Relationship between Speech Prosody and Conversational Effectiveness in Youth with and without ASD

H. Lehnert-LeHouillier*, Communication Disorders, New Mexico State University, Las Cruces, NM*

Background: Deficits in speech prosody in individuals with autism spectrum disorders (ASD) are one of the hallmarks of the disorder and are often one of the earliest symptoms (Traeger-Flusberg et al., 2005). Prosodic impairment in individuals with ASD is reported to persist even if other areas of language improve (Peppé & McCann, 2003). Although verbal children and adolescents with high-functioning autism score well on prosodic tasks that are related to the grammatical structure of utterances (Paul et al., 2005; Peppé et al., 2011), their overall prosody is still perceived as odd by listeners (Filipe et al., 2014). Deficits in word and sentence level prosody in individuals with ASD have been the focus of prosody research in this population. However, the impact of prosody deficits on discourse and conversational level phenomena are as of yet not well understood. The current study contributes to the limited corpus of research investigating the relationship between prosodic abilities and conversational success in youth with and without ASD.

Objectives: The objective of the current study was to investigate the relationship between prosodic ability and conversational effectiveness in children and adolescents with and without ASD. It was hypothesized that those performing well on receptive and expressive prosody tasks would be more successful communicators at the conversational level.

Methods: A total of 28 children and adolescents between the ages of 9 and 15 years - 14 participants diagnosed with ASD and 14 age, gender, and non-verbal IQ matched neuro-typical peers - completed the current study. Each group consisted of 11 male and three female participants. All participants completed IQ and language testing, and the participants in the ASD group were also administered the ADOS-2. The prosodic abilities of all participants were assessed using the Profiling Elements of Speech Prosody in Communication (PEPS-C) (Peppé & McCann, 2003), and conversational effectiveness was assessed using the Diapix task (Baker & Hazan, 2011) – a goal oriented conversational task during which conversation partners engage in a conversation in order to find differences in a set of pictures. Conversational effectiveness was measured as the number of differences found per each minute of conversation. Results were analyzed using linear regression modeling.

Results: As expected, prosody skill as measured by PEPS-C scores were significantly different between the two groups with the neuro-typical peers scoring on average 16.4 points more than the ASD group ($F(1,26)=5.69$, $p=0.02$). The main predictor for conversational success was the time that conversation partners were engaged in the task ($\beta = -0.2$, $t=-12.544$, $p< 0.001$) with those who found the largest number of differences per minute also taking less time overall to complete the conversation. This was true for both groups. However, neither the total PEPS-C score nor the expressive or receptive prosody sub-scores were correlated with conversational success.

Conclusions: The results of this study suggest that prosodic ability does not impact how effective children and adolescents – regardless of ASD diagnosis - are in goal-oriented conversation.

414.077 *(Poster)* The Role of Imageability in Early Word Learning of Children with Autism Spectrum Disorder

K. R. Lin[1]*, L. Wisman Weil*[1]*, A. Thurm*[2]*, C. Lord*[3] *and R. J. Luyster*[1]*, (1)Communication Sciences and Disorders, Emerson College, Boston, MA, (2)National Institute of Mental Health, Bethesda, MD, (3)University of California, Los Angeles, Los Angeles, CA*

Background: Throughout typical development, children rely on perceptual, social, and linguistic cues to learn words (Hollich et al., 2000). Early words are often perceptually salient and highly imageable, with nouns dominating children's early lexicons (Gentner, 1982; Fenson et al., 1994). Imageability quantifies the perceptual salience of a word by rating the ease in which it evokes a mental image and is a strong predictor for word acquisition in TD children (McDonough et al., 2011). Children with autism spectrum disorder (ASD) often have delayed language acquisition compared to their typically developing (TD) peers, characterized by intact lexical mechanisms but differences in linguistic processing (Charman et al., 2003; Arunachalam and Luyster, 2015). Individuals with ASD have difficulty learning words with multiple, ambiguous conceptual representations and demonstrate an atypical reliance on perceptually-based processing for words with low imageability (Schafer et al., 2013; Kana et al., 2006, Gaffrey et al., 2007). This study contributes preliminary data on the lexicosemantic features that facilitate early noun and verb learning in children with ASD.

Objectives: The purpose of this study was to investigate the extent to which imageability predicts early noun and verb acquisition in children with ASD.

Methods: Secondary data analyses were conducted using data obtained from the NIH supported National Database for Autism Research (NDAR) (NIMH Data Archive Collection ID #2368) and a previous longitudinal study (Lord, Luyster, Guthrie & Pickles, 2012). The productive vocabularies of 157 children with ASD (13-107 months of age) were measured using the MacArthur Bates Communicative Development Inventory (MB-CDI; Fenson et al., 2007). Most children contributed multiple data points, yielding 379 data points from the 157 children. To prevent item repetition, only the MB-CDI Words and Sentences Form was used. One hundred twenty-three items (78 nouns, 45 verbs) were included in our analysis based upon the overlap of MB-CDI words and published imageability ratings from Masterson & Druks (1998).

Results: Preliminary results indicate that the average imageability of words produced was significantly negatively correlated with total words produced ($r = -.732$, $p < .01$), suggesting that the first words acquired were highly imageable. This pattern held across word class; however, imageability was more strongly correlated with total nouns than total verbs. The average imageability of nouns had a strong negative correlation with total nouns produced ($r = -.949$, $p < .01$), while average imageability of verbs was moderately correlated with total verbs produced ($r = -.367$, $p < .01$).

Conclusions: Consistent with literature on TD children, these results demonstrate that the first words – both nouns and verbs – of children with ASD are ones that are highly imageable. As children with ASD become more proficient word learners, they appear to depend less on imageability. These findings support that children with ASD rely on similar word-learning strategies as their TD peers, and point to the importance of multimodal, visual input (e.g., photographs, videos, animations, etc.) for establishing mental images during early word learning for children with ASD (Schlosser et al., 2012).

414.078 *(Poster)* The Roles of Pragmatic Language and Theory of Mind in the Adaptive Communication Skills of Children with and without Autism Spectrum Disorder

T. Estrada *and B. J. Wilson, Seattle Pacific University, Seattle, WA*

Background: Children with autism spectrum disorder (ASD) exhibit marked social communication impairments (APA, 2013). Research suggests these deficits often lead to delays in adaptive functioning, such as adaptive communication (AC; Bolte & Poustka, 2002). These adaptive outcomes have also been related to later social skills deficits and ASD symptom severity (Billstedt et al., 2007). It is important to study factors that predict low AC outcomes in order to develop targeted interventions. Several factors such as pragmatics and theory of mind (ToM) have been shown to predict later adaptability (Bennett et al., 2013). These constructs are most often examined in samples of older children (Bennett et al., 2013; Whyte & Nelson, 2015). They have yet to be examined in a sample of younger children using a typically developing (TD) control group.

Objectives: The aim of this study was to examine the direct and indirect effects of pragmatic language and ToM in the AC of young children with and without ASD.

Methods: The sample consisted of 13 children with ASD and 24 children with TD ages 3:0 to 6:5. AC was measured by the *BASC-2*. Pragmatic language was assessed by the *CASL*. ToM was measured through a laboratory task battery. Verbal abilities were measured by the *DAS-II* Verbal Cluster. Children needed to have average or greater Verbal Cluster scores in order to participate in study.

Results: A serial mediation analysis was conducted using the SPSS macro PROCESS to examine the direct and indirect effects of pragmatics and ToM on the association between status (i.e., ASD vs TD) and AC. Covariates included gender, age, and verbal abilities. Results indicated significant direct effects of status on AC [$F(1, 35) = 28.61$, $p < .001$], status on pragmatics [$F(1, 35) = 8.17$, $p = .001$], and pragmatics on ToM [$F(1, 35) = 7.03$, $p = .01$]. Results did not support the hypotheses that the relation between status and AC would be mediated by pragmatics alone, ToM alone, or pragmatics predicting ToM. Post-hoc analyses were conducted to examine levels of clinical importance for the measures that showed significant group differences (i.e., pragmatic language and AC). Analyses revealed that only children with ASD had at-risk or clinically significant pragmatic and/or AC skills.

Conclusions: Initial findings supported my hypotheses that children with ASD would exhibit lower AC and pragmatics than children with TD. Results did not support my hypothesis that pragmatics and ToM would mediate the relation between status and AC. Exploratory analyses showed that only children with ASD exhibited pragmatics and AC scores that fell into the range of clinical importance. Specifically, almost two-thirds of the children with ASD exhibited clinically important levels of AC, pragmatics, or both. These results suggest that children with ASD who demonstrate average or greater structural language scores (e.g., *DAS-II* inclusion criteria) may still exhibit significant AC and pragmatics challenges. These results suggest children with ASD as young as three years may benefit from treatment targeting pragmatics and AC. Previous literature shows this may improve overall adaptive functioning (Bennett et al., 2013).

414.079 *(Poster)* The Social Orienting Continuum and Response Scale (SOC-RS) with Bilingual Preschool Children with ASD

K. Jalalian-Chursky[1]*, S. Ghods*[2]*, S. Corrigan*[3] *and S. J. Webb*[4]*, (1)Seattle Pacific University, Seattle, WA, (2)UCSF, San Francisco, CA, (3)Seattle Children's Research Institute, Seattle, WA, (4)Psychiatry and Behavioral Sciences, University of Washington, Seattle, WA*

Background: The development of communication, or lack thereof, is integral to diagnosing children with Autism Spectrum Disorders (ASD), (American Psychiatric Association, 2013). Families of ASD children have received advice discouraging exposure to multiple languages (Kremer-Sadlik, 2005). The relationship between language development in ASD children and exposure to multiple languages has been investigated in recent years (Hambly & Fombonne, 2012). These studies suggest that language in children with ASD is not adversely affected by exposure to multiple languages. Furthermore, for typically developing children, bilingualism has practical and economic gains, as well as several cognitive advantages (Kuhl, 2016).

Objectives: We examined the Social Orienting Continuum and Response Scale (SOC-RS; Mosconi et al., 2008) to assess the communicative development of preschoolers with ASD to further our understanding of the relationship between bilingual language exposure and social-communication.

Methods: Children with ASD (N=53), aged 37 to 59 months, from bilingual and monolingual families were selected. At Time 1 (T1), 25 bilingual and 28 monolingual ASD children were included. At Time 3 (T3), 16 bilingual children and 24 monolingual ASD children had data available. The study included the ADOS-2 (Lord et al., 2012), nonverbal cognition (Mullen Scales of Early Learning; Mullen, 1995), and expressive and receptive language (Preschool Language Scale IV; Zimmerman et al., 2002) measures. Measures were administered in English. Coding of the SOC-RS was done from video analysis; including 23 behavioral and 3 state codes. SOC-RS was developed by Mosconi et al. (2008) for additional coding of social communication abilities during the ADOS; our team updated the coding manual and added codes related to language.

Results: ANOVA's were used for analysis. The ASD bilingual (Bi) and monolingual (Mono) children revealed no significant differences on all 23 SOC-RS behavioral codes. There were no significant differences between the two groups on the SOC-RS *language, joint attention response,* and *orienting to name* codes. The ASD-Bi children differed from the ASD-Mono children on several items: (A) ASD-Bi produced more *echolalia* at both T1 (M Bi=2.86 SD=2.8; M Mono=1.6, SD=2.6) and T3 (M Bi=3.88 SD=4.3; M Mono=2.33; SD =4.7), (ps=.100 to .298); (B) The ASD-Bi children produced slightly more *joint attention eye gaze* at both T1 (M Bi=.28 SD=.614; M Mono=.25, SD=.585) and T3 (M Bi=2.13 SD=1.8;M Mono=2.08, SD=2.0), (ps=.334 to.934), and *joint attention point* at T3 (M Bi=.80 SD=1.14; M Mono=.48, SD=1.0), (ps=.765 to .372); (C) The ASD-Bi scored higher on *orienting to name experimenter* at both T1 (M Bi=1.20, SD=2.1; M Mono=.57, SD=.742) and T3 (M Bi=.87, SD=.640; M Mono=.72, SD=.843), (ps=.157 to.565).

Conclusions: Our findings suggest that bilingualism does not negatively impact early social communicative behaviors such as joint attention and language in young children with ASD and may, result in more joint attention behaviors and language. The results provide additional support for maintaining bilingualism in children with ASD. We note that all measures were conducted in English and that children had at least 50% environmental exposure to English, thus inclusion of children with broader language exposure and administration of measures in multiple languages are needed.

414.080 *(Poster)* The Utility of Automated Vocalisation Indices Collected in a Clinical Setting for Preschool Children on the Autism Spectrum.

R. P. Sulek[1], *J. A. Smith*[2], *D. Trembath*[3], *C. Dissanayake*[4] *and T. Victorian ASELCC Team*[5], *(1)Olga Tennison Autism Research Centre, La Trobe University, Melbourne, VIC, Australia, (2)School of Psychology and Public Health, Olga Tennison Autism Research Centre (OTARC), Melbourne, Australia, (3)Menzies Health Institute, Griffith University, Australia, (4)Olga Tennison Autism Research Centre, La Trobe University, Melbourne, Australia, (5)Victorian Autism Specific Early Learning and Care Center, La Trobe University, Melbourne, Australia*

Background: There is a growing understanding of the need to capture abilities of children with autism using multiple instruments (Kasari et al., 2013; Neville et al., 2017; Plesa Skwerer et al., 2016). Automated vocalisation indices (AVI), such as the Language ENvironment Analysis (LENA®) software, can provide a low burden tool for capturing child language, which may provide additional insight into their language profiles. Designed for use with children aged between 2 and 48 months, LENA® produces several metrics, including key child vocalisations (CVs), conversational turns (CTs), with novel measures such as vocalisation ratios (VRs: comparison of speech vs. non-speech vocalisations) and reciprocal conversational turns (RCTs: a more social measure of language which examines a three-part conversational contingency) also able to extracted. While LENA® was developed to capture whole day recordings of children in naturalistic settings, we need to determine the validity of LENA metrics in clinical practice settings where children are often seen (Harbison et al. 2018).

Objectives: In the context of children with autism receiving group-based early intervention, we sought to explore the validity of AVI (i.e., CV, RCT, and VR) collected during short 1:1 clinical interactions in relation to other commonly-used standardised language measures.

Methods: LENA recordings were collected for 53 children (*M*=26 months, *SD*=6.9 at time of first recording; 35 boys, 18 girls) enrolled in a group-based Early Start Denver Model (G-ESDM) intervention program, between 2015 and 2018. Language samples were captured during a 1:1 unstructured play-based interaction (*M*=53.53 min, *SD*=15.86 mins) with an adult at the beginning of the intervention year. These interactions provided naturalistic opportunities for the child to spontaneously vocalise and take turns in conversation. Data were extracted and processed using specialised software in preparation for analysis. Autism symptomatology, developmental abilities and adaptive behaviours were collected using the Autism Diagnostic Observation Schedule (ADOS), Mullen Scales of Early Learning (MSEL), and Vineland Adaptive Behaviour Scales (parent interview; VABS) respectively, also administered pre-intervention.

Results: Analyses revealed moderate positive correlations between average CVs and age equivalence scores in receptive and expressive subscales of the VABS (r=.338, p=.014; r=.357, p=.009), and a moderate negative association with overall language scores on the ADOS (r_s=-.433, p=.001). VRs were moderately positively associated with both verbal and non-verbal DQ (r=.356, p=.010; r=.320, p=.005), and age equivalence scores in receptive and expressive subscales of the VABS (r=.344, p=.013; r=.381, p=.005), with a moderate negative association with language scores on the ADOS (r_s=-.315, p=.024). Moderate positive correlations were found between average RCTs and age equivalence scores in receptive, and relationship subscales of the VABS (r=.348, p=.012; r=.333, p=.016), with a moderate negative association with language scores on the ADOS (r_s=-.395, p=.004).

Conclusions: The findings provide preliminary evidence that novel LENA AVIs collected during brief individual play-based interactions with a clinician may be a valid and useful measure of children's naturalistic language abilities that may not be captured by standardised assessments such as the MSEL. Additional data on a larger cohort of children will be available by INSAR 2020.

414.081 *(Poster)* Using Mlu to Evaluate the Reliability of ADOS Transcription

A. C. Salem[1], *H. MacFarlane*[1], *J. K. Dolata*[2], *G. O. Lawley*[1] *and E. Fombonne*[3], *(1)Oregon Health & Science University, Portland, OR, (2)Pediatrics, Oregon Health & Science University, Portland, OR, (3)Psychiatry, Pediatrics & Behavioral Neurosciences, Oregon Health & Science University, Portland, OR*

Background: Despite the recommendation of publishing transcription protocol and annotator reliability for data generated from a speech corpus, most research does not include that information. Re-transcribing and directly comparing transcripts requires a very costly and labor intensive undertaking. Instead of using word-by-word re-transcription, Mean Length of Utterance in Morphemes (MLUM) can be easily calculated from transcripts and used as a reliability measure for intra- and inter-transcriber comparisons.

Objectives: Develop a computational method to determine transcriber consistency across a large speech corpus, beginning with an initial assessment of intra-annotator reliability.

Methods: Participants were recruited for an fMRI study at OHSU. Inclusion criteria were: age 7 to 17, IQ ≥ 70, having fluent/phrase speech, being native English speakers. The main data used in this study consist of the Autism Diagnostic Observation Schedule (ADOS-2) Module 3 that was administered at baseline. All administrations were recorded and transcribed according to transcription guidelines based on conventions used by Systematic Analysis of Language Transcripts (SALT) software. Transcripts for three tasks were selected: *Emotions*, Social Difficulties and *Annoyance*, and *Friends* and Marriage Conversations. Each activity for each child was split into two parts by selecting even and odd lines. MLUM was then calculated for each part. Intra-annotator agreement was evaluated using the intraclass correlation (ICC) calculated for two-way mixed effects models, single measurement, absolute agreement type.

Results: The sample comprised 57 children with ASD (mean age:11.3 years; 78.9% male; mean IQ: 101.7) and 60 controls without ASD (mean age:11.4 years; 56.7% male; mean IQ: 111.9). Across tasks and groups, means MLUMs ranged from 5.6 to 6.7 and mean number of utterances ranged from 43.2 to 72.8. ICC between the even and odd MLUM was 0.714 for *Emotions* (95% CI: 0.613 < ICC < 0.792), 0.624 for *Annoyance* (95% CI: 0.5 < ICC < 0.723), and 0.708 for *Friends* (95% CI: 0.604 < ICC < 0.788), indicative of moderate to good levels of reliability (see Figure). Paired-t-tests between the MLUM halves were all non significant, indicating very good within task intra-rater agreement between the two randomly generated MLUM estimates. When examined by ASD status, ICC did not differ significantly between the two groups although reliability in ASD was higher than for controls on the three tasks. Using age and IQ median splits (11.3 years and 110, respectively), we further established that age had no discernable effect on ICC across tasks, and that there was a trend for lower reliability on two tasks among subjects with higher IQ. However, all ICCs across age and IQ groups remained in the moderate (>.50) range.

Conclusions: Calculating MLUM for two random halves within each activity, while not ideal, provides an efficient and valid measure of intra-annotator reliability. Comparing this across an entire transcription team offers a substitute when full inter-annotator reliability is not feasible. We emphasize that all research conducted on speech corpora should present associated reliability data.

414.082 *(Poster)* Validation of a Behavioral Pitch-Discrimination Paradigm for Young Children with ASD

A. Hogstrom *and I. M. Eigsti, Psychological Sciences, University of Connecticut, Storrs, CT*

Background: Research has consistently demonstrated that children with autism spectrum disorder (ASD) show enhanced auditory perception (e.g., Boets et al., 2014; Remington & Fairnie, 2017), perhaps reflecting Enhanced Perceptual Processing in the auditory domain (Mottron, et al., 2012). In older children, differences in perception may contribute to delayed language development (Eigsti & Fein, 2013), but behavioral measures of auditory discrimination are not appropriate for young children or those with developmental delays (Abramson & Lloyd, 2016; Schwartz et al, 2018).

Objectives: We introduce a validated behavioral pitch discrimination task, based on mouse models (Truong et al., 2015), which requires minimal verbal ability and which is appropriate for use in children ages 3-6 with developmental delays. In adults, we demonstrate the relationship between performance on (1) this novel task and (2) a well-studied pitch discrimination paradigm previously used with adults and adolescents. Second, we demonstrate the utility of this task for young children in a sample of typically developing children. These steps are critical precursors to testing the hypothesis that auditory acuity (e.g., particularly strong perceptual skills) predicts language delays in ASD.

Methods: In the two-alternative forced-choice (2AFC) pitch discrimination paradigm, participants heard pairs of 100ms pure tones and made a same/different judgment. Tone pairs differed by 3% (Easy), 2%, 1% (Hard), or 0% (Identical) of overall frequency. In the novel, child-friendly paradigm, participants listened to a pure tone of variable duration, followed by a 150ms cue tone which differed in frequency as in the 2AFC task. The participant's task was to respond to a subsequent visual target as quickly as possible. Pitch discrimination was operationalized as the RT difference to cued versus uncued trials. Data from 27 college students were collected to validate the novel methodology. Thirty typically-developing children (mean age=5.9) completed the children-friendly pitch-discrimination task.

Results: Table 1 displays correlations of adult accuracy (d') on the 2AFC paradigm and ΔRT on the child-friendly paradigm at each difficulty level. Performance across the two tasks was significantly correlated when tones differed by 3% (r=.41, p=.03) and 2% (r= .48, p=.01), but not by 1%, (r=.25, p=.19); d' values indicate that most participants were at chance at the 1% condition, consistent with prior findings in a typical group. For children, log(ΔRT) differed significantly across conditions, $F(2,58)=5.47$, $p<0.01$, suggesting sensitivity of this RT measure to the difficulty of the perceptual task; see Figure 1. Preliminary examination of results indicated marked performance variability across participants. In 12 participants with available language history, there was a trend-level relationship between task performance and first word milestones (r=-.50, p=.09).

Conclusions: Results suggest that this novel pitch discrimination task displays a moderately strong relationship with performance on a more traditional 2AFC task. Furthermore, results with young children displayed the expected pattern of results. This task minimizes cognitive requirements (e.g., auditory working memory, conceptual knowledge) which have impeded the behavioral characterization of pitch discrimination abilities in young children with ASD. Data collection assessing the relationship between language milestones and pitch discrimination in preschoolers with ASD is on-going.

414.083 *(Poster)* Visual Salience Increases Attention to Relevant Information in a Familiar Word Processing Task

C. E. Venker[1] *and D. Neumann*[2]*, (1)Communicative Sciences and Disorders, Michigan State University, East Lansing, MI, (2)Information and Media, Michigan State University, East Lansing, MI*

Background: Children with autism spectrum disorder (ASD) demonstrate differences in visual attention across both social and non-social domains. These attentional differences create situations in which the visual input children see is not directly related to the auditory input they hear—a phenomenon known as auditory-visual misalignment. Because it involves a mis-match of the auditory and visual statistics that are relevant for language learning, auditory-visual misalignment is hypothesized to contribute to vocabulary delays in children with ASD.

Objectives: The current study investigated whether increasing the salience of visual stimuli reduced the amount of auditory-visual misalignment experienced by children with ASD. Specifically, we tested whether making an image wiggle on the screen during an experimental word processing task would increase children's attention to relevant information.

Methods: The initial sample included 15 children with ASD; five were excluded from the analyses due to excessive missing data. The remaining 10 children were between 2 and 4 years of age (M = 39 months, SD = 10). ASD diagnoses were determined through parent report, the ADOS-2, and expert clinical judgment. On average, participants displayed considerable delays in language and cognitive skills and a high level of autism-related symptoms (ADOS-2 Comparison Score: M = 8.2, SD = 1, range = 6-10). Children took part in a looking-while-listening task that presented pairs of familiar images on a screen (e.g., a cookie and a dog), along with spoken language describing one of the images (e.g., *Where's the cookie?*). In the first 10 trials (the Static condition), neither image moved. In the second 10 trials (the Moving condition), the named image wiggled on the screen at the end of the trial.

Results: Accuracy was quantified as the amount of looking to the target (i.e., named) image, divided by the amount of looking to both images. Just after the target image was named (300-2000 ms after target noun onset), children's accuracy was .60 in the Static condition and .57 in the Moving condition, indicating recognition of the named image. Accuracy during this period (when images in both conditions were static) did not significantly differ between the two conditions. From 2400-4000 ms after noun onset—when the target image wiggled in the Moving condition—accuracy was significantly higher in the Moving condition (M = .81, SD = .18) than in the Static condition (M = .57, SD = .19; $p < .01$).

Conclusions: These findings provide evidence that increasing visual salience (i.e., making something more visually appealing) can reduce auditory-visual misalignment in children with ASD. In this way, manipulating visual salience may be a useful tool to maximize the likelihood that children with ASD are looking at the aspects of their environment that are most relevant for learning—in other words, the "right thing at the right time." These findings have implications for increasing auditory-visual alignment in both screen-based activities and everyday social interactions in ways that increase learning opportunities and facilitate vocabulary development in children with ASD.

414.084 *(Poster)* What Really Matters? Characterizing “the Presence of Useful Speech” in 5-Year-Olds with ASD

***K. J. LeGrand**, L. Wisman Weil and R. J. Luyster, Communication Sciences and Disorders, Emerson College, Boston, MA*

Background: Eisenberg (1956) reported that “the presence of useful speech” at age 5 predicts later outcomes in individuals with Autism Spectrum Disorder (ASD). Numerous studies have since replicated this finding, but each provided a different, often vague definition of the predictive factor “useful speech” and reported varying results (see Table 1). Thus, the meaning of “useful speech” remains ambiguous, preventing the generation of clear conclusions about the importance of specific spoken language features in ASD.

Objectives: This exploratory study investigates which aspects of expressive language at age 5 best correlate with adult cognitive and language-related outcomes in individuals with ASD.

Methods: Data for this study come from a longitudinal dataset, as described in Lord et al. (2006). To date, videos of 20 5-year-olds with ASD completing the Pre-Linguistic Autism Diagnostic Observation Schedule (PL-ADOS; DiLavore, Lord, & Rutter, 1995) or the Autism Diagnostic Observation Schedule (ADOS; Lord et al., 2000) have been transcribed and coded for features of morphosyntax (mean length of utterance [MLU] in morphemes), lexical diversity (noun diversity, verb diversity) and pragmatics (number of communicative functions). Adult outcome measures include verbal IQ, nonverbal IQ, Peabody Picture Vocabulary Test Fourth Edition (PPVT-4; Dunn & Dunn, 2007) standard scores, ADOS algorithm communication and social totals, and Vineland Adaptive Behavior Scales II (VABS-II; Sparrow, Ciccheti, & Balla, 2005) Communication domain standard scores.

Results: Partial correlations controlling for age 5 nonverbal IQ were run between age 5 language features and adult outcome scores. Our age 5 measure of morphosyntax—MLU in morphemes—was significantly correlated with adult VABS-II communication scores (r=.62, p=.023), verbal IQ (r=.68, p=.01), and PPVT-4 standard scores (r=.65, p=.017), but not with adult nonverbal IQ or ADOS algorithm scores. A similar pattern was observed for one age 5 measure of lexical diversity, verb diversity, which was significantly correlated with adult VABS-II communication scores (r=.56, p=.046), verbal IQ (r=.64, p=.018), and PPVT-4 standard scores (r=.62, p=.023), but not with adult nonverbal IQ or ADOS algorithm scores. The other measure of vocabulary (noun diversity) and the measure of pragmatics (number of communicative functions) at age 5 were not significantly correlated with any adult measures.

Conclusions: These preliminary findings demonstrate that MLU in morphemes and verb diversity at age 5 were significantly associated with performance on adult language and communication measures in individuals with ASD. Noun diversity was not significantly correlated with performance on adult language measures, suggesting that the long-term significance of early vocabulary may depend partly on word type. Our measure of childhood pragmatics was not associated with adult language and communication outcomes.

414.085 *(Poster)* What's a Chinchilla? Question Asking in Children with ASD

***K. Fung**[1], S. G. Edwards[2], S. Arunachalam[3] and R. J. Luyster[2], (1)Emerson College, Boston, MA, (2)Communication Sciences and Disorders, Emerson College, Boston, MA, (3)Communicative Sciences and Disorders, New York University, New York, NY*

Background: In typical development, the tendency to ask questions emerges and peaks in the preschool and early school-age years. This skill is an important strategy for cognitive, linguistic and social development, as well as academic achievement. Although research suggested that children with Autistic Spectrum Disorder (ASD) may learn best from language that follows their attention and interests, little is known about the ways in which children with ASD use questions in their daily lives.

Objectives: We aimed to ascertain the frequency and content of question-asking in a semi-structured task (based on Greif et al., 2006) presenting images of objects and animals. This task emulates the activities that young children are often presented in classroom and home settings (e.g., book reading, “circle time” presentations, etc.).

Methods: English-speaking children with ASD 4.0-6.11 years old completed standardised diagnostic, IQ & language testing, and finally a semi-structured question-eliciting task on an iPad with images of unfamiliar animals and objects. Children were presented with an array of images and invited to ask questions; the examiner answered each question. Children were encouraged to ask as many questions they liked; the task was complete when the child had no further questions (Greif et al., 2006). Each session was transcribed, and the questions were coded by trained examiners according to question form, function and content.

Results: To date, we have completed data collection with 15 participants. The average age of the participants was 5.5 years old (SD=11 months); the group had average NVIQ (M=99.25; SD=30.04) and expressive language scores (CELF P2 Expressive Language Score M=99.25; SD=18.46). Our analyses are descriptive and compare our preliminary findings to data reported by Greif et al. (2006), who studied typically developing children slightly younger than our sample (the mean age in Greif et al. was 4.6 years old).

In terms of frequency, Greif et al. (2006) reported that, in their TD sample, children asked (on average) 26.1 questions during the task. Contrastingly, in our sample, children asked -- on average -- 7.93 questions (SD=7.65) during the task.

In terms of content, Greif et al. (2006) reported that their TD sample primarily asked questions about the names, function/behavior and categories of objects/animals. Similarly, in our results: out of a total of 119 questions asked by the children, 58 focused on names, and 36 queried function/behavior. However, only 5 addressed category membership.

Conclusions: Compared to typically developing children and using an identical task, children with ASD asked strikingly fewer questions. This discrepancy does not seem to be due to cognitive or language skills, which were both average. Nevertheless, the kinds of questions asked were similar, focusing on the names and traits of objects/animals. Interestingly, the children with ASD did not query category membership with the same regularity that the TD children did. Given the importance of question-asking for cognitive, linguistic, social and academic success, our findings suggest that supporting this skill in children with ASD is an important strategy for parents, caregivers and teachers.

414.086 *(Poster)* Why Are Parents Better Than Researchers at Eliciting Speech from Minimally and Low-Verbal Children and Adolescents with ASD?

***M. Barokova**, C. G. La Valle and H. Tager-Flusberg, Department of Psychological and Brain Sciences, Boston University, Boston, MA*

Background: Natural language samples (NLS) are an excellent source of information about the expressive language abilities of minimally and low-verbal (MLV) individuals with ASD, who often cannot go through standardized assessment procedures (Tager-Flusberg & Kasari, 2013). Yet, there are no agreed upon guidelines about the best way to elicit NLS from this population. One important avenue for investigation is the role of conversational partner, considering past research showing that children speak more with their parents than with trained examiners (in preschoolers Kover et al., 2014; in MLV Barokova & Tager-Flusberg, 2018 - SRCD). Yet, no study has examined potential differences between parent and examiner speech, and how they relate to child/adolescent speech.

Objectives: I. To compare the speech of parents to that of examiners. **II.** To examine associations between adult and child/adolescent speech.

Methods: Twenty-two (4 females) children and adolescents with ASD between the ages of 6;6 and 19;7 (M = 12;6) were included in this study. Standardized measures of language, communication, and nonverbal IQ were used: VABS, SCQ, and Leiter (Table1). Examiners in the lab and parents in their home collected a NLS following the same protocol (described in Barokova & Tager-Flusberg, 2017). Both parents and examiners had good administration fidelity. The parent- and examiner-NLS were transcribed following standard procedures (Miller et al., 2011). We have already reported that in these samples, MLV children and adolescents, on average, produced more utterances per minute and used a higher number of different words (NDW) when with their parents than with examiners. To compare parent vs. examiner speech across the language domains, we extracted adults' mean length of utterance (MLU) to assess syntax, NDW for lexical diversity, and number of statements, exclamations, and questions per minute for examine pragmatic function of utterances.

Results: I. No differences were found between parent and examiner MLU and NDW (all results in Table 1). On average, parents produced more statements per minute and asked more questions than examiners. In contrast, examiners made significantly more exclamations per minute than parents. **II.** No significant associations were found between participant frequency of utterances and any of the parent or examiner language measures. Participants' NDW was significantly correlated with examiners' MLU ($rs(20)= .590$, $p<.01$), but was not correlated with any of the parent language measures. Participants' frequency of utterances during parent and examiner samples was significantly correlated($rs(20)= .794$, $p<.01$), and so were their NDW ($rs(20)= .877$, $p<.01$).

Conclusions: Parent and examiner language did not differ in structural aspects, but differed in the number of utterances by pragmatic function. Despite these differences in the domain of pragmatics, adult speech was not related to child/adolescent speech. Nevertheless, MLV participants' language measures were significantly correlated across parent- and examiner-collected samples. This suggests that parents elicit more speech from their children not because of a unique characteristic of their speech, but perhaps due to familiarity or some non-verbal aspect of their communication. Although the role of familiarity has been assumed in the language sampling literature, it has not been shown empirically.

414.087 *(Poster)* "the Moral of the Story Is Don't Anger an Entire Hive of Bees": Narrative in ASD and First-Degree Relatives

***C. J. Stevens**[1], K. Nayar[2], S. Pirog[1], E. Landau[2], G. E. Martin[3] and M. Losh[4], (1)Northwestern University, Evanston, IL, (2)Feinberg School of Medicine, Department of Psychiatry and Behavioral Sciences, Northwestern University, Evanston, IL, (3)Communication Sciences and Disorders, St. John's University, Staten Island, NY, (4)Communication Sciences and Disorders, Northwestern University, Evanston, IL*

Background: Narration (i.e., storytelling) is a primary form of social communication, used to relate events and experiences in socially and psychologically meaningful ways. Narrative production is a well-documented challenge for individuals with ASD, with subtle differences also manifesting among their first-degree relatives, who often display subtle personality and social-communicative traits mirroring the core features of ASD (i.e., the broad autism phenotype, BAP). Prior work has also indicated atypical visual attentional patterns in individuals with ASD and their parents, and relationships between narrative abilities and visual attention (Lee et al., 2019).

Objectives: To disentangle known heterogeneity in the social-communicative profiles of ASD by implementing a detailed hand-coding system to sensitively quantify features of narrative and associated visual attention during narration impacted in ASD, and first-degree relatives who may display subclinical social communicative differences that index genetic liability to ASD.

Methods: Participants included 55 individuals with ASD and 49 controls, as well 161 parents of individual with ASD (ASD parents) and 61 parent controls. Participants narrated a wordless picture book presented on an eye tracker. Narratives were coded for key aspects of narrative ability including evaluation of characters' internal states (e.g., thoughts, emotions) and descriptions of key story scenes. Proportions of fixations and fixation duration towards social and nonsocial elements in the picture book were analyzed in relationship to narrative quality within groups.

Results: Individuals with ASD more often missed key story elements in their narratives ($p<.05$) and used fewer internal state terms than controls ($p<.05$). No significant differences emerged between parent groups. In individuals with ASD, visual attention to animate and inanimate aspects of the stimuli did not correlate with narrative scores, but they did in controls. In contrast, greater visual attention to animate features of narrative scenes was associated with greater usage of affective state terms and lower overall narrative quality in ASD parents.

Conclusions: Differences on key narrative parameters were detected in ASD but not in parents, underscoring the subtlety of subclinical BAP traits. Importantly, visual attention related to narrative parameters in all groups, highlighting the utility of eye tracking as a more sensitive measure to capture subclinical traits related to ASD. Specifically, proband controls and both parent groups provided richer narratives when attending more to inanimate elements of the picture book, suggesting that unlike individuals with ASD, these groups did not need to rely on illustrated social information to provide social details in their stories.

Communication and Language / Neuroimaging

ORAL SESSION — COMMUNICATION AND LANGUAGE / NEUROIMAGING
308 - Social and Language Learning; and Sex Differences

308.001 *(Oral)* Examining a Sequential Mediation Model Among Preschoolers with ASD: Playing, Engaging and Communicating

W. I. Shih[1], *Y. C. Chang*[2], *S. Y. Shire*[3] *and C. Kasari*[4], *(1)Loma Linda University, Loma Linda, CA, (2)Special Education and Counseling, California State University, Los Angeles, Los Angeles, CA, (3)University of Oregon, Eugene, OR, (4)University of California, Los Angeles, Los Angeles, CA*

Background: Early intervention can improve core social communication challenges including joint engagement (JE) and initiations of joint attention (IJA, Kasari et al., 2006). Gains in IJA have been linked to better language outcomes (Kasari et al, 2008). Increases in JE are hypothesized to be the mechanism by which children make gains in IJA and which lead to downstream improved language skills (Shih et al., 2017). In the JASPER early intervention approach, JE is improved through targeting play development. In this study the role of play diversity is examined as a potential sequential mechanism with JE in improving IJA (Figure-2).

Objectives: In this secondary analysis, we examine: 1-the mediating effect of play diversity on JE in the context of a JASPER trial (Figure-1), and 2- explore the sequential mediation effect of play diversity with JE on IJA (Figure-2).

Methods: Participants. 66 children were 50.26 months old (M = 50.26; SD = 6.38) and 89 % were male. Children ranged in developmental level at study entry (range 11.00–57.67 months; M = 35.41 months: MSEL mental age) and were of diverse ethnic backgrounds (69 % ethnic minorities) (Chang et al., 2016).

Intervention. Classrooms were randomized to immediate JASPER or waitlist (WL). JASPER teachers implemented JASPER 30 minutes a day with their students for 3 months, while teachers in the WL continued with school curriculum as usual for 3 months.

Measures. Ten-minute teacher-child interactions were videotaped at entry, exit, and follow up and coded by independent blinded assessors for the duration of children's joint engagement and initiations of joint attention.

Structured Play Assessment (Lifter and Bloom, 1989). The number of unique spontaneous play types and their frequency were coded based on 16 levels of functional and symbolic play. Total play diversity is the sum of unique spontaneous play types across levels.

Results: Mediation analyses (Preacher & Hayes, 2008) was used to explore the potential mediating effect of play diversity on JE and sequential mediation effect with JE on IJA in a JASPER intervention.

There was a significant treatment difference in total play diversity, joint attention, and joint engagement where children in the JASPER intervention made significantly more improvements compared to WL children (Chang et al., 2016). Total play diversity was significantly associated with JE (p=0.002). and IJA (p=0.047) even after adjusting for the treatment effect suggesting that play diversity may be a mechanism of change for increasing JE and IJA (Figure-1,2). However, after adjusting for JE (i.e. downstream skill) and treatment, play diversity is no longer significantly associated with IJA (p=0.325; Figure-2). Consequently, play diversity mediated the effect of treatment on IJA and may be an upstream development skill prior to JE.

Lastly, IJA was significantly associated with expressive (p=0.01) and receptive language (p=0.025).

Conclusions: These results suggest that play diversity is a potential path by which increases in young children's JE influences the development of IJA. These findings highlight the need to maximize both play skills and JE in order to foster development in more distal core challenges such as IJA and language.

308.002 *(Oral)* Community Implementation of the Social ABCs Parent-Mediated Toddler Intervention: Domains and Drivers of Treatment Response

J. A. Brian[1], *I. Drmic*[2], *E. M. Dowds*[3], *C. Roncadin*[2], *A. Solish*[1], *L. Zwaigenbaum*[4] *and S. E. Bryson*[5], *(1)Holland Bloorview Kids Rehabilitation Hospital, Toronto, ON, Canada, (2)Autism Spectrum Disorder Service, McMaster Children's Hospital - Hamilton Health Sciences, Hamilton, ON, Canada, (3)Autism Research Centre, Holland Bloorview Kids Rehabilitation Hospital-Autism Research Centre, Burlington, ON, Canada, (4)University of Alberta, Edmonton, AB, Canada, (5)Dalhousie University, Halifax, NS, Canada*

Background: Advances in the dissemination of parent-mediated intervention for toddlers with autism spectrum disorder (ASD) require evidence of effectiveness beyond randomized control designs conducted in tightly controlled laboratory settings.

Objectives: To evaluate the effectiveness of a parent-mediated intervention for toddlers with confirmed or suspected ASD in a large community implementation. The Social ABCs^{TM} parent-mediated intervention (supported by published RCT evidence) was one of four models funded through a government demonstration initiative in Ontario, Canada (2016-2019). We build on preliminary data presented orally at INSAR 2019, now with a complete data set and novel analyses of outcomes and predictors.

Methods: The Social ABCs^{TM} developers trained 6 front-line staff ("coaches") to deliver the intervention through a regional service-provider in Hamilton Ontario (pop. 500,000; 24% born outside Canada). Coaches attained fidelity, and 136 families completed the 12-week 1:1 coaching program (with follow-up at week 24). Participants included 98 boys (72%) and 38 girls (28%); mean age 25.36 months (range = 14-34 months). Coached parents included 118 mothers, 11 fathers, and 7 grandmothers; 35% had full-time employment and 22% reported having English as a subsequent language (ESL). Thirty-seven toddlers (27%) were in full-time daycare. Measures included video-coded indices (parent implementation fidelity and toddler responsivity to parent language opportunities) and standardized measures at baseline and 6 months later: Vineland Adaptive Behavior Scales (VABS-II), Mullen Scales of Early Learning (MSEL), and Autism Diagnostic Observation Schedule-2 (ADOS-2).

Results: Repeated measures ANOVA revealed significant increases in parent fidelity ($F_{(1,78)} = 1344.58$, $p < .001$) and toddler responsivity ($F_{(1,63)} = 113.89$, $p < .001$) from week 1 to 12. Parent week-12 fidelity exceeded our target of 75% ($M = 79.60$) and significantly predicted toddler responsivity ($p = .024$). ADOS-2 revealed significant decreases in symptoms in the Social Affect domain ($M = 12.97$ vs. 10.91; $t = 4.51$, $p < .001$), but not the Restricted/ Repetitive Behavior domain ($p = .56$). MSEL age equivalents (AE) for both Receptive and Expressive Language improved significantly (p's < .001), and MSEL standard t-scores also increased significantly for Receptive ($p = .001$) but not Expressive Language ($p = .52$), which remained stable over time. Standard scores for VABS-II Communication (but no other domain) increased significantly ($p < .001$). Toddlers' receptive and expressive language levels at baseline significantly predicted week-12 responsivity (p's < .02), but did not predict *change* in responsivity (p's > .50). No demographic variables (sex, parent coached, ESL status, daycare attendance) predicted parent fidelity or toddler outcomes.

Conclusions: Findings demonstrate the feasibility and effectiveness of the Social ABCs™ within a large community implementation. Parents exceeded our fidelity target and toddlers made significant gains on video-coded and standardized measures. Indeed, on some measures, toddlers made gains at a greater rate than expected by development alone, as indexed by standard score increases. Findings support the effectiveness of brief parent-mediated intervention for a wide range of families and their toddlers with emerging or confirmed ASD within a community service-delivery model.

308.003 *(Oral)* Trajectories and Timing of English Proficiency Among English Language Learners with ASD in Schools

A. Sturm[1], *J. A. Pan*[2], *J. R. Williams*[2], *F. A. Castellon*[3] *and C. Kasari*[4], *(1)Psychology, Loyola Marymount University, Los Angeles, CA, (2)Biostatistics, UCLA, Los Angeles, CA, (3)University of California Santa Barbara, Santa Barbara, CA, (4)University of California, Los Angeles, Los Angeles, CA*

Background: In 2015, approximately 4.8 million students – 9.5% - were identified as English language learners (ELL) in the U.S. Early work has revealed disproportionate representation of ELLs in the autism designation, however studies have yet to evaluate trajectories and timing of English proficiency and service use among students with autism spectrum disorder (ASD) in schools.

Objectives: The present study aimed to examine differences in the development of English proficiency and service use by educational placement among students with ASD by (1) identifying changes in English language proficiency by classroom placement, (2) examining the probability of continued ELL classification by classroom placement and (3) identifying the top services received by students classified as ELL.

Methods: The current study utilized annual longitudinal special education administrative record data including students served under a primary eligibility of autism from the academic years 2011-2012 through 2016-2017. Primary placement (>50%) for each student was classified as *general education* (GE) or in a dedicated *special day class* (SDC). The percentage of students who transitioned from ELL to English proficient was computed for GE and SDC. For students who transitioned to English proficient, mean age of classification change was computed. Kaplan Meier curves were generated to determine the probability of students remaining classified as ELL across time (measured by student age) for GE and SDC, respectively. Finally, top three services used by students in GE and SDC classes were tabulated.

Results: Of the students with ASD in GE, 25.9% (N=1624; 86% male, 86% Hispanic/LatinX, M_{age}=8.96, $M_{observations}$=3.7) were classified as ELL at the time of their first observation. Of the students with ASD in SDC, 43.7% (N=684; 86% male, 91% Hispanic/LatinX, M_{age}=10.14, $M_{observations}$=3.65) were classified as ELL at first observation. Only 31% of students classified as ELL in GE at their first available observation were English proficient by the time of their last observation. The mean age at which students in GE transitioned to English proficient was approximately 11.8 years old. Only 15% of students classified as ELL in SDC at their first available observation were English proficient by the time of their last observation. The mean age at which students in SDC were no longer classified as ELL was approximately 13.2 years old. Kaplan Meier curves (Figures 1a and 1b) revealed that the probability of classification as ELL decreased as students aged, plateauing at ~70% probability of continued classification as ELL around age 8 through age 18 for GE and at ~80% probability of ELL classification for SDC around age 9. Finally, for both students in GE and SDC classes, Language and Speech, Counseling and Guidance, and Occupational Therapy were the most frequent services received.

Conclusions: The present study revealed the striking number of students with ASD classified as ELL who are served in a large urban school district. A minority of ELLs with ASD gain English proficiency by middle childhood, a finding most notable for students in SDC placements. Future work is required to identify methods to best support ELLs with ASD in schools.

308.004 *(Oral)* Neuro-Biological Sex Differences in the Autistic Brain: A Systematic Review

K. Mo[1,2], *T. Sadoway*[3], *S. Bonato*[2], *S. Ameis*[1,2], *E. Anagnostou*[1,4], *J. P. Lerch*[1,5,6], *M. J. Taylor*[1,6] *and M. C. Lai*[1,2], *(1)University of Toronto, Toronto, ON, Canada, (2)Centre for Addiction and Mental Health, Toronto, ON, Canada, (3)Pediatric Laboratory Medicine, The Hospital for Sick Children, Toronto, ON, Canada, (4)Holland Bloorview Kids Rehabilitation Hospital, Toronto, ON, Canada, (5)Wellcome Centre for Integrative Neuroimaging, University of Oxford, Oxford, United Kingdom, (6)The Hospital for Sick Children, Toronto, ON, Canada*

Background: Our current understanding of autism is largely based on clinical practice and studies involving males given (1) the male predominance in prevalence and (2) females are often under-recognized and diagnosed cases frequently present with co-occurring epilepsy and low intelligence quotient and likely excluded from studies. As a result, there is a significant "male lens" in this field and females with autism are often poorly understood. To date, the effects of sex in brain development in autism has not been well-defined.

Objectives: To undertake a systematic review to 1) provide an overview of the literature that examines sex differences in the brain of individuals with autism and 2) summarize key brain areas with reported sex differences in autism.

Methods: Inclusion criteria: peer-reviewed studies of the brain involving samples of participants with an autism diagnosis that exclude case series. Databases (including EMBASE, Medline, PsycINFO, and Web of Science) were searched using relevant subject headings and keywords for concepts of 'sex' OR 'gender' AND 'autism' AND 'brain'. The risk of bias assessment tool (Hoy et al. 2012) was used to evaluate internal and external validity by two independent raters.

Results: The search generated a total of 10,095 articles (including grey literature, n=92). After removing duplicates (n=3,140), 6,863 unique articles were reviewed for relevance. 2,051 articles were screened by title and abstract and categorized by subject to give an overview of the current research landscape. After screening (n=1,188 removed), 863 articles were assessed for eligibility by full-text review. 66 neuroimaging studies that included analysis of sex and/or gender variables were retained for qualitative synthesis. Included papers varied in methodology and neuroimaging modalities (e.g., diffusion MRI, resting-state/task fMRI, structural MRI) and analysis of sex and/or gender variables. A total of 25 studies reported a significant result from analysis of sex-by-diagnosis interactions and/or sex-stratified analysis. Due to high heterogeneity in study design and participant demographics, very few studies were available for comparison and there was no clear consensus for specific areas of the brain with sex-modulating effects. One notable finding was the right inferior fronto-occipital fasciculus where two studies reported sex-by-diagnosis interaction effects; however, the direction of findings differed as one reported greater fractional anisotropy (FA) in teenage males with autism and the other reported lower FA in adult males with autism. In addition, there was a lack of studies that examined the effect of gender and lack of clear differentiation between sex and gender in these studies.

Conclusions: This systematic review demonstrates a significant research gap in sex-modulating effects in the autistic brain. The few available studies do not point to any well-supported brain regions with consistent sex-modulating effects. Studies so far may be underpowered to detect sex-by-diagnosis interaction effects and this information suggests a greater need for future investigations of sex-based heterogeneity with larger sample sizes. Future studies should also measure and investigate the effects of gender. Understanding the effect of biological sex in the risk of autism is an imperative first step to extend beyond the male lens in this field.

Diagnostic, Behavioral, Sensory and Intellectual Screening and Assessment

PANEL SESSION — DIAGNOSTIC, BEHAVIORAL, SENSORY AND INTELLECTUAL SCREENING AND ASSESSMENT

205 - Finally Capturing the Whole Picture: An Update on ICF Research in Autism

Panel Chair: Sven Bolte, *Center of Neurodevelopmental Disorders (KIND), Centre for Psychiatry Research; Department of Women's and Children's Health, Karolinska Institutet, & Stockholm Health Care Services, Region Stockholm, Stockholm, Sweden*

Discussant: Sonya Girdler, *School of Occupational Therapy, Social Work and Speech Pathology, Curtin University, Perth, WA, Australia*

Traditionally, autism spectrum disorder (ASD) is assessed almost exclusively from the clinical symptomatology perspective. Still, for autistic individuals, their families and large parts of society, the impact on functioning is both more significant and accessible Unfortunately, the diagnostic manuals provide no qualification as to how this impact should be assessed in more detail. The International Classification of Functioning (ICF) provides a bio-psycho-social framework for conceptualising functioning and health. The ICF takes a holistic perspective of disability, aligning with contemporary views of the functioning of autistic individuals, as resulting from an interaction of autistic symptomatology, participation within major life areas and many environmental facilitators and barriers. The ICF also provides a framework which focuses our attention on not only disability, but also the strengths and abilities of autistic individuals as a personal factor. This panel will present international research from Sweden, Australia and South Africa, which have utilised the ICF and the ICF core sets for ASD to further improve our understanding of functioning capturing the whole picture.

205.001 *(Panel)* The Whole Functional Picture of Autism: Development and Future Plans for the ICF Core Sets

***S. Bolte**, Center of Neurodevelopmental Disorders (KIND), Centre for Psychiatry Research; Department of Women's and Children's Health, Karolinska Institutet, & Stockholm Health Care Services, Region Stockholm, Stockholm, Sweden*

Background: Autism spectrum conditions are associated with diverse social, educational, and occupational challenges. To date, no standardized, internationally accepted tools exist to assess autism–related functioning. The World Health Organization's International Classification of Functioning, Disability and Health can serve as foundation for developing such tools.

Objectives: This lecture will review the development of the recently published ICF core sets for autism (Bölte et al., 2019; *Autism*), based on four international preparatory studies, and current efforts to validate the core sets, and derive psychometrically sound assessment tools from the sets for research, clinical, educational and vocational practice.

Methods: The core sets are based on four preparatory studies, a systematic review, an expert survey, a qualitative study, and a clinical study, involving several hundred researchers, clinicians and stakeholders from multiple disciplines and all WHO regions. The core sets have been validated (Schiariti et al., 2018; *Dev Med Child Neurol*; Black et al., 2019; *Aut Res*). Currently, the core sets for autism are further validated in different contexts (e.g. employment), translated into hands-on computer-based psychometric instruments using a Delphi method, iterative approach involving clinical, educational and vocational organizations in Sweden and in different WHO regions to establish reliability and validity.

Results: The ICF core sets for autism contain 111 second-level ICF categories in the comprehensive ore sets, and 60 in the common brief core set comprised 60 categories, while the age-appropriate core sets included 73 categories in the preschool version (0- to 5-year-old children), 81 in the school-age version (6- to 16-year-old children and adolescents), and 79 in the older adolescent and adult version (⩾17-year-old individuals). The majority of categories in the core sets describe participation and the environment. The core sets show good diagnostic validity against ADHD and cerebral palsy, and a high coverage (90%) for issues around employment of autistic people. Derived scales will use a pool of items to operationalize the core set categories, applying the ICF Research Branch numeric scale, and artificially intelligent solutions for use on mobile devices.

Conclusions: Past and current ICF core set research demonstrates the core set's potential to meaningfully complement categorical clinical information from DSM-5 and ICD-11 to achieve a thorough assessment of impairment and environmental barriers, on one hand, and facilitators and individual strengths, on the other. The latter will improve treatment planning, reimbursement systems, and communication among professionals and stakeholders.

205.002 *(Panel)* Development and Piloting of ICF Core Set Based Assessment of Functioning Tools for Young People Diagnosed with Autism or Other Neurodevelopmental Conditions

S. J. Girdler[1], *E. D'Arcy*[2], *M. Hayden-Evans*[3], *A. Chamberlain*[4], *B. T. Milbourn*[1], *A. O. Whitehouse*[5], *S. Bolte*[6], *V. Eapen*[7], *J. Wray*[8] *and K. Evans*[9], *(1)School of Occupational Therapy, Social Work and Speech Pathology, Curtin University, Perth, WA, Australia, (2)Cooperative Research Centre for Living with Autism (Autism CRC), Brisbane, Australia, (3)School of Occupational Therapy, Speech Pathology and Social Work, Curtin University, Perth, WA, Australia, (4)Autism Research Team, Telethon Kids Institute, Perth, Australia, WA, Australia, (5)Telethon Kids Institute, University of Western Australia, Perth, WA, Australia, (6)Center of Neurodevelopmental Disorders (KIND), Centre for Psychiatry Research; Department of Women's and Children's Health, Karolinska Institutet, & Stockholm Health Care Services, Region Stockholm, Stockholm, Sweden, (7)Cooperative Research Centre for Living with Autism (Autism CRC), Long Pocket, Brisbane, Australia, (8)State Child Development Service, Western Australia Department of Health, Perth, Western Australia, Australia, (9)Telethon Kids Institute, University of Western Australia, Perth, Western Australia, Australia*

Background: Children and adults on the autism spectrum experience a range of activity limitations and participation restrictions, impacting on daily life and long term role outcomes. International guidelines recommend that functioning be evaluated as part of a diagnostic evaluation, and both the DSM-5 and ICD-11 include functioning related diagnostic criteria for autism spectrum disorder (ASD). The 'Australian National Guideline for the Assessment and Diagnosis of ASD' advocates a strengths-focused and comprehensive assessment of functioning and support needs for all individuals referred for an assessment of ASD concerns. This Australian guideline suggests the International Classification of Functioning, Disability and Health (ICF) as a conceptual framework for an assessment of functioning, along with the use of standardised assessments that cover a broad range of domains, with a suggestion for researchers to develop and validate a fit-for-purpose tool based on the ICF Core Sets for ASD.

Objectives: This program of research aimed to develop and validate assessment of functioning tools based on the ICF Core Sets for ASD that are suitable for individuals on the autism spectrum across the lifespan and available in clinician-administered, self-report and proxy-report versions.

Methods: Prototype assessment of functioning tools were developed in clinician-administered, self-report and proxy-report versions with input from researchers, clinicians and the autism community (n>37). These prototype tools include simplified definitions, examples and symbolic images for each of the ICF Core Sets for ASD items. The clinician-administered version was piloted with at least 75 parents/caregivers of young autistic individuals up to 20 years of age (alongside the PEDI-CAT and Vineland, two established standardised tools). Feedback on the clinician-administered version was also obtained from parents/caregivers (n>30) on acceptability and clinicians (n>30) on clinical utility. The self-report and proxy-report versions will be piloted with autistic adolescents/adults and parents/caregivers of autistic individuals of all ages (expected n>50) between January – March 2020 and feedback will be sought regarding acceptability.

Results: Preliminary psychometrics properties of the clinician-administered version suggest that most activity and participation domains have good to excellent internal consistency, along with excellent inter-rater reliability at the item level. Parent/caregivers and clinicians provided early feedback that the clinician-administered version was holistic and strengths-focused, although time-consuming, and a full set of psychometric properties and normative data for a manualised final version would be necessary prior to wide spread adoption. Further investigation of the psychometric properties and usability of the clinician-administered, self-report and proxy-report versions will be available at the INSAR meeting.

Conclusions: These prototype assessment of functioning tools represent an important first step in operationalising the ICF Core Sets for ASD, which will provide a suite of comprehensive assessment of functioning tools that are feasible and acceptable to the autism and clinical communities.

205.003 *(Panel)* Formalising an Assessment of Functioning Process for Individuals Undergoing an Autism Diagnostic Evaluation and/or Service Planning in Australia

K. Evans[1], *A. Chamberlain*[2], *S. J. Girdler*[3], *B. T. Milbourn*[3], *E. D'Arcy*[4], *M. Hayden-Evans*[5], *S. Bolte*[6], *V. Eapen*[7], *J. Wray*[8] *and A. O. Whitehouse*[9], *(1)Telethon Kids Institute, University of Western Australia, Perth, Western Australia, Australia, (2)Autism Research Team, Telethon Kids Institute, Perth, Australia, WA, Australia, (3)School of Occupational Therapy, Social Work and Speech Pathology, Curtin University, Perth, WA, Australia, (4)Cooperative Research Centre for Living with Autism (Autism CRC), Brisbane, Australia, (5)School of Occupational Therapy, Speech Pathology and Social Work, Curtin University, Perth, WA, Australia, (6)Center of Neurodevelopmental Disorders (KIND), Centre for Psychiatry Research; Department of Women's and Children's Health, Karolinska Institutet, & Stockholm Health Care Services, Region Stockholm, Stockholm, Sweden, (7)Cooperative Research Centre for Living with Autism (Autism CRC), Long Pocket, Brisbane, Australia, (8)State Child Development Service, Western Australia Department of Health, Perth, Western Australia, Australia, (9)Telethon Kids Institute, University of Western Australia, Perth, WA, Australia*

Background: An international review of autism diagnostic guidelines revealed functioning as an important topic to evaluate during a diagnostic evaluation, however varied emphasis was placed on an assessment of functioning as a necessary component. The 'Australian National Guideline for the Assessment and Diagnosis of Autism Spectrum Disorder' (ASD) articulates an assessment of functioning as the first step when an individual is referred for an assessment of ASD concerns. This assessment of functioning:

- may be undertaken by a range of medical/allied health professionals with relevant training and expertise in specified areas;

- should cover a broad range of domains of functioning, activity and character related strengths, environmental barriers and facilitators, and both observed and expressed support needs;
- should involve information collection within natural contexts through multiple methods (e.g. interviews, observations, standardised assessment tools; and,
- outcomes should include specific support needs and connection with appropriate services.

The Australian guideline concludes with a recommendation for researchers to investigate the psychometric properties of existing tools that assess functioning.

Objectives: This program of research aimed to investigate the psychometric properties and usability of existing standardised assessment of functioning tools, specifically the Vineland-3 and PEDI-CAT (ASD).

Methods: All items from the Vineland-3 and PEDI-CAT (ASD) were linked to the International Classification of Functioning, Disability and Health – Children and Youth (ICF-CY) using established rules. Feedback from clinicians (n>30) regarding the clinical utility of the Vineland-3 and PEDI-CAT tools was obtained through focus groups. Clinical assessments were conducted with approximately 170 parents/caregivers of young people diagnosed with neurodevelopmental conditions (primarily autism) at multiple time points. Parents/caregivers completed computer-based administrations of the Vineland-3 Parent/Caregiver Form and PEDI-CAT (ASD and Original). A sub-sample (n>81) completed a comprehensive assessment of functioning in the home setting with an occupational therapist, involving a clinician-administered Vineland-3 Interview and ICF Core Set tool. Finally, parents/caregivers provided feedback (n>35) on the tools. Data were analysed using a quantitative and qualitative approaches.

Results: Linking results revealed that both the Vineland-3 and PEDI-CAT (ASD) focus on a restricted range of activity and participation items of the ICF-CY, and do not adequately cover all items with the ICF Core Sets for ASD. Clinician feedback indicated that neither the Vineland-3 and PEDI-CAT (ASD) is suitable to be used in isolation to assess functioning. Preliminary analysis of the psychometric properties of these tools suggested that both the Vineland-3 and PEDI-CAT (ASD) have acceptable test-retest reliability and moderate concurrent validity with each other, whilst the Vineland-3 Interview has good to excellent inter-rater reliability (based on a single administration) and mixed alternate forms reliability with the Parent/Caregiver Form. Parent/caregiver acceptability results indicated that there are strengths and weaknesses of both assessment tools. Final findings on the psychometric properties and usability of the Vineland-3 and PEDI-CAT (ASD) will be available at the INSAR meeting.

Conclusions: Existing tools, when used in isolation, are not sufficiently holistic for a comprehensive assessment of functioning. Tools based on the ICF Core Sets for ASD Documentation Form should be developed and evaluated for future translation into clinical practice.

205.004 *(Panel)* Understanding ASD in Context: A Cross-Cultural Comparison of Family Perceptions of Functioning in Sweden and South-Africa

M. Viljoen[1], *S. Mahdi*[2], *J. Shelly*[1], *D. Griessel*[3], *S. Bolte*[4] *and P. J. de Vries*[1], *(1)Centre for Autism Research in Africa, Division of Child & Adolescent Psychiatry, University of Cape Town, Cape Town, South Africa, (2)Karolinska Institutet Center of Neurodevelopmental Disorders (KIND), Karolinska Institute Center of Neurodevelopmental Disorders, Stockholm, Sweden, (3)Department of Paediatrics and Child Health, University of the Free State, Bloemfontein, South Africa, (4)Center of Neurodevelopmental Disorders (KIND), Centre for Psychiatry Research; Department of Women's and Children's Health, Karolinska Institutet, & Stockholm Health Care Services, Region Stockholm, Stockholm, Sweden*

Background: Autism Spectrum Disorder (ASD) affects individuals from all continents, cultures and socio-economic backgrounds. Functional outcomes can be highly variable across diverse populations. The World Health Organization International Classification of Functioning, Disability and Health (ICF) is used to describe functioning and recent efforts have been made to develop ICF core sets for ASD. The core set development process included a qualitative study that examined caregiver perspectives from divergent countries (Canada, Sweden, India, Saudi Arabia and South Africa). This provided the unique opportunity to examine the association between contextual factors and functioning in children with ASD from diverse socio-economic settings by directly comparing parent/caregiver perspectives.

Objectives: First, to understand the global landscape of parental perceptions of functioning in their children with ASD, and to identify the predominant ICF themes raised by parents in existing literature. Second, to perform a systematic and direct comparison of functional themes raised by parents/caregivers in a Low/Middle-Income Country (South Africa) and a High-Income Country (Sweden) during the ICF ASD Core Set Development process.

Methods: To meet aim one, we performed a scoping review. Two researchers conducted a comprehensive search of peer-reviewed studies and key findings were linked to ICF first or second-level categories. Next we performed secondary analysis of data from focus groups and semi-structured interviews analysed for the ICF ASD core set study. Using frequency and content analysis we compared South African (n=22) and Swedish (n=13) participants.

Results: Thirty-three studies were included in the scoping review, and most were conducted in High-income Countries (HIC, n = 25/33, 76%) with only six studies in Low/Middle-income Countries (LMIC, n = 6/33, 18%). Two studies compared perspectives from LMIC and HIC (n = 2/33, 6%). Functional themes from HIC included a range across the ICF bio-psychosocial framework with body functions, activities & participation, environmental factors and personal factors all represented. Functional themes from LMIC were predominantly focused on environmental factors, but included some categories from body functions and activities & participation.

Complete frequency agreement was seen in 4 ICF categories in Sweden and South Africa - carrying out daily routines, dressing, complex interpersonal interactions and immediate family. Obvious differences in frequency of reporting were observed in one environmental factors category, six body functions categories, and three activities & participation categories. Only three ICF categories differed in content between South Africa and Sweden.

Conclusions: Although existing literature focused more on environmental factors in LMIC compared to HIC, environmental factors were not reported more frequently in South Africa (LMIC) than Sweden (HIC) in the direct comparison of qualitative data. In fact, parent/caregiver perspectives more frequently differed regarding body functions and activities & participation. The content of perceptions was mostly similar.

Given the universality of findings, our results support the global usefulness of the recently developed ICF core sets for ASD. We recommend that more comparative studies on ASD and functioning should be conducted, and that similar comparisons in other disorders where core sets have been developed, such as ADHD, may also be of value.

PANEL SESSION — **DIAGNOSTIC, BEHAVIORAL, SENSORY AND INTELLECTUAL SCREENING AND ASSESSMENT**

206 - New Measures in Autism: Progress Toward Optimal Endpoints

Panel Chair: Antonio Hardan, *Psychiatry & Behavioral Sciences, Stanford University, Stanford, CA*

Discussant: Thomas Frazier, *Autism Speaks, New York, NY*

Significant progress has been made in the development and validation of instruments for measuring autism spectrum disorder (ASD) symptoms. However, despite strengths, current measures have limited (i) content coverage, often missing key symptoms that can have significant clinical impact and are therefore an important treatment target, (ii) ability to capture co-occurring symptoms whose presentation might be specific to ASD, therefore underestimating important areas of clinical need, (iii) ability to track symptom change, and (iv) alignment with the current dimensional frameworks including the Research Domains Criteria (RDoC). The proposed panel brings together state of the art empirical work aimed at addressing noted measurement limitations. Proposed investigations span a range of approaches including (i) parent rated measure of typical and atypical anxiety in ASD, (ii) quantitative measure of social motivation and other key social domains aligned with RDoC, (iii) multi-step conceptual and big-data analytic approach towards the development of new measure of repetitive behaviors, and (iv) brief observation measure for capturing change in core ASD symptoms. Given that research efforts are needed to ensure that practitioners and policy-makers have robust data on ASD instruments, the proposed panel is particularly timely and holds promise for positively impacting both research and clinical practice.

206.001 *(Panel)* Extending the Usefulness of the Brief Observation of Social Communication Change (BOSCC)

A. Holbrook[1], *K. Byrne*[1], *R. L. Grzadzinski*[2], *S. H. Kim*[3] *and C. Lord*[1], *(1)University of California, Los Angeles, Los Angeles, CA, (2)University of North Carolina Chapel Hill, Chapel Hill, NC, (3)Psychiatry, Center for Autism and the Developing Brain, White Plains, NY*

Background: There are several limitations to current practices of measuring treatment response for individuals with Autism Spectrum Disorder (ASD), including but not limited to: reliance on caregiver/clinician reports, limited number of flexible and standardized measures for use across studies, and the application of measures that were not designed for or sensitive enough to measure change over brief periods of time. The BOSCC was developed to provide a standardized and efficient method of measuring subtle changes in social communication in individuals with ASD. The BOSCC administration and BOSCC coding system have been used to validly and reliably measure social communication change in minimally verbal children (Grzadzinski et al., 2016; Kim et al., 2018), addressing the need for appropriate treatment measures in this population. However, due to the wide heterogeneity in language abilities within ASD, there remains a need for a measure that can be used for individuals across a range of language levels. The BOSCC has been expanded to include a module that can be used with individuals with phrase speech.

Objectives: 1) Use preliminary data to explore if the BOSCC measures change in social communication behaviors over time in children with phrase speech. 2) Compute basic psychometrics for the BOSCC phrase speech module.

Methods: Participants included 13 children with ASD (M_{age}= 4.15 years, *SD*=1.47 years). Six children were enrolled in a targeted intervention program while the remaining seven children received treatment as usual (TAU).

The BOSCC is a 12-minute videotaped play interaction between an individual and a play partner blind to treatment status. It was designed to be easy to administer and was implemented with research assistants who had received minimal instruction.

The BOSCC coding consists of two 6-minute segments, each watched twice and coded. Codes are averaged across the segments. The BOSCC coding system uses decision trees to increase ease of use. The BOSCC phrase speech module was developed by modifying 15 of the original items and adding two new items to reflect social communication behaviors of individuals with phrase speech. Behaviors are coded on a 6-point scale ranging from 0 (atypical behavior not present) to 5 (atypical behavior present and significantly impairs functioning). Inter-rater reliability was calculated using percent agreement within 1 point on overall totals.

Two paired-samples t-tests were conducted to determine change in BOSCC scores across time within each treatment group.

Results: Significant changes were observed in BOSCC Total Scores over the course of intervention (pre:*M*=30.5, *SD*=6.2 vs. post:*M*=26.2, *SD*=6.3); *t*(5)=2.70, *p*=0.04, Cohen's D=0.68. No significant changes were observed in BOSCC Total Scores over time for TAU (pre:*M*=26.3, *SD*=8.9 vs. post:*M*=24.6, *SD*=11.8); *t*(6)=0.67, *p*=0.53. Preliminary inter-rater reliability was high (percent agreement=94%; ICC=.99).

Conclusions: Preliminary data suggests that the BOSCC phrase speech module is sensitive to and reliably measures small changes in social communication in children with ASD with phrase speech. The high inter-rater reliability indicates coding ease and precision in using a modified decision tree system. Data collection is ongoing and more data with a larger sample will be available for analyses by May 2020.

206.002 *(Panel)* Reliability and Validity of the New Parent-Rated Anxiety Scale in Youth with Autism Spectrum Disorder

L. Scahill, *Marcus Autism Center, Atlanta, GA*

Background: Anxiety is common in youth with autism spectrum disorder (ASD). Anxiety symptoms vary from mild to severe in this population. Due to language and cognitive challenges in youth with ASD, measures of anxiety used in the general pediatric population may not be suitable for youth with ASD.

Objectives: This presentation reports on the development, reliability and validity of a new parent-rated measure of anxiety in youth with ASD.

Methods: Seventy-two candidate scale items were derived from a series of focus groups with parents of youth with ASD. Parents of 990 youth with ASD (age 5-17; 80.8% male) completed the 75-item survey (scored 0-3) online. Factor analysis and item response theory (IRT) analyses reduced the number of items resulting in a single factor with 25 items. A separate sample of children with a least mild anxiety (N=116; age 5-17; 79.3% male) participated in a comprehensive in-person clinical assessment to evaluate validity and reliability of the 25-item Parent-rated Anxiety Scale for ASD (PRAS-ASD).

Results: In the online sample, the mean PRAS-ASD score was 29.04 ± 14.9 **(**range 0 to 75; coefficient alpha = 0.93). The IRT results indicated excellent reliability across a wide range of scores with low standard errors. In the clinical sample (N=116), the PRAS-ASD mean was 31.0 $\pm$15.6 (range 1-65). Pearson correlations with parent ratings of repetitive behavior and disruptive behavior ranged 0.33 to 0.66 supporting divergent validity of the PRAS-ASD. The correlation with a parent-rated measure of anxiety used in the general pediatric population of 0.83 supports convergent validity. Forty participants (32 boys, 8 girls; mean age of 11.9 $\pm$ 3.4) returned at Time 2 (mean =12.2 days) and Time 3 (mean = 24.2 days). Intraclass correlation showed test-retest reliabilities of 0.88 and 0.86 at Time 2 and Time 3, respectively.

Conclusions: Not all children with ASD are anxiety. Anxiety ranges from little or no anxiety mild to severe. The 25-item PRAS-ASD is a reliable and valid scale for measuring anxiety in youth with ASD.

206.003 *(Panel)* The Stanford Social Dimensions Scale: A New Instrument to Assess Social Domains in Autism

J. M. Phillips[1]*, M. Uljarevic*[2]*, R. K. Schuck*[3]*, S. Schapp*[4]*, E. S. Loyola*[5]*, E. E. Salzman*[6]*, R. Libove*[7]*, T. W. Frazier*[8] *and A. Y. Hardan*[1]*, (1)Psychiatry & Behavioral Sciences, Stanford University, Stanford, CA, (2)Department of Psychiatry and Behavioral Sciences, School of Medicine, Stanford University, Stanford, CA, (3)Psychiatry and Behavioral Sciences, San Jose State University, Palo Alto, CA, (4)Psychiatry, Kaiser, Redwood City, CA, (5)Palo Alto University, Palo Alto, CA, (6)Psychiatry, UCSF, San Francisco, CA, (7)Psychiatry and Behavioral Sciences, Stanford University, Stanford, CA, (8)Autism Speaks, New York, NY*

Background: Social motivation theory has been suggested to provide a potentially useful framework for understanding the emergence of social impairments in autism spectrum disorder (ASD). In addition, a number of early interventions including the Early Start Denver Model and Pivotal Response Treatment target social motivation. Social motivaiton is also an importnat component of the Research Domain Criteria's (RDoC) Affiliation and Attachment construct. Much like the heterogeneity observed in cognitive abilities of children with ASD, there is similar variability in the degree of social motivation seen across the autism spectrum. Differing levels of social motivation may have important implications for treatment selection and expected outcomes. However, despite the prominence of this construct in treatment, there are few available tools specifically designed to capture individual differences in social motivation and related aspects of social behavior, particularly in a manner that can be useful for tracking change across time.

Objectives: To validate a newly developed quantitative instrument—the Stanford Social Dimensions Scale (SSDS)—designed to capture individual differences in distinct components of social motivation and other key dimensions of social functioning aligned wiht the RDoC framework and to explore its utility for differentiating social subtypes among a sample of individuals with ASD.

Methods: The validation sample consisted of 175 parents of autistic individuals (35 females; *M*age= 7.19 years, *SD*age= 3.96) who completed the SSDS, the Social Responsiveness Scale (SRS-2) and the Child Behavior Checklist (CBCL). The replication sample consisted of 624 parents of children who were either typically developing (TD) or had a reported neurodevelopmental or psychiatric condition (437 TD; *M*age= 11.49 years, *SD*age= 4.48); these parents completed the SSDS and the SRS-2.

Results: Exploratory Structural Equation Modeling indicated that a five-factor model provided best fit to the data across both the initial ASD sample (comparative fit index [CFI]= .940, Tucker Lewis Index [TLI]= .919, root mean square error of approximation [RMSEA]= .048, standardized root mean square residual [SRMR]= .038) and the replication sample (CFI= 946, TLI= .930, RMSEA= .044, SRMR= .026). The five factors that emerged were described as Social Motivation, Social Affiliation, Expressive Social Communication, Social Recognition, and Unusual Approach. All subscales had good to excellent consistency (Composite Reliability scores of ≥ .72), showed good convergent and divergent validity, as evidenced by the pattern of correlations with relevant SRS-2 and CBCL domains, and strong discriminant validity, with the ASD sample showing significantly higher impairment than the non-ASD clinical sample, which, in turn, had significantly higher impairments than the typically developing sample. Within the ASD sample, Latent Profile Analysis yielded five profiles showing distinct patterns of strengths and weaknesses across different SSDS scales. Profiles were further differentiated in terms of cognitive ability, ASD and internalizing symptom severity.

Conclusions: Our findings provide validation of a new scale designed to comprehensively capture individual differences in social motivation and other key social dimensions in ASD. Results further suggest the potential utility of this scale in identifying subgroups of individuals with ASD who share particular constellations of strengths and weaknesses across key social dimensions.

206.004 *(Panel)* A Big Data Approach Toward the Development of a New Quantitative Measure of Restricted and Repetitive Behaviors

M. Uljarevic[1]*, B. Jo*[2]*, T. W. Frazier*[3]*, R. Libove*[4] *and A. Y. Hardan*[5]*, (1)Department of Psychiatry and Behavioral Sciences, School of Medicine, Stanford University, Stanford, CA, (2)Department of Psychiatry and Behavioral Sciences, Stanford University, Stanford, CA, Stanford, CA, (3)Autism Speaks, New York, NY, (4)Psychiatry and Behavioral Sciences, Stanford University, Stanford, CA, (5)Psychiatry & Behavioral Sciences, Stanford University, Stanford, CA*

Background: Despite their clinical significance, etiology behind the restricted and repetitive behaviors (RRB) domain is poorly understood and effective treatments are currently lacking. Inconsistencies in the organization, division, and measurement have pervaded RRB research to date, presenting a major obstacle for a better understanding of the underlying mechanisms thus stifling the development of effective individually tailored treatments. Most pressingly, existing RRB measures have major limitations, including: (i) poor ability to systematically and comprehensively capture all relevant RRB domains, (ii) limited psychometric properties, (iii) lack of sensitivity to subtle symptom expressions and ability to capture change.

Objectives: To conduct (i) a systematic review of RRB factor analytic studies to date, and (ii) a series of factor analyses across existing RRB measures using multiple high-quality data sets. This conceptual and empirical process will derive a comprehensive RRB taxonomy and inform the development of a new quantitative RRB measure—the Comprehensive Assessment of Restricted and Repetitive Behaviors (CARRB).

Methods: For systematic review Medline, PsychInfo and Scopus databases were searched for published articles available through October 2019. A series of complex exploratory and confirmatory factor analyses were conducted in large, well-characterized existing data sets (N > 40,000) including ASD and other neurodevelopmental disorders to enable identification of core RRB domains generalizable across existing measures and to identify under-represented RRB domains.

Results: Systematic search identified 33 factor analytic studies evaluating 8 scales. Almost half of the studies (n=16) focused on the Autism Diagnostic Interview-Revised, eight on the Repetitive Behavior Scale-Revised, four on the Repetitive Behavior Questionnaire-2; other instruments were evaluated in only one or two studies. While Repetitive Motor Behaviors (RMB), Insistence on Sameness (IS) and Circumscribed Interests (CI) factors emerged most frequently, factors such as compulsions and sensory sensitivity also emerged albeit inconsistently. The majority of studies utilized modest sample sizes, limited statistical methods, and relied on single measures that varied widely in terms of comprehensiveness. None of the studies explored the content agreement across scales. The item content of the factors was inconsistent, even when the same measure was used. Integration across a range of large data sets (including the Autism Genetic Research Exchange, the National Database for Autism Research and the Simons Simplex Collection) and the application of the exploratory structural equation modelling and multi-trait multi-method approaches confirmed the existence of RMB and IS factors (although the content varied widely across measures). The CI factor was under-sampled and under-specified (five or less items irrespective of the scale). Item level analyses identified the existence of unusual sensory interests, sensory sensitivity, compulsions and tics represented by ≤ 4 items each. Derived RRB domains served as the basis for developing the pilot version of the CARRB.

Conclusions: A combination of systematic review of the current literature and the application of advanced latent variable approaches enabled fine-grained differentiation between distinct RRB domains and identification of domains not adequately captured by the existing measures. This knowledge is essential for the development of a new RRB measure designed to provide comprehensive assessment of the identified RRB domains.

PANEL SESSION — DIAGNOSTIC, BEHAVIORAL, SENSORY AND INTELLECTUAL SCREENING AND ASSESSMENT

207 - Screening for Autism Spectrum Disorders in the ASD PEDS Network: Building Capacity, Engaging Communities, and Improving Detection

Panel Chair: Alice Carter, *Department of Psychology, University of Massachusetts Boston, Boston, MA*

Discussant: Sarabeth broder-Fingert, *Boston Medical Center, Boston, MA*

This session will highlight results from the projects that comprise the NIMH ASD PEDS Network. Each of the NIMH ASD PEDS Network projects were designed to address health disparities in rates of and age at detection of ASD. The projects are diverse with respect to the screening approaches that were adopted. Specifically, there is variability across the contexts of screening (i.e., pediatrics versus Part C Early Intervention), engagement of community partners, screening tools employed, formats of screening (questionnaire, interview, observation), and study design (e.g., randomized clinical trial of the added value of family navigation, quasi-experimental design using difference in difference analyses to compare intervention sites to contrast sites using administrative data). Most of the studies in the network included both quantitative outcomes related to screening results as well as qualitative data regarding parent and provider experiences with screening. Each project will present their screening model and present key findings and lessons learned. Taken together, these studies suggest that routine early screening in universal and targeted settings can reduce age at detection, enhance rates of early detection, and may be most beneficial for families from historically marginalized statuses (e.g., racial and ethnic minorities). The discussion will focus on cross-study implementation science.

207.001 *(Panel)* Evaluation of the Screen-Refer-Treat Model for Increasing Early Detection and Intervention for Toddlers with ASD across Community Systems of Care: A One-Year Follow-up

W. L. Stone[1], *L. V. Ibanez*[2], *K. J. Steinman*[3], *S. Dorsey*[4], *A. Vander Stoep*[5], *K. Myers*[6] *and C. Zhou*[7], *(1)Psychology, University of Washington, Seattle, WA, (2)UW READi Lab, Seattle, WA, (3)Neurology, University of Washington and Seattle Children's Hospital, Seattle, WA, (4)Department of Psychology, University of Washington, Seattle, WA, (5)Department of Psychiatry and Behavioral Sciences, Department of Epidemiology, University of Washington, Seattle, WA, (6)Department of Psychiatry and Behavioral Sciences, University of Washington, Seattle, WA, (7)Department of Pediatrics, Seattle Children's Research Institute, University of Washington, Seattle, WA*

Background: Despite the availability of evidence-based interventions for toddlers and young children with ASD, many obstacles limit access to these treatments. Primary care providers (PCPs) often lack knowledge about the early signs of ASD and/or fail to use validated screening tools as recommended by the American Academy of Pediatrics. The publicly funded Part C Early Intervention (EI) system, which offers treatment for families of toddlers with developmental delays and is available in all U.S. states, operates under a generalist model, with few providers having specialized ASD training. This paucity of specialized ASD intervention services in their community creates a further disincentive for PCPs to identify children with ASD.

Objectives: The Screen-Refer-Treat (SRT) project aims to overcome these challenges and improve early access to ASD-specialized services by implementing a multisystem heath care intervention to increase capacity in both primary care and early intervention sectors within the same community. Specific goals are to: (1) increase PCPs' use of universal ASD *screening* at 18-month well-child visits and *referral* of positive screens to EI programs, and (2) increase EI providers' use of an evidence-based *treatment* when ASD is suspected.

Methods: The SRT model was conducted in four underserved counties in one U.S. state; 10 PCP practices (n=53 PCPs) and 9 EI programs (n=80 EI providers) were enrolled. To increase PCPs' universal use of ASD screening at 18 months, practices received an online version of the Modified Checklist for Autism in Toddlers Revised/with Follow-up (M-CHAT-R/F; Robins et al., 2014), which reduces their time burden by automatically presenting follow-up interview questions when appropriate. A 2-hour workshop on ASD recognition and care was also provided. EI providers received two 1-day trainings on an evidence-based interactive screener (Screening Tool for Autism in Toddlers [STAT]; Stone et al., 2004) and an evidence-based ASD intervention, Reciprocal Imitation Training [RIT], that is easily implemented and can be taught to parents (Ingersoll & Schreibman, 2006). Counties were randomly assigned to the timing of their training using a stepped-wedge cluster design. Provider outcomes included ratings of feasibility and adoption of the tools, as well as changes in self-efficacy regarding ASD care post-SRT training. Separate cohorts of parents were enrolled before and after the SRT training and completed measures of parenting stress, efficacy, satisfaction with health care, and child social communication.

Results: Results obtained one year post-SRT training indicate high feasibility and use of the online M-CHAT-R/F, the STAT, and RIT. Paired samples *t*-tests indicated significant increases from pre- to post-SRT in: (1) PCP and EI provider self-efficacy in providing ASD care and treatment; and (2) PCP use of routine ASD screening at 18 months. An independent samples *t*-test indicated increased satisfaction with health care for the post-SRT parent cohort relative to the pre-SRT cohort. All *p* values range from < .01 to < .05.

Conclusions: The SRT model was effective in changing the practices of community-based providers to increase early ASD screening and specialized intervention for toddlers with, or suspected of having, ASD. Additional data analyses comparing the parent cohorts are ongoing.

207.002 *(Panel)* Addressing Health Disparities in Early Detection of ASD: Screening in Part C Early Intervention

A. S. Carter[1], *R. C. Sheldrick*[2], *A. Eisenhower*[3], *T. Mackie*[4], *F. Martinez-Pedraza*[5], *N. A. Hoch*[6] *and S. M. Brunt*[7], *(1)Department of Psychology, University of Massachusetts Boston, Boston, MA, (2)Boston University School of Public Health, Boston, MA, (3)University of Massachusetts Boston, Boston, MA, (4)Institute for Health, Health Care Policy and Aging Research, School of Public Health, Rutgers Univer, New Brunswick, NJ, (5)Center for Children and Families, Florida International University, Miami, FL, (6)Clark University, Worcester, MA, (7)Psychology Department, University of Massachusetts Boston, Boston, MA*

Background: Children screened in pediatrics and suspected of having ASD are often referred to Part C Early Intervention (EI) services without an ASD evaluation referral. Thus, after a positive ASD screener, developmental concerns (e.g., language delays) may be acknowledged without referral to ASD specific services. Access barriers may further limit receipt of evaluation following referral. These barriers are associated with health disparities in children's receipt of early diagnosis, affecting access to ASD specific evaluation and intervention. We partnered with community-based EI agencies to implement multi-stage ASD screening and referrals to university-based diagnostic evaluation to increase access to early detection of ASD among all children, minimizing health disparities in rates of diagnosis.

Objectives: To determine if a community-based, EI-administered multi-stage screening protocol and referral to university-based diagnostic evaluation increases rates of ASD diagnosis and minimizes health disparities in rates of ASD diagnosis. To contextualize findings in parent experiences.

Methods: A mixed methods approach was adopted. Quantitative analyses involved tracking 4943 children (mean age: 22.0 months; 62.9% boys, 73.3% children of color, 34.9% non-English-primary language, 64.5% publicly-insured) who were eligible for screening through the multi-stage screening and diagnostic protocol. Stage 1 screening included the Brief Infant-Toddler Social Emotional Assessment and Parent Observations of Social Interactions, Second stage screening involved the Screening Tool for Autism in Toddlers. A positive screener or parent or provider concern triggered eligibility for the next stage/referral for evaluation. State-level administrative demographic and diagnostic data from the Department of Public Health were used to conduct difference-in-difference analyses comparing rates of diagnosis in screening intervention sites relative to contrast sites that showed similar trajectories of diagnostic rates in the baseline, pre-intervention period. Finally, qualitative analyses of 65 longitudinal interviews with 22 parents provide insight into parent experiences of the multi-stage screening process.

Results: Participation and follow-through were high (64.9% and 65.3% at first-and second-stage screening, 84.6% at diagnostic evaluation), with 83.7% of children participating in a diagnostic evaluation receiving an ASD diagnosis, Difference-in-difference analyses document that rates of diagnosis improved significantly at each intervention site relative to comparison sites (See Figure). Analyses will be elaborated in relation to health disparities. Logistic regressions identified the following predictors of ASD diagnosis relative to the full screen eligible sample: children receiving diagnoses were older [Exp(*B*)=1.03, *p*=.004, 95% C.I.=1.01-1.05], more likely to be boys [Exp(*B*)=0.40, *p* < .001, 95% C.I.=0.31-0.52], and more likely to be children of color than all other eligible children [Exp(*B*)=1.39, *p*=.026, 95% C.I.=1.04-1.86]. No differences in language [Exp(*B*)=0.96, *p*=.71, 95% C.I.=0.75-1.21] or insurance [Exp(*B*)=1.20, *p*=0.16, 95% C.I.=0.93-1.54] were observed. Parents reported the written and observational screening tools facilitated understanding their child's behaviors within an ASD interpretive framework in unique and synergistic ways, facilitating shared decision-making with the EI provider.

Conclusions: Our EI-implemented multi-stage screening model increased rates of ASD diagnosis and appears to address health disparities in receipt of ASD diagnosis. Expanding screening to EI settings offers opportunities to aid parents in understanding their children's ASD symptoms and facilitate shared decision-making and access to ASD specific interventions.

207.003 *(Panel)* The Get SET Early Model As a Mechanism for the Very Early Detection of ASD: Examination of Influencing Factors Including Parent Concern, Sex, and Age

K. Pierce[1], *V. Gazestani*[2], *E. Bacon*[3], *A. Cheng*[3], *C. Barnes*[4], *S. Nalabolu*[3], *E. Courchesne*[1], *L. Lopez*[3], *S. J. Arias*[3] *and C. Pham*[3], *(1)Autism Center of Excellence, Neurosciences, University of California, San Diego, La Jolla, CA, (2)Neurosciences, Univeristy of California, San Diego, La Jolla, CA, (3)Neurosciences, University of California, San Diego, La Jolla, CA, (4)University of California, San Diego, La Jolla, CA*

Background: Studies have shown that very early engagement in treatment (by age 2 years) is associated with a range of positive changes including increases in social orienting, language ability, and overall IQ for toddlers with ASD[1-3]. Why then, is ASD not consistently identified and treated early? Several factors including generally low rates of referral for an evaluation on the part of pediatricians even when a toddler has failed a screen[4], variability in the level of parent concern, even when autism is present, age at which screening occurs, and sex likely play a role.

Objectives: Here we examine the efficacy of our 12-component *Get SET Early* model (S=Screen, E=Evaluate, and T=Treat) as a mechanism to detect ASD in the general population at young ages within the context of a repeat screen approach using the CSBS DP IT Checklist[5]. **Figure 1.** Our goals are to: (1) determine median age of ASD detection and treatment referral stratified by age at screen; (2) determine the total number of ASD cases as well other delays detected and; (3) examine pediatrician referral rates based on age at screen, gender, and presence or absence of parent concern.

Methods: Two hundred and three pediatricians participated. Parents filled out the CSBS at 12, 18 and/or 24 month well baby check ups and also denoted whether or not they were concerned about their child's development. Pediatricians denoted whether or not they were referring a toddler for an evaluation following screening. Logistic regression was used to examine factors relating to pediatrician referral, with sex, age at screen, and presence or absence of parent concern as variables.

Results: Pediatricians administered 59,411 CSBS screens at 12, 18 and/or 24 month well baby check-ups. Seven hundred and sixty-nine toddlers were referred to the *Get SET Early* model based on failure of the CSBS or parent concern and completed one or more diagnostic evaluations by licensed psychologists. Overall median age at 1st screen was 17.07 months; first evaluation 19.3 months, and most recent (last) evaluation 29.24 months. Toddlers that were screened at 12 months received their first diagnostic evaluation and were referred for treatment by 15.6 months, which is several years earlier than the national average of 56 months[6]. **Figure 2.** Diagnostic outcomes were: 355 ASD, 414 other delays (e.g., DD) and 73 false positives. Pediatricians were more likely to refer a toddler for an evaluation if the child was male, and at older rather than younger ages. They were also twice as likely to refer if a parent also had concerns. **Figure 3.**

Conclusions: With an overall median age of ASD detection and treatment referral of 19 months, with some children receiving an evaluation and referral for treatment as young as 12 months, the Get SET Early model is an effective mechanism for the early detection of ASD. When making referrals for an in-depth evaluation, pediatricians were highly influenced by whether or not a parent was concerned, suggesting that querying of parent concern should be incorporated into screening as standard practice.

207.004 *(Panel)* Novel Strategies to Support Early Identification and Engagement in Autism Services: Family Navigation and the Autism Navigator

E. Feinberg[1], *A. Wetherby*[2], *S. broder-Fingert*[3], *A. Bennett*[4], *C. Weitzman*[5], *M. Augustyn*[6], *J. L. Stapel-Wax*[7], *A. Klin*[8], *C. J. Newschaffer*[9], *C. Lord*[10] *and N. Blum*[4], *(1)Boston University School of Public Health, Boston, MA, (2)Florida State University Autism Institute, Tallahassee, FL, (3)Boston Medical Center, Boston, MA, (4)The Children's Hospital of Philadelphia, Philadelphia, PA, (5)Yale University, New Haven, CT, (6)Developmental and Behavioral Pediatrics, Boston Medical Center, Boston, MA, (7)Emory University School of Medicine, Atl, GA, (8)Marcus Autism Center, Children's Healthcare of Atlanta and Emory University School of Medicine, Atlanta, GA, (9)College of Health and Human Development, Pennsylvania State University, University Park, PA, (10)University of California, Los Angeles, Los Angeles, CA*

Background: Engaging historically underserved children in autism diagnostic and treatment services requires strategies that address structural and family-level barriers. Two such strategies are Family Navigation (FN) and the Autism Navigator. FN is a care management strategy designed to reduce disparities in care through individually-tailored care coordination. Our multisite randomized trial of FN versus usual care (n=250) found that FN significantly impacted time to diagnostic ascertainment among families of young children at risk for ASD. The benefit was most pronounced among Hispanic families (Hazard ratio (HR) non-Hispanic children: 1.36 (1.20, 1.54); HR Hispanic children: 3.28 (3.12, 3.45)). (Figure 1). Autism Navigator is a collection of online courses and tools for professionals and families with a new web-based platform for universal screening for communication delay and autism, designed to reduce the age of screening and referral.

Objectives: We will report on results from two trials in 6 states that collectively screened over 25,000 young children for ASD risk. The trials used different approaches to screening and support for rapid engagement in services. Our goals are to assess the efficacy and implementation of each approach to affect autism diagnostic ascertainment and referral for early intervention.

Methods: For FN, we used a mixed-methods approach to assess navigator training, fidelity to FN delivery, and implementation. Fidelity was assessed quantitatively in two domains from randomly selected audiotaped visits: adherence to visit content based on a pre-specified checklist and use of motivational interviewing (MI), using the Motivational Interviewing Supervision and Training Scale Revised (MISTS). Concurrently, we interviewed 7 Family Navigators and 14 parents who received FN to understand fidelity and intervention implementation. For the Autism Navigator, we recruited providers in 4 states who completed the Autism Navigator for Primary Care training and screened children with the new web platform from 9 to 18 months of age. We assessed age at first screen and rate of referral to early intervention.

Results: Both studies successfully recruited diverse families (race/ethnicity, parent education, and income) (Table 1). The FN curriculum, which included training in ASD management, psychoeducation, and principles of patient navigation, was standardized based on the training of 5 bicultural navigators and augmented with MI training. Content and MI fidelity was 78% and 75%, respectively. In interviews, both navigators and parents expressed interest in expanding the navigator role, particularly longer duration of support. 315 providers completed the Autism Navigator for Primary Care and screened a total of 10,259 children. The average age of first screening was 15.5 months, and rate of referral to early intervention for positive autism screens was 40% at 12 months, 64% at 15 months, and 67% at 18 months.

Conclusions: The findings of FN trial and the use of Autism Navigator tools have important implications for lowering the reachable age of early detection of ASD and access to early intervention among traditionally underserved populations. The next step of our collaborative team is to incorporate FN and Autism Navigator into an intervention package to rapidly engage families of children with early signs of autism in early intervention.

PANEL SESSION — **DIAGNOSTIC, BEHAVIORAL, SENSORY AND INTELLECTUAL SCREENING AND ASSESSMENT**

208 - Understanding Individual Differences in Autism: Predictors of Developmental Trajectories and Intervention Outcomes

Panel Chair: Catherine Bent, *Victorian Autism Specific Early Learning and Care Centre, La Trobe University, Melbourne, Australia*

Discussant: Cheryl Dissanayake, *Olga Tennison Autism Research Centre, La Trobe University, Melbourne, Australia*

Individual differences in autism have been documented since Kanner (1943) first described the condition. A large degree of heterogeneity is evident in the profile of symptoms and skills and individual developmental trajectories over time, including in individual responses to interventions. This panel seeks to explore the theme of individual differences in autism by examining predictors of developmental trajectories and early intervention outcomes across a variety of cohorts. The first presentation will examine trajectories of symptom emergence and predictors of ASD/NON-ASD status in a cohort of infant siblings of children with ASD. The second and third presentations examine predictors of response to specific interventions in preschool aged children, describing profiles associated with more and less favorable responses. The final presentation extends into adulthood, examining predictors of diagnostic stability across the lifespan. The discussant will synthesize key learnings and common themes that emerge from these presentations, with the objective of highlighting what is needed to move the field forward.

208.001 *(Panel)* Early Predictors and Developmental Characteristics of ASD/Non-ASD Trajectories from 14 to 36 Months

R. Landa[1,2] *and C. B. Holingue*[3,4]*, (1)Center for Autism and Related Disorders, Kennedy Krieger Institute, Baltimore, MD, (2)Department of Psychiatry & Behavioral Sciences, Johns Hopkins University School of Medicine, Baltimore, MD, (3)Mental Health, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, (4)Neuropsychology, Kennedy Krieger Institute, Baltimore, MD*

Background: Longitudinal prospective research with infant siblings of children with ASD (Sibs-A) shows that trajectory of autism spectrum disorder (ASD) is characterized by a prodromal period during infancy followed by symptom emergence in the 2^{ne}-3rd years of life. Little is known about trajectories of ASD/Non-ASD status in that symptom-emergence phase, or predictors of those trajectories. Identification of such predictors and first-birthday behavioral characteristics could inform assessment and intervention decisions.

Objectives:

1. To identify early predictors of ASD status trajectory between 14-36 months.
2. To determine whether expressive language, cognitive, or social characteristics differ across trajectory groups during transition from the prodromal to symptomatic phases of ASD trajectory.

Methods: 372 children (sibs-A, non-sibs-A) were assessed at 6, 14 and 36 months. Clinical Best Estimates (CBE) of ASD or non-ASD at 14 and 36 months obviated four trajectory categories: Stable ASD; Stable Non-ASD; Improving (ASD to Non-ASD); and Worsening (Non-ASD to ASD). Dependent variables included: summed score of clinician-rated ASD-related qualities; Mullen Scales of Early Learning (MSEL) Fine Motor, Expressive Language, and Visual Reception T scores; frequency of initiation of joint attention (IJA). Analyses: multinomial logistic regression (separate models for males and females); pairwise t-tests of differences.

Results: At 14 months, 18% of children had CBE of ASD; at 36 months, 59% of these children still had ASD (Stable ASD) and 41% did not (Improving). Of those without ASD at 14 months, 81% remained Non-ASD (Stable Non-ASD); 19% transitioned to ASD (Worsening). Males and sibs-A were more likely to belong to Stable ASD and Worsening groups compared to females or non-sibs-A (Table 1, $p<0.0001$).

For males and females, higher Fine Motor score at 6 months was associated with reduced odds of having Stable ASD relative to Stable Non-ASD trajectory (females: OR=0.77, 95% CI: 0.6-0.99, $p<0.05$; males: OR=0.9, 95% CI 0.82-0.99, $p<0.05$). In males only, higher loading of ASD-related qualities at 6 months also was associated with greater odds of having a Stable ASD trajectory (OR=1.13, 95% CI 1.00-1.27, $p<0.10$).

Children with ASD at any point (Stable ASD, Improving, Worsening) had lower IJA at 14 months relative to children who never exhibited ASD (Stable Non-ASD). At 14 months, Fine Motor and Visual Reception scores were significantly lower in children in the Improving group (concurrent ASD) than those without ASD regardless of ASD/Non-ASD status at 36 months (Stable Non-ASD and Worsening groups). The Stable ASD group had lower Expressive Language scores compared to the other three trajectory groups. See Table 1, all differences were significant at $p<0.05$.

Conclusions: During the prodromal phase of ASD, fine motor skills predicted later ASD/non-ASD trajectory. Males with later ASD appear to exhibit earlier ASD-related behavioral qualities than females. During transition from the prodromal to symptom-emergence phase of ASD trajectory, low IJA is associated with ASD, regardless of its stability or timing of onset, and low expressive language is associated with early and persistent ASD symptomatology. Children with mid-infancy disruption in motor development require developmental surveillance. Those with IJA or language delays at 14 months should receive tier 2 ASD screening.

208.002 *(Panel)* 'What Works for Whom?': Understanding Early Intensive Behavioural Intervention for Autism

C. A. Bent[1]*, C. Dissanayake*[2]*, S. Glencross*[3]*, K. McKinnon*[3]*, K. Hudry*[4] *and G. Vivanti*[5]*, (1)Victorian Autism Specific Early Learning and Care Centre, La Trobe University, Melbourne, Australia, (2)Olga Tennison Autism Research Centre, La Trobe University, Melbourne, Australia, (3)Autism Partnership, Melbourne, VIC, Australia, (4)Victorian Autism Specific Early Learning and Care Center, Olga Tennison Autism Research Centre, Melbourne, Australia, (5)A.J. Drexel Autism Institute, Drexel University, Philadelphia, PA*

Background: Autism is characterized by remarkable variability, with important differences apparent in almost every aspect of the condition including onset, presentation, early trajectories, long-term outcomes, and response to early intervention. It therefore seems likely that different types of early intervention might be best suited to different children, depending on their unique learning profiles. Currently, however, knowledge on what programs work best for which children is limited.

Objectives: We expect that, at the group level, children will make significant gains in cognition in response to both the Group Early Start Denver Model (G-ESDM) and a Comprehensive Applied Behaviour Analysis (ABA) program. The primary aim in this project was to identify characteristics associated with improved child outcomes across both programs (i.e., Prognostic Indicators) and characteristics associated with better outcomes in response to one or other particular intervention approach (i.e., Predictors of Intervention response).

Methods: The study included 80 children with autism (78% boys), aged between 17 and 59 months (*M*=37.67) at entry into community-based intervention, with half receiving G-ESDM and half receiving ABA. Intake assessments (T1) included the Mullen Scales or Early Learning (MSEL), Autism Diagnostic Observation Schedule (ADOS-2), as well as a battery of eye-tracking tasks designed to measure putative prognostic indicators and predictors of Intervention response. These included tasks designed to assess early learning processes that are theoretically and/or empirically related to developmental outcomes and response to early intervention, including Sustained Attention, Joint Attention, Social Attention and Attention to Actions. The primary outcome of interest (T2) was children's MSEL Verbal and Non-Verbal Age Equivalent scores (V/NV AE) following one year of intervention. T2 data is currently available for 60 children, with the remaining assessments to be completed in late 2019. The current data allow the examination of prognostic indicators for abstract submission, with examination of differential predictors of intervention response completed by May 2020.

Results: As predicted, large variability was evident in developmental gains across the two groups, but at the group level children receiving G-ESDM and ABA made significant gains in VAE (T1 *M*(SD)=15.68(9.18), T2 *M*(SD)=26.25(11.85), $p<.001$) and NVAE (T1 *M*(SD)=21.32(7.47), T2 *M*(SD)=30.59(10.42), $p<.001$) scores. Hierarchical regressions examining the unique predictors, controlling for site, child age and ADOS Calibrated Severity Score at intake indicated that T2 VAE scores were predicted by Sustained Attention, Social Attention and Attention to Actions. The only significant unique predictor of T2 NVAE score was Sustained Attention.

Conclusions: Knowing which children with autism benefit most from which particular intervention models will allow families and clinicians to make informed decisions about how best to support children's learning. Identifying predictors that are specific and modifiable will better inform the tailoring of intervention programs by identifying proximal intervention targets.

208.003 *(Panel)* A Second Look at the ASAP Intervention: Examining Sample Heterogeneity and Predictors of Treatment Response

***B. A. Boyd**, Juniper Gardens Children's Project, University of Kansas, Kansas City, KS*

Background: Advancing Social-communication And Play (ASAP) is a manualized, classroom-based intervention for preschool-aged children with autism spectrum disorder. The initial efficacy of the ASAP intervention was examined using a cluster randomized controlled trial (n=161). The findings demonstrated statistically significant differences and small to moderate effects in favor of the ASAP group on the secondary outcomes of child engagement and teacher burnout. However, no significant differences were found for the primary outcomes of social-communication and play. Given that significant differences were found for the secondary outcomes, ASAP is not an ineffective intervention; therefore, it is important to explore sources of sample heterogeneity and predictors of treatment response to understand discrepancies in primary versus secondary outcomes.

Objectives: There were two study objectives: (1) To use empirical methods to examine how children group by subtype based on pre-treatment, child level variables as well as predictors of group membership; and (2) To examine if group membership changed over time as a function of treatment.

Methods: The initial ASAP study used a randomized trial design (child n=85 ASAP, n=76 control). For this study, secondary data analysis was undertaken. Specifically, latent profile analysis (LPA) was used to examine group membership based on pre-treatment child characteristics (i.e., symptom severity, challenging behavior, social-communication skills, play skills, and classroom engagement) and demographic variables were examined as predictors of group membership (i.e., child sex, baseline cognitive ability). In addition, latent profile transition analysis (LPTA) will be used to examine changes in group membership from pre- to post-test.

Results: After comparing fit statistics (i.e., Akaike Information Criterion, Bayesian Information Criterion, Adjusted Bayesian Information Criterion, Vuong-Lo-Mendell Rubin, Lo-Mendell-Rubin, bootstrap likelihood ratio test, entropy) of a 2 to 7 class solution, results suggested a 3 class solution fit best. Mean conditional probabilities for the 3 class solution ranged from 92.5-95.2, indicating good fit. For the LPA, all latent classes were differentiated by pre-treatment characteristics. Children in latent class 2 (n=23), which accounts for 14% of the sample, had the lowest severity scores (i.e., ADOS severity scores and challenging behavior) and highest skill scores (i.e., social-communication, play, and engagement); whereas, children in class 3 (n=43) had the opposite profile to those in latent class two. Fifty-nine percent of children (n=95) fell into latent class 1 showing a mild to moderate symptom and skill profile; essentially their scores fell in the middle of children in latent classes two and three. Gender was not a predictor of group membership; however, latent class 2 was nearly differentiated by a higher likelihood of being female (= -3.09; $p=0.06$) when compared to latent class 3. Cognitive ability significantly differentiated latent class 2 and 3, with latent class 2 having a higher IQ score (= 0.19; $p=0.05$). Additional analyses will define how the latent classes changed over the course of one school year.

Conclusions: Results suggest three distinct pre-treatment profiles emerged, which may account for differences in treatment response during the ASAP intervention. Examining pretreatment heterogeneity may be a useful strategy for understanding predictors of treatment response.

208.004 *(Panel)* Diagnostic Stability in Individuals with Autism Spectrum Disorder: Insights from a Longitudinal Follow-up Study

***R. Elias**[1], J. B. McCauley[2] and C. Lord[2], (1)University of California Los Angeles, Los Angeles, CA, (2)University of California, Los Angeles, Los Angeles, CA*

Background: Regarded as a fixed diagnosis, most individuals with ASD show clinical impairments across the lifespan. Adulthood is associated with a unique set of challenges (Magiati, Tay, & Howlin, 2014) sometimes contributing to overall poor outcomes (Seltzer, Shattuck, Abbeduto & Greenberg, 2005). Little research exists examining individuals who change diagnostic status to a presentation with few signs or impairments associated with ASD as adults, comparable to that of typically developing peers (Anderson, Liang, Lord, 2014; Billstedt, Gillberg, & Gillberg, 2005; Fein et al., 2013).

Objectives: The present study seeks to upwardly extend the work of Anderson, Liang, and Lord (2014) to examine the stability of autism diagnoses in a cohort of participants who were longitudinally assessed at ages 2 to 26 years. Further, potential predictors of diagnostic status among adult participants will be explored. Consistent with prior research, we hypothesized that a small minority of participants would no longer display diagnostic symptoms of ASD in adulthood.

Methods: Ninety-eight participants were seen for diagnostic assessments at several time-points spanning 24 years. Participants comprise a clinically referred sample with diverse races, geography, and socioeconomic status. Those ever given a diagnosis of ASD (86.7%) comprise the focus of analyses (M_{age} = 26.05 years; 82.7% male). Developmental trajectories of adult participants will be described both quantitatively by examining a variety of psychodiagnostic measures and qualitatively through clinical case summaries. Characteristics identified early in childhood (i.e., IQ, ASD symptom severity, & adaptive skills) will also be discussed with respect to later adult outcome and diagnostic status.

Results: At age 26, eleven individuals (12.9%) with a previous diagnosis of ASD no longer met current diagnostic criteria based on consensus-agreement by blinded clinicians. Of the eleven individuals identified, 81.8% no longer displayed diagnostic symptoms after age 9. Interestingly, another 15.3% of the sample converted to a diagnosis of ASD after initial assessment ($M_{age\ of\ autism\ diagnosis}$ = 14.19 years, *SD* = 6.66). Trajectories of each individual presented in the form of individual clinical case studies will be discussed. For example, for one individual no longer displaying symptoms, clinical severity scores (CSS) on the ADOS followed a steady pattern until adulthood (*Mean CSS age 2* = 7; *age 3= 6; age 5= 7; age 9= 6; age 18=4; age 21= 3; age 25=1).* For others, inconsistent patterns were observed (e.g., *Mean CSS age 2* = 4; *age 3= 7; age 5= 1; age 9= 5; age 18=3; age 21= 2; age 25=2)* where lower CSS scores indicate less autistic impairment. Additionally, IQ, adaptive skills, and treatment history will be reviewed longitudinally as these are potent predictors among more and less able individuals with ASD (Anderson et al., 2014).

Conclusions: The majority of individuals diagnosed with ASD retain their diagnosis into adulthood based on clinical symptom presentation. However, understanding the trajectories of diagnostic retention and change over time yields high clinical value. The present study presents unique features of an understudied subset of those with a previous diagnosis of ASD.

ORAL SESSION — DIAGNOSTIC, BEHAVIORAL, SENSORY AND INTELLECTUAL SCREENING AND ASSESSMENT

309 - Quantitative Diagnosis and Subtyping Autism

309.001 *(Oral)* Rethinking Measurement of Autism Symptomology in Fragile X Syndrome

H. Fielding-Gebhardt[1]*, S. Bredin-Oja*[2]*, K. K. Fleming*[3]*, S. F. Warren*[4] *and N. Brady*[2]*, (1)1000 Sunnyside Avenue, University of Kansas, Lawrence, KS, (2)University of Kansas, Lawrence, KS, (3)Life Span Institute, University of Kansas, Lawrence, KS, (4)Speech-Language-Hearing: Sciences and Disorders, University of Kansas, Lawrence, KS*

Background: DSM-V diagnostic criteria for autism spectrum disorder (ASD) require symptoms in three social communication (SC) subdomains and two of four restricted and repetitive behaviors (RRBs) subdomains (American Psychiatric Association, 2013). The ADOS-2 (Lord et al., 2012) is the current "gold-standard" assessment of ASD. Sole reliance on the ADOS-2 as a measure of ASD in fragile X syndrome (FXS) research is problematic because individuals with FXS often demonstrate impairments in SC. Over-identification of ASD in FXS may artificially inflate prevalence estimates and may result in inappropriate interventions for FXS.

Objectives: Examine the classification of clinically-relevant symptoms of ASD in adolescents with FXS using three standardized assessments and a parent interview to determine whether use of the ADOS-2 in research may lead to over-identification of ASD in FXS.

Methods: We assessed 42 adolescents with FXS (9 females) using the ADOS-2, the CARS2-ST (Schopler et al., 2010), the Vineland Adaptive Behavior Scales II (VABS-II; Sparrow et al., 2005), and a maternal semi-structured interview (SSI). Based on ADOS-2 and CARS2-ST scores, participants were divided into three groups. Individuals in the Disagree (n = 15) group received "autism or autism spectrum" classifications on the ADOS-2 but "minimal-to-no symptoms" on the CARS2-ST. Individuals in the Agree (n = 15) group received a classification of "autism or autism spectrum" on the ADOS-2 and "mild-to-moderate or moderate-to-severe symptoms" on the CARS2-ST. The No Autism (n = 12) group received "non-spectrum" and "minimal-to-no symptoms" classifications. Responses to items from the VABS-II maladaptive scale and the SSI were equated with DSM-V diagnostic criteria.

Results: Differences in ADOS-2 RRB scores indicated significantly higher incidence of RRBs for the Agree than the Disagree group and for the Disagree than the No Autism group (p <0.001 and p = 0.037, respectively). Although there was no significant difference in ADOS-2 SC scores between the Agree and Disagree groups (p = 0.29), both scored significantly higher than the No Autism group (p < 0.001).

To determine whether adolescents in each group would meet DSM-V criteria for ASD, we calculated the number of subdomains in which each adolescent demonstrated symptoms using the VABS-II and SSI items. There were no significant differences between the No Autism and Disagree groups on the number of SC and RRB subdomains nor on the total scores. The Agree group scored significantly higher than the Disagree group on number of RRB subdomains and on total scores but not SC subdomains.

Conclusions: 79% of boys and 44% of girls met criteria for ASD on the ADOS-2. However, our results suggest that 36% received ASD classifications from the ADOS-2 but not the CARS2-ST. Only 27% would meet DSM-V diagnostic criteria for ASD. Within research, reliance on a single measure of ASD may lead to biased reporting of sample characteristics, limiting replication and generalizability. Similarly, ASD classification as an all or none should be avoided to better consider the severity of autism symptomology in FXS (Abbeduto, McDuffie, & Thurman, 2014). Researchers should include multiple measures of ASD to best represent the variable FXS phenotypes.

309.002 *(Oral)* Validating the Beck Depression Inventory–II in Adults with Autism Spectrum Disorder

Z. J. Williams[1] *and K. O. Gotham*[2]*, (1)Medical Scientist Training Program, Vanderbilt University School of Medicine, Nashville, TN, (2)Department of Psychology, Rowan University, Glassboro, NJ*

Background: Depressive disorders are common in adults with autism spectrum disorder (ASD), with current and lifetime prevalence estimates of 27% and 42% in this population, respectively (Hollocks et al., 2019). Despite the frequency of these conditions, few studies have examined the extent to which common measures of depression are psychometrically appropriate for use in adults with ASD (Cassidy et al., 2018). Those that have typically utilized such small samples that modern large-sample psychometric techniques are not feasible.

Objectives: This study aims to examine the psychometric properties of a commonly used measure of depressive symptomatology, the Beck Depression Inventory-II (BDI-II), in a large sample of adults with ASD within an Item Response Theory (IRT) framework.

Methods: A sample of 881 adults with self-reported ASD (M_{Age} = 30.94 years, 53% Female, 9% non-binary, 79% Caucasian) was recruited from the Simons Foundation's SPARK database (Feliciano et al., 2018). Current diagnosed or suspected depression was self-reported in 57.7% of the sample, respectively. The latent structure of the BDI-II was evaluated using full-information item factor analysis. A bifactor graded response model was then fit to the BDI-II to detect problematic items and calculate estimated latent trait scores. These latent trait scores were then compared to BDI-II total scores in their ability to predict self-reported depression in the SPARK sample as well as SCID-5-based diagnoses of mood disorders in a rigorously-phenotyped clinical sample of 66 autistic adults (24 with depressive disorders).

Results: A bifactor model with specific "Somatic" and "Cognitive-Affective" factors (Brouwer et al., 2013) fit the BDI-II data well. However, two pairs of BDI-II items (*Loss of Pleasure/Loss of Interest* and *Agitation/Irritability*) were found to be locally dependent (i.e., redundant), and thus the second item in each set was removed. BDI-II item 21 (*Loss of Interest in Sex*), was found to exhibit significant differential item functioning (DIF) by age and was also removed. The 18-item BDI-II scale exhibited improved fit to the data, strong marginal reliability for the general factor (ρ_{xx} = 0.872), no local dependence, and no significant DIF by age, sex, gender, race, sexual orientation, education level, comorbid anxiety, or comorbid ADHD. Three items exhibited DIF by depression status, but these effects canceled each other to produce a negligible impact on BDI-II scores between groups (standardized mean score difference [ETSSD] = -0.03). IRT scores discriminated moderately between individuals with and without depression in both the SPARK sample (*AUC* = 0.80 [0.77, 0.83) and the clinical sample (*AUC* = 0.73 [0.59, 0.85]), exhibiting slightly better performance than BDI-II total scores in both cases. Using our proposed screening cutoff (θ_G = -0.195), the BDI-II IRT score had a sensitivity of 0.82 [0.79, 0.86] and specificity of 0.63 [0.58, 0.68] in the SPARK sample and sensitivity of 0.79 [0.61, 0.95] and specificity of 0.60 [0.45, 0.74] in the clinical sample.

Conclusions: The modified BDI-II can be viewed as a reliable and valid depression screening tool or dimensional measure of depressive symptoms in autistic adults, but its diagnostic specificity is suboptimal in this population.

309.003 *(Oral)* In Search of Subtypes of Children with Autism Using the WISC-V: A Latent Profile Analysis

K. G. Stephenson[1]*, M. Norris*[2]*, T. Ibañez*[3] *and E. Butter*[1]*, (1)Nationwide Children's Hospital, Columbus, OH, (2)Child Development Center, Nationwide Children's Hospital, Westerville, OH, (3)Behavioral Health, Nationwide Children's Hospital, Columbus, OH*

Background: Identifying subtypes within Autism Spectrum Disorder (ASD) has been attempted to better understand the significant heterogeneity within the spectrum. Profiles of cognitive functioning have frequently been investigated as one possible subtype. Some studies suggest differential patterns of Performance/Verbal IQ split as possible subtypes, but most studies have relied on relatively small sample sizes and higher-functioning samples and few have used advanced statistical techniques to obtain estimates of underlying profiles of IQ in ASD.

Objectives: The purpose of this study was to use Latent Profile Analysis (LPA) to identify possible subgroups of children with ASD using the Wechsler Intelligence Scale for Children-5th Edition (WISC-V) across a range of ability levels. A secondary objective was to identify meaningful predictors of IQ group membership.

Methods: The sample included 340 children, ages 6-16 (*M*=10.5, *SD*=2.7; 17% Female), who were diagnosed with ASD at a large developmental assessment center between 10/1/2014 and 12/31/2018. Full-scale IQ scores ranged from 42-134 (*M*=90, *SD*=17.4). The primary LPA model consisted of scores on the five WISC-V Index Composites. We then tested a follow-up model consisting of the 10 primary subscales. Multinomial logistic regression was used to predict group membership in the primary model with ASD symptoms (Autism Spectrum Rating Scale), age, biological sex, and Index-level scatter as predictors.

Results: A 4-group solution best fit both the primary and follow-up models. Groupings were similar between both models and generally aligned with traditional classification ranges (i.e., 1-*high average*, 2-*average*, 3-*low average*, 4-*very low*; see figure 1). However, there was a pattern of relatively lower "Cognitive Proficiency" scales across groups, particularly Processing Speed (see figure 1a). This pattern appeared strongest in group 1. Small discrepancies between Verbal Comprehension (VCI) and Fluid Reasoning (FRI) were present in group 1 (VCI<FRI) and group 4 (VCI>FRI). Groups 2 and 4 tended to show the most within-Index subtest discrepancies (see figure 1b). Coding was the lowest subtest score within each group. Significant predictors of group membership emerged in the Composite model (group 2 as reference). Group 4 membership was positively associated with age (Odds Ratio[OR]=1.20, *p*=.02). Group 1 membership was positively associated with social communication difficulties (OR=1.05, *p*=.05) and negatively associated with self-regulation difficulties (OR=0.93, *p*=.01). Group 3 membership was positively associated with repetitive/restricted behaviors (OR=1.05, *p*=.05). Biological sex and Index-level scatter were not significantly associated with group membership.

Conclusions: Overall, data-derived IQ subgroups in ASD generally aligned with traditional IQ classification ranges. Although there were some small variations in profiles between groups, profiles generally showed more similarities than differences. These parallel profiles add evidence to the dimensionality of intellectual functioning within the autism spectrum (versus distinct categorical subtypes). There was also evidence for a possible ASD-related profile consisting of relatively lower processing speed ability, which was found across a range of ability levels. Additional research is needed to identify whether this finding is specific to autism. Core ASD symptoms (i.e., social communication difficulties and repetitive behaviors) were differentially related to being in a *high* or *low average* group compared to an *average* group.

309.004 *(Oral)* Diagnosing DSM-5 Autism Spectrum Disorder in Toddlers: Caregiver Report & Direct Observation

K. Coulter[1], *H. Boorstein*[2], *M. Barton*[1], *D. L. Robins*[3], *W. L. Stone*[4] *and D. A. Fein*[1], *(1)Psychological Sciences, University of Connecticut, Storrs, CT, (2)Center School District 58, Kansas City, MO, (3)A.J. Drexel Autism Institute, Drexel University, Philadelphia, PA, (4)Psychology, University of Washington, Seattle, WA*

Background: Diagnostic evaluations of children presenting for autism spectrum disorder (ASD) concerns integrate caregiver report and direct observation to improve diagnostic validity (Kim & Lord, 2012; Risi et al., 2006). The Toddler Autism Symptom Inventory (TASI) is a novel caregiver interview designed for the assessment of toddler-specific manifestations of autism in children under three years.

Objectives: To evaluate whether the TASI and ADOS-2 Toddler Module independently contribute diagnostic information relevant for the diagnosis of autism in young children, thus improving diagnostic accuracy compared to either measure alone.

Methods: Children (*n*=282) 12-30 months of age (*M*=18.9) referred for diagnostic evaluation. completed the ADOS-2 Toddler Module; parents were interviewed using the TASI. Clinical Best Estimate (CBE) diagnosis was assigned by expert clinicians. Seventy-one children were diagnosed with ASD; the non ASD group included subthreshold autism symptoms (*n*=1), global developmental delay (*n*=61), language disorder (*n*=60), and no diagnosis (*n*=89).

TASI algorithms align with DSM-5 ASD diagnostic criteria and “relaxed” criteria for toddlers (Barton et al., 2013). ADOS-2 Mild-to-Moderate (Mild/Mod) and Moderate-to-Severe (Mod/Severe) classifications were considered. Algorithms were compared to CBE diagnosis. Sensitivity and specificity were calculated for meeting threshold for TASI alone, ADOS-2 alone, either, and both.

Results: Validity data are presented in Table 1. While the ADOS-2 Mild/Mod cutoff demonstrated excellent validity, 28 children were misclassified. Requiring both ADOS-2 Mild/Mod and TASI "relaxed" resulted in high sensitivity (0.87) and specificity (0.93), and reduced misclassification to 20 children.

There was significant agreement between the TASI and ADOS-2 (Figure 1); 86% of children in the ADOS-2 Mod/Severe range met TASI cutoffs (Figure 1). Total scores on TASI and ADOS-2 were significantly and positively correlated (r = 0.68).

Conclusions: The TASI with "relaxed" criteria and ADOS-2 both separately and together show good sensitivity and specificity. Most (94%) children who score as Mild-Mod or higher on ADOS-2 and meet “relaxed" DSM-5 TASI algorithm received a CBE diagnosis of autism. Moderate correlations suggest that while each measure broadly quantifies autistic symptoms, each contributes distinct information important for a diagnosis. More specifically, the TASI contributes parent report of the child’s typical communication strategies, play, sensory responses to a wider range of stimuli, and repetitive behaviors that might not be seen in an evaluation. Comparison of the two measures will also allow us to characterize children who meet diagnostic criteria on only one measure compared to those who exceed thresholds on both measures.

ORAL SESSION — DIAGNOSTIC, BEHAVIORAL, SENSORY AND INTELLECTUAL SCREENING AND ASSESSMENT

310 - Subtypes and Trajectories in Diagnosis and Development

310.001 *(Oral)* Exploring Latent Subdimensions of Social Communication: A Cross-Measure Factor Analysis

S. Zheng[1], *A. J. Kaat*[2], *C. Farmer*[3], *S. Georgiades*[4], *S. Kanne*[5], *C. Lord*[6], *A. Thurm*[3] *and S. Bishop*[7], *(1)Psychiatry, University of California, San Francisco, San Francisco, CA, (2)Department of Medical Social Sciences, Northwestern University, Chicago, IL, (3)National Institute of Mental Health, Bethesda, MD, (4)McMaster University, Hamilton, ON, Canada, (5)Thompson Center for Autism and Neurodevelopmental Disorders, Columbia, MO, (6)University of California, Los Angeles, Los Angeles, CA, (7)University of California San Francisco, San Francisco, CA*

Background: Social communication deficits are a core diagnostic feature of autism spectrum disorders (ASD). Therefore, measures designed to assess ASD symptoms (e.g., Autism Diagnostic Observation Scale [ADOS], Autism Diagnostic Interview [ADI], and Social Responsiveness Scale [SRS]) include several items capturing various aspects of social communication. While there is great interest in understanding different profiles of social communication abilities (Bishop at el., 2019), success in identifying more nuanced sub-dimensions of social communication has been limited and only with one measure at a time (e.g. Bishop, Havdahl, Huerta & Lord, 2016 with ADOS Module-3; Tanguay, Robertson & Derrick, 1998, with the ADI; and Frazier et al., 2014 with the SRS). No study to date has examined the factor structure of social communication behaviors across multiple measures of ASD symptoms.

Objectives: To explore meaningful latent subdomains of social communication behaviors captured by commonly used ASD diagnostic instruments.

Methods: A large clinically-referred sample was aggregated from six data sources: 1513 children aged from 4 to 10 years old with complete data on 57 social communication items from the ADOS, ADI (current), and SRS. We randomly split the sample into training and validation datasets. The procedure for the novel cross-measure factor analysis was conducted in RStudio with R packages *lavaan* and *blavaan*. First, we introduced orthogonal factors to account for each method of measurement. Then we compared near-saturated nested models with substantive factors composed of items from multiple scales. Once the optimal number of factors was determined, we iteratively constrained item loadings on substantive factors to arrive at an interpretable and parsimonious model.

Results: Based on the fit indices and interpretability as indicated in Table 1, the 4 substantive-factor model was selected. After multiple iterations with additional restrictions and adjustments, the majority of items had a large loading (|λ|>0.3) on at least one factor and cross-loadings were minimized. Items were considered to load on the factors with the largest factor loading.

The final model with the training dataset had a reasonable fit in the training dataset (χ^2_{1607} =3744.668, p=0.000; CFI=0.97; TLI=0.97; RMSEA=0.043; SRMR=0.06). Based on the item content, we labeled the four factors as Conversation Quality and Reciprocity (ni=6); Social Understanding and Behavior Modification during Interactions (ni=15); Social Motivation and Participation (ni=6); and Early Emerging Basic Social Communication Skills (ni=22) (see Table 2). Eight items failed to load highly on any substantive factor. Factor 2 and Factor 4 were highly correlated (r=0.79); other factor correlations were more modest (range: 0.27 to 0.36). The same factor structure was replicated with the validation dataset.

Conclusions: The current analysis expanded previous understanding of subdomains within social communication by identifying four abilities across 57 items drawn from three commonly used measures: a) Conversation Quality and Reciprocity, b) Social Understanding and Behavior Modification during Interactions,c) Social Motivation and Participation, and d) Early Emerging Basic Social Communication Skills. The four-factor structure showed good model fit and was replicated with a validation sample. These findings could inform the development of future measures specific to social communication.

310.002 *(Oral)* Contrasted Clinically and Genetically Relevant Correlates of High-Certainty Autism and ASD Diagnosis

B. Rodríguez-Herreros[1,2], A. Zeribi[2,3], V. Courchesne[1,4], M. P. Poulin-Lord[2,5,6], E. A. Douard[2,3], D. Gagnon[1,7], G. Huguet[2], S. Jacquemont[3,8] and ***L. Mottron, M.D.****[1,2], (1)Autism Research Group, CIUSSS du Nord-de-l 'Île-de-Montréal, Montréal, QC, Canada, (2)Université de Montréal, Montréal, QC, Canada, (3)UHC Sainte-Justine Research Center, University of Montreal, Montreal, QC, Canada, (4)Department of Neurology and Neurosurgery, McGill University, Montréal, QC, Canada, (5)Département de neurosciences, Université de Montréal, Montréal, QC, Canada, (6)Research Center of UHC Sainte-Justine, Montreal, QC, Canada, (7)Département de psychiatrie, Université de Montréal, Montréal, QC, Canada, (8)UHC Sainte-Justine Research Center, University of Montreal, Montréal, QC, Canada*

Background: The heterogeneity of the autistic spectrum disorder (ASD) phenotype, currently favored by inclusive and moderately specific diagnostic criteria, has been implicated in the gradual decrease over time of neurocognitive differences between individuals with and without autism (Rødgaard et al, 2019). Consequently, the stratification of the DSM-5 autistic spectrum by levels of clinical prototypicality may increase our future ability to detect structural, functional, and cognitive differences grounding mechanistic models in neurocognitive and genetic research. Accordingly, subtle autistic phenotypes are probably more prone to represent phenocopies of autism and to be influenced by extraneous factors than ''frank'' autism (De Marchena et al, 2017), quickly and reliably diagnosed by experts, which would unravel intrinsic autistic neurobiological characteristics.

Objectives: Estimate the contribution of the cognitive, behavioral and genetic dimensions on the diagnostician's certainty of autism spectrum disorder.

Methods: Ordinal regression models were used to quantify the effect of core descriptive phenotypic variables of 2,348 autistic individuals from the Simon Simplex Collection (SSC) on the certainty of autism diagnosis a 1 to 15 points scale ranging from very low confidence of having ASD (1 point) to high certainty of being autistic (15 points), based on best clinical judgement. The number of rare deletions and duplications (copy number variations, CNV) were also integrated in statistical models to explain the certainty of diagnosis. An interaction was introduced in each model to test whether the main effects were statistically similar in probands diagnosed with "frank" autism compared to the spectrum group.

Results: Overall, autism core behavioral and neurological phenotypic features are correlated with the certainty of diagnosis (fig. 1a). However, this relationship is statistically different, and sometimes opposite, in frank autistic individuals compared to the spectrum group (fig. 1a). The association between an increase of the social-communication and the RRB ADOS scores with the certainty of diagnosis is stronger in the autism group (β=0.74; p=<2e-16 and β=0.68; p=<2e-16, respectively) compared to the spectrum group (β=0.16; p=0.1 and β=0.35; p=6e-04). A lower verbal/nonverbal IQ ratio, a larger head size than expected from parental head size and body mass, and a delayed language were associated with the certainty of diagnosis exclusively in the autism group (fig. 1a). A higher number of deletion CNVs correlates with a lower certainty of autism diagnosis in the autism group (β=-0.10; p=0.004), but not of the spectrum group (fig.1b). Conversely, a higher number of duplication CNVs is associated with a higher certainty of diagnosis in the spectrum group (β=0.16; p=0.001) but not in the autism group.

Conclusions: Relying on a ''frank'' autism clinical presentation in research increases neurocognitive, structural and genetic signals such as macrocephaly or verbal versus nonverbal IQ ratio, which may be shadowed and considered less sensitive when measured in a broader autism spectrum population. A distinct analysis and interpretation of neurobiological features between "frank" and spectrum individuals is justified.

310.003 *(Oral)* Autism Symptom Trajectories from Early to Middle Childhood in the Children of the Autism Phenome Project

E. Waizbard-Bartov*[1], E. Ferrer[1], B. Heath[2], C. M. Kerns[3], B. Winder-Patel[4], S. J. Rogers[2], C. W. Nordahl[2], M. Solomon[2] and D. G. Amaral[2], (1)UC Davis, Davis, CA, (2)Department of Psychiatry and Behavioral Sciences, The Medical Investigation of Neurodevelopmental Disorders (MIND) Institute, UC Davis School of Medicine, University of California Davis, Sacramento, CA, (3)University of British Columbia, Vancouver, BC, Canada, (4)MIND Institute, University of California, Davis, Sacramento, CA*

Background: Previous studies have generally shown autism symptom severity remains stable over time, with small groups decreasing or increasing (1-4). We previously evaluated autism symptom trajectories based on the Autism Diagnostic Observation Schedule-2, Calibrated Severity Score (ADOS-2 CSS) in the UC Davis MIND Institute Autism Phenome Project (APP) cohort between 3 and 6 years of age. Children were grouped according to shared trajectories of change. A Decreased Severity Group (28.8%) decreased by 2 or more points; a Stable Severity Group (54.4%) changed by 1 point or less; and an Increased Severity Group (16.8%) increased by 2 or more points. Girls showed a greater tendency to decrease in severity than boys. Severity decreases were associated with being female and having higher IQ and adaptive functioning, while severity increases were associated with having lower and stable IQ and adaptive functioning. Anxiety has been shown to be a prevalent comorbidity of ASD (5), to associate with impairment in social function (6) and might be related to decreases in symptom severity (7).

Objectives: To examine the trajectories of autism severity from early to middle childhood for the children of the APP and evaluate the relationship between change in severity and anxiety.

Methods: One hundred and sixty nine children with ASD (119 boys, 50 girls) were assessed at approximately age 3 (Time 1), age 6 (Time 3) and age 8-12 (Time 4). Each participant was measured in at least two time points. We used ADOS-2 to evaluate trajectories of general autism severity as well as Social Affect (SA) and Restricted, Repetitive behaviors (RRBs). IQ was assessed using MSEL and DAS-II and adaptive functioning was assessed using VABS-II. Data regarding anxiety were collected using the ADIS/ASA (Anxiety Disorders Interview Schedule/ Autism Spectrum Addendum) and CBCL. Symptom severity trajectories were created using latent change score (8) and latent mixture models (9) and other variables were used as covariates.

Results: We identified a decrease in symptom severity across early childhood (age 3 to age 6) followed by an increase in middle childhood (age 6 to age 12), with large variability between individuals in the magnitude of change. Trajectories of RRBs showed a general decline over time whereas Social Affect symptoms showed a decrease during early childhood followed by a robust increase during middle childhood (Figure 1). Consistent with our previous findings, girls showed a consistent tendency to decrease in symptom severity and to have lower ADOS scores compared with boys. Higher IQ and adaptive functioning were associated with decreasing severity, an association that became stronger with age. Externalizing behaviors were associated with increasing severity. Anxiety levels were also associated with symptom severity change; a decrease in ADOS symptom severity during early childhood was associated with higher anxiety levels in middle childhood.

Conclusions: Our findings suggest symptom severity might show more change than previously appreciated. We noted a tendency to decrease across early childhood and increase across middle childhood. Decreases in severity were associated with being female and having higher IQ and adaptive functioning, but also higher anxiety levels.

310.004 *(Oral)* Developmental Trajectories of Adaptive Behavior from Toddlerhood to Middle Adulthood in Autism

B. Tomaszewski[1,2,3], *N. Bagatell*[4], *E. M. Lamarche*[5], *A. T. Meyer*[6], *P. S. Powell*[7], *M. R. Klinger*[8] *and L. G. Klinger*[9], *(1)Frank Porter Graham Child Development Institute, University of North Carolina at Chapel Hill, Chapel Hill, NC, (2)TEACCH Autism Program, University of North Carolina at Chapel Hill, Chapel Hill, NC, (3)Psychiatry, University of North Carolina at Chapel Hill, Chapel Hill, NC, (4)University of North Carolina at Chapel H, Chapel Hill, NC, (5)TEACCH Autism Program, University of North Carolina, Chapel Hill, NC, (6)JFK Partners, University of Colorado School of Medicine, Aurora, CO, (7)School of Psychology, Georgia Institute of Technology, Atlanta, GA, (8)UNC TEACCH Autism Program, Chapel Hill, NC, (9)TEACCH Autism Program; Psychiatry, University of North Carolina, Chapel Hill, NC*

Background: Adaptive behavior is a critical indicator of quality of life and employment in adults with Autism Spectrum Disorder (ASD). Individuals with ASD experience difficulties in adaptive behavior regardless of their intellectual functioning (Tillmann et al., 2019). There is evidence for a plateau of adaptive behavior skills in adolescence and early adulthood (Meyer et al., 2018; Smith et al., 2012). Few studies have examined trajectories of adaptive behavior beyond young adulthood.

Objectives: The present study examined developmental trajectories of adaptive behavior in individuals with ASD from toddler to middle adulthood.

Methods: Participants included 55 individuals with ASD seen between 1969 and 2000 at the University of North Carolina TEACCH Autism Program. At the time of the first evaluation participants were between 2 and 16 years old (M = 6.39 SD = 3.58) Participants had records of up to 8 follow-up evaluations between the ages of 3-31, and an assessment was completed when individuals were 27-55 (M = 36.7, SD =6.78). Adaptive behavior was measured at multiple timepoints using the Vineland Social Maturity Scale (Doll, 1953), Vineland Adaptive Behavior Scales (Sparrow et al., 1984), and the Vineland Adaptive Behavior Scales, 2nd Edition (Sparrow et al., 2005), with 60% of participants having more than three assessments. Clinical records included the overall adaptive behavior composite measuring communication, daily living skills, and socialization in everyday activities. Vineland age equivalence scores were used to examine developmental change over time.

All growth models were estimated using MPlus Version 8. Fixed effects for linear and quadratic growth models were estimated for adaptive behavior trajectories controlling for IQ trajectories. Model fit criteria was assessed using fit using the -2 Loglikelihood, Akaike's information criterion (AIC) and Bayesian information criterion (BIC).

Results: Controlling for IQ, the best fitting growth model for the adaptive behavior age equivalency scores from ages 3-55 included significant fixed effects for linear and quadratic growth. The average adaptive behavior age equivalence score at 17.5 years was 6.0 years. Scores increased at an average rate of 3 months in age equivalency score per year of age across adulthood. However, the rate of increase slowed over time as indicated by a negative quadratic estimate of -.01. While a majority of adults made gains in their adaptive skills over time, a subset of 9 individuals declined over time creating an overall trajectory of decline (see figure). These adults were older (M = 44.11, SD = 8.10) and had higher CARS scores (M = 35.61, SD = 6.86).

Conclusions: Adaptive behavior scores increased at a slower rate than expected for chronological age, similar to findings across adulthood in daily living skills (Smith et al., 2012). It appears that rather than a plateauing of skills during adulthood (Meyer et al., 2018), there is a slow growth of skills across adulthood. However, some adults show declining skills. It is likely that there is variability in subgroups of adults with ASD in their adaptive behavior trajectories. Future research examining the characteristic of adults with declining trajectories is important to identifying intervention targets.

POSTER SESSION — **DIAGNOSTIC, BEHAVIORAL, SENSORY AND INTELLECTUAL SCREENING AND ASSESSMENT**

415 - Diagnostic, Behavioral, Sensory and Intellectual Screening and Assessment Posters

415.001 *(Poster)* A Case Study: Longitudinal Diagnostic Group Changes from Typical Development to Autism in Four Male Participants

C. Herrera[1], *S. Averill*[2], *A. Mlodnicka*[3], *M. Solomon*[4], *J. B. Schweitzer*[5], *I. Hertz-Picciotto*[6] *and S. Dufek*[7], *(1)Research Clinic Supervisor, UC Davis MIND Institute, Sacramento, CA, (2)Public Health Sciences, University of California, Sacramento, CA, (3)Psychiatry and Behavioral Sciences, The MIND Institute UC Davis, Sacramento, CA, (4)Department of Psychiatry and Behavioral Sciences, The Medical Investigation of Neurodevelopmental Disorders (MIND) Institute, UC Davis School of Medicine, University of California Davis, Sacramento, CA, (5)Department of Psychiatry and Behavioral Sciences, US Davis MIND Institute, Sacramento, CA, (6)University of California at Davis, Davis, CA, (7)Psychiatry, University of California, Davis, Sacramento, CA*

Background: The Childhood Autism Risks from Genetics and the Environment (CHARGE) study is a comprehensive study of environmental and genetic risk factors for autism and other developmental delays. Children ages 24–60 months were enrolled into one of three groups: autism spectrum disorder (AU), developmental delays (DD), and general population with typical development (TD). Since 2003, over 2000 children and their families have participated. The Revisiting CHARGE (ReCHARGE) study is designed to follow up with CHARGE participants, at 8-19 years of age, to assess longitudinal change in cognitive ability, adaptive functioning, and diagnostic group.

Objectives: To describe the longitudinal diagnosis change of four participants from the TD group to the AU group.

Methods: Diagnostic groups were determined by cognitive, adaptive, and autism diagnostic assessments during CHARGE and ReCHARGE visits. The exit diagnostic criteria in CHARGE for TD children was defined by both the Mullen Scales of Early Learning (MSEL) and Vineland Adaptive Behavior Scales (VABS) standard scores of ≥70, and the Social Communication Questionnaire (SCQ) total score of <15. Clinical judgement was used with elevated SCQ scores to determine the need for further AU evaluation in the TD group. The Autism Diagnostic Interview-Revised (ADI-R) and the Autism Diagnostic Observation Schedule (ADOS) were administered to confirm that possible TD cases met or did not meet DSM-IV criteria. The ReCHARGE final diagnosis for TD children was determined by Stanford-Binet Intelligence Scale, Fifth Edition – Abbreviated Battery score of ≥70, VABS-3 composite score of ≥70, and the SCQ total score of <15. To confirm AU cases, the ADOS-2, an informal parent interview, and a DSM-V checklist were used.

Results: Of 118 TD children seen in ReCHARGE, six changed diagnostic groups from TD to AU. Two participants were omitted from our analysis. One had an incomplete SCQ at the CHARGE time point with 11 missing questions. The other had an SCQ score of 16 in CHARGE; clinical judgement was used to determine that further AU evaluation was not needed. The four remaining participants met TD criteria for MSEL, VABS, and SCQ between the ages of 24–60 months. Participants 1 and 4 received an AU diagnosis after their CHARGE evaluation by a community clinician; these diagnoses were both confirmed at ReCHARGE by ADOS, and DSM-V checklist. The remaining participants were identified by clinician judgement and met criteria on the ADOS-2 and DSM-V checklist. Refer to *Table 1* and *Table 2.*

Conclusions:The diagnostic change from TD to AU was unexpected, especially as **no developmental concerns** were noted in their CHARGE files. In pediatric research a multitude of problems may exist in obtaining accurate data including parent report and consistency, parent understanding of developmental milestones, and difficulty in testing young children. This study shows the challenges parents and providers have in reporting and identifying all AUT cases in children ages 2–5 years. Further research is warranted to explore causes of late diagnoses. Additional assessments and secondary AUT screening during middle childhood could prove helpful in these cases as well as in cases when SCQ scores are elevated.

415.002 *(Poster)* A Latent Profile Analysis of Infants' Sensory, Motor, and Social Communication Risk on the First Years Inventory and Age-3 Outcomes in a Community Sample

Y. J. Chen[1], *J. Sideris*[1], *L. R. Watson*[2], *E. Crais*[2] *and G. T. Baranek*[1], *(1)Chan Division of Occupational Science and Occupational Therapy, University of Southern California, Los Angeles, CA, (2)Department of Allied Health Sciences, University of North Carolina at Chapel Hill, Chapel Hill, NC*

Background: Autism spectrum disorder (ASD) is a complex condition that encompasses difficulties in sensory reactivity and motor coordination, in addition to social communication problems. Thus, it is important for an ASD-specific screener, such as the First Years Inventory, version 3.1 (FYI), to cover the breadth of developmental domains that may be implicated as potential risk markers early in development. Assessing the behavioral manifestations of risk, which may vary across developmental domains, is therefore critical to parsing ASD heterogeneity and testing the predictive validity of the FYI.

Objectives: To better understand variations in early risk signs of ASD, this study adopted latent profile analysis (LPA), a person-based approach to classifying infants based on three FYI domain scores: Social Communication (SC), Sensory-Regulatory Functions (SR), and Motor Development (MD). We also aimed to examine whether the identified profiles (i.e., subgroups) differed in demographics and later parent-report outcomes.

Methods: A community sample of parents who had a child 8-16 months of age completed the FYI A- or B-form, each consisting of 48 items across three domains: SC, SR, and MD. When children reached 3 years of age, 2,194 parents who had previously returned the FYI completed the Developmental Concerns Questionnaire (DCQ), Social Responsiveness Scale (SRS-2) and Sensory Experiences Questionnaire, version 2.1 (SEQ) as follow-up measures of children's clinical outcomes. Using the FYI domain scores as indicators, LPA was conducted to identify profiles. After choosing the optimal model based on fit statistics, means or proportions across the identified profiles were compared on demographics (e.g., child's age upon FYI completion) and age-3 outcomes, using ANOVA or equivalence tests for odds ratios.

Results: LPA indicated that the best-fitting model was a four-profile solution (Figure 1) for both A/B-form cohorts. The largest profile (Profile 1) had the lowest risk levels in all three domains. Both Profile 2 and Profile 3 scored high on SC and MD, while Profile 3 showed higher overall severity. Profile 4 scored particularly high on SR. The odds ratios relative to base rate (Table 1) indicated that children in Profile 2 were more likely to be premature and to have motor-related concerns at age 3. Children in Profile 3 and 4 were more likely to have a later outcome of ASD or sensory processing disorder (SPD). Also, the odds of having various types of parental concerns differed across the four profiles. Profile 4 had significantly higher SEQ scores at age 3, particularly in hyperresponsiveness and seeking behavior.

Conclusions: These findings revealed heterogeneous manifestations of early ASD-related risk in a large community sample, with four subgroups differing in demographics and later developmental outcomes. The two most severe profiles, based on FYI scores at 8-16 months of age, were related to higher probabilities of ASD-related outcomes at age 3; however, one of these profiles showed higher risk in SR, while the other showed more risk in SC and MD. These findings stress the importance of dimensional assessments in parsing heterogeneity of early ASD risk profiles, and may have implications for better tailored interventions in the future.

415.003 *(Poster)* A Novel Framework for Autism Diagnosis Using Structural MRI

M. T. Ali[1]*, O. Dekhil*[1]*, Y. ElNakieb*[1]*, A. Shalaby*[1]*, A. Mahmoud*[1]*, G. Barnes*[2] *and A. S. El-Baz*[3]*, (1)Bioengineering, University of Louisville, Louisville, KY, (2)Neurology, University of Louisville School of Medicine, Louisville, KY, (3)University of Louisville, Louisville, KY*

Background: Autism spectrum disorder (ASD) is a neuro-developmental disorder that has three main associated characteristics: (i) social functioning disorders, (ii) communication impairments, and (iii) restricted and repetitive behaviors. In order to study various types of abnormalities correlated with ASD, several magnetic resonance imaging (MRI) based modalities have been used, such as:(i) structural MRI (sMRI) for anatomical abnormalities, (ii) functional MRI (fMRI) for brain activity abnormalities, and (iii) diffusion tensor imaging (DTI) for connectivity abnormalities. In this work, we study the differences between autistic and typically developed (TD) subjects using sMRI anatomical features.

Objectives: To distinguish among TD and autistic subject using sMRI anatomical features per area to achieve both global and local classifications.

Methods: Morphological and volumetric features are calculated for each subject's MRI volume. Each subject is then to be classified either autistic or typically developed based on combinations of these features and random forest classifier. First, preprocessing is done using FreeSurfer as follows: 1. Intensity normalization, 2. Brain extraction and skull stripping, and 3. Brain segmentation and areas labeling. Second, extract our features as follows: For each subject and for every feature, a 68×68 areas delta matrix is created. Where each element in this matrix is the difference between the value of a feature of this area and the value of the same feature of a different area.

Results: Using the proposed framework on several datasets of total 1112 subjects obtained from the Autism Brain Imaging Data Exchange (ABIDE), 8 features were extracted from 68 brain regions for each subject. In this experiment, we used random forest classifier for each dataset. CMU has demonstrated accuracy, sensitivity and specificity of 100%, KKI 94% accuracy, 93% sensitivity and 95% specificity, MaxMun showed 98% accuracy, 100% sensitivity, and 96% specificity. Rest of sites has shown accuracy, sensitivity and specificity all over 90% except NYU showed 73% accuracy, 72% sensitivity, and 76% specificity.

Conclusions: In this work, a new sMRI brain volume representation is proposed that might be more robust against confounding variables like IQ and age. The new framework is tested on ABIDE dataset which is collected from different sites and has high variability in the confounding variables we are targeting. The framework shows promising results that we aim to generalize of other datasets and prove that this framework can be a first step towards generalized autism diagnosis system.

415.004 *(Poster)* A Novel Sensory Perception Measurement As a Possible Bio-Marker for Autism Spectrum Disorder

R. (. Rembrand[1] *and A. Aran*[2]*, (1)SensPD Ltd., Kiriat Tivon, Israel, (2)Shaare Zedek Medical Center, Jerusalem, Israel*

Background: Hyper- or hypo- reactivity to sensory input and sensory integration impairment are common to people on the autism spectrum. Sensory perception (SP) activity of the brainstem affects auditory efferents activity. Auditory efferents control the selective production of stochastic auditory signals: oto-acoustic emissions (OAEs) by the outer hair cells (OHCs). Therefore, OAEs response measurement is an indication of SP reactivity.

Objectives: To assess the potential of a novel non-invasive and easy to administer method for measuring sensory perception as a diagnostic biomarker in autism spectrum disorder (ASD).

Methods: We used an OAE measurement device to record the auditory efferents' activity. The test instrument includes two earphones and two microphones to capture both the ipsi- and the contra-lateral responses of all stimuli. The stimuli used are longer and more complex compared with those used in standard OAE tests. Two of the stimuli were used for analysis: The first part of the word "Enrich" ("Eh") and a short gap in pure tone delivery. The OAE patterns we were looking for in the response are time/frequency distribution patterns relative to the basic stimulus profile. We have measured OAEs from 12 children with ASD (ages 2-9 years) and 12 age and gender matched typically developing (TD) children. Exclusion criteria included: serous otitis media, absence of OAE activity, hearing loss of sounds quieter than 45dB., and in the TD group also a family history of ASD.

Results: Sub-sections analysis of the OAE time/frequency measured response matrix revealed a significant group difference between the ASD and TD groups. In some sections, similar responses were found but at different frequencies and in others sections the frequencies were the same but the ASD group response was delayed. The stratified mean accuracy of ASD/TD discrimination, across all folds was: 89.7% ± 3.2% for EH responses, and 83.8% ± 3.5% for gap responses.

Conclusions: We found different OAE response profiles in children with ASD compared with TD children. These results support the feasibility of OAE measurement as a diagnostic and possibly stratifying biomarker for ASD. Further studies are required to assess the stratification validity of OAE measurement and its correlation with sensory perception.

415.005 *(Poster)* A Roadmap for Using Applied Research to Tailor Clinical Practice Recommendations for ASD Screening Using the M-CHAT

***P. Doehring**, ASD Roadmap, Chadds Ford, PA*

Background: While concerns about ASD's prevalence and delays in diagnosis have mobilized significant investments in research in the US, recent reports indicate persistent gaps in timely and accurate identification. Last year at IMFAR, we modeled a research roadmap capturing the potential progress from basic to applied research focused on improving identification, and suggesting downstream impacts on practice, policy, and outcomes. Applying this roadmap to applied research involving the Modified Checklist for Autism in Toddlers (M-CHAT) yielded many clinical validation studies suggesting the potential for improving identification. Nonetheless, some researchers remain skeptical because of variability across low- and high-risk samples, and across key validity metrics. Community-based practitioners deciding whether to use the M-CHAT - especially those who struggle with statistics - may be unable to untangle contradictory recommendations. This is further complicated by the mismatch between the certainty sought by researchers, and the urgency experienced by community-based clinicians eager to help their patients now. For reasons we have outlined elsewhere, we believe that practitioners have other opportunities to mitigate some uncertainty, and might consider a decision model that re-balances priorities once the risks are clarified.

Objectives: (1) To demonstrate a practitioner-friendly template for summarizing key validity metrics by applying it systematically to eligible M-CHAT studies; (2) Drawing from this template, to model 3 standards guiding decisions to adopt the M-CHAT.

Methods: Building on an earlier, comprehensive review that categorized all applied research involving the M-CHAT along the research roadmap, we coded validity studies as focusing on low-risk (i.e., no concerns) versus high-risk populations (i.e., concerns or family history of ASD) of children not yet diagnosed with any developmental disability. Excluding studies that did not confirm an ASD diagnosis, we extracted key data on validity, study design, and other characteristics. We tracked studies on separate publication timelines for low- versus high-risk samples that capture accumulating evidence relative to three different standards for balancing uncertainty and opportunity: (1) a model prioritizing the detection of True Positives; (2) a model that balances True Positives, False Negatives, and False Positives identified with other previously undetected conditions, and; (3) a traditional model seeking a high degree of certainty across key metrics, with more restrictive study inclusion criteria.

Results: We discovered more than 40 eligible studies reporting at least one key metric. About one half of these studies involved a low-risk population, but fewer met the more restrictive selection criteria for Model 3. For both Low- and High-Risk populations, Model 1 rapidly accumulated consistent support, at the cost of significant uncertainty regarding False Negatives and False Positives. Support for Model 3 was difficult to establish because of the limited and sometimes contradictory conclusions. Model 2 clearly supported a decision to adopt the M-CHAT, as long as some False Negatives are tolerated and False Positives capture other important, un-diagnosed conditions.

Conclusions: These analyses suggest that flexible standards may help practitioners make best use of available research when deciding whether to adopt the M-CHAT, and support the implementation research needed to begin to close persistent gaps in identification.

415.006 *(Poster)* A Survey on Private Rehabilitation & Education Services for Children with ASD in Guangzhou China

***D. Huang**[1], X. Wu[2] and C. Chen[2], (1)Guangzhou Rehabilitation & Research Center for Children with Autism, Guangzhou Cana School, Guangzhou, China, (2)Guangzhou Rehabilitation & Research Center for Children with ASD, Guangzhou, China*

Background: In the recent 10 years, quite a number of rehabilitation and education service facilities for ASD(autism spectrum disorder, ASD) emerged in China largely due to increasing market demand. However, the quality of the services can vary significantly especially in the private sector. It is necessary to characterize the key aspects of these service providers for service improvement and policy-making.

Objectives: This study aimed to provide data on the current state of private rehabilitation & education services for children with ASD in Guangzhou. The results are expected to assist with governmental decision making in respect of monitoring and supporting healthy growth of these services.

Methods: In 2019, questionnaires, telephone interviews, on-site visits, social media were employed to collection information from teachers and parents on the scale (number of ASD children practitioner), intervention approach(ABA,SIT,ST), teacher's education background, monthly fees , etc.

Results: Sixty-five facilities participated in the survey. NPOs (non-profit organization) and commercially registered companies accounted for 64.6% and 35.4%. of the surveyed facilities, respectively. From the perspective of teachers, only 4 facilities require all teachers to hold bachelor's degree or above, 14(21.5%) facilities had staff graduated from polytechnic schools or with lower education level. There were 20 facilities (30.8%) that required new teachers hold teacher certificate or a training certificate in the field of autism rehabilitation and education.

The average number of staff of surveyed facilities was 25. Among them, 63.1% facilities had less than 20 teachers. Regarding intervention, ABA, sensory integration, speech therapy, structural education, music therapy, were the most commonly applied. Floor-time and Sand play were also adopted in some facilities.

Fifty-one facilities （78.4%） charged 3000 ~10000 RMB per month. Seven centers charged more than RMB10000/month among which 2 centers charged up to RMB 20000/month or above. Forty-five facilities (69.2%) had not received any governmental subsidies. Parents' questionnaires showed that 57% families paid all expenses out of pocket, and 42.86% of surveyed parents reported that their autistic children had not received any intervention due to financial difficulty.

Conclusions: In Guangzhou, the majority of private service facilities did not require minimum education of teachers, which raises concerns about the professional quality of their service. Invention costs were high, but government subsidies were relatively low and only covered a fraction of families in need. Government supervision is lagging behind the development of autism service due to a lack of matching laws and regulations. Unlicensed operations over profit-seeking, deceptive advertisement have been reported from time to time. Given the limited number and capacity of public special education schools and lack of inclusive education support in mainstream schools, the overall rehabilitation and education services for children with ASD in China are still far from sufficiency in terms of quality and quantity.

415.007 *(Poster)* A Systematic Review of Diagnostic Tools for Autism in Chinese Populations

Y. Shek[1]*, C. Barnes*[1]*, S. Bignell*[1] *and S. Lipka*[2]*, (1)School of Human Sciences, University of Derby, Derby, United Kingdom, (2)School of Human Sciences, Univeristy of Derby, Derby, United Kingdom*

Background: Autism screening and diagnostic tools help clinicians identify autism-like behaviours through observations and interviews with parents and inform the judgement of the autism team when making a diagnosis. Most tools were originally developed in the West world, some have been adapted or translated across the years to increase the cultural validity for different population. Previous studies have reviewed screening tools for autism rather than diagnostic in Chinese populations. This study aims to identify which diagnostic tools have been used with this population and the processes undertaken when translating.

Objectives: To review all diagnostic tools for autism that have been used with Chinese populations and report on the relative methodological and cultural quality of these tools.

Methods: Studies from nine databases were retrieved from each database and between 2001 through October 2019. To be included, the study must have used an autism diagnostic tool with someone of Chinese ethnicity and be published in English. Quality assurance and appraisal was carried out by the co-authors of this study.

Results: Among the 57 papers included in the review, 39 were from conducted in China, 13 in Taiwan, 3 in Hong Kong, 1 in the USA and 1 in both China and Taiwan. Four autism diagnostic tools were located in the studies, namely the Childhood Autism Rating Scale (CARS [N=29]), the Autism Diagnostic Interview- Revised (ADI-R [N=21]), the Autism Diagnostic Observation Schedule (ADOS [N=16]) and the Developmental, Dimensional and Diagnostic Interview (3Di [1]). The combine use of both ADOS and ADI-R during autism assessment have been regarded as the gold standard assessment method for autism. Among the 57 papers, 10 (14.9%) adopted such method. Over 40% of the papers stated the use of adapted or translated versions of existing tools specifically (3Di: 100%, ADI-R: 52,4%, CARS: 44.8% and ADOS 1.9%). The cultural appropriateness and the methodological quality of the papers are also evaluated and rated.

Conclusions: Only one paper involved the use of an adapted diagnostic tool with the Chinese population in an English-speaking country. Therefore, it is unclear whether such practice is common for other researchers and practitioners within Western countries with Chinese migrant populations. We recommend that improved steps need to be taken when using diagnostic tests for autism with Chinese populations to enhance the reliability and cultural relevance with this population .

415.008 *(Poster)* A Systematic Review of Tools Used to Measure Suicidality Among Children and Youth with and without ASD

S. J. Howe[1]*, K. J. Hewitt*[1]*, J. Baraskewich*[1]*, C. A. McMorris*[1] *and S. A. Cassidy*[2]*, (1)Werklund School of Education, University of Calgary, Calgary, AB, Canada, (2)School of Psychology, University of Nottingham, Nottingham, United Kingdom*

Background: Suicidality (suicidal thoughts and behaviours) is exceptionally common, and often overlooked in individuals with autism spectrum disorder (ASD), affecting up to two-thirds of individuals. Importantly, the risk of death by suicide is seven times higher in individuals with ASD than in the general population. Cassidy and colleagues (2018) found that despite the growing number of studies assessing suicidality in this population, no studies involving autistic adults had used a validated suicide assessment tool. To date, no study has identified what tools are currently being to measure suicide risk in children and youth in both research and clinical contexts. Furthermore, it is not known whether existing suicide assessment tools are reliable or valid for use in children and youth with ASD. Identifying valid assessment tools is crucial to understanding, recognizing, and treating suicidality, as well as preventing premature death in this vulnerable population.

Objectives: The present study aimed to extend Cassidy and colleagues' (2018) study of suicidality in adults with ASD, to systematically examine the suicide assessment tools used with children and youth. Specifically, we aimed to: 1) identify measures commonly used to assess suicidality in children and youth in the general population, as well as in children and youth with ASD; and 2) provide suggestions for future research in this area.

Methods: A systematic literature search was conducted using the following bibliographic databases: PsycINFO, Medline, Embase, and Web of Knowledge. Searches were carried out for 1) children and youth with ASD, and 2) the general population of children and youth.

Results: Overall, we did not identify any tools that were commonly used in children and youth with ASD. Majority of studies screened utilized single-item measures of suicidality either independently or taken from tools that assess for depression or psychopathology more broadly (e.g. K-SADS; CBCL; MINI-KID, etc.). Several studies also used measures of their own creation with no evidence of validity. Of tools that measure suicidality specifically, we identified five tools (Columbia-Suicide Severity Rating Scale [C-SSRS] Paykel Suicide Scale [PSS]; Self-Injurious Thoughts and Behaviours Interview [SITBI]; Suicide Behaviours Questionnaire-Revised [SBI-R]; Beck Scale for Suicidal Ideation [BSS]) commonly used in general population youth.

Conclusions: Results highlight the absence of any tool that has consistently been utilized to measure suicidality in children and youth with ASD. Additionally, there is a lack of research examining the validity of utilizing existing suicide risk assessment measures in children with ASD. Future research should aim to either validate the use of existing tools in this population; adapt existing measures to reliably capture the unique presentation of suicidality in this population, and/or develop new measures to facilitate clinically meaningful research to further understand and prevent suicidality in autistic children and youth. We will propose a framework for future research and clearly define steps that should be taken to fill this gap.

415.009 *(Poster)* A Systematic Review on the Psychometric Properties of Motor Assessments for Young Children with Autism Spectrum Disorder

L. Qu[1]*, Y. Lu*[2]*, X. Liang*[3]*, S. Xie*[4] *and D. A. Ulrich*[5]*, (1)School of Kinesiology, University of Michigan, Ann Arbor, MI, (2)Department of Kinesiology, College of Education, Michigan State University, East Lansing, MI, (3)Department of Sports Science and Physical Education, Faculty of Education, The Chinese University of Hong Kong, Hong Kong, China, (4)Beijing Sport University, Beijing, China, (5)University of Michigan, Ann Arbor, MI*

Background: The diagnosis of Autism Spectrum Disorder (ASD) is often delayed till 38 months of age or older, because the defining features of ASD do not fully emerge until the second year (Daniels & Mandell, 2014). However, children with ASD start to show multidimensional developmental delays in infancy. Despite being most frequently identified behaviors by parents to raise concerns (Flanagan et al., 2012), motor differences among young children with ASD are often neglected by clinicians during screening and early interventions. In fact, children with ASD experience different levels of motor delays from an early age (Koterba, Leezenbaum, & Iverson, 2014). With an increasing interest in early motor development of young children with ASD, there is a need to identify which motor assessments are the most accurate and sensitive to use with this population. By systematically reviewing the psychometric properties of existing motor assessments, clear recommendations can be provided to clinicians.

Objectives: To systematically evaluate the psychometric properties of motor assessments and screening tools for young children with ASD from birth to 6 years old.

Methods: A comprehensive search strategy was performed in February, 2019 in seven English databases (Medline [Ovid], Embase, Scopus, CINAHL, ERIC [Proquest], SportDiscus, and PsycInfo) and four Chinese databases (Chinese National Knowledge Infrastructure, Wanfang DATA, and CUHK Libraries) to avoid Tower of Babel bias. Studies that met the following criteria were included: 1) The studied instrument contains an isolated score in the motor domain; 2) Included studies report ≥1 psychometric property outcome; 3) Participants ranged in age from birth to 6 years old; 4) Studied population: children with ASD. Methodological quality was assessed with the Critical Appraisal Tool for Validity and Reliability Studies of Objective Clinical Tools and the Quality Assessment of Diagnostic Accuracy Studies (QUADAS-2).

Results: A total of 6574 articles were identified during the title and abstract screening (180 published in Chinese). 400 full-text studies were screened for eligibility. Nine articles were included in the data extraction (PRISMA Flowchart). Nine assessment tools from nine studies met the inclusion criteria: Test of Gross Motor Development-3 (TGMD-3), Mullen Scales of Early Learning, Peabody Developmental Motor Scales-2 (PDMS-2), Miller Function and Participation Scales (M-FUN), Child Development Inventory, Skills Assessment, Preschool Imitation and Praxis Scale (PIPS), Ages and Stages Questionnaires (ASQ), and Tokyo Child Development Schedule. Methodological quality varied from poor to excellent and validity and reliability varied from fair to excellent.

Conclusions: This systematic review summarized the psychometric properties of existing motor assessments, developmental scales and screening tools for young children with ASD. The majority of assessments included have fair-excellent reliability and validity. The tools demonstrated moderate to high levels of agreement in identification of motor delays in young children with ASD. Future research on evaluating motor assessment tools for young children with ASD is urgently needed. Clear assessment and screening recommendations for clinicians have the potential to improve the comprehensive evaluation process, so that young children with ASD can receive proper early intervention services sooner.

415.010 *(Poster)* ADOS Characterization of a Broad Sample of Women with Autistic Traits

K. M. Normansell[1]*, M. South*[2]*, R. A. Lundwall*[2]*, T. P. Gabrielsen*[3]*, J. Cox*[4]*, J. S. Beck*[5] *and H. Vogeler*[6]*, (1)Clinical Psychology, Brigham Young University, Provo, UT, (2)Psychology & Neuroscience, Brigham Young University, Provo, UT, (3)Counseling & Special Education, Brigham Young University, Provo, UT, (4)Counseling and Career Center, Brigham Young University, Provo, UT, (5)Psychology, Brigham Young University, Provo, UT, (6)Brigham Young University, Provo, UT*

Background: Females are diagnosed with autism at much lower rates than males. It is still uncertain how much of this discrepancy is because different trait presentations in girls and women are not recognized by standard diagnostic measures. This discrepancy may be especially pronounced for women with autistic traits, who often report significant social and mental health concerns but have been frequently underdiagnosed or misdiagnosed and thus do not receive appropriate services.

Objectives: We aimed to characterized profiles on standard diagnostic measures in a broad sample of fully verbal women with average- to above-average IQs, who self-report that social situations are difficult. We explored relationships between diagnostic measures and previous autism diagnosis and looked at the standard vs. revised algorithm for Module 4 of the ADOS-2.

Methods: Adult women with social difficulties were recruited from existing research databases and by posted flyers that asked 'Do you find social situations confusing or exhausting.' Participants did not need to have an established diagnosis of autism. Those who scored 3.0 or above on the BAPQ screening measure administered online were invited for in-person lab visit. Participants in the in-person study included 66 women (mean age=24.8; mean estimated IQ=114.25). Module 4 of the Autism Diagnostic Observation Schedule-2nd Edition was administered by trained clinicians supervised by research-reliable administrators. We calculated ADOS-2 scores using both the standard and revised algorithms (Hus and Lord, 2014). We also looked at ADOS-2 vis-à-vis CATQ camouflaging scores for a subset of women (n=56) who had both measures.

Results: One third (n=22) of the sample had a previous diagnosis of autism. Of these, 12 had been diagnosed in childhood, 4 as teenagers and 6 as adults. For all participants, 20 of the 66 women scored at or above the autism spectrum range on the ADOS-2 revised algorithm. This is 30% more than the number above cut-scores on the old algorithm (n=14). ADOS-2 scores were not significantly correlated with autism trait self-report ratings (the AQ, r=.191; the SRS-2 r=.158) though these ratings were highly correlated with each other (r=.556). There were no group differences in camouflaging scores from the CAT-Q, for those above or below the ADOS cut scores (t=.060) or the dimensional trait measures. However, many women scored high on these trait measures, with SRS-2 mean scores (92.02) and AQ mean scores (28.48) well into the range of concern for autism symptoms.

Conclusions: The revised algorithm for Module 4 identified many more participants in the autism spectrum or autism range than the previous algorithm. However, overall there is a large discrepancy between self-reported social distress (on the BAPQ, SRS-2, AQ) and functional impairment identified by the ADOS. This gap poses many questions. Which is more correct? Are these women camouflaging social distress and able to "pass" the ADOS despite everyday disruption in social function? Or do the dimensional questionnaires exaggerate or mix distress related to anxiety and other concerns? There remains an urgent need to develop and validate multi-modal measurements of social distress and impairment in females and in women especially.

415.011 *(Poster)* Age of Concern and Evaluation Trajectory in Developmental Coordination Disorder (DCD) and Autism Spectrum Disorder (ASD) with Co-Occurring DCD

K. Kata[1], *S. Chang*[2], *A. Ganesh*[2], *J. Mauk*[3], *W. P. Bowman*[2], *L. Bailey*[4], *T. Hamby*[5] *and H. L. Miller*[2], *(1)Texas College of Osteopathic Medicine, University of North Texas Health Science Center, Fort Worth, TX, (2)University of North Texas Health Science Center, Fort Worth, TX, (3)Child Study Center/Cook Children's Medical Center, Fort Worth, TX, (4)Cook Children's Medical Center, Fort Worth, TX, (5)Research Operations, Cook Children's Medical Center, Fort Worth, TX*

Background: Motor symptoms in ASD include abnormalities of gait and balance, postural instability, and incoordination, and for some individuals these are significant enough to warrant a diagnosis of Developmental Coordination Disorder (DCD). Despite the documented presence of significant motor symptoms in patients with ASD, motor function is often not prioritized in assessment or intervention. There are few published studies examining the pathways used for diagnosis, referral, and early management of pediatric patients with ASD, DCD, and ASD+DCD with regard to age of first concern and follow-up motor assessments.

Objectives: Our aim was to assess differences in the timing of initial developmental concerns and follow-up care among patients with ASD, DCD, and ASD+DCD in a local children's hospital. We hypothesized that the groups would not differ in age of first concern, first concern visit, or age at referral visit with specialist.

Methods: We retrospectively evaluated the records of patients who were 0-21 years old at the time of first chart entry (1994-2017), with a diagnosis of ASD, DCD, or ASD+DCD based on DSM-IV or DSM-5 criteria. The number of patients since 1994 was 7540 (ASD = 6,779, DCD = 470, ASD+DCD = 291). We collected primary and co-occurring diagnoses; age at which patients met developmental milestones; age at first concern, first concern visit, and follow-up visit with specialist; demographics.

Results: The mean age of first concern for the DCD group was 46 months, 24 months later than the ASD+DCD group. Though this difference did not reach statistical significance ($p = 0.07$), a 2-year delay in addressing developmental concerns is clinically significant. There was a significant main effect of group on age at first concern visit ($p = 0.001$). Mean age at first concern visit for the ASD+DCD group was approximately 3 years lower than the DCD group and 2 years lower than the ASD group. A similar pattern persisted for age at referral visit with a specialist. Children in the DCD group continued to lag approximately 34 months behind the ASD+DCD group in their care trajectory. In our current study sample, of 81 patients, 38% of children were either noted as having a Global Delay and 50% Delayed in Some Areas. 12.3% of children were marked as Within Normal Limits regarding developmental milestones, but were eventually diagnosed with a developmental disorder. Global Delay was noted less often in the DCD group ($p = 0.03$) relative to the ASD and ASD+DCD groups.

Conclusions: This study highlights differences in the timeline from concern to care for children diagnosed with ASD, DCD, and ASD+DCD. For children with DCD, the average age of first concern drove later care (nearly 3 years) compared to children with ASD and ASD+DCD, and we observed wide variability in age of first concern in the DCD group. It's plausible that ASD and ASD+DCD may manifest as greater functional impairment or symptom severity, prompting earlier caregiver or provider action. The long-term goal is to clarify which elements of the care can be improved to increase diagnostic efficiency and access to services.

415.012 *(Poster)* Age of Initial ASD Diagnosis By Gender, Race, and SES Based on Insurance Type

K. J. Tepper[1], *B. Cauley*[1], *J. Schuttler*[1] *and R. Jamison*[2], *(1)Pediatrics, University of Kansas Medical Center, Kansas City, KS, (2)Center for Child Health and Development, Pediatrics, University of Kansas Medical Center, Mission, KS*

Background: Autism spectrum disorder (ASD) occurs more frequently in males than females (Kogan et al., 2009; Lai et al., 2015; Rynkiewicz et al., 2016) with some evidence suggesting females are misdiagnosed or diagnosed later than males (Haney, 2016). In addition, there are disparities in age of diagnosis based on a child's race/ethnicity and insurance type (Mandell et al., 2002). A better understanding of how gender, race/ethnicity, and SES (e.g., insurance type) impact age of diagnosis could inform practice guidelines that promote screening and earlier diagnosis.

Objectives: The purpose of this study was to identify the potential influence of gender, race/ethnicity, and SES (as measured by private or public insurance/Medicaid) on age of referral for autism evaluation and for receiving a diagnosis.

Methods: Retrospective analysis of de-identified clinical data included 1,089 children or adolescents who were referred for an evaluation of autism spectrum disorder at an academic medical center in the Midwestern United States (mean age = 6.01 years, SD = 3.99). The sample was primarily White (66.1%; 33.9% racial/ethnic minority) and male (74.4%; 25.6% female) with about equal rates of public/Medicaid (47.2%) or private (52.8%) insurance. Following evaluation 594 (54.5%) received a diagnosis of ASD. Those diagnosed with ASD had an average age of 5.69 (SD = 4.04), were predominantly White (62.5%; 37.5% racial/ethnic minority), male (76.3%; 23.7% female) and had private insurance (59.4%; 40.6% public/Medicaid). A linear regression was conducted to examine the relationship between gender, race/ethnicity, and SES with age of clinic evaluation. A second regression examined the relationship between demographic variables and age of receiving a diagnosis of ASD.

Results: Among all children evaluated in the clinic, race/ethnicity was significantly related to age of evaluation ($p < .001$), such that racial/ethnic minorities were evaluated 1.3 years earlier (i.e., at a younger age) than White children. Gender was marginally significantly related to age of evaluation ($p = .08$), such that females were evaluated 6 months later than males.

Among those individuals who were diagnosed with ASD, race/ethnicity was significantly related to age at ASD diagnosis ($p < .001$), such that racial/ethnic minorities received a diagnosis, on average, 1.5 years earlier than White children. Gender and SES were not significant predictors.

Conclusions: Findings within this clinical sample suggest children from racial/ethnic minority groups were evaluated for ASD at a younger age compared to their White peers. This is contrary to previous findings in which White children were evaluated earlier than African American children (Mandell et al., 2002), suggesting further exploration within this sample. The marginally significant finding that females were evaluated later than males is consistent with previous literature (Rutherford et al., 2016). Plans for subsequent analyses will examine individual characteristics related to cognitive ability, age, and enrollment in early intervention as additional factors.

415.013 *(Poster)* Am I Autistic? Utility of the GQ-ASC As an Autism Assessment in Adult Women.

C. M. Brown[1], *T. Attwood*[2], *M. Garnett*[3] *and M. A. Stokes*[4], *(1)School of Psychology, Deakin University, Melbourne, Australia, (2)School of Applied Psychology, Griffith University, Queensland, QLD, Australia, (3)Minds & Hearts: A Clinic for Autism Spectrum Conditions, West End, QLD, Australia, (4)Deakin University, Burwood, Australia*

Background: There are a number of factors that prevent or delay autistic females from being diagnosed. These include gender bias in referral processes and assessment tools, misattribution of autistic traits to other causes, and camouflaging by autistic females. As a consequence, autistic females frequently reach adolescence or adulthood without a diagnosis. The rate of identification and diagnosis in girls has improved over time, though females as a whole are still thought to be under-represented. So, while the future for autistic girls continues to improve, it begs an important question: Where are all the autistic women?

Objectives: This study aimed to explore the structure of a modified version of The Girls Questionnaire for Autism Spectrum Condition (GQ-ASC; Attwood et al. 2011) to test its utility as an autism screening measure for adult women.

Methods: We recruited 672 women aged between 18 and 72 online. The sample contained 350 diagnosed autistic women (*M* age=36.21, *SD*=10.10), and 322 non-autistic women (*M* age=34.83, *SD*=9.93), each screened using the Autism Quotient (AQ). A Principle Component Analysis (PCA) of GQ-ASC items was contrasted against a Monte Carlo Parallel Analysis (1000 permutations) to determine their appropriateness for use in autistic women over the age of 18 years. Group differences between autistic and non-autistic women on the extracted components of the GQ-ASC were assessed, and a Receiver Operating Characteristic (ROC) curve was used to define a scoring cut-off value that demonstrated good sensitivity and specificity in discriminating between autistic and non-autistic cases.

Results: The PCA and Parallel Analysis revealed a five-component solution that accounted for more than 40% of the total variance. The extracted components were consistent with the female profile of autism, and interpreted as 1) Inner world: describes interest in fantasy, fiction, and reflection on the quality and content of imaginative play in childhood; 2) Camouflaging: describes effortful attempts to reduce the visibility of autistic traits; 3) Sensory Sensitivities: describes sensory processing abnormalities across various modalities; 4) Social Challenges: describes barriers to social understanding and participation; 5) Interests: describes age advanced, and non-stereotypically feminine interests. Significant differences were observed between autistic and non-autistic women across all extracted components, and the GQ-ASC total score. A ROC analysis indicated an excellent level of discrimination, with an area under the curve of 0.89, (95% CI 0.87 to 0.92). When applying a cut-off score of 57, the GQ-ASC correctly identified 80% of autistic cases.

Conclusions: The modified GQ-ASC is an effective and highly discriminant screening tool for use in adult autistic women. It provides valuable insight into the shared features and experiences of this under-recognised and under-represented subset of the autistic community. It has the potential to allow autistic women access to diagnostic services and supports that they may have otherwise missed.

415.014 *(Poster)* An Innovative Way to Screen for Nutritional Risk in Individuals with ASD

N. A. Withrow*, Nutrition and Dietetics, University of Northern Colorado, Greeley, CO*

Background: It is well established that feeding disorders occur in approximately 25-35 percent of typically developing children and as high as 90 percent in children with ASD. Based on the literature and clinical practice, children with an ASD are reported to have problematic eating behaviors such as food refusal, unwillingness to consume a large variety of foods, repetitive and ritualized eating behaviors, motor impairments and due to the complexities of problematic eating behaviors, there is a need for a comprehensive eating screening inventory.

Objectives: This pilot study was to develop a comprehensive eating screening inventory, named the Sensory Processing, Aberrant Mealtime Behaviors, Motor, Inventory for Eating (SAMIE). The SAMIE accurately screens for nutritional risk by identifying the four primary domains that affect eating in children with an ASD.

Methods: The development of the questions was executed in three steps. First, a review of the literature was conducted. Second, expert opinion was acquired in developing the questions. The eight experts had at least five years of experience in their area of expertise. Third, ten think-aloud protocols were made to simplify the first draft and to ensure that the questions were accurately addressing each of the domains and that primary caregivers understood the question. Recruitment of the primary caregivers to children with an ASD for the TAP sessions and for the completion of the SAMIE occurred through elementary schools, private practitioners, local Autism conferences and local Autism organizations. Prior to the pilot study, four participants were recruited to complete the SAMIE online. The final version for the pilot consisted of 78 questions, not including demographic information.

Results: To better understand the sample of participants, descriptive statistics (frequencies, means, standard deviations, and minimums)were calculated with the demographic variables (age, sex, height and weight of the child, primary caregiver income and education level), sample size and power calculations were performed. A two sample t-test was performed for continuous variables such as weight and height, whereas a chi-square or Fisher's exact test were performed to compare binary or categorical data, such as age category and sex of child. A total of 162 participants completed the online demographic questionnaire and the SAMIE. Overall, participants did not differ between groups for demographic characteristics, BMI status and dietary intake. After conducting a series of statistical tests, results illustrated that the SAMIE is a valid measure to screen nutritional risk in children with ASD.

Conclusions: Failure to accurately screen, diagnose and treat the complexities of eating difficulties in children with ASD exists due to the relative lack of knowledge and limited standardized eating assessments. Current identification of eating difficulties relies primarily on qualitative methods such as observation and primary caregiver interviews that are expensive and time-consuming. Therefore, the SAMIE was developed to include the four domains that impact eating and nutritional risk in children with ASD and to fulfill a need to have a validated screening inventory, and, in doing so, laying the foundational work toward the development of an in-depth eating assessment instrument, and empirically-validated eating treatment interventions

415.015 *(Poster)* Assessing Autistic Traits in Adult Population in Russia: A Pilot Study

A. A. Varlamov[1,2]*, I. V. Skorokhodov*[1]*, I. L. Shpitsberg*[1] *and K. P. Vergeles*[2]*, (1)Our Sunny World, Moscow, Russian Federation, (2)Center for Neurocommunicative Research, Pushkin State Russian Language Institute, Moscow, Russian Federation*

Background: In 2017 Russian Ministry of Health issued a letter of instructions prohibiting an unfounded change of diagnosis from ASD to another mental condition for individuals reaching adulthood. Until then the diagnosis was routinely changed from ASD to schizoaffective disorder and/or mental retardation, and it was virtually impossible to get an official recognition of ASD for high functioning adolescents and adults. In this situation the need for self-assessment tools in the autistic community was always high, and several attempts were made to provide Russian versions of internationally recognized questionnaires, even if just for a rough reference. Despite that, to our best knowledge, no self-assessment tools for evaluating autistic traits and/or risk of ASD in adult population or adolescents has been officially developed, adapted or validated on Russian-speaking samples. There are anecdotal evidences that most tools used with cut-offs established for European samples tend to overestimate the prominence of autistic traits but no data on this issue has been published in peer-reviewed journals.

Objectives: The aim of the study is to perform initial translation and cross-cultural adaptation of two self-assessment tools, RAADS-14 (a screening tool for ASD in an adult psychiatric population) and AQ (Autism Spectrum Quotient, a continuous, quantitative measure of autistic traits, adult version) on Russian adult neurotypical population in order to provide initial estimates of their reliability and validity.

Methods: Both RAADS-14 and AQ were translated into Russian (front and back translation by a professional team including a representative from autism community; the authors are grateful to Antonina Steinberg for her input to the project). The data collection was performed online, and factor structure, item loads, and score distributions were assessed for each questionnaire for adult neurotypical population.

Results: RAADS-14. The factor structure of the Russian RAADS-14 (sample size 325 participants) corresponded well to the factor structure of the original, yielding domains of mentalizing deficits, social anxiety, and sensory reactivity. The most important culture-specific issue was related to a distinctly different score distribution for the Russian sample (Mean = 17.03, Median = 17, Mode = 15, SD = 8.37) probably stemming from response bias.

AQ. The factor structure of the Russian AQ (sample size 140 participants) best fitted a 2-factor solution (Social interaction and Attention to detail), akin to the data from a Dutch version validation. Several items yielded low loads to the both factors; the Russian AQ may further benefit from excluding these questions or performing some wording alterations. There was no response bias as 50% of the items have reverse scoring, and the scoring distribution was similar to the European samples (Mean = 17.35).

Conclusions: Russian versions of RAADS-14 and AQ were characterized by reasonably good factor structure but RAADS-14 yielded culture-specific changes in score distributions. Further research and validation on clinical samples is needed, and particular measures (like balancing direct and reverse scored items) may be required to minimize response bias.

415.016 *(Poster)* Assessment Profiles of Toddlers Referred for ASD Concerns Based on Foster Care Status

L. J. Dilly[1] *and K. Railey*[2,3]*, (1)Marcus Autism Center, Children's Healthcare of Atlanta, Atlanta, GA, (2)University of Kentucky, Lexington, KY, (3)School of Medicine, Emory University, Atlanta, GA*

Background: Research indicates that the overall risk of experiencing foster care in childhood is roughly 6% (Wildeman & Emmanuel, 2014), and approximately 104,000 children under the age of 3 are in foster care on any given day in the United States (U.S. Department of Health and Human Services, 2017). Young children in foster care placement are known to have an increased risk for autism spectrum disorder (ASD) and developmental disabilities (Cidav, Xie, & Mandell, 2018; Kistin et al., 2016). Although it is difficult to disentangle the specific consequences of early adversity (e.g., maltreatment, unstable caregiving conditions) on developmental and behavioral functioning, research suggests that children in foster care experience an increased risk for delayed language development, social delays, and behavioral problems (Leve et al., 2012; Stock & Fisher, 2006). Given that differentiating between the presence of ASD from general developmental delays that are often present in children in foster care can be difficult, research in this area is warranted.

Objectives: The purpose of the current study is to consider differences in assessment profiles of toddlers referred for ASD based on foster care status and final diagnosis.

Methods: Retrospective chart reviews were conducted for toddlers who received the Autism Diagnostic Observation Schedule, 2nd Edition (ADOS-2) Toddler Module from 2/2015 to 5/2019 at a large autism center. Children were referred by pediatricians due to concerns of possible ASD. Child-level demographic, assessment results, and diagnostic information was gathered. Children in the foster care group were either in a foster care placement with a relative, foster family, or group home at the time of evaluation or had previously been in a foster care placement.

Results: See Table 1 for demographic information. A chi-square test of independence, which examined the relation between ASD diagnosis and foster care placement, was significant, ^{2} (1, N = 302) = 16.48, p < 0.01. Results indicate that children in foster care (M = 12.11, *SD = 7.87*) had significantly lower Total ADOS-2 scores than children who were not in foster care (M = 22.45, *SD = 6.08),* t(299), = -6.69, p = < 0.01. In addition, when considering *Little to No Concern* and *Moderate to Severe Concern* ADOS-2 severity levels, the overall sensitivity of the ADOS-2 for children in foster care placement and those with no foster care involvement, respectively, was 100% and 83%. The respective specificities were 88% and 97%.

Conclusions: Toddlers in foster care referred for ASD evaluations are less likely to receive an ASD diagnosis than toddlers who are not in foster care. However, children in foster care who do not receive ASD diagnoses demonstrate similar developmental profiles as children who are not in foster care and receive ASD diagnoses (Stock & Fisher, 2006). Results indicate that the ADOS-2 reliably identifies toddlers in foster care with and without ASD. Findings also highlight the continued need for research on factors that may differentiate between common developmental deficits from ASD-specific deficits in children in foster care.

415.017 *(Poster)* Assessment of Early ASD Signs and Outcomes in Children with Severe Visual Impairment: Does Social Communication Abilities at 2-3 Years Predict ASD Diagnostic Outcomes at 4-7 Years?

***N. J. Dale**, Great Ormond Street Hospital NHS Foundation Trust, London, United Kingdom*

Background: Children with congenital visual impairment (VI) are at high risk of ASD (risk ratio of 31 times typically developing children (Do et al, 2017), with socio-communicative difficulties becoming evident from the early years. Existing tools used to measure socio-communicative development and ASD are highly vision-dependent and not validated for children with VI. We recently validated the modified ADOS (fluent language) with 97 children aged 4-7 years with severe VI, leading to a new diagnostic algorithm with high sensitivity and specificity against clinician formulation. Twenty (20.6%) were classified as ASD; nineteen (19.6%) with borderline ASD according to clinician formulation. A subgroup (36; 37%) were investigated longitudinally in an earlier study (Dale et al, 2019). As part of their earlier assessments the children participated at 2-years-old in standard behavioural items and social 'presses' to elicit social and communicative behaviours and coded using the novel Social Communication Schedule (SCS-2).

Objectives: To establish whether early social communication measures (SCS-2) at 2 years predict the independent clinician formulation and diagnostic algorithm scores on the modified ADOS at 4-7 years in children visual impairment. The aim is to establish predictive validity and continuity between newly validated social communication assessments and to consider the SCS-2 as a screener for early risk.

Methods: The reliability and validation methods of the modified ADOS and the SCS are described briefly. Thirty-eight children (M=25.51m, SD=2.36) with congenital severe-profound VI were rated using the SCS-2 (high scores indicated better social communicative abilities), whilst engaging in social and independent play tasks. The same children were assessed 3 years later with the modified ADOS (M=63.75m, SD=8.27). A longitudinal analysis of the SCS-2 scores and later clinician ratings and ADOS algorithm ratings are undertaken.

Results: A Kruskal-Wallis test examined differences in three clinician categories (Non-ASD, Borderline, ASD) and SCS. A significant difference was found between groups on SCS scores $\chi^2(2)=7.2$, $p=.027$. A Dunn-Bonferonni pairwise test revealed the significant difference between the Non-ASD group and the ASD group, $p<0.05$; children in the ASD group (N = 6; M=10.50) scored lower SCS scores than children in the Non-ASD group (N= 26; M=22.69). A ROC analysis on the modified algorithm for ADOS scores based on the clinician formulation groups had revealed good discriminant validity (AUC=1.00), with sensitivity/specificity of 100 for clinician ratings and identified a modified ADOS threshold score for *High Risk for ASD* (≥9.5) or *Non-Spectrum* (<7.5). Using these cut-off scores the two groups differed significantly on SCS scores (High Risk for ASD N=5; M=23.00, SD = 7.21 vs Non-Spectrum N=26; M=25.95, SD = 5.93) U= 27.50 p=.04; Cohen's d effect size of 0.78 suggesting a medium effect.

Conclusions: The SCS-2 scores differed significantly according to later diagnostic thresholds, providing predictive validity for the novel diagnostic thresholds on the modified ADOS with children with VI. The findings provide further support for the social communication constructs of the two assessment measures and suggest the SCS-2 as a future screener of early signs of high autism risk in young children with VI. The clinical practice implications are discussed.

415.018 *(Poster)* Assessment of Sensory Issues in Adults with ASD: The Senses; A New Questionnaire

*M. Turkensteen, M. L. Bezemer and **E. M. Blijd-Hoogewys**, INTER-PSY, Groningen, Netherlands*

Background: Sensory issues are a key DSM-5 diagnostic feature of ASD (APA, 2013). There is no standardized Dutch questionnaire available that measures both (1) hyper-, hyporeactivity, and unusual sensory interests, and (2) a broad range of sensory modalities, including interoception.

Objectives: We wanted to develop and validate a self-report sensory questionnaire for adults with ASD.

Methods: We developed the Senses (63 items), based on extensive literature search, clinical impressions and examination of other questionnaires.

In total, 381 adults filled in the Senses and the AQ-10 (Alison et al, 2012). There was a norm-group (N = 180) and a clinical group (N = 201).

The norm-group was gathered from the general population (age: $M = 40.94$, $SD = 10.99$; 33 men, 147 women). The clinical group consisted of adults suspected for ASD, who underwent an extensive ASD assessment at a general mental healthcare institution (age: $M = 32.62$, $SD = 11.91$; 94 men, 107 women). Ultimately, 73% received an ASD diagnosis (ASD group, N = 147); the others received other psychiatric diagnoses (non-ASD group, N = 54).

A sub-group also filled in an AASP (Brown & Dunn, 2002) (N = 20). Another sub-group participated in retesting the Senses within two months (N = 19).

The mean AQ10 was different for group membership (ASD: $M = 6.10$, $SD = 2.28$; non-ASD: $M = 4.87$, $SD = 2.47$; norm: $M = 1.71$, $SD = 1.53$) (Welch's $F(2, 127.85) = 214.18$, $p < .001$).

Results: Cronbach's alpha for the Senses was excellent (ASD group, $\alpha = .930$). Test-retest reliability was good ($M_1 = 67.12$, $SD_1 = 24.34$; $M_2 = 67.95$, $SD_2 = 21.84$; $r = .87$, $p < .001$). Senses Total Score was correlated with AQ-10 Total Score (N = 381; $r = .67$, $p < .001$), AASP Scales Low registration and Sensory sensitivity ($r = 68$, $p = .001$ and $r = .72$, $p < .001$, respectively). Senses Scale Hyperreactivity correlated highly with AASP Scale Sensory sensitivity ($r = .91$, $p < .001$), not with AASP Scale Low registration ($r = .35$, ns). Senses Scale Hyporeactivity correlated highly with AASP Scale Low registration ($r = .70$, $p = .001$), not with AASP Scale Sensory sensitivity ($r = .24$, ns).

Senses Total Score was significantly different for group membership (ASD-group: $M = 66.30$, $SD = 25.83$; non-ASD group: $M = 46.20$, $SD = 26.17$; norm-group: $M = 24.06$, $SD = 15.20$) (Welch's $F(1, 127.11) = 158.46$, $p < .001$; Games-Howell post hoc analysis, $p < .001$). Using the 95th percentile of the norm-group as a cut-off, 78% of the ASD-group reported sensory issues.

Conclusions: The Senses has strong psychometric qualities: excellent internal consistency, good test-retest reliability and good convergent validity with the AASP. The amount of sensory issues was associated with the amount of ASD characteristics, supported by the different Senses mean scores over the three research groups and a strong positive correlation of the Senses with the AQ-10

In subsequent factor analysis, we will explore which items are eligible for removal and we will develop subscales.

415.019 *(Poster)* Autism Symptomatology in Children with Neurofibromatosis Type 1

A. Porthukaran[1] *and K. J. Sinopoli*[2]*, (1)Psychology, York University, Toronto, ON, Canada, (2)Neurology, Hospital for Sick Children, Toronto, ON, Canada*

Background: Neurofibromatosis Type 1 (NF1) is an autosomal dominant genetic condition (Nordlund et al., 1993). Sequelae varies, but often includes characteristic café au lait spots and neurofibromas, and in some cases, neural abnormalities such as optic gliomas or focal areas of signal intensities on brain imaging. Cognitive difficulties are also prevalent in NF1 including visual-perceptual deficits, attention deficit hyperactive disorder, and learning disabilities (Gutmann, 1999). Recent studies have focused on the presence of autism spectrum disorder (ASD) traits in some children with NF1 (Walsh et al., 2013), yet the nature of such symptoms and the behavioural correlates in NF1 is not well understood.

Objectives: We examined whether children with NF1 and ASD symptomology displayed a similar behavioural profile as children with ASD without NF1. To this end, we focused on a key ASD behavioural phenotype: poor theory of mind (i.e., attributing others' mental states). The findings will provide insight into whether the ASD symptoms commonly observed in NF1 manifest in their behaviour, which has implications not only for our understanding of the disorder, but also in the types of interventions used.

Methods: Twenty-four children and adolescents with NF1 were recruited from a large children's hospital in Toronto, Canada. Typically developing controls (n=20) were recruited from the community. Parent ratings using the Social Responsiveness Scale (SRS-2) screened for ASD symptoms in all groups, and was primarily used to identify participants with ASD (e.g. Garg et al., 2013, Walsh et al., 2013). All participants completed a computerized task where they made judgments of a character's perception of a task based on prior experience. The key dependent variable was performance in the false belief (theory of mind) condition (e.g., Jack moves a ball to a hat in view of the children, but Jill cannot see this. The children are then asked where Jill will look for the ball). Children with NF1 who scored above the cut-off on the SRS-2 were expected to exhibit difficulties with the false belief condition due to difficulties with theory of mind inherent in ASD.

Results: Fifteen children with NF1 were assigned to the ASD symptom group based on an SRS-2 total score of 60, indicating mild clinical symptoms. Compared to the control group, the children with NF1 and ASD symptoms did not display significant differences on the baseline, working memory or true belief conditions of the task, but did perform worse on the false belief condition ($p = 0.049$) with a large effect size (Cohen's $d = 0.77$). There were no behavioural differences between the children with NF1 without ASD symptoms.

Conclusions: Over half of the participants with NF1 exhibited clinically significant symptoms of ASD. These children also performed poorer than controls on a false belief task, indicating difficulties with theory of mind that requires perspective-taking; the phenotypic behaviour of children with ASD. This study raises important clinical considerations regarding the co-occurrence of ASD traits and behaviours in children with NF1.

415.020 *(Poster)* Autistic Adults' Views of Their Own Social and Executive Functioning Do Not Correlate with Informants' Views of Them

S. C. Taylor[1]*,* ***B. N. Gehringer***[2]*, H. C. Dow*[2]*, A. Langer*[2]*, E. Rawot*[2]*, L. S. Perez*[2]*, A. A. Pallathra*[3]*, M. Grewal*[2]*, Z. L. Smernoff*[2]*, S. Steeman*[2]*, O. Eshraghi*[2]*, L. Almasy*[4]*, D. J. Rader*[4]*, M. Bucan*[4] *and E. S. Brodkin*[5]*, (1)Neuroscience Graduate Group, University of Pennsylvania, Philadelphia, PA, (2)University of Pennsylvania, Philadelphia, PA, (3)Department of Psychiatry, Catholic University of America, Washington, DC, (4)Department of Genetics, University of Pennsylvania, Philadelphia, PA, (5)Department of Psychiatry, University of Pennsylvania, Philadelphia, PA*

Background: There is growing recognition of the importance of including the perspectives of autistic individuals in autism research. Research has only begun to explore how autistic individuals' views of themselves differ from those of informants. Lerner et al. (2019) found that autistic youth reported less impairment on the Social Responsiveness Scale (SRS) Self Report than their parents reported on the informant SRS. Regarding executive functioning, there is evidence for discrepancy between self-report and informant Behavior Rating Inventory of Executive Functioning (BRIEF) scores in older adults and youth with impaired executive functioning (Rabin et al., 2006; Wilson et al., 2011). More data are needed to understand the relationship between autistic adults' views of themselves and informants' views of them.

Objectives: We sought to evaluate the degree of discrepancy between self and informant reports on core autism and autism-related traits in autistic adults and their family members.

Methods: Eighty-two autistic adults without intellectual disability (54 male, 28 female; aged 18 to 76 years) and 128 of their family members (52 male, 76 female; aged 18 to 81 years) were recruited via the Autism Spectrum Program of Excellence genetics study. For autistic adults, diagnosis was confirmed through detailed clinical and developmental history and DSM-5 criteria. All participants completed self-report versions of questionnaires measuring autistic traits (SRS-2-Adult) and executive functioning (BRIEF-Adult). Informant report versions of the same questionnaires were collected on each participant. Discrepancy scores were calculated by subtracting the self-report score from the informant score for the same questionnaire.

Results: Pearson correlation analyses showed that, among autistic adults, there was no significant association between the self-report and informant scores on the SRS-2-Adult (self-report range 48-90; informant range 39-92; $r = 0.08$, $p > 0.05$) and BRIEF-Adult (self-report range 40-92; informant range 41-84; $r = 0.09$, $p > 0.05$). In contrast, their family members showed a moderate to strong association between the self-report and informant scores for the SRS-2-Adult (self-report range 37-77; informant range 36-93; $r = 0.53$, $p < 0.001$) and BRIEF-Adult (self-report range 35-94; informant range 35-87; $r = 0.50$, $p < 0.001$). Hierarchical regression analyses for the SRS-2-Adult and the BRIEF-Adult showed that ASD status of the participant ($\beta = -0.27$, $p < 0.001$; $\beta = -0.27$, $p < 0.01$) affects the discrepancy score, while participant age, participant sex, relation of the informant to the participant, informant sex, and informant ASD status have no effect (see Table 1 and Table 2).

Conclusions: These results demonstrate, in adults with ASD, a discrepancy between self-report and informant scores on questionnaires measuring autistic behaviors and executive function, yet greater agreement among family members of autistic individuals. Discrepancy is driven by the ASD status of the participant and not by other tested characteristics of the participants or tested informant characteristics (including ASD status) of the informant. The inconsistency in discrepancy direction in the ASD group suggests that there are individual traits that drive the direction. Future research is needed to identify the specific traits that drive inconsistencies in self- vs. informant report.

415.021 *(Poster)* Autoscreen: Phase I Results of a Digital Tool for Clinically Efficient Assessment and Decision Making for Toddlers with ASD Concerns

J. W. Wade[1], *D. Adiani*[2], *M. Schmidt*[2], *P. Sultana*[2], *A. R. Swanson*[3], *A. S. Weitlauf*[4], *Q. Humberd*[5], *N. Sarkar*[6] *and Z. Warren*[3], *(1)Adaptive Technology Consulting, Murfreesboro, TN, (2)Adaptive Technology Consulting, LLC, Nashville, TN, (3)Vanderbilt University Medical Center, Nashville, TN, (4)Vanderbilt Kennedy Center, Vanderbilt University Medical Center, Nashville, TN, (5)Blanchfield Army Community Hospital, Fort Cambell, KY, (6)Mechanical Engineering; Electrical Engineering and Computer Science, Vanderbilt University, Nashville, TN*

Background: Early identification of Autism Spectrum Disorder (ASD) is essential for early intervention, which has been shown to improve lifespan outcomes. The American Academy of Pediatrics endorses ASD screening during well child visits at 18 and 24 months, but a wide range of challenges result in many children waiting until 4-5 years of age for a diagnosis. These challenges include limited screening in primary care and—where screening is available—low specificity of screening instruments, often resulting in long waitlists for access to specialty diagnostic services.

Objectives: In previous work, we developed Autoscreen: a digital ASD screening platform for pediatric providers that incorporates an interactive 15-minute assessment method and an embedded rating system. Autoscreen is the first tool of its kind to provide real-time guided instruction via a simple user interface along with a novel risk assessment algorithm derived from computational analysis of a large diagnostic dataset. The current work concerns the complete results of our Phase I pilot as well as recent technological enhancements based on iterative stakeholder interviews with more than 40 providers. Our three primary aims were: (1) to assess overall usability, (2) to assess preliminary instrument validity, and (3) to identify, through stakeholder interviews, means by which to enhance and improve the technology.

Methods: Participants included 42 children (ages 18-36 months) clinically referred for ASD evaluation. Forty-two pediatric providers representing a range of professional backgrounds (e.g., developmental-behavioral pediatricians; clinical psychologists) were recruited to conduct screening assessments using Autoscreen. A separate provider, blinded to the results of the Autoscreen assessment, were then asked to provide a "best estimate" clinical diagnosis (Yes/No ASD) for each child.

Results: Providers reported a mean System Usability Scale (SUS) index of 85.65 (SD = 10.8), which is regarded as "excellent" usability. Regarding preliminary instrument validity, compared to best estimate clinical diagnosis, Autoscreen demonstrated 80% accuracy with a sensitivity of 0.77 and specificity of 0.88. Over the course of more than 40 post-session interviews with providers, we identified a set of features that providers desired in a next iteration of Autoscreen. Specifically, providers wanted a simple means by which to log structured notes in Autoscreen; these notes could be used to log specific pieces of information relevant to a given activity (e.g., observed instances of response to name) and could be valuable when forming clinical impressions.

Conclusions: The results of our pilot study provide preliminary, but compelling, evidence that Autoscreen is a highly user-friendly digital platform for guided, interactive ASD screening. A larger clinical evaluation of Autoscreen is ongoing in order to demonstrate its validity, specifically its accuracy, sensitivity, specificity, test-retest reliability, and inter-rater reliability as compared to gold standard comprehensive evaluation.

415.022 *(Poster)* Calling Attention to Children Who Are Not Diagnosed with ASD Who Exhibit Social Difficulties, Excessive Interest in Specific Topics or Repetitive Behaviors

H. Nagar Shimoni*, Child Development, Marrot Autism Center/Ichilov Hospital, Tel Aviv, Israel*

Background: Troyb et al (2014) claimed that Restricted and repetitive behaviors (RRB's) persist among children who "grew out of Autism" . Harrop et al (2014) found that in both ASD and TD groups , a higher frequency of RRB's was associated with lower language abilities . Following these works, we describe a group of 38 boys who are not diagnosed with ASD, exhibit social difficulties , intact Social affect, excessive interest in specific topics or repetitive behaviors and linguistic difficulties.

Objectives: The aim of this presentation is to call attention to a unique clinical group of children who do not meet the critetia for ASD diagnosis but nevertheless needs further evaluation and treatment .

Methods: A cross sectional study that compared 40 children who were diagnosed with ASD to 38 children who were not diagnosed with ASD. All children were referred to an Autism clinic in a major children's hospital due to social difficulties . They were evaluated with ADOS-2 and DSM 5 by a team of neurologists, psychiatrists and psychologists . IQ ,age and gender were controlled.

Results: Three characteristics of this unique clinical group are described :

1) The group had significantly lower mean scores on the Social Affect Domain of the ADOS-2 (4.73; SD = 3.53) as compared to the mean of the group of children who were diagnosed as having ASD (8.54; SD = 4.41; F = 17.113; p = .000). (e.g., properly functioning non-verbal communication with the clinician such as eye, facial and hand expressions.)

2) High percentage of children who presented behaviors delineated in item D4 in ADOS-2: "Excessive interest in unusual or highly specific topics/objects or repetitive behaviors". 30.8% of the children who were diagnosed as having ASD presented behaviors delineated in item D4 in ADOS-2 as compared to 52.6% among the non-ASD group.

3) The children had various linguistic difficulties in the realms of naming and retrieval, and scanty vocabulary

60 percent

of the 38 children of the group were referred to a speech therapist at the end of the assessment for further assessment and treatment. This percentage is about six times higher than that of typically developing children referred to a speech therapist for a professional assessment .

Additional data characterizing the group relates to the following three background variables: Family status of parents; type of school (i.e. special vs. regular); and use of medication.

Conclusions: We propose that having RRBs with no impairment in social affect should be examined and studied to determine whether this clinical group described above represents a unique disorder. Tentatively, we suggest naming this disorder ISA-RRB to denote Intact Social Affect Repetitive Restricted Behaviors. Children who belong to the ISA-RRB group are characterized by an intact social affect and repetitive and restricted behaviors, excessive interest in unusual topics or objects, as evaluated by the ADOS-2.

The lecture will present further therapeutic interventions for this group .

415.023 *(Poster)* Can Autism Spectrum Disorder be Validly and Reliably Screened with Combination of a Short Caregiver Interview and Play Observation?; Behavior Development Screening for Toddlers (BeDevel)

Background: Early childhood screening for autism spectrum disorder (ASD) leads to timely referrals and diagnosis, which results in quicker access to interventions and improved long-term outcomes.

Objectives: To confirm the validity and reliability of new instruments for the screening of ASD, Behavior Development Screening for Toddlers (BeDevel) which utilizes the combination of short caregiver interviews and semi-structured observations in the large samples and to examine the most potent risk markers under 42 months.

Methods: We developed BeDevel, a new culturally relevant ASD screening instrument with high diagnostic predictive value that accounts for a range of characteristics. BeDevel is an early screening instrument that includes caregiver interviews (BeDevel-Interview: BeDevel-I) and semi-structured observations (BeDevel-Play: BeDevel-P) that can be administered by healthcare professionals specializing in ASD as well as paraprofessionals trained to work with young children. Both instruments cover five age ranges: 9~11, 12~17, 18~23, 24~35, and 36~42 months. The study included 621 toddlers (ASD, n=268; developmental delay, n=79; typically developing, n=274), aged 9~42 months without significant medical conditions, neurological disorders, sensory and/or motor deficits, which limit participating in activities needed for observations. For all participants, BeDevel-P and BeDevel-I were conducted along with the diagnostic procedures using ADOS, ADI-R, CARS, and VABS. The existing screening questionnaire, SCQ and SRS, were also implemented. We analyzed sensitivity, specificity, positive predictive value, and negative predictive value of the BeDevel Classification in relation to the clinical best estimate diagnosis that provides ASD/non-ASD classification. χ^2-test were used to analyze validity of individual items and *kappa* validation was used to check the consistency of diagnosis and screening result.

Results: A total of 613 toddlers (mean [SD] age=30.21[8.31] month; 65.7% male; 12-17 months, n=57; 18-23 months, n=87; 24-35 months, n=259; and 36-42 months, n=210) were included in the analysis. The *k* values of BeDevel-I and BeDevel-P items were .02~.64 and 0.12~0.67, respectively. Items related to social referencing in BeDevel-P had a particularly high diagnostic validity across age groups (*k*=.37~.62). Reliabilities of BeDevel-I and BeDevel-P were sufficient with the average Cronbach's α values of 0.874 (range=0.857~0.887) and 0.939 (range=0.919~0.953), respectively. Based on *k* values, items with a high degree of diagnostic consistency were selected as *primary items* and sensitivity, specificity, PPV, and NPV were identified accordingly. BeDevel-I and BeDevel-P showed high sensitivity (83.72~90.00%, 85.00~91.47%), specificity (84.15~86.99%, 82.19~94.03%), PPV (66.67~89.26%, 79.37~91.47%), and NPV (76.67~96.67%, 86.59~95.45%), respectively. The agreement between the composite BeDevel score and ADOS, ADI-R, K-CARS, and SCQ were all above 70% (range=71.1%~87.2%). The results showed that, items related to *Social Referencing* appear to be consistently high discriminant and the low validity of *Social Interest and Social Relationships* was contrasted with the high validity of *Interest in Peers* and *Levels of Play* in the older age group.

Conclusions: Combination of short interview with caregiver and direct observation is valid and reliable screening process, and more studies on social referencing as an important early marker is needed. BeDevel can be utilized as a secondary screening instrument before diagnostic confirmation in clinical and community settings possibly after primary screening with a caregiver-rated questionnaire.

415.024 *(Poster)* Caregiver-Examiner Consensus: Assessing the Relationship between Caregiver Report and Direct Assessment of ASD Symptomology in Toddlers

A. Rouhandeh[1], *N. Shanok*[2], *E. Brooker Lozott*[2], *M. Sotelo*[2], *J. Buxbaum*[3], *A. Kolevzon*[1], *S. De Rubeis*[4], *P. M. Siper*[1], *J. H. Foss-Feig*[1] *and C. Honsberger*[2], *(1)Seaver Autism Center, Department of Psychiatry, Icahn School of Medicine at Mount Sinai Hospital, New York, NY, (2)Els for Autism Foundation, Jupiter, FL, (3)Department of Psychiatry, Icahn School of Medicine at Mount Sinai, New York, NY, (4)Seaver Autism Center for Research and Treatment, Icahn School of Medicine at Mount Sinai, New York, NY*

Background: The Modified Checklist for Autism in Toddlers - Revised (M-CHAT-R, Robbins, Fein, & Barton, 2009) is widely used as a caregiver-reported screening tool for autism spectrum disorder (ASD) and has demonstrated sensitivity in identifying children for further evaluation for developmental delays/disorders including ASD (Kleinman, et al., 2008; Toh, et al., 2018). The M-CHAT uses total score to indicate risk-status and referrals, however, research has not thoroughly explored the accuracy of reporting on specific items, which assess subtle social communication behaviors that are critical to the determination of high-risk status as well as to eventual ASD diagnosis. The Autism Diagnostic Observation Schedule, Second Edition (ADOS-2) is a gold-standard ASD diagnostic tool that is clinician administered and evaluates many of the same early indicators that appear on the M-CHAT. Examining the consistency between caregiver reported symptoms and the observations of trained examiners may clarify the extent to which caregivers accurately report the presence of critical social communication deficits without the requisite training.

Objectives: To assess the relationship between caregiver responses on the M-CHAT and examiner ratings on the ADOS-2 regarding social communication behaviors including pointing, eye contact, response to name, showing, and initiating and responding to joint attention.

Methods: Data were collected from six toddlers between the ages of 18-36 months (*m*=28.3 months, *SD*=6.3; 2 females) anticipating enrollment into an early intervention study. The M-CHAT was administered to the caregiver during a screening visit and the ADOS-2 (Module 1 and Toddler Module) was administered at each child's first visit. The research team selected individual items from the M-CHAT and ADOS-2 that a) reflected core basic social communication behaviors, and b) had corresponding items on both measures. Spearman's rank correlations were calculated between individual M-CHAT and ADOS-2 items capturing pointing, response to name, response to/initiation of joint attention, showing, and eye gaze.

Results: Correlations between caregiver responses on the M-CHAT and examiner scores on the ADOS-2 were strong across social communication behaviors. Caregiver ratings of pointing to ask for help (M-CHAT question 6) as well as pointing to show something interesting (M-CHAT question 7) were both strongly correlated with pointing on the ADOS-2 (r_s= -.95, *p*=.01, r_s=-.71, *p*=.12, respectively). Caregiver reported response to name (M-CHAT question 10) was significantly correlated with performance on the ADOS-2 response to name task (r_s=-.89, *p*=.02). There was also a strong correlation for reporting (M-CHAT question 1) and observation of response to joint attention (r_s=-.89, *p*=.02). There was a moderate correlation for showing (r_s= -.42, *p*=.41). M-CHAT and ADOS-2 scores were not strongly correlated for eye gaze and initiation of joint attention.

Conclusions: Parent ratings on the M-CHAT and examiner scores on the ADOS-2 were significantly correlated across multiple domains, suggesting that parents are able to accurately detect and report early and subtle ASD symptomology including pointing and response to name. Continued data collection is underway to examine these relationships in a larger sample and with additional measures. Future studies aim to identify which caregiver report items may require additional clarification when administered.

415.025 *(Poster)* Childhood Autism Rating Scale (CARS) Factor Scores Vs. Total Score for Predicting Longitudinal Outcomes in Children with ASD

P. Towle[1] *and N. Turygin*[2]*, (1)Westchester Institute for Human Development, Valhalla, NY, (2)Behavioral Psychology, Westchester Institute for Human Development, Valhalla, NY*

Background: The Childhood Autism Rating Scale (CARS) is a widely used tool to assess autism symptom severity in both clinical and research settings, but it has been criticized for combining items from different domains of symptoms. Having only an omnibus score is inconsistent with DSM-IV and -5 criteria structure as well as gold standard measurements that differentiate, at the least, social communication (SC) from restricted and repetitive behavior (RRB) domains. Recently Moulton et al. (2016) published a factor analysis study using CARS scores from young children with ASD, suggesting three factors of Social Communication, Stereotyped Behaviors, and Emotional Regulation. No studies to date, however, have examined subscales based on CARS factor scores for prediction and validity purposes. This study applies such scores within a longitudinal study of children with ASD followed from toddlerhood to school age to determine their predictive validity and if they offer more precise information than the total CARS scores.

Objectives: To examine ifCARS Total and CARS factor scores are differentially predictive of 1) concurrent adaptive behavior scores at Time 1 (before age 3 years), and 2) with adaptive behavior and autism symptom scores at Time 2 (school age).

Methods: This was a longitudinal study that followed children diagnosed with ASD before age 3. 51 children had CARS and Vineland scores at Time 1 (M_{age}=28.5 mos, SD=2.8 mos, 75% male,) and 29 had Vineland and GARS at Time 2. Instruments. *Childhood Autism Rating Scales*represented autism symptom severity at Time 1. Based on the factors generated by Moulton et al. (2016), three subscales were created: Social Communication (SC), Stereotyped Behaviors and Sensory Sensitivities (RRBs) and Emotional Reactivity (ER). Adaptive behavior at Time 1 and 2 was measured with the *Vineland Adaptive Behavior Scale (VABS-2).*Autism severity at school age was measured using the parent-rated *Gilliam Autism Rating Scale (GARS-3).*Procedure. Time 1 CARS and VABS scores were recorded from early intervention charts containing multidisciplinary evaluation reports. Time 2 VABS was completed through phone interview with caregivers, andparents completed the GARS as part of a questionnaire-by-mail follow-up study. Data analysis. Pearson correlations and Steiger's Z-test for significance between non-independent correlation coefficients were employed.

Results: Between Time 1 CARS Total and CARS subscales and concurrent Time 1 VABS domains, few differences occurred except for the ER subscale, which showed no significant relationships to the VABS domains scores, whereas others tended to correlate, often significantly. This was also the case for Time 2 GARS. In contrast, a number of CARS subscale scores were highly significantly correlated with Time 2 VABs domains and ABC scores *and* there were significant differences in magnitude between CARS Total and the various CARS subscales, depending on the VABS domain score. Of particular note was the predictive value of the CARS Hyperactivity item on its own (ranging from -.57 to -.65).

Conclusions: CARS subscales appear to provide additional information over the Total score alone, depending on the criterion being examined. The predictive value of the CARS Hyperactivity item during early childhood was particularly striking.

415.026 *(Poster)* Clinical Assessment of Repetitive and Restricted Behaviors in Toddlers on the Autism Spectrum

K. S. Porto[1]*, M. Barton*[1]*, J. Burke*[1]*, D. A. Fein*[1] *and D. L. Robins*[2]*, (1)Psychological Sciences, University of Connecticut, Storrs, CT, (2)A.J. Drexel Autism Institute, Drexel University, Philadelphia, PA*

Background: Repetitive and restricted behaviors (RRBs) are core symptoms of ASD and often emerge in the first year of life. Despite early onset, parents cite RRB concerns far less often than language and social concerns when presenting for diagnostic evaluation (Herlihy et al., 2015). Given low rates of reporting and the importance of accurate, complete information for clinical diagnosis, it is important to understand how best to integrate diagnostically relevant information from multiple methods of assessment in clinical settings. Few studies have directly compared the utility of multiple methods to assess RRBs for facilitating diagnosis.

Objectives: Characterize the association between parent report and clinical observation of RRBs in order to determine the utility of each method for eliciting information on RRBs in toddlers at the time of initial diagnosis.

Methods: Participants were 65 children ages 18-39 months diagnosed with ASD. Associations between a parent report rating scale (Repetitive Behavior Scale Revised (RBS-R)), clinician-driven parent interview (Toddler Autism Symptom Inventory (TASI)) and clinician observation (Autism Diagnostic Observation Schedule (ADOS)) were determined using Kendall's tau-b and point biserial correlations where appropriate. Correlations were run for each of six behavioral subdomains: (1) sensory (2) hand and finger stereotypy (3) whole body stereotypy (4) combined stereotypy (5) self-injurious behavior (SIB) and (6) repetitive behavior. Non-significant correlations were further investigated using incidence of behavior on each measure.

Results: Parent report on the RBS-R and TASI were correlated in all domains, except sensory behaviors (Table 1), indicating good association between the rating scale and clinical interview. Sensory behaviors were reported on the RBS-R in 65% of cases compared to 48% on the TASI. The ADOS was not correlated with either the TASI or RBS-R in any domain except hand and finger stereotypy. In the domains of repetitive behavior, whole body stereotypy, and SIB, behaviors were reported more frequently on parent report measures compared to clinician observation (Table 2). The reverse was true for sensory behaviors; clinicians indicated more sensory behaviors on the ADOS (77%) compared to either parent report measure.

Conclusions: In most behavioral subdomains, parent report of RRBs on a behavioral rating scale and clinical interview were consistent. The method of assessment did not impact parent report. Clinical observation on the ADOS revealed fewer RRBs than parent report in four of six subdomains and comparable report on one subdomain. Differences may be due to the brief observation window or the introduction of novel toys. Notably, none of the measures were correlated for sensory behaviors. Clinicians reported more atypical sensory behaviors on the ADOS, followed by parent report on the RBS-R and TASI. Overall, parent report offers valuable information on RRBs that go beyond what is typically observed by clinicians in an evaluation. However, clinical observation appears to be particularly important for identifying sensory behaviors. Sensory behaviors may be difficult for parents to identify or discriminate as atypical, particularly in young children. Results indicate that both parent report and observation contribute to a more complete representation of RRBs and should be included in diagnostic assessment.

415.027 *(Poster)* Clinical Implications of Ratings By Parents and Preschool Staff: Introducing a Multi-Informant Model for Diagnostic Assessment

E. Nilsson Jobs[1]*, T. Falck-Ytter*[2] *and S. Bolte*[3]*, (1)Karolinska Institute, Stockholm, Sweden, (2)Karolinska Institutet & Uppsala University, Uppsala, Sweden, (3)Center of Neurodevelopmental Disorders (KIND), Centre for Psychiatry Research; Department of Women's and Children's Health, Karolinska Institutet, & Stockholm Health Care Services, Region Stockholm, Stockholm, Sweden*

Background: Autistic symptoms should be present in multiple contexts to meet the DSM-5 criteria for autism spectrum disorder (ASD). In the diagnostic assessment of young children this condition can be hard to fulfil if the clinician find significant autistic symptoms in the clinical context but parents do not in the home context. In these cases, autistic behaviors could be evaluated by preschool staff in the preschool setting. In a recent high-risk-for-ASD-sibling-study regression analyses showed that preschool staff rated general autistic symptoms more in line with both diagnosis and clinically assessed autistic behaviors than parents. However, we know little about how to approach multi-informant report in the diagnostic process.

Objectives: To present a multi-informant model to be used in diagnostic clinical practice and to investigate the value of adding preschool report to the assessment of ASD.

Methods: Results for a high-risk sibling group with and without ASD were analysed at 36 months based on 10 participants (five girls) with ASD diagnosis and 32 (18 girls) participants with no diagnosis. All but one child in the ASD group had IQ within normal ranges.The pervasive developmental problem subscale from the Child Behavior Checklist 1,5-5 and the Caregiver Teacher Report Form (Achenbach and Rescorla 2000, 2004) were filled in by parents and preschool staff, blind to the result of the diagnostic assessment. Sensitivity and specificity were calculated in relation to diagnosis with cut-off at T- score ≥ 65 indicating significant autistic symptoms. In the model parent report was considered first and preschool report second as is common in clinical practice. In the model at least one informant should be in agreement with clinical observation of autistic symptoms in order to fulfill the criteria of symptoms present in multiple contexts. Support for no significant autistic behaviors was also evaluated requiring at least one informant to rate in agreement with clinical observation to rule out ASD.

Results: By including report on autistic behaviors from preschool staff, true positive rate (sensitivity) increased from 50% to 70%. True negative rate (specificity) increased from 91% to 97% when considering negative ratings of autistic symptoms by preschool.

Conclusions: Ratings by preschool staff complementary to parent report add support for clinical findings of significant autistic behaviors. In future studies the model should be applied to larger clinical samples with ASD and other neurodevelopmental disorders.

415.028 *(Poster)* Common M-CHAT-R/F Endorsement Patterns Among Children Who Screen Negative for Autism Spectrum Disorder

S. M. Attar[1]*, C. C. Dick*[2]*, H. Neiderman*[2]*, T. DesChamps*[2]*, L. V. Ibanez*[3] *and W. L. Stone*[2]*, (1)University of Washington, Seattle, WA, (2)Psychology, University of Washington, Seattle, WA, (3)UW READi Lab, Seattle, WA*

Background: Screening for Autism Spectrum Disorder (ASD) improves long-term child and family outcomes via early diagnosis and intervention (Zwaigenbaum et al., 2015). The most commonly used screening measure, the Modified Checklist for Autism in Toddlers–Revised with Follow-up (M-CHAT-R/F; Robins et al., 2014), is a well-validated, open-source 20-item parent checklist, and includes a follow-up interview when there is an initial score between 3 and 7. A positive screen for ASD risk is associated with an earlier ASD diagnosis by 7.5 months to 2 years (Guthrie et al., 2019; Robins et al., 2014). However, studies suggest that the M-CHAT-R/F has significant shortcomings in its predictive validity. A recent longitudinal study assessing universal screening in a large sample (n=21,543) revealed that the M-CHAT-R/F missed 60% of children who later received an ASD diagnosis (Guthrie et al., 2019). Considering that the M-CHAT-R/F is widely used and that a positive screen decreases the ASD detection to treatment pipeline, it is important to better understand the patterns of endorsement for children who pass the initial stage of the M-CHAT-R/F, but may be at-risk nonetheless.

Objectives: To characterize the patterns of M-CHAT-R/F endorsed items for children who receive a score one point below the cut-off for the follow up interview (i.e., a total score of 2).

Methods: A digital version of the M-CHAT-R/F (webM-CHAT-R/F) was developed for use by primary care providers in traditionally underserved communities. The webM-CHAT-R/F uses REDCap (Harris et al., 2009) and a tablet interface to digitally present the initial 20 items and automatically trigger the follow-up questions when appropriate. Sixty-one primary care providers (PCPs) participating in a statewide research project designed to expedite access to ASD-specialized services administered 6,143 webM-CHAT-R/F records at 18- and 24-month well-child visits over a 32-month period. The R statistical program was used to identify common response patterns using flat contingency tables.

Results: The mean child age at screening was 21.80 months (SD = 3.96). Tables 1 and 2 present summary statistics on the webM-CHAT-R/F scores and the most frequent endorsement patterns. For the group with 2 failed items (n=602), 190 possible endorsement patterns exist; however, a majority of responses (69.93%) fall into 13 endorsement patterns, each with a minimum of 10 respondents. The modal endorsement pattern, which occurred in 211 (35%) screens, had two failed restricted and repetitive behavior (RRBs) items out of a total of three possible RRB items. Nine prevalent patterns represented a combination of a failed social communication item and an RRB item. Three prevalent patterns included two failed items in the social communication domain.

Conclusions: Our results suggest that there are common endorsement patterns on M-CHAT-R/F screens that yield a total score 1 point below the cut-off to receive the follow-up interview (i.e. an initial screen negative). These endorsement patterns fall into a minority of possible 2-item response patterns. The most common screen negative pattern included two items from the RRB domain. Further study of item content and failure patterns, especially if diagnostic outcome is available, may improve the screening properties of the M-CHAT-R/F.

415.029 *(Poster)* Comparing the Clinical Utility of the ADOS-2 in a Children with Psychiatric Disorders in Both and Inpatient and Outpatient Setting.

J. Palilla[1]*, M. Norris*[2] *and M. Wojnaroski*[3]*, (1)Nationwide Children's Hospital, Columbus, OH, (2)Child Development Center, Nationwide Children's Hospital, Westerville, OH, (3)Nationwide Children's Hospital, Westerville, OH*

Background: The ADOS-2 is widely used for the assessment of Autism Spectrum Disorder (ASD) but there is little information regarding its clinical utility for those with significant psychiatric concerns. As comorbid mental health conditions occur at higher levels in those with ASD than the general population (e.g., Hudson et al., 2019) and accurate diagnosis is essential for accessing appropriate intervention, having better understanding of how instruments perform in complex populations is of significant interest. One recent study (Colombi, Fish, and Ghaziuddin, 2019) examined the sensitivity and specificity of the ADOS-2 in an inpatient psychiatric setting (N=58) and found underwhelming values. Little additional research has been conducted in this area, particularly with children and adolescents.

Objectives: To examine the utility of the ADOS-2 for children and adolescents with complex presenting conditions, specifically those with psychiatric conditions such as psychosis, mood disorders, and/or disruptive behavior disorders, in both inpatient and outpatient settings.

Methods: The sample includes two groups. The first group (n=79) is comprised of children and adolescents receiving a targeted ASD evaluation while hospitalized in an inpatient psychiatric unit housed within a large children's hospital between 2014 and 2019. Assessment on the unit was conducted as part of a consultation/liaison (C/L) service requested by inpatient staff, and typically included administration of the ADOS-2 as well as comprehensive review of the medical record, and when possible, a thorough caregiver interview and the administration of rating scales. The second group is comprised of children and adolescents presenting to an outpatient clinic for ASD-specific assessment (n=500). Assessments in this setting were completed over two days, by an interdisciplinary team and included a range of assessments which included the ADOS. For both groups, the children and/or adolescents had presenting concerns of psychosis, mood disorder, and/or disruptive behavior. All of the children and/or adolescents were administered the Module 3 or Module 4 of the ADOS-2.

Results: Of the inpatient sample, over 50% individuals received an ASD diagnosis. In other cases, ASD was ruled out, or the patient was referred for additional assessment at the outpatient clinic. Additional analyses will further compare use of the ADOS-2 and autism diagnosis in a psychiatric inpatient setting with more traditional outpatient assessments in a similarly complex population. Sensitivity and specificity calculations will be conducted with the available data for each module and setting.

Conclusions: In the inpatient sample, we anticipate similar results as found by Columbi et al. It is notable that the majority of the patients referred for evaluation on the inpatient psychiatric unit receive an ASD diagnosis. Even with increased recognition, many children with ASD do not receive a diagnosis early in the developmental period, possibly placing them at higher risk for mental health conditions, lack of access to intervention services, and unmet needs.

415.030 *(Poster)* Comparison of Adaptive Behavior Profiles between Children with Autism and Children with Down Syndrome and Comorbid Autism Symptoms

R. K. Ramsey*, R. Kirchner and K. M. Walton, Nisonger Center, The Ohio State University, Columbus, OH*

Background: The rate of comorbidity between autism spectrum disorder (ASD) and Down syndrome (DS) is 5-39% (Reilly, 2009), making it important to understand how their co-occurrence might impact adaptive behavior. Research suggests that children with DS and ASD have more impaired adaptive functioning than children with DS only (Molloy et al., 2009), but no comparisons have been made to children with ASD only. Furthermore, little is known about adaptive behavior profile differences based on autism symptom severity in children with DS.

Objectives: The current study analyzes whether adaptive behavior profiles differ between children with DS and low autism symptom severity (low ASD-DS), children with DS and high autism symptom severity (high ASD-DS), and children with ASD only.

Methods: Parents of children with ASD and/or DS between 6-18 years of age completed an online survey. The sample included 76 children with DS (M_{age}=11.88 years, *SD*=3.28) and 39 children with ASD (M_{age}=11.96 years *SD*=3.61). Diagnostic and demographic information, as well as the Social Communication Questionnaire (SCQ), the Autism Spectrum Rating Scales (ASRS), and the Adaptive Behavior Assessment System, third edition (ABAS-3) were collected for each child. Based on SCQ screen positive cut off scores, children with DS were divided into high ASD-DS (n=17) and low-ASD-DS (n=59) groups, which corresponded with high and low autism symptom severity on the ASRS. Adaptive behavior profiles based on the ABAS-3 were compared across the high and low ASD-DS groups and the ASD only group.

Results: Analyses revealed a significant difference between the high ASD-DS, low ASD-DS, and ASD only groups across the Conceptual, Social, and Practical domains on the ABAS-3 (*p*'s<.001). The high ASD-DS group had significantly more weaknesses in the Conceptual and Practical domains compared to the low ASD-DS and the ASD only groups (*p*'s<.001), who did not significantly differ from each other on those two domains. For the Social domain, children in the low ASD-DS group displayed better social functioning compared to children in the high ASD-DS group and children in the ASD only group (*p*<.001), suggesting similar impairments in social skills between those two groups. Overall adaptive functioning as measured by the ABAS-3 General Adaptive Composite score was more impaired in children in the high ASD-DS group compared to the other two groups (*p*'s<.001).

Conclusions: Overall, children with DS and high autism symptom severity tend to be more impaired in their adaptive functioning compared to those with ASD only or DS and low autism symptom severity. The relative strengths in social skills typically observed in children with DS appear to be affected by more severe autism symptoms, as these children have similar social impairments to children with ASD only. While social impairments are similar to children with ASD, impairments in the Conceptual and Practical domains appear to be magnified in children with DS and severe autism symptoms. Understanding how autism symptom severity and DS interact can help inform diagnostic practices to avoid diagnostic overshadowing of ASD in DS, as well as help create more targeted inventions for each unique adaptive behavior profile.

415.031 *(Poster)* Comparison of Social Communication Deficits and Restricted Repetitive Behaviours in Children with ADHD and Children with ASD

J. Lim[1]*, E. Anagnostou*[2] *and J. Collins*[3]*, (1)Holland Bloorview, Toronto, ON, Canada, (2)Holland Bloorview Kids Rehabilitation Hospital, Toronto, ON, Canada, (3)Independent Statistician, Toronto, ON, Canada*

Background: There is a growing awareness of the overlap in symptomatology of Attention Deficit Hyperactive Disorder (ADHD) and Autism Spectrum Disorder (ASD) which were once seen to be distinct. While social communication deficits are not a core diagnostic feature of ADHD, these deficits have frequently been reported in these children. Other features such as difficulties with emotional regulation, attention, and sensory sensitivities have also been reported in both conditions. This research looks at the similarities and differences in the social communication deficits and repetitive, restricted behaviours in children with ADHD and children with ASD, comparing across different measures.

Objectives:

- To compare the Social Communication Questionnaire (SCQ) scores of the children who are diagnosed with ADHD vs those with ASD vs typically developing (TD)
- To determine if there a subset of children diagnosed with ADHD who behave more like those diagnosed with ASD
- To compare the social communication deficits between children with ADHD and children with ASD across different measures
- To compare the repetitive and restricted behaviours and interests between children with ADHD and children with ASD across different measures

Methods: SCQ, Child Behaviour Checklist (CBCL), and Repetitive Behaviour Scale – Revised (RBS-R) scores from the Province of Ontario Neurodevelopmental Network (POND) data were analyzed using Analysis of Variance (ANOVA) and logistic regression model, with gender and age controlled, across those who have a primary diagnosis of ASD, ADHD, and those who are typically developing.

The SCQ is a screening measure for symptoms associated with autism spectrum disorder. The CBCL is a screening measure for internalizing and externalizing behaviours of a child (preschool and school-age), which includes measures of social deficits.

Results: Preliminary results reveal that, as expected, SCQ scores (n= 1,688) of those diagnosed with ASD (n=817) are significantly higher than those who are diagnosed with ADHD (n=648), and both of these groups have scores that are higher than those who are typically developing ($p<2X10^{-16}$; F=936; df=2). However, there were children diagnosed with ADHD who scored as high as those diagnosed with ASD, on both SCQ and CBCL. Subgroup analyses of domains across groups with SCQ scores greater or equal to 9 and 11 show similar communication deficits between ASD and ADHD groups but no repetitive behaviours in ADHD group. SCQ scores of 15 and greater across groups show children with ADHD having similar social communication deficits and restricted, repetitive behaviours as those diagnosed with ASD.

Analyses of the CBCL social communication subdomains (T-score equal or greater than 65 and 70) reveal similar results.

Conclusions: Almost 40% of children with ADHD present with social communication deficits. Children with ADHD, with SCQ scores in the range of 9-14, show a pattern of social communication deficits consistent with social communication disorder. Children with ADHD, with SCQ scores of 15 or greater, have both social communication deficits and restricted, repetitive behaviour patterns that are presenting more similar to children with ASD.

415.032 *(Poster)* Comparison of a Video-Based ASD Screening Tool in Infancy across High-Risk and Community Samples

C. Parikh*, G. S. Young and S. Ozonoff, Psychiatry and Behavioral Sciences, University of California at Davis, MIND Institute, Sacramento, CA*

Background: There are multiple ASD screening tools available, but few were developed for use in the first year of life. Although feasible for large-scale screening, written questionnaires rely on subjective interpretation and parental knowledge of developmental milestones, which may be challenging in infancy. We developed the Video-referenced Infant Rating System for Autism (VIRSA), an online screening measure that depicts a range of social-communication ability in infants 6-24 months of age, relying solely on video without written descriptions of behaviors. It has been demonstrated that the VIRSA can detect ASD in infancy when used by parents who already have a child with ASD (Young et al., 2019). This pilot examined whether the VIRSA would also be useful in a large community sample, when rated by parents without familiarity with ASD.

Objectives: 1) compare VIRSA usage metrics (time to completion, trial duration, etc.) and scores in infancy across two independent prospective samples representing different recruitment strategies, and 2) examine if the VIRSA detects ASD within both samples.

Methods: Parents of infants without a family history of ASD in the Community sample completed the VIRSA and the Modified Checklist for Autism in Toddlers (M-CHAT-R) online at 6, 9, 12, 18, and 24 months. Any child screening positive on the M-CHAT-R was seen for a diagnostic evaluation (n = 3 diagnosed with ASD). In the Infant Sibling sample (Young et al., 2019), parents of infants with and without a family history of ASD completed the VIRSA online at similar ages and were also directly assessed from 6 through 36 months (n = 21 with ASD diagnosis).

Results: There were no significant differences found in VIRSA usage metrics between the Community and Infant Sibling samples (Table 1). There were also no group differences in VIRSA scores at most ages (9 months: t = -.71; 12 months: t = .14; 18 months: t = .47; all ps > .05). At 6 months, VIRSA scores of the samples were significantly different (t = -2.18, p = .03). The VIRSA distinguished ASD, as evidenced by the ASD group having significantly lower scores than the non-ASD group, in both samples (Table 2). VIRSA scores of the ASD subgroup in the Community sample were lower than those in the Infant Sibling sample, at most ages, but this was only statistically significant at 9 months (t = 4.52, p < .01), likely due to the small size of the Community sample (6 months: t = 1.59; 12 months t = .91; 18 months t = 2.08; all ps > .05).

Conclusions: VIRSA is operating similarly when used by parents without a family history of ASD as it did in high-risk families (Young et al., 2019). The ASD subgroup differences found between the Community and Infant Sibling samples are likely driven by random variation in the proportion of infants presenting with early symptoms. In the future, as sample size increases and all participants reach 36 months, we will calculate VIRSA's psychometric properties (i.e. sensitivity, specificity, positive and negative predictive values).

415.033 *(Poster)* Computational Phenotyping Detects Atypical Patterns of Facial Expression in Toddlers with Autism Spectrum Disorder

K. L. Carpenter[1], *J. Hashemi*[2], *K. Campbell*[3,4], *S. J. Lippmann*[5], *S. Espinosa*[2], *G. Sapiro*[2] *and G. Dawson*[6], *(1)Duke Center for Autism and Brain Development, Department of Psychiatry and Behavioral Sciences, Duke University, Durham, NC, (2)Department of Electrical and Computer Engineering, Duke University, Durham, NC, (3)Duke Center for Autism and Brain Development, Durham, NC, (4)University of Utah, Salt Lake City, UT, (5)Duke University, Durham, NC, (6)Department of Psychiatry and Behavioral Sciences, Duke Center for Autism and Brain Development, Durham, NC*

Background: Despite progress in early screening for autism spectrum disorder (ASD), commonly-used screening tools continue to rely on caregiver questionnaires and clinician observations. Reliable behavioral observation is expensive, time consuming, and requires significant expertise. As such, there remains a critical need to develop scalable, quantitative, and reliable assessment methods that can characterize ASD symptoms and identify those children who are most in need of follow-up by an ASD specialist. In an effort to address this need, we have embarked on a program of research using strategically-designed brief movies shown on ubiquitous devices combined with computer vision analysis (CVA) of recorded behavior to assess early symptoms of ASD.

Objectives: This study assessed the utility of a scalable and objective tablet-based behavioral assessment for eliciting and detecting reduced emotional expression or flat affect, one of the earliest emerging risk signs for ASD, and evaluated whether patterns of facial expression differentiate toddlers with and without autism.

Methods: Participants were 104 children between 16–31 months of age, 22 of which met criteria for ASD based on the Autism Diagnostic Observation Schedule. The mean (SD) age of children was 22 (3.8) months in the non-ASD group and 26.2 (4.1) months in the ASD group with a higher proportion of males in the ASD group (17 males, 5 females vs. 48 males, 34 females). A portable tablet displayed carefully-designed brief movies and used the camera embedded in the tablet to record child responses which were automatically coded with CVA. The movies were designed to capture children's attention, elicit affective responses to novel and interesting events, and assess the ability of the toddler to sustain their attention to the movies and share attention with others. Movies consisted of cascading bubbles, a mechanical bunny, animal puppets interacting with each other, and a split screen showing a woman singing nursery rhymes on one side and dynamic noise-making toys on the other. Based on video recordings of elicited behavioral responses, CVA automatically detected and tracked facial landmarks which were used to estimate head position and facial expressions (Positive, Neutral/no active facial action units, and Other expressions).

Results: Using CVA, we identified certain points throughout the movies in which we were able to differentiate between children with and without ASD based on their patterns of facial expressions. During these instances, children with ASD more frequently displayed Neutral expressions compared to children without ASD, who showed a range of other expressions ("Other" category). Using ROC curves for each video, we demonstrate reliable differentiation of children with ASD from non-ASD children (AUCs for individual movies ranging from .62-.73). Detailed analysis indicated that this was driven by non-ASD children more frequently displaying raised eyebrows and an open mouth, an expression characteristic of engaged/interested looking.

Conclusions: These results suggest that computational coding of facial expressions via a tablet-based assessment involving symptom-eliciting movies can detect one of the early, core symptoms of ASD, namely, reduced affective expression. Computational phenotyping of elicited behaviors may offer a scalable objective method of early autism symptom detection.

415.034 *(Poster)* Concurrent and Predictive Validity of Language and Communication Assessments in Infancy

O. Boorom[1], *S. Camarata*[2], *M. Watson*[1], *V. A. Munoz*[1], *T. Liu*[1] *and M. D. Lense*[1], *(1)Vanderbilt University Medical Center, Nashville, TN, (2)Hearing & Speech Sciences; Psychiatry & Behavioral Sciences, Vanderbilt University Medical Center, Nashville, TN*

Background: Valid and reliable assessment of language and communication skills is a critical component of early ASD assessment and characterization. A variety of standardized measures are used across research and clinical settings to assess these domains including measures reliant on clinician administered assessments, parent interviews, and/or parent questionnaires. Some assessments focus on specific components of communication (e.g., vocabulary) while others assess broader ranges of communication skills. While these measures are generally thought to tap into overlapping constructs of communication, the concurrent and predictive validity of these assessment measures at young ages has not been thoroughly examined. This information is needed to inform interpretation of assessment results in infants/toddlers with implications for improving study design as well as assessment and diagnostic practices for children under two years.

Objectives: To examine the concurrent and predictive validity among assessments of early language in infants, specifically among the MacArthur Bates Communication Development Inventory, Second Edition (CDI; Fenson et al., 2007), the Mullen Scales of Early Learning (MSEL; Mullen, 1995) the Preschool Language Scales, Fifth Edition (PLS-5; Zimmerman et al., 2011), and the Vineland Adaptive Behavior Scales, Third Edition (VABS-III; Sparrow et al., 2016).

Methods: Infants at low or high risk for ASD based on diagnostic status of their older sibling were recruited as part of a longitudinal study on language and social development (current n=58, 27 girls; anticipated n=70). Participants were seen at 9-months, 12-months, and 18-months of age and were administered the MSEL (direct assessment), CDI (parent questionnaire), PLS-5 (assessment/parent interview), and VABS-III (parent interview) at one or all of these time points as part of comprehensive evaluations. Relationships across measures and ages were examined separately for expressive language (EL) and receptive language (RL) skills.

Results: In regard to concurrent validity, preliminary results indicate generally moderate to strong significant correlations among expressive language measures at 9, 12, and 18-months of age as measured in age equivalents ($r's \geq 0.472$, $p's \leq 0.039$). Relationships among receptive language measures were weaker and more inconsistent. In regard to predictive validity, for expressive language, there were generally moderate to strong correlations within a given standardized measure (e.g., MSEL EL scores at 9 and 18-months of age: $r=0.524$, $p = 0.045$) and across standardized measures (e.g., 9-month PLS-5 and 18-month Vineland EL scores: $r = 0.499$, $p = 0.041$). Across timepoints, correlations between receptive language measures were less consistent.

Conclusions: Expressive language measures at 9, 12, and 18 months show stronger and more consistent concurrent and predictive validity than measures of receptive language at these age points, which may highlight the difficulty in accurately capturing receptive abilities at very young ages. Follow-up analyses will compare developmental trajectories across measures and also explore whether the nature and/or magnitude of the concurrent and predictive relationships is moderated by infant risk status. Implications for selecting and interpreting measures for assessment of language skills in infancy will be discussed.

415.035 *(Poster)* Consolidating Clinical Pathways for Screening of Attention Deficit / Hyperactivity Disorder (ADHD), Anxiety and Irritability in Children and Adolescents with Autism Spectrum Disorder (ASD)

D. L. Coury[1], *J. S. Anixt*[2], *D. A. Iannuzzi*[3], *A. Fedele*[4] *and D. S. Murray*[5], *(1)Nationwide Children's Hospital, Columbus, OH, (2)Division of Developmental & Behavioral Pediatrics, Cincinnati Children's Hospital Medical Center, Cincinnati, OH, (3)125 Nashua Street, MassGeneral Hospital, Boston, MA, (4)Autism Speaks, Mullica Hill, NJ, (5)Autism Speaks, Boston, MA*

Background: The Autism Learning Health Network (ALHN), which includes 12 autism specialty care centers committed to improving care and outcomes for children with ASD, has been identifying co-occurring behavioral and medical issues in children with ASD using clinical practice pathways previously developed by the Autism Intervention Network on Physical Health (AIR-P), and the Autism Treatment Network (ATN). They developed clinical pathways for treating co-occurring conditions in individuals diagnosed with ASD related to ADHD (published in 2012), Anxiety (published in 2016), and Irritability (published in 2016). Over time, clinicians reported the clinical treatment pathways were useful but there was no clear guidance for identifying those patients who should follow the pathways. Clinicians requested help in achieving desired screening goals. Given the high prevalence of challenging behaviors in children enrolled in ALHN (94% by parent report), especially in the areas of ADHD (63%), anxiety (47%), and irritability (54%), our network prioritized the development of a consolidated reliable screening tool by merging all 3 pathways into one.

Objectives: To encourage reliable screening of commonly occurring behavioral health conditions in children and adolescents with ASD receiving care at Autism Learning Health Network (ALHN) sites.

Methods: Learning Labs (LL), or workgroups, were convened for each of the 3 priority behavioral symptom domains (ADHD, anxiety and irritability). LL members met weekly to biweekly using an online video meeting platform. A literature review was also conducted of the evidence regarding the diagnosis and treatment for each condition individually. Identification of commonalities in the initial phases of screening for these conditions were discussed on line and in an in-person meeting with all 3 learning labs combined, which led to both refinements in each practice pathway and the development of a new consolidated screening approach to identifying all 3 concerns.

Results: Commonalities were found as we developed clinical pathways to screen for anxiety, irritability, and ADHD. The LL members concluded the importance of the need for a single screening pathway to capture overlapping or co-occurring behavioral health conditions. A consolidated approach was developed that guides clinicians to assess for not only the priority behavioral health conditions but also increases identification of medical concerns and psychosocial stressors within and outside the home. Benefits of the new approach include broader screening of physical health issues and more detailed assessment of associated factors while streamlining the behavioral health screening process into a single practice pathway.

Conclusions: Screening for co-occurring behavioral health and co-occurring medical conditions in children and youth with ASD can be systematically done to promote reliability without extensive impact on clinic patient flow. It is anticipated that consistent use of these clinical pathway tools will improve the identification and treatment of common challenging behaviors in children with ASD.

415.036 *(Poster)* Contradictions between DSM-5 and ADOS-2 Classification – a Preliminary Study

H. Nagar Shimoni*, Child Development, Marrot Autism Center/Ichilov Hospital, Tel Aviv, Israel*

Background:

As both over- and under-diagnosis of ASD are problematic, a standard approach to assessment, employing relevant and psychometrically sound measures, and employing them accurately is of critical importance for evaluation and intervention (Ozonoff, Goodlin-Jones & Solomon, 2005).

Objectives:

To call attention to the possible contradictions between DSM-5 ASD diagnosis and ADOS-2 ASD classification .

To emphasize the need for a combination of a skilled clinician's observation of the child's behavior combined with other sources of information in order to endorse or discard a diagnosis of autism.

Methods:

In the current study, we present four cases of children (mean age -8.87) that were referred to Marot Center at the Tel Aviv Sourasky Medical Center during an eight-month period. These children were referred with complaints of communication and social difficulties, and suspicion of autistic spectrum disorder. All the cases were evaluated by certified child and adolescent neurologists, psychiatrists and psychologists. They were evaluated by clinical observation, ADOS-2 and DSM-5. According to ADOS-2, they were classified as being on the autistic spectrum or with autism. Conversely, none of the children met the criteria for Autism Spectrum Disorder according to DSM-5.

Results:

A summary of the evaluation data of the four cases are presented in Table 1. These data present the diagnoses of the cases using four sources of information – other professionals' impression, the ADOS-2, the DSM-5 and the CAST self-report questionnaire (Scott et al., 2002). Notably, none of the case studies met the criteria for a DSM-5 diagnosis of ASD. Conversely, three of the four cases were above the cut-off score for ASD according to CAST, and they were all on the autistic spectrum according to ADOS-2.

Table 1. Diagnosis of four cases using four sources of information (professional's impression, ADOS-2, DSM-5 and CAST self-report questionnaire

Cases	Case 1	Case 2	Case 3	Case 4
Suspected Diagnosis according to source of referral	Suspected ASD	Suspected ASD	Suspected ASD	Suspected ASD
Previous diagnoses	ADHD Learning Disability Language Disability	ADHD Language Disability Tourette syndrome	ADHD Learning Disability	ADHD
*ADOS-2 Classification	ASD (7)	ASD (8)	Autism (13)	Autism (9)
DSM-5 Diagnoses	No ASD	No ASD	No ASD	No ASD
**CAST (Parent report)	12	18	17	21

Conclusions:

The study points to disparities between ADOS-2 and DSM-5 diagnoses in children ages 8-10 y with additional diagnoses. This can be highly relevant to both clinical practice and research, as in the latter the ADOS is often used as a single source for validating the diagnosis. These preliminary findings point to the confounding influence of age and additional diagnoses and the importance of paying note to specific biases in this regard.

415.037 *(Poster)* Coproducing Holistic Proxy- and Self-Report Assessment of Functioning Tools Based on the ICF Core Sets for Autism Spectrum Disorder

M. Hayden-Evans[1]*, E. D'Arcy*[2]*, S. J. Girdler*[3]*, B. T. Milbourn*[3]*, S. Bolte*[4]*, A. Chamberlain*[5]*, A. O. Whitehouse*[6]*, V. Eapen*[7] *and K. Evans*[8]*, (1)School of Occupational Therapy, Speech Pathology and Social Work, Curtin University, Perth, WA, Australia, (2)Cooperative Research Centre for Living with Autism (Autism CRC), Brisbane, Australia, (3)School of Occupational Therapy, Social Work and Speech Pathology, Curtin University, Perth, WA, Australia, (4)Center of Neurodevelopmental Disorders (KIND), Centre for Psychiatry Research; Department of Women's and Children's Health, Karolinska Institutet, & Stockholm Health Care Services, Region Stockholm, Stockholm, Sweden, (5)Autism Research Team, Telethon Kids Institute, Perth, Australia, WA, Australia, (6)Telethon Kids Institute, University of Western Australia, Perth, WA, Australia, (7)Cooperative Research Centre for Living with Autism (Autism CRC), Long Pocket, Brisbane, Australia, (8)Telethon Kids Institute, University of Western Australia, Perth, Western Australia, Australia*

Background: Autismis a lifelong neurodevelopmental condition associated with social and communication difficulties, persistent repetitive behaviours, and lower outcomes across various domains of functioning. However, describing the functional impact and support needs of autistic individuals is challenging, and there is currently no widely accepted tool taking a holistic approach to capturing ability and disability in autism. The International Classification of Functioning, Disability and Health (ICF) Core Sets for autism have recently been developed for infants, children, and adults, supporting the development of new assessments of functioning for each of these age brackets. In their current form, the ICF Core Sets provide comprehensive descriptions of functioning relevant to autism across the lifespan, but are difficult for autistic individuals and their families to interpret.

Objectives: This study is embedded within a larger program of research developing and evaluating assessment of functioning tools based on the ICF Core Sets for autism and other neurodevelopmental conditions. This study aimed to simplify the definitions of functioning included in the ICF Core Sets for autism and inform the development of proxy- and self-report versions of an assessment of functioning tool for autistic individuals.

Methods: This qualitative project utilised inclusive research methods of co-production, involving autistic individuals and their families in the research process. A consumer reference group consisting of two autistic adults and three caregivers of individuals on the spectrum was convened, providing feedback on all aspects of the research process. Interactive workshops with autistic adults and caregivers were then conducted in four cities across Australia, as well as online via teleconferences. To date 16 participants (seven autistic adults and nine parents/caregivers) have participated in workshops, with data collection continuing in 2019. Participants were involved in co-producing simplified definitions, generating questions and examples, and commenting on the symbolic diagrams used by the research team to portray the ICF items. Qualitative data obtained during these discussions were analysed thematically.

Results: Participants provided simplified definitions for each ICF item, suggesting a more directive style of questioning, with the inclusion of concrete examples. Participants provided what they saw as more appropriate wording of questions and examples for each ICF item, commenting that the current symbolic illustrations were ambiguous and may negatively influence their understanding of the items. There was consensus across participants that photographic illustrations of each item should be used, with ideas for photographic illustrations provided for the majority of ICF items. This feedback has been included in a prototype proxy- and self-report assessment of functioning tool, which is being pilot tested with school-aged children on the spectrum and their parents/caregivers.

Conclusions: This project represents an important first step in operationalising the ICF Core Sets for ASD, which will provide a comprehensive assessment of functioning tool that is both feasible and acceptable to end-users. This assessment will be the first tool co-produced with autistic individuals and their families.

415.038 *(Poster)* Cross-Sectional Comparisons of Autism Symptoms from 2 to 12 Years for Children with Pre-Verbal or Single Words: Implications for Diagnosing Younger and Older Children.

H. Zhu[1], *B. Chen*[1], *Q. Peng*[2], *J. Chen*[3], *Y. Zou*[1], *E. Bai*[1], *Y. Zhang*[1], *S. Lv*[1], *Y. Xu*[1], *H. Chu*[1] *and X. Zou*[1], *(1)Child Development and Behavior Center, Third Affiliated Hospital of SUN YAT-SEN University, Guangzhou, China, (2)South China Academy of Advanced Optoelectronics, South China Normal University, Guangzhou, China, (3)Chalmers University of Technology, Gothenburg, Sweden*

Background: Existing literature show that autism spectrum disorder (ASD) symptoms change across childhood and early adolescence. However, many studies have been limited by small sample size or age range, making it difficult to compare various symptoms within a rather large age range. Most researches have focused on early detection and/or stability of diagnosis during younger age (e.g. less than 3 years old). It is also important to differentiate symptoms that improve or worsen over time from those that remain stable across younger to older childhood.

Objectives: We aimed to investigate how social-communicative symptoms and restricted, repetitive patterns of behavior, interests, or activities change from younger to older childhood for ASD children with pre-verbal or single words speech ability. Based on these comparisons, we distinguished between improving, worsening and stable behaviors and demonstrated the implications of diagnosis and assessments on children at different ages.

Methods: Participants were drawn from an autism database from the Child Development and Behavior Center from 2015 to 2017 consisted of 828 children (ages ~2 to 12) who were referred to Autism Diagnostic Observation Scales Module 1 to assess for possible ASD. The present study involves 702 children who received ASD diagnoses and completed Module 1 assessments. Clinical diagnoses were made based on the clinical interview and other assessments (e.g. Autism Diagnosis Interview-Revised, WISC). All 702 participants (age range 15 - 116 months, average age 43.16±18.29 months, 597 boys) met the criteria for diagnosis of ASD in DSM-5, and were included in further analyses. The frequencies and weighted means for each item from A(Communication), B(Reciprocal social interaction), C(Imagination/Creativity/Play), D(Stereotyped Behaviors and Restricted interests), E(Other Abnormal Behaviors) were calculated by difference age intervals. Spearman correlation and autocorrelation functions were utilized to analyze and test the stability of the time serial data. Furthermore, the permutation test (10,000 times with FDR corrections) was adopted to analyze gender differences.

Results: Results from correlation analysis showed significant heterogeneity of symptom development across different ages. Among Module 1 items, A1, A8, B2, B6, B8, B10, D1, D2, D3, D4, E1 and D3 remained stable over different ages, while A3, A4, and A5 worsened over time. A2, A6, A7, B1, B3, B4, B5, B7, B9, B11, B12, C1, C2 and E2 were significantly improving ($|R_{min}| =0.112$, $P_{max} = 0.007$). Furthermore, boys showed more shared enjoyment of interaction compared to girls (B5, $P_{corrected} = 0.032$).

Conclusions: An ambiguity is present in choosing Module 1 or 2 for older children since results have shown an improved verbal language ability. The relative stability of items suggests that gesture, responsive social smile, response to name, giving, spontaneous joint attention, and unusual repetitive interests or stereotyped behaviors may be core features of ASD with preverbal or single words speech ability. Improvements in symptoms suggest that behaviors used to diagnose younger children may no longer be qualified diagnostic markers for older children. The present study demonstrates the necessity of developing different scoring strategies based on age and gender.

415.039 *(Poster)* Cross-Sectional Comparisons of Autism Symptoms from 2 to 14 Years for Children with Phrase Speech: Implications for Diagnosis

H. Zhu[1], *Q. Peng*[2], *B. Chen*[1], *Y. Zou*[1], *E. Bai*[1], *J. Chen*[3], *X. Zou*[1], *Y. Zhang*[1], *H. Chu*[1], *Y. Xu*[1] *and S. Lv*[1], *(1)Child Development and Behavior Center, Third Affiliated Hospital of SUN YAT-SEN University, Guangzhou, China, (2)South China Academy of Advanced Optoelectronics, South China Normal University, Guangzhou, China, (3)Chalmers University of Technology, Gothenburg, Sweden*

Background: Existing literature provides some evidence to show that autism symptoms change across childhood and early adolescence. However, many studies have been limited by small sample size or age range, making it difficult to compare various symptoms within a rather large age range. Most researches have focused on early detection and/or stability of diagnosis during younger age (i.e. less than 3 years old). It is also important to differentiate symptoms that improve or worsen over time from those that remain stable across younger to older childhood.

Objectives: We aimed to investigate how social-communicative symptoms and restricted, repetitive patterns of behavior, interests, or activities change from younger to older childhood for phrase speech children with autism spectrum disorder (ASD). Based on these comparisons, we distinguished between improving, worsening and stable behaviors, and demonstrated the implications of diagnosis and assessments based on child age and gender.

Methods: Participants were drawn from an autism database from the Child Development and Behavior Center at the Third Affiliated Hospital of Sun Yat-Sen University in China from 2015 to 2017. 424 children were referred to Autism Diagnostic Observation Scales Module 2 to assess for possible autism spectrum disorders. Participants were assessed from ages ~2 to 14. The present study includes 372 children who received ASD diagnoses and completed Module 2 assessments. Clinical diagnoses were made based on the clinical interview and other assessments, including Autism Diagnosis Interview-Revised, WISC, etc. All 372 participants (age range 27.5-143 months, average age 62.73±21.45 months, 318 boys) met the criteria for clinical diagnosis of ASD in DSM-5 and were included in further analyses. The frequencies and weighted means for each item from A(Communication), B(Reciprocal social interaction), C(Imagination/Creativity), D(Stereotyped Behaviors and Restricted interests), E(Other Abnormal Behaviors) were calculated by difference age intervals. Spearman correlation and autocorrelation functions were utilized to analyze and test the stability of the time serial data. Furthermore, the permutation test (10,000 times with FDR corrections) was adopted to analyze gender differences.

Results: Correlation analysis results showed significant heterogeneity of symptom development across different ages. Among all the items of Module 2, A2, A5, A8, B1, B2, B4, B8, B10, C1, C2, D4 showed significant improvement ($|R_{min}| = 0.137$, $P_{max} = 0.009$). Other items were relatively stable. Furthermore, boys displayed significantly more impairment in spontanous using discriptive, conventional, instrumental and informative gestures (A8, $P_{corrected} = 0.020$), unusual eye contact (B1, $P_{corrected} = 0.020$), and stereotyped behaviors and restricted interests (D4, $P_{corrected} = 0.030$).

Conclusions: Improvement in symptoms indicate that older phrase speech children have better skills in communication, social reciprocity, imagination and creativity, and less stereotyped behaviors and restricted interests. Only 5 out of 12 scoring items remained stable across different ages. The present study demonstrates the necessity of developing different scoring strategies based on gender and age.

415.040 *(Poster)* Cross-Sectional Comparisons of Autism Symptoms from 2 to 14 Years for Children with Phrases Speech: Implications for Diagnosis.

H. Zhu[1]*, Q. Peng*[2]*, B. Chen*[1]*, J. Chen*[3]*, Y. Zou*[1]*, E. Bai*[1]*, Y. Zhang*[1]*, S. Lv*[1]*, Y. Xu*[1]*, H. Chu*[1] *and X. 415.041 *(Poster)* DAS-II Cognitive Profiles Do Not Distinguish Children with Autism: A ROC Analysis

C. C. Clements[1]*, R. T. Schultz*[1]*, B. E. Yerys*[1]*, M. W. Watkins*[2] *and T. Sparding*[3]*, (1)Center for Autism Research, Children's Hospital of Philadelphia, Philadelphia, PA, (2)Educational Psychology, Baylor University, Waco, TX, (3)Institute of Neuroscience and Physiology, Department of Psychiatry and Neurochemistry, the Sahlgrenska Academy, University of Gothenburg, Gothenburg, Sweden*

Background: Intelligence assessment is an integral part of a comprehensive autism evaluation. Many past studies have described a cognitive profile of autistic individuals characterized by higher nonverbal than verbal IQ scores (Giofrè et al., 2019; Jones & Lord, 2013; Kuriakose, 2014; Li, Du, Luan, Li, & Ousley, 2017; Mayes & Calhoun, 2008). Using a discriminant validity approach that emphasizes group differences, some have interpreted the Nonverbal > Verbal IQ profile as a clinical indicator of ASD (Lennen et al., 2010; Tager-Flusberg & Joseph, 2004; Nowell et al., 2015; Mayes & Calhoun, 2008). However, group differences speak to the typical member of a group, not to each individual within that group (Kraemer, Frank, & Kupfer, 2011). Meehl and Rosen (1955) warned clinicians against using psychometric patterns or cut scores to aid diagnostic decision-making when the cut score is based on *between-group differences*, instead of on the cut score's accuracy in making *individual correct decisions*. Thus, when studying a nonverbal-verbal difference or any proposed cognitive profile cut-score, the utility of the cut-score should be evaluated in terms of decisions about individuals, not overall group differences. The true diagnostic utility of the Nonverbal > Verbal IQ profile remains unknown.

Objectives: To determine whether any cognitive profiles (e.g., nonverbal IQ > verbal IQ) serve as useful aides in the ASD diagnostic decision by evaluating the sensitivity, specificity, and Area Under the Curve (AUC) of each profile

Methods: We leveraged Receiver Operating Characteristic (ROC) methods to determine the sensitivity, specificity, and Area Under the Curve (AUC) of three different IQ profiles in a large sample of children who have an autism spectrum disorder diagnosis (N =1228, Simons Simplex Collection) who completed the Differential Ability Scales Second Edition (DAS-II), School Age compared to the normative sample provided by the DAS-II publisher (N =2,200).

Results: The frequently discussed Nonverbal > Verbal IQ profile performed near chance at distinguishing ASD from normative individuals (AUC: 0.54, 95% CI [0.52-0.56]). The Nonverbal > Verbal IQ profile performed significantly worse for females than males (AUC: females: 0.46 [0.41-0.52]; males: 0.55 [0.53-0.58]). The Verbal-Spatial and Nonverbal-Spatial IQ profiles were also examined. All cognitive profiles evaluated showed AUC < 0.56.

Conclusions: We conclude that while significant differences between verbal and nonverbal IQ scores exist at the group level, these differences are small in an absolute sense, and not meaningful at an individual level. Cognitive testing is not likely to be a valuable tool in the ASD diagnostic process in school-age children, even though cognitive testing remains an essential source of information to specify level of functioning and intellectual disability. We do not recommend using cognitive profiles to aid in autism diagnostic decision-making.

415.042 *(Poster)* Demographic, Functional, and Psychological Profiles of ADOS-2 False Positives

***R. K. Greene**, K. R. Bradbury, J. Vasile and S. W. Duvall, Oregon Health & Science University, Portland, OR*

Background: The Autism Diagnostic Observation Schedule, Second Edition (ADOS-2) is a diagnostic gold standard measure for the assessment of autism spectrum disorder (ASD). Although this measure reliably differentiates ASD from typically developing controls, few studies have examined the accuracy of the ADOS-2 when assessing individuals with a variety of psychiatric conditions. Furthermore, there is little information regarding individuals with clinically elevated ADOS-2 scores who do not meet diagnostic criteria for ASD.

Objectives: Examine demographic, cognitive, adaptive, and psychological profiles of individuals with clinically elevated ADOS-2 scores who did not receive an ASD diagnosis.

Methods: This sample included 177 patients aged 5 to 21 years who were evaluated at an interdisciplinary, outpatient autism diagnostic clinic and had clinically elevated ADOS-2 scores (i.e., met clinical cutoff for spectrum or autism). Some received an ASD diagnosis (true positive, n=133), while others did *not* (false positive, n=44). A regression was conducted to determine which demographic, functional, and psychological characteristics predict false positive or true positive group membership. Chi square analyses were then employed to analyze group differences in rates of psychiatric diagnoses other than ASD.

Results: Descriptively, the groups did not differ on age, sex, or race/ethnicity (see Table 1). Regression analyses revealed that higher adaptive skills and greater number of psychiatric diagnoses were significantly predictive of false positive outcome, while greater CSS scores were significantly predictive of true positive outcome. Chi-square analyses showed that the false positive group had greater prevalence of anxiety, ADHD, and disruptive behavior disorders.

Conclusions: These findings indicate that individuals with higher adaptive ability may be less likely to receive an ASD diagnosis despite exceeding clinical cutoff scores on the ADOS-2. Additionally, the presence of various psychiatric disorders other than ASD is associated with decreased likelihood of an ASD diagnosis. Specifically, individuals with anxiety, ADHD, or disruptive behavior disorders may be more likely to present with clinically elevated ADOS-2 scores but not meet diagnostic criteria for the condition.

Table 1. Descriptive Demographic Information

	True Positive (n=133)	False Positive (n=44)	Group Differences
Age (in months)	122.25 (49.99)	136.16 (41.90)	t = 1.66, p =.098
Sex (% female)	30.1%	15.9%	2 = 3.402, p =.065
Race/Ethnicity (%)			2 = 6.05, p =.301
Caucasian	58.6%	61.4%	
Black	5.3%	0.0%	
Hispanic	22.6%	22.7%	
Asian/Pacific Islander	2.3%	0.0%	

Other	3.0%	9.1%
Multiracial	7.5%	6.8%

Note. * = $p < .05$.

Table 2. Regression Results

	b	SE b	β	*t*	*p*
(Intercept)	4.155	.399			
Age	-.001	.001	-.088	-.811	.420
Sex	.35	.102	0.34	.339	.735
Cognitive Ability	.00009	.003	.004	.033	.974
Adaptive Ability	-.009	.004	-.290	-2.40	.019*
ADOS-2 CSS	.069	.030	.255	2.30	.024*
# Psych Diagnoses	-.138	.052	-.273	-2.66	.009*

Note. * = $p < .05$. CSS = Calibrated Severity Score. # Psych Diagnoses = number of DSM-5 psychological diagnoses (not including ASD) given at or maintained after the evaluation. The dependent variable, diagnostic group, was coded such that false positives=3 and true positives=4.

415.043 *(Poster)* Detection of Pathological Cries in Infants Utilizing the Chatterbaby App

J. A. Estabillo[1,2], *S. Frei*[3], *H. Duan*[3], *S. J. Poulhazan*[4], *B. H. Dang*[5], *P. Kaur*[6], *Y. Quezada*[6], *S. Zhang*[6], *S. Yoon*[6], *A. Razzak*[6], *J. Parga*[7], *S. Jeste*[6], *C. Kasari*[6], *M. Dapretto*[8], *S. Y. Bookheimer*[8] *and A. Anderson*[6], *(1)Psychiatry, UCLA Semel Institute for Neuroscience & Human Behavior, Los Angeles, CA, (2)Psychology, UCLA, Los Angeles, CA, (3)UCLA, Los Angeles, CA, (4)Molecular, Cell and Developmental Biology, University of California, Los Angeles, Los Angeles, CA, (5)Department of Neuroscience and Psychiatry, UCLA, Los Angeles, CA, (6)University of California, Los Angeles, Los Angeles, CA, (7)Division of Neonatology, CHOP, Philadelphia, PA, (8)Dept of Psychiatry and Biobehavioral Sciences, University of California, Los Angeles, Los Angeles, CA*

Background: Literature has suggested that infants who have major pathologies exhibit acoustic differences in their cries from typically developing infants. Vocal differences may be related to both structural abnormalities as well as muscle tone differences that are present in disorders such as Down syndrome and cerebral palsy. Additionally, recent evidence suggests infants at risk for autism spectrum disorder (ASD) may cry differently from low-risk infants. Acoustic differences in a high-risk infant's cry may emerge as early as one month old. At 6 months, high-risk infants uttered pain cries that had higher and more variable fundamental frequency than low-risk infants. At one year, infants later diagnosed with ASD showed less waveform modulation and dysphonation than typically developing children. Additionally, cries of 18-month-old children later diagnosed with ASD were judged by blinded listeners to be more atypical and irregular. Given that children with autism often have medical diagnoses, we hypothesized that a machine learning algorithm could discriminate between pathological and healthy cries using acoustic features.

Objectives: To assess whether infants with parent-reported medical diagnoses exhibit differences in cry patterns from control infants.

Methods: Data were collected from (n = 508) users of *Chatterbaby*, a smartphone app that translates a baby's cry for parents. The "*Chatterbaby* Autism Risk Survey" obtains participants' consent for their information to be used in research, collects demographic information of the infant and parents, and screens for ASD-associated behaviors. Major diagnoses included seizure, stroke, Down syndrome, failure to thrive, surgery requiring anesthesia, re-hospitalization following initial hospital discharge, small for gestational age, low birthweight, premature birth <32 weeks, extracorporeal membrane oxygenation, infant respiratory distress syndrome, and intracranial hemorrhage. A total of 452 pathological cries (infant age M = 5 months) were compared to 2945 non-pathological cries (M = 3 months). Roughly 10% of children had a family history of ASD. Over 6000 acoustic features were extracted using OpenSmile, including pitch (F0), energy, jitter, and shimmer measures. A random forests model was trained using the IS13 feature set on 95% of the data to predict whether a cry belonged to an infant with or without a diagnosis. The model was then tested on the held-out dataset, revealing 81.25% Positive Predictive Value and 97.5% True Positive Rate.

Results: By analyzing the acoustic features of cries, the algorithm was able to successfully identify infants who had major medical diagnoses. Babies with diagnoses were found to have weaker cries containing fewer cry waves, lower overall energy, and limited ability to project in the higher frequency ranges compared to controls.

Conclusions: Vocal abnormalities in infant cries may be non-specific indicators of medical risk. Given that ASD is frequently comorbid with the diagnoses included, additional research is needed to assess if children at-risk for ASD exhibit acoustic differences in cry patterns compared to the general pathological cry. Results from this study will be utilized as the foundation for follow-up work focused on this aim.

415.044 *(Poster)* Development and Validation of Assessment of Functioning Tools Based on the ICF Core Sets for ASD Suitable for Individuals on the Autism Spectrum across the Lifespan

S. J. Girdler[1], *E. D'Arcy*[2], *M. Hayden-Evans*[3], *A. Chamberlain*[4], *B. T. Milbourn*[1], *A. O. Whitehouse*[5], *S. Bolte*[6], *V. Eapen*[7], *J. Wray*[8] *and K. Evans*[9], *(1)School of Occupational Therapy, Social Work and Speech Pathology, Curtin University, Perth, WA, Australia, (2)Cooperative Research Centre for Living with Autism (Autism CRC), Brisbane, Australia, (3)School of Occupational Therapy, Speech Pathology and Social Work, Curtin University, Perth, WA, Australia, (4)Autism Research Team, Telethon Kids Institute, Perth, Australia, WA, Australia, (5)Telethon Kids Institute, University of Western Australia, Perth, WA, Australia, (6)Center of Neurodevelopmental Disorders (KIND), Centre for Psychiatry Research; Department of Women's and Children's Health, Karolinska Institutet, & Stockholm Health Care Services, Region Stockholm, Stockholm, Sweden, (7)Cooperative Research Centre for Living with Autism (Autism CRC), Long Pocket, Brisbane, Australia, (8)State Child Development Service, Western Australia Department of Health, Perth, Western Australia, Australia, (9)Telethon Kids Institute, University of Western Australia, Perth, Western Australia, Australia*

Background: Children and adults on the autism spectrum experience a range of activity limitations and participation restrictions, impacting on daily life and long term role outcomes. International guidelines recommend that functioning be evaluated as part of a diagnostic evaluation, and both the DSM-5 and ICD-11 include functioning related diagnostic criteria for autism spectrum disorder (ASD). The 'Australian National Guideline for the Assessment and Diagnosis of ASD' advocates a strengths-focused and comprehensive assessment of functioning and support needs for all individuals referred for an assessment of ASD concerns. This Australian guideline suggests the International Classification of Functioning, Disability and Health (ICF) as a conceptual framework for an assessment of functioning, along with the use of standardised assessments that cover a broad range of domains, with a suggestion for researchers to develop and validate a fit-for-purpose tool based on the ICF Core Sets for ASD.

Objectives: This program of research aimed to develop and validate assessment of functioning tools based on the ICF Core Sets for ASD that are suitable for individuals on the autism spectrum across the lifespan and available in clinician-administered, self-report and proxy-report versions.

Methods: Prototype assessment of functioning tools were developed in clinician-administered, self-report and proxy-report versions with input from researchers, clinicians and the autism community (n>37). These prototype tools include simplified definitions, examples and symbolic images for each of the ICF Core Sets for ASD items. The clinician-administered version was piloted with at least 75 parents/caregivers of young autistic individuals up to 20 years of age (alongside the PEDI-CAT and Vineland, two established standardised tools). Feedback on the clinician-administered version was also obtained from parents/caregivers (n>30) on acceptability and clinicians (n>30) on clinical utility. The self-report and proxy-report versions will be piloted with autistic adolescents/adults and parents/caregivers of autistic individuals of all ages (expected n>50) between January – March 2020 and feedback will be sought regarding acceptability.

Results: Preliminary psychometrics properties of the clinician-administered version suggest that most activity and participation domains have good to excellent internal consistency, along with excellent inter-rater reliability at the item level. Parent/caregivers and clinicians provided early feedback that the clinician-administered version was holistic and strengths-focused, although time-consuming, and a full set of psychometric properties and normative data for a manualised final version would be necessary prior to wide spread adoption. Further investigation of the psychometric properties and usability of the clinician-administered, self-report and proxy-report versions will be available at the INSAR meeting.

Conclusions: These prototype assessment of functioning tools represent an important first step in operationalising the ICF Core Sets for ASD, which will provide a suite of comprehensive assessment of functioning tools that are feasible and acceptable to the autism and clinical communities.

415.045 *(Poster)* Development of AIIMS-Modified-Indt-ASD Diagnostic Tool for the Age Group 1-14 Years. and a Screening Tool for Identifying the Early Signs of Autism Spectrum Disorder in Children Aged 1-18 Months in a Premier Teaching Institute in North India

S. Gulati[1], *A. Gupta*[2], *J. S. Kaushik*[3], *L. Saini*[3], *V. Sondhi*[3], *P. K. Panda*[2], *S. Sharma*[3], *P. Madaan*[3], *R. Manokaran*[3], *K. Sikka*[3] *and R. Pandey*[4], *(1)Center of excellence and advanced research for childhood neurodevelopmental disorders, Child Neurology Division, Department of Pediatrics, All India Institute of Medical Sciences, New Delhi, India, (2)Child Neurology Division, Department of Pediatrics, All India Institute of Medical Sciences, New Delhi, India, (3)Child Neurology Division, Department of Pediatrics, All India Institute of Medical Sciences, New Delhi, New Delhi, India, (4)Department of Biostatistics, All India Institute of Medical Sciences, New Delhi, New Delhi, India*

Background: Point of care diagnostic tools based on DSM V criteria for Autism Spectrum Disorder , as well as a screening tool to identify children <18 months at risk for autism are likely to help clinicians.

Objectives: To describe the process of development of AIIMS-Modified-INDT-ASD Tool for 1-14 years age and a screening tool for identifying early signs of ASD in children aged 1-18 months in a premier teaching institute in North India.

Methods: DSM-IV-TR based INCLEN Diagnostic Tool for ASD was modified to incorporate the DSM-5 related changes by Child Neurology Division, Department of Pediatrics, AIIMS, New Delhi, using Delphi method. It included: (a) Rearrangement of questions from the previous tool; and (b) Addition of new questions on sensory symptoms. This AIIMS-Modified-INDT-ASD Tool was validated against DSM-5 diagnostic criteria. Receiver Operating Characteristic (ROC) curves were used to determine the cut-off for total score as compared to Childhood Autism Rating Scale (CARS) score to grade the severity of ASD.

The second study was designed to generate a pool of questions by Delphis technique to identify early signs of Autism Spectrum Disorder in 1-18 months of age. To develop and administer the questionnaire in 4 study groups (ASD vs Healthy & Disease Controls aged 24-30 months) with the aim of developing a tool to identify children between 1-18 months of age predisposed to developing ASD. The study was conducted in three parts. The first part was to generate a pool of questions using Delphi's technique to identify early signs of ASD. The second step consisted of applying this questionnaire in the 4 groups mentioned above. The third and the final part consisted of drawing cut off scores in age specific strata across various domains thus identifying sensitive and specific questions and developing a final tool.

Results: Two-hundred-twenty-five children (159 boys, median age = 47months) were enrolled. for the first study. The AIIMS-Modified-INDT-ASD Tool demonstrated sensitivity of 98.4% and specificity of 91.7% to diagnose ASD. A score ≥14 on the tool was suggestive of severe ASD (CARS>36.5) with a sensitivity and specificity of 80% and 80.7% respectively [Area under the curve = 0.89].

In the second study, 200 Children aged 24-30 months (50 in each group) with diagnosis of ASD, global development delay, hearing loss and typically developing children were enrolled in the study. Out of the 62 questions in the original questionnaire in second study, 30 questions were identified with >80% sensitivity and specificity to screen for ASD in young children. Only six questions could be identified for children in the first 6 months of age and contributed least in terms of identification of the ASD characteristics. The subsequent two age strata had equal representation of the representative questions. Sensitivity of the tool was comparable across each of the age groups, however specificity of the tool increased with age (87.5% at 12 months and 95% at 18 months).

Conclusions: Both AIIMS-Modified-INDT-ASD Diagnostic Tool (age group 1-14 yrs)and screening tool for ASD in 1-18 months children have good psychometric properties.

415.046 *(Poster)* Development of the Tactile and Auditory Observation Schedule (TAOS)

M. Glod[1]*, D. M. Riby*[2] *and J. Rodgers*[1]*, (1)Institute of Neuroscience, Newcastle University, Newcastle Upon Tyne, United Kingdom, (2)Department of Psychology, Durham University, Durham, United Kingdom*

Background: Sensory atypicalities are highly prevalent in both autism spectrum disorder (ASD) and Williams syndrome (WS). Particularly, auditory filtering has been found to be significantly elevated in autistic[1] and WS[2] children; and relationships between auditory and tactile modalities and other symptoms (e.g. restricted and repetitive behaviours) are reported in both conditions[3,4,5]. This evidence highlights the importance of making distinction between tactile and auditory, and other sensory modalities in order to examine their distinct patterns.

A semi-structured direct observation is a thorough and accurate assessment[6]. Yet, there are only a handful of observational tools administered directly to participants that have been used to assess sensory processing in children with ASD and/or WS. Furthermore these tools either focus on only one modality, one pattern of sensory processing (e.g. overresponsivity), or are not widely accessible.

Objectives: The aim of this study was to develop, administer and evaluate the Tactile and Auditory Observation Schedule (TAOS) with typically developing (TD), autistic children and children with WS.

Methods: Twenty TD children, twenty-three autistic children and seventeen children with WS between 4 and 9 years old and their parents were recruited to the study.

All children undertook:

1. Raven's Coloured Progressive Matrices[7] and British Picture Vocabulary Scale - Third Edition[8] to assess non-verbal reasoning ability and child's receptive vocabulary
2. TAOS - a new play-based measure assessing hypo- and hyper-responsiveness to auditory and tactile stimuli. It consists of a free-play time, auditory and tactile tasks. The content was guided by the content of a number of range of sensory questionnaires and relevant literature. Parents of children with ASD and WS were also consulted to make sure that all appropriate items were considered and included in the tool.

Results: A Chi-squared test/Fisher's exact test was performed to examine whether there was a difference in the distribution of the TAOS scores for both auditory and tactile processing domains, across the three groups. For the TD and ASD groups and TD and WS groups, a significant difference in the distribution of the scores was found in the auditory domain (p=.006; p=.007, Fisher's exact test respectively), but not in the tactile domain (p=.589; p=.196, Fisher's exact test respectively). For the ASD and WS groups Fisher's exact tests were non-significant.

Using item distribution analysis, items related to sound seeking and a range of background noise in the auditory domain and those related to being messy or being made messy in the tactile domain were best at distinguishing between all the three groups.

Conclusions: The ASD and WS groups, in general, performed similarly. Six items were best at distinguishing between all the three groups. The administration of these tasks takes up to 25 minutes and only these could be used when assessing auditory and tactile hypo- and hyper-responsivity in children with typical and atypical development. Further work is required on the validation of the TAOS and its psychometric properties to provide researchers and clinicians with an accurate measure of auditory and tactile processing in children with and without neurodevelopmental disorders.

415.047 *(Poster)* Diagnosis of Autism in Toddlers Using Telemedicine Tools

A. F. Berman[1]*, L. Corona*[1]*, A. Miceli*[1]*, E. Grimes*[1]*, A. Nicholson*[2]*, A. S. Weitlauf*[3]*, C. S. Reichstein*[4]*, N. Broderick*[5]*, J. F. Hine*[5]*, R. J. Hundley*[5]*, S. Francis*[6]*, L. Wagner*[5] *and Z. Warren*[5]*, (1)Vanderbilt University Medical Center - Treatment and Research Institute for Autism Spectrum Disorder, Nashville, TN, (2)Vanderbilt University, Pleasant View, TN, (3)Vanderbilt Kennedy Center, Vanderbilt University Medical Center, Nashville, TN, (4)Treatment and Research Institute for Autism Spectrum Disorders, Vanderbilt University Medical Center - Kennedy Center, Nashville, TN, (5)Vanderbilt University Medical Center, Nashville, TN, (6)Vanderbilt University Medical Center - Treatment and Research Institute for Autism Spectrum Disorder, Nashville, NY*

Background: The use of telemedicine in assessment for autism spectrum disorder (ASD) presents an opportunity to increase access to care for children and families. Previous work provided preliminary support for accuracy of telemedicine-based diagnosis of ASD (Juárez et al., 2018). However, such work has relied on expert remote psychologists observing a standardized interactive assessment (i.e., the Screening Tool for Autism in Toddlers and Young Children [STAT]) administered by a trained early intervention provider on site with the toddler and caregiver(s). This procedure requires two providers, presenting a major burden to scalability of telemedicine-based ASD diagnosis. In the present study, we evaluated preliminary diagnostic accuracy and perceived diagnostic certainty of psychologists following a telemedicine-based screening procedure. Psychologists verbally guided parents through structured interaction with their toddlers using telemedicine either tools adapted (TELE-STAT) or developed explicitly for (TELE-ASD-PEDS) caregiver-mediated remote assessment by clinician. Afterwards, psychologists indicated a diagnostic decision and rated their certainty of that diagnosis.

Objectives: This study evaluated diagnostic accuracy and clinician certainty in diagnosing ASD after telemedicine assessment using two different parent-led telemedicine tools.

Methods: Clinicians indicated diagnostic impression and certainty after either the administration of assessment alone (Phase 1, n=51) or use of the assessment with a diagnostic interview (Phase 2, n=35). Data collection for Phase 2 is ongoing. In both phases, psychologists interacted with families using HIPAA-compliant video platforms allowing for audiovisual communication. Diagnostic accuracy was determined by comparing psychologists' diagnostic impressions following telemedicine-assessment with toddlers' independent clinical diagnoses. See Table 1 for demographic and diagnostic information.

Results: In Phase 1, accuracy of psychologists' diagnostic impressions following telemedicine assessment (ASD vs. no ASD) was 86 percent. Psychologists accurately identified 33 toddlers as meeting criteria for ASD. Five toddlers with developmental delays were incorrectly identified as having ASD, and two toddlers with clinical ASD diagnoses were not identified as having ASD following telemedicine assessment. In Phase 2, diagnostic accuracy following telemedicine assessment was 94 percent. Following tele-assessment, twenty-nine toddlers were accurately identified as having ASD. Two toddlers with clinical ASD diagnoses were not identified as having ASD. Clinician certainty did not differ as a function of the assessment procedure used (i.e., TELE-STAT vs. TELE-ASD-PEDS) in both Phase 1 ($t(49)= 0.76$, $p = 0.45$) and Phase 2 ($t(33)=.143$, $p=.887$). Clinician certainty also did not differ based on whether the telemedicine assessment included a diagnostic interview ($m=3.03$, $SD=1.07$) or relied only on observation of the TELE-STAT or TELE-ASD-PEDS ($m=3.30$, $SD=0.71$; $t(83)=1.3$,$p=.195$). More information on diagnostic certainty and diagnostic agreement is displayed in Table 2.

Conclusions: This study provides preliminary evidence for the utility and diagnostic accuracy of telemedicine procedures for toddlers with ASD, particularly when parent-led interactions are coupled with diagnostic interviewing. The parent-led tools used in this study represent promising avenues for future use in telemedicine assessment. As Phase 2 continues, we will continue to evaluate diagnostic accuracy, clinician certainty, and parent feedback on these procedures.

415.048 *(Poster)* Diagnostic Accuracy of the Autism Diagnostic Observation Schedule within a Clinical Cohort in Melbourne, Australia

A. Ure[1,2,3,4,5]*, K. Williams*[1,2]*, P. Date*[5] *and K. Robertson*[6]*, (1)Department of Paediatrics, Monash University, Clayton, VIC, Australia, (2)Monash Children's Hospital, Clayton, VIC, Australia, (3)Department of Paediatrics, University of Melbourne, Parkville, VIC, Australia, (4)Royal Children's Hospital, Parkville, VIC, Australia, (5)Murdoch Children's Research Institute, Parkville, VIC, Australia, (6)Djerriwarrh Health Services, Melton, VIC, Australia*

Background: The prevalence of Autism Spectrum Disorder (autism) is growing and autistic features increasingly recognised among children and families with a range of conditions. Diagnosing autism spectrum disorder (autism) is complex, however, particularly in clinical samples where a broad range of developmental difficulties are common and/or when adverse life experiences, including neglect or trauma, have occurred. Accurate assessment methods are imperative so that resources for comprehensive neurodevelopmental assessment are used appropriately. The Autism Diagnostic Observation Scale, Second Edition (ADOS2) is a commonly used diagnostic tool in research and clinical settings. The tool has good sensitivity but concerns about overdiagnosis have been raised, particularly in cohorts where comorbidities are common.

Objectives: This study aims to assess the diagnostic accuracy of the ADOS2 in a clinical community sample and describe the clinical characteristics of children whose scores did not match their clinical diagnosis.

Methods: Assessment information was collected from 247 participants (aged 2 – 16 years) attending a multidisciplinary clinic in a community health centre in Melbourne, Australia between May 2016 – March 2019. During these assessments, information was collected about childhood exposure to significant adverse events, including witnessing family violence, periods of homelessness, significant parent mental or physical ill health, newly arrived refugee status, substance misuse and/or child protection involvement.

Results: Within this clinical sample, the prevalence of autism was 86% and 33% had experienced a significant adverse event. The sensitivity of the ADOS was 0.96 (CI = 0.93 – 0.98) and specificity was 0.22 (CI = 0.12 – 0.38). Children who were below clinical cut-off on the ADOS (N = 15) were more likely to be female (63%) and older (mean age = 9.4 years) than the 232 children who scored above the clinical cut off (27% female [p =0.05], mean age = 7.1 years [p = 0.03]) regardless of diagnosis. Of children diagnosed with autism, false negatives (N = 8) were more likely to be female (63%) and older (mean age = 8.7 years) than the 204 true positives (27% female [p = 0.01], mean age = 7.3 years [p = 0.07]). Notably, within the group who were not diagnosed with autism, 19 of the 28 children (68%) who were above clinical cut-off on the ADOS (false positives) had been exposed to a traumatic event compared with 3 of the 7 children (42%) who were true negatives, although this difference was not statistically significant (p=0.23).

Conclusions: The ADOS has reasonable sensitivity overall but may be lower in older cohorts with a higher proportion of females. The high proportion of children with a trauma history amongst false positives raises concerns about using the ADOS in isolation within high risk clinical samples.

415.049 *(Poster)* Differential Item Functioning Based on Level of Autism Features and Age on the Parent-Report Version of the Screen for Child Anxiety Related Disorders Among Youth with Autism

H. K. Schiltz *and B. Magnus, Psychology, Marquette University, Milwaukee, WI*

Background: Although anxiety negatively affects quality of life for many children on the autism spectrum (Adams et al., 2019; van Steensel et al., 2017), few studies have examined the psychometric properties of anxiety measures in this population. Preliminary evidence suggests acceptable psychometric performance of the Screen for Child Anxiety Related Disorders (SCARED) in an autism sample (Stern et al., 2014). The validity of research on this topic, however, also requires that questionnaires capture true differences in latent constructs rather than systematic differences in measurement across youth of different ages and level of autism features. Studies have posited that due to potential overlap of anxiety and autism symptoms, scores on these questionnaires may be falsely inflated (McVey et al., 2018), yet this has yet to be empirically tested. Moderated nonlinear factor analysis (MNLFA; Bauer, 2018) allows for testing of threshold and discrimination differential item functioning (DIF) across continuous covariates.

Objectives: The present study sought to first replicate the 5-factor structure of the SCARED, a parent-report measure of anxiety, and subsequently explore DIF across age and level of autism features using MNLFA in a sample of youth with autism.

Methods: Data were from the National Database for Autism Research, a NIH-funded data repository. Participants met criteria for autism on the Autism Diagnostic Observation Schedule (ADOS) (Lord et al., 2000). The sample (N=198) was 83% male (Mage=11.18). Parent-report on the SCARED and Social Communication Questionnaire (SCQ) were used as measures of anxiety and autism features, respectively. Moderated nonlinear factor analysis (MNLFA) in MPlus was used to test each item within a subscale of the SCARED for differential item functioning (DIF). Significant regression paths between the covariates and the candidate item indicates threshold DIF, and significant regression paths between the candidate item and the interaction between the covariate and the latent variable indicates discrimination DIF. A final model was run for each subscale, simultaneously accounting for all items with DIF on that subscale.

Results: A confirmatory factor analysis indicated good fit of the 5-factor structure (CFI = 0.94; TLI = 0.93; RMSEA = 0.05). MNLFA revealed multiple items with threshold and discrimination DIF based on level of autism features and age (Table 1). For items with threshold DIF, parents of children with greater levels of autism features or older age are more/less likely to endorse those items at the same level of the latent construct (anxiety). For items with discrimination DIF, the association between the latent construct (e.g. panic disorder) and that item may be weaker/stronger dependent upon levels of autism features and age.

Conclusions: This study replicated the 5-factor structure identified within neurotypical literature and by a prior study on autism. Results of DIF analyses, however, also provide evidence that multiple items on the SCARED have systematically different measurement properties dependent upon a child's level of autism features and age, and thus, the tool may not capture true differences in anxiety for all children on the spectrum. Clinicians and researchers need to be especially vigilant in measuring anxiety symptoms in autism.

415.050 *(Poster)* Differential Item Functioning of the Social Communication Questionnaire in African Americans

E. Moody[1]*, E. Dahl*[2]*, B. Barger*[3]*, C. DiGuiseppi*[4]*, M. D. Fallin*[5]*, L. C. Lee*[6]*, L. Wiggins*[7] *and S. Rosenberg*[8]*, (1)Wyoming Institute for Disabilities, University of Wyoming, Laramie, WY, (2)WIND, University of Wyoming, Laramie, WY, (3)Georgia State University, Atlanta, GA, (4)Colorado School of Public Health, University of Colorado Anschutz Medical Campus, Aurora, CO, (5)Wendy Klag Center for Autism and Developmental Disabilities, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, (6)Department of Epidemiology, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, (7)Centers for Disease Control and Prevention, Atlanta, GA, (8)University of Colorado Anschutz Medical Campus, Aurora, CO*

Background: The American Academy of Pediatrics (AAP) recommends that all children be screened for autism spectrum disorder (ASD) at 9, 18 and 30 months of age. The Social Communication Questionnaire (SCQ) is a screening tool commonly used to detect ASD risk in children. Prior research suggests that the SCQ has lower sensitivity and specificity among black versus white children. Further psychometric evaluation is needed to understand whether specific items on the SCQ contribute to racial differences in screener performance.

Objectives: To determine the degree to which specific items on the SCQ perform differently among white and black children.

Methods: Data for this analysis come from The Study to Explore Early Development (Phase 1 enrollment: 2007- 2011; Phase 2 enrollment: 2012-2016), a multi-site study that evaluated children 30 to 68-months of age with ASD, non-ASD developmental disorders, and those from the general population (total N=7271). The SCQ was administered by phone interview. The SCQ is comprised of 40 yes/no items completed by the caregiver of the child; additional demographic data (maternal race/ethnicity, etc.), were collected via a standardized parent interview.

Differential Item Functioning (DIF) is a psychometric method to determine if different groups perform similarly on specific items of a measure. Analyses of DIF for this study utilized logistic regression. Separate models were computed for each SCQ item with race as a fixed factor. White children were used as the reference group based on high sensitivity and specificity of the SCQ in this group. This DIF method allows for the comparison of white versus black children on performance of each item in predicting total score, factoring out the contribution of that item to the total score. Items will perform differentially between groups if race is a significant factor in the model. Negative betas indicate that black respondents are less likely to endorse that item. Positive betas mean black respondents are more likely to endorse that item.

Results: Logistic regression analyses showed that black respondents were significantly less likely to endorse 10 items and significantly more likely to endorse 9 items relative to white respondents (Table 1). Examples of items with the highest probabilities of differential performance found that black respondents as compared to white respondents were less likely to endorse that their child used odd phrases or socially inappropriate statements and were more likely to endorse that their child used inappropriate facial expressions.

Conclusions: Black parents responded significantly differently than white respondents on 48% of items from the SCQ. This suggests that responses to items on the SCQ may be influenced by racial culture, which may contribute to overall screening differences between these groups (Moody, et al., 2017). It is important that ASD screeners are equally valid among those with diverse backgrounds so that they do not contribute to persistent racial disparities. More research is needed to ensure that the screeners perform similarly at the item and test level, and to determine if DIF is the result of true group differences or the result of the test's construction.

415.051 *(Poster)* Discrepancies in Answering on Suicide Relevant Questions between Autistic Adults and Parents Answering in Their Stead, an Insight into Risk and Masking

E. Diamond[1]*, P. Dwyer*[2] *and Z. J. Williams*[3]*, (1)The Wright Institute, Berkeley, CA, (2)Department of Psychology, University of California, Davis, Davis, CA, (3)Medical Scientist Training Program, Vanderbilt University School of Medicine, Nashville, TN*

Background: We have been developing a new adult autism screening measure (AutCQ) with responses from an international sample of autistic individuals (N=631) or, because not all may use spoken language, parents answering in their stead (N=75). Here we report results relating to an important part of the experiences of many autistic respondents, depression and suicidality.

There has been a general increase in suicide with rates rising by about 2% a year since 2006. Suicide and suicidality rates appear particularly elevated in those diagnosed as autistic, and in tandem with that, there is growing discussion and awareness of how masking and camouflaging correlate with risk for self-harm and suicide. We are taking the opportunity to highlight discrepancies in responses by parents compared with autistic adults.

Objectives: Our objectives are fourfold. A comparison affords the opportunity to learn how on critical items, where crisis or life-time burden of psychological pain are involved, there are differing response profiles of autistic adults compared to parents. There is the need to understand how the AutCQ performs when a parent is assisting their adult child who may have difficulty with language. There is the need to better understand masking or hidden psychological states and to place them on the developmental timeline. Lastly, we hope to track constellations of responses indicating risks of suicide and crisis.

Methods: The AutCQ's items cited in the research as suicide risk factors were examined. These were: Anxiety, Depression or Sadness, Feeling isolated, Aggression towards self or others, and Suicidal thoughts, and Problems getting adequate sleep. The measure has 6 potential response options, with three focused on when the issue began: ages 2-5 years old, 6-12, and 13 and older; *Never an issue*; and that the issue had been outgrown. *I don't know* was a response not included in this analysis.

Results: Fisher's exact tests indicated that responses differed on all items, $p \leq .02$, except "Anxiety or worry," where $p = .10$. Most powerfully, on the item pertaining to Depression and sadness, the response option that it was "Never an issue" was endorsed by only 3.8% of autistic adults but 20% of parents. Looking specifically at suicidal thoughts, 33.3% of parents reported it was "Never an issue," compared with 16.6% of autistic adults. Similarly, 24.7% of autistic adults but only 16% of parents selected feeling isolated beginning at ages between 2 to 5.

Conclusions: On items related to psychopathology and psychological pain, autistic adults responding for themselves and parents answering for their child provided critically different responses. Where parents are assisting their child to fill out the AutCQ, this should be kept in mind. As the design of the AutCQ helps to place struggles along a developmental timeline, results show struggles occurring out of the awareness of parents. This suggests masking by children which may increase the risk for self-harm, suicide and psychological pain. Results also suggest important interventions are needed, regardless of how other AutCQ are answered. AutCQ is being designed to track intensity of current distress.

415.052 *(Poster)* Disparities in Access to Services for Children Undergoing Routine Autism/Developmental Screening in Primary Care

C. Pittard[1], *L. Hansen*[1], *S. Nyp*[2,3] *and C. Nadler*[1,4], *(1)Children's Mercy Kansas City, Kansas City, MO, (2)Pediatrics, University of Missouri Kansas City School of Medicine, Kansas City, MO, (3)Pediatrics, Children's Mercy Kansas City, Kansas City, MO, (4)University of Missouri Kansas City School of Medicine, Kansas City, MO*

Background: The American Academy of Pediatrics recommends screening for Autism Spectrum Disorder (ASD) at 18 and 24/30 months (Johnson et al., 2007), along with developmental screening at 9, 18 and 24/30 months (AAP, 2006). The Modified Checklist for Autism in Toddlers (M-CHAT; Robins et al., 2001) and Parents' Evaluation of Developmental Status (PEDS; Glascoe, 1999) are routinely used to meet these requirements. High rates of screening are not correlated with rates of service referral (Monteiro et al., 2019) and health disparities service access have been documented for children with ASD and developmental concerns (e.g., Khetani et al., 2017; Mandell et al., 2002). As children who receive intervention earlier have improved outcomes (e.g., Reichow, 2012), exploration of the sources of these disparities is warranted.

Objectives: The objective of the study is to examine the predictive validity of the M-CHAT and PEDS for diagnoses of ASD and developmental delay (DD), and if this varies by race or sex. The study also sought to examine the relation between the screening measure scores and access to services. Similarly, moderation of this relation based on sex and race was examined.

Methods: A retrospective review of well visits ($n = 1448$ children) at an urban primary care center housed was conducted. The sample was 90.8% non-White (9.2% White) and 52.3% male (47.7% female). The Time 1 visit consisted of data for the 18-month M-CHAT (total items failed) and PEDS (number of predictive concerns). The Time 2 visit consisted of a well visit between ages 4 to 6 years where diagnoses were extracted (e.g., autism, DD). Access to services was measured by the cumulative number of active and referred developmental services across Time 1 and Time 2 visits.

Results: When examined simultaneously, higher scores on the M-CHAT (but not the PEDS) was a significant predictor of a later diagnosis of ASD or DD (B = 0.28 [SE = 0.09] $p = .002$). This relationship did not vary by race or sex. Higher scores on both the M-CHAT and PEDS were significantly related to access to services (M-CHAT: B = 0.55 [SE = 0.07] $p < .001$; PEDS: B = 2.02 [SE = 0.26] $p < .001$). Demographic differences in this relationship also emerged, such that females and non-White children had access to fewer services (Race: B = -0.40 (SE = 0.12) p = .001 B; Sex: B = -0.24 (SE = 0.06) p = .001). Race and sex also moderated each relation between scores on the M-CHAT and PEDS and service access. When screening measure scores were held constant across groups, females and non-White children had less access to services.

Conclusions: While higher scores on the M-CHAT predicted later diagnosis of ASD/DD, the PEDS did not provide incremental predictive power. Non-White and female patients had lower rates of services access, such that increased risk on the M-CHAT or PEDS was less associated with access. While screening was related to services access overall, findings signal the importance of addressing barriers to access for female and non-White children.

415.053 *(Poster)* Do Self-Diagnosed Adult Women Differ from Those Having Received a Diagnosis from a Multidisciplinary Team?

F. Cazalis[1], *A. Lacroix*[2], *J. Cumin*[3,4], *G. Radecki*[5], *P. Duret*[3,6], *A. Valren*[3] *and L. Mottron, M.D.*[3,4], *(1)École des hautes études en sciences sociales - CNRS, Paris, France, (2)Université de Grenoble Alpes, Grenoble, France, (3)Autism Research Group, CIUSSS du Nord-de-l 'Île-de-Montréal, Montréal, QC, Canada, (4)Université de Montréal, Montréal, QC, Canada, (5)Auticonsult France, Courbevoie, France, (6)Université de Lyon 1, Lyon, France*

Background: Some autistic women may remain undiagnosed, possibly because of gender-biased diagnostic procedures and/or camouflage effects. However, clinicians also report a trend towards over-diagnosis in adult women, driven by a lack of use of differential diagnosis, fear of discriminatory practice, or behavioral consequences of refusing an autism diagnosis to women with borderline personality disorders.

Objectives: Determine on which items of a self-report questionnaire self-diagnosed women most resemble clinically diagnosed women, making these items sensitive enough to screen for "true" autism.

Methods: The Questionnaire for Autism Spectrum Conditions (Q-ASC, Attwood, Garnett, Rynkiewicz. Cf. https://mindsandhearts.net/gq-asc-girls-questionnaire-for-autism-spectrum-conditions/) was adapted into a self-administered questionnaire for adults by duplicating questions into past and present forms. The questionnaire was then translated into French and published & advertised online: https://maca.huma-num.fr/femmes-autistes/. People assigned female at birth with and without autism diagnosis enrolled in the study. Between-groups comparison for each questionnaire item were carried out using t-tests ($p<0.01$) in order to determine whether they differentiated (1) women with autism diagnosis validated by a multidisciplinary center, (2) women without autism diagnosis but self-identifying as autistic, and (3) women without autism diagnosis and not identifying as autistic.

Results: 506 adult women were included (194 clinically diagnosed, 210 self-diagnosed, 102 controls). Answers to 98 questions were analyzed. 35 questions yielded significant between groups differences. 25 of these items were objective (i.e. related to observable behaviors) and could be investigated through a proxy; 10 were subjective (related to inner states or subjective experience) and could be explored through clinical interviews. 13 questions resulted in similar responses between clinically and self-diagnosed women, but differed in controls, and therefore could be useful to detect true autism cases (e.g. “Do you express distress during grooming or when you are touched?”); 11 questions differentiated the clinically diagnosed from the control group, but not the clinically diagnosed from the self-diagnosed group. These items may be useful to discriminate between true and false autism cases within the self-diagnosed population (e.g. “Are you bothered by bright lights or certain kind of lights (e.g. fluorescent light)?”); 11 questions differentiated the self-diagnosed group from the control group, but no difference was found between the clinically diagnosed and control groups. These questions were mostly related to camouflaging strategies (e.g. “Do you copy or ‘clone’ yourself on other women?”). These questions may be sensitive to non-autistic atypical thoughts and behaviours.

Conclusions: Self-reported screening questionnaires may help to facilitate accurate referral and differential diagnosis, especially in people who have already self-diagnosed as autistic. The Q-ASC may provide information differentiating self-diagnosis grounded in a plausible autistic phenotype (which could be corroborated by multidisciplinary assessment), from misguided identification to the autism spectrum.

415.054 *(Poster)* Early ASD Screening: Can We Reduce Average Age of Diagnosis?

A. T. Wieckowski[1]*, S. E. Nanovic*[1]*, S. Y. Eldeeb*[1]*, T. Hamner*[1]*, L. B. Adamson*[2]*, D. A. Fein*[3] *and D. L. Robins*[1]*, (1)A.J. Drexel Autism Institute, Drexel University, Philadelphia, PA, (2)Psychology, Georgia State University, Atlanta, GA, (3)Psychological Sciences, University of Connecticut, Storrs, CT*

Background: Early screening and diagnosis for children with ASD are critical (Filipek et al., 1999), as early detection and intervention are associated with better outcomes (e.g., Dawson et al., 2010). The American Academy of Pediatrics (AAP; Johnson et al., 2007) recommends universal ASD screening at 18 and 24 months, however, empirical evidence is lacking regarding optimal time points for ASD screening, and whether screening at an earlier age leads to earlier detection. The current study compares children initially screened at 12 months to children screened at the recommended 18 months.

Objectives: This study aimed to: 1) Determine the average age of attending an ASD evaluation when screening is initiated at 12 months compared to 18 months of age; 2) Explore differences in evaluation follow-up by screening age.

Methods: Toddlers (n = 4556) were screened for ASD during primary care check-ups. Sixteen primary care clinics were randomized to begin screening for ASD at 12 months (8 clinics; n = 1506) using the Infant Toddler Checklist (ITC; Wetherby & Prizant, 2002) and the First Year Inventory Lite (FYI-L; Baranek et al., 2009) or 18 months of age (8 clinics; n = 3050) using the Modified Checklist for Autism in Toddlers, Revised, with Follow-Up (M-CHAT-R/F; Robins, Fein, & Barton, 2009). Children enrolled at 12 months were rescreened using the M-CHAT-R/F at 18 months and 24 months of age. Children enrolled at 18 months were rescreened with the M-CHAT-R/F at 24 months of age. Of these children, 272 children who screened positive attended a comprehensive autism evaluation (12m n = 112; 18m n = 160).

Results: Children screened at 12 months were evaluated at a younger age (M = 16.72 m, SD = 3.81) than children screened at 18 months (M = 23.65 m, SD = 6.77; $t(270) = -9.79$, $p < .001$). Earlier screening led to evaluations at younger ages across diagnostic outcome (ASD: $t(99) = -5.16$, $p = .02$; DD: $t(105) = -6.09$, $p < .001$; TD: $t(62) = -6.05$, $p < .001$). However, following a positive screen, evaluation attendance prior to a subsequent screen was lower for the 12 month vs. 18 month group (29.13% vs. 43.30%; X^2 (1, N=515) = 11.16, $p < .001$).

Conclusions: Earlier initial screening, at 12 months of age, compared to later initial screening, at 18 months of age, led to earlier age of receiving an ASD evaluation. Although children who are screened earlier obtain evaluations at a younger age, families are less likely to attend the evaluation following a positive screen compared to children initially screened at 18 months. Caregivers’ acceptance of ASD risk appears to be lower for younger children. However, when they do attend an evaluation, diagnosis can occur even before 18 months, allowing for potentially earlier treatment. Further studies are needed to explore factors associated with evaluation attendance and strategies for ensuring that children who do not attend very early evaluation are rescreened and evaluated if ASD risk remains indicated.

415.055 *(Poster)* Early Autism Identification Disparities in Rural and Medically Underserved Populations

S. N. Brasher[1] *and J. L. Stapel-Wax*[2]*, (1)School of Nursing, Emory University, Atlanta, GA, (2)Emory University School of Medicine, Atl, GA*

Background: Research indicates the sooner children with autism spectrum disorder (ASD) are diagnosed and begin evidence-based treatments, the better their long-term health outcomes. While a valid ASD diagnosis can be achieved at age 2, the current average age of diagnosis is between 4 and 5. These delays more profoundly impact families of children with ASD living in rural and medically underserved areas (MUAs). Little is known about the geographical health disparities encountered by these families and ways to effectively minimize them.

Objectives: To identify barriers and facilitators to ASD diagnosis and treatment for families living in rural or MUAs.

Methods: Three focus groups were conducted in-person and online (e.g., Zoom) with parents of children with ASD living in rural and MUAs. A total of twenty participants engaged in focus group sessions. Open- and closed-ended questions were used to identify barriers and facilitators to treatment in rural or MUAs, as well as patient-centered solutions to minimize disparities. Sessions were audio recorded and transcribed. Data were analyzed by three independent qualitative coders using interpretive description qualitative methods.

Results: Identified barriers to ASD diagnosis included distance to healthcare services, limited access to providers, inadequate insurance coverage, lengthy wait times, and lack of education on ASD. Barriers to ASD treatment included distance, limited number of providers, insurance, cost, and competing demands of the family. Facilitators to ASD diagnosis included school system referrals, research studies, and large ASD research centers. Facilitators to ASD treatment included online support groups (e.g., Facebook), school-based treatments, and insurance extenders. Parent-identified ways to minimize barriers were to increase education, enhance awareness of ASD and needs of rural and MUAs, and improve access to care. Parents proposed interventions of telehealth and mobile clinics to improve access to diagnostic and treatment services. Qualitative analysis revealed recurring parental themes of decreased parental autonomy, frustration, disappointment, uncertainty, and desire for support. Results of this study found the use of online (e.g., Zoom) and in-person focus groups to be equally effective in engaging families of children with ASD living in remote and underserved areas.

Conclusions: Early diagnosis and treatment are critical for improved long-term health outcomes of children with ASD. However, little is known regarding factors that contribute to such delays among children in disadvantaged rural or MUAs. Engaging parents of children with ASD is an important step to identifying ways to break the cycle of health disparities. Families living in rural and MUAs face many barriers related to ASD diagnosis and treatment. Future interventions should address these barriers by increasing awareness of ASD, increasing knowledgeable providers, and utilizing electronic technologies to engage individuals in these areas. Research is currently being planned to further engage families of children living in rural and MUAs to better understand effective ways to reduce barriers to diagnosis and treatment in rural and MUAs.

415.056 *(Poster)* Early Detecting for Autism in Young Children before 36 Months of Age in Taiwan: A Five-Year Follow-up Study

***C. C. Wu**, Department of Psychology, Kaohsiung Medical University, Kaohsiung, Taiwan*

Background: Autism spectrum disorder (ASD) is thought as an innate neurodevelopmental disorder. Over past decade, some studies reported that prevalence of ASD has increased markedly. However, compared to Western countries, the prevalence of ASD in Taiwan is lower, especially for young children. There are a few reasons that cause the differences of the prevalence, such as stigma in Chinese culture, policy of government, and limitation of screening tools for young children etc. Previous studies reported that early intervention improved outcomes for toddlers with ASD. The benefits of early intervention highlighted the importance of earlier identification of young children with ASD. Thus, there is a clear need for improvements in the early identification for ASD in Taiwan.

Objectives: The purpose of this longitudinal study was planned to investigate the predictive accuracy and stability of the Modified Checklist for Autism in Toddlers (M-CHAT）, the Taiwan Version of Screening Tool for Autism in Two-Year-Olds, (T-STAT）and the Autism Diagnostic Observation Schedule (ADOS) which used to detect ASD in young children before 36 months of age at initial assessment who were followed up 5 years after initial assessment.

Methods: We recruited 97 young children with developmental problems aged from 18 to 36 months (Time 1) in this study. Both T-STAT and ADOS are interactive tools which provide a chance for examiner to observe and assess all young children while the M-CHAT is parent-report scale for caregivers to fill out based on daily behaviors of their children. All of M-CHAT, T-STAT and ADOS were used to assess and classify participants at initial assessment (Time 1). And, at 5 years after initial assessment (Time 2), all of young children received assessment again for making final diagnosis. Finally, there are 45 children with ASD and 52 children with Non-ASD.

Results: The classification of the M-CHAT showed poor predicative accuracy (.42-.76) and stability (.53-.71) for detecting ASD in young children before 36 months of age. And, the classification of the T-STAT showed fair predictive accuracy (.76) and stability (.76) for detecting ASD in young children before 36 months of age. In addition, the classification of the ADOS had high predictive accuracy (.82) and stability (.86) for detecting ASD in young children before 36 months of age. Compared to screening tools of parent-report scale (i.e. M-CHAT), the screening tools of interactive method (i.e., T-STAT, ADOS) showed better predictive accuracy and stability.

Conclusions: The findings showed that the accuracy and stability of the ADOS and the T-STAT was high than the M-CHAT, especially for ADOS. However, due to the limit of time in the clinical setting and burden of clinical staff in Taiwan, the T-STAT is still worth to be promoted for screening ASD in young children before 36 months of age as it is a less time-consuming screening tool while its validity was only a bit lower than the ADOS. The finding of this study needs to replicate with large participants and provides implications for early screening.

415.057 *(Poster)* Early Sensory Reactivity Is Associated with Changes in ASD Symptoms from 14 to 23 Months

***R. Grzadzinski**[1], S. Zheng[2], H. Lee[3], J. Sideris[4], L. Turner-Brown[5], G. T. Baranek[3] and L. R. Watson[6], (1)Carolina Institute for Developmental Disabilities, University of North Carolina, Chapel Hill, NC, (2)Psychiatry, University of California, San Francisco, San Francisco, CA, (3)Chan Division of Occupational Science and Occupational Therapy, University of Southern California, Los Angeles, CA, (4)Frank Porter Graham Child Development Institute, Chapel Hill, NC, (5)UNC TEACCH Autism Program, University of North Carolina at Chapel Hill, Chapel Hill, NC, (6)Department of Allied Health Sciences, University of North Carolina at Chapel Hill, Chapel Hill, NC*

Background: Children with Autism Spectrum Disorder (ASD), and those at elevated likelihood to develop ASD (EL-ASD), often display atypical patterns of sensory reactivity, including hyporeactivity, hyperreactivity, and sensory seeking behaviors. More atypical sensory reactivity patterns have been associated with poorer social skills, increased mood and anxiety symptoms, and worse adaptive behaviors. To date, little research has explored the relationship between early sensory reactivity patterns and changes in ASD symptoms over time.

Objectives: (a) Examine associations between sensory reactivity at 14 months and changes in ASD symptoms by 23 months. (b) Determine if sensory reactivity at 14 months moderates intervention effects on ASD symptoms by 23 months.

Methods: Participants included 87 EL-ASD children (60 boys) identified at 12 months based on community screenings with the *First Year Inventory 2.0*(Baranek et al., 2003). Children were administered the *Sensory Processing Assessment*(SPA) and parents completed the *Sensory Experiences Questionnaire*(SEQ). Both the SPA and the SEQ yield domain scores in hyporeactivity, hyperreactivity, and sensory seeking behaviors. Assessment with the *Mullen Scales of Early Learning*(MSEL) yielded scaled scores for visual reception (VR). The *Brief Observation of Social Communication Change*(BOSCC), a treatment response measure that quantifies changes in ASD symptoms, was applied to parent-child free-play videos using standard coding procedures at Time 1 and Time 2 (23 months of age; +/- 0.86) to examine changes in child ASD behaviors in the social-communication (BOSCC-SC) and restrictive/repetitive behavior (BOSCC-RRB) domains.Children participated in a randomized controlled trial of parent-mediated intervention and were randomly assigned to an experimental (Adapted Responsive Teaching; ART; n=45) or control group (Referral to Early Intervention and Monitoring; REIM; n=42); there were no main effects of group on BOSCC outcome. Linear regressions were conducted to examine the relationship between sensory domains scores on changes in BOSCC-SC and BOSCC-RRB, controlling for VR at Time 1. Moderation analyses were also conducted to examine the interaction effects (Group x SPA hyporeactivity or SEQ seeking).

Results: Higher SPA hyporeactivity scores at Time 1 were significantly associated with less improvement in BOSCC-SC (r=0.31, p=0.02). Moderation results revealed that there was a statistically significant moderation effect of SPA hyporeactivity at Time 1 (group x SPA hyporeactivity; p=0.01), indicating that SPA hyporeactivity at Time 1 differentially impacted the relationship between treatment group and improvements in BOSCC-SC (more BOSCC-SC improvement was seen in the ART group with lower SPA hyporeactivity scores compared to the REIM group). See Figure 1. Higher SEQ Seeking scores at Time 1 predicted more improvement on the BOSCC-RRB domain (r=0.25, p=0.03). Moderation results indicated that there was not a statistically significant moderation effect of SEQ Seeking at Time 1 (group x SEQ seeking p=0.13). Results were not statistically significant for SPA hyperreactivity, SPA seeking, SEQ hyperreactivity, or SEQ hyporeactivity.

Conclusions: Specific types of sensory reactivity may be associated with differential patterns of change in ASD symptoms and differential response to early intervention. This work may contribute to defining empirically supported ASD subtypes and provide novel targets for early interventions.

415.058 *(Poster)* Examination of Racial and Sex Differences in Restricted and Repetitive Behaviors in Toddlers Diagnosed with Autism Spectrum Disorder

B. Brooks[1]*, C. Aoki*[2]*, N. Hendrix*[3] *and C. Klaiman*[1]*, (1)Marcus Autism Center, Children's Healthcare of Atlanta and Emory University School of Medicine, Atlanta, GA, (2)Marcus Autism Center, Emory University School of Medicine, Atlanta, GA, (3)Marcus Autism Center, Emory University School of Medicene, Atlanta, GA*

Background: Research investigating restricted and repetitive behaviors (RRB) in males and females has yielded mixed results. Hiller et al. (2014) found that females demonstrated less severe and less frequent RRBs when compared to males. Additionally, Ramsey et al. (2018) found that parents of males tended to report more RRB-related symptoms when compared to parents' report of females. In contrast, studies of young children have found males and females to be similar when examining the presence and frequency of RRBs (Harrop, Gulsrud, & Kasari, 2015; Frazier et al., 2014). In terms of age-related differences, RRB's tend to present more frequently and intensely in early childhood (Esbensen, Selzter, Lam, & Bodfish, 2009). Though research often examines age and sex related differences in RRBs, race remains a largely unexplored variable. Given that African-American children are more likely to be diagnosed with disruptive behavior disorders prior to receiving an ASD diagnosis (Mandell et al., 2007; Mandell et al., 2009) it is possible that elevations in RRB symptomology may be a contributing factor.

Objectives: This study investigated the racial and sex differences in ADOS-2 RRB total scores in a sample of toddlers diagnosed with ASD. We hypothesized that AA males will demonstrate higher levels of RRBs in comparison to CA males.

Methods: Toddlers (N = 340, M_{age} = 25.05 months, SD = 3.75) were evaluated in an insurance-based academic medical center clinic in Georgia after receiving a referral from their pediatrician regarding concerns for ASD. All toddlers in the sample were diagnosed with ASD using the Mullen Scales, ADOS-2, and a diagnostic interview.

Results: Exploratory findings using an independent samples t-test from the completed dataset at time of submission indicate, AA males (N = 102, M = 4.83, SD = 2.03) did not significantly differ from CA males (N = 151, M = 4.43, SD = 4.43) in total RRB scores; t (251) = -1.50, p = .14. Additionally, no differences were found between AA females (N = 44, M = 4.39, SD = 1.86) and CA females (N = 39, M = 4.21, SD = 1.91) total RRB scores; t (81) = -.44, p = .66. There were also no significant racial differences between males and females at item level of RRB scores.

Conclusions: In our sample of toddlers who received a diagnosis of ASD, there were no racial or sex differences observed in RRB total score on the ADOS-2. Further, there were no differences in the individual items that comprise this domain. This suggests that the RRB profiles of toddlers with ASD are similar across race and sex. It is important to continue to discern how sociodemographic factors influence differences in the early assessment of autism.

415.059 *(Poster)* Examining Symptoms of Autism Spectrum Disorder in Children with Neonatal Abstinence Syndrome

J. F. Scherr[1] *and J. Hamel-Lambert*[2]*, (1)Behavioral Health, Nationwide Children's Hospital, Columbus, OH, (2)Nationwide Children's Hospital, Westerville, OH*

Background: Neonatal Abstinence syndrome (NAS) is characterized by symptoms of withdrawal shortly after birth observed in newborns exposed to drugs, such as opioids, in utero. Withdrawal symptoms are caused by hyperactivity of the central and autonomic nervous systems and include irritability, hypertonia, sleep disturbances, gastrointestinal system dysfunction, seizures, excessive weight loss, and respiratory distress (Reddy, Davis, Ren, & Greene, 2017). Infants with NAS are at increased risk for later neurodevelopmental problems including language delay, impulsivity/hyperactivity, learning difficulties, inattention, and social-communcations problems (Hunt et al., 2007; Maguire et al., 2016; Oei et al., 2017; Sundelin, Wahlsten, & Sarman, 2013); however, there is limited research that has examined symptoms of Autism Spectrum Disorder (ASD) in children with a history of NAS. It is important to identify populations that may be at greater risk for developmental and behavioral problems to inform differential diagnosis and treatment practices.

Objectives: The present study aims to charactize symptoms of ASD in children with a history of NAS with and without a clinical diagnosis of ASD.

Methods: Data was gathered through a retrospective chart review study. Total participants consisted of 31 children between the ages of 2-10 years that presented at a tertiary care hospital between the years 2010-2016. This sample was further characterized to include children with NAS that were diagnosed with ASD (NAS+ASD; N = 16) and children with NAS without a diagnosis of ASD (NAS-; N = 15). Evaluations and diagnostic impressions were completed by a team of psychologists, developmental pediatricians, speech and language pathologists, and psychology trainees. Symptoms of ASD were assessed using a multi-method approach including direct observation and parent report. Total raw scores and individual item scores on the *Childhood Autism Rating Scale* (CARS) were used in the present study to assess ASD symptomology across the groups.

Results: Results from independent samples t-tests were performed to analyze differences in ASD symptom presentation in children with NAS that were diagnosed with (NAS+ASD) or without ASD (NAS-). There was a significant difference in total raw scores on the CARS for the NAS+ASD (M= 35.04; SD= 3.72) and NAS- (M = 22.61; SD = 5.67) groups; t (24) = -6.48, p <.001. There also were significant group differences, with the NAS+ASD group displaying more impairment, across the following items on the CARS-2: emotion regulation, relating to people, body use, object use, visual response, listening response, fear/anxiety, verbal communication, nonverbal communication, imitation, and general ASD impressions. No significant group differences were found on the following items of the CARS-2: adaptation to change, taste/smell/touch response, level/consistency of intellectual functioning, and activity level.

Conclusions: We found a unique profile of similarities and differences in ASD symptom presentation in children with NAS with or without ASD. This preliminary investigation suggests that children with NAS may be at increased risk for ASD and present with a unique symptom profile. It is critical to gain a better understanding of how behavioral symptoms emerge and present in children with a history of NAS to better inform diagnostic decisions and intervention efforts.

415.060 *(Poster)* Executive Functioning Is Associated with Autistic Traits in Preschoolers

A. B. Ratto[1]*, A. C. Armour*[2] *and L. Kenworthy*[1]*, (1)Center for Autism Spectrum Disorders, Children's National Hospital, Washington, DC, (2)Children's National Health System, Washington, DC*

Background: Several studies have reported a relationship between executive functioning (EF) and autistic symptoms, including social communication (Leung et al., 2016) and restricted/repetitive behaviors (Miller et al., 2015). However, this work has focused predominantly on school-aged youth, making it unclear how EF profiles relate to autistic traits in young children. There are indications that EF relates to school readiness in autistic preschoolers (Pellicano et al., 2017); if also related to early autistic traits, EF would be an important target for early intervention.

Objectives: Evaluate the hypothesis that EF is associated with autistic traits in young children.

Methods: Participants were drawn from a clinic-based sample of >2,000 children seen in an autism specialty clinic in Washington, DC. A final sample (N=106) was identified who were <6 years; met DSM-5 criteria for ASD; and completed cognitive testing and the Autism Diagnostic Observation Schedule-2 (ADOS-2): Module 1, 2, or 3. Full-scale IQ (FSIQ) and vocabulary were assessed using a standardized measure (e.g., Wechsler Preschool and Primary Scales of Intelligence-IV). Autistic traits were based on the Comparison Severity Score (CSS) of the ADOS-2, and parent report on the Social Responsiveness Scale-Preschool: Social Communication and Interaction (SCI) and Restricted Interests and Repetitive Behaviors (RRB), and the Communication and Socialization domains of the Vineland Adaptive Behavior Scales-II. EF was measured via parent report on the Behavior Rating Inventory of Executive Functioning-Preschool (BRIEF-P), using the Global Executive Composite (GEC) and the Flexibility Index (FI). See Table 1 for demographics and measures. Stepwise regression analyses were used to assess the association between EF and autistic traits with the following variables considered for entry into the model: gender, FSIQ, vocabulary, and BRIEF-P GEC and FI.

Results: Results generally supported the hypothesis that EF would be significantly associated with autistic traits. The SRS SCI was significantly and uniquely associated with the BRIEF-P FI (β=.60, t=6.98, p<.0001), with the model accounting for large variance (R^2=.60, F=48.78, p<.0001). The SRS RRB was significantly associated with the BRIEF-P GEC (β=.40, t=2.63, p=.01) and FI (β=.50, t=3.25, p=.003), with the full model accounting for large variance (R^2=.74, F=6.90, p=.01). Vineland Communication was significantly associated with the BRIEF-P GEC (β=-.41, t=-3.80, p<.0001) and FSIQ (β=.46, t=5.41, p<.0001), with the full model accounting for large variance (R^2=.44, F=14.45, p<.0001). Vineland Socialization was significantly associated with the BRIEF-P GEC (β=-.39, t=-2.97, p=.004) and FSIQ (β=.32, t=3.06, p=.003), with the full model accounting for moderate variance (R^2=.25, F=8.82, p=.004). Across analyses, increased EF problems were associated with higher autistic traits. Higher IQ was associated with better social and communication skills. The ADOS CSS was not significantly associated with any variables.

Conclusions: EF is significantly related to autistic traits in young children in our analyses, in some cases more strongly than cognitive abilities. It is notable that this association held only for parent-report measures, and thus may be driven by known associations of informant report across domains. Further studies are warranted to evaluate the association of EF and autistic traits over development and across measurement contexts.

415.061 *(Poster)* Exploratory and Confirmatory Factor Analyses of Aberrant Behavior Checklist Ratings By Special Education Staff in Autism Spectrum Disorder Samples

R. Birnbaum[1]*, M. A. Volker*[2]*, J. A. Toomey*[3]*, J. G. Fine*[2]*, G. Lee*[4]*, C. Sung*[5]*, T. Zeng*[6]*, N. Bergamo*[2]*, M. Stoll*[2] *and N. Mathes*[2]*, (1)Pediatrics, Division of Pediatric Psychology, Michigan Medicine/University of Michigan, Ann Arbor, MI, (2)Counseling, Educational Psychology, and Special Education, Michigan State University, East Lansing, MI, (3)Summit Educational Resources, Getzville, NY, (4)Michigan State University, East Lansing, MI, (5)Department of Counseling, Educational Psychology and Special Education, Michigan State University, East Lansing, MI, (6)Curriculum and Instruction, University of Massachusetts Boston, Boston, MA*

Background: The Aberrant Behavior Checklist-Community (ABC-C; Aman & Singh, 1994, 2017), originally designed for individuals with intellectual disabilities (ID), is now frequently used in autism spectrum disorder (ASD) intervention research. Though the ABC-C has a proposed five-subscale structure, the existing ABC-C factor-analytic research from ASD samples is limited and has resulted in inconsistent factor solutions and marginally fitting models across studies (e.g., Brinkley et al., 2007; Kaat et al., 2014; Mirwis, 2011). This has raised questions about some previous factor analytic methodology, type of correlation matrix analyzed, factoring strategy, range of factor solutions examined, the criteria for factor retention, and the impact of different rater types.

Objectives: The primary objective of the present study was to examine the factor structure of the ABC-C for students with ASD rated by special education staff. Using robust methods, this was accomplished via an initial EFA in a sample of students with ASD, followed by a CFA assessing the fit of available ABC-C factor models for ASD in a separate validation sample.

Methods: Ratings were completed by special education staff members from a center-based, educational agency in New York state that services students with developmental disabilities. The EFA sample consisted of 300 students with ASD, ages four to 21 years (M = 9.17, SD = 4.38), and mean IQ of 56.49 (SD = 18.25). An EFA of the inter-item polychoric correlation matrix was performed using principle axis factoring and direct oblimin rotation. Number of factors retained was determined through a combination of parallel analysis, Velicer's MAP, Kaiser criterion, scree plot, and factor interpretability. The CFA sample consisted of 243 students with ASD, three to 21 years of age (M = 10.79, SD = 4.53), with a mean IQ of 56.69 (SD = 18.71). The CFA was performed using the weighted least squares mean and variance adjusted estimator (WLSMV) in Mplus 8.2 with the inter-item polychoric correlation matrix as input. (Supplemental information criterion indices were generated, using the maximum likelihood estimator, for cross-model comparisons.) Fit of six available ABC-C factor models, from other ASD studies and the EFA, was assessed using absolute and relative fit indices, and information criterion indices.

Results: EFA results led to retention of nine correlated factors. CFA fit indices for the nine-factor model were generally reasonable to marginal (χ^2[1560, N = 243] = 3021.42, p < .001; RMSEA = .062; SRMR = .083; CFI = .941; and TLI = .938). However, all other models yielded poorer fit estimates across all indices. Furthermore, information criteria indices (AIC and BIC) were lowest for the nine-factor model, suggesting that it fit better than competing models from the ASD ABC-C factor analytic literature. Close inspection of the nine-factor solution suggested aspects of the ABC-C in need of revision.

Conclusions: Results from the EFA and CFA clearly suggested the presence of more than five interpretable ABC-C factors based on ratings from special education staff—with a nine-factor solution fitting best. Findings also highlighted the need for scale revisions to improve interpretability and model fit.

415.062 *(Poster)* Exploring Extraordinary Skills and Relative Strengths in Children with Autism Spectrum Disorder and Cognitive Impairment

***E. Wilkinson**, G. B. Gunin, M. Turley and V. H. Bal, Graduate School of Applied and Professional Psychology, Rutgers University-New Brunswick, Piscataway, NJ*

Background: Although approximately one-third of children with ASD have intellectual disability (ID) (Baio et al., 2016), they are considerably underrepresented in research (Russell et al., 2019). Research on the strengths of these individuals is particularly lacking. In a study of individuals with ASD or ID, every participant had at least one parent-reported strength, but profiles of strengths varied widely (Carter et al., 2015). This important study, however, included only a small proportion of individuals with both ASD and ID. Further research is needed to characterize strengths in individuals with ASD who also have cognitive impairment. This knowledge will inform the development of interventions and supports that leverage and promote strengths.

Objectives: 1) To examine the frequency of parent-reported relative strengths and extraordinary skills in children with ASD and nonverbal IQ≤70. 2) To characterize the cognitive and behavioral profiles of children with parent-reported strengths.

Methods: Participants were 424 school-age children with NVIQ ≤70 from the Simons Simplex Collection (see Table 1). Children were grouped based on parent report of no outstanding skill (NS), relative strength (RS), and extraordinary skill (ES) in six different skill areas assessed on the Autism Diagnostic Interview-Revised (items 88-93). Paired-sample T-tests were used to examine within group cognitive profiles (verbal, nonverbal reasoning and spatial). One-Way ANOVAs were used to compare verbal, nonverbal reasoning and spatial skills across groups. Independent-sample T-tests were used to compare the NS group to children with any parent-reported RS/ES on scores from the Differential Abilities Scale-II, Vineland Adaptive Behavior Scales-II, Aberrant Behavior Checklist, and ADI-R.

Results: Fifty-four percent of children had at least one parent-reported strength (RS n=156, ES n=105). Frequency of parent-reported strengths varied greatly by domain. Music was the most frequently reported RS (23%) and ES (16%), while computation and drawing were the least frequently endorsed (<4% each). As shown in Figure 1, across skill areas, children in each group (e.g., ES, RS, NS) exhibited higher nonverbal reasoning and spatial skills, relative to verbal abilities ($p<0.05$). One exception was the ES-Reading group, which showed a more even profile. The ES-Reading group also exhibited higher verbal abilities compared to the NS- and RS-Reading groups (d=.81, p=.02; d=.87, p=.05, respectively), while nonverbal skills did not differ across groups. Those with at least one reported strength did not differ from those who had no outstanding skills reported on measures of adaptive behavior, behavior problems, or autism symptoms.

Conclusions: More than half of parents of children with cognitive impairment endorsed relative strengths or extraordinary skills. Children with and without parent-reported outstanding skills were highly similar across other behavioral domains. The relative lack of group differences on broad assessments of cognition and behavior suggests a need for more research to directly assess and characterize skills in these domains reported by parents. Regardless, the high endorsement of outstanding skills suggests a need for research to investigate strengths more broadly. By focusing solely on areas of impairment, we are likely to miss opportunities for improved supports and targeted interventions to promote each individual's potential.

415.063 *(Poster)* Expressive Communication Growth Trajectories of Young Children with Autism: Exploring a Novel Progressing Monitoring Tool

A. Wallisch[1], *J. Buzhardt*[1], *D. Irvin*[1], *B. A. Boyd*[1], *B. Salley*[2] *and F. Jia*[3], *(1)Juniper Gardens Children's Project, University of Kansas, Kansas City, KS, (2)Pediatrics, University of Kansas Medical Center, Kansas City, KS, (3)Department of Psychology, University of California, Merced, Merced, CA*

Background: Social-communication and language skills are important intervention targets for children with ASD because they represent pivotal skills that affect children's developmental potential. The field has made progress in developing measures to characterize and diagnose the language and social-communication patterns of children with ASD. However, to date few standardized measures exist that are sensitive to change over time (Anagnostou et al, 2015; Bolte & Diehl, 2013) and can be used by early childhood practitioners to inform intervention decision making. The Early Communication Indicator (ECI) is one of the Individual Growth and Development Indicators (IGDIs) for Infant and Toddlers (Carta, Greenwood, Walker, & Buzhardt, 2010) developed to address the need for easily administered and scored measures to monitor children's growth and inform intervention decisions for children 6-42 months. Despite evidence that the ECI is sensitive to a child's general disability status, to date, there have been no formal investigations of the measure's sensitivity to specific diagnoses, such as ASD.

Objectives: In the current study, we sought to conduct exploratory analyses of ECI scores of children known to either have an ASD diagnosis at the time of administration or would receive a diagnosis in the future.

Methods: We performed a secondary analysis with data drawn from two registries. One registry is from a university diagnostic center and the other registry is from the IGDI Online Data System. We matched participants from the IGDI registry with those in the diagnostic registry who received an ASD diagnosis, and this resulted in n=23 matches. We used multilevel growth modeling with two levels in each growth model, observation-level and child-level.

Results: Children with ASD had significantly lower ECI total weighted scores than the benchmark sample (-11.66, se = 3.06, $p < .01$) at 42 months of age, but there was no significant difference in the linear or quadratic slopes between the two samples. For the key skill elements, the ASD sample demonstrated significantly higher rates of vocalizations than the benchmark sample at 42 months of age (1.63, se = 0.54, $p < .01$), as well as a faster growth rate (0.07, se = 0.03, p = .03). Conversely, for single words, the ASD sample used fewer single words at 42 months of age (-2.50, se =0.48, $p < .01$), and they had a lower linear growth rate than the benchmark sample. For multiple words, a similar pattern was observed whereby children with ASD demonstrated fewer multiple words at 42 months of age (-3.73, se = 0.78, $p < .01$) and had a slower rate of linear growth (-0.19, se = 0.06, $p < .01$).

Conclusions: These exploratory findings suggest that the ECI can be used to characterize the communication profiles and trajectories of young children with ASD. We found that the magnitude of both prelinguistic (i.e., vocalizations, gestures) and linguistic (i.e., single and multiple words) communication skills, as well as the rate for growth differed between children with ASD when compared to a benchmark sample.

415.064 *(Poster)* Factors Contributing to Age of Autism Spectrum Disorder Diagnosis in Children

C. Jorgenson[1] *and K. Nowell*[2], *(1)University of Missouri - Columbia, Columbia, MO, (2)Thompson Center for Autism & Neurodevelopmental Disorders, Columbia, MO*

Background: Clinicians can reliably diagnose autism spectrum disorder (ASD) in children as young as 2 years (Kleinmann et al., 2008). Many individuals are diagnosed later, with some undiagnosed until adolescence. Early intervention improves outcomes for individuals with ASD (Fuller et al., 2019) and those diagnosed in adolescent years miss earlier opportunities for treatment and support. A recent review concluded greater symptom severity and increased parental concern are associated with younger age of diagnosis, but findings regarding the impact of other sociodemographic and phenotypic factors (e.g., socioeconomic status, IQ, comorbid diagnoses) have been mixed (Daniels & Mandell, 2014). This could be due to heterogeneity across and within samples.

Objectives: To (1) evaluate sociodemographic and phenotypic variables that may differentially predict age of ASD diagnosis in verbally fluent individuals (as operationalized by being administered ADOS-2 Module 3) and (2) compare secondary and tertiary diagnoses among verbally fluent individuals diagnosed with ASD near the mean age of diagnosis and those diagnosed with ASD during their adolescent years.

Methods: Assessment results were reviewed for 222 individuals (*M* age = 9.64 years; 79.3% male) who received an ASD diagnosis at a tertiary care clinic. Standard multiple regression models were conducted with age of diagnosis as the dependent variable. Two standard multiple regression models were conducted evaluating sociodemographic variables (i.e., gender, income) and phenotypic variables independently (i.e., verbal and nonverbal IQ, ADOS-2 scores). Two groups were also formed from the participants: those diagnosed within 0.5 SD of the average age of diagnosis in the sample (n=97, *M* age=6.90 years) and individuals diagnosed more than 1.5 SDs above the average age of diagnosis in the sample (n=47, *M* age = 15.26 years).

Results: With regard to phenotypic variables, age of diagnosis was correlated with nonverbal IQ (r=-0.35, p <.000), verbal IQ (r=-0.18, p<.01), and ADOS-2 RRB total (r=-0.18, p<.01). Multiple R for the regression model was statistically significant, F (9, 159)=6.28. p<.000. Only nonverbal IQ contributed significantly to the prediction of age of diagnosis (p<.000), with higher nonverbal IQ predicting a younger age of diagnosis. With regard to sociodemographic variables, there were no significant correlations between age of diagnosis, gender, and income level. A significantly larger proportion of older participants received tertiary diagnoses (c^2=[1, N=139]=5.36, p=.02). Though there were no significant differences between the younger and older participants regarding specific secondary or tertiary diagnoses, two trends emerged. A larger proportion of participants in the younger group received a secondary diagnosis of ADHD (31.5% compared to 17.0%; c^2=[1, N=139]=3.35, p=.067). A larger proportion of participants in the older group received a secondary diagnosis of intellectual disability (12.8% compared to 4.3%; c^2=[1, N=139]=3.30, p=.069).

Conclusions: The only variable that was a significant predictor of age of diagnosis was nonverbal IQ. Themes emerged in rates of secondary and tertiary diagnoses, however, there were no significant differences in younger and older participants by specific diagnosis. Significantly more participants in the older group received a tertiary diagnosis, which may reflect more clinically complex cases being diagnosed at a later age.

415.065 *(Poster)* Factors Contributing to Late Diagnosis in Females with Autism Spectrum Disorder

A. Aitken[1], *C. A. McMorris*[2], *J. Ninowski*[3] *and A. Prichard*[4], *(1)School and Applied Child Psychology, University of Calgary, Calgary, AB, Canada, (2)Werklund School of Education, University of Calgary, Calgary, AB, Canada, (3)Autism Spectrum Disorder Diagnostic Clinic, Alberta Children's Hospital, Calgary, AB, Canada, (4)Child Development Services, Alberta Health Services, Calgary, AB, Canada*

Background: Children who receive an autism spectrum disorder (ASD) diagnosis at an older age (i.e., at or above the age of 5 years) may miss out on early behavioural supports and intervention (Mussey et al., 2017). Factors impacting the age at which a child receives an ASD diagnosis include cognitive and adaptive functioning, severity of ASD symptoms, and the complexity of symptoms a child presents with. For instance, children with higher cognitive and adaptive functioning, and milder ASD symptoms, often receive a diagnosis of ASD at an earlier age (Duvekot et al., 2017; Hull, Mandy, & Petrides, 2017; Ratto et al., 2018; Salazar et al., 2015). However, findings from existing literature have been mixed examining what clinical factors impact diagnosis in females with ASD, in particular. As females typically receive a diagnosis of ASD at an older age compared to males, understanding what unique factors contribute to this delay is essential in ensuring early access to intervention.

Objectives: The present study aimed to: 1) replicate previous research demonstrating that females often receive a diagnosis at an older age than males; and 2) identify the clinical factors (e.g., cognitive functioning, ASD symptom severity, adaptive functioning, and co-occurring disorders) that might impact late diagnosis, particularly in females.

Methods: Psychological reports of 58 males and 32 females seen at The Autism Spectrum Disorder Diagnostic Clinic (Calgary, AB) for a comprehensive assessment were reviewed. Date of birth; biological sex; language spoken at home; family status; schooling information; assessments completed and services obtained to date; co-occurring diagnoses present prior to attending the diagnostic clinic; age at ASD diagnosis; and scores on specific assessment measures (cognitive, adaptive, ASD severity) were abstracted from each file.

Results: Females did not receive a diagnosis of ASD at an older age (M = 10.50, SD = 4.08) than males (M = 9.43, SD = 2.78). Cognitive functioning, ASD symptom severity, and adaptive functioning did not predict receiving a diagnosis later in life, and biological sex did not influence this relationship. The presence of co-occurring disorders predicted age at diagnosis, in that participants with more pre-existing co-occurring developmental and mental health disorders received a diagnosis at an older age. However, biological sex did not influence this relationship.

Conclusions: Females are at a particular disadvantage of missing out on early supports as on average females receive their ASD diagnoses at an older age than males. However, results from this study indicate there may be more males diagnosed at an older age than previously thought, and that perhaps there is a unique presentation of ASD that is not solely seen in females. TO ensure access to early intervention, it is crucial the health community understands why some individuals with ASD are being diagnosed much later than others, and how to detect these unique profiles in individuals at an earlier age.

415.066 *(Poster)* Gender Differences in Compensation Among Adolescents with ASD

E. J. Libsack[1] *and M. D. Lerner*[2], *(1)Stony Brook University, Stony Brook, NY, (2)Department of Psychology, Stony Brook University, Stony Brook, NY*

Background: Some individuals with autism spectrum disorders (ASD) may employ specific cognitive strategies to alter social behaviors to appear less impacted by ASD symptoms, despite persisting impairments at cognitive and/or neurobiological levels, a phenomenon recently coined as "compensation" (Livingston et al., 2017 & 2018). Previous research has contrasted overt social behavior with Theory of Mind (ToM) performance to specify four compensation patterns in ASD (high, low, deep, and unknown) and have found gender may influence manifestation of particular compensation strategies (with males being more likely to exhibit the "unknown" pattern; Livingston et al., 2018). However, this research has relied on expensive and idiosyncratic measures that limit estimation of compensation in other ASD populations. It remains unclear whether other widely-used measures of social behavior and cognition may offer more accessible, cost-effective means for measuring compensation in ASD. Identification of such tools is an important step toward identifying individuals who may otherwise evade formal ASD diagnosis and/or be at greater risk of experiencing negative mental health outcomes, which have been associated with compensation in ASD (Livingston et al., 2019).

Objectives: To explore 1) whether the four compensation patterns could be specified using accessible measures of social behavior and cognition, 2) whether those patterns differ by gender, thereby partially replicating previous compensation research (Livingston et al., 2018).

Methods: Participants were 99 adolescents (77 male) ages 11-17 (M_{age}=14.04, SD_{age}=2.03) with IQ ≥ 70 and ADOS-2 confirmed ASD diagnosis. Social communication skills were measured as the Social Communication and Interaction subscale fom the parent-report Social Responsiveness Scale, Second Edition (SRS-2-SCI; Constantino, et al., 2012). ToM performance was assessed using adolescents' accuracy during an accessible, computerized ToM paradigm (McKown et al., 2015; Russo-Ponsaran et al., 2019). Moderation analyses were performed to assess whether the relationship between social communication and ToM (i.e., the 4 compensation patterns) differs between genders.

Results: A significant interaction was found between SRS-2-SCI and ToM accuracy in predicting participants' gender (b = XX, p = XX), such that higher ToM accuracy is related to a greater likelihood of being male when SRS-2-SCI scores are low (i.e. deep compensation), while higher ToM accuracy is related to greater likelihood of being female when SRS-2-SCI scores are high (i.e. unknown condition; Figure 1). Low and high compensation groups were equally likely to be male or female.

Conclusions: These results replicate the presence of the four compensation patterns using more widely-used and -accessible measures of social cognition and behavior in a large sample of adolescents with ASD. Findings show the deep compensation pattern was associated with male gender. Conversely, female gender was associated with the unknown compensation pattern. Results contrast with prior findings showing the highest male:female ratio in the "unknown" condition (Livingston et al., 2018). However, findings suggest that compensation may indeed differ by gender, but that the combination of social cognitive and social behavioral measures used may uniquely influence estimates of these gender differences. Future research should further explore various measurement approaches of compensation to further elucidate this emerging construct.

415.067 *(Poster)* Hidden Literacy in Minimally Verbal Individuals with ASD Revealed By Involuntary Eye Movements

K. Ellert[1], *N. Shefer - Kaufmann*[2] *and Y. S. Bonneh*[3], *(1)School of Optometry and Vision Science, Bar-Ilan University, Ramat-Gan, Israel, (2)Clalit institute for child development, Tel-Aviv, Israel, (3)School of Optometry and Vision Science, Bar-Ilan University, Ramat Gan, Israel*

Background: Minimally-verbal individuals with ASD (MV-ASD), estimated as 30% of the spectrum, who have little or no spoken language, are typically assumed cognitively impaired after failing conventional tests for cognitive abilities. However, it is yet unclear whether these failures reflect a true cognitive impairment or, alternatively, a severe deficit in behavioral expressions of cognitive skills. Here we suggest that for some or many of the MV-ASD individuals, the main barrier for communication is a severe difficulty in the initiation and control of reliable voluntary or intentional actions, i.e. an "output problem", which calls for using involuntary or physiological measures that could possibly bypass the action-control barrier, such as involuntary eye movements. We presented preliminary results from this study in INSAR 2019.

Objectives: Assess basic reading and lexical-semantic knowledge in young adults with MV-ASD using eye movement measures in comparison to pointing performance.

Methods: Young adults with MV-ASD (N=18, ages 15-24, all with less than 30 communicative words) were tested on a novel "cued looking" paradigm (adaptation of "looking-while-listening"; Fernald et. al., (2008)). Participants watched a sequence of stimuli while their eyes were tracked. In each trial, a text word was presented at fixation (1s), followed by a pair of familiar objects pictures (fruits, animals, vehicles etc., 10 pairs) presented (1s) side by side (~6 deg each side), with next trial following after 800ms. There were 4 short runs (<1 min) repeated 3-6 times in random order with breaks. In a second experiment, the written words were replaced by recorded words. In a third (reading) and fourth (listening) experiments, the same pictures and text were used on 20 cards to measure performance via pointing. We analyzed the lateralization of the eye-gaze according to target side, the time course of correct gaze side, saccade direction and rate modulation. Statistics were obtained via non-parametric permutation tests.

Results: 16 of the 18 MV participants showed a significant effect of reading as reflected by correct lateralization estimates of 75-100% (average 81%), significant from 240-800ms post stimulus onset (group average, p=0.001). In comparison, a control group of young adults (n=10) showed correct lateralization of 90-100% (average 96%). Overall, the MVs made smaller lateral eye movements (3 vs 6 deg.) but were as fast in terms of movement onset. The results of experiment 2 (vocal words) were similar, but only for 10 of 15 MVs tested. In a striking contrast, 14 of the 16 MVs who showed significant reading with the eyes were at or near chance level in pointing (40-65%, 55% on average, compared to 100% of controls).

Conclusions: These results provide the first systematic evidence for reading ability in individuals typically assumed to be severely language and cognition impaired. The results also demonstrate a striking gap between pointing performance and gaze fixation, which opens the way for uncovering unknown cognitive abilities in people with MV-ASD. This would have a significant impact on the way these individuals are treated, and on the intervention young minimally verbal children receive.

415.068 *(Poster)* How Clear Are the Differences between ADHD and ASD Diagnoses in Gifted Children?

T. C. Kalmus[1], *L. G. Casten*[1], *T. Koomar*[2], *T. Nickl-Jockschat*[2], *T. Abel*[3], *S. Assouline*[2] *and J. Michaelson*[4], *(1)Psychiatry, The University of Iowa, Iowa City, IA, (2)The University of Iowa, Iowa City, IA, (3)University of Pennsylvania, Philadelphia, PA, (4)Division of Computational and Molecular Psychiatry, Iowa City, IA*

Background: Twice-exceptional (2e) individuals are often under- or misdiagnosed due to limitations in the current diagnostic paradigms for autism spectrum disorders (ASD) and related conditions. Specifically, the cognitive and behavioral profiles of these individuals have not yet been well established, nor have boundaries between diagnoses been defined in high-ability individuals.

Objectives: 1 - Observe cognitive and behavioral functioning in 2e individuals with ASD; 2 - Contrast functional patterns to other 2e groups and gifted/talented controls

Methods: Gifted and 2e individuals were assessed by licensed clinicians at a midwestern-US assessment clinic for talented youth. Of the children assessed (n = 1,366), 506 individuals completed both the Weschler IQ Scale and the Behavior Assessment System for Children (BASC). Diagnostic status varied: 203 were 2e with ADHD, 31 were 2e with ASD, 26 were 2e with ADHD+ASD, and 246 were gifted, IQ-matched controls.

One-way analysis of covariance (ANCOVA) was conducted to explore diagnostic group differences in IQ and BASC sub scores corrected for age. Tukey HSD and Cohen's d were calculated for sub scores with a significant main effect for diagnostic group difference in functioning or a significant diagnostic group by age interaction difference in functioning.

Results: Diagnostic group differences existed in two IQ indices. A significant main effect for diagnostic group($F = 5.002$, $p = 0.002$) and a diagnostic category by age interaction($F = 3.501$, $p = 0.015$) for Processing Speed was noted. Here, individuals with ASD only had significantly lower processing speed than their ADHD and gifted peers. Working Memory demonstrated significant diagnostic group by age interaction($F = 5.696$, $p < 0.001$), yet no significant main effects were found in working memory between groups. The remaining IQ subscales did not display differences in functioning due to diagnostic category.

Intriguing behavioral profiles emerged from the BASC. Aggression($F = 10.769$, $p < 0.001$) and Attention($F = 55.769$, $p < 0.001$) differed between affected and unaffected groups. Differences in Adaptability($F = 34.002$, $p < 0.001$), Atypicality($F = 31.415$, $p < 0.001$), Functional Communication($F = 27.943$, $p < 0.001$), and Leadership($F = 28.697$, $p < 0.001$) distinguished all groups from one another while ASD and ADHD+ASD were statistically indistinguishable. Conduct Problems($F = 7.239$, $p < 0.001$) was associated with ADHD, but not with either ASD or ADHD+ASD. ASD and ADHD+ASD were statistically indistinguishable from one another on Withdrawal($F = 13.892$, $p < 0.001$), as were ADHD and gifted controls. Anxiety scores did not reach significance across diagnostic groups.

Conclusions: Twice-exceptional individuals with ASD demonstrated a behavioral pattern indicative of "classic autism", regardless of a co-morbid ADHD diagnosis. BASC scores suggest 2e with ASD is often associated with struggles in Adaptability, Functional Communication, and more. IQ data demonstrated a key reduction in processing speed for 2e with ASD. Interestingly, 2e individuals with ADHD+ASD do not exhibit the same deficit in cognitive functioning, while still exhibiting the same behavioral struggles. These findings suggest that diagnostic boundaries exist in 2e individuals. Interventions tailored to the unique weaknesses of 2e with ASD may foster best outcomes for affected individuals.

415.069 *(Poster)* Identification of Parent-Report Questions Which Elicit the Most Accurate Estimates of Language Ability

C. Farmer[1], *V. Ardulov*[2], *M. Kumar*[2], *A. J. Kaat*[3], *A. Thurm*[1], *S. Kanne*[4], *S. Georgiades*[5], *S. Narayanan*[2], *S. Bishop*[6] *and C. Lord*[7], *(1)National Institute of Mental Health, Bethesda, MD, (2)University of Southern California, Los Angeles, CA, (3)Department of Medical Social Sciences, Northwestern University, Chicago, IL, (4)Thompson Center for Autism and Neurodevelopmental Disorders, Columbia, MO, (5)McMaster University, Hamilton, ON, Canada, (6)University of California San Francisco, San Francisco, CA, (7)University of California, Los Angeles, Los Angeles, CA*

Background: Autism spectrum disorder (ASD) is characterized by heterogeneity in symptom presentation and severity; at least some of this is explained by variability in cognitive and language ability. Because social communication skills are highly dependent on language, the latter must be accounted for by any attempt to measure the presence or severity of the symptoms of ASD. One example of this is within the Autism Diagnostic Observation Schedule (ADOS), wherein module is selected by the clinician based on a language sample. In the absence of an expert clinician or a language sample, most parent report measures which modulate content based on language ability rely on gross categorizations like *some speech* versus *no speech*. However, precise routing on measures of parent-reported social communication ability relies upon the accurate ascertainment of specific language level (e.g., no words, simple phrases, three-word phrases, fluent speech), which parents report less reliably.

Objectives: Our goal was to identify the combinations of parent-reported items which most accurately identify the specific language level of the child (operationalized as the ADOS module). The results of this study will inform the composition of routing items on a new developmentally based measure of social communication skills. In these initial analyses we explore the Communication items (n=74) of the Vineland Adaptive Behavior Scales, Second Edition (VABS).

Methods: Data were aggregated across eight clinical and research datasets yielding 10,051 individuals with and without neurodevelopmental disability from 27 sites; for the current analysis the sample was limited to the first available observation from each individual which contained item-level data on the VABS (n=490) (84% male, mean age 51±31 months). The first stage of analysis was a random forest classification model with stratified K-fold cross validation to compare the null model (age only) to a model with age and VABS Communication items.

Results: The proportion of participants with each ADOS module were as follows: Toddler/Module 1, 65% (n=318); Module 2, 23% (n=114); Module 3/4, 12% (n=58). Model accuracy of the null model was 0.67±0.08 and the F1 score (an index of the balance between sensitivity and specificity) was 0.58±0.08. The addition of VABS features improved model accuracy to 0.74±0.04 and F1 to 0.84±0.02. Age and Expressive item 24 (tells about experiences in simple sentences...) were the most important features, followed by several other Expressive Language items (e.g., tells basic parts of story..., uses 'and'...) (Figure 1).

Conclusions: The initial results of this study confirm that data from parent-reported VABS items may be used to discriminate between the discrete language levels operationalized by the ADOS module. Content analysis of the most important features suggests that providing context for parents may be important; for example, asking whether a child uses sentences to describe experiences rather than simply asking whether a child uses sentences may elicit a response more consistent with clinical impression based on a language sample. In future work, we will perform incremental feature selection methods to perform ablation studies for feature importance, and ultimately will pilot different versions of routing questions based on these results.

415.070 *(Poster)* Identifying Measured Characteristics on ADOS, ADI-R and SRS Differentiating ASD from ADHD

V. Ardulov[1], *K. Somandepalli*[1], *N. Anand*[1], *S. Zheng*[2], *E. E. Salzman*[3], *S. Bishop*[4], *C. Lord*[5] *and S. Narayanan*[1], *(1)University of Southern California, Los Angeles, CA, (2)Psychiatry, University of California, San Francisco, San Francisco, CA, (3)Psychiatry, UCSF, San Francisco, CA, (4)University of California San Francisco, San Francisco, CA, (5)University of California, Los Angeles, Los Angeles, CA*

Background:

Attention Deficit/Hyperactivity Disorder (ADHD) and Autism Spectrum Disorder (ASD) are neurodevelopmental disorders that can be challenging to differentiate, especially in verbal, school-age children (Grzadzinski et al. 2016). Clinicians would benefit from more information about specific ASD-related behaviors that best differentiate ASD and ADHD cohorts.

Objectives: To identify items from three widely used ASD symptom measures (ADI-R, ADOS-Module-3, and SRS) that maximally differentiate children with ASD from ADHD..

Methods: Participants were selected from an existing registry of children assessed clinically for ASD or as part of research on ASD and other NDDs. Participants with ASD were selected to match the ADHD sample for age, IQ, and verbal ability. The final sample consisted of 463 verbal school-aged children (49-158 months) with a best estimate clinical diagnosis of ADHD (119 (25.7%)) or ASD (344). Of the 463 children examined, 254 (54.8%; n_{ASD}=177; n_{ADHD}=77) had SRS scores available, enabling an additional analysis including SRS items.

For each item we estimated Student's two-sample *t-statistic* (*t*) to quantify the difference in scores between the diagnoses, and further confirmed the findings using relative entropy (Kullback-Leibler divergence D_{KL}). A value of 0 for D_{KL}or *t* indicates that the two distributions are identical. Larger estimates indicate dissimilar distributions.

Results:

Our results over all 463 reports show that the ADOS and ADI-R items corresponding to facial expression and unusual eye contact have the highest relative entropy between the two clinical groups. Next, scores corresponding to language and speech patterns, social communication and conversational skills in that order were the most differentiating. Applying the same analysis to a subsample of children with available SRS scores, yielded similar results highlighting the same ADOS and ADI-R items as most differentiating.

Among the SRS items, "Does not join group activities unless told to do so", and "Has trouble keeping up with the flow of a normal conversation" yielded the largest t-statistic and entropies with t=-5.5417 ($p<0.01$; D_{KL}=0.3238) and t=-5.3922 ($p<0.01$; D_{KL}=0.3925) respectively.

The two estimates provide complementary information suggesting that the distributions of item scores across the diagnostic conditions were likely sampled from different populations, and hence maximally differentiating between the ADHD and ASD symptoms.

Conclusions:
Consistent with previous research (Grzadzinski et al. 2016, Bishop et al. 2016), we identified directly observed basic social communication behaviors (e.g. eye contact, facial expression) as being most effective in differentiating ASD from ADHD. Language abnormalities and difficulties with conversation also emerged as key differentiating items. Notably, conversational skills were the most differentiable items among those reported by parents, while eye contact, facial gestures, and language ability were identified by clinicians.This suggests that, especially among children referred for ASD assessment, parent-reported atypicalities in basic social-communication and language are less useful than direct observation by clinicians when it comes to certain basic aspects of social-communication.

415.071 *(Poster)* Implementing and Evaluating Social Attention and Communication Surveillance (SACS) to Prospectively Identify Autism in Very Young Children in Nepal

R. Shrestha[1]*, C. Dissanayake*[1] *and J. Barbaro*[2]*, (1)Olga Tennison Autism Research Centre, La Trobe University, Melbourne, Australia, (2)Olga Tennison Autism Research Centre, La Trobe University, Melbourne, VIC, Australia*

Background: Early identification of Autism Spectrum Disorder (ASD) is the key first step in early intervention. Although children can be identified as early as 12 months and diagnosed reliably by 24 months, the mean age of diagnosis of ASD in Nepal is ~58 months, with many children missing the opportunity to access early intervention. There is an urgent need for a low-cost, easily accessible, early identification approach in Nepal.
Objectives: The objective in the current study was to implement and evaluate a Nepali version of Social Attention and Communication Surveillance (SACS-N), to identify children between 11-30 months who are at "high likelihood" of ASD in a local community (Kirtipur Municipality) in Nepal. The implementation of SACS-N was evaluated through: 1) referral rates of children identified at 'high likelihood" of ASD when monitored at 12, 18 and 24 months, 2) the PPV (the proportion of children identified as high likelihood on the SACS-N who were diagnosed with ASD, and 3) prevalence estimates of ASD in 11-30-month-olds in Kirtipur.
Methods: Sixty Female Community Health Volunteers (FCHVs) were trained on typical and atypical development of social attention and communication, the early signs of ASD, and how to monitor "key" markers of ASD in infants and toddlers using SACS-N. They were also trained to refer children who showed these early signs to the AutismCare Nepal Society (ACNS).
Results: A total of 1926 children were monitored using the SACS-N during the period of November 7, 2016, to July 16, 2018, with a total of 11 children (0.57%) referred for further assessments to the ACNS (8 male; 3 female;– M:F ratio 3:1) at 11-15 months (n = 4), 16-21 months (n = 4), and 22-30 months (n = 3). Of these 11 children, no information was available on one child (n = 1) who migrated out of Kirtipur. All remaining children (n = 10) had a developmental disorder, including ASD and Global Developmental Delay (GDD). Hence, the overall PPV of SACS-N for all developmental disorders was 100%. Of the children who attended the diagnostic/development assessment at ACNS (n = 7), three had ASD giving a PPV for ASD of 43%. The estimated prevalence of ASD in the current study ranged between 0.16 % to 0.26%.
Conclusions: The findings provide preliminary evidence of the feasibility of implementation of SACS-N by trained FCHVs in a local community in Nepal, which served to identify both children with ASD and GDD. Community-based developmental monitoring of ASD and other developmental delays by FCHVs is a cost-effective and sustainable approach to promoting early identification of developmental disorders in Nepal. However, further training and awareness of ASD is needed to increase referral rates using the SACS-N, including regular supervision of FCHVs.

415.072 *(Poster)* Implications of Developmental Screening and Monitoring Receipt for Reducing Racial/Ethnic Disparities in Early Autism Identification.

B. Barger[1]*, T. W. Benevides*[2] *and S. Rizk*[3]*, (1)Georgia State University, Atlanta, GA, (2)Occupational Therapy, Augusta University, Augusta, GA, (3)Department of Occupational Science and Technology, University of Wisconsin-Milwaukee, Milwaukee, WI*

Background: Minority children are less likely to receive an early ASD diagnosis. Furthermore, recent research suggests that conjoint receipt of screening and monitoring is associated with children having greater odds of receiving early intervention and treatment than receipt of screening or monitoring alone. While there is a large body of research outlining racial/ethnic disparities in early ASD identification, there is little work on understanding the interaction between race/ethnicity with screening and monitoring receipt in decreasing early identification disparities.
Objectives: The study reports preliminary findings on the relationship between screening and monitoring and early ASD receipt, and seeks to determine if racial/ethnic disparities in receipt of screening and monitoring are associated with differences in early identified ASD cases. We will test the following hypotheses:

- The odds of identified ASD before the age of 5 will be strongest for children receiving conjoint screening and monitoring and weaker for children receiving screening or monitoring alone;
- There will be minimal racial differences in early identified ASD among populations receiving conjoint screening or monitoring; and
- In populations receiving screening and monitoring alone, compared to White children, Black and Hispanic children will have lower odds of identified ASD

Methods: For these analyses, we used the combined National Survey of Children's Health (NSCH) 2016, 2017, and 2018 with weights appropriately combined per Census Bureau guidance. Reported analyses are survey weighted and stratified logistic regression models ($N_{non\text{-}asd}$ = 28855; N_{asd} = 332). The core model is a *screening/monitoring* (Conjoint, Alone, and None [ref]) X *race/ethnicity* (White [ref], Black, Hispanic, Other) interaction, statistically controlling for: child health, state early intervention Child Find screener cut-off policy, metropolitan status, whether child has a personal doctor or nurse or usual source of care, poverty level, caretaker education status, insurance status, marital status of parents, English language status of caretaker.

Results: Compared to populations receiving none, populations receiving conjoint screening and monitoring had more early identified ASD cases (β=2.58, OR=13.21[4.68-37.32], p<.001) followed by monitoring (β=1.80, OR=6.05[1.98-18.52], p=.002), but not screening (β=0.10, OR=1.10[0.22-5.49], p<.91). Race/ethnic differences between early identified ASD cases in populations receiving conjoint screening and monitoring trended toward statistical significance with Black children having higher (Black: β=2.39, OR=10.95[0.97-123.57], p=.05) and Hispanic lower (Hispanic: β=-1.59, OR=0.20[0.04-1.02], p=.05) ASD compared to White; no differences for Other races (Other: β=-0.64, OR=0.53[0.10-2.81], p=.45). Black children differed from White in screened (Black: β=4.31, OR=74.61[3.83-145.50], p=.004) and monitored populations (Black: β=3.88, OR=48.51[4.04-582.52], p=.002), though not in the hypothesized direction. ASD rates did not differ between White and other races/ethnicities receiving screening (Hispanic: β=1.51, OR=4.53[0.47-44.06], p=.19; Other: β=-0.64, OR=1.16[0.08-16.87], p=.92) or monitoring (Hispanic: β=-0.83, OR=0.44[0.05-3.47], p=.43; Other: β=0.52, OR=0.44[0.27-10.69], p=.58).

Conclusions: Conjoint screening and monitoring received by children 5 and under is associated with greater odds of identified ASD cases, and lower racial/ethnic differences. Notably, across all screening/monitoring populations, Black children were more likely to be identified with ASD compared to White. These data underscore the importance of providing developmental screening and monitoring to minority populations to decrease early ASD identification disparities.

415.073 *(Poster)* Importance of Age of Initial Diagnosis: A Comparison of Factors in Early and Delayed Initial ASD Diagnosis

C. Shulman[1,2]*, Z. Nir*[1] *and D. Shmueli*[3]*, (1)The School of Social Work, The Hebrew University of Jerusalem, Jerusalem, Israel, (2)The Hebrew University of Jerusalem, The Autism Center, Jerusalem, Israel, (3)Child Development, Clalit HMO, Jerusalem, Israel*

Background: Autism spectrum disorder (ASD) is a heterogeneous neurodevelopmental disorder, in which symptoms are present in the early developmental period. Although there is increasing evidence that clinicians can reliably identify children on the autism spectrum as young as 2 years of age, some individuals receive the ASD diagnosis later, presumably only when social demands exceed their capabilities. Because these individuals may present with a more subtle phenotype and/or exhibit a prolonged course of symptom development, early diagnosis is precluded. It is important to study ASD manifestation at initial diagnosis in order to avoid misdiagnosing or under-diagnosing ASD after the preschool years. The present study focuses on children referred for initial ASD diagnosis at three time periods in an attempt to analyze similarities and differences in the heterogeneity of ASD.

Objectives: The overall goal of the present research is to compare ASD symptomatology in children referred for an initial ASD assessment at various time periods. Analyses contend with heterogeneity in the severity of symptoms, language and cognitive skills, and co-occurring conditions in girls and boys referred for an initial ASD diagnosis at 3 age periods.

Methods: In order to investigate similarities and differences in the profiles of children with ASD diagnosed for the first time at different ages we have analyzed cross-sectional data from 30 children at each of three formative time periods: (1) early diagnosis group between 18-30 months; (2) transition from early childhood to elementary school between 5-6 years; and (3) school-aged children who are coping with increasing social demands at age 8-10. Variables include autism severity, cognitive abilities, language capabilities, behavioral profiles, and associated conditions.

Results: All age groups revealed heterogeneous profiles for the variables, with some patterns emerging. The early diagnosis group was the most homogeneous, with some intellectual and language developmental delay, while the two older groups revealed more co-occurring conditions. In addition, the later diagnosis group showed less intellectual and language disability. Autism comparison scores on the ADOS were less severe in the 8-10 age group, many of whom came with prior diagnoses. In particular, more than half of the older group had a previous diagnosis of either attention deficit disorder and/or specific language impairment. Males and females revealed different behavior profiles, with girls exhibiting more anxiety and boys more externalizing behaviors.

Conclusions: Overall, our data suggest that individual factors contribute to variation in age of diagnosis. The older the age of diagnosis, the milder the autism symptomatology, which means that some individuals are overlooked. If these disparities can be addressed in diagnostic instruments and clinical expertise, these children would receive appropriate intervention earlier, increasing their opportunities for optimal outcomes. Our data can inform public health officials and clinicians identify and explore methods for earlier identification and intervention, even after the preschool years.

415.074 *(Poster)* Improving Autism Spectrum Disorder Diagnosis Using the Screening Tool for Toddlers with Autism and Checklist for Autism Rating Scale

A. Wedel[1]*, J. Grauzer*[2]*, A. Miller*[2] *and M. Roberts*[2]*, (1)Northwestern University Feinberg School of Medicine, Chicago, IL, (2)Communication Sciences and Disorders, Northwestern University, Evanston, IL*

Background: Although a reliable diagnosis of Autism Spectrum Disorder (ASD) can be made at 24 months, the median age of diagnosis in the U.S. is 52 months. With evidence that earlier ASD-specific intervention predicts better outcomes, there is an urgent need to improve the diagnosis of children with autism. Limitations to diagnosis include limited use of ASD-specific screening measures by pediatricians, coupled with the low sensitivity of some of the current tools. Once a child is identified for concern for ASD, they are often referred to a developmental evaluation, where wait times range from 4-12 months, further delaying diagnosis. Better diagnostic tools are needed that could reasonably be used within a general pediatrician's office in order to facilitate early identification of children with ASD, and reserve more complex cases for full developmental evaluations.

Objectives: The aim of this study is to evaluate how adding a checklist, the Childhood Autism Rating Scale (CARS), to the Screening Tool for Autism in Toddlers (STAT), a 20-minute behavioral assessment, improves the diagnostic accuracy of an autism diagnosis in toddlers.

Methods: The sample includes 134 toddlers between 24-36-months-old who were evaluated for a diagnosis of ASD by a multidisciplinary team. Diagnostic outcomes were determined based on the expertise of the team, using their best clinical estimate. As a part of their assessment, the STAT was performed and scored in real time, while the CARS was scored later based on the video of the STAT by expert raters who were blind to diagnostic outcomes. Expert raters achieved scoring reliability and inter-rater reliability was completed for 20% of the videos. LASSO regressions were used to determine which items were the most predictive, and were further used to create two-threshold cutoffs to divide participants into diagnostic groups.

Results: The original cutoff scoring of the CARS yielded a sensitivity of 0.79, specificity of 0.78, and a positive predictive value (PPV) of 0.90. The original cutoff scoring of the STAT yielded a sensitivity of 0.92, a specificity of 0.72, and a PPV of 0.89. A LASSO regression model for the STAT and CARS items related to restricted and repetitive behaviors (RRBs) was used to determine an optimal threshold which yielded a sensitivity of 0.97, specificity of 0.75, and a PPV of 0.91. A two-threshold scoring method was employed, using LASSO regression of CARS RRB items and the STAT, to create three diagnostic groups, no ASD, unknown, and has ASD, and 54% of the sample was accurately identified as not having ASD or having ASD.

Conclusions: The current ASD screening methods used in general pediatric offices are not sufficient to address the discrepancy between when children can and actually are diagnosed. Using a 20-minute behavioral assessment, the STAT, along with a checklist of RRB items from the CARS would allow general pediatric practices to accurately diagnose a majority of their patients, reserving the remaining, more ambiguous cases for referral to developmental evaluations. This would allow for earlier targeted interventions for those diagnosed, and shorter wait times for those referred.

415.075 *(Poster)* Influence of Family Structure on Age at Diagnosis Among Children with Autism Spectrum Disorder

L. Kalb[1,2], *C. B. Holingue*[3,4], *G. F. Azad*[1], *E. F. Dillon*[2], *P. Danika*[5], *R. Reetzke*[2], *B. Freedman*[6] *and R. Landa*[2], *(1)Department of Mental Health, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, (2)Center for Autism and Related Disorders, Kennedy Krieger Institute, Baltimore, MD, (3)Mental Health, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, (4)Neuropsychology, Kennedy Krieger Institute, Baltimore, MD, (5)Kennedy Krieger Institute, Baltimore, MD, (6)Center for Disabilities Studies, University of Delaware, Newark, DE*

Background: Despite the importance of early detection and intervention, differences in age of Autism Spectrum Disorder (ASD) diagnosis remain due to various sociodemographic factors. The nature and quality of the relationship between the child's biological parents plays an important role during the diagnostic process, and in turn may be one such factor contributing to disparities in age of diagnosis. While several studies have examined changes in family structure (e.g., parental divorce, separation) after a child receives an ASD diagnosis, little, if any, research has examined the relationship between family structure and the age at which the child receives their ASD diagnosis.

Objectives: To understand the extent to which age of ASD diagnosis differs between children with biological parents who are married/together and those who are separated, divorced, or were never married.

Methods: Data for this study came from parents of 517 youth who were evaluated at a Mid Atlantic, urban, ASD outpatient specialty clinic. Youth were only included if: a) parents reported their clinic appointment was the youth's first ASD evaluation; b) the youth received an ASD diagnosis per DSM-V criteria; c) the evaluation included the Autism Diagnostic Observation Schedule, Second Edition (ADOS-2); and d) parents agreed to join the clinic research registry (83% consented; consent status was not related to study outcome).

The median age at diagnosis was 4.5 years (Mean = 5.8 y, Min = 1.5 y, Max = 18.1 y, SD = 3.7 y). Eighty percent of the sample were males, 41% were receiving Medical Assistance, 48% were Caucasian (24% African American, 12% Multiracial, 9% Asian, 6% Hispanic, 1% Other), and 58% of parents did not have a Bachelor's degree. Measures in this study included autism-symptom severity (ADOS-2 Total Score; Lord et al., 2012), child mental health (Child Behavior Checklist; Achenbach, 1992), and demographics, including family structure (via custom clinic forms). Bivariate (Wilcoxon) and multivariate (linear regressions) analytic methods were used to address the study objective.

Results: Most (69%) biological parents were together during the child's initial diagnosis, of which 91% were married and 9% were living together but not married. Among biological parents who were not together (31%), most were never married (65%) and the remaining were divorced (24%) or separated (10%). Median age at ASD diagnosis was 1.9 years later among children whose biological parents were not together, when compared to those who were (4.0 y vs. 5.9 y, $z = -4.8$, $p < .001$).

After adjusting for child race, gender, insurance-type, parental education, ADOS-2 Total scores and module-type, child mental health, number of current (non-diagnostic) services, calendar year, referral source, and number of siblings, children of biological parents who were not together were diagnosed 1.6 years later than children of parents who were together ($\beta = 1.64$, 95% CI: 0.9, 2.4, $t = 4.39$, $p < .001$).

Conclusions: Family structure was a robust predictor of age at first ASD diagnosis, second only to medical comorbidities. Providing support for these families could provide an important pathway to increasing access to early screening, diagnosis, and intervention.

415.076 *(Poster)* Longitudinal Change in Core Symptoms of Autism Spectrum Disorder in Children: Online Survey of Caregivers

C. Liu[1], *G. Durán-Pacheco*[1], *M. Silkey*[1], *M. Johnson*[2], *J. K. Law*[3,4] *and G. Loss*[1], *(1)Personalized Health Care Data Science, Real World Data, F. Hoffmann-La Roche Ltd, Basel, Switzerland, (2)Personalized Health Care Data Science, Real World Data, F. Hoffmann-La Roche Ltd., Welwyn Garden City, United Kingdom, (3)Maryland Center for Developmental Disabilities, Kennedy Krieger Institute, Baltimore, MD, (4)Johns Hopkins University School of Medicine, Baltimore, MD*

Background: To assess the efficacy of interventions for autism spectrum disorder (ASD), it is important to identify reliable and valid outcome measures that reflect changes in a real-world setting. The Autism Impact Measure (AIM) is a caregiver-administered outcome assessment designed to capture subtle changes in core symptoms of ASD. A longitudinal study was conducted to explore the utility of the AIM score to capture annual changes in symptom severity.

Objectives: This study aimed to describe longitudinal (1-year) changes in AIM scores, by deriving anchor-based clinically important responder (CIR) thresholds, describing determinants of changes measured by those thresholds, and assessing the impact of ASD on caregivers.

Methods: This was a longitudinal electronic caregiver survey with two assessments, 1 year apart, sampled from the US-wide Simons Foundation Powering Autism Research for Knowledge (SPARK) online research initiative. Online surveys assessed demographics, AIM, caregiver impressions of ASD symptoms, and ASD-related caregiver strain among SPARK participants (caregivers of dependents with a professional diagnosis of ASD and aged 3–17 years at baseline). Primary analyses focused on changes in total AIM score (i.e. change of overall core symptoms) between baseline and follow-up. CIR thresholds were derived from coefficients of a linear model of AIM score change during the year as a function of caregivers' assessment of improvement or deterioration during that time as reported in a Caregiver-reported Global Impression of ASD symptom Change survey (CaGI-C; designed to assess caregivers' perceptions of change in severity of ASD symptoms).

Results: Children with ASD (N=2,761 at second assessment) were mostly male (79.2%) with a median (interquartile range) age of 9.0 years (7.0–13.0). Of the 1,078 with reported IQ scores, 74.0% had an IQ score ≥71. Among the total study population, a correlation (r=0.16, p<0.01) was observed in the expected direction between the total AIM score change and the CaGI-C anchor. The relative change in estimated AIM CIR threshold (95% CI) over 1 year for symptom improvement was –2.6% (–4.0, –1.1) and 4.3% (2.1, 6.6) for symptom deterioration. Lower caregiver-reported severity, and children being verbal, lacking cognitive impairment, and being less prone to wandering or eloping, were all found to be associated with symptom improvement (p<0.05). Use of prescription medication, cognitive impairment, inclination to wander or elope, higher rate of hospitalization for mental care, and higher caregiver-reported severity were found to be associated with symptom deterioration (p<0.05). Reports of strain across all assessed caregiver-strain domains (personal time, work, finances, relationships, happiness, fears for child's future, and tiredness) positively correlated with higher AIM scores at follow-up, i.e. worsened ASD symptoms (r=0.39–0.53).

Conclusions: Among a large sample of individuals with ASD in the United States, anchor-based CIR thresholds for, and determinants of, 1-year changes in AIM scores were identified, representing an important benchmark for a relatively new measure. AIM has potential to be used as a clinically meaningful outcome assessment of the core symptoms of ASD. Future longitudinal research at longer time intervals could be conducted to further assess how AIM scores might be used in a real-world setting.

415.077 *(Poster)* Longitudinal Stability of Intelligence Function in Autism Spectrum Disorder: From Age 3 to Adulthood

M. D. Prigge[1]*, E. Bigler*[2]*, N. Lange*[3]*, A. L. Froehlich*[4]*, J. Morgan*[1]*, C. K. King*[4]*, J. B. King*[4]*, B. A. Zielinski*[5]*, J. S. Anderson*[1]*, A. L. Alexander*[6] *and J. E. Lainhart*[7]*, (1)Radiology and Imaging Sciences, University of Utah, Salt Lake City, UT, (2)Brigham Young University, Provo, UT, (3)McLean Hospital, Cambridge, MA, (4)University of Utah, Salt Lake City, UT, (5)Pediatrics and Neurology, University of Utah, Salt Lake City, UT, (6)Medical Physics & Psychiatry, University of Wisconsin - Madison, Madison, WI, (7)Psychiatry, University of Wisconsin - Madison, Madison, WI*

Background: Intelligence measures are often used to classify individuals as having an intellectual disability as well as between "low" and "high" functioning autism. Lower levels of intellectual functioning have been associated with higher levels of autism symptom severity and as a factor in assessing long-term outcome. However, little has been reported about the stability of intelligence metrics in autism spectrum disorder (ASD), especially during the transitions from childhood through adolescence and into adulthood.

Objectives: Examine age-related changes and stability of measures of intelligence in the Utah Longitudinal Autism study, an NIH funded project that began testing individuals in 1995, where children as young as 3 years of age were enrolled and have been tracked to the current time frame.

Methods: This descriptive analysis examined all available intelligence scores collected from 1995-2018 from 127 participants on the autism spectrum (120 male, 7 female; mean age 19.9 years, range 2.9-57.9; n=449 visits) and 128 participants as a typically developing comparison group (TDC: 122 male, 6 female; mean age 20.1 years, range 3.6-39.7; n=222 visits). Due to the participant age range and changing protocols over the course of the study, a number of intelligence measures were collected (Mullen, DAS, WISC-III, WASI, WAIS-III, WAIS-IV) providing summary Intelligence Quotients (Full-Scale IQ (FSIQ), Verbal IQ (VIQ), Performance IQ (PIQ)) and Index scores (Verbal Comprehension (VCI), Perceptual Organization (POI), Working Memory (WMI), Processing Speed (PSI)). Linear mixed effects models examined longitudinal changes in intelligence scores over time in the ASD group compared to the TDC sample.

Results: In ASD, all intelligence quotients (FSIQ, VIQ, PIQ) and index scores (VCI, POI, PSI) significantly increased with age except for WMI. FSIQ and VIQ increased with age in the ASD group at a greater rate than the TDC sample. To examine whether age-related changes were driven by the younger ASD participants or persisted throughout adulthood, we reran the mixed models only including participants 18+ years of age (ASD n=96, 235 visits; TDC n=98, 132 visits). We no longer found significant age effects for VIQ or VCI, suggesting stable verbal scores during adulthood in our ASD sample. Finally, an evaluation of IQ stability in those with repeated test scores showed intraclass correlation coefficients (ICCs) ranging from .76 (PIQ) to .85 (WMI). The ASD subgroup with repeated full Wechsler testing (WAIS-III or WAIS-IV) had higher ICCs that ranged from .84 (PIQ, PSI) to .92 (WMI).

Conclusions: Despite similar intelligence summary scores, test version must be taken into account when examining stability of IQ metrics over time. In our sample, verbal intelligence, that may tap into communication impairment evident for the diagnosis of ASD, improved during childhood. Working memory remained the most stable intelligence score throughout the age range sampled. Which intellectual measures remain stable or are variable in ASD over transitions from childhood throughout adolescence and into adulthood has implications with regards to educational planning, vocational training as well as treatment focus.

415.078 *(Poster)* Low Median County Level Income Associated with Higher Rates of Missed Cases of Autism in Georgia Public Schools

T. W. Benevides[1]*, B. Barger*[2] *and B. Trueblood*[3]*, (1)Occupational Therapy, Augusta University, Augusta, GA, (2)Georgia State University, Atlanta, GA, (3)Augusta University, Augusta, GA*

Background: A large body of literature suggests that differences in access to services among children with autism spectrum disorder (ASD) are not accounted for by actual differences in need for services. These disparities in access can prevent children with ASD from receiving both medically indicated and educationally relevant supports. Some literature suggests that factors at the child or family levels, such as race/ethnicity or insurance status, impacts service receipt. Other literature suggests that system-level factors such as availability of resources or policies impact service receipt. There is a need to understand local and state-level factors contributing to lack of access so that system-level interventions aimed at reducing disparities for children with ASD can be developed.

Objectives: The purpose of this study was twofold—first, we aimed to identify rates of unidentified children with ASD using county-level and state-level education records in Georgia; second, we aimed to understand county level socio-demographic factors that related to lower expected rates of autism identification at the county level.

Methods: We used linear regression to evaluate the contribution of county factors on rates of unidentified children with ASD. The outcome variable of interest, *unidentified children with ASD in the school district*, was calculated by comparing actual number of children with an educationally-relevant 'autism' classification (per GA Department of Education records) to the expected number of children with ASD. Expected number of children with ASD was calculated using CDC estimates and the Census Bureau totals of children for that county in 2013. County level predictors included: median household income, high-school graduation rate, minority population rate, and number of primary-care providers per 100,000 people.

Results: In Georgia, 113 (71%) of 159 counties had available educational data on autism in 2013. Counties without educational data on autism classification were significantly more likely to be rural than those with data. Counties ranged in rates of *unidentified children* (15.28-84.12%), with higher rates of unidentified children reflecting lack of children being served with an autism classification in the school district. A statistically significant linear regression ($F[6,103]=3.27$, $p=.006$) was found ($R^2 = .16$). The only significant variable was county median household income ($B= - 0.0006$, $p=.002$). Geographical representation of the counties with low median household income (<$40,000) and high rates of unidentified children (> 60% missing) is pictured (Figure 1).

Conclusions: Research on differences in ASD identification frequently focuses on racial/ethnic disparities, insurance characteristics, and provider biases. Our analysis suggests that median household income at the county level is an important predictor related to school-based autism classification in Georgia, even after controlling for other non-significant factors such as county-level education, availability of providers, minority rates, and rural county status. For each $10,000 reduction in median income, the estimated ASD missing rate increased by 6%. School districts are often the primary providers of autism-relevant identification and intervention services, especially for families who may lack resources. Consideration of the impact of household income on school district resources, and addressing income inequality, may be important aspects of reducing disparities in autism service provision in schools.

415.079 *(Poster)* Maternal Perinatal Depression and Risk of Autism: Preliminary DATA of the "SOS Mood" Project, a Longitudinal Evaluation in Offspring.

M. Siracusano[1,2], *G. Lisi*[3], *A. Benvenuto*[4], *A. Baratta*[4], *A. Riccioni*[4], *L. Paoletti*[4], *M. Ferrara*[4], *G. Tarantino*[3], *L. Emberti Gialloreti*[1], *P. Curatolo*[4], *C. Niolu*[3] *and L. Mazzone*[4], *(1)Biomedicine and Prevention, University of Rome Tor Vergata, Rome, Italy, (2)Department of Biotechnological and Applied Clinical Sciences, University of L'Aquila, L'Aquila, Italy, (3)Systems Medicine, Division of Adult Psychiatry, University of Rome Tor Vergata, Rome, Italy, (4)Systems Medicine, Division of Child Psychiatry, University of Rome Tor Vergata, Rome, Italy*

Background: The increasing prevalence of maternal Perinatal Depression (PD) within pregnant women (10-20%) and the rising use of psychotropic medications during pregnancy (>8%) claims attention on the potential long-term effects on offspring neurodevelopment. A possible association between maternal PD and higher risk of Autism Spectrum Disorder (ASD) has been reported in literature with contrasting results. The question whether prenatal pharmacological exposure or maternal psychiatric disorder is linked with an increased risk of ASD remains inconclusive and requires longitudinal studies.

Objectives: Primary aim of the SOS MOOD project (MOOD of **MO**thers and **O**ffspring's **D**evelopment) is to longitudinally evaluate long-term effects of maternal Perinatal Depression on offspring's socio-communicative and behavioral phenotype, with a focus on the increase of ASD risk. Secondary objective is to characterize the clinical phenotype of Offspring of Perinatal Depressed women pharmacologically Treated during pregnancy [O-PD-T] compared to offspring not exposed to drug treatment [O-PD-NT].

Methods: Pregnant women are enrolled during the 1st-2nd trimester of pregnancy. Currently, data are available for 31 women but the recruitment is still ongoing. Women's psychiatric evaluation of PD was performed during the 2nd trimester of pregnancy (Edinburgh Perinatal Depression Scale-EPDS).Offspring's standardized assessment of developmental quotient (Griffith-III), autistic symptoms (Autism Diagnostic Observation Schedule-ADOS-2; Social Responsiveness Scale-SRS) and hyperkinetic-inattentive behaviour (Conners' Parents), was performed at a mean age of 4 years.

Results: We report preliminary results on 31 women (mean age 34 years) and 31 children (mean age 4 years) (Figure1). 18 women were affected by PD, whereas 13 women did not receive diagnosis of PD. Amongst the 18 PD women, 12 women received pharmacological treatment during pregnancy [PD-T], instead 6 women were not pharmacologically treated [PD-NT]. Within PD women, two children received diagnosis of ASD, whereas amongst healthy control women [HC] no child was affected by ASD. No significant statistical difference emerged between the offspring of women affected by PD [O-PD] and the children of HC women [O-HC], in the level of autistic symptoms and socio-communicative difficulties, measured by ADOS 2-Total Score (mean value: 3.00 O-PD vs 2.5 O-HC), ADOS 2-Calibrated Severity Score CSS (mean: 1.7 O-PD vs 1.5 O-HC), SRS total score (mean: 55.25 O-PD vs 51 O-HC).O-PD-NT scored higher on ADOS 2-Total Score (O-PD-NT mean 4.1 vs 2.5) and ADOS 2-CSS (O-PD-NT mean 2 vs 1.6) compared to O-PD-T. Instead, O-PD-T scored higher on Social Problems (O-PD-T mean 53 vs 44.8), ADHD Index (O-PD-T mean 57.4 vs 47.4) and Total Score of Conners' Parents (O-PD-T mean 52.3 vs 46).

Conclusions: Our preliminary results don't show a significant increased risk of ASD in the children of women affected by perinatal depression compared to offspring of healthy control mothers. However, within O-PD, a different behavioural phenotype emerged, depending on the prenatal exposure to psychotropic medications. In particular, higher subtreshold autistic symptoms and lower defiant-inattentive behaviour currently characterize O-PD-NT. Further analysis on the total sample are necessary in order to clarify the possible long-term impact of maternal PD and prenatal use of psychotropic medications on offspring's socio-communicative and behavioural outcome.

415.080 *(Poster)* Measuring Self-Injurious Behavior to the Head Using a Wearable Acceleration Sensor in Individuals with Autism Spectrum Disorders

M. Inoue[1], *K. Nakatani*[2], *S. Matsuda*[3], *A. Harada*[4] *and K. Suzuki*[5], *(1)Department of Clinical Psychology, Tottori University, Yonago, Tottori, JAPAN, (2)Graduate School of Engineering, Tottori University, Tottori, Japan, (3)Tennodai 1-1-1 Tsukuba, Tsukuba University, Tsukuba, Japan, (4)National Institute of Technology, Yonago College, Yonago Tottori, Japan, (5)University of Tsukuba, Tsukuba, Japan*

Background: Self-injurious behavior (SIB) is apparent in a high proportion of individuals with autism spectrum disorder (ASD). In particular, it has been noted that SIB to the head is likely to be permanent, and early intervention is required.

Objectives: The purpose of this study was to develop a SIB measurement system using an acceleration sensor.

Methods: Participants: Two individuals with ASD participated. Both participants had severe intellectual disabilities. Participant 1 was a 20-year-old woman who had SIB such as hitting her temples or chin with her hand and scratching her head. Participant 2 was a 13-year-old boy and had SIB that involved hitting his head and hips with his hands. For both individuals, their SIBs occurred frequently throughout the day despite behavioral interventions and medications provided.

Materials: A short-wear measurement using an acceleration sensor (Empatica E4 ™ wristband) was performed in the playroom. In this study, we used only acceleration data.

Measurement: The participants wore an acceleration sensor on the wrist on the side where SIB was performed. The measurement was performed 2 to 5 times. At the same time, video recordings of behaviors performed while wearing the wristband were made and the time was synchronized with the behaviors observed. Using the synchronized data, the time periods in which SIB occurred frequently were included in the analysis.

Data analysis: Attempts were made to identify SIB from the sum of the absolute values of the sampled x, y, and z axes of the acceleration and the integration of the sampling interval (hereinafter referred to as ASA). The threshold was examined based on the maximum value of ASA in other behaviors occurring without SIBs such as movement and sitting, and the minimum value of ASA when SIB occurred. When the value is lower, the second smallest value is treated as the minimum value. The coincidence rate was calculated by dividing the number of times the SIB, as assessed by moving image data, occurred by the number of times the threshold in the obtained ASA graph was exceeded and multiplying by 100.

Results: In participant 1, the threshold was set to 0.060. A total of 6 SIBs were observed, 5 of which exceeded the threshold, and the concordance rate was 83.33%. Participant 2 was set to 1.20 as the threshold. A total of 5 SIBs were observed, 4 of which exceeded the threshold, and the concordance rate was 80%. However, the other behaviors without SIBs exceeded the threshold three times.

Conclusions: The findings suggest that the occurrence of SIB can be estimated by the amount of acceleration, and agreement with the coding by the evaluator and the video data was also obtained. However, the other behaviors that exceeded the threshold were also observed. Therefore, it was shown that for individuals with hyperactivity, a method that simply uses a specific value as a threshold may cause false detection of SIB. Measuring self-injurious behavior to the head using a wearable acceleration sensor in individuals with autism spectrum disorders

415.081 *(Poster)* Microanalysis of Daily Living Skills in Adolescents with Autism Spectrum Disorder without an Intellectual Disability

*M. Glover, C. Fassler and **A. Duncan**, Developmental and Behavioral Pediatrics, Cincinnati Children's Hospital Medical Center, Cincinnati, OH*

Background: Daily living skills (DLS) have been associated with a more successful adult outcome in areas such as independent living, postsecondary education, and employment in individuals with autism spectrum disorder (ASD) without an intellectual disability (ID) (Farley et al., 2009). A microanalysis of DLS, as measured by the Vineland Adaptive Behaviors Scales, 2nd Edition and 3rd Edition (Vineland-2 and Vineland-3) will provide insight into the strengths and weaknesses of adolescents with ASD without an ID. An in-depth understanding of the DLS profiles of adolescent can then be used to develop interventions to effectively target DLS and lead to a more successful adult outcome.

Objectives: The aim of the current study was to examine the specific strengths and weaknesses in DLS in adolescents with ASD without an ID as measured by the Vineland-2 and Vineland-3.

Methods: Adolescents with ASD were included in the current study if they had an IQ score ≥70, were between 14-20 years of age, had a diagnosis of ASD based on Module 4 of the Autism Diagnostic Observation Schedule, 2nd Edition (ADOS-2) and/or clinician judgment, and had a complete Vineland-2 and Vineland-3. Subdomain and domain scores from VABS-2 and VABS-3 were analyzed separately due to marked differences in item order and content. Vineland DLS subdomains (i.e., Personal, Domestic, and Community) were analyzed by v-scale scores and age equivalents (AE). Related items within the DLS subdomains were grouped into item sets, (as determined by the VABS-2 item sets and the VABS-3 interview topics), and analyzed at item set level and individual subdomain item level.

Results: The total sample consisted of 70 adolescents with ASD. A paired sample t-test was run to determine if there was a significant difference between the average chronological age and the average AE for each of the DLS subdomains. Because a significant difference was found for each DLS subdomain (all p's < .001), the data was then analyzed at item set and item level. The average score for each item was computed and every item with an average of <1.5 (items are scored at 0, 1, or 2 – with a score of 2 indicating an item is competed independently most of the time) was categorized as a weakness. Items sets were also analyzed for weaknesses by computing the percentage of items that were weaknesses within an item set.

Conclusions: A microanalysis of the DLS domain of the VABS-2 and VABS-3 provided valuable insight into strengths and weaknesses for adolescents with ASD without an ID. On both the VABS-2 and VABS-3, the Domestic subdomain (e.g., cleaning, doing laundry, cooking) had the largest percentage of weaknesses. The item sets with the largest percentage of weaknesses in VABS-2 and VABS-3 were: Health Care, Kitchen Chores, Housekeeping, Job Skills, Money Skills, Going Places Independently, and Achieving Goals (only VABS-3). A larger percentage of items were labeled as weaknesses in VABS-3 compared to VABS-2. The results have important implications and suggest that it is critical to target certain DLS in interventions for adolescents with ASD without ID.

415.082 *(Poster)* Missed Diagnoses of Autism Spectrum Disorder after Initial Negative Developmental Evaluation

***T. Smith**[1], T. L. Hill[2], T. C. White[3], J. Reaven[4], B. Harris[5], N. Reyes[4], B. J. Anthony[6] and L. Anthony[6], (1)University of Cincinnati, Cincinnati, OH, (2)Pediatric Mental Health Institute, Children's Hospital, Colorado, Aurora, CO, (3)Center for Health and Environmental Data, Colorado Department of Public Health and Environment, Denver, CO, (4)JFK Partners, University of Colorado Anschutz Medical Campus, Aurora, CO, (5)Department of Pediatrics, University of Colorado, Denver, CO, (6)University of Colorado, Denver, Aurora, CO*

Background: In 2014, 572 8-year-old children were identified with autism spectrum disorder (ASD) by the Colorado Autism and Developmental Disabilities Monitoring (ADDM) Project, as part of the Centers for Disease Control and Prevention's ADDM Network, which is a population-based surveillance system of ASD. Of the 572 children identified with ASD in Colorado in 2014, 243 (42%) did not have a documented ASD diagnosis in their education and/or health records, indicating a number of children in Colorado may not be receiving optimal services. Notably, these 243 children had documented developmental concerns and underwent at least one developmental evaluation, but were not diagnosed with ASD.

Objectives: To describe a group of children who underwent one or more developmental evaluations, through which they were not diagnosed with ASD, but were identified with ASD during the 2014 surveillance year by the Colorado ADDM Project.

Methods: The current study analyzed data collected by the Colorado ADDM Project for the 2014 surveillance year. Our sample included 243 8-year-old children who resided in Colorado in 2014 and met the ADDM Network ASD case definition, but did not have a documented educational identification or clinical diagnosis of ASD in their records at the time of review. Children's records were reviewed for the number of evaluations completed, type of evaluations received, diagnostic impressions, and documentation of suspicion of ASD.

Results: The children in our sample underwent one to 14 developmental evaluations (M=4.03; SD=2.65), with the age of their first evaluation ranging from three to 104 months (M=51.94; SD=24.64). Many of the children received an occupational therapy evaluation (51%), speech and language evaluation (44%), psychological evaluation (42.8%), or a comprehensive developmental evaluation (42.4%). Suspicion of autism was noted in 65% of the children's records. Furthermore, 58% of children had an autism screener or diagnostic tool documented in their records. Diagnoses given in lieu of ASD included language deficits (57.6%), motor difficulties (49.4%), cognitive difficulties (48.6%), attention deficits (30%), regulatory (i.e., sleeping, eating, and/or sensory processing) difficulties (28%), emotional problems (17.3%), behavior difficulties (11.5%), and genetic conditions (3.7%). For children with identified educational exceptionalities (n=55), documented exceptionalities included specific learning disabilities (27.3%), orthopedic impairments (18.2%), speech or language impairments (16.4%), emotional disturbance (12.7%), other health impairments (9.1%), intellectual disability (7.3%), multiple disabilities (5.5%), developmental delay (1.8%), and traumatic brain injury (1.8%).

Conclusions: Although the majority of children in our sample had suspicion of ASD noted in their records, these children were frequently diagnosed with language disorders, motor difficulties, and cognitive difficulties, which suggests that the presence of other developmental concerns may have masked or overshadowed ASD symptoms, resulting in missed ASD diagnoses. Additionally, our results support the importance of adequate developmental screening and evaluation procedures, as many of the children in our sample did not receive a comprehensive developmental evaluation (e.g., children only underwent an occupational therapy evaluation) and/or did not have an autism screener or diagnostic tool documented in their health or educational records. Furthermore, some of the evaluators may not be allowed to or feel comfortable diagnosing ASD.

415.083 *(Poster)* Modified Checklist for Autism in Toddlers, Revised with Follow-up: A Comparison of Total Scores and Screen Positive Rate By Race/Ethnicity

M. F. Skapek[1]*, Y. G. Dai*[1]*, K. S. Porto*[1]*, M. Barton*[1]*, T. Dumont-Mathieu*[2]*, D. A. Fein*[1] *and D. L. Robins*[3]*, (1)Psychological Sciences, University of Connecticut, Storrs, CT, (2)University of Connecticut, Storrs, CT, (3)A.J. Drexel Autism Institute, Drexel University, Philadelphia, PA*

Background: Children of racial/ethnic minority background receive Autism Spectrum Disorder (ASD) diagnoses substantially later than White, Non-Hispanic children, despite similar prevalence and symptom profiles (CDC 2006; Fombonne, 2003). The Modified Checklist for Autism in Toddlers, Revised with Follow-Up (M-CHAT-R/F; Robins et al., 2014), a widely used two-stage screener, was normed on a predominantly White, non-Hispanic sample. Most previous studies evaluating the performance of the M-CHAT or the M-CHAT-R/F grouped racial/ethnic minorities together (Scarpa et al., 2013; Khowaja et al., 2014). Analyses suggest that M-CHAT-R items yielding the best diagnostic classifications may differ between racial/ethnic groups (Achenie et al., 2019). Furthermore, a recent universal screening study identified several sociodemographic factors that may affect the M-CHAT/F's performance, though the study did not use the revised screener (Guthrie et al., 2019). Previous research by the authors found that the positive predictive value (PPV) of M-CHAT-R/F was similar in non-Hispanic Black and non-Hispanic White children (Dai et al., INSAR 2019). Further evaluation of the M-CHAT-R/F's effectiveness in these groups is warranted.

Objectives: To compare M-CHAT-R/F total scores and proportion of children who screen positive on each item prior to follow-up interview for non-Hispanic Black and non-Hispanic White children in order to determine whether race/ethnicity predicts the likelihood of an initial positive screen (i.e., ASD risk).

Methods: Data from a multi-site early detection study were used. Children (102 Black, 183 White) were included after screening positive on the M-CHAT-R/F at their 15- or 18- month well-child care visit and completing diagnostic evaluations. Demographic characteristics and screening modality were compared between racial/ethnic groups using independent t-tests, chi-square tests, or Fischer's exact tests depending on variable type. M-CHAT-R total scores and item-level positive screen rates were compared using an independent t-test and chi-square tests of independence, respectively.

Results: Non-Hispanic Black and Non-Hispanic White children differed on screening modality ($\chi^2(1, N = 285) = 14.05$, $p < .001$), screening age ($t(283) = 6.29$, $p < .001$), maternal education ($\chi^2(5, N = 278) = 50.14$, $p < .001$), and annual household income ($U = 13218.50$, $p < .001$). A greater proportion of Black children were evaluated with electronic versions of the M-CHAT-R/F. On average, non-Hispanic White children were screened at a younger age and had higher parental education and income. M-CHAT-R total scores were similar in both groups ($t(285) = 1.80$, $p = .373$). One item-level difference was evident following Bonferroni correction; non-Hispanic Black children were more likely to endorse the item "Does your child make unusual finger movements near his or her eyes?".

Conclusions: Findings indicate that the M-CHAT-R/F detects initial ASD risk similarly in both non-Hispanic Black and non-Hispanic White children in the United States supporting the use of this tool in universal screening efforts. Future studies should continue to evaluate the performance of ASD-specific screening tools in diverse populations as a means of promoting early detection and intervention.

415.084 *(Poster)* NIMH, Under Grant Number R01-MH104400-01, and HRSA, Under Grant Number R40MC26195 Maternal & Child Health Research. and HRSA.

L. Andoni[1]*, L. P. Thammathorn*[1]*, A. Eisenhower*[2]*, A. S. Carter*[3]*, M. Feldman*[2]*, M. Petruccelli*[1]*, B. Willoughby*[1] *and S. Kim*[1]*, (1)University of Massachusetts, Boston, MA, (2)University of Massachusetts Boston, Boston, MA, (3)Department of Psychology, University of Massachusetts Boston, Boston, MA*

Background: Research suggests that there may be distinct sex differences in clinical presentation found in high versus low cognitive functioning samples of individuals with ASD. However, when examining sex differences specifically in toddlers with ASD, the evidence for differences in clinical presentation remains largely inconclusive. The ABCD Early Screening Project, a community-based, two-stage screening protocol implemented in Part C early intervention, provides a platform to explore sex differences in clinical presentation during early screening and diagnostic evaluation for ASD.

Objectives: We explore sex differences in ASD symptoms and developmental functioning on a parent-reported screener, an observational play-based screener, and measures used in a developmental and diagnostic evaluation among a group of toddlers with ASD and Developmental Delay (ASD-DD group) and a group of toddlers with ASD without DD (ASD-no DD). DD status was measured as a Mullen visual reception T score under 30.

Methods: Participants were 476 boys and 126 girls (age = 14-36 months), enrolled in Early Intervention (EI) services who screened positive on the two-stage screening protocol and obtained an ASD diagnosis following a diagnostic evaluation. Stage 1 screening consisted of parent-report on the Brief Infant-Toddler Social Emotional Assessment (BITSEA) and Parent Observations of Social Interaction (POSI) and report of parent and EI provider concern. Children who screened positive at Stage 1 were referred to Stage 2, a brief play-based observational screener (the Screening Tool for Autism in Toddlers; STAT). Those screening positive at Stage 2 were referred for a diagnostic evaluation involving the ADOS-2, Mullen Scales of Early Learning, and the Vineland Adaptive Behavior Scales (VABS-3). Linear regressions examined the role of sex on symptomology and developmental functioning for the ASD-DD group and the ASD-no DD group.

Results: There were no differences in ASD symptoms and developmental functioning between boys and girls for the group of toddlers with ASD-DD. On the other hand, girls and boys with ASD-no DD were similar across most domains with a few exceptions. Within the ASD-no DD group, boys and girls had similar ASD symptoms, play skills, and adaptive functioning. However, boys in the ASD - no DD group had higher non-ASD specific (internalizing, externalizing, and regulation) problems on the parent-reported BITSEA compared to girls. [$F(1,266.2)=5.32$, $p<.05$, Cohen's $f = .016$]. Girls in the ASD-no DD group showed a higher level of expressive language skills compared to boys as evidenced by parent-report on the Vineland-3 [$F(1, 264.2)= 45.1$, $p <.05$, Cohen's $f =.331$] and performance on the Mullen [$F(2,264.2) = 43.50$, $p <.05$, Cohen's $f =.319$].

Conclusions: Among children with ASD-no DD, girls exhibited higher expressive language skills and lower non-ASD specific behavior problems than boys. Our study is consistent with the literature in that sex differences in ASD presentation are more evident in children with ASD without cognitive impairment. These results have implications for detection and early diagnosis and contribute to our understanding of the different presenting profiles of boys and girls with ASD.

415.085 *(Poster)* On Which Traits and Behaviours Do Clinicians Rely When Confirming or Excluding Autism in Adult Women?

J. Cumin[1,2]*, S. Peláez*[1]*, N. Cusson*[2,3]*, C. Paquette-Houde*[4]*, A. Beauchamp Chatel*[2,4] *and L. Mottron, M.D.*[1,2]*, (1)Université de Montréal, Montréal, QC, Canada, (2)Autism Research Group, CIUSSS du Nord-de-l 'Île-de-Montréal, Montréal, QC, Canada, (3)Psychology, Université de Montréal, Montréal, QC, Canada, (4)CIUSSS de l'Est-de-l'Ile-de-Montréal, Montréal, QC, Canada*

Background: Autism without Speech Onset Delay or Intellectual Disability can present uniquely in adult women, making them vulnerable to misdiagnosis of a mental health condition (Bargiela, Steward, & Mandy, 2016). Under current DSM-5 criteria, clinicians must also decide whether difficulties additional to autistic traits constitute a comorbidity or an alternative diagnosis. For example, checking behaviors could be the result of a standalone anxiety disorder, anxiety comorbid to autism, or an autistic trait within itself. However, the reported increase in prevalence of autism raises the issue of potential *overdiagnosis* in psychiatric populations presenting with social difficulties (Rødgaard, Jensen, Vergnes, Soulières, & Mottron, 2019). There is a pressing need to better delineate alternative from comorbid diagnoses, particularly in women. Given that expert clinicians recognise autism more reliably than DSM-5 criteria, based on long-standing exposure to a behavioural phenotype (de Marchena & Miller, 2017), investigating clinical expertise may bring unique insight to this issue.

Objectives: The aim of this study was to investigate the clinical diagnostic decision-making process of expert clinicians evaluating adult women for autism.

Methods: Semi-structured interviews on evaluating *adult women for autism* were carried out with expert clinicians (>100 autism assessments during career) in 5 countries (Canada, USA, UK, France, Australia). 20 clinicians will be included in final analyses. The following topics were addressed: (1) specific traits and past diagnoses which interfere with assessment procedure, (2) diagnostic tools and interview topics used to obtain diagnostic information, (3) most salient traits and behaviours when assessing for autism, whether present in DSM-5 or not, (4) common comorbidities and alternative diagnoses, and (5) close-ended questions on handling cases where the diagnosis is not given. Interviews were recorded, transcribed verbatim, and resulting data was analysed using thematic analysis in NVivo.

Results: Preliminary results (n=5) show (1) an increasing trend towards self-diagnosis of autism prior to evaluation, bolstered by online availability of information on autism, (2) a lack of specificity of instruments such as the AQ, on which most psychiatric condition screen positive, (3) in contrast, behaviours considered specific to adult autistic women included an inability to vulgarise special interests, negatively experienced life events which appear banal, and qualitative differences in the telling of life narratives (temporal associations lacking in context), (4) mood disorders more often considered comorbidities, whereas eating and personality disorders more often considered as alternatives, and (5) increasing proportions of patients exhibiting distress when autism diagnosis was not obtained.

Conclusions: Clinicians have unique insight on the specific behaviours which differentiate autism from psychiatric conditions, and this expertise could be particularly relevant in populations who frequently present in complex ways and are most at risk for misdiagnosis. Investigating clinicians' reasoning mechanism suggest potential mechanisms for overdiagnosis in adult populations, and provide clinically-relevant data to the differential diagnosis literature in adult women.

415.086 *(Poster)* Parent Concerns Prior to ASD Evaluations: Potential Influence of Gender

R. Jamison[1]*, A. Wallisch*[2]*, S. Behrens*[3] *and B. Salley*[4]*, (1)Center for Child Health and Development, Pediatrics, University of Kansas Medical Center, Mission, KS, (2)University of Kansas, Kansas City, KS, (3)Juniper Garden's Children's Project, University of Kansas, Kansas City, KS, (4)Pediatrics, University of Kansas Medical Center, Kansas City, KS*

Background:

Prevalence rates in autism result in early identification methods, autism assessments, and interventions that are largely based on male samples (Lai et al., 2015). Research examining differences between males and females vary across studies and with respect to age or cognitive ability (Lai, 2014). Some studies suggest females camouflage symptoms (Hull, 2017) or require elevated concerns to receive a diagnosis (Dworzynski et al; 2012). Gender differences in social-communication and behavior within the general population should also be considered. Parents of toddlers were more likely to endorse ASD related concerns for males regardless of eventual diagnosis (Ramsey et al, 2018) and less likely to report concerns related to social interactions for girls (Little et al., 201).

Objectives:

Examine how patterns of parent concerns preceding a diagnosis predicted likelihood of group (gender and diagnosis).

Methods:

We conducted a secondary analysis of data including children (n = 273) ages 36-72 months who presented for an interdisciplinary autism evaluation, divided into an ASD diagnosis group (n=168) and DD group (i.e., global developmental delay, language delay; n=105). Data were drawn from clinical assessments and intake paperwork completed by parents prior to evaluation. Parents reported “yes” or “no” to a list of potential concerns (i.e., internalizing, social communication, repetitive behaviors, speech/language, problem solving), later grouped into related categories (DSM criteria, disruptive behaviors, etc). We used multinomial regression with four diagnostic/gender categories (i.e., ASD females, ASD males, DD females, DD males) as the dependent variables and parent behavior concerns as the independent variables.

Results:

Results are described with ASD females as the comparison group and suggest an overall significant model (x^2= 51.55, *df*= 24, p<0.01). ASD males were significantly differentiated from ASD females by a higher likelihood of repetitive behavior (b = 1.38, p = 0.05), and speech and language concerns (b = 1.08, $p < 0.05$). Females with DD were significantly more likely to have problem-solving concerns (b = 1.58, $p < 0.05$); whereas, males with DD were less likely to have social communication concerns (b = -1.98, $p < 0.05$) compared to ASD females. Play and internalizing concerns did not differentiate ASD females from other groups. Additional findings suggest differences regarding social-communication as well and the need for further analyses to examine if, or how, age and cognitive ability might greater influence females compared to males.

Conclusions:

Our results suggest that parent concerns differentiated females with ASD from males with ASD/DD. Results indicate gender differences for parent concerns regardless of eventual diagnosis, suggesting analyses that collapse across groups. These findings support the notion that girls with ASD demonstrate a different behavioral profile compared to males and the need to consider expected patterns of behavior for males and females (Dean et al., 2017). Given the distinct patterns of parent concerns for girls with ASD, this means we need to be vigilant listeners when discussing parent concerns and recognize these may be less salient for girls with ASD and to consider expected patterns of behavior for males and females without ASD.

415.087 *(Poster)* Parent Perceptions of a Clinician-Guided, Parent-Led Screening for Autism Risk in Toddlers Using Telemedicine Tools

L. Corona[1]*, A. Miceli*[1]*, A. Nicholson*[2]*, A. S. Weitlauf*[3]*, C. S. Reichstein*[4]*, N. Broderick*[5]*, J. F. Hine*[5]*, R. J. Hundley*[5]*, S. Francis*[6]*, L. Wagner*[5] *and Z. Warren*[5]*, (1)Vanderbilt University Medical Center - Treatment and Research Institute for Autism Spectrum Disorder, Nashville, TN, (2)Vanderbilt University, Pleasant View, TN, (3)Vanderbilt Kennedy Center, Vanderbilt University Medical Center, Nashville, TN, (4)Treatment and Research Institute for Autism Spectrum Disorders, Vanderbilt University Medical Center - Kennedy Center, Nashville, TN, (5)Vanderbilt University Medical Center, Nashville, TN, (6)Vanderbilt University Medical Center - Treatment and Research Institute for Autism Spectrum Disorder, Nashville, NY*

Background: Telemedicine tools have potential to increase access to diagnostic and treatment services for individuals with autism spectrum disorder (ASD). Previous work has documented the feasibility, acceptability, and diagnostic accuracy of a telemedicine assessment procedure in which a remote psychologist observed administration of the Screening Tool for Autism in Toddlers and Young Children (STAT) by a trained, on-site early intervention provider (Juárez et al., 2018). Although promising, this approach relies on the availability of two expert providers (i.e., administrator and observing clinician), which limits its efficiency and scalability. The present study examined the feasibility and acceptability of a parent-led screening procedure guided solely by a remote clinician. Evaluation of telemedicine diagnostic accuracy in comparison to gold-standard diagnostic evaluation is pending and will be presented separately.

Objectives: This study sought parent feedback on a telemedicine approach to ASD assessment, in which a clinician guided parents via live video to complete an ASD screening procedure with their toddlers.

Methods: Participants were 51 caregivers (42 mothers, 6 fathers, 2 other caregivers) and toddlers (71% male; mean age 2.49 years, SD = 0.35). Thirty-five toddlers had diagnoses of ASD; 10 had diagnoses of developmental delay; and 6 toddlers were typically developing. Remote clinicians were psychologists with expertise in diagnosing ASD in young children. Using tele-evaluation rooms equipped with HIPAA-compliant video platforms, clinicians verbally instructed parents to complete one of two brief tele-assessment tools: the TELE-STAT or the TELE-ASD-PEDS. Both tools are interactive assessments of social communication skills, including opportunities for joint play, shared attention, and social routines. The tele-screening procedure took an average of 23 minutes (SD=5.00), with no significant difference between the two screening tools. Following tele-screening, parents completed a questionnaire eliciting their feedback about the experience.

Results: Quantitative parent feedback indicated that most parents felt comfortable playing with their children during the tele-screening and found the spoken instructions easy to follow (See Table 1). Some parents (12%) indicated that screening activities did not elicit the child behaviors about which they were most concerned. Independent samples t-tests yielded no differences on these items between parents who completed the TELE-STAT and those who completed the TELE-ASD-PEDS. When asked whether they would prefer to play with their child as part of screening or observe a psychologist play with their child, 19% of parents indicated that they would prefer to play with their child, 4% would prefer to observe, and 77% would prefer to both play and observe. Parents provided a total of 111 written comments, including comments about technology (n=25), the parent-led nature of the screening process (n=21), comparisons between full evaluation and tele-screening (n=14), and the convenience of the process (n=8). Parent comments are further summarized in Table 2.

Conclusions: Parents reported that tele-screening was convenient and comfortable. Many enjoyed playing with their children during the screening and noted that this may be preferable to only observing a psychologist interact with their child. Future work will investigate the diagnostic accuracy of tele-screening procedures and incorporate parent feedback to further adapt telemedicine for autism assessment.

415.088 *(Poster)* Parent Report of Social Communication and Language at 18 Months

L. Swineford[1] *and S. Langell*[2]*, (1)Speech and Hearing Sciences, Washington State University, Spokane, WA, (2)Washington State University, Spokane, WA*

Background: Universal screening for ASD at 18 and 24 months of age as recommended by the American Academy of Pediatrics (AAP) remains an area of interest as recent studies report high feasibility, but sub-optimal accuracy using ASD-specific screening tools for universal screening (e.g., Guthrie et al., 2019). Recent estimates suggest that only 17% of pediatricians are conducting universal screenings as suggested by the AAP and there is significant variability in the screening tools used (Crais et al., 2014). Further, many pediatricians report concerns or challenges in utilizing current ASD-specific screening tools.

Objectives: The purpose of this study was to examine the parent report of social communication and language skills at 18 months of age on commonly used non-ASD specific checklists.

Methods: Sixty participants, between the ages of 9- and 36-months of age, were recruited for a longitudinal research project focused on behavioral risk factors for ASD. Advertisements were designed to recruit children with parental concern regarding their development (language and/or general), which included specific parental concerns for ASD, and children without parental concerns; resulting in a sample of toddlers with heterogeneous social communication and language skills. Of 60 enrolled participants, 25 (males n=16) had completed behavioral assessments at the 18-month age interval, with inclusionary age criteria 18-months +/- 2 months (mean age: 18.65 months, range: 18.0 to 20.01). At the time of the behavioral assessments, parents completed several checklists including the Communication and Symbolic Behavior Scales Infant Toddler Checklist CSBS ITC; Wetherby & Prizant, 2002), Ages and Stages Questionnaire (ASQ; Squires & Bricker, 2009), Ages and Stages Questionnaire-Social Emotional (ASQ-SE; Squires, Bricker, & Twombly, 2002), and the Language Development Survey (Rescorla, 1989). Social communication and expressive language skills were directly assessed using the Toddler Module of the Autism Diagnostic Observation Schedule (Lord et al., 2012) and the Mullen Scales of Early Learning (Mullen, 1995), respectively.

Results: Parents endorsed more concerns and/or lower abilities in the areas of speech and language compared to social communication across measures. Specifically, the Language Development Survey yielded the highest percentage of concern (33.3%), followed by the speech composite on the CSBS ITC (16%) and the ASQ Communication Scale (12%). Only a minority of social communication scores (8%) fell within a concern range on the CSBS ITC social composite and the ASQ SE based on parent report. Based on the Mullen Scales of Early Learning, 32% of the sample had expressive language delays with scores falling ≤ 1.5 SD below the mean. Twenty-four percent of the sample met the research cut-off for ASD on the ADOS with 12% falling in the moderate-to-severe concern range, 16% in the mild-to-moderate concern range, and 72% in the little-to-no concern range.

Conclusions: Only a minority of parents of our sample endorsed skills within the concern range across the checklists completed. More concerns were noted regarding early speech and language skills as compared to social communication development with vocabulary on the LDS yielding the highest percentage of concern. A similar pattern was observed on our direct observation measures.

415.089 *(Poster)* Parent and Teacher Inter-Rater Agreement of Middle Childhood Bullying Experiences in Children with Autism Spectrum Disorders

S. Saqui[1]*, M. C. Hunsche*[1]*, P. Mirenda*[1]*, T. Vaillancourt*[2]*, M. Elsabbagh*[3]*, M. Chalupka*[4]*, C. Waddell*[5]*, E. Duku*[4]*, S. Georgiades*[4]*, L. Zwaigenbaum*[6]*, W. J. Ungar*[7]*, P. Szatmari*[8]*, A. Zaidman-Zait*[9]*, T. Bennett*[10]*, I. M. Smith*[11] *and C. M. Kerns*[1]*, (1)University of British Columbia, Vancouver, BC, Canada, (2)University of Ottawa, Ottawa, ON, Canada, (3)McGill University, Montreal, QC, Canada, (4)McMaster University, Hamilton, ON, Canada, (5)Simon Fraser University, Vancouver, BC, Canada, (6)University of Alberta, Edmonton, AB, Canada, (7)University of Toronto / The Hospital for Sick Children, Toronto, ON, Canada, (8)The Hospital for Sick Children, Toronto, ON, Canada, (9)Tel-Aviv University, Tel-Aviv, Israel, (10)Offord Centre for Child Studies, McMaster University, Hamilton, ON, CANADA, (11)Dalhousie University / IWK Health Centre, Halifax, NS, CANADA*

Background: Children with ASD are more susceptible to bullying than their typically developing peers (Sreckovic et al., 2017). However, teachers and parents may have distinct perceptions of bullying experiences. Some studies report higher levels of parent-reported than teacher-reported bullying (Nowell et al., 2014) while other studies (Maïano et al., 2016) report comparable levels across raters. Such informant discrepancies are common and influenced by the different contexts in which raters observe children and the types of behaviours being rated (De Los Reyes, 2005). As such, it is plausible that inconsistencies in parent/teacher ratings of bullying in ASD may be explained, in part, by the type of bullying being assessed (physical, verbal, social). Further, we hypothesize that agreement may differ at different stages of middle childhood, a period when the forming and sustaining peer relations is rapidly evolving (Sroufe et al., 1993).

Objectives: To examine the inter-rater agreement of teachers' and parents' endorsements of three forms (physical, verbal, and social) of bullying experienced in children with ASD in early vs. later middle childhood.

Methods: Our sample included children with ASD, for whom both teachers and parents completed a modified version of the *Olwues Bullying/Victim Questionnaire* (CBE; Vaillancourt et al., 2008) as part of an ongoing longitudinal study (Pathways in ASD) at either early (N=140; *M* age = 7y:8m; T1) and/or late (N=116; *M* age = 10y:9m; T2) middle childhood with some (N=70) having data across both timepoints. The CBE is a brief screening measure that queries the frequency (from '*never'* to '*several times a week'*) of physical, verbal, and social bullying. ICC estimates were calculated for each type of bullying on parent and teacher CBE questionnaires based on a mean-rating (*k* = 2), absolute-agreement, 2-way random-effects model at T1 and T2.

Results: At T1 parents and teachers, respectively, reported one or more incidents of physical bullying (18.4%, 15.5%), verbal bullying (34.5%, 23.4%), and social bullying (34.8%, 26.9%) of children with ASD. By time T2, these overall rates were more similar per parent and teacher report: physical bullying (12.9%, 11.3%), verbal bullying (28.4%, 29.3%), and social bullying (28.4%, 28.4%). Nonetheless, ICC were generally weak to moderate (range: .15–.49) and only statistically significant for verbal bullying (T1 ICC=.36, T2 ICC=.49), suggesting significant differences in the frequency of bullying, particularly of social and physical bullying, being report by teachers at both timepoints. See Tables 1 and 2.

Conclusions: Findings suggest that parents and teachers provide important, complementary information about the frequency with which children with ASD experience bullying in middle-childhood. Further, they suggest that discrepancies in these reports vary by bullying type and child age. Social and physical bullying may vary or occur more covertly across contexts. Further, these forms of bullying may be less often observed by or reported to teachers, overall. Findings encourage communication between parents and teachers regarding their perceptions of bullying to ensure adequate detection and continuity of care across settings.

415.090 *(Poster)* Parent and Teacher Reports on Screening Instruments As Predictors of Diagnostic Instrument Scores

S. Israel Yaacov[1,2] *and O. Golan*[1,2]*, (1)Department of Psychology, Bar-Ilan University, Ramat-Gan, Israel, (2)Association for Children at Risk, Givat Shmuel, Israel*

Background: Multiple informants are considered important in the assessment of ASD (Kim & Lord 2012). Parents and teachers, as key informants, are considered to provide unique and complementary information about the child's behavior, since they see the child in different contexts and have different perspectives (van der Ende et al. 2012).

Despite the potential additional value of information obtained from parents and teachers in the assessment of ASD, only a few studies have examined the two together.

Objectives: To examine the association of parent and teacher reports on ASD screening questionnaires, with clinician administered gold-standard diagnostic instruments.

Methods: One hundred and thirty-five children and adolescents (23 girls), aged 5-18 (M=10.89, S.D.=3.46) attended an Israeli tertiary clinic (Bait-Echad Center) for an ASD diagnostic assessment. Participants' parents filled out the Childhood Autism Spectrum Test (CAST; Scott et al., 2002) and teacher completed the Social Responsiveness Scale (SRS-2; Constantino & Gruber, 2012). Participants were assessed by clinical psychologists, using the Autism Diagnostic Observation Schedule (ADOS-2; Lord et al., 2012) and the Autism Diagnostic Interview-Revised (ADI-R; Lord et al., 1994).

Results: Four Linear regression analyses were conducted with ADOS-2 Calibrated Severity Score (CSS), and ADI-R Social Interaction, Communication, and Restricted, Repetitive Behavior (RRB) scores as dependent variables. For all regressions, participants age and gender were entered on the first block and parent-reported CAST and teacher-reported SRS-2 scores were entered on the second block.

ADOS-2 CSS were predicted only by teachers' SRS-2 Total scores (β=.26, p<.01; total model R^2=.10). ADI-R Social Interaction scores were predicted only by parent CAST scores (β=.50, p<.001; total model R^2=.26). Similarly, ADI-R Communication scores were predicted only by parent CAST scores (β=.49, p<.001; total model R^2=.23). Finally, ADI-R RRB scores were predicted jointly by gender (β=.17, p<.05, Males>Females, t[130]=2.08, p<.05) and parent CAST scores (β=.37, p<.001; total model R^2=.16).

Conclusions: The findings indicate the unique value of parent and teacher report in their prediction of different components of the diagnostic assessment. Parents report was predictive of the ADI-R, as they provide invaluable information on the child's development over time. On the other hand, teachers' report was predictive of the ADOS-2 CSS scores, as they regularly observe how the child interacts with other children in the school setting and have the opportunity to compare the behavior of the child with that of many other children, which may allow them to better distinguish between typical and atypical behavior. Gender differences in the prediction of participants' RRB highlight the importance of adapting existing diagnostic instruments to represent RRB manifestations in females.

415.091 *(Poster)* Parent-Reported Internalizing, Externalizing, and Dysregulation Behaviors during ASD Screening: A Latent Profile Analysis of Young Children Diagnosed with ASD

A. E. Chavez*, R. Parigoris and A. S. Carter, Department of Psychology, University of Massachusetts Boston, Boston, MA*

Background: Early detection of autism spectrum disorder (ASD) has included use of both ASD-specific and broadband screening tools to identify children with ASD. Though studies have followed developmental profiles of children once they receive a diagnosis, limited work has examined constellations of emotional, behavioral, and regulatory problems that parents report prior to children's diagnosis. Grouping children based on ASD symptomatology (i.e., ASD risk status) and co-occurring emotional, behavioral and regulatory problems may inform the range of resources that would benefit children with ASD and their families.

Objectives: To identify latent profiles of young children diagnosed with ASD based on parent-reported non-ASD symptom screening data from the Brief Infant-Toddler Social and Emotional Assessment (BITSEA).

Methods: Data were drawn from a multi-stage screening trial in partnership with Early Intervention. Participants were 556 children (ages 14-33 months; 80.3% male) whose parents completed a BITSEA at an early screening stage and subsequently received a diagnosis of ASD (ADOS average Calibrated Severity Score [CSS] = 8.25). Families resided in an urban area in the US Northeast; a majority were Latinx (46.9%) and had a primary parent with more than a high school education (57.7%). Latent profile analysis (LPA) was conducted to identify latent subgroups. Classes were based on patterns of BITSEA internalizing, externalizing, and dysregulation problems subscales, with ASD items removed. Chi-square analyses were used to determine differences among classes.

Results: A four-class solution was identified to best fit the data (See Table and Figure 1). Class 1 represented children with low scores on all scales (20.3% of sample). Class 2 represented children with a single elevation in the externalizing scale (6.3% of sample). Class 3 represented low-to-medium internalizing, externalizing, and dysregulation behaviors (51.3% of sample). Class 4 represented medium-to-high internalizing, externalizing, and dysregulation behaviors (22.1% of sample). Chi-square analyses revealed a significant association between class membership and indicators of parent education ($\chi^2(3)=10.12$, p=.02) and household federal poverty level (FPL), ($\chi^2(3)=12.71$, p=.01). A higher percentage of children in Class 2 had parents with less than a high school education (56.3%) as compared with children in other classes. A higher percentage of children in Class 1 lived in households >185% FPL (54.2%) as compared with children in other classes. Family race, ADOS CSS, restricted and repetitive behavior scores, and the Mullen Scales of Early Learning composite were not associated with class membership.

Conclusions: An acceptable class structure based on indicators of internalizing, externalizing, and dysregulation behaviors emerged for children with ASD. Parent education and household poverty level were associated with the four identified classes. Although a minority of the sample fit into Class 2 (6.3%), characterized by high externalizing and low internalizing and dysregulation symptoms, this group is of clinical importance, as parents may need additional support to manage their children's elevated activity, impulsivity, aggression and defiance. Similarly, parents raising children in Class 4, a profile characterized by elevated symptoms across the three domains assessed (22.1% of sample) may benefit from additional support. Notably, approximately 25% of children had significant challenging behaviors independent of ASD symptoms.

415.092 *(Poster)* Pathway from Community Pediatric Provider Evaluation Referral to Treatment for Autism Spectrum Disorder (ASD): Where Do Families Get Off Track?

S. Dufek[1], *S. J. Fernandes*[2], *L. Just*[3], *G. Perez Liz*[2], *A. Stahmer*[4], *D. A. Fein*[5] *and D. L. Robins*[2], *(1)Psychiatry, University of California, Davis, Sacramento, CA, (2)A.J. Drexel Autism Institute, Drexel University, Philadelphia, PA, (3)University of Connecticut, Storrs, CT, (4)Psychiatry and Behavioral Sciences, UC Davis MIND Institute, Sacramento, CA, (5)Psychological Sciences, University of Connecticut, Storrs, CT*

Background: Universal toddler screening can detect many cases of ASD younger than the national average (Robins et al., 2014). However, in order to maximize the benefits of universal screening, community pediatric providers (providers) must consistently refer positive-screen toddlers for an ASD evaluation. Providers report many barriers to making ASD evaluation referrals, one of which is family reluctance to participate in the evaluation process (Robins et al., 2019). Providers may be reluctant to refer a toddler for an evaluation if they believe the family will ultimately refuse or have difficulty participating in the evaluation and treatment process.

Objectives: Determine family retention rate at each stage of the ASD evaluation process, from initial provider referral to family adherence to treatment recommendations in a large multi-site study.

Methods: Providers referred toddlers (n = 133) for an ASD evaluation as part of an RCT designed to evaluate how detection strategies in primary care impact the age of diagnosis and treatment onset, and subsequent outcomes for a diverse sample (e.g., traditionally underrepresented groups and lower-resourced families). Study coordinators called referred families directly to schedule an initial ASD evaluation. Families were considered "unable to contact" for scheduling if they did not respond after three phone calls and a letter mailed to their home address. Retention rate was calculated by percentage of adherence for families at each stage who 1) agreed to schedule an ASD evaluation after referral, 2) attended and completed the ASD evaluation, and 3) subsequently participated in treatment if the toddler was diagnosed with ASD.

Results: Community referred families exhibited a fairly high retention rate at every stage of the ASD evaluation to treatment process. Only 6% of families refused the diagnostic evaluation and 11% of families were "unable to contact". Ten percent of families failed to attend their scheduled evaluation appointment and decided not to reschedule. Thirteen percent of families whose toddlers received an ASD diagnosis declined treatment from our study team. Ultimately, almost 2/3 (approximately 63%) of families whose toddlers were identified at-risk during a pediatric check-up in a participating community practice participated in the entire process, from scheduling an ASD evaluation to treatment.

Conclusions: Many possible barriers may impede a provider from making a referral for an ASD evaluation. Parent response to this referral, specifically reluctance to complete an evaluation, has been cited as one possible deterrent. Our data indicate that after referral the majority of families ultimately participated in not only the evaluation process, but also accepted the recommended treatment plan. It should be noted that providers and families were enrolled in a research study, which may have increased willingness to refer for, as well as complete, an ASD evaluation. In addition, providers were supported throughout the screening process, and families received support for scheduling the evaluation, paying for the evaluation, and the wait-time for the evaluation was minimal, all of which likely contributed to the completion of the evaluation process.

415.093 *(Poster)* Patterns of Special Education Eligibility and Age of First Autism Spectrum Disorder (ASD) Eligibility Among US Children with ASD

A. N. Esler[1], *J. Poynter*[2], *L. Wiggins*[3], *J. A. Hall-Lande*[4], *A. Hewitt*[5], *C. Rice*[6], *B. Harris*[7] *and R. S. Kirby*[8], *(1)University of Minnesota, Minneapolis, MN, (2)Pediatrics, University of Minnesota, Minneapolis, MN, (3)Centers for Disease Control and Prevention, Atlanta, GA, (4)UCEDD, University of MN, Minneapolis, MN, (5)U of MN, Minneapolis, MN, (6)Emory University, Atlanta, GA, (7)Department of Pediatrics, University of Colorado, Denver, CO, (8)College of Public Health, University of South Florida, Tampa, FL*

Background: Age of ASD identification remains later than desired at 36 months despite increased public health initiatives and awareness (Baio et al., 2018). Research on when children are first identified with autism spectrum disorder (ASD) typically has focused on clinical diagnoses. However, some children are identified after they enter elementary school (Yeargin-Allsopp et al., 2003). For young children, use of the non-specific Developmental Delay (DD) special education category has increased over time for children with ASD (Rubenstein et al., 2018), even though this category may not be adequate in describing the needs of children with ASD.

Objectives: Using data from the CDC's Autism and Developmental Disabilities Monitoring (ADDM) Network, we compared age of first ASD identification for children with ASD who had records from school sources only and those who had records from (a) both school and non-school sources and (b) non-school sources only. Next, we compared information contained in educational evaluations that resulted in DD eligibility and evaluations that resulted in ASD eligibility.

Methods: ADDM utilizes systematic record review to identify and describe children with ASD. ASD identification was defined as the presence of a clinical diagnosis or ASD special education eligibility noted in records. Children with records from schools only, from school + non-school sources, and non-school sources only were compared across age at first ASD identification and age of first comprehensive evaluation. Medians are presented to reduce the impact of outliers; significance tests were conducted using the Kruskal-Wallis test to detect significant differences in median age.

Results: Six ADDM sites that had access to records from both educational and health sources were included. The study sample included 20,461 evaluations from 3,206 8-year-olds identified as ADDM ASD cases in surveillance year 2014. Children with ASD with records from school settings only had significantly later median age of ASD identification (76.5 months) than children with records from school and non-school sources (51 months) or non-school sources only (48 months; p<.001). Age of first evaluation was also later: 56.5 months compared to 37 and 40 months (p<.001). Overall, evaluations that resulted in ASD eligibility included an ASD-specific measure 40% of the time. For children who first qualified under DD eligibility and later received ASD eligibility, their initial evaluations for DD eligibility contained an ASD-specific measure 22% of the time.

Conclusions: Children with school records only were evaluated and identified later than those with non-school records, which highlights the need for outreach efforts to identify and address barriers to access to both school and non-school services. Evaluations resulting in DD eligibility infrequently included ASD-specific measures that may have documented needs relevant to individualized education plans and services for children who ultimately were identified as ASD eligible. The American Academy of Pediatrics guidelines on administration of ASD-specific measures can be considered within school evaluations since they are a critical component of identifying children with ASD and defining their individual treatment needs.

415.094 *(Poster)* Pediatric Provider Reported Concerns for Autism Spectrum Disorder in a Racially and Socioeconomically Diverse Sample of Young Children

P. E. Vidal[1], *K. S. Porto*[2], *D. A. Fein*[2], *L. B. Adamson*[3] *and D. L. Robins*[4], *(1)Boston Children's Hospital: Labs of Cognitive Neuroscience, Boston, MA, (2)Psychological Sciences, University of Connecticut, Storrs, CT, (3)Psychology, Georgia State University, Atlanta, GA, (4)A.J. Drexel Autism Institute, Drexel University, Philadelphia, PA*

Background: Screening is important for early detection of ASD and has been shown to reduce disparity in age of first diagnosis for children of color (Herlihy et al., 2014). Pediatric providers have an important role in facilitating the detection of ASD, and referral for assessment can be crucial for timely diagnosis. Despite recommendations for universal screening, screening rates in primary care remain low to moderate in many regions of the United States. Accurate, timely referral relies in part on provider expressed concern for ASD risk, particularly in practices with low screening compliance. Thus, it is important to understand potential differences in provider concern and how well concern predicts diagnosis that may contribute to diagnostic disparity.

Objectives: This study considers the impact of a child's race, family income, and age on the frequency and accuracy of provider reported concern for ASD.

Methods: Participants were 134 toddlers ages 12.2-41.07 months evaluated as a part of a larger study on the early detection of ASD. Data was collected from three sites in the United States. Children were screened with one of several validated developmental screeners, and providers completed a Provider Concern Questionnaire (PCQ) to document any concerns for ASD. Children who either screened positive on a developmental screener or were identified on the PCQ were offered a no-cost diagnostic assessment. Participants were divided into two samples; Black (n=40) or White (n=94), based upon parent report of the child's race. To determine provider accuracy, responses on the PCQ were compared to the results of diagnostic assessment.

Results: Of evaluated children, 32.1% (n=43) received an ASD diagnosis. Providers expressed concern for ASD in 62.8% (n= 27) of these cases and 36.6% of cases overall. Binary logistic regression and chi-square analyses revealed no significant relationship between provider accuracy and the demographic variables (race, income, age). Providers were accurate in their concern in the majority (71.6%) of cases. For frequency of provider concern, binary logistic regression revealed no significant effect of race or income. Analysis did reveal a significant effect of age on frequency of concern for ASD (p<.001). Frequency of concern and age were positively correlated (r =.342, p<.001) with a moderate effect size. Providers expressed ASD concern for 61.2% of evaluated children aged 18-months or older compared to 20.9% of children younger than 18-months.

Conclusions: Results revealed that neither race nor family income influenced the frequency or accuracy of reported pediatric providers' concern for ASD. Age was significantly positively correlated with frequency of concern but not accuracy. This may be because pediatric providers are more reluctant to identify concern in very young children, or because behaviors are more readily identifiable in slightly older children. When providers do express concern, however, they are often accurate, even at young ages. A limitation to these findings is that healthcare providers had the option to provide a referral for no-cost diagnostic assessment. Rates of provider referral may be different in typical care settings where such evaluations are not readily available.

415.095 *(Poster)* Phenotypic Resemblance between Autism Spectrum Disorder and Schizophrenia Spectrum Disorder

***M. R. Altschuler**, Institute of Child Development, University of Minnesota, Minneapolis, MN*

Background:

Autism spectrum disorder (ASD) is characterized by abnormalities in social interaction and communication, whereas schizotypal personality disorder (SPD) is a schizophrenia spectrum disorder (SCZ) characterized by social and interpersonal deficits. The debate about the phenotypic distinction between ASD and SCZ persists nearly 70 years after "autism" was first described as the self-absorbed and withdrawn behaviors that were characteristic of adults with schizophrenia.

Objectives: The objectives of this review were to: 1) comprehensively review the empirical support for the phenotypic similarities and differences between ASD and SCZ and 2) suggest data-driven classification of ASD and SPD.

Methods: A systematic database search was conducted of the academic literature comparing ASD and SPD or SCZ. The search was limited to journal articles and postgraduate theses published in English during the past decade. Search terms (title, abstract and key word) were establish synonyms for ASD, SCZ, and SPD. CINAHL, Cochran Library, Embase, Medline, Proquest, PsychInfo, PubMed, Science Direct, Scopus and Web of Science were searched.

Results:

Despite differences in clinical presentation and age of onset, data provide empirical support for a conceptual overlap in diagnostic criteria and symptomology between both disorders, especially on the mild ends of the spectra. The data suggest negative symptoms of SPD share a strong relationship with ASD social and communication difficulties, and the main differences between ASD and SPD are positive features (i.e., hallucinations and delusions).

Conclusions: The majority of studies demonstrate that when using a dimensional approach, SPD features and behaviors cannot be easily differentiated from ASD features and behaviors. The broad overlap between schizotypal and autistic traits is primarily driven by interpersonal difficulties, but there is still some overlap in positive and disorganized symptoms as well. Although deficits common to both spectra may not necessarily share the same underlying cause, the resemblance in clinical phenotypes calls into question the notion that the disorders exist on separate spectra and suggests, instead, that they should be conceptualized dimensionally.

415.096 *(Poster)* Psychometric Evaluation and Adaptation of the Autism Traits Questionnaire in Mainland China

***D. Huang**[1], S. Wang[2] and L. Yu[2], (1)Guangzhou Rehabilitation & Research Center for Children with Autism, Guangzhou Cana School, Guangzhou, China, (2)South China Normal University, Guangzhou, China*

Background: The Autism Spectrum Quotient questionnaire (AQ) was developed to assess autistic traits in the general population (Baron Cohen., 2009). Despite of being widely used across the globe, the AQ-Child has not been adapted into Mandarin Chinese.

Objectives: Research has suggested potential differences in the manifestation of autistic traits cross-culturally. Thus, it is necessary to systematically examine the psychometric performance of AQ among children who reside in a region hosting 1/5 of world population, namely, Mainland China.

Methods: Chinese AQ-child was first obtained through a translation and back-translation procedure. Pilot testing was administered with parents of 30 Typical developed children. The measure was further revised based on feedback from the pilot testing to maximize linguistic and cultural appropriateness. A total of 756 TD children' data was collected using the revised AQ translation.

Results: Item analysis identified 8 items with high double load. A total of 22 poor-performing items were removed from the following analysis, resulting in 28 items and 7 factors in the subcategories of

Social Skill items (item 11, 17, 38, 44, 48), Attention to Details (item 29, 30, 33, 42, 45, 49) ,Types of Interest(item 6,9,19,41) , Imagination (item 24,40,50), Attention(item 4,16,34) and Compulsivity(item 15,25,39). In addition, confirmatory factor analysis suggested good fit of 7-factor construct ($\chi 2/df = 1.61$, RMSEA = .03, CFI = .92, NFI = .81). However, internal consistency within each factor measured by Cronbach α coefficient did not produce satisfactory overall reliability (0.76、0.63、0.62、0.45、0.38、0.40, and 0.14).

Conclusions: The Chinese translation of AQ-child failed to produce similar AQ construct as produced in Western context. Potential behavioral sampling bias may exist cross-culturally and we call for further studies in this field.

415.097 *(Poster)* Psychometric Properties of the Eyberg Child Behavior Inventory in Children with Autism Spectrum Disorder Receiving Community Mental Health Services

***K. Martinez**[1,2], C. Chlebowski[3,4], S. Roesch[5], E. Hurwich-Reiss[6] and L. Brookman-Frazee[4,7,8], (1)Child and Adolescent Services Research Center (CASRC), San Diego, CA, (2)Clinical Psychology, San Diego State University / University of California, San Diego Joint Doctoral Program in Clinical Psychology, San Diego, CA, (3)University of California San Diego, La Jolla, CA, (4)Child and Adolescent Services Research Center, San Diego, CA, (5)San Diego State University, San Diego, CA, (6)University of California, San Diego, La Jolla, CA, (7)Psychiatry, University of California, San Diego, La Jolla, CA, (8)Autism Discovery Institute, Rady Children's Hospital-San Diego, San Diego, CA*

Background: The Eyberg Child Behavior Inventory (ECBI) has been used to assess co-occurring challenging behavior in children with ASD[1-6]. To date, only one published study has conducted a detailed examination of the psychometric properties of the ECBI in ASD[7]. However, the sample was predominantly Caucasian (74%) and young. In response, our group previously examined the factor structure of the ECBI in an ethnically-diverse sample of children with ASD receiving publicly-funded outpatient and school-based mental health services. The factor structure in the sample was best explained by a two-factor model of *Dysregulation* and *Attention/Hyperactivity*.

Objectives: The aim of the current study was to conduct further psychometric analysis of the identified *Dysregulation* and *Attention/Hyperactivity* factors.

Methods: Data were drawn from the baseline assessment of families participating in the community effectiveness trial of "An Individualized Mental Health Intervention for ASD (AIM HI)"[5]. Caregivers self-reported child challenging behaviors using the ECBI and the Social Skills Improvement System (SSIS). Cognitive functioning was assessed with the Differential Ability Scales (DAS-II) or Weschler Abbreviated Scale Intelligence (WASI-II) and co-occurring psychiatric conditions were assessed using an adapted version of the MINI parent intervention version. The sample (n=201) included 84% males, with a mean age of 9.12 (SD = 2.44). Approximately 80% of the children were from an ethnic minority background. Composites reflecting mean item scores for items on the *Dysregulatio*n and *Attention/Hyperactivity* factors were calculated. Cronbach's alpha values were computed to assess internal consistency of each scale. Convergent and divergent validity were assessed by examining the correlations between each scale and theoretically related and unrelated variables including the SSIS Problem Behavior scale and Full-Scale IQ. Discriminant function analyses were used to assess discriminative validity by examining the scales' ability to discriminate between diagnostic groups (ODD, ADHD, Mood, and Anxiety).

Results: Both *Dysregulation* and *Attention/Hyperactivity* demonstrated good internal consistency (a = .89 and .86, respectively). Strong convergent validity with the Problem Scale of the SSIS and its five corresponding subscales (r = .18 to .80, p < .001), as well as strong divergent validity with Full Scale IQ (r = -.03 to -.10, n.s.) were demonstrated. Good discriminant validity was demonstrated as well. Diagnostic groups differed on *Dysregulation* and *Attention/Hyperactivity* for ODD, ADHD, and Mood disorders, but not for Anxiety. Linear Discriminant Functions were significant with medium-to-large effect sizes for ODD and ADHD. For ODD, *Dysregulation* carried more of the weight (= .854) compared to *Attention/Hyperactivity* (= .249). For ADHD, *Attention/Hyperactivity* carried more of the weight (= .787) compared to *Dysregulation* (= .311).

Conclusions: Psychometric analyses of the ECBI in an ASD sample using the previously identified *Dysregulation* and *Attention/Hyperactivity* factors demonstrated good internal consistency, convergent/divergent validity, and discriminant validity. Next steps will include examining clinical factors (e.g. number of co-occurring diagnoses, ASD symptom severity) associated with these scores as well as the AIM HI intervention effects over time. Results may inform best practices for providers using the ECBI to assess challenging behaviors among community samples of children with ASD and co-occurring mental health conditions.

415.098 *(Poster)* Reliability and Criterion-Related Validity of the Asessment of Basic Language and Learning Skills-Revised

M. Stoll[1]*, M. A. Volker*[1]*, J. A. Toomey*[2] *and N. Bergamo*[1]*, (1)Counseling, Educational Psychology, and Special Education, Michigan State University, East Lansing, MI, (2)Summit Educational Resources, Getzville, NY*

Background: The *Assessment of Basic Language and Learning Skills–Revised* (ABLLS-R; Partington, 2010) is a comprehensive, observation-based, criterion-referenced assessment tool assessing skill attainment in basic behavior, language, social, self-care, and academic skills. The ABLLS-R has two primary uses: (a) specifying and quantifying critical domains of skill development (i.e., repertoires) associated with deficits in autism spectrum disorder (ASD) and/or intellectual disability (ID), and (b) Individualized Education Program (IEP) development, goal setting, and progress monitoring. Two prior studies examined aspects of ABLLS-R reliability and content validity (Partington, 2016; Usry, 2015). However, no study has examined relationships between ABLLS-R scores and scores from more traditional psychometric instruments intended to measure the same or similar constructs. Lack of such criterion-related validity evidence has limited its potential for wider use as an outcome measure in research and practice contexts.

Objectives: The objectives of the present study were to examine the internal consistency reliability and criterion-related validity of the ABLLS-R in a sample of students with ASD and/or ID.

Methods: Data were collected from a sample of 68 students with ASD and/or ID and substantial functional impairments between the ages of four and 12 years (M = 7.2, SD = 1.9). The sample was 72.1% male, 82.4% ASD (17.6% ID/non-ASD), with a mean IQ of 45.9 (SD = 15.3). Participants were evaluated with the ABLLS-R by either a special education teacher or staff psychologist. Correlations were generated between the ABLLS-R scores and scores from four external criterion measures (i.e., DAS-II [Elliott, 2007], PPVT-IV [Dunn & Dunn, 2007], EOWVT-4 [Martin & Brownell, 2011], and ABAS-II teacher ratings [Harrison & Oakland, 2003]) that were administered during the same time period. Cronbach's alpha internal consistency estimates were obtained for the ABLLS-R domains, while convergent and divergent relationships (i.e., Spearman's *rho* correlation coefficient comparisons) were examined between the ABLLS-R domains and scores from the criterion measures. Specific hypotheses were tested by examining theoretically convergent vs. divergent median correlation comparisons for statistical significance using the R-based cocor package (Diedenhofen & Musch, 2015). Only a limited number of targeted statistical comparisons were possible due to the limited sample size. However, all available descriptive correlations between the ABLLS-R and criterion instruments are reported.

Results: Internal consistency results across the 25 ABLLS-R domains ranged from .78 to .98 (Mdn = .92). Relationships between 23 of the 25 ABLLS-R domains, referred to as repertoires, and criterion measure scores were examined in groups of theoretically convergent vs. divergent coefficients. Median convergent coefficients ranged from .24 to .67 (Mdn = .47), while median divergent coefficients ranged from .15 to .46 (Mdn = .33). All correlations, correlation comparisons, and comparison effect size estimates will be reported.

Conclusions: The current study examined the reliability and criterion-related validity of the ABLLS-R, providing broad preliminary evidence of internal consistency, convergent validity, and divergent validity for several of its domains—either as a group or individually. Future research should investigate the ABLLS-R factor structure and provide targeted estimates of criterion-related validity, for specific domain scores, in larger samples.

415.099 *(Poster)* Ruling out ASD Is Easier Than Ruling It in, after a Brief Encounter with an at-Risk Toddler

A. T. Wieckowski[1], *A. de Marchena*[2], *L. Nichols*[1], *S. J. Fernandes*[1], *R. P. Thomas*[3], *D. A. Fein*[3], *L. B. Adamson*[4], *S. Dufek*[5], *A. C. Stahmer*[6] *and D. L. Robins*[1], *(1)A.J. Drexel Autism Institute, Drexel University, Philadelphia, PA, (2)University of the Sciences, Philadelphia, PA, (3)Psychological Sciences, University of Connecticut, Storrs, CT, (4)Psychology, Georgia State University, Atlanta, GA, (5)Psychiatry, University of California, Davis, Sacramento, CA, (6)Psychiatry and Behavioral Sciences, University of California at Davis MIND Institute, Sacramento, CA*

Background: Clinicians' initial diagnostic impressions of patients have significant implications for accurate final diagnoses of ASD (Hedley et al., 2016), yet the literature raises questions about the accuracy of clinician impressions of ASD compared to the final diagnosis (Gabrielson et al., 2014). Clinicians demonstrate increased confidence in their impressions when positively identifying ASD vs. ruling ASD out (McDonnell et al., 2018), but this has not been explored in terms of initial impressions, made after brief interactions with very young children.

Objectives: This study aimed to: 1) Explore clinicians' diagnostic impressions made within the first 5 minutes of meeting a toddler; 2) Investigate the relationship between accuracy and confidence in their initial impressions.

Methods: Participants were children (n=255, aged 12 to 53 months) referred for an ASD evaluation as part of multi-site studies screening toddlers for ASD during primary care check-ups (see Table 1 for sample demographics). Five minutes after the initial introduction, evaluating clinicians were asked to record if they believed the child would meet criteria for ASD or not following a complete evaluation, and how confident they were, on a scale of 1-5, regarding their initial classification. Each child was evaluated by one experienced senior clinician (psychologist who is research reliable on the ADOS-2), and one junior clinician (advanced trainee in a clinical discipline).

Results: There was substantial agreement between senior clinicians' initial impressions and final diagnosis (κ=.641, p<.001) and moderate agreement between junior clinicians' initial impressions and final diagnosis (κ=.531, p<.001). Clinicians' first impressions were highly consistent with the final diagnosis when the final diagnosis was not ASD (Senior clinician: 95.27%; Junior clinician: 93.02%). When the final diagnosis was ASD, senior clinicians more consistently reported impression of ASD (64.37%) compared to junior clinicians (58.14%). Clinicians' confidence in the accuracy of their impression was significantly higher for children not diagnosed with ASD, compared to children with final ASD diagnosis, both for senior clinicians (t(224)=6.00, p<.001) and junior clinicians (t(221)=4.49, p<.001). Clinicians' confidence was also significantly higher when their impression accurately matched the final diagnosis compared to when there was a mismatch between the impression and final diagnosis for senior (t(224)=-4.84, p <.001) as well as junior clinicians (t(201)=-7.34, p<.001).

Conclusions: Within the first 5 minutes of meeting a toddler at risk for ASD, clinicians' impressions of children's diagnoses often matched children's final diagnoses following a diagnostic assessment. The impressions were especially consistent with the final diagnoses for children who did not receive an ASD diagnosis, indicating that clinicians are generally able to rule out ASD in typically developing children and children with developmental disabilities within the first 5 minutes of the encounter. All clinicians indicated higher confidence when there was a match between their impression and final diagnosis, compared to mismatch, perhaps indicating their uncertainty. Lower concordance between the initial impression and the final diagnosis for toddlers with ASD indicate challenges to identifying symptoms of ASD in a brief, initial observation, and points to the importance of conducting a comprehensive evaluation.

415.100 *(Poster)* Screening for Autism Spectrum Disorder in Females with Polish Social Communication Questionnaire, SCQ – the Importance of Sex-Specific Formulated Questions for Parents/Caregivers

A. Rynkiewicz[1,2], *M. Karwowska*[3], *A. Kozak*[3], *D. Bernaciak*[3] *and M. Szura*[3], *(1)Department of Psychiatry, Medical College of Rzeszow University, Rzeszow, Poland, (2)Center for Diagnosis,Therapy and Education SPECTRUM ASC-MED, Gdansk, Poland, (3)Medical College of Rzeszow University, Rzeszow, Poland*

Background: Sex/gender has a significant impact on the symptomatology of autism spectrum disorder (ASD) henceforth autism. ASD characteristics demonstrate in females in the distinctive ways from males with this disorder. Cultural and social aspects may also impact the autistic characteristics presented by autistic females. Symptoms of ASD present in the early developmental period in the majority of cases. However this condition can be diagnosed in adolescence or adulthood too. It is especially true for ASD females when social demand exceed limited capacities and learned strategies used to camouflage or mask the difficulties. The ASD standardised assessments to identify females with autism are still under-explored in Poland, as in other countries of Central and Eastern Europe. The researchers postulate that the screening assessments need sex-specific formulated questions for parents/caregivers.

Objectives: To investigate whether differences between Polish females and males with autism (ASD) exist based on the responses provided by Polish parents/caregivers to Polish *Social Communication Questionnaire, SCQ, "Lifetime"* and *"Current"* forms with main focus on variables within unusual interests and sensory abnormalities.

Methods: The study included 91 Polish participants, 30 females and 61 males with no intellectual disability, IQ average and above, with no profound communication difficulties. Study groups were divided based on age: children (3-11 y.o.), adolescents (12-17 y.o.) and adults (20-37 y.o.). Recruited participants were from Mental Health Services and Autism Clinics in Pomeranian, Carpathian and Wielkopolskie voivodeships in Poland. Co-occurring psychiatric conditions are extremely common among people with ASD thus patients (n=34) with any additional conditions e.g. anorexia nervosa, mutism, epilepsy, depression, schizophrenia, tic disorders and the others also qualified for this study. Parents provided information on the author-reviewed Polish research translation of SCQ - Current and Lifetime. The results were analyzed and compared between two sexes and the age groups.

Results: ASD boys presented more special, unusual interests than ASD girls while there was no difference in this area for both sexes for ASD adults. The intensity of these special interests however were significantly higher for adult males with autism than ASD females. No differences were found in the area of unusual sensory interests between ASD boys and girls and the results were equally significant in this area for this age group with autism. Sensory difficulties tended to decrease with age in ASD adult women.

Conclusions: Parents of ASD young girls may not report the special interests of their children in SCQ as the themes may not be viewed as unusual and traditionally linked to autism. The study raises questions about parent-report screening measures where the examples in questions are male-oriented e.g. maps, dinosaurs, timetables, traffic lights etc. Parents of females may be biased while completing such questionnaire with no supervision. Retrospective interview from parents of ASD adults can be burdened with a recall bias too. The results contribute to further understanding of ASD in females.

415.101 *(Poster)* Screening for Developmental Deceleration across Domains: A New Strategy for Early Autism Detection

***W. Guthrie**, C. J. Zampella, L. S. Cubit and J. S. Miller, Center for Autism Research, Children's Hospital of Philadelphia, Philadelphia, PA*

Background: Emerging research from high-risk cohorts suggests that many children later diagnosed with ASD show early *developmental deceleration* – or slowing of developmental progress – and that this pattern is sometimes evident before clear autism symptoms emerge. Research from our lab demonstrated that developmental deceleration can also be detected in a low-risk, general population sample using the Survey of Well-being of Young Children (SWYC), a broadband screening tool recommended by the American Academy of Pediatrics (AAP) to screen for developmental delays. While we found that a pattern of generalized developmental deceleration indicates a significantly elevated risk for ASD, it is not yet clear whether this pattern is present across all developmental domains or driven by any specific domain(s) (e.g., communication, motor).

Objectives: Determine whether early developmental deceleration is (1) observed in specific domains and (2) associated with elevated risk for ASD.

Methods: Children from ten Children's Hospital of Philadelphia (CHOP) primary care sites were administered the Ages and Stages Questionnaire–Third Edition (ASQ-3) at 9, 18, 24, and 30-month well-child visits, according to AAP guidelines. Children with at least one ASQ-3 who received care at CHOP through ≥4 years were included in this study (*N*=8,124). This cohort was racially (68.1% non-white) and socioeconomically (50.4% public insurance/Medicaid) diverse, and received an average of 1.5 of the three recommended developmental screenings. ASD prevalence was 3.1%.

Results: Growth mixture models (GMM) identified distinct developmental trajectories of ASQ-3 scores from 9-30 months, with separate models run for each of the five ASQ-3 domains. GMMs identified four Fine Motor classes, five Communication and Problem-Solving classes, and six Gross Motor and Social classes.

Final models for Communication, Social and Problem-Solving domains each identified one or two classes characterized by decreasing ASQ-3 scores from 9-30 months, which were associated with increased risk for ASD. For example, children with typical and borderline Communication skills at 9 months and a significant decrease from 9-30 months had an 11.4% and 25.0% risk of ASD respectively (compared to 3.1% rate in the entire cohort). Models also revealed that children with low scores at 9 months that were stable over time also had an elevated ASD risk (Gross Motor: 16.8%, 16.9%, Fine Motor: 19.4%, Social: 34.1%, Problem-Solving: 25.4%).

Conclusions: Children with developmental deceleration in social, communication, and problem-solving skills appear to be at elevated risk for ASD, suggesting that screening for trajectories in these domains may detect more at-risk children than screening at a single timepoint. In addition, deficits in any domain that emerge early and persist may also indicate ASD risk. Findings from the Social domain were of particular interest, as over a third of infants with clear deficits at 9 months that persisted were later diagnosed with ASD. While these developmental patterns were not perfectly predictive of ASD, the positive predictive values of developmental deceleration and early, persistent deficits were at or above those of autism-specific screening tools (Guthrie et al., 2019). Thus, repeated screenings with broadband developmental tools may be a fruitful avenue for earlier and more sensitive ASD detection.

415.102 *(Poster)* Self-Management of Daily Life Tasks for Adolescents with ASD without Intellectual Disability

***E. G. Munsell**, G. I. Orsmond and W. J. Coster, Department of Occupational Therapy, Boston University, Boston, MA*

Background: Managing the tasks and responsibilities of daily life is a key feature of transition into adulthood. However, youth with autism spectrum disorder (ASD), including those without intellectual disability (ID), have poorer daily living skills compared to typically developing peers (Pugliese et al., 2014). Limitations in managing daily life tasks may contribute to the poor outcomes seen in this population (Roux et al., 2015). The Pediatric Evaluation of Disability Inventory – Computer Adaptive Test - ASD (PEDI-CAT-ASD): Responsibility Scale (Haley et al., 2012) targets this domain of function. The instrument operationalizes the shift in management of daily life tasks from caregivers to youth. Because the domain items require application of cognitive and social knowledge and skills, it may be especially useful to understand the challenges youth with ASD face in daily life.

Objectives: Our aim was to describe the transfer of responsibility in this population across a period of significant developmental change. We hypothesized that adolescents with ASD without ID would demonstrate below average levels of responsibility in comparison to typically developing peers.

Methods: This is a secondary analysis of PEDI-CAT-ASD data of adolescents (ages 14-22) with ASD without ID (n = 125). Part of the sample was from the PEDI-CAT-ASD development study and the remainder is from an ongoing study examining factors related to post-high school outcomes for youth with ASD. Parents completed the Responsibility domain reporting on their youth's level of responsibility for daily life tasks. We examined the distribution of norm-referenced scores and Fit scores to describe our sample.

Results: The PEDI-CAT-ASD is sensitive to the range of variation seen in this population. Overall, youth performed below expected levels based on their intellectual level. T-scores for the sample ranged from <10-51, (50 is average for age). 46% of the sample fell in the significantly delayed range (T-score ≤30). An additional 40% of youth were in the borderline delayed range. Notably, 61% of youth age 18 and older were significantly delayed, compared to 38% ages 14-17, indicating that as youth grow older and expectations for responsibility increase, the discrepancy in performance compared to peers widens. The PEDI-CAT-ASD item maps identify the areas where youth are having difficulty. For example, an 18 year old with a T-score of 30 is not yet taking full responsibility in many common life tasks, including planning and following a weekly schedule or informing school or work when absent.

Conclusions: Inability to manage daily responsibilities may impact an individual's success in adulthood. The findings from the PEDI-CAT-ASD are consistent with other literature and provide detailed and precise information about the daily life tasks in which youth show difficulty. In comparison to traditional assessments (e.g. VABS-III), PEDI-CAT-ASD captures an individual's ability to coordinate multiple functional skills to carry out tasks in their daily lives. The findings demonstrate that many youth with ASD without ID demonstrate significant delays in taking over management of daily life tasks. If this challenge is not addressed, it may create significant barriers to success in work and independent living post-high school.

415.103 *(Poster)* Self-Reported Executive Functioning Challenges in Autistic Youth Compared to Attention Deficit/Hyperactivity Disorder Youth

C. Jeppsen[1], *G. L. Wallace*[2], *G. Jost*[1], *A. C. Armour*[3], *A. Verbalis*[4], *C. E. Pugliese*[4], *J. Greene*[5] *and L. Kenworthy*[4], *(1)Children's National Hospital, Rockville, MD, (2)The George Washington University, Washington, DC, (3)Children's National Health System, Washington, DC, (4)Center for Autism Spectrum Disorders, Children's National Hospital, Washington, DC, (5)Psychological Assessment Resources, Tampa, FL*

Background: Previous research suggests that self-report in a variety of clinical conditions enhances assessment of internal states (Verhulst & van der Ende, 1992; Robins, Fraley and Kruger, 2009, Keith et al., 2019; Barkley et al., 1991). Parent report on autistic youth indicates global executive functioning (EF) problems, with peak deficits in flexibility and metacognition (Granader et al., 2014; Wallace et al., 2016). In spite of the importance of gauging inner experiences, self-reported EF challenges in ASD have yet to be fully investigated. We previously reported (Clinton et al., 2019) that parent-report and self-report from autistic youth show similar peak problems with flexibility and metacognitive issues. Autistic youth report a lower overall level of EF problems than their parents report, however. ADHD represents another developmental disability that is associated with significant EF problems (e.g., Gioia et al., 2002).

Objectives: Investigate whether autistic youth report an equivalent level of EF problems as youth with ADHD report on the BRIEF-2, and if the pattern of problems the two groups report are distinctive.

Methods: BRIEF-2 self-report data were compared between a sample of 203 autistic youth (148 male, 55 female, ages 11–18 years, *M* FSIQ=97.6, *SD*=18.9) and a sample of 109 ADHD youth without comorbid medical diagnoses (62 male, 45 female, ages 11-18.0 years, *M* FSIQ=94.5, *SD*=13.3) using repeated measures ANOVA. Follow-up independent samples t-tests were used to compare differences in peak EF problems between groups, corrected for multiple comparisons using the Bonferroni method.

Results: A main effect of diagnosis on BRIEF subdomain scores (F=4.26, p=.04) suggests that autistic youth reported significantly greater EF problems than did ADHD youth. Examination of subscales indicated autistic youth reported greater problems on the Self-Monitor (p<.001), Emotional Control (p=.001) and Shift (p<.001) subscales, than the ADHD youth. Both ASD and ADHD youth reported elevated and equivalent levels of problems on the Metacognition Indices, including subscales of Working Memory, Task Completion, Planning and Organizing, and Inhibition.

Conclusions: Autistic youth report overall greater EF problems than ADHD youth, and specifically greater problems with self-monitoring, emotional control, and flexibility on the BRIEF-2. Both groups report similar difficulties with inhibitory control and metacognition. These self-report findings indicate that autistic youth report significant levels of EF problems, even when compared to youth with ADHD; moreover, their profile is distinctive and consistent with parent and clinician observed patterns of EF weaknesses in ASD. These findings highlight the importance of utilizing self-report from autistic youth to better understand their EF profiles and inform intervention.

415.104 *(Poster)* Sensory Reactivity in a Sample of 12-Month-Old Siblings of Children with ASD: Factor Structure of the Sensory Experiences Questionnaire

R. Grzadzinski[1], *M. H. Boynton*[2], *K. Botteron*[3], *S. R. Dager*[4], *A. Estes*[5], *R. T. Schultz*[6], *L. Zwaigenbaum*[7], *J. Piven*[8], *J. Wolff*[9], *H. C. Hazlett*[10] *and .. The IBIS Network*[10], *(1)Carolina Institute for Developmental Disabilities, University of North Carolina, Chapel Hill, NC, (2)Department of Health Behavior, University of North Carolina, Gillings School of Global Public Health, Chapel Hill, NC, (3)Psychiatry (Child) and Radiology, Washington University School of Medicine, St. Louis, MO, (4)Radiology, University of Washington, Seattle, WA, (5)Speech and Hearing Sciences, University of Washington, Seattle, WA, (6)Center for Autism Research, Children's Hospital of Philadelphia, Philadelphia, PA, (7)University of Alberta, Edmonton, AB, Canada, (8)*Co-senior author, University of North Carolina, Chapel Hill, NC, (9)University of Minnesota, Minneapolis, MN, (10)University of North Carolina, Chapel Hill, NC*

Background: Studies suggest that 70-90% of children with, or at high risk for, autism spectrum disorder (ASD) display atypical sensory reactivity, including hyporeactivity, hyperreactivity, and/or sensory seeking behaviors. The Sensory Experiences Questionnaire (SEQ) Version 2.1 is a 43-item parent-report measure of sensory reactivity appropriate for children as young as 5 months. Although frequently used to characterize sensory symptoms for at risk children, to date, there has been limited factor analytic research exploring the theorized factor structure of the scale, and none for populations limited to infants.

Objectives: 1) To conduct confirmatory (CFA) and exploratory (EFA) factor analyses of the SEQ Version 2.1 using data from a sample of 12-month-old children to evaluate whether the theorized factors are supported in this sample, and 2) to determine whether the factor structure of the scale is consistent across different ASD risk and diagnostic groups.

Methods: Children were participating in the Infant Brain Imaging Study (IBIS)—a prospective, longitudinal study of infants with either high or low familial risk of developing ASD, denoted by either the presence or absence of a first degree relative with ASD, respectively. Parents completed the SEQ Version 2.1 for their child at 12 months of age. ASD diagnostic evaluations were subsequently conducted at 24 or 36 months, yielding three groups: low risk without an ASD diagnosis (LR-Neg; n=122), high risk without an ASD diagnosis (HR-Neg; n=242), and high risk with an ASD diagnosis (ASD; n=72). Factor analyses were conducted using M*plus*8. CFA was used to fit the theorized 3 factor latent variable model and an EFA with 1, 2, 3, 4, 5, and 6 factor model solutions was tested using geomin rotation. In both models each analysis was stratified by risk-diagnosis group and all indicators were treated as categorical.

Results: CFA results for the posited three factor model resulted in poor to marginal model fit for the three groups (CFIs from .59-.84). EFA results identified non-social-sensory seeking and non-social-hyperreactive factors for all three groups. A third factor, social-hyporeactive was identified for the ASD group ($M\beta$ = .61) and HR-Neg group ($M\beta$ = .66), but not for the LR-neg group ($M\beta$ = .34). See Figure 1.

Conclusions: Characterizing the features of sensorimotor behaviors for both low and high-risk infants is essential to a fuller understanding and early diagnosis of ASD. Examining the factor structure of the SEQ may help identify specific sensory profiles in subgroups of children, both in terms of age and ASD risk. Such profiles can be used to further our understanding of ASD phenotypes in early development. Future research would benefit from examining whether and how the factor structure of the SEQ evolves over the course of the developmental lifespan and how the nature of SEQ symptoms may predict long-term outcomes for children with ASD.

415.105 *(Poster)* Sex Differences in Autism Phenotype and Adaptive Functioning: Does Intellectual Disability Play a Role?

E. Sadikova *and M. O. Mazurek, University of Virginia, Charlottesville, VA*

Background: Although 30-50% of individuals with Autism Spectrum Disorder (ASD) also have an intellectual disability (ID) (CDC, 2018; Charman et al., 2011), most individuals who have co-occurring ASD and ID are excluded from research (Russell et al., 2019). Recent studies have indicated sex differences in the behavioral phenotype of girls with ASD (for review, see Lawson, 2019). However, many of these studies excluded individuals with co-occurring ID, or did not include a representative sample.

Objectives: The aim of this study was to examine sex differences in ASD presentation and adaptive functioning in children with and without ID. Considering previous literature, we hypothesized that there would be main effects of sex differences in specific autism symptom domains and adaptive functioning. We also hypothesized that the sex differences would be larger in those without ID, resulting in an interaction effect between sex and ID.

Methods: The sample included 606 children (123 female, 483 male, mean age: 9.69 y.o.) diagnosed with ASD, who were enrolled in the Autism Treatment Network Registry Call-Back Study. We examined autism phenotype characteristics using the Autism Impact Measure (AIM) and its five domains: Repetitive Behavior, Communication, Atypical Behavior, Social Reciprocity, and Peer Interaction (Mazurek et al., 2018). Adaptive functioning was examined using the Vineland Adaptive Behavior Scales, Second Edition (Vineland-II) domains: Communication, Daily Living Skills (DLS), and Socialization (Sparrow et al. 2005). Analyses of the outcomes were evaluated using a Factorial ANOVA to compare the main effects of gender, ID, and the interaction of gender and ID.

Results: Male and female participants were not statistically different in age. Results indicated a main effect of ID on the AIM Repetitive Behavior, Communication, Social Reciprocity, and Peer Interaction domains, but not on the AIM Atypical Behavior scale or the AIM total score. Gender was not a significant predictor of either the total score or any subdomain, and none of the interactions of gender and ID were significant (AIM total: Total: $F(1,454) = 0.63$, $p = .43$, Repetitive Behavior: $F(1,476) = 0.20$, $p = .65$; Communication: $F(1,471) = 0.002$, $p = .97$; Atypical Behavior: $F(1,472) = 0.10$, $p = .74$); Social Reciprocity: $F(1,471) = 2.03$, $p = .15$; Peer Interaction: $F(1,474) = 1.29$, $p = .26$). On the Vineland-II, all of the subdomains showed significant main effect of ID, but not any main effects of gender, or the interaction between gender and ID (Communication: $F(1,499) = 1.81$, $p = .18$; DLS: $F(1,499) = 0.76$, $p = .38$; Socialization: $F(1,499) = 1.38$, $p = .24$).

Conclusions: Contrary to previous literature and our hypotheses, we did not find sex differences in specific types of ASD symptoms or adaptive functioning. There were also no statistically significant interaction effects between sex and ID with any of the outcomes. It is essential to further examine evidence of sex differences in ASD and to ensure the inclusion of individuals with ID.

415.106 *(Poster)* Sex Differences in Toddler ASD Screening

S. Y. Eldeeb[1]*, A. T. Wieckowski*[1]*, D. A. Fein*[2]*, A. C. Stahmer*[3]*, L. B. Adamson*[4] *and D. L. Robins*[1]*, (1)A.J. Drexel Autism Institute, Drexel University, Philadelphia, PA, (2)Psychological Sciences, University of Connecticut, Storrs, CT, (3)Psychiatry and Behavioral Sciences, University of California at Davis MIND Institute, Sacramento, CA, (4)Psychology, Georgia State University, Atlanta, GA*

Background: Sex differences in the diagnostic rate of autism spectrum disorder (ASD) remain one of the most consistent findings in the literature (e.g. Wing, 1981, Fombonne, 2009). Despite these unequivocal findings, few studies have examined whether sex differences are also apparent in screening and diagnosis early in life. Previous work in toddlers with ASD have found few or no apparent sex differences in symptom presentation (Lawson, Joshi, Barbaro, & Dissanayake, 2018; Reinhardt, Wetherby, Schatschneider, & Lord, 2015), highlighting a critical period to examine sex differences in screening results. This study explores whether screening tools are identifying males and females with ASD at similar rates for potential downstream implications of receiving early intervention.

Objectives: This study aimed to explore sex differences in toddlers screened for ASD in: 1) Risk levels in initial screening for ASD using the Modified Checklist for Autism in Toddlers, Revised (M-CHAT-R); 2) M-CHAT-R Follow-Up (M-CHAT-R/F) scores, warranting evaluation; and 3) M-CHAT-R/F psychometric properties.

Methods: Data from multiple screening studies were aggregated to maximize statistical power. Across all studies, toddlers (N=18701; males=9594, females=9107) were screened for ASD during primary care check-ups at community pediatric providers (M=20.62 months, SD =3.16) using the M-CHAT-R/F (Robins, Fein, & Barton, 2009). Of these children, 400 attended an autism evaluation (M=24.86 months, SD=6.24) from a positive screen or provider referral.

Results: The proportion of males and females screened who scored in the low, medium, and high risk range on the M-CHAT-R significantly differed (X^2 (2, n=18,701) = 57.43, $p < .001$); females were less likely to score in medium or high risk groups (Table 1). Females also were less likely than males to screen positive on the structured Follow-Up, and therefore were invited in for evaluations at a lower rate (33.9% vs. 40.4%; (X^2 (1, n = 1038) = 4.55, p =.03; Table 1). Positive predictive value (PPV) was significantly lower for females than males (.386 vs .586; X^2 (1, n = 329) = 11.94, p =.001), but negative predictive value was higher for females than males (.999 vs. .997; X^2 (1, n=17,616) = 7.09, p=.008). No significant sex differences emerged for sensitivity (X^2 (1, n = 204) = .005, p =.943) or specificity (X^2 (1, n=17,741) = 1.77, p =.183) of the M-CHAT-R/F (Table 2).

Conclusions: Sex differences are evident starting from the first stages of identification in toddlers whose parents complete standardized screening at check-ups. Females were more likely to score at low risk for ASD, and were subsequently less likely to be invited for an evaluation than males. The M-CHAT-R/F detected ASD and nonASD in males and females equally (i.e., sensitivity and specificity), highlighting a strength of the tool. However, screen positive females were less likely to be diagnosed with ASD than males (i.e., PPV), which may reduce confidence that a positive screen in a female warrants referrals for evaluation and intervention. Future studies should examine whether items in the M-CHAT-R/F should be weighted differently or removed from scoring to improve the confidence in a positive screen result in females.

415.107 *(Poster)* Sex and Chronological Age in Relation to Sensory Processing in ASD

S. E. Schulz[1]*, E. Anagnostou*[2]*, E. Kelley*[3]*, S. Georgiades*[4]*, X. Liu*[5] *and R. A. Stevenson*[1]*, (1)Western University, London, ON, Canada, (2)Holland Bloorview Kids Rehabilitation Hospital, Toronto, ON, Canada, (3)Queen's University, Kingston, ON, Canada, (4)McMaster University, Hamilton, ON, Canada, (5)Genomics, Queen's Genomics Lab at Ongwanada, Kingston, ON, Canada*

Background: Current estimates suggest that the ratio of boys to girls with autism spectrum disorder (ASD) diagnoses is approximately 4:1. Sex differences have also been reported in levels of symptomatology, with girls on average exhibiting more severe symptoms than boys. Few studies, however, have explored sex differences in the presentation of sensory processing issues in ASD, a very common issue that has been recently included as a diagnostic criterion. We aim to address the question of whether there are sex differences in sensory processing issues in ASD across development.

Objectives: This project explores the differences in sensory processing between autistic girls and boys across development from early childhood to early adulthood. We expect to see greater issues across all sensory processing domains in girls relative to boys, in line with sex differences observed in other symptomatology. We also expect to see improvements in sensory processing issues as age increases. Finally, we predict a sex*age interaction such that autistic girls exhibit fewer improvements in sensory processing throughout development when compared to autistic boys.

Methods: Parents of 339 participants from the Province of Ontario Neurodevelopmental Disorder Network (Girls=72, Boys=267, Age range=2-22, Mean age=10.24) completed a questionnaire on sensory processing, the Short Sensory Profile (SSP). Sex differences in sensory processing were initially assessed using t-tests for each SSP subscale, while initial age-related changes were assessed using correlations between sensory processing and age. The primary analysis consisted of linear regressions predicting each sensory processing subscale based on sex, age, and the interaction term between sex and age.

Results: Significant sex differences were found specifically in *Underresponsive/Sensory Seeking* in which girls displayed more severe symptoms (see Table for all regression statistics). Developmental changes were observed in the symptom severity of *Underresponsive/Sensory Seeking*, which became more severe with age, as well as of *Low Energy/Weak*, which became less severe with age. Non-significant sex*age interaction terms indicate similar developmental trajectories for boys and girls.

Conclusions: Sex differences were observed in sensory processing patterns but were restricted to *Underresponsive/Sensory Seeking* and as expected, girls were found to have more severe symptoms. Given the prominent sex difference across other symptom domains within ASD, we were surprised ubiquitous and larger effects were not observed throughout the sensory processing symptoms. Regardless of sex, there were opposing age-related changes in sensory processing, with *Low Energy/Weak* improving with age as expected, but with, *Underresponsive/Sensory Seeking* tending to increase in severity with age.

415.108 *(Poster)* Sex/Gender Modulates the Relationship between Social Communication and Motor Skills in Autism Spectrum Disorder

A. Crippa[1]*, S. Busti Ceccarelli*[1]*, F. Craig*[2]*, N. Scionti*[3]*, A. Cremascoli*[3]*, C. Ferrante*[3]*, C. Visioli*[3]*, G. M. Marzocchi*[3]*, M. Nobile*[1] *and M. Molteni*[1]*, (1)Scientific Institute, IRCCS Eugenio Medea, Bosisio Parini, Italy, (2)Scientific Institute, IRCCS E. Medea, Brindisi, Italy, (3)Department of Psychology, University of Milano-Bicocca, Milano, Italy*

Background: Although not included in the diagnostic criteria, autism spectrum disorder (ASD) is significantly associated with extensive alterations in motor performance, with a noteworthy effect size of 1.20 (Fournier et al., 2010). These difficulties generally occur in the first years of life (Bhat et al., 2012) and may even precede the socio-communicative deficits (Sacrey et al., 2018). They also tend to increase with age (Freitag et al., 2007) and to impact individuals' adaptive functioning and life quality (Bremer and Lloyd, 2016). Despite the reported sex/gender bias in the prevalence of the disorder, the impact of sex/gender differences on ASD-related motor abnormalities remains often overlooked. Examining clinical manifestations and motor profiles, as well as their interaction in boys and girls with ASD, may have significant implications for the development of adequate assessment and treatment strategies for patients with ASD.

Objectives: To explore possible differences in the motor profile of boys and girls with ASD using standardized neuropsychological tests and kinematic analysis of a simple upper limb movement. To examine how clinical symptoms and motor skills are interrelated in each sex.

Methods: One hundred ten children with ASD (89 boys, 21 girls), ages 2 through 11 years, and 98 typically developing (TD) children (72 boys, 26 girls) matched by age participated to the study. We assessed motor proficiency using the Movement Assessment Battery for Children—2, the Beery-Buktenica Developmental Test of Visual-Motor Integration and an abbreviated battery of tests from NEPSY-II. In addition, 3D kinematic data of a reach-to-drop movement were collected by a motion-capture system. Lastly, parents filled the Developmental Coordination Disorder Questionnaire and the Social Responsiveness Scale. Data were analyzed using a 2x2 analysis of covariance (independent factors: sex/gender, diagnosis; covariate: IQ). Moreover, Pearson's correlations were computed between the severity of ASD symptom measures and motor functioning.

Results: As expected, children with ASD (both boys and girls) performed significantly worse than TD group in almost all motor abilities investigated. We observed a significant sex/gender by diagnosis interaction for the NEPSY-II imitating hand positions sub test and for kinematic features related to movement planning, with girls with ASD obtaining better performances than boys. Lastly, a significant positive correlation between motor coordination and socio-communicative abilities was observed for all TD children and in boys with ASD, but not in girls with ASD.

Conclusions: The present study adds to a growing body of evidence documenting sex/gender differences in children with ASD. Our findings suggested that sex/gender might play a significant role for specific motor domain in ASD, such as imitation of hand postures and movement planning. Furthermore, this study provides intriguing evidence that sex/gender could modulate the relationship between social communication and motor skills. Overall, the present findings highlighted the need for more sex/gender specific diagnostic and intervention strategies in ASD.

415.109 *(Poster)* Similarities and Differences in Executive Functioning Profiles of ASD and ADHD

***E. Wilkinson**, C. Janicki, M. Rinaldi and K. V. Christodulu, Center for Autism and Related Disabilities, Albany, NY*

Background: Many children with autism spectrum disorders (ASD) and attention deficit hyperactivity disorder (ADHD) have executive functioning (EF) impairments (Demetriou et al., 2017; Pennington & Ozonoff, 1996). Studies comparing EF profiles across diagnoses have mixed results. A recent review indicated ASD children had greater deficits in flexibility and planning while ADHD children demonstrated greater deficits in response inhibition (Craig et al., 2016). In contrast, other findings suggest that response inhibition, working memory, and flexibility are more impaired in ASD and that there are no differences in planning (Corbett et al., 2010; Simrud-Clikeman et al., 2010). Understanding similarities and differences in EF across diagnoses can inform research and practice by identifying common underlying factors as well as differentiating factors that may be unique to autism. If profiles are similar, interventions targeted at teaching specific EF skills in ADHD could be modified for ASD, and vice versa.

Objectives: To compare EF domains between children with ASD and children with ADHD in a clinic-referred sample using the Behavior Rating Inventory of Executive Function (BRIEF; Gioia, Isquith, Guy, & Kenworthy, 2000).

Methods: The BRIEF parent form was completed for 20 children with ADHD (5-15 years; 17 males, 3 females) and 36 children with ASD (5-18 years; 26 males, 10 females) in a community clinic. All children also completed the Stanford Binet Intelligence Scales 5th Edition (Roid & Pomplun, 2012).

Results: Children with ASD had significantly elevated scores on the BRIEF Initiate domain (M = 72.28, SD = 10.06) compared to children with ADHD (M = 65.4, SD = 11.97), and the Plan/Organize domain (ASD: M = 72.44, SD = 13.47; ADHD: M = 63.65, SD = 14) ($p < .05$). Groups did not differ on Inhibit, Shift, Emotional Control, Working Memory, Organization of Materials, Monitoring, Behavior Regulation, Metacognition, and Global domains. Children with ASD were older (M = 11.42, SD = 4.25) than ADHD children (M = 7.65, SD = 3.3) ($p < .05$). Groups did not differ by gender or IQ.

Conclusions: Our results indicate that children with ASD have more difficulty initiating tasks, planning, and organizing than children with ADHD. These results support findings that planning is particularly impaired in ASD (Craig et al., 2016; Bramham et al., 2009) and also suggest initiating tasks is particularly difficult in ASD. Given the age difference between groups, it is possible that these relative deficits emerge at a later age and therefore weren't seen within the ADHD group. ASD and ADHD share many similarities in their EF abilities, suggesting that EF deficits in domains of inhibiting, shifting, working memory, material organization, and monitoring may not be diagnosis-specific. Interventions targeting these skills could be applicable to both populations. Future directions may involve investigating EF similarities and differences in children with comorbid ASD and ADHD as well as exploring cognitive mechanisms specific to ASD that contribute to deficits in initiating and planning/organizing. Collection of the BRIEF 2nd edition is ongoing and future aims include exploring EF profiles using the updated measure and comparison to the current findings.

415.110 *(Poster)* Social-Communication Subgroups in ASD: Individual Differences in Peer Interactions

***A. Shefer**[1] and N. B. Bauminger-Zviely[2], (1)School of Education, Bar Ilan University, RAMAT GAN, Israel, (2)School of Education, Bar Ilan University, Ramat Gan, Israel*

Background: While individuals with ASD are characterized by impaired social communication skills and repetitive patterns of behavior, interests and activities, they are diverse in their symptom manifestations and severity) Eldevik, Hastings, Jahr, & Hughes, 2012; Hayward, Eikeseth, Gale, & Morgan, 2009(. These deficits are more noticeable during peer interaction, as opposed to interactions with adults. But individual differences in peer-engagement and the heterogeneity in high-functioning ASD (HFASD; IQ > 75) are not yet well explored. Thus information gathered via direct observation is critical for comprehensively assessing these children's social-interactive skills.

Objectives: The current study set out to examine the contribution of IQ, adaptive skills, and social impairment to the explanation of individual differences in the social-communication profile of preschoolers with HFASD during peer engagement. We also explored the classification of within social-communicative subgroups via peer interaction.

Methods: Fifty pre-schoolers, aged 3-6 years, with HFASD participated in the study. Our measures included the "Autism Peer Interaction Observation"-APIOS (Shefer & Bauminger-Zviely, 2016). The APIOS is comprised of a 3-hour observational procedure assessing pre-schoolers' social-communication abilities during spontaneous peer interactions spanning various preschool activities (e.g., indoor and outdoor free play, mealtime). The APIOS includes 9 categories and 17 subcategories for adaptive social functioning (e.g., nonverbal communication, functional and complex social behaviors, prosocial behaviors, social and imaginary play, conversation) rated by the observer along a 4-point scale from 1 (typical) to 4 (very atypical). To evaluate adaptive skills and social capabilities, the Vineland and SRS-2 were completed by teacher reports. To assess cognitive functioning and symptoms severity, the Mullen and the ADOS-2 were used.

Results: All children were HFASD, yet they showed different abilities in peer interaction**.** Children with HFASD were classified into three subgroups (see Figure 1): children who showed a severe social –communication deficit on APIOS behaviors (n=12); children who showed a mild social-communication deficit (n=11); and children who showed a mixed profile that reflected mild difficulties in most APIOS social-communication categories, with a moderate to severe deficit in pro-social behavior and imaginary play (n=27). The subgroup with the most severe social –communication deficit on APIOS behaviors also had lower general IQ and verbal IQ scores than the subgroup with mild social communication deficit. Furthermore, the severe subgroup's non-verbal IQ was lower than average range. All three subgroups showed below average social functioning on the VABS-II social skills, though the mixed subgroup had better social functioning in comparison to the severe subgroup. More impaired social symptoms were also seen for the severe subgroup in comparison to the mild subgroup on the Social Affect and Interaction variable of the SRS-2.

Conclusions: Significant subgroup differences (severe/mild APIOS profile) within HFASD were found on IQ scores, social and communication skills on the VABS-II and the SRS-2, with the mild subgroup outperforming the severe subgroup. This value is important in order to better identify targets of intervention.

415.111 *(Poster)* Sources of Distress: A Behavior Focused Assessment of Psychiatric and Medical Conditions in Individuals with ASD

J. Davis[1], *T. P. Singh*[2], *W. Worsham*[2], *M. Weaver*[2], *J. Olafson*[3] *and D. A. Bilder*[4], *(1)Educational Psychology, University of Utah, Salt Lake City, UT, (2)University of Utah, Salt Lake City, UT, (3)Self employed, Salt Lake City, UT, (4)Psychiatry, University of Utah, Salt Lake City, UT*

Background: Individuals with autism spectrum disorders (ASD) who have low verbal ability regularly have difficulty communicating their sources of distress, discomfort or frustration. Often times these individuals communicate their needs indirectly through irritability and problem behavior. These behaviors can create a substantial barrier in their capacity to access appropriate medical care, participate in their community, and maintain residence with their parents or other caregivers. To address the needs of this population, medical providers must develop facility in translating observable behaviors to appropriate treatment protocols.

Objectives: The primary objective of the current project is to convert parent and caregiver social capital (e.g. resources and knowledge) into improved health outcomes for adolescents and adults with ASD or other developmental disabilities. In addition, this project seeks to improve medical provider efficiency via a carefully designed and sequenced delivery of questions that focus on known behaviors associated with specific psychiatric and medical conditions in this population.

Methods: The current study will evaluate results from a parent/caregiver assessment. This assessment examined participant's reasons for seeking medical treatment, present medication use, and mental health diagnosis history. The assessment targets several psychiatric and medical/physical conditions known to contribute to distress or maladaptive behaviors in individuals with non-verbal or limited verbal abilities. Psychiatric conditions targeted in the measure include Depression, Self-Injurious Behavior (SIB), Anxiety, Mania, and Psychosis. Medical/physical conditions include Sleep, Gastrointestinal (GI), Sensory, and Dental. Descriptive statistics are reported. In addition, results were disaggregated by sex and evaluated for statistical significance using the Mann-Whitney U test.
