**417.039 (Poster) What Do Teachers Know about Sex Differences in Autism? Survey Study on Recognition of Autism in Girls**

*E. F. Hemingway<sup>1</sup>, D. M. Riby<sup>2</sup> and M. Hanley<sup>3</sup>, (1)Psychology Dept, Durham University, Durham, United Kingdom, (2)Department of Psychology, Durham University, Durham, United Kingdom, (3)South Road, Durham University, Durham, United Kingdom of Great Britain and Northern Ireland*

---

**Background:** Females with Autistic Spectrum Conditions (ASC) without intellectual disability (ID) are currently under-recognised (Van Wijngaarden-Cremers et al., 2014). Teachers have a crucial gatekeeping role to the diagnostic pathway. The literature suggests that girls with ASC without ID may superficially look and sound more like typically developing girls than boys with similar levels of impairment in social communication and interaction (Dean et al., 2017; Hiller et al., 2014; Parish-Morris et al., 2017; Rynkiewicz et al., 2016). Late-diagnosed autistic women and parents of autistic girls have cited lack of knowledge about ASC in females amongst teachers as a factor in delayed diagnosis (Bargiela et al., 2016; Cook et al., 2018; Leedham et al., 2019). Yet very little is known about knowledge of sex differences in ASC presentation amongst teachers, and their confidence in recognising autism in girls.

**Objectives:** The aim of this exploratory study was to investigate levels and sources of knowledge of sex differences in ASC presentation amongst UK teachers. A further aim was to explore differences in teachers' confidence in recognising undiagnosed ASC in girls and in boys.

**Methods:** Ninety teachers and teaching assistants in mainstream and special education settings in the UK were surveyed using a bespoke questionnaire and convenience sampling through social media. Questions covered knowledge of ASC focussing in on sex differences in ASC presentation and confidence in recognising undiagnosed ASC in boys and girls.

**Results:** Most participants (n = 66; 73.3%) thought ASC presents differently across the sexes, with 47 participants (of 68; 69.1%) citing the "ability to mask symptoms" in females as the main reason. Other reasons for sex differences in ASC presentation included: "emotional & social maturity" in females (n = 53; 63.1%), "coping skills" in females (n = 42; 50.6%), "gender-related social expectations" in females (n = 40; 47.6%), and "aggression" in males (n = 50; 60.2%). Just over half of participants (n = 46; 51.1%) thought boys were more impaired than girls in social communication and interaction. Whilst 60% (n = 54) of respondents had received training for working with children with ASC, most participants (n = 74; 83.1%) had never received training for sex differences in ASC. More participants were "confident", "fairly confident" or "very confident" in recognising undiagnosed ASC in boys (n = 73; 81.1%) than in girls (n = 49; 54.4%). Over half (56%) of participants' suggestions to support teachers in recognising ASC in girls related to increasing training, understanding and awareness.

**Conclusions:** The key finding from this study suggests that whilst respondents were aware of sex differences in ASC presentation, behaviours observed in girls were interpreted as differences and/or coping mechanisms rather than indicating concealment of similar levels of difficulties to boys, and therefore warranting referral for assessment. Furthermore, participants were less confident in their ability to recognise ASC in girls and would welcome further training and understanding of ASC in girls.

**417.040 (Poster)** Written Language Adapted Tele-Assessment Practices during COVID-19: Successes and Challenges with Elementary-Age Children with Autism Spectrum Disorder

*M. C. Zajic<sup>1</sup>, A. R. Henry<sup>2</sup>, C. Conner<sup>2</sup> and E. J. Solari<sup>3</sup>, (1)Health & Behavior Studies, Teachers College, Columbia University, New York, NY, (2)University of Virginia, Charlottesville, VA, (3)Curriculum, Instruction, and Special Education, Curry School of Education University of Virginia, Charlottesville, VA*

---

## **Background:**

The COVID-19 pandemic has led many researchers to adopt adapted tele-assessment practices (i.e., the use of telecommunication technology to administer face-to-face normed assessments; Krach et al., 2020). Though professional organizations have offered some best-practice recommendations, concerns remain about the use of adapted psychoeducational tele-assessments for children with autism spectrum disorder (ASD), particularly in challenging skill areas like writing (Zajic & Wilson, 2020). This presentation examines the successes and challenges of conducting written language adapted tele-assessments via Zoom to children with ASD.

## **Objectives:**

This presentation will discuss the process of collecting writing assessment data collected at pretest during a telecommunication comprehension intervention. Information will be provided about the choices made in redesigning these assessments (based on guidance from professional organizations and practical considerations), the process of conducting these assessments (including the spaces and people involved), and the participants' performance.

## **Methods:**

Fourteen verbal children with ASD (ages 7-9) from across the United States were administered the VMI-6, the WJ-IV (Sentence Writing Fluency [SWF] and Writing Samples [WS]), and an experimenter-designed assessment (Name Writing, Letter Writing, Word Writing, and Sentence Story Writing). A trained team member administered and scored all assessments, and all children completed the activities using either unlined paper with a pen or pencil, or a whiteboard and marker. All assessments were redesigned to be administered using Microsoft PowerPoint.

## **Results:**

Participants demonstrated few difficulties completing the VMI-6, but some participants frequently forgot to show their drawings or were unable to align the paper/whiteboard with the webcam. SWF appeared difficult for some participants, as some did not

write complete sample sentences following error correction ( $n = 4$ ) and others finished early due to time taken ( $n = 8$ ). Visuals and explicit directions provided for WS appeared helpful, though all participants generally scored below their in-person, age-expected scores. Participants showed minimal difficulties with Name Writing and Letter Writing but often struggled with Word Writing (auditory difficulties and no visual prompts) and Sentence Story Writing (properly understanding the task demands via Zoom). Participants often redrew the conversation bubble for Sentence Story Writing, a step not required during in-person administration.

A parent was often present ( $n = 12$ ) to help their child stay on task. While parents assisted with physically showing the child's writing to the webcam after each item, parents also often provided unintended hints to their children by sounding out words when repeating questions or assisted with idea generation (even when prompted and instructed not to). Many participants also often looked to their parents for spelling assistance and would become frustrated when they could not help them. Additional results (scores and relationships between scores and parental involvement) will be finalized before INSAR 2021.

### **Conclusions:**

Participants appeared to engage well with most of the assessments, but the role and level of parent involvement makes score interpretation difficult. Parents looked to play both supportive and adverse roles to the assessment process to obtain valid scores of child performance. Considerations for future literacy-focused telecommunication assessment research will be discussed with applications to instructional contexts.

# Emotion

## PANEL SESSION — EMOTION

### Panel 211 - Self-Regulation and Associated Clinical Features in Autism across the Lifespan

**Panel Chair:** Deanna Swain, *Virginia Polytechnic Institute and State University, Blacksburg, VA*

**Discussant:** So Hyun Kim, *Psychiatry, Center for Autism and the Developing Brain, White Plains, NY*

Self-regulation (SR) encompasses emotional, behavioral, and cognitive processes. Impairment in SR, especially as it relates to emotion dysregulation, has been well documented in individuals with ASD, which may emerge as early as one year of age. Less is known regarding the underlying mechanisms of SR development as well as outcomes associated with impairments in SR. This session directly targets possible determinants of SR (Presentation 1 and 2), co-occurring behavioral features (Presentation 3), and clinical outcomes related to SR (Presentation 3 and 4) across the developmental span from early childhood to adulthood. Specifically, the first presentation examines the caregiver role as it relates to behavioral regulation in toddlers with ASD. The second presentation explores the relationship between ASD characteristics and SR in a diverse sample of school-children. The third presentation describes the co-occurrence of emotion dysregulation and other challenging behaviors (self-injurious behavior or aggression) in an in-patient setting. The fourth presentation examines the predictive role of emotion regulation response patterns on co-occurring psychopathology and life satisfaction for individuals with ASD during emerging-adulthood. Finally, the discussant will highlight themes and future directions regarding SR studies in ASD.

**211.001 (Panel)** Exploring the Effects of Treatment and Caregiver Requests on Behavioral Self-Regulation in Toddlers with Autism

**A. D. Nunnally<sup>a</sup>, A. Gulsrud<sup>b</sup> and C. Kasari<sup>c</sup>,** (1)*UC Davis MIND Institute, University of California, Davis, Sacramento, CA,* (2)*UCLA Semel Institute for Neuroscience & Human Behavior, Los Angeles, CA,* (3)*University of California, Los Angeles, Los Angeles, CA*

#### Background:

Children's ability to comply with caregiver requests is considered to be the earliest indication of self-regulation processes in early childhood and is closely linked to children's burgeoning emotion regulation abilities (Kopp, 1982). This ability to comply with caregivers' requests is predictive of a host of positive future outcomes including social competence, mental health and less parenting stress (Kochanska, 2002; Kuczynski & Kochanska, 1990; Patterson 2002), and may be especially important for children with ASD, who are pre-disposed to deficits in social-communication that may make caregiver-child interactions more challenging. Although compliance to caregivers' requests has been studied in children with autism, studies have largely focused on older children. There is also a scarcity of research exploring the effect of early caregiver-mediated intervention on compliance in very young children with autism, an area that warrants more study given the importance of children's compliance for future outcomes.

#### Objectives:

Characterize the use of caregiver requests and compliance to requests among toddlers with ASD and explore the effects of treatment on children's compliance to caregiver requests.

#### Methods:

This study is a secondary data analysis of data collected as part of a randomized controlled efficacy trial of a naturalistic, parent-mediated social-communication intervention for children with ASD (JASPER; Kasari et al., 2015). Upon entry, participants were randomized to receive either JASPER (n = 39) or a caregiver psychoeducation intervention (PEI; n = 36). At three timepoints (entry, exit and follow-up), caregivers engaged their children in a video-taped clean-up task that was later coded for caregivers' use of requests and children's compliance. Baseline analyses were conducted to characterize dyadic behavior at entry and GLMMs were used to determine the effect of treatment on children's compliance to caregivers' requests over time.

#### Results:

At baseline, caregivers made an average of 8.39 requests ( $SD = 4.71$ ) of their child, averaging 2.89 direct requests ( $SD = 3.12$ ) and 5.85 indirect requests ( $SD = 3.12$ ). Children's average proportion of compliance to direct requests (compliance to direct request/total requests) was 0.48 ( $SD = 0.42$ ) and their proportion of compliance to indirect requests (compliance to indirect request/total requests) was 0.39 ( $SD = 0.35$ ). Results of GLMMs revealed a significant main effect for the interaction between treatment and time on children's proportion of compliance to direct requests over time ( $F(1,112) = 3.20, p = .045$ ). Post-hoc analyses indicate significant increases in children's proportion of compliance to direct requests at exit and 3-month follow-up for participants in the JASPER condition only. No significant main effects were found for the effect of either treatment on children's proportion of compliance to indirect requests over time ( $F(2,184) = 0.819, p = .443$ ).

#### Conclusions:

The findings of this study describe caregivers' use of requests and children's compliance behavior in young children with ASD, an area that has been largely unexplored. Findings also suggest that caregiver-mediated social-communication interventions, such as JASPER, may be effective in improving children's compliance with caregivers' direct requests, indicating the need for further exploration of the effects of intervention on behavioral and emotional regulation among young children with ASD.

**211.002 (Panel) Examining Predictors of Emotion Dysregulation in Children with ASD and Co-Occurring Psychopathology**  
**D. Swain<sup>1</sup>, N. Cristallo<sup>2</sup>, H. F. Branyan<sup>3</sup>, C. Lord<sup>4</sup> and S. H. Kim<sup>2</sup>,** (1)Virginia Polytechnic Institute and State University, Blacksburg, VA, (2)Psychiatry, Center for Autism and the Developing Brain, White Plains, NY, (3)Center for Autism and the Developing Brain, White Plains, NY, (4)University of California, Los Angeles, Los Angeles, CA

---

**Background:** While it is well accepted that individuals with ASD demonstrate high rates of emotion dysregulation (ED), underlying mechanisms remain unclear. White and colleagues (2014) proposed a theoretical model linking characteristics of ASD to heightened ED and co-occurring psychopathology. To date, there are mixed findings supporting the relationship between ASD symptoms and ED, with some suggesting method invariance may play an important role when interpreting findings (Uljarevic et al., 2018). The current study empirically examines the proposed link between ASD symptoms and ED in children with ASD with and without co-occurring psychopathology across a critical developmental age span.

#### Objectives:

1. Explore ED patterns across co-occurring psychopathology.
1. Examine the predictive role of ASD symptoms on ED across diagnostic groups.

**Methods:** Participants included 874 children between the ages of 1.5 and 12 years ( $M_{age} = 69.6$  months; 66% Caucasian, 15.8% Hispanic; 19.7% female) with ASD seen at ASD-specialty clinics for clinical or research purposes. Regarding diagnostic classification, 57% had a diagnosis of ASD only, 25.3% comorbid with Intellectual Disability or Learning Disorder (ID/LD), 12.8% with externalizing (Ext), 3.5% with internalizing (Int), and 1.1% with Ext and Int. Emotion dysregulation was quantified by caregiver report on the Child Behavior Checklist - Dysregulation Profile (CBCL-DP; Althoff, Ayer, Rettew, & Hudziak, 2010), which allows for categorical and continuous measurement of ED. ASD symptoms were calculated by the ADOS-2 Calibrated Severity Scores for Social Affect (CSS-SA) and Restricted and Repetitive Behavior domains (CSS-RRB). Additional demographic variables included child age, gender, observed spontaneous language from ADOS (OLANG), most recent NVIQ estimate, and maternal education. For aim 1, ANCOVAs were run to compare ratings of ED across diagnostic groups controlling for age, NVIQ, OLANG, and CSS total. For aim 2, hierarchical linear regressions were run to examine predictors of ED across diagnostic groups. Predictors were entered into two blocks: 1) age, NVIQ, OLANG, maternal education; 2) CSS-SA and CSS-RRB.

**Results:** Based on caregiver report on CBCL, 48.4% ( $n = 423$ ) of the total sample presented with heightened ED. Results from ANCOVA revealed significant differences in ED across 5 diagnostic groups ( $F[4,842]=5.91, p < .001$ ; Figure 1), which remained significant when collapsing into 2 groups (ASD/ID/LD vs. ASD/Int/Ext). When predicting CBCL-DP for those without Int/Ext comorbidities, there were no main effects for CSS-SA ( $\beta = -.03, p = .39$ ) or CSS-RRB ( $\beta = -.02, p = .65$ ) after controlling for key child and family factors. Similarly, for those with Int/Ext comorbidities, CSS-SA ( $\beta = -.16, p = .05$ ) and CSS-RRB ( $\beta = -.06, p = .46$ ) remained non-significant.

**Conclusions:** Results from the current study provide limited support for the link between core ASD symptoms and ED in children with ASD with/without co-occurring psychopathology. Past findings showing significant relationships have primarily relied on caregiver report for both constructs. Thus, the limited link observed in the present study may be a function of

methodological differences, with autism symptom severity being quantified via clinician observation and ED measured by caregiver report. Results also suggest that identification and treatment of ED in children with ASD should consider the levels of co-occurring symptoms, especially internalizing and externalizing problems.

**211.003 (Panel)** Mapping the Time Course of Emotion Dysregulation and Challenging Behaviors in Psychiatrically Hospitalized Youth with Autism Spectrum Disorder

*J. B. Northrup<sup>1</sup>, M. S. Goodwin<sup>2</sup>, Q. Chen<sup>3</sup>, C. Peura<sup>4</sup>, M. Siegel<sup>5,6</sup> and C. A. Mazefsky<sup>1</sup>, (1)Department of Psychiatry, University of Pittsburgh School of Medicine, Pittsburgh, PA, (2)Northeastern University, Boston, MA, (3)University of Pittsburgh, Pittsburgh, PA, (4)Spring Harbor Hospital, Westbrook, ME, (5)Maine Medical Center - Tufts School of Medicine, Westbrook, ME, (6)Maine Medical Center - Tufts School of Medicine - Spring Harbor Hospital, Westbrook, ME*

---

**Background:** Emotion dysregulation (ED) is a common and clinically significant problem in individuals with ASD associated with challenging behaviors, such as self-injurious behavior (SIB) and physical aggression. Prior research on these behaviors is limited mainly to parent reports or small case studies. How ED, SIB, and aggression present in real-time and how the timing of these behaviors relate to one another is underexplored. Understanding the time course and the relationship between ED and challenging behaviors, including individual differences in these features, is an essential step towards determining their function and predicting their onset.

**Objectives:** The present study aimed to describe the occurrence and relationship between ED, SIB, and aggression—observed and coded during everyday activities across three specialized inpatient psychiatric units.

**Methods:** Participants were 56 individuals (83% male, mean age 11.7) from the Autism Inpatient Collection. Participants were observed for an average of 6.3 hours across several sessions (mean # of sessions = 5.43). Start and stop times of ED, SIB, and aggression were coded live through a mobile phone app. Double coding performed on 20% of cases indicated good inter-rater reliability (mean kappa = .74). Temporal relations between the three behaviors were analyzed using cross-recurrence quantification analysis (CRQA), which examines whether co-occurrence and lagged associations between variables exceed chance (e.g., ED precedes SIB).

**Results:** Table 1 reports descriptive statistics showing the number of participants displaying each behavior and the rate per hour and mean duration of behaviors. Episodes of ED were the longest lasting on average (mean duration = 42.7 seconds), and ED and SIB occurred at a higher rate than episodes of aggression. As shown in the table, many of these measures had a high degree of variability amongst participants. Figure 1 displays plots of the temporal relations between behaviors. CRQA analyses revealed that only ED and SIB co-occurred at above chance levels for the sample as a whole. We observed above chance co-occurrence of ED and SIB in 67.5% of participants, ED and aggression in 51% of participants, and SIB and aggression in 27% of participants. As shown in the figures, ED occurred in the 10 seconds preceding SIB more than would be expected by chance, and this relationship was more substantial than SIB preceding ED. A similar pattern emerged for ED and aggression; however, fewer participants demonstrated these lagged relationships. Further analyses will examine individual participant profiles and potential predictors of individual differences (e.g., verbal ability, IQ, autism severity).

**Conclusions:** To our knowledge, this is the first study to examine the real-time presentation of SIB and aggression and their relation to observable emotion dysregulation. ED and SIB had the highest co-occurrence. About half of the participants did not show significant co-occurrence of ED and aggression, suggesting that aggression occurs without observable signs of dysregulation for many individuals. These results provide useful insights into individual differences in presenting challenging behaviors, and future analyses will explore predictors of these differences.

**211.004 (Panel)** The Impact of Emotion Regulation Strategies on Mental Health in Adults with Autism

*A. M. Brewe<sup>1</sup>, I. Smith<sup>2</sup> and S. W. White<sup>1</sup>, (1)Psychology, The University of Alabama, Tuscaloosa, AL, (2)Virginia Tech, Blacksburg, VA*

---

**Background:** Difficulties with effective emotion regulation (ER) are common for individuals with autism spectrum disorder (ASD) and associated with a host of poor outcomes including increased risk of psychiatric problems. Despite the link between ER impairment and increased psychopathology, limited research has identified specific ER responses that are associated with co-occurring psychopathology, particularly depression, and other mental health outcomes for emerging adults with ASD.

**Objectives:** The current study sought to identify whether specific ER response patterns were differentially related to co-occurring depression and anxiety symptoms, loneliness, and life satisfaction for emerging adults with ASD.

Methods: Fifty-one cognitively able older adolescents and young adults with ASD (M age: 19.13, 81.60% male, 91.70% White) participated in the study. They were recruited as a part of a larger randomized, controlled trial of a college transition support program for emerging adults with ASD. Participants completed a battery of questionnaires related to mental health outcomes (i.e., depression and anxiety symptoms, loneliness, and life satisfaction). Self-reported ER strategies were measured across two domains of controlled responses: approach-based voluntary engagement (i.e., cognitive reappraisal, emotion acceptance, problem-solving) and avoidance-based voluntary disengagement (i.e., avoidance, denial, distraction).

Results: A series of linear regressions were used to analyze the relationship between ER strategies and co-occurring anxiety and depression, as well as loneliness and life satisfaction. Both voluntary engagement strategies ( $\beta = -.28, p = .010$ ) and voluntary disengagement strategies ( $\beta = .61, p < .001$ ) were significant predictors of co-occurring depression symptoms, such that more frequent use of voluntary disengagement and less frequent use of voluntary engagement strategies were associated with increased depression symptoms [ $F(2, 50) = 19.98, p < .001, R^2 = .43$ ]. Voluntary disengagement strategies ( $\beta = .60, p < .001$ ) were similarly predictive of anxiety symptoms, although voluntary engagement ( $\beta = -.18, p = .112$ ) was not [ $F(2, 50) = 15.64, p < .001, R^2 = .37$ ]. Analyses revealed that increased voluntary disengagement ( $\beta = .51, p < .001$ ), but not voluntary engagement ( $\beta = -.20, p = .108$ ), predicted loneliness [ $F(2, 51) = 10.67, p < .001, R^2 = .28$ ]. Finally, unique relationships appeared between life satisfaction and the two ER domains; specifically, voluntary disengagement ( $\beta = -.36, p = .003$ ) negatively predicted life satisfaction, whereas voluntary engagement ( $\beta = .47, p < .001$ ) positively predicted life satisfaction, [ $F(2, 51) = 13.26, p < .001, R^2 = .33$ ].

Conclusions: Emerging adults with ASD experienced poorer mental health outcomes when using voluntary disengagement strategies to purposefully avoid experiencing uncomfortable emotions. In fact, adults with ASD who chose to tolerate and engage with, or alter, uncomfortable emotions via voluntary engagement strategies like emotion acceptance and cognitive reappraisal experienced more life satisfaction and better mental health outcomes. The divergent relationships between mental health and these two ER responses suggests the importance of building emotion acceptance and tolerance, instead of avoidance and distraction, when treating anxiety and depression in this population. Given the initial success of mindfulness and acceptance-based treatment protocols in ASD samples, additional research into these treatments and their impact on ER response patterns is warranted.

## POSTER SESSION — EMOTION

### Poster 418 - Emotion Posters

**418.001** (Poster) A Positive Youth Development Framework to Understand Positive Mental Health in Autistic Youth  
*T. Sellitto and J. A. Weiss, Psychology, York University, Toronto, ON, Canada*

Background: Positive mental health (PMH) has been conceptualized as the combination of positive psychological and social functioning, rather than just the absence of mental health problems (Keyes, 2002). This includes a continuum ranging from languishing (the absence of PMH) to flourishing (high levels of PMH). No studies have explored this continuum in autistic youth, despite support for its use in young people (Keyes, 2006). Positive Youth Development (PYD) frameworks posit that youth experience more positive outcomes when there is an alignment between an individual's strengths (e.g., adaptive behaviours) and ecological assets (e.g., environmental supports; Lerner et al., 2010), including in youth with autism (Weiss & Burnham Riosa, 2015).

Objectives: To determine the individual and ecological correlates of PMH in autistic youth.

Methods: Data were collected from 137 family caregivers of youth between 11 and 22 years of age ( $M = 16.81, SD = 3.21, 77\%$  male) with a diagnosis of autism and intellectual disability in Ontario (Canada). Caregivers completed surveys on their children's adaptive behaviours (Maenner et al., 2013; Mazurek et al., 2012), mental health problems (Goodman, 1997), and ecological resources (Byles et al., 1988; Coster et al., 2012; Emerson et al., 2006). PMH was measured using the six C's of PYD (Caring, Character, Contribution, Competence, Confidence, Connectedness; Lerner et al., 2005), and three categories were created based on the number that were endorsed, similar to strategies categorizing PMH in adults (Keyes, 2002).

Results: Adaptive behaviour and sociocommunicative and functional cognitive ability were significantly higher in the flourishing group compared to the moderate well-being group (both  $p < 0.01$ ), who in turn was higher than the languishing group (both  $p < 0.01$ ). The languishing group had significantly higher severity of mental health problems compared to the flourishing and moderate well-being groups (both  $p < 0.01$ ), though the latter two groups did not differ from each other ( $p = 0.08$ ). Similarly, the languishing group was reported to have lower rates of access to resources to enable participation in home activities (both  $p < 0.01$ ) and school (both  $p \leq 0.001$ ) compared to both other groups, who did not differ from each other ( $p > 0.05$ ). Parents of youth in the flourishing and moderate well-being groups reported higher rates of their own self-efficacy compared to parents of youth in

the languishing group (both  $p < 0.01$ ), though they did not differ from each other ( $p > 0.05$ ). The moderate well-being group had significantly greater family functioning than the languishing group ( $p < 0.05$ ), though there was no difference between the flourishing and moderate well-being groups ( $p = 0.44$ ) and flourishing and languishing groups ( $p = 0.15$ ).

**Conclusions:** For autistic youth, flourishing was associated with the highest level of adaptive behaviours, and the presence of any level of PMH was associated with fewer mental health problems, and greater parent self-efficacy, family functioning, and resources/support at home and school. Future research can investigate individual and ecological correlates of dual continua mental health outcomes in autistic youth.

**418.002 (Poster)** Adaptive Behavior and Emotion Dysregulation Profiles in Young Children with Autism Spectrum Disorder

Hoffmann-La Roche Ltd., Basel, Switzerland, (12)Psychiatry, New York State Psychiatric Institute / Columbia University, New York, NY

**Background:** Daily functioning of children with autism spectrum disorder (ASD) is often impacted by factors beyond ASD core symptoms. Emotion dysregulation is commonly observed and significantly impacts parent stress and children's behavioral health. Up to 50% of children with ASD have co-occurring attention-deficit/hyperactivity disorder (ADHD) symptoms, which are also associated with emotion dysregulation. Despite research linking difficulties with emotion dysregulation to functional impairment, the relationship between emotion dysregulation and adaptive behavior in ASD is relatively unexplored. Additionally, the impact of co-occurring ADHD symptoms on this relationship is unknown. Elucidating the interrelationships between emotion dysregulation, ADHD symptoms, and adaptive behavior is critical because adaptive skills provide an indicator of functional impairment and are often used to measure ASD treatment outcomes.

**Objectives:** We examined whether emotion dysregulation and ADHD symptoms were associated with adaptive functioning in young children with ASD. In addition, we explored whether emotion dysregulation impacted adaptive functioning over-and-above the impact of ADHD symptoms.

**Methods:** Participants were N=185 children with ASD ages 3-7 years old (mean=4.9, std=1.2). Adaptive functioning was assessed through parent-report on the Vineland Adaptive Behavior Scales, which yields scores in the areas of Socialization, Daily Living Skills, Communication, and an overall composite score. Emotion dysregulation and ADHD symptoms were assessed through parent report on Aberrant Behavior Checklist (ABC), using the Irritability and Hyperactivity subscales, respectively. We hypothesized that lower levels of adaptive behavior will be associated with poorer emotional regulation and this will be over-and-above the impact of co-occurring symptoms of ADHD. To test these hypotheses, we employed a series of Pearson's partial correlations, controlling for both age and IQ.

**Results:** Emotion dysregulation, as reflected in the ABC Irritability subscale, was negatively correlated with communication ( $r(183) = -.20, p < .01$ ), social skills ( $r(183) = -.31, p < .0001$ ), daily living skills ( $r(183) = -.20, p < .01$ ), and overall adaptive behavior ( $r(183) = -.21, p < .01$ ). Additionally, ADHD symptoms, as reflected in the ABC Hyperactivity subscale, were negatively correlated with communication ( $r(183) = -.27, p < .001$ ), social skills ( $r(183) = -.16, p < .05$ ), and overall adaptive behavior ( $r(183) = -.26, p < .001$ ), but not daily living skills ( $r(183) = -.12, p = .12$ ). Furthermore, the ABC Irritability and Hyperactivity subscale scores were positively correlated with one another ( $r(183) = .36, p < .0001$ ). Finally, when controlling for ADHD symptoms, only difficulties with social skills ( $r(183) = -.27, p < .001$ ) and daily living skills ( $r(183) = -.17, p < .05$ ), remained negatively correlated with emotion dysregulation.

**Conclusions:** Emotion dysregulation and ADHD symptoms are separately correlated with adaptive behavior in young children with ASD. After adjusting for the effect of co-occurring ADHD symptoms, we found emotion dysregulation continued to be moderately negatively correlated with socialization and daily living skills. Understanding the relationship between emotion dysregulation and adaptive behavior is important for informing interventions for ASD and understanding treatment outcomes.

**418.003** (Poster) An Ecological Momentary Assessment (EMA) Study of Parent Emotion Regulation, BAP, and Child Behavior Problems

*A. Rovane<sup>1</sup>, T. N. Worley<sup>2</sup> and R. Hock<sup>2</sup>, (1)Psychology, University of South Carolina, Columbia, SC, (2)University of South Carolina, Columbia, SC*

---

Background:

Emotion regulation (ER) within and between family members is unique when there is a child with autism spectrum disorder (ASD). Two commonly used ER strategies are cognitive reappraisal and emotion suppression. Parents of children with ASD tend to use more maladaptive coping skills, which may increase their likelihood of exhibiting distressed parenting responses to child emotion. Furthermore, parents who exhibit features of the Broader Autism Phenotype (BAP) may also have ER deficits. It has become apparent that parents who respond in more adaptive ways fare better in terms of their own wellbeing and their child's outcomes. However, it less clear what strategies parents select in the moment their child is having a behavior problem, and how distressed parenting style and BAP affect their selection.

Objectives:

The current study examined how parents regulate their emotions in the moment their child is demonstrating challenging behavior, and how parenting style and genetic load affect their choice of ER strategy. The aims of this study were twofold: 1) To examine the ER strategies parents use during the challenging behavior, and 2) To understand how distressed parenting and BAP presentation (rigidity) influence strategy selection (cognitive reappraisal or emotion suppression).

Methods:

Participants were mothers ( $N = 20$ ) of children with ASD who were recruited for an ecological momentary assessment (EMA) study examining family patterns in ASD. Participants completed the Coping with Child Negative Emotion Scale –Distressed Parenting subscale and the Broader Autism Phenotype Questionnaire –Rigidity subscale. Parents then participated in a 7-day EMA study and answered questions about their child's behavior and what ER strategy they used. Proportion scores were calculated for each strategy summing a participant's use of that strategy over the week, and then dividing by total response opportunities (occurrence of challenging child behaviors). Two regression models were constructed to predict whether distressed parenting and BAP rigidity predicted momentary use of cognitive reappraisal and emotion suppression.

Results:

Parents were more likely to help or distract their child ( $M = 42.2\%$  of total responses), hold in their emotion ( $M = 27.6\%$ ), use a calming strategy ( $M = 22\%$ ), express their emotion/raise their voice ( $M = 20.2\%$ ), or reframe their thought ( $M = 14.8\%$ ) compared to other ER strategies. Distressed parenting trended toward significance ( $b = -.06, p = .10$ ) for predicting less momentary cognitive reframing, whereas BAP rigidity was nonsignificant ( $p > .05$ ). BAP rigidity was a significant predictor of momentary emotion suppression ( $b = .19, p = .03$ ), but distressed parenting was nonsignificant ( $p > .05$ ).

Conclusions:

Distressed parenting seems to have a negative association with using cognitive reappraisal during their child's challenging behavior, which limits their ability to effectively reframe a negative thought to a more helpful one. Likewise, parents with high BAP rigidity were more likely to suppress their emotions, which would preclude them from expressing or acknowledging their emotions (i.e., a precursor to adaptive ER). Studying momentary parent ER in response to child behavior is necessary for understanding how to best improve outcomes for both parents and children with ASD.

**418.004** (Poster) Assessing Automatic Emotion Processing in Boys with Autism Via Eye Tracking and Facial Mimicry

*S. Van der Donck<sup>1,2</sup>, S. Vettori<sup>1,2</sup>, M. Dzhelyova<sup>3</sup>, S. S. Mahdi<sup>4,5</sup>, P. Claes<sup>1,5,6</sup>, J. Steyaert<sup>1,2</sup> and B. Boets<sup>1,2</sup>, (1)Center for Developmental Psychiatry, KU Leuven, Leuven, Belgium, (2)Leuven Autism Research Consortium (LAuRes), KU Leuven, Leuven, Belgium, (3)Psychological Sciences Research Institute and Institute of Neuroscience, UCL, Louvain-la-Neuve, Belgium, (4)Department of Electrical Engineering (ESAT/PSI), KU Leuven, Leuven, Belgium, (5)Medical Imaging Research Center, MIRC, UZ Leuven, Leuven, Belgium, (6)Department of Human Genetics, KU Leuven, Leuven, Belgium*

---

**Background:** Difficulties in automatic facial emotion processing in individuals with autism spectrum disorder (ASD) might remain concealed in behavioral studies due to the use of compensatory strategies.

**Objectives:** In the present study, we wanted to overcome influences of compensatory strategies and turned to measures tapping more automatic social processing behavior. More specifically, to gain more insight in the underlying facial emotion processing mechanisms in ASD, we simultaneously investigated gaze behavior and spontaneous facial mimicry of boys with and without ASD.

**Methods:** We recorded eye tracking and facial mimicry data of 20 school-aged boys with ASD and 20 matched typically developing controls while performing an explicit emotion recognition task. We analyzed proportional looking times to specific face regions (eyes, nose and mouth) and we modeled face exploration dynamics by mapping temporal scan paths using observable Markov models. Facial mimicry was assessed using automatic video decoding via FaceReader software.

**Results:** We found that boys with ASD and controls were equally capable to recognize facial expressions and did not differ in proportional looking times, and number and duration of fixations. However, TD boys adapted their gaze behavior more in function of the displayed expression, in comparison to boys with ASD. Furthermore, both groups showed similar face exploration dynamics, although boys with ASD demonstrated smaller saccadic amplitudes. Pertaining to the facial mimicry, we found no emotion specific facial responses and no group differences in the responses to the displayed facial expressions.

**Conclusions:** Our results indicate that boys with and without ASD employ similar eye gaze strategies to recognize facial expressions. However, the smaller saccadic amplitudes in boys with ASD suggest a less exploratory face processing strategy. Nevertheless, considering the similar behavioral performances, this slightly more persistent visual scanning behavior in boys with ASD does not imply less efficient emotion information processing. Finally, results on the facial mimicry data indicate similar facial responses to emotional faces in boys with and without ASD.

**418.005 (Poster)** Associations between Objectively Measured Facial Expressions during the ADOS-2 and the Calibrated Severity Scores in 3-Year-Olds with Suspected ASD

*Y. A. Ahn<sup>1</sup>, J. M. Moffitt<sup>1</sup>, S. Custode<sup>1</sup>, A. L. Beaumont<sup>1</sup>, S. M. Cardona<sup>1</sup>, M. Parladé<sup>2</sup>, J. Durocher<sup>2</sup>, M. N. Hale<sup>2</sup>, M. Alessandri<sup>2</sup>, L. K. Perry<sup>1</sup> and D. S. Messinger<sup>2</sup>, (1)Psychology, University of Miami, Coral Gables, FL, (2)University of Miami, Coral Gables, FL*

Background: Autism spectrum disorder (ASD) is defined by restricted, repetitive patterns of behavior, and persistent disturbances of social communication. Children with ASD tend to exhibit more negative emotion (Macari et al., 2017) and engage in less frequent eye contact than typically developing peers (Barbaro & Dissanayake, 2012). Current best practice for measuring children's ASD symptom severity is based on expert, but subjective, clinician observation during the Autism Diagnostic Observation Schedule-2 (ADOS-2). Objective, automated detection of children's facial expressions from first-person videos during the ADOS-2 may quantify child expressive behavior. The current study examined associations between objectively measured expressive behavior and ASD symptom severity during the ADOS-2.

Objectives: To investigate associations between objectively quantified facial expression and gaze behavior measured from a low-cost video camera and examiner-adjudicated ADOS-2 calibrated severity scores (CSS).

Methods: Sixty-six children (49 boys,  $M_{age}=39.97mo$ ,  $SD=10.58$ ) with suspected ASD (61 confirmed ASD) were administered the ADOS-2. A hypothesis-blind examiner provided a total CSS and subscales for Social Affect (SA CSS) and restricted/repetitive behavior (RRB CSS). Children's facial expressions during the assessment were recorded with a small camera (Pivothead or Orca) contained in eye-glasses worn by the examiner. We processed first-person video from the camera with Affectiva algorithms in the iMotions software suite to automatically detect child facial expressions. Measures included the durations of child facial action units associated with negative affect and child gaze at the examiner—all expressed as proportions of ADOS-2 duration.

Results: There were positive associations between brow furrowing and the ADOS-2 total CSS ( $r=.29$ ,  $p=.02$ ) and the SA CSS ( $r=.34$ ,  $p=.01$ ). The proportion of lip stretching was positively associated with the total CSS ( $r=.25$ ,  $p=.04$ ). Likewise a composite index of negative expression brow furrowing or lip stretching) showed positive associations with the total CSS ( $r=.35$ ,  $p=.004$ ) and the SA CSS ( $r=.38$ ,  $p=.002$ ). Finally, there was a negative association between the proportion of gaze at the examiner and the RRB CSS ( $r=-.31$ ,  $p=.01$ ).

Conclusions: The current study examined associations between automated measurements of child expressive behavior during the ADOS-2. Greater levels of facial expressions indexing higher levels of negative emotion were modestly associated with social affect and total symptom severity scores. By contrast, greater attention to the examiner was associated with lower levels of repetitive behavior symptoms. The results suggest that negative affect may index higher levels of autism symptoms, while attention to the examiner may index lower levels of repetitive behaviors or an ability to disengage from those behaviors.

**418.006** (Poster) Characteristics Associated with Anxiety in Youth with Autism Spectrum Disorders

**S. L. de Marchena<sup>1</sup>, B. Hayse<sup>1</sup>, S. Hunter<sup>2</sup>, C. Jorgenson<sup>3</sup> and K. Nowell<sup>4</sup>,** (1)University of Missouri, Columbia, MO, (2)Thompson Center, University of Missouri, Columbia, MO, (3)Special Education, University of Missouri, Columbia, MO, (4)Thompson Center for Autism & Neurodevelopmental Disorders, Columbia, MO

---

**Background:** Anxiety disorders are commonly diagnosed in typically developing youth (Merikangas, et al. 2009). Research suggests that anxiety occurs at higher rates in individuals with autism spectrum disorder (ASD) (Rosenberg, et al. 2011) with estimated rates ranging between 11 to 84% (Kerns et al., 2015). Studies have investigated several factors including cognitive ability, gender, age, and severity of ASD to determine their role in the development of anxiety-related symptoms in youth with ASD (Dubin, et al., 2015; Eussen et al., 2013; Mazurek et al., 2010). However, efforts to identify correlates and risk factors for anxiety in cases of ASD have yielded inconsistent findings (Vasa et al., 2015). These variable conclusions present challenges for treatment planning (Dubin et al., 2015) as well as for researchers attempting to measure and better understand anxiety and ASD (Kerns, et al. 2017).

**Objectives:** The aim of this cross-sectional study was to extend prior research by (a) evaluating the prevalence of comorbid anxiety disorders among a well-characterized sample of youth with ASD, and (b) investigate potential correlates for anxiety disorders.

**Methods:** Data were analyzed from youth between the ages of three and 21 ( $N=685$ , 77% male,  $M$  age=8.3) who were evaluated at a specialist center providing autism specific diagnostic evaluations *and* who received a diagnosis of ASD *and* who had data recorded for all variables of interest. Data were extracted from an on-site database. Variables of interest were as follows: age, gender, verbal IQ, nonverbal IQ, ADOS-2 Comparison Score, and ADOS-2 Module. A dichotomous variable “Anxiety” was calculated. Presence of an anxiety disorder was indicated if any anxiety related diagnostic label were listed as a final diagnosis (i.e., “anxiety”, “Anxiety-disorder NOS”, generalized anxiety disorder, social anxiety, separation anxiety). Most of the sample (66%;  $n=492$ ) were administered Module 3 of the ADOS-2; thus, additional analyses were completed on that subgroup using ADOS-2 Social Communication, RRB, and Total Scores. Descriptive statistics were used to measure prevalence of anxiety diagnoses and to characterize the sample. Simultaneous logistic regression was used to investigate potential predictor variables with “Anxiety” as the outcome variable.

**Results:** In the total sample, 15.3% were provided an anxiety diagnosis and VIQ, NVIQ and age were significantly correlated ( $p<.01$ ) with the presence of an anxiety disorder. The model including the predictors was significant,  $\chi^2(5) = 99.72, p<.001$ . Age ( $p<.001$ ), verbal IQ ( $p=.05$ ), and nonverbal IQ ( $p=.02$ ) were significant predictors of an anxiety diagnosis. For the Module 3 subsample, the model was significant,  $\chi^2(7) = 45.94, p<.001$  but only age was a significant predictor ( $p<.001$ ).

**Conclusions:** Lower rates of anxiety disorders were found in this sample than expected, though prevalence in this sample was within the broad, estimated range of 11 to 84% (Kerns et al., 2015). Notably, the only reliable predictor of receipt of an anxiety disorder diagnosis was age with older individuals being more likely to receive a diagnosis. Neither gender, IQ, nor severity of ASD symptoms were reliable predictors. Implications for clinical practice and future research will be discussed.

**418.007** (Poster) Characterizing Difficulties with Emotion Regulation in Toddlers with ASD

**T. N. Day<sup>1,2</sup>, C. A. Mazefsky<sup>2</sup> and A. M. Wetherby<sup>3</sup>,** (1)Florida State University, Tallahassee, FL, (2)Department of Psychiatry, University of Pittsburgh School of Medicine, Pittsburgh, PA, (3)Florida State University Autism Institute, Tallahassee, FL

---

**Background:** Difficulties with emotion regulation (ER) underlie emotional/behavioral problems in autism spectrum disorder (ASD), yet very little is known about the early development of emotion dysregulation. Based on parent-report of the affective characteristics of temperament, toddlers with ASD demonstrate lower positive affect, higher negative affect, and fewer regulatory strategies than toddlers without ASD (Garon et al., 2009, 2016; Macari et al., 2017). However, to date, no observational studies have *concurrently* documented how emotional reactivity and regulation strategies may differ in toddlers with ASD relative to their non-ASD peers. Prior work has indicated that initial emotional reactivity and the regulation of those emotions are best explained by a single factor (Mazefsky et al., 2018, 2020; Zelkowitz & Cole, 2016), highlighting the need to examine both domains to best understand the ER construct in early childhood.

**Objectives:** This presentation will examine how toddlers with and without ASD express and regulate their emotions during tasks eliciting joy, fear, and frustration.

**Methods:** Thirty-seven toddlers (18 ASD, 19 non-ASD; 22-28mos) were recruited from a longitudinal study focused on ASD screening and early detection; children underwent gold-standard testing for ASD. Participating children completed nine tasks from the *Laboratory Temperament Assessment Battery* (Lab-TAB). Video-recordings of these tasks were coded by undergraduate

research assistants using a behavioral coding scheme tapping facial, bodily, and vocal affect and the frequency of employed ER strategies. Profile analyses were performed to examine the mean affect and total regulation strategies across each task, with a priori pairwise comparisons by task.

#### Results:

There were significant task-by-diagnosis interactions for bodily affect and vocal affect. Additionally, there were significant main effects for facial affect, but the interaction was non-significant. A priori pairwise comparisons revealed that relative to toddlers without ASD, toddlers with ASD demonstrated more facial, bodily, and vocal distress during a task in which they were told they could not play with engaging toy (End of the Line). Likewise, toddlers with ASD displayed increased negative facial expressions when they were unable to open a clear locked box that contained a desired object (Attractive Toy in a Transparent Box). There was a differential pattern during the Modified Peek-a-Boo task, such that toddlers with ASD displayed incongruent negative facial affect whereas toddlers without ASD displayed expected positive facial affect. With regard to regulatory strategies, there was only a significant main effect for task. A priori posthoc analyses revealed that toddlers with and without ASD displayed comparable frequencies of ER strategies, except during the End of the Line task during which toddlers with ASD utilized more ER strategies than their non-ASD peers.

Conclusions: Toddlers with ASD were characterized by high negative affect and low positive affect despite frequent and age appropriate attempts to regulate their emotions. These findings provide preliminary evidence that observable indicators of emotion dysregulation are present around two years of age and map onto to findings documenting patterns of ineffective ER in older children with ASD (e.g., Jahromi et al., 2012; Mazefsky et al., 2014). Clinical implications and future research directions will be discussed.

**418.008** (Poster) Correlates of Anxiety in Autistic and Non-Autistic Individuals with Moderate-Profound Intellectual Disability or Those Who Speak Few or No Words

*G. Edwards<sup>1</sup>, J. Tarver<sup>1</sup>, C. Oliver<sup>2</sup> and J. Waite<sup>1</sup>, (1)Aston University, Birmingham, United Kingdom, (2)Cerebra Centre for Neurodevelopmental Disorders, Birmingham, United Kingdom*

---

Background: Individuals diagnosed with Autism Spectrum Disorder (ASD) are at heightened risk of experiencing mental health difficulties. More specifically, the prevalence of anxiety is estimated at 11-84% with most studies reporting a rate of approximately 40%. Individuals with intellectual disability (IQ<70) are also at heightened risk of anxiety. Sensory processing differences and repetitive behaviour have been found to be associated with anxiety in these groups. However, the majority of research has focused on autistic individuals without intellectual disability or individuals who speak in sentences. Therefore, there is a paucity of research exploring this in autistic and non-autistic children and adults with moderate-severe intellectual disability or those who speak few or no words. Identifying those individuals most at risk of experiencing anxiety will enable early and targeted intervention. Efforts towards improving mental health and developing interventions specifically aimed at reducing anxiety has been identified by autistic individuals, their families and professionals as top priorities for autism research via the James Lind Alliance.

Objectives: To explore relationships between anxiety, repetitive behaviour and auditory sensory processing differences in autistic and non-autistic children and adults with moderate-severe intellectual disability or those who speak few or no words.

Methods: Parents/carers completed an online questionnaire battery including the Wessex Questionnaire (a proxy measure of adaptive ability), the Social Communication Questionnaire (SCQ), Repetitive Behaviour Questionnaire-2 (RBQ-2), subscales from the Sensory Profile-II and the Anxiety, Depression and Mood Scale (ADAMS).

Results: To date, 44 parents/carers of autistic individuals have participated in the online questionnaire study (63.6% male;  $M_{age} = 20.07$  years ( $SD = 11.52$ ), range: 4-63). Diagnoses included individuals with idiopathic autism ( $n = 20$ ) and autistic individuals who also had a comorbid diagnosis of a genetic syndrome associated with intellectual disability ( $n = 24$ ). Repetitive behaviour and auditory sensory processing differences were significantly correlated with generalised anxiety ( $r_s = .577, p < 0.01$ ;  $r_s = .565, p < 0.01$  respectively). When adjusting for age, ability level and autism characteristics, hierarchical regression analyses indicated that higher rates of repetitive behaviour and auditory sensory processing differences predicted higher levels of anxiety ( $p < 0.05$ ). This model explained 41% of the variance in anxiety scores. By May 2021, we will present data from 100 families after additional questionnaire completions and the inclusion of individuals with a diagnosis of a genetic syndrome associated with intellectual disability and autism characteristics.

Conclusions: Preliminary analyses suggest that repetitive behaviour and auditory sensory processing differences are associated with anxiety in autistic and non-autistic individuals with moderate-severe intellectual disability or those who speak few or no words. Identifying potential pathways between repetitive behaviour, sensory processing differences and anxiety will allow us to

explore how these factors are implemented in the development and maintenance of anxiety, informing the development of tailored anxiety interventions.

**418.009 (Poster) Debunking the Myth of Autism and Empathy: Exploring Alexithymia As a Mediator**

**E. J. Adler, H. K. Schiltz, S. A. Lehman, N. Gordon and A. V. Van Hecke, Psychology, Marquette University, Milwaukee, WI**

---

**Background:** The pervasive misconception that autistic people lack empathy has been perpetuated by inconsistencies in how researchers define empathy and imprecise measurement (Fletcher-Watson & Bird, 2020). Moreover, there is growing evidence to suggest that alexithymia, the diminished ability to identify and understand one's emotions, affects many autistic adults (Hall et al., 2004; Oakley et al., 2020), and may be closely related to expressions of empathy in autism (Bird et al., 2010; Mul et al., 2018). It remains unclear, however, whether the link between autistic features and empathy may be in part *explained by* alexithymia.

**Objectives:** Among a sample of autistic and non-autistic adults, the present study aimed to 1) assess the association between autism features, empathy, and alexithymia, 2) explore the role of alexithymia as a mediator of the association between autistic features and empathy, and 3) evaluate whether effects are similar in both autistic and non-autistic samples.

**Methods:** 259 young adults aged 17-29 ( $M=19.45$ ; 48.5% female) completed measures assessing autistic features (AQ; Baron-Cohen et al., 2001), alexithymia (TAS-20; Bagby et al., 1994), and empathy (EQ; Baron-Cohen & Wheelwright, 2004). Participants were combined across a study involving autistic young adults participating in a social skills intervention ( $N=99$ ) and a study of non-autistic college students ( $N=160$ ) in order to capture a wide range of autistic features, alexithymia, and empathy. Diagnoses of autism were confirmed using the ADOS-G. IQ among autistic participants was  $\geq 70$ . The PROCESS 3.5 macro on SPSS version 27 was used to estimate the direct effect of autistic features (AQ) on empathy (EQ) and the indirect effect through alexithymia (TAS-20). Bootstrapped confidence intervals were used to estimate the indirect effect.

**Results:** Bivariate Pearson correlations revealed more autistic features were significantly associated with higher levels of alexithymia ( $r(257)=.519, p<.001$ ) and lower levels of empathy ( $r(257)=-.643, p<.001$ ). Alexithymia and empathy were also significantly negatively associated ( $r(257)=-.586, p<.001$ ). Mediation analyses indicated a significant indirect effect of autistic features on empathy through alexithymia (Figure 1:  $b=-.32, CI: -.44, -.22$ ). Evidence of a significant direct effect from autistic features to empathy ( $b=-.84, p<.001$ ) indicates partial mediation. There was no evidence for moderated mediation based on autism diagnosis (index of moderated mediation = 0.0562, CI:  $-.1177, .2595$ ); as such, the mediating role of alexithymia seems to be invariant across non-autistic and autistic young adults.

**Conclusions:** Findings from our study add to the emerging evidence that alexithymia and empathy are closely related among autistic individuals. Importantly, our analyses also revealed that alexithymia partially accounted for the association between autistic features and empathy in a sample of non-autistic and autistic adults. This effect was consistent across both autistic and non-autistic adults. Therefore, myth of autistic people having less empathy may be driven by the substantial percentage of autistic people with alexithymia. Future research should seek to clarify the degree to which these associations are due to measurement, as alexithymia may affect responses on measures of empathy that include questions about emotions in oneself and others.

**418.010 (Poster) Do Alexithymia Traits or Autism Traits Specifically Explain Depression in Autism?**

**C. Bloch<sup>1,2</sup>, L. Burghof<sup>1</sup>, F. G. Lehnhardt<sup>1</sup>, K. Vogeley<sup>2,3</sup> and C. M. Falter-Wagner<sup>1,4</sup>, (1)Department of Psychiatry and Psychotherapy, LMU Hospital Munich, Munich, Germany, (2)Department of Psychiatry and Psychotherapy, University Hospital Cologne, Cologne, Germany, (3)Institute of Neuroscience and Medicine (INM3), Research Center Jülich, Jülich, Germany, (4)Department of Psychology, University of Cologne, Cologne, Germany**

---

**Background:** Contemplating alarming depression rates in adults with autism spectrum disorder (ASD) there is need to find factors that are associated with increased symptoms in this population. Alexithymia, assessed by difficulties in identifying and describing emotions and an externally-oriented style of thinking was found to be a prevalent condition in ASD. Beyond a possible relation with autism traits, alexithymia traits should be considered as candidate for explaining why individuals with ASD report higher levels of depressive symptoms.

**Objectives:** In this cross-sectional study we target the question to what extent autism traits on the one hand and alexithymia traits on the other hand indicate depressive symptoms in ASD and whether the pattern of association is specific to ASD.

**Methods:** Data of a large ( $N=400$ ) representative clinical referral population of adults referred to autism diagnostics have been investigated and split into cases with confirmed ASD diagnosis ( $N=281$ ) according to ICD-10 criteria and cases with ruled out ASD diagnosis ( $N=119$ ). Dominance analysis was chosen as adequate method for evaluating relative predictive power of single

predictors in a multivariate comparison within each group (ASD and non-ASD). Models contained age, gender and IQ as control variables and the three subscales of the *20-Item Toronto Alexithymia Scale (TAS-20)* and the *Autism Quotient (AQ)* as predictors.

Results: Dominance analysis revealed the alexithymia factor *difficulties in identifying feelings (DIF)* as strongest predictor for depressive symptomatology in ASD, outweighing autism traits and other alexithymia factors. This pattern of prediction was not specific to ASD and was shared by clinical controls from the referral population with ruled out ASD diagnosis.

Conclusions: Results imply that clinical interventions should take weakened abilities in assessing emotions in consideration when targeting depression in autism. As predictive patterns were similar in the non-ASD group, the association of alexithymia traits with depression may not be unique to ASD and may constitute a general psychopathological mechanism in clinical samples.

**418.011** (Poster) Emotion Dysregulation in Young Children with ASD: Exploring Individual- and Family-Level Factors  
**H. F. Branyan<sup>1</sup>, D. Swain<sup>2</sup> and S. H. Kim<sup>3</sup>,** (1)Center for Autism and the Developing Brain, White Plains, NY, (2)Virginia Polytechnic Institute and State University, Blacksburg, VA, (3)Psychiatry, Center for Autism and the Developing Brain, White Plains, NY

---

Background:

Emotional dysregulation (ED), or the failure to regulate emotions appropriately and effectively, occurs at increased rates in individuals with ASD. Cibralic and colleagues (2019) conducted a systematic review of determinants of ED in young children with ASD, finding mixed evidence for various individual factors (ASD symptom severity, IQ, language, and executive functioning). Family factors (parental education level, income, number of siblings, etc.) are rarely factored into this relationship. Given current literature highlighting the significance of ED and SES in neurotypical populations (Backer-Grøndahl, 2016.; Troy et al., 2017) and a call for the inclusion of family factors into ASD outcome research (Karst & Van Hecke, 2012), this study aims to explore the relationship between individual and family factors on ED in a large sample of young children with ASD.

Objectives:

1. Explore the relationship between family factors and child ED.
1. Examine the predictive nature of individual and family factors on child ED.

Methods:

Participants included 433 children between 1.5 and 5 years of age with ASD seen at ASD-specialty clinics for clinical/research purposes. Emotion regulation was quantified by caregiver report on the Child Behavior Checklist Ages 1.5-5 years - Dysregulation Profile (CBCL-DP; Achenbach, 1991), which allows for categorical and continuous measurement of ED. Individual-level factors included child age, non-verbal IQ, language level, and ASD symptoms (measured by the ADOS-2 Calibrated Severity Scores for Social Affect [CSS-SA] and Restricted and Repetitive Behavior domains [CSS-RRB]). Family factors included race, ethnicity, income, and caregiver education level; for a subsample, information regarding siblings were available. For Aim 1, chi square tests were run to examine differences in ED across family factors. For Aim 2, hierarchical linear regressions were run to examine predictors of ED. Predictors were entered into two blocks: 1) age, gender, NVIQ, observed spontaneous language level, CSS-SA and CSS-RRB; 2) highest caregiver education and family income (entered together and separately).

Results:

In the current sample, 38.3% (n = 166) presented with heightened ED, according to caregiver report on CBCL. Chi square analyses revealed significant differences in child ED across family income (X(8)=35.80,  $p < .001$ ) and highest caregiver education (X[3]=8.84,  $p = .03$ ) but not child race (X[3]=3.82,  $p = .28$ ) or ethnicity (X[1]=2.73,  $p = .10$ ). Within a subsample (n=263), child ED was not related to number of siblings (X[2]=3.82,  $p = .15$ ) or sibling with ASD (X[1]=.54,  $p = .46$ ). When predicting ED and controlling for individual-level factors, combined caregiver education level explained approximately 10% of the variance when entered as the single family factor ( $\beta = .16$ ,  $p = .04$ ). Similarly, income explained 14% of the variance when entered as the single family factor ( $\beta = -.25$ ,  $p < .01$ ). When both were entered together, only income remained as a significant predictor of child ED ( $\beta = -.21$ ,  $p = .03$ ).

Conclusions:

The current study provides supporting evidence for the inclusion of family factors (caregiver education level and family income) when examining child ED. Family factors should not only be taken into consideration in regard to assessment for ASD and co-occurring behavioral dysregulation; however, further exploring the effects of family factors on ER may be imperative for tailoring treatments and exploring outcomes.

**418.012** (Poster) Emotion Regulation Strategies, Autistic Traits and Socialisation

*L. S. Iao, Department of Psychology, Nottingham Trent University, Nottingham, United Kingdom*

---

**Background:** Individuals with Autism Spectrum Conditions (ASC) generally show maladaptive emotion regulation strategy use which may lead to various behavioural, emotional and mental health problems. To prevent negative and promote positive outcomes, identifying factors that predict emotion regulation strategy use is crucial. However, it is not clear whether ASC symptom severity predicts emotion regulation strategy use.

**Objectives:** Given that ASC is a multidimensional spectrum, this research examined whether severities of individual ASC traits, in addition to general ASC symptom severity, predicted emotion regulation strategy use in adults (Study 1) and children (Study 2) to extend the very sparse literature in this area. Study 2 also investigated whether parental responses to child's emotions predicted child's emotion regulation strategy use.

**Methods:** Study 1 included 172 adults (106 females) with a mean age of 26.41 years ( $SD = 6.84$  years, range = 18 – 40 years) who completed questionnaires on ASC traits and emotion regulation strategies. Study 2 included 126 parents (99 mothers, 27 fathers) who had children with a mean age of 4.29 years ( $SD = 1.06$  years, range = 3 – 6 years; 62 girls; 4 unspecified gender) and completed questionnaires on their children's ASC traits and emotion regulation strategies as well as their responses to children's emotions.

**Results:** Results suggested that emotion regulation strategy use was predicted by (1) difficulties in social skills and tendency to attend to detail in adults, (2) difficulties in mind-reading and imagination in children, and (3) parental encouragement of expression and minimizing/punitive responses. Despite different ASC traits predicted emotion regulation strategy use at different developmental stages, individuals with higher ASC traits were more likely to show maladaptive patterns of strategy use in both studies. Moreover, higher child ASC traits and greater parental responses to child's emotion predicted child's adaptive emotion regulation strategy use in opposite directions.

**Conclusions:** This research provides the first evidence that shows the impact of ASC traits on emotion regulation strategy use was present since early childhood but manifested through different ASC traits at different developmental stages. Although individuals with higher ASC traits are more likely to show maladaptive patterns of strategy use, greater parental responses to child's emotion, especially encouragement of expression, may facilitate adaptive emotion regulation strategy use in children. These findings contribute to our understanding of emotion regulation strategy use across the multidimensional spectrum of ASC and the lifespan, providing implications to parenting, educational and interventive strategies to facilitate adaptive emotion regulation strategy use and promote positive outcomes throughout the lifespan.

**418.013** (Poster) Emotional Regulation in Children with Autism: The Role of Ethnicity

*M. Mahjoob<sup>1</sup>, R. Cardy<sup>2</sup>, S. Monga<sup>3</sup>, A. Dupuis<sup>4</sup>, J. A. Brian<sup>5</sup>, B. Andrade<sup>6</sup>, E. Anagnostou<sup>6</sup> and A. Kushki<sup>7</sup>, (1)University of Toronto, Toronto, ON, Canada, (2)Holland Bloorview Kids Rehabilitation Hospital, Toronto, ON, Canada, (3)The Hospital for Sick Children, Toronto, ON, Canada, (4)Biostatistics, University of Toronto, Dalla Lana School of Public Health, Toronto, ON, Canada, (5)Centre for Addiction and Mental Health, Toronto, ON, Canada, (6)Autism Research Center, Bloorview Research Institute, Holland Bloorview Kids Rehabilitation Hospital, Toronto, ON, Canada, (7)Bloorview Research Institute, Toronto, ON, Canada*

---

**Background:** From the 1 in 66 children diagnosed with autism spectrum disorder (ASD), up to 84% experience anxiety symptoms. In children with ASD, impaired emotional regulation (ER) may contribute to development or exacerbation of these symptoms. ER is the ability to control one's emotional experience. In neurotypical (NT) populations, ER ability is suggested to be influenced by ethnicity, as ethnicities can differ in value systems, social status, emotional socialization, and emotional expression. Ethnic differences in ER and its underlying neural correlates have been reported. Studies examining the effect of ethnicity on ER in children have had mixed results; some studies found higher levels of emotional difficulties in white populations compared to non-white populations, while others suggest the opposite. Despite these mixed results, a common finding across studies is that some non-white, NT populations use emotional suppression, a maladaptive ER strategy, more than white populations. However, in these non-white, NT groups, emotional suppression is not linked to adverse psychological effects, as it is in white, NT populations. These differences suggest that approaching ER difficulties with an ethnic lens may be critical to developing targeted interventions for ER-related psychopathology. To our knowledge, no studies have investigated the effect of ethnicity on ER ability in ASD.

**Objectives:** The goal of this study was to examine the association between ethnicity and ER ability in a sample of children with ASD. Specifically, we explored whether (1) individual differences in ER ability were associated with ethnic differences in children with ASD; and (2) differences in the effect of ethnicity on ER ability in children with ASD compared to NT children.

**Methods:** A sample of children with a diagnosis of ASD ( $n=27$ ;  $M_{age}=10.85$  years,  $SD_{age}=2.05$ ; 10 non-white; 17 white) and typical controls were recruited ( $n=36$ ;  $M_{age}=9.41$  years;  $SD_{age}=1.71$ ; 21 non-white; 15 white). Participants self-reported their ethnic backgrounds. The sample was pooled into two groups based on ethnicity: non-white (African-American, Asian/Pacific Islander, Hispanic, Native-American, Multiracial) and white (European-American/White). ER ability was measured by the Emotion Dysregulation Inventory (EDI), a caregiver report standardized for ASD. We also characterized internalizing and externalizing behaviours using the Child Behaviour Checklist (CBCL), a caregiver report assessing problem behaviour in children.

**Results:** The Wilcoxon Rank Sums Test demonstrated that children of white ethnicity had significantly higher scores on the EDI-Dysphoria subscale ( $p=0.017$ ) and the CBCL internalizing score ( $p=0.039$ ) compared to non-white ethnicities. Linear regression did not show a significant interaction effect of diagnosis and ethnicity. The effect of ethnicity on the other EDI subscales as well as the CBCL externalizing scores was not significant.

**Conclusions:** The results of this preliminary study suggest that there are ethnicity-related differences in children's ER abilities, and these differences appear similar among children with ASD and NT. If replicated in larger samples, this may suggest that ethnicity is a clinically-important variable when considering ER interventions.

**418.014 (Poster)** Investigating the Mediating Effects of Alexithymia, Intolerance of Uncertainty and Anxiety on the Relationship between Sensory Processing and Restricted and Repetitive Behaviours in Autistic Adults

**H. L. Moore<sup>1</sup>, S. Brice<sup>2</sup>, M. Freeston<sup>3</sup>, B. Ingham<sup>4</sup>, J. R. Parr<sup>2</sup> and J. Rodgers<sup>2</sup>,** (1)Newcastle University, Newcastle upon Tyne, United Kingdom, (2)Population Health Sciences Institute, Newcastle University, Newcastle upon Tyne, United Kingdom, (3)School of Psychology, Newcastle University, Newcastle upon Tyne, United Kingdom, (4)Cumbria, Northumberland, Tyne and Wear NHS Foundation Trust, Newcastle upon Tyne, United Kingdom

Background:

Autistic people often experience sensory processing (SP) differences that may affect homeostatic arousal leading to over- or under-responsiveness. Some restricted and repetitive behaviours (RRB) may function in response to these difficulties and serve to regulate arousal levels, and consequently ease distress and discomfort that may accompany these sensory experiences. RRB comprise insistence on sameness (IS) and repetitive motor behaviours (RMB). In autistic children, the relationship between SP and both IS and RMBs has been shown to be mediated by intolerance of uncertainty (IU; a tendency to react negatively to unforeseen/unpredictable situations and events) and anxiety together, but research has only partially explored this relationship in autistic adults. Moreover, there is evidence to suggest that alexithymia (difficulty identifying and describing emotions) may play an additional mediating role, through its impact on IU and anxiety, but this has not yet been explored.

Objectives:

This study aimed to explore the serial mediating effects of alexithymia, IU, and anxiety on the relationships between sensory processing and restricted and repetitive behaviours in autistic adults.

Methods:

Participants with an autism diagnosis were recruited from the Adult Autism Spectrum Cohort-UK, to take part in the Personalised Anxiety Treatment-Autism study. Data were available from 426 autistic adults. Participants completed four self-report questionnaires measuring: SP (Sensory Preferences Questionnaire (SPQ)); RRB (Adult Repetitive Behaviour Questionnaire-2 (subscales RBQ-2A IS and RBQ-2A RMB)); alexithymia (Toronto Alexithymia Scale-20 (TAS-20)); IU (Intolerance of Uncertainty Scale; IUS-12); and anxiety (Hospital Anxiety and Depression Scale; HADS Anxiety). Mediation models were run using serial mediation (model 6) of Hayes' (2013) PROCESS macro for SPSS, applying bootstrapped 95% confidence intervals (10,000 resamples). Age and gender were included as covariates in the models.

Results:

There was a significant direct effect from SP to IS (SPQ-->IS,  $B=.1881$ ,  $SE=.0151$ ,  $CI=.1585-.2177$ ) and significant indirect effects through IU alone (SPQ-->IU-->IS,  $B=.0215$ ,  $SE=.0062$ ,  $CI=.0106-.0347$ ) and Alexithymia and IU (SPQ-->Alexithymia-->IU-->IS,  $B=.0078$ ,  $SE=.0025$ ,  $CI=.0036-.0132$ ). There was a significant direct effect from SP to RMB (SPQ-->RMB,  $B=.1390$ ,  $SE=.0107$ ,  $CI=.1180-.1600$ ) and a significant indirect effect through all three mediators (SPQ-->Alexithymia-->IU-->Anxiety-->RMB,  $B=.0008$ ,  $SE=.0005$ ,  $CI=.0000-.0020$ ). The figures below illustrate significant pathways (direct: solid lines, indirect: dashed lines).

#### Conclusions:

There were two potentially distinct pathways between sensory processing and restricted and repetitive behaviours in autistic adults, indicating that different mechanisms may underpin insistence on sameness and repetitive motor behaviours although alexithymia and IU are involved in both. We did not discriminate between hyper- and hypo-sensory processing differences in this analysis, and it remains to be seen whether distinct relationships emerge when considering these subtypes in an adult sample. Difficulties with emotional processing, alongside IU and anxiety, should be considered when understanding the relationship between sensory processing and restricted and repetitive behaviours, and when offering interventions to support autistic people.

#### **418.015** (Poster) Measuring Functional Deficits in Relation to Emotion Regulation Problems in Autism Spectrum Disorders Using the Cafas

**J. Golt<sup>1</sup>**, **C. A. Mazefsky<sup>2</sup>** and **S. W. White<sup>3</sup>**, (1)*The University of Alabama, Tuscaloosa, AL*, (2)*Department of Psychiatry, University of Pittsburgh School of Medicine, Pittsburgh, PA*, (3)*Psychology, The University of Alabama, Tuscaloosa, AL*

---

**Background:** Emotion regulation (ER) difficulties are common in autism spectrum disorder (ASD) and have linked to higher psychiatric symptoms. It has been suggested that ER difficulties may also contribute to poor functional outcomes in ASD, as has been shown in typically developing children (Cloitre, et al., 2005). However, measures used to establish this relationship in the general population, such as the Child and Adolescent Functional Assessment Scale (CAFAS; Hodges & Wong, 1996), have not been utilized in ASD. Further, previous research suggests that psychometric properties of valid assessments differ when used in ASD (White, et al., 2016). Better understanding and assessment of functional outcomes, in relation to ER, in ASD is important to consider for both research and clinical applications.

**Objectives:** This study investigates the measurement of functional problems as measured by clinician interview, compared to ER problems measured via clinician interview in an ASD sample.

**Methods:** A total of  $n = 57$  participants with ADOS-confirmed ASD, without intellectual disability, and selected for having ER problems. This sample was 73.7% male, 87.7% white with an average age of  $M = 15$  years ( $SD = 2.59$ ) and an average IQ of  $M = 105.31$  ( $SD = 18.49$ ). Both measures were collected through an interview with a parent by an independent evaluator within a clinical trial. The CAFAS is a valid and reliable rating scale which assesses functioning level across contexts. The Emotion Dysregulation Inventory (EDI; Mazefsky et al., 2018) is a valid and reliable measure of ER in ASD. The EDI measures Reactivity, intense negative emotion, and Dysphoria, low positive affect. Pearson correlations were conducted between EDI T-scores and the CAFAS subscales.

**Results:** Analyses indicate EDI subscales are not significantly correlated with any CAFAS subscales. When comparing the EDI Dysphoria to the CAFAS Mood/Emotion Subscale  $r = .120$ ,  $p = .451$ , Self-Harm Scale  $r = .110$ ,  $p = .488$ , School/Work  $r = .097$ ,  $p = .542$ , Home Behavior  $r = .201$ ,  $p = .193$ , Community Behavior  $r = -.188$ ,  $p = .232$ , Substance Use  $r = -1.88$ ,  $p = .232$ , Thinking Problems  $r = .027$ ,  $p = .865$ , and Behavior Towards Others  $r = .050$ ,  $p = .755$ . EDI Reactivity is not correlated to CAFAS Mood/Emotion Subscale  $r = .091$ ,  $p = .568$ , Self-Harm Scale  $r = .181$ ,  $p = .251$ , School/Work  $r = .256$ ,  $p = .102$ , Home Behavior  $r = .058$ ,  $p = .715$ , Community Behavior  $r = -.004$ ,  $p = .980$ , Substance Use  $r = .004$ ,  $p = .980$ , Thinking Problems  $r = .128$ ,  $p = .420$ , and Behavior Towards Others  $r = -.043$ ,  $p = .785$ . Additionally, CAFAS skewness = 1.634 ( $SE = .365$ ).

**Conclusions:** The CAFAS did not indicate functional problems related to ER in ASD, within a sample of participants specifically selected for having problems with ER. Additionally, distribution on the CAFAS was not normal, indicating potential problems in psychometric properties in this population. Given previous research, it would have been expected that there would be functional deficits as a result of ER problems. Additionally, the Mood/Emotions subscale was not related to dysregulation, which may indicate differences in measurement of ER in ASD using the CAFAS. This work highlights the importance of the development and validation of functional outcome measures in ASD.

#### **418.016** (Poster) Modeling Prospective Predictors of Mental Health Symptoms across the First Semester of College

**Background:** Prevalence rates suggest autistic adults are more likely than their allistic peers to experience anxiety and depression (Hollocks et al., 2019). Increased risk of social disappointment (Smith & White, 2020) and greater repetitive thinking (Rieffe et al., 2014) may contribute to this increased prevalence. Understanding these factors and their relationship with mental health over time is a key step to improving interventions for autistic adults.

**Objectives:** The current study examines negative repetitive thinking and satisfaction with social connectedness as prospective predictors of depression and anxiety symptoms in a longitudinal sample of first-semester college students. We hypothesize that (1) students who report greater capacity for social reward at baseline and lower social involvement throughout the semester will experience greater depressive symptoms over time; (2) on average, increases in negative repetitive thinking will precede increases in depressive and anxiety symptoms. While we predict no difference in the model of these mechanisms between autistic and allistic groups, we hypothesize that a higher proportion of autistic students will exhibit repetitive thinking and lack of social fulfillment.

**Methods:** We recruited incoming college students who reported either no history of autism (n=28) or suspected or previously diagnosed autism (n=15). Participants first completed a baseline survey including demographic information and constructs related to behavioral and physical health, such as Beck Depression Inventory, 2nd edition (BDI-II; Beck et al., 1996), and Anticipatory and Consummatory Interpersonal Pleasure Scale (ACIPS; Gooding & Pflum, 2014), among other measures (see Table 1). Participants then completed 10-question surveys twice per week for 12 weeks; surveys included markers of negative repetitive thinking, social satisfaction, depressive and anxiety symptoms. Participants will complete a semester-end battery in mid-December.

Structural equation modeling (SEM) will be used to test explicit hypotheses about the association between hypothesized predictors (repetitive negative thinking and social engagement) and outcome variables related to emotional health. We plan to use bivariate dual change score models to evaluate reciprocal effects of the predictor and outcome variables. We will compare effect sizes for exploratory analyses (e.g., by gender).

**Results:** Preliminary results on baseline data suggest that greater self-reported social motivation (ACIPS;  $M = 82.13$ ,  $SD = 16.95$ ) was associated with lower depression (BDI-II;  $M = 11.22$ ,  $SD = 0.91$ ) scores at baseline ( $r = -0.46$ ,  $p < 0.01$ ). Additionally, repetitive behavior (RBS-R;  $M = 14.74$ ,  $SD = 15.90$ ) during the baseline was positively correlated with sadness scores five weeks later ( $M = 2.35$ ,  $SD = 1.26$ ) ( $r = 0.41$ ,  $p = 0.04$ ). After December 2020 we will be able to model the data (see Figure 1) within individuals and across groups to comment on etiological hypotheses.

**Conclusions:** This is the first known longitudinal investigation of the relationships between rumination, social fulfillment, and emotional health in autistic adults. Preliminary results suggest mechanisms related to depression risk are unlikely to be different between autistic and non-autistic adults, but autistic adults may be more likely to experience some of these psychosocial predictor variables.

**418.017 (Poster)** Mothers of Autistic Children Recognize Emotions As Well As College Women  
*A. J. Lampi* and *V. K. Jaswal*, University of Virginia, Charlottesville, VA

---

**Background:**

One characteristic associated with autism is reduced accuracy in the recognition of facial emotional expressions (e.g. Uljarevic & Hamilton, 2013; but see Cook et al., 2012). Studies investigating whether parents of autistic individuals also show difficulties in emotion recognition have yielded conflicting results, with some finding lower accuracy compared to non-autistic individuals (e.g., Kadak et al., 2014; Palermo et al., 2006) and others finding no difference (e.g. Bolte & Poustka, 2003). It has also been suggested that alexithymia, a subclinical trait reflecting difficulty in identifying and distinguishing between emotions, may better explain performance on emotion-related tasks than levels of autism symptomatology (Bird & Cook, 2013).

**Objectives:**

We compared how well mothers of autistic children performed on a standard emotion recognition task with how well college women did on the same task. We additionally investigated the contribution of individual difference measures of autistic-like traits and alexithymia.

## Methods:

We recruited a sample of 24 mothers ( $M_{\text{age}} = 52.52$  years,  $SD = 5.92$ ) with an autistic child ( $M_{\text{child-age}} = 17.88$ ,  $SD = 4.72$ ) and a comparison sample of 151 college women ( $M_{\text{age}} = 19.15$  years,  $SD = 1.13$ ). Participants completed an emotion recognition task that required them to identify which of six emotions each of 72 faces showed (Ebner et al., 2010). In addition, participants completed the Toronto Alexithymia Scale (TAS-20; Bagby et al., 1994) and the Autism-Spectrum Quotient (AQ; Baron-Cohen et al., 2001). We examined group differences in overall emotion recognition accuracy in addition to accuracy within each emotion, both before and after accounting for level of alexithymia and autism symptomatology.

## Results:

Mothers correctly recognized the emotions in the emotion recognition task marginally more often than the college women, and mothers had significantly lower scores on the TAS-20 and AQ than college women (Table 1). Figure 1 shows the average accuracy for each of the six emotions. To analyze these data, we used linear mixed effects modelling. A model including group (mothers vs. college women) better fit the data than one that only included the six emotions,  $\chi^2(6) = 32.06$ ,  $p < .001$ . There were no significant main effects, but there was a significant interaction between group and emotion depicted,  $F(5,865) = 5.80$ ,  $p < .001$ . The only emotion that showed a difference between groups was sadness: Mothers were more accurate at identifying sad faces than college women,  $t(921) = 5.37$ ;  $p < .001$ . Adding AQ and TAS scores to this model did not result in an improved fit.

## Conclusions:

Although some past studies have found that parents of autistic children have reduced emotion recognition abilities, this study did not. Mothers of autistic children recognized emotions on a standard emotion recognition task at least as well as college women. Indeed, the only difference between the two groups showed an advantage for the mothers, who were better at recognizing sad faces than the comparison group. AQ and TAS-20 scores did not predict performance on the emotion recognition task above participant group alone.

### **418.018** (Poster) Multimodal and Dimensional Emotion Recognition Among Children with and without ASD: Examining the Impact of ASD Symptoms and Alexithymia

*S. Sivathanan, J. Burack and E. M. Quintin, Educational & Counselling Psychology, McGill University, Montreal, QC, Canada*

**Background:** The unique social characteristics of persons with ASD are thought to contribute to their similarly distinctive emotion recognition (ER) abilities, as generally measured with forced-choice verbal-label ER paradigms. Alternatively, we suggest that alexithymia, a trait characterized by a difficulty in verbalizing emotions that is more prevalent among persons with ASD than those in the general population, may be a more powerful indicator of their ER abilities. In doing so, we used a multimodal and multimethod paradigm to test ER among children with and without ASD.

**Objectives:** The aim of this study was to assess the extent to which alexithymia and ASD symptoms are related both to basic ER across multiple modalities (face, voice, music) and to participant responses on either a traditional forced-choice paradigm or dimensional ratings of emotional arousal (low to high energy) and valence (negative to positive) among children with ASD as compared to TD children.

**Methods:** Fifteen children with ASD and 19 TD children aged 6-12 years (mean verbal mental age [VMA] = 9.14 years) participated in the study. A parent or teacher completed the Children's Alexithymia Measure (CAM; Way et al., 2010) and the Social Responsiveness Scale-2 (SRS-2; Constantino & Gruber, 2012) for each child. The participants completed a task of ER in which they were asked to identify basic emotions (happy, sad, and fear) in facial, vocal, and musical stimuli, by selecting a corresponding verbal label (forced-choice condition) and by rating how energetic and positive/negative each stimulus was on 5-point Likert scales.

**Results:** Compared to the TD participants, the participants with ASD scored significantly higher on the CAM and the SRS-2. In the forced-choice condition, partial correlations controlling for VMA revealed no significant associations between CAM scores and ER accuracy overall, or at the group level. However, among the TD children, higher SRS-2 scores were correlated with less accurate identification of emotions in voices ( $r = -.59$ ,  $p = .010$ ) and of sad emotions ( $r = -.72$ ,  $p = .001$ ) across sad faces ( $r = -.66$ ,  $p = .003$ ) and sad voices ( $r = -.63$ ,  $p = .005$ ). In the dimensional condition, the participants with higher CAM scores rated happy music as more positively valenced ( $r = .502$ ,  $p = .003$ ) and sad music as less energetic ( $r = -.55$ ,  $p = .001$ ) as compared to the participants with lower CAM scores. Further, the participants with higher SRS-2 scores rated happy music as more positively valenced than those with lower SRS-2 scores ( $r = .48$ ,  $p = .005$ ).

Conclusions: These preliminary findings suggest that both ASD symptoms and alexithymia may be related to how children recognize and rate emotions across specific emotions or modalities. Alexithymia traits may play a greater role in the group differences in dimensional ratings of valence and arousal, whereas social differences appear to be more associated with forced-choice ratings of emotions, particularly in TD children. Overall, these findings highlight the importance of considering social differences and alexithymia traits in studying ER among children with ASD as well as TD children.

**418.019 (Poster)** Multisensory Perception of Expressions of Emotion in Autistic Children and Adolescents

**K. Ainsworth<sup>1</sup>, F. Falagiarda<sup>2</sup>, O. Collignon<sup>3</sup> and A. Bertone<sup>1</sup>, (1)McGill University, Montreal, QC, Canada, (2)Université Catholique de Louvain, Louvain, Belgium, (3)Université Catholique de Louvain, Louvain, QC, Belgium**

---

Background: Atypical sensory perception has been recognized in autistic individuals since its earliest descriptions, and is now considered as one of the key characteristics of autism (APA, 2013). The *integration* of sensory information (multisensory integration; MSI) may be particularly altered in autistic individuals, with research suggesting that atypical MSI may underlie the different sensory profiles seen in autism (e.g. Feldman et al., 2018) and may also have cascading effects on development (e.g. Stevenson et al., 2018).

Objectives: Our study is the first to define time-resolved discrimination of MSI expressions of emotion across development in individuals with and without autism. Using a novel gating paradigm (Falagiarda and Collignon, 2019), we demonstrated that precise discriminatory decisions are achieved at different time points during the unfolding of emotional expressions (anger, fear, happiness and sadness) across different periods of development.

Methods: Detection of dynamic emotion expressions (anger, fear, happiness and sadness) was tracked separately for auditory, visual and bimodal cues in 32 autistic, ( $M_{age}$  12.13 (3.45),  $M_{IQ}$  99.96) and 56 typical participants ( $M_{age}$  11.91 (3.41),  $M_{IQ}$  106.4). Stimuli were separated into 10 progressively longer ‘gates’, increasing in increments of ~33ms (one frame), reaching a maximum of 400ms. Participants were grouped into children (age 6-12 years) and adolescents (age 13-18 years), and logistic psychometric curves were fitted for each group. Thresholds were extracted from each model at 0.625 proportion of correct responses, where  $p(\text{threshold}) = (1 - p(\text{chance})) / 2$ , and were analyzed using a generalized linear mixed model with group, modality and emotion as fixed effects and subjects as a random effect (marginal  $R^2 = 0.21$ ; conditional  $R^2 = 0.42$ ).

Results: An ANOVA was conducted on the model, revealing a significant main effect of group  $F = 4.33$ ,  $p < 0.01$ . Bonferroni post-hoc tests indicated that the group effect was driven by a significant difference between autistic children and autistic adolescents ( $t = 3.69$ ,  $p < 0.01$ ), with children having significantly higher thresholds. A significant overall effect of modality was also observed ( $F = 84.17$ ,  $p < 0.01$ ). Bonferroni post-hoc comparisons indicated that bimodal stimuli lead to better discrimination of emotion, compared to unimodal, and visual stimuli provided better discrimination than auditory stimuli (auditory sig. higher than visual ( $t = 8.51$ ,  $p < 0.01$ ); auditory sig. higher than bimodal ( $t = 12.82$ ,  $p < 0.01$ ); visual sig. higher than bimodal ( $t = 4.40$ ,  $p < 0.01$ ). An overall significant effect of emotion was also found ( $F = 6.10$ ,  $p < 0.01$ ), with post-hoc analyses indicating that fear thresholds were significantly lower than anger ( $t = 3.48$ ,  $p < 0.01$ ).

Conclusions: Our study is the first to define time-resolved discrimination of audiovisual expressions of emotion across development in autistic individuals. Our results support previous evidence that MSI profiles differ between childhood and adolescence in the autistic population (e.g. Feldman et al., 2019), and provides a platform for further exploration of temporal emotion discrimination across neurodiverse development.

**418.020 (Poster)** Self-Reported Outcomes of School-Aged Children at Elevated Likelihood for Autism Spectrum Disorder: Preliminary Results of a Longitudinal Study

**F. Vlaeminck<sup>1</sup>, I. Schietecatte<sup>1</sup>, P. Warreyn<sup>1</sup> and H. Roeyers<sup>1</sup>, Department of Experimental-Clinical and Health Psychology, Ghent University, Ghent, Belgium**

---

Background:

Autism spectrum disorder (ASD) has an estimated prevalence of about 1% (Baird et al., 2006), but several groups are at elevated likelihood (EL) to develop ASD. Children with an older brother or sister diagnosed with ASD – the so-called EL-siblings – have up to 20% chance of developing ASD (Ozonoff et al., 2011). Despite the importance of gaining insight into their longer-term outcomes, only few studies assessed EL-siblings after age three (Miller et al., 2016; Shephard et al., 2017). However, they did not include self-report measures, nor did they explore predictors of school-age outcomes. Adding these aspects to the follow-up design could significantly improve our understanding of their school-age functioning.

Objectives:

Explore self-reported outcomes and their predictors in a sample of EL-siblings and children at typical ASD-likelihood (TL).

#### Methods:

Participants were 37 EL-siblings (18 girls, mean age=11.7 years, sd=1.766) and 20 TL-children (7 girls, mean age=13.7 years, sd=.348), between 9 and 16 years old. They previously participated in this longitudinal study at six timepoints before their third birthday. Of the 37 EL-siblings, 11 (30%) received a best-estimate research diagnosis of ASD at the age of three and/or had a clinical diagnosis at follow-up (EL-ASD-siblings). At age three, Mullen Scales of Early Learning, ADOS and Child Behavior Checklist (CBCL) were administered, while at school-age social-emotional functioning was assessed: depression (Children's Depression Inventory; CDI-2), peer problems (Strengths and Difficulties Questionnaire; SDQ subscale peer problems), emotion regulation (FEEL-KJ), anxiety (SCARED-NL) and self-concept (CBSK/CBSA).

#### Results:

Internal consistency of the self-report measures was satisfactory, except for the SDQ-peer problems subscale. A factor analysis on this subscale resulted in two components: "detached/bullied" and "unpopular". Subsequently, a MANOVA was performed, with three groups (EL-ASD-siblings, EL-nonASD-siblings and TL-children), and eight dependent variables: "detached/bullied", "unpopular", total z-score for anxiety and self-concept, T-scores for adaptive/maladaptive/external emotion regulation strategies, and percentile-based-categories of CDI-2-scores. EL-ASD-siblings scored significantly higher than TL-children on "detached/bullied" ( $p=.006$ ), marginally higher on depressive symptoms ( $p=.062$ ), and significantly lower on self-concept ( $p=.034$ ). No group differences were found for EL-nonASD-siblings, except for a marginally lower score on "detached/bullied" compared to EL-ASD-siblings ( $p=.093$ ). Three linear regressions were performed to predict the variables with (marginally) significant group differences. Depressive symptoms and self-concept could not be predicted by Mullen Developmental Index, ADOS\_SA (social affect) or internalizing CBCL T-scores at 36 months. However, the model was significant for "detached/bullied" ( $F(3,38)=3.119$ ,  $p=.037$ ,  $R^2=0.198$ ), with higher ADOS\_SA being predictive for higher scores on "detached/bullied" ( $\beta=.290$ ,  $t=2.828$ ,  $p=.007$ ).

#### Conclusions:

This was the first longitudinal study in EL-siblings that included self-report measures of social-emotional functioning, which is important given that self-report does not always correspond with parent-report. Unlike in the EL-nonASD-siblings – who seemed to have no elevated social-emotional problems despite their EL-status – self-reported outcome in children with an ASD-diagnosis was poorer than in TL-children. Social-communicative functioning at age 3 predicted difficulties with peers later on. It should, however, be noted that our sample was rather small and our sibling group had average cognitive abilities (mean FSIQ=105), which might limit the generalizability of the results.

#### **418.022 (Poster)** Studying How Physiological Arousal and Emotion Regulation Interact in Children Diagnosed with Autism Spectrum Disorder

**B. Syed<sup>1</sup>, R. Cardy<sup>2</sup>, S. Monga<sup>3</sup>, A. Dupuis<sup>4</sup>, J. A. Brian<sup>5</sup>, B. Andrade<sup>6</sup>, E. Anagnostou<sup>6</sup> and A. Kushki<sup>7</sup>**, (1)University of Toronto, Toronto, ON, Canada, (2)Holland Bloorview Kids Rehabilitation Hospital, Toronto, ON, Canada, (3)The Hospital for Sick Children, Toronto, ON, Canada, (4)Biostatistics, University of Toronto, Dalla Lana School of Public Health, Toronto, ON, Canada, (5)Centre for Addiction and Mental Health, Toronto, ON, Canada, (6)Autism Research Center, Bloorview Research Institute, Holland Bloorview Kids Rehabilitation Hospital, Toronto, ON, Canada, (7)Bloorview Research Institute, Toronto, ON, Canada

Background: Up to 84% of children with ASD experience clinically significant anxiety, which negatively impacts academic achievement, employment outcomes, and physical and mental health. Despite the prevalence and significance of anxiety, very few evidence-based interventions exist. A key challenge to developing such treatments is that the biological, physiological, and emotional factors contributing to anxiety in ASD remain largely unknown. Two mechanisms suggested to underlie anxiety in ASD are physiological arousal and emotion regulation (ER). This knowledge is critically needed to inform targeted treatment approaches for anxiety in ASD populations.

Objectives: Are physiological arousal and ER associated in children diagnosed with ASD?

Methods: The study sample consisted of 44 children (7-14 years) who were TD ( $n=24$ , median age=9.6, IQR=2, 15 male) or had a diagnosis of ASD ( $n=20$ , median age=11.4, IQR=2.2, 17 male). All children had full-scale IQ greater than 85. The experiment consisted of participants playing video games in between two baseline movie-watching sessions (BL1 and BL2). For short intervals, the video game controls were inverted/unresponsive to elicit frustration. Physiological arousal was measured via the

participants' heart rate (HR) and respiratory sinus arrhythmia (RSA), to index overall arousal and parasympathetic activity, respectively. Mean HR and RSA were calculated for BL1, BL2, and each video game. HR and RSA reactivity were calculated for each video game relative to BL1 and BL2. ER ability was measured via the Emotion Dysregulation Inventory (EDI), a 64-item parent-reported questionnaire validated in samples of children with ASD, in which a higher score reflects lower ER ability. Wilcoxon-Mann-Whitney tests and linear regression analyses were used to examine group differences and arousal-EDI associations, respectively.

Results: There were no significant differences in mean HR, RSA, or RSA reactivity between the ASD and TD groups. However, though both groups increased in HR, the ASD group had a significantly smaller increase on average in HR from BL1 to the frustrating video gameplay ( $p < 0.01$ , Figure 1) as well as from BL2 ( $p < 0.01$ ). There were no significant associations between physiological indices and the EDI totals (reactivity full or short, dysphoria), even though the ASD group scored significantly higher on each (full,  $p < 0.01$ , Figure 2; short,  $p < 0.01$ ; dysphoria,  $p < 0.05$ ).

Conclusions: While both groups' HR increased from resting state to negative modulation during video gameplay, the ASD group had a significantly smaller increase than the TD group (Figure 1). This difference was not explained by parasympathetic activity (RSA) and did not relate to ER, even though groups differed on ER difficulties (Figure 2). Future studies can investigate whether physiological arousal and ER significantly contribute to anxiety symptoms in children diagnosed with ASD.

**418.023 (Poster)** The Link between Emotion Regulation Abilities in Children with ASD and Depressive Symptomatology in Their Parents

*A. P. Costa<sup>1</sup>, K. Schneider<sup>2</sup> and G. Steffgen<sup>3</sup>, (1)University of Luxembourg, Esch sur Alzette, LUXEMBOURG, (2)University of Luxembourg, Esch-sur-Alzette, Luxembourg, (3)Institute for Health and Behaviour, University of Luxembourg, Luxembourg, Luxembourg*

---

Background: Research shows that parents of children with autism spectrum disorder (ASD) have more depressive symptomatology than parents of typically developing (TD) children (Cohrs & Leslie, 2017). However, studies with TD children also show that children of depressed parents are at risk of developing low emotion regulation (ER) ability (Feng et al. 2008). Therefore, it is hypothesized that emotion regulation abilities in children with ASD and depressive symptoms in their parents are related.

Objectives: To analyze the relationship between emotion regulation difficulties in children with ASD and depressive symptomatology in their parent.

Methods: 108 parents (84% mothers) answered to questionnaires about themselves and their children. Parents were aged 26 to 53 years old ( $M = 40.47$ ,  $SD = 5.13$ ) and their children 4 to 12 years old. 19 were parents of children diagnosed with ASD with intellectual disability (ID; children's age:  $M = 8.79$ ,  $SD = 2.79$ ), 17 were parents of children diagnosed with ASD without ID (children's age:  $M = 9.28$ ,  $SD = 2.46$ ), and 72 were parents of TD children (children's age:  $M = 8.59$ ,  $SD = 2.27$ ). The Center for Epidemiologic Studies Depression Scale (CES-D scale; Radloff, 1977) was used to assess parents' depressive symptomatology; the Autism Spectrum Quotient Questionnaire for Children (AQ-Child; Auyeung et al. 2008) was used to control children's autistic traits; and the Emotion Regulation Checklist for children (ERC; Shields & Cicchetti, 1997) was used to assess children's emotion regulation ability.

Results: The analyses showed that children with ASD had less emotion regulation ability than TD children ( $t(106) = 7.68$ ,  $p < .001$ ,  $ES r = .60$ ). Analyzing parents' depressive symptomatology, no differences were found between fathers and mothers ( $t(106) = .11$ ,  $p = .92$ ). However, a significant difference was found among parents of children with ASD and TD children: the odds of having clinically significant depressive symptomatology (CES-d score  $> 16$ ) were 5 times higher for parents of children with ASD than TD ( $\chi^2(1) = 13.29$ ,  $p < .01$ ,  $OR = 5$ ). Furthermore, it was also found that children of depressed parents (CES-d  $> 16$ ) had more emotion regulation difficulties ( $t(106) = 3.18$ ,  $p < .01$ ,  $ES r = .30$ ). Regression analyses revealed that taking children's age into account, children's emotion regulation difficulties were a better predictor of parents' depressive symptomatology than children's diagnosis (Table 1).

Conclusions: As expected, it was found that children with ASD had more emotion regulation difficulties and that their parents had more depressive symptomatology than TD children and their parents, respectively. Furthermore, children of depressed parents had more emotion regulation difficulties than children of non-depressed parents. Finally, it was found that emotion regulation difficulties incrementally predicted parents' depressive symptomatology above and beyond the children's diagnostic group. These results suggest that children's difficulties with emotion regulation might be an important aspect in the understanding of depression in parents of children with ASD. However, further research is needed to better understand the

relation between the emotional difficulties of children with ASD and their parents' depressive symptomatology.

**418.024** (Poster) The Operationalisation of Uncertainty in Experimental Research in Autism and Anxiety: A Systematic Review  
**L. Lennuyeux-Commene<sup>1</sup>, S. B. Gaigg<sup>2</sup> and F. Rigoli<sup>3</sup>**, (1)Department of Psychology, City, University of London, London, United Kingdom, (2)Autism Research Group, City, University of London, London, United Kingdom, (3)Psychology, City, University of London, London, United Kingdom

---

**Background:** A growing consensus in the mental health literature is that a construct known as 'Intolerance of Uncertainty (IoU)' (Carleton, 2014) represents a transdiagnostic risk-factor for anxiety disorders that are very common in autism. A limitation in this literature to date, however, is that this construct is measured almost exclusively through self-report (e.g. Maisel et al., 2016; Wigham et al., 2014.), which has led to somewhat of a theoretical vacuum regarding the precise mechanisms that link IoU to the behavioural expression of anxiety in the general population vs those with a diagnosis of ASD.

**Objectives:** The overarching aim of this review was to examine the effects of experimental manipulations of 'uncertainty' on overt behaviour, in order to derive a formal description of the construct of 'Uncertainty' and how this has been operationalised in the existing anxiety and autism literatures.

**Methods:** Six electronic databases were searched using the following terms: Uncertainty AND Anxiety; Uncertainty AND Autism OR Autism Spectrum Disorder OR ASD. Studies had to include either participants with a diagnosis of an autism disorder or an anxiety disorder, or a group of neurotypical participants for whom levels of autistic traits and/or anxiety were quantified as a continuous variable through validated instruments. Studies also had to consider the influence of experimental manipulations of 'uncertainty' on overt behaviour. The guidelines from the Centre for Reviews and Dissemination (CRD) were used to extract data and assess them for quality and risk of bias.

**Results:** The search identified 10,051 studies, of which 77 were included in this review. Data analysis is ongoing but preliminary results indicate that in both the anxiety and autism literatures uncertainty is frequently operationalised as a manipulation of the probabilities of stimulus-outcome contingencies. In both literatures, this is defined in terms of ambiguity (differing but stable probabilities), risk (smaller likelihood with higher stakes) or conditioning (with known or volatile contingencies) in tasks involving monetary gains or losses. However in autism research, the emphasis is on whether autistic people use contextual priors in order to make predictions regarding the likelihood of future events rather than on direct correlations between affect and behaviour. In anxiety research, other tasks involved interpreting ambiguous scenarios or being given delayed or deceptive feedback and then measuring self-confidence; whereas in autism research, uncertainty was manipulated by modifying physical cues (rubber hand illusion) or visual stimuli (dot-probe) and then measuring self-awareness.

**Conclusions:** Despite research pointing to the key role IoU plays in anxiety in autism, unlike in the anxiety literature, none of the included studies in the autism literature included a self-report measure alongside a behavioural measure of IoU and only four explored the relationship between autism, uncertainty and anxiety – only one of which found a correlation. Our preliminary results show, therefore, that there is a gap in the existing literature in terms of linking self-reported intolerance of uncertainty to the behavioural expression of such intolerance and the experience and expression of anxiety in autism.

**418.025** (Poster) The Recognition of Speech and Song-Evoked Emotions Among Children with ASD and Typical Development: Does Emotion Intensity Impact Performance?  
**T. Fernandes, J. Burack and E. M. Quintin**, Educational & Counselling Psychology, McGill University, Montreal, QC, Canada

---

**Background:** The commonly accepted dogma of difficulties in inferring others' emotions from various social cues among persons with ASD needs to be recast in relation to context. For example, the emotion recognition abilities of persons with ASD, like those of others, are highly influenced by factors such as the intensity to which emotions are conveyed and level of social pragmatic language skills. Emotion recognition also varies across modality. For example, persons with ASD can accurately recognize music-evoked emotions.

**Objectives:** In order to fine-tune our understanding of emotion recognition in ASD, we examined the relation between specific emotions, emotion intensity, and social pragmatic language skills on the recognition of speech and song-evoked emotions.

**Methods:** Twenty-six children with ASD (mean age = 10.9 years; VCI = 77.8) and 21 TD children (mean age = 9.0 years; VCI = 101.6) completed a computerized task in which they identified emotions of high or normal intensity from spoken or sung sentences with neutral semantic content. The Verbal Comprehension Index (VCI) of the WISC-V was administered to the

participants and caregivers completed three subscales of the Child Communication Checklist-2 measuring quality of initiating social conversations, scripted language, and adapting conversation to different contexts.

Results: A repeated-measures ANOVA with stimuli modality (speech vs. song), emotion (happy, sad, angry), and intensity (high vs. normal) as within-subject factors, participant group (ASD vs. TD) as a between-subject factor, VCI as a covariate, and emotion recognition accuracy as the dependent variable revealed a significant main effect of emotion ( $p = .046$ ), in which anger was the most easily recognized emotion. VCI, and not participant group, had a significant effect on emotion recognition accuracy. A significant group X intensity interaction ( $p = .035$ ) indicated that children with ASD, but not those with TD, responded more accurately in recognizing high intensity as compared to normal intensity emotions. A separate repeated-measures ANOVA with response time as the dependent variable revealed a marginally significant group X intensity X stimuli interaction ( $p = .05$ ) such that the ASD group showed faster response times for high (vs. normal) intensity emotions conveyed in speech but not in song, while the response times of the TD group showed similar response times across intensity and modalities. A regression analysis revealed that a component of social pragmatic skills (i.e., quality of initiating social conversations) was associated with emotion recognition accuracy for the TD group but not for the ASD group.

Conclusions: These findings suggest that emotion recognition among children with ASD is impacted by intensity, particularly for speech-evoked emotions, while an effect was not observed among the children with TD, who performed comparably across intensity conditions and modalities. Findings replicate previous work showing associations between verbal skills and emotion recognition of children with ASD. In contrast, social pragmatic language skills were not related to emotion recognition of children with ASD. These findings suggest that interventions targeting emotion recognition of children with ASD may be ameliorated by first teaching emotions that are intensely conveyed followed by those that are more subtle.

**418.026** (Poster) Two Pathways: The Contribution of Autistic and Alexithymic Traits to Emotion Recognition Difficulties  
*C. T. Keating and J. L. Cook, School of Psychology, University of Birmingham, Birmingham, United Kingdom*

---

Background:

Recent developments suggest that alexithymia, and not autism, is responsible for the difficulties with emotion recognition that are often documented in the autistic population. Whilst research has not yet elucidated the mechanisms behind its involvement, there are speculations that being high in alexithymic traits results in more variable representations of emotion, thus leading to poorer emotion recognition accuracy.

Objectives:

We aimed to investigate variability of emotion representations and emotion recognition accuracy in a sample of autistic and non-autistic adults. We hypothesised that alexithymic, and not autistic traits, would be linked to increased variability and reduced accuracy.

Methods:

25 autistic and 25 non-autistic controls, matched on age, gender, non-verbal reasoning (NVR) and alexithymia, completed two emotion-based tasks which employed dynamic point light displays (point light faces; PLFs) of happy, angry and sad facial expressions. In the first of these tasks, on each trial, participants viewed a PLF and rated the extent to which the expression looked angry, happy and sad. Emotion recognition accuracy was calculated as the correct emotion rating minus the mean of the two incorrect emotion ratings. In the second of these tasks, on each trial, participants viewed a PLF stimulus (that looped such that it played continuously) and were required to manipulate its speed (by moving a slider) until the PLF moved at the speed of a typical angry, happy or sad expression. Variability was calculated as the standard deviation of the speeds attributed to angry, happy and sad PLFs. The Autism Quotient (AQ) and the Toronto Alexithymia Scale (TAS) were used to index autistic and alexithymic traits respectively.

Results:

First, we constructed a linear mixed effects model of accuracy as a function of mean variability with subject, age, gender and NVR as random intercepts. This revealed that mean variability [ $t(72.54) = -3.42, p < .01$ ] was a significant predictor of accuracy. Next, we constructed two linear mixed effects models with accuracy and variability as the outcome variables respectively. Whilst accuracy was negatively predicted by total AQ score [ $t(95.13) = -2.56, p < .05$ ] (and not total TAS score), variability was not predicted by total AQ or TAS scores [all  $p > .05$ ]. We ran these analyses again, entering all of the AQ and TAS subscales as potential predictors. Whilst accuracy was not predicted by any of these subscales [all  $p > .05$ ], variability was predicted by scores

on the TAS Externally Oriented Thinking (EOT) subscale [ $t(51.04) = 3.148, p < .01$ ]. Finally, we ran a mediation analysis (see Figure 1), which revealed that TAS EOT exerted an indirect effect on emotion recognition accuracy by influencing variability [standardized beta =  $-.19, z(50) = -9.50, p < .001$ ].

#### Conclusions:

Our results illuminate the presence of two ‘pathways’ to emotion recognition difficulties. On one hand, being high in autistic traits *directly* contributes to lower emotion recognition accuracy. On the other hand, being high in certain alexithymic traits (specifically externally oriented thinking) contributes to greater variability, which in turn results in lower accuracy (thus partially supporting our hypothesis).

**418.027 (Poster)** Understanding the Influence of Social Interactions on Negative Affect in Autistic Adults with Social Anxiety  
**D. L. Limon<sup>1</sup>, D. Gifford<sup>2</sup>, D. Melanson<sup>3</sup>, K. M. Normansell-Mossa<sup>3</sup>, J. A. Nielsen<sup>1</sup> and M. South<sup>4</sup>,** (1)Brigham Young University, Provo, UT, (2)Neuroscience, Brigham Young University, Provo, UT, (3)Clinical Psychology, Brigham Young University, Provo, UT, (4)Psychology & Neuroscience, Brigham Young University, Provo, UT

---

Background: Social anxiety disorder affects approximately 15 million American adults and is common among autistic individuals alongside differences in social communication. Studies using ecological momentary assessment methods (EMA) have shown that individuals with elevated social anxiety show increased benefit from close social interactions, including reduced levels of daily negative affect (NA). However, little is known about how types of social interactions affect individuals with autism and concurrent social anxiety, who may show varying levels of social motivation.

Objectives: To examine how daily social interactions--including both face-to-face and digital interactions--are associated with daily NA in adults with combined autism and social anxiety relative to non-autistic socially anxious adults and autistic but non-anxious adults.

Methods: Participants included adults (18+ years) who are participating in an on-going mental health longitudinal study. Participants consisted of 100 adults evenly split across non-clinical (NOCLIN), autistic (AUT), and socially anxious (SOCANX) groups. Social anxiety was measured using the Liebowitz Social Anxiety Scale (LSAS). We leveraged smart-phone based EMA surveys to examine daily NA and data about the individual’s social interactions. EMAs are collected in real-time, limiting retrospective reporting bias which allows us to track fluctuating emotional experiences that contribute to risks for potential and/or worsened mood disorders.

Results: One-way ANOVA showed a significant effect for total score on the LSAS, as both clinical groups scored higher than the NOCLIN control group. There was no significant difference in mean LSAS score between the AUT (mean = 67.82, SD = 28.4) and SOCANX group (mean = 73.71, SD = 24.09). The same pattern of (AUT = SOCANX) > NOCLIN was true for the daily measures of negative affect and positive affect. We specifically analyzed SOCANX and AUT participants with moderate- to high-scores on the LSAS. For both autism and non-autism socially-anxious groups, a decrease in negative affect was significantly correlated with increased feelings of face-to-face social connectedness, although NA was *positively* correlated with the *number* of daily interactions in the SOCANX group.

Conclusions: Results indicate that social interactions, particularly face-to-face connectedness, help socially anxious autistic individuals in the same way as non-autistic individuals. Interventions based on improving opportunities for social interaction and reducing associated anxiety may improve mental health for autistic and socially anxious individuals.

### PANEL DISCUSSION — EPIDEMIOLOGY/POPULATION STUDIES

#### Panel 204 - Insights into Autism from Longitudinal Studies Spanning Infancy to Adulthood

**Panel Chair:** Jessica Girault, *Carolina Institute for Developmental Disabilities, University of North Carolina, Chapel Hill, NC*

**Discussant:** Alycia Halladay, *Autism Science Foundation, New York, NY*

Longitudinal studies have revealed that changes over time in symptomology, behavior, and neurobiology represent a fundamental aspect of autism spectrum disorder (ASD). In this panel, we discuss findings from four longitudinal studies spanning infancy through adulthood that highlight the dynamic nature of ASD and emphasize the importance of longitudinal research in clarifying our understanding of etiology and the natural history of ASD. Presenters discuss key early predictors of later outcomes, transition points in trajectories, and the individual, family, and contextual factors that contribute to intra- and inter-individual variability in ASD.

**204.001** (*Panel Discussion*) The Infant Brain Imaging Study: Exploring the Role of Family Traits  
**J. B. Girault**, *Carolina Institute for Developmental Disabilities, University of North Carolina, Chapel Hill, NC*

**Objective:** The Infant Brain Imaging Study (IBIS) is a prospective longitudinal study of infant siblings of children with autism who are at increased likelihood of developing autism themselves. The overarching goal of the project is to identify the developmental precursors of autism in order to improve early detection and inform intervention targets. The infant sibling study design provides a powerful framework to determine what is “familial” in autism by placing the infant sibling in the context of the family and family genetics. Here we discuss findings demonstrating that the phenotypic severity of older siblings with autism (probands) can inform behavioral and neurodevelopmental trajectories in their younger siblings.

**Methods:** The sample consists of 384 proband-sibling pairs. Infant siblings (60% male) were assessed with a neuroimaging (structural, diffusion, functional) and behavioral battery (direct assessment, parent interviews and questionnaires) at 6, 12, and 24 months; siblings are currently being followed-up at school-age. Siblings received a clinical best estimate diagnosis at 24 months using DSM-IV-TR criteria. Probands (mean age 5.5 years; 86% male) were phenotyped using parent interviews and questionnaires; autism diagnosis was confirmed with clinical records. A total of 89 proband-sibling pairs (23%) were concordant for a diagnosis of autism. Two main aims were addressed: (1) to determine whether proband characteristics are predictive of autism diagnosis in siblings, and (2) to assess associations between proband traits and sibling (a) behavior and (b) brain development from 6 to 24 months of age.

**Results:** Proband autism severity was a significant predictor of diagnosis in younger siblings at 24 months. Quantitative variation in proband adaptive behavior, communication, and language was significantly associated with sibling behavior in the same domains at 24 months, but not at earlier ages. Proband autism severity explained significant variation in cerebral volume and cortical surface area from 6 to 24 months and white matter microstructure of the splenium at 6 months among infants who were later diagnosed with ASD. Neuroimaging results linking proband traits to sibling brain development converged around cortical regions, fiber pathways, and functional networks involved in visual attentional behaviors.

**Conclusions:** The family study design revealed that autistic traits in probands can inform: (1) likelihood of later diagnosis, (2) adaptive, communicative, and language behaviors at 24 months, and (3) neurodevelopmental trajectories from 6 to 24 months in younger siblings. This suggests that quantitative autistic traits in first-degree family members may serve as important markers of genetic liability for ASD in infants and toddlers. The family study design coupled with prospective longitudinal follow-up could serve as a framework to elucidate pathways from familial genetic liability, to early brain development, to the emergence of autism.

**204.002** (*Panel Discussion*) The Canadian Pathways Study  
**P. Szatmari**, *The Hospital for Sick Children, Toronto, ON, Canada*

**Objective:** The Canadian Pathways in ASD prospective study focuses on identifying factors associated with good outcomes in an inception cohort of children with ASD. The objectives of this presentation are to provide a summary of the study, its design and some key findings.

**Methods:** Sampling occurred through autism services in 5 Canadian provinces (N=421) soon after an ASD diagnosis was made (mean age 41.17 months). Follow-up assessments occurred approximately yearly; the participants are now in late adolescence. Aspects of developmental health, highlighted as outcome domains, include communication, socialisation, activities of daily living and mental health. Multiple measures of autism symptoms and other behaviour were also obtained. Attributes associated with developmental health trajectories and outcomes included both child-level factors such as sex, IQ and language skills, as well as contextual factors such as family income, ethnicity, and functioning, and some data on services received.

**Results:** Individual children with ASD follow different developmental trajectories. Specific outcome domains have heterogeneous, independent trajectories. The shape of these trajectories may shift at key transition points such as entry to school. A substantial number of children are 'doing well' by mid to late childhood in at least one developmental health domain. Importantly, many parents report strengths seen in their children both at home and at school. Doing well is associated with both child-level and contextual-level factors such as language skills and family functioning. In this cohort, measures of the timing, type and duration of services received did not have a large impact on outcomes.

**Conclusions:** Prospective studies of autism reveal a greater degree of heterogeneity than expected. No single 'good' outcome should be expected, as this is inconsistent with the natural history of the condition. Youth with ASD have many strengths that are as important to appreciate as the challenges they may face. The Pathways study can assist us in understanding what contexts are most supportive of youth with ASD and their families, whatever trajectories they follow.

**204.003 (Panel Discussion) The Early Diagnosis Longitudinal Study**  
**C. Lord, University of California, Los Angeles, Los Angeles, CA**

---

**Objective:** The Early Diagnosis Longitudinal Study is a prospective study of children referred for possible autism or neurodevelopmental delays at age 2 and an additional group of children of the same age, but who entered the study about age 9. All have been followed up to age 30. The initial goal of the project was to determine if clinical diagnoses of autism in 2 year-olds were reliable and stable. Years later, our goals are to better describe the various outcomes of the participants, map different trajectories to adulthood and identify factors that may support or create barriers for more positive outcomes.

**Methods:** The sample consists of two cohorts of consecutive referrals of all children under age 3 to 4 TEACCH clinics in North Carolina and a similar autism clinic in Chicago (n=192, mean age = 29 months), 21 children with developmental delays from the sources of referral for the preceding group for whom no one suspected autism (mean age = 30 months) and 54 children from Michigan referred for an autism evaluation who joined the study at approximately age 9. Face to face follow up assessments occurred by blinded teams at 3, 5, 9, 19, 25 and 30, with a long phone interview at 14 and questionnaire packets (now online) mailed approximately twice a year over the entire period. Data about demographic, child factors and family variables have been collected, as well as treatment logs.

**Results:** There is tremendous heterogeneity in outcomes, with a number of health and behavioral characteristics still changing as the participants moved from emerging adulthood into their late 20's. Factors such as language level (even as early as age 3), adaptive skills, and autistic symptoms each had different trajectories from toddler to adult years with predictability for objective outcomes quite high, though subjective outcomes and more general mental health concerns much more difficult to predict. We propose factors that operationalize positive outcomes for individuals with autism with intellectual disability and those without intellectual disability and show that subjective outcomes, self-reported by those who had sufficient language and reported by parents for those who could not, were definable in terms of positive and negative feelings, well-being and absence of mental health problems.

**Conclusions:** We have much more to learn about the various trajectories of development and learning that occur within the heterogeneous group of adults referred at early ages for autism. Although some early predictive factors are very powerful, other aspects of development continue to change in major ways into adulthood. If we can understand these changes, we hope we can help more individuals achieve outcomes that they desire.

**204.004 (Panel Discussion) The Special Needs and Autism Project Cohort**  
**E. Simonoff, King's College London, Institute of Psychiatry, Psychology and Neuroscience, London, United Kingdom**

---

**Objectives:** Conceptualizations and definitions of autism have changed markedly over the past 30 years, leading to prevalence rates in register-based and epidemiological studies increasing substantially. Does this mean that we are identifying less severely affected individuals who have overall better outcomes in adult life? At the same time, there has been an increasing appreciation of heterogeneity within autism, the role of mental health problems in the experiences of the autistic person and the need to consider outcomes from the perspective of the autistic person.

**Methods:** The Special Needs and Autism Project cohort comprises 158 autistic participants born in 1990-91 and residing in south-east England when the sample was drawn in 2000 from those either with a clinical diagnosis of autism or who were registered as having special educational needs (SEN). The sample was drawn with the original aim of accurately identifying the prevalence of autism and therefore a sample of 255 participants were selected at high, moderate and low probability of having autism based on parent-reported SCQ scores, along with clinical diagnosis. Of those receiving a gold-standard research autism diagnosis, only 58% had received a local clinical diagnosis (although most had an alternative clinical diagnosis) and the sample is particularly pertinent in taking a wider-population approach. Assessments have taken place at ages 12, 16 and 23 years.

**Results:** From the original sample, 126 (80%) have been followed up to age 23 years. Longitudinal findings show significant growth in IQ but little change in reported autistic symptoms. Although mental health symptom scores declined with age, 37% and 21% met suggested cutoffs for likely emotional disorder or ADHD at 23 years, respectively. Stability in symptom domains is particularly strong for emotional problems and ADHD, with longitudinal symptom correlations over 11 years of 0.43 and 0.44. Finally, we will endeavor to take the autistic persons perspective, examining their self-reported quality of life and the factors influencing this.

**Conclusions:** The SNAP longitudinal cohort differs from other longitudinal autism studies in being population-derived, although it is still likely to under-represent those without cognitive impairment and/or behavioral problems. Comparing findings across cohorts may help to identify additional factors that influence presentation and outcome, as well as clarifying the most robust predictors. Future research will benefit from more direct comparison and calibration across samples.

## ORAL SESSION — EPIDEMIOLOGY/POPULATION STUDIES

### Oral 309 - Early Determinants of Autism Risk

**309.001 (Oral)** Prenatal Exposure to Air Pollution and Children's Autism Spectrum Disorder: Identifying Sensitive Windows and Sex Differences

*M. M. Rahman<sup>1</sup>, Y. H. Shu<sup>2</sup>, T. Chow<sup>2</sup>, F. W. Lurmann<sup>1</sup>, M. P. Martinez<sup>2</sup>, S. P. Eckel<sup>1</sup>, J. C. Chen<sup>1</sup>, Z. Chen<sup>1</sup>, J. Schwartz<sup>4,5</sup>, R. McConnell<sup>1</sup> and A. H. Xiang<sup>2</sup>, (1)Department of Preventive Medicine, Keck School of Medicine, University of Southern California, Los Angeles, CA, (2)Department of Research & Evaluation, Kaiser Permanente Southern California, Pasadena, CA, (3)Sonoma Technology, Inc., Petaluma, CA, (4)Department of Environmental Health, Harvard T.H. Chan School of Public Health, Boston, MA, (5)Department of Epidemiology, Harvard T.H. Chan School of Public Health, Boston, MA*

**Background:** A growing number of studies have reported associations between prenatal particulate matter with aerodynamic diameter < 2.5  $\mu\text{m}$  (PM<sub>2.5</sub>) exposure and increased risk for autism spectrum disorder (ASD). However, susceptibility based on gestational time of exposure and sex is uncertain. ASD is four times more likely in boys than girls. Emerging data from animal and human studies support the sexual dimorphism in the neurotoxicity of prenatal PM<sub>2.5</sub> exposure, as well as heterogeneous exposure effects across gestational windows. The fetal brain develops in stages beginning in utero; thus, the effect of air pollution on the subsequent development of ASD may differ by sex, dose, and exposure timing.

**Objectives:** We aimed to identify sensitive time windows for the effects of prenatal exposure to ambient PM<sub>2.5</sub>, NO<sub>2</sub>, and O<sub>3</sub> on ASD risk separately in boys and girls of a large pregnancy cohort.

**Methods:** This population-based retrospective birth cohort study included 294,937 mother-child pairs with singleton deliveries at  $\geq 37$  weeks gestation in Kaiser Permanente Southern California (KPSC) hospitals between January 1, 2001, and December 31, 2014, all had complete residential addresses during pregnancy. Children's follow-up times were accrued from age one until a clinical diagnosis of ASD, last date of KPSC health plan membership, death, or December 31 of 2019, whichever occurred first. Incident ASD cases were ascertained by ICD codes in electronic medical records from at least two separate visits. Weekly mean PM<sub>2.5</sub>, NO<sub>2</sub>, and O<sub>3</sub> exposures at the maternal residential addresses, were estimated using validated satellite-based spatio-temporally resolved high-resolution (1km x 1km) land use regression models. Cox proportional-hazard models with distributed lags estimating the independent effect of each week's exposure with ASD risk were constructed to assess the time windows of increased vulnerability, separately for boys and girls and adjusting for covariates.

**Results:** Over a median of 9.04 (IQR = 5.93 –13.15) years of follow-up after birth, 5,694 children (4,636 boys and 1,058 girls) had ASD. We found that elevated weekly PM<sub>2.5</sub> exposure in the first two trimesters (1-27 weeks) of pregnancy was significantly associated with increased ASD risk (Figure). The cumulative hazard ratio over the first two trimester was 1.20 (95% CI= 1.09 – 1.32) per 10  $\mu\text{g}/\text{m}^3$  increase in PM<sub>2.5</sub>, after adjusting for child sex, maternal race/ethnicity, maternal age at delivery, parity, education, maternal comorbidities, medical centers, household income, birth year, and season. No associations were observed with NO<sub>2</sub>. For O<sub>3</sub>, exposure during 34-37 gestational weeks was associated with ASD risk [cumulative HR=1.03, 95% CI=1.01–

1.06; per 10 ppb increase]. When stratified by sex, the significant ASD risk associated with PM<sub>2.5</sub> exposure in the early gestational weeks were stronger for boys, and O<sub>3</sub> exposure in the later gestational weeks were observed only in boys (Figure).

**Conclusions:** Exposures to higher levels of PM<sub>2.5</sub> in the first two trimesters and O<sub>3</sub> in the late 3<sup>rd</sup> trimester may increase ASD risk in children, especially among boys. Further studies are needed to delineate the underlying mechanisms of the vulnerable window of susceptibility and sexually dimorphic effect of air pollution neurotoxicity on ASD risk.

**309.002 (Oral) Optimal Interpregnancy Interval in Autism Spectrum Disorder: A Multi-National Retrospective Cohort Study of a Modifiable Risk Factor**

**D. Schendel**<sup>1,2</sup>, G. Pereira<sup>3</sup>, M. Gissler<sup>4</sup>, S. Hansen<sup>5</sup>, A. Kodesh<sup>6</sup>, H. Leonard<sup>7</sup>, S. Levine<sup>8</sup>, V. Mitter<sup>9</sup>, E. Parner<sup>10</sup>, A. K. Regan<sup>11</sup>, A. Reichenberg<sup>12</sup>, S. Sandin<sup>13</sup>, A. Suominen<sup>14</sup> and R. Francis<sup>15</sup>, (1)Aarhus University, Aarhus, Denmark, (2)AJ Drexel Autism Institute, Drexel University, Philadelphia, PA, (3)School of Public Health, Curtin University, Perth, WA, Australia, (4)National Institute for Health and Welfare, Helsinki, Finland, (5)Aarhus University, Aarhus C, Denmark, (6)Department of Community Mental Health, University of Haifa, Haifa, Israel, (7)Disability, Telethon Kids Institute, West Perth, Western Australia, Australia, (8)University of Haifa, Haifa, Israel, (9)Centre for Fertility and Health (CeFH), Norwegian Institute of Public Health, Oslo, Norway, (10)University of Aarhus, DK-8000 Århus C, Denmark, (11)School of Nursing and Health Professions, University of San Francisco, San Francisco, CA, (12)Seaver Autism Center, Department of Psychiatry, Icahn School of Medicine at Mount Sinai Hospital, New York, NY, (13)Department of Psychiatry, Icahn School of Medicine at Mount Sinai, New York, NY, (14)University of Turku, Turku, Finland, (15)Telethon Institute for Child Health Research, Subiaco, Australia

**Background:** Several studies report elevated autism spectrum disorder (ASD) risk at both short and long interpregnancy intervals (IPI) which is biologically plausible. Empirically-derived estimates of the IPI associations with ASD, however, have not been established in large-scale studies controlling for shared family factors, or contrasted in multinational settings.

**Objectives:** Quantify associations between IPI and ASD in three high-income countries with similar health care and parental leave systems, using a common protocol and controlling for family-level factors, to identify the optimal IPI at which ASD risk might be minimized.

**Methods:** Our retrospective cohort study population comprised all singleton, non-nulliparous live births, 1998-2007 inclusive, in Denmark, Finland, and Sweden with a minimum 5-year follow-up for ASD through 2012 (N = 925,523 births). IPIs were derived as the time between the conception date of the index birth and date of the preceding live birth. Optimal IPIs were defined as the IPI (continuous variable) at which minimum risk was observed, and used as the reference level. Generalized additive mixed effects log-binomial regression was used to estimate unadjusted and adjusted relative risks (RR) of ASD and their associated 95% Confidence Intervals (CI). Adjustment was made for parental and demographic factors and maternal mean IPI as a proxy for unmeasured confounding at the family level. Population attributable fractions (PAF) and potential impact fractions (PIF) for ASD were estimated under different scenarios for shifts in the IPI distribution.

**Results:** The association between ASD (n=9302) and IPI was U-shaped across all countries. ASD risk was lowest (optimal IPI) at 35 months, all countries combined. By country, optimal IPI was 30, 33 and 39 months in Denmark, Finland and Sweden, respectively, although there was negligible difference in risk across IPIs of 30 - 39 months. All countries combined, fully adjusted RRs at IPIs of 6, 12, 24, 48 and 60 months were 1.41 (95% CI: 1.08, 1.85), 1.26 (95% CI: 1.02, 1.56), 1.06 (95% CI: 0.95, 1.18), 1.08 (95% CI: 0.95, 1.22), and 1.24 (95% CI: 0.98, 1.58) compared to an IPI of 35 months. RRs for short IPIs in Sweden were higher than in Denmark and Finland, but RRs for long IPIs were similar across countries. PAFs for ASD from non-optimal IPIs were 9.27% (95% CI: 2.95%, 15.48%) for Denmark, 18.85% (95% CI: 11.11%, 26.13%) for Finland, and 18.26% (95% CI: 11.89%, 24.44%) for Sweden. Under the most conservative IPI shift scenario, PIFs were 4.50% (95% CI: 1.23%, 7.64%) for Denmark, 8.28% (95% CI: 4.62%, 11.62%) for Finland, and 8.80% (95% CI: 5.74%, 11.72%) for Sweden.

**Conclusions:** Minimum ASD risk followed IPIs of 30-39 months across three countries with similar health care and family leave policies. Although 9% to 18% of ASD cases may be attributable to sub-optimal IPI and 5% to 9% may be potentially preventable by modifying IPI, these results reflect both direct IPI effects and other, closely related social and biological pathways. Limiting non-optimal IPI via family counselling, health and family leave practices may reduce risk of ASD and other adverse reproductive and child outcomes.

**309.003** (Oral) Establishing Developmental Milestone Norms in 20,000 Individuals with Autism Spectrum Disorder: Associations with Skill Regression and Early Diagnosis

**S. S. Kuo**<sup>1,2</sup>, **C. van der Merwe**<sup>3</sup>, **C. E. Carey**<sup>3</sup>, **S. Bishop**<sup>4</sup> and **E. B. Robinson**<sup>5</sup>, (1)Stanley Center for Psychiatric Research, Broad Institute of MIT and Harvard, Cambridge, MA, (2)Analytic and Translational Genetics Unit, Massachusetts General Hospital, Boston, MA, (3)Broad Institute of MIT and Harvard, Cambridge, MA, (4)University of California San Francisco, San Francisco, CA, (5)Department of Epidemiology, Harvard School of Public Health, Boston, MA

---

**Background:** Autism spectrum disorder (ASD) is characterized by substantial heterogeneity in motor, communication, and physiological development, challenging efforts towards developmental screening and early detection. Although an important step to parse this heterogeneity is creating autism-specific developmental milestone charts, few investigations that may inform these norms have been adequately powered.

**Objectives:** We aimed to characterize the ages at which individuals with ASD attain developmental milestones and to determine whether delays in milestone attainment are associated with skill loss (regression) and earlier ages at autism detection.

**Methods:** We aggregated four cohorts from clinic and community settings across the United States: The Autism Simplex Collection (N=1,514), Autism Genetics Research Exchange (N=3,675), Simons Simplex Collection (N=2,726), and Simons Foundation Powering Autism Research (N=12,127), yielding a total sample of 20,042 participants with ASD (80.8% male), aged 1.1 to 25.0 years (mean=9.3, sd=4.6 years). During clinical interview, caregivers recalled the ages at which participants first acquired ten foundational skills and whether participants later lost any skill. We conducted multivariate ANOVAs to model associations with regression status and age at diagnosis for all milestones, covarying age, sex, and cohort. From the largest cohort, comprising 60% of this sample, we separately characterized milestones for 5,029 biological siblings without ASD to evaluate possible reporting bias (telescoping).

**Results:** Of those who attained a given milestone by age 7, participants on average attained motor milestones with little delay, including smiling (3m), sitting (7m), crawling (9m), walking (14m), and spoon-feeding (20m). However, they showed on average marked delays in attaining communication milestones such as saying their first word (23m), phrase (35m), and phrase combination (39m), a sequence that typically progresses from 12 to 24 months. Participants also demonstrated substantial delays in attaining physiological milestones of sustaining bladder control (44m) and bowel control (46m), and 9-16% of those older than age 4 had not yet attained these milestones. Notably, participants who had experienced regression attained later milestones (first phrase, first phrase combination, bladder control, and bowel control) 4 to 6 months later than those who had not experienced regression. Furthermore, compared to participants diagnosed after age 5, participants diagnosed before age 3 demonstrated delays ranging from 4 to 10 months for spoon-feeding, first word, and subsequent communication and physiological milestones. Siblings without ASD were reported to attain milestones on average within age-expectation, suggesting that caregivers were unlikely to consistently overestimate delays in milestone attainment.

**Conclusions:** As one of the largest studies to date investigating developmental milestones in ASD, our findings indicate that individuals with ASD generally attain motor milestones on par with neurotypical individuals throughout their first year but then show significant delays in attaining communication and physiological milestones. These delays are especially pronounced in individuals who ultimately show regression or receive an early diagnosis, such that late diagnosis overlaps substantially with attaining early skills on time and without noticeable losses. Overall, our autism-specific developmental milestone charts can provide caregivers and clinicians alike with key reference points for seeking diagnostic evaluation and for recalibrating expectations regarding developmental progress after receiving an ASD diagnosis.

**309.004** (Oral) Predictors of Autism Diagnosis Age in a Community Sample of Australian Adults

**Y. Huang**<sup>1,2</sup>, **S. Arnold**<sup>1,2</sup>, **K. R. Foley**<sup>3,4</sup> and **J. N. Trollor**<sup>1,2</sup>, (1)Department of Developmental Disability Neuropsychiatry, UNSW, Sydney, NSW, Australia, (2)Cooperative Research Centre for Living with Autism (Autism CRC), Brisbane, QLD, Australia, (3)Department of Developmental Disability Neuropsychiatry, The University of New South Wales, UNSW Sydney, NSW, Australia, (4)Southern Cross University, Bilinga, QLD, Australia

---

**Background:** The prevalence of autism diagnosis has increased across all age groups over recent decades, including first-time diagnosis in adulthood. Although adulthood diagnosis has been attributed to older birth cohort, subtler autistic traits, and lower support needs, researchers have also identified late-diagnosed adults who did not meet these criteria. Previous studies examining autism diagnosis age in children identified greater developmental delays, higher socioeconomic status, and absence of specific co-occurring conditions as predictors of earlier diagnosis. Predictors of diagnosis age in adults has not yet been examined.

**Objectives:** To examine demographic and autism-related predictors of diagnosis age among Australian autistic adults, and whether these predictors explain additional variance after controlling for current age and autistic traits.

**Methods:** Demographics and autism-related data was combined cross-sectionally from three Australian survey-based studies. The Australian Longitudinal Study of Autism in Adulthood (ALSAA) and the Study of Australian School-Leavers with Autism were longitudinal questionnaires of autistic and non-autistic Australians in the  $\geq 25$  and 15-25 age groups respectively. The *Pathways* study was a cross-sectional self-report online survey of Australian adults' (age  $\geq 18$ ) experiences of autism diagnosis. Participants in the combined data ( $N=619$ , 40.7% male) ranged in current age from 15 to 80 years with a mean reported diagnosis age of 29.60 years. Hierarchical multiple regression modelling was performed with data source as Step 1, current age and self-reported autistic traits as Step 2, and gender, diagnosis subtype, intellectual disability, language, ethnicity, family autism history, and other psychiatric diagnoses as Step 3.

**Results:** Each step of the hierarchical regression model significantly improved model fit. Older age and higher autistic traits significantly predicted older diagnosis age after controlling for data source. In the final model, female gender, lack of reported intellectual disability, and speaking a non-English language predicted older diagnosis age after controlling for data source, current age, and autistic traits. Interestingly, Asperger's diagnosis predicted younger diagnosis age in the final model. Co-occurring psychiatric conditions were not significant predictors. Analysis of possible mediation and moderation effects are in progress.

**Conclusions:** Predictors of diagnosis age in adults were mostly consistent with previous research involving children, with some exceptions. That higher self-reported autistic traits predicted later diagnosis was counterintuitive and may be due to characteristics of the tool used, biased self-evaluation, and/or camouflaging strategies. Later diagnosis of women is consistent with existing research into under-detection of autism in girls and women. People from linguistically diverse backgrounds may have reduced access to autism information, healthcare, and culturally appropriate assessment. Our study has important implications not only on providing early diagnosis to disadvantaged demographics, but also on recognition and diagnosis of adults who may need support to navigate everyday life.

## ORAL SESSION — EPIDEMIOLOGY/POPULATION STUDIES

### Oral 324 - Effects of Sex and Environment on Autism Phenotypes and Trajectories

**324.001** (Oral) The Relationship between Greenspace, Greyspace and Positive Developmental Screening in Children with Autism, Children with Special Health Care Needs (CSHCN), and Typical Children

**B. Barger**<sup>1</sup>, **L. Larson**<sup>2</sup>, **J. Torquati**<sup>3</sup>, **E. Moody**<sup>4</sup> and **S. Rosenberg**<sup>5</sup>, (1)Georgia State University, Atlanta, GA, (2)LR.Larson@ncsu.edu, NC State, Raleigh, NC, (3)U of Nebraska, Lincoln, NE, (4)Wyoming Institute for Disabilities, University of Wyoming, Laramie, WY, (5)University of Colorado Anschutz Medical Campus, Aurora, CO

**Background:** There is a large body of evidence showing that natural environments have positive physical and mental health impacts on typical populations of youth and children with ADHD. Recent research suggests the mental health impacts of natural environments on children with ASD may be mixed: greenspace may be associated with decreased conduct problems and increased anxiety in children with ASD. Notably, developmental outcomes of infants and toddlers are rarely considered in the natural environment and health literature for either typical children or children with ASD.

**Objectives:** This study investigated the effects of greenspace and greyspace (i.e., constructed non-natural surfaces) on the odds of whether children with and without an ASD screen positive on the Parents Evaluation of Developmental Status (PEDS).

**Methods:** The 2012 NSCH is a large cross-sectional public health survey of U.S. children birth to 17 years old. It includes data on the ASD status of children and caretakers of children 5 and under received PEDS items. Greenspace and greyspace metrics were derived from the National Land Cover Database (NLCD). Data from the 2012 NSCH and the NLCD were merged at the zip-code level and data were analyzed with survey weighted and stratified logistic regression models using R's survey package. Co-variables included children with special healthcare status; whether they had anxiety or conduct problems; sex, age, race/ethnicity, socio-economic status, maternal education, insurance status, and metropolitan size.

**Results:** The study sample includes 21,240 typically developing children, 226 children with autism, and 2,963 non-autistic children with special healthcare needs (CSHCN) ages 10 months to 5 years. Multi-variate models with just greenspace and greyspace showed that greenspace was unassociated ( $p = 0.50$ ) and greyspace predicted increased odds of PEDS indicating developmental concerns ( $p = 0.002$ ). Inclusion of covariates did not change the relationship between greyspace and developmental concerns ( $p = 0.024$ ) and revealed that children with ASD and CSHCN had greater odds of positive PEDS screens than typical children; older children had greater odds of positive screens than younger children; males had greater odds than females; Black children had greater odds than White children; children with conduct problems had greater odds than those without; and privately insured children had greater odds than those without insurance. A greenspace X clinical group interaction

indicated that the relationship between greenspace and positive PEDS scores was lower in children with ASD compared to typical children ( $p = 0.003$ ) suggesting that greenspace is associated with fewer developmental concerns in children with ASD.

**Conclusions:** This is the first analysis investigating the effects of green and built environments on developmental outcomes using a general developmental screening tool (i.e., PEDS) and a nationally representative sample. The findings suggest that built space is associated with increased odds of developmental concerns and greenspace is associated with decreased odds of developmental concerns for children with ASD only. While intriguing, findings are limited as environmental metrics are measured at the zip-code level. Future research should seek to replicate these findings with greenspace measures in children's immediate environments.

**324.002 (Oral)** Caregiver and Neighborhood Factors Associated with Treatment Outcomes for School-Aged Children with ASD and Co-Occurring Mental Health Needs in a Community Effectiveness Trial of AIM HI.

**B. Caplan**<sup>1,2</sup>, **T. Lind**<sup>2,3</sup>, **K. Martinez**<sup>4,5</sup>, **G. May**<sup>6</sup>, **C. Gomez Alvarado**<sup>7</sup>, **C. Chlebowski**<sup>1,2</sup> and **L. Brookman-Frazee**<sup>1,2,8,9</sup>, (1)Psychiatry, UC San Diego, La Jolla, CA, (2)Child and Adolescent Services Research Center, San Diego, CA, (3)Child and Family Studies, San Diego State University, San Diego, CA, (4)Child and Adolescent Services Research Center (CASRC), San Diego, CA, (5)Clinical Psychology, San Diego State University / University of California, San Diego Joint Doctoral Program in Clinical Psychology, San Diego, CA, (6)Psychology, University of Nebraska-Lincoln, Lincoln, NE, (7)Psychology, UCLA, Los Angeles, CA, (8)UC San Diego Dissemination and Implementation Science Center, La Jolla, CA, (9)Autism Discovery Institute, Rady Children's Hospital-San Diego, San Diego, CA

**Background:** Caregiver and neighborhood factors (e.g. income, education, household composition) are associated with developmental and mental health outcomes for children with or without autism spectrum disorder (ASD; Garner et al., 2012). High levels of social adversity are also associated with decreased engagement in children's mental health treatment (Haine-Schlagel & Walsh, 2015), and higher levels of caregiving strain have been linked to poorer treatment response in parent-mediated interventions in ASD (Stadnick et al., 2015). AIM HI ("An Individualized Mental Health Intervention for ASD") is an evidence-based intervention that is designed to target co-occurring challenging behaviors in school-aged children with ASD served in publicly-funded mental health settings (Brookman-Frazee et al., 2019). The present study will assess whether caregiver and neighborhood factors are associated with changes in child behaviors when therapists were trained to deliver AIM HI within a community effectiveness trial.

**Objectives:** The present study seeks to assess caregiver and neighborhood-level factors that are associated with treatment outcomes for children with ASD whose community therapists received AIM HI training. The objectives are to identify: (1) whether caregiver demographic factors (e.g. income, education level), caregiving strain, and neighborhood factors are associated with parent reported child behavior problems at baseline, and (2) which factors predict trajectories of behavior problems over 18 months.

**Methods:** Data were obtained from the caregivers of 156 children with ASD receiving care from mental health programs randomized to the AIM HI training condition within the community effectiveness trial of AIM HI. Participant children were 57.7% Latinx; 92.3% male, with a mean age of 9.1 years ( $SD = 2.4$ ). Parents reported family demographics and caregiver strain (CGSQ) at baseline as well as child behavior problems (ECBI) at the baseline, 6-month, 12-month and 18-month assessments. A caregiver score and neighborhood score were calculated based on the following demographic characteristics at the participant and zip code level: income/poverty, education, household composition (both); foreign born population, population density (neighborhood only).

**Results:** Higher levels of caregiver strain, but not caregiver demographic or neighborhood scores, were positively associated with ECBI Problem ( $B = 6.23$ ,  $p < .001$ ) and Intensity ( $B = 6.31$ ,  $p < .001$ ) scores at baseline. Results of three-level models (time, child, program) revealed that higher caregiver demographic risk scores ( $B = 1.66$ ,  $p = .02$ ) and caregiving strain ( $B = 2.13$ ,  $p < .001$ ), but not neighborhood score, were associated with relatively less decline on ECBI Problem scores across 18 months. Only higher caregiving strain ( $B = 1.78$ ,  $p < .001$ ) predicted relatively less decline on ECBI Intensity scores over time.

**Conclusions:** Results are consistent with prior work suggesting a strong relationship between caregiving strain and behavior problems for this population (Estes et al., 2009), as well as the association between caregiving strain and treatment outcomes within parent-mediated interventions for ASD (Stadnick et al. 2015). Overall, findings suggest that factors more proximal to the caregiver and family (caregiving strain, caregiver demographics) may be more closely linked to treatment response than neighborhood factors, and should be considered in tailoring and implementing parent-mediated interventions in ASD.

**324.003 (Oral)** Sex Differences in Trajectories of Language Development in Autism Spectrum Disorder and Typical Development

**D. Parmaksiz<sup>1</sup>, S. Koirala<sup>2</sup>, S. Yuan<sup>3</sup>, E. Kushner<sup>4</sup>, S. Shultz<sup>5</sup>, A. Klin<sup>5</sup>, C. Klaiman<sup>5</sup>, W. Jones<sup>6</sup> and L. A. Edwards<sup>5</sup>,** (1)Marcus Autism Center, Atlanta, GA, (2)Department of Pediatrics, Emory University School of Medicine, Marcus Autism Center, Atlanta, GA, (3)Emory University School of Medicine, Marcus Autism Center, Atlanta, GA, (4)Emory University, Marcus Autism Center, Atlanta, GA, (5)Marcus Autism Center, Children's Healthcare of Atlanta and Emory University School of Medicine, Atlanta, GA, (6)Pediatrics, Emory University, Atlanta, GA

---

**Background:** Autism spectrum disorder (ASD) diagnoses are more common in males than females. This skewed sex ratio in autism, ranging from 3:1 to 4:1, suggests increased risk for ASD in males and a possible protective effect in females (Robinson et al. 2013, Werling and Geschwind 2013). However, diagnostic criteria for ASD were established based on predominantly male populations (Kirkovski et al. 2013) and the female phenotype of ASD remains poorly understood (Head et al., 2014). Camouflaging, or use of (un)conscious compensatory strategies to overcome social and behavioral difficulties in females may be contributing to under-detection of ASD in females (Hull et al., 2017a; Livingston et al., 2019). For example, females with ASD have been found to have higher levels of social motivation, restricted interests in more “normative” content areas (Hiller et al. 2014), and more developmentally appropriate vocabulary and core language skills than their male counterparts (Messinger et al., 2015). Also, in typical development, females acquire language faster and have larger vocabulary than males (Barel and Tzischinsky, 2018; Fenson et al., 1994). Precocious language development in females across typical and atypical development may hence not only function as a compensatory developmental mechanism, but may also contribute to differential diagnosis of ASD in females.

**Objectives:** This study examines sex-based differences in trajectories of language development across the first two years of life in a longitudinally-followed cohort of ASD and TD infants.

**Methods:** Typically developing (TD) infants (N=268;121 female) and those later diagnosed with ASD (N=42;9 female), were followed longitudinally over the first 2 years of life. Language development was measured using the Mullen Scales of Early Learning (MSEL) at a maximum of 5 time points between 6 and 24 months of age. A MATLAB implementation of the Principal component Analysis by Conditional Expectation (PACE) package for Functional Data Analysis and Empirical Dynamics (Yao et al., 2005) was used to analyze trajectories of MSEL Expressive and Receptive age equivalent scores, separated by sex and diagnostic group. Mean curves were quantified using Functional Principle Components Analysis and contrasted using Functional Regression.

**Results:** In the TD group, trajectories of MSEL expressive (EL) and receptive language (RL) scores were significantly different by sex, with females acquiring skills more rapidly than males ( $F_{EL}=8.51, p_{EL}=0.004; F_{RL}=15.74, p_{RL}<0.001$ ). In the ASD group, both EL and RL score trajectories significantly differed by sex as well ( $F_{EL}=8.96, p_{EL}=0.005; F_{RL}=5.40, p_{RL}=0.025$ ). Diagnostic comparisons revealed significant differences between trajectories of EL and RL development in males with ASD and TD males ( $F_{EL}=27.15, p_{EL}<0.001; F_{RL}=37.38, p_{RL}<0.001$ ), whereas females with ASD significantly differed from TD females in the trajectories of their RL scores only ( $F_{EL}=0.77, p_{EL}=0.382; F_{RL}=6.55, p_{RL}=0.012$ ).

**Conclusions:** Our longitudinal analyses indicate that language development varies by sex and diagnosis, with females across diagnoses maturing more rapidly in language abilities and the TD group as a whole developing language ability more quickly. These findings support the notion that females with ASD display a unique narrative profile that overlaps with males with ASD and TD females/males (Boorse et al., 2019). This feature may contribute to reduction of perceived symptom severity in females.

**324.004 (Oral) Sex-Differences in Pain Behaviors and Related Health in Autistic Children and Adults in the SPARK Cohort**  
**M. D. Failla<sup>1</sup>, J. I. Feldman<sup>2</sup>, C. J. Cascio<sup>3</sup> and T. G. Woynaroski<sup>2</sup>,** (1)College of Nursing, The Ohio State University, Columbus, OH, (2)Department of Hearing and Speech Sciences, Vanderbilt University Medical Center, Nashville, TN, (3)Department of Psychiatry and Behavioral Science, Vanderbilt University Medical Center, Nashville, TN

---

**Background:** Clinicians have noted “reduced pain sensitivity” from the earliest clinical reports of autism. Yet, recent data suggest that autistic children experience a greater number of painful medical conditions compared to their peers and that autistic adults have altered neural processing of pain, higher reports of pain, and increased pain anxiety. However, these studies come from relatively small samples, which are unlikely to represent the broader population of persons affected by autism. Further, no prior investigations have explored the extent to which pain varies in males versus females with autism, a pressing question given growing literature highlighting phenotypic variations by biological sex.

**Objectives:** To characterize pain, pain behaviors, and health outcomes related to pain for autistic children and adults, with a focus on sex differences.

**Methods:** Using the US research cohort SPARK, we recruited three groups of autistic individuals for short surveys regarding pain behaviors and related health: 1) independent adults (n=482, 298 females and 183 males, age 18-78), 2) jointly reporting dependents (parent and self-report, n=589, 135 females and 454 males, age 13-49) and 3) dependents (with parent report, n=882, 150 females and 732 males, age 2-64). Data were collected electronically, using the Pain and Health Questionnaire and Pain Behavior Short version from the Patient-Reported Outcomes Measurement Information System (PROMIS). Self- and proxy-report versions were used as appropriate.

**Results:** Most independent autistic adults reported pain within the last week (72.6%), with 46.2% of women reporting daily pain compared to 28.4% of autistic men  $\chi^2(6) = 33.1, p < .001$ . Over the last year, more autistic women than men missed work due to pain (59.4% compared to 38.0%,  $\chi^2(4) = 17.2, p < .01$ ). A Wilcoxon test indicated that, on the PROMIS Pain Behavior Scale, women reported more pain behaviors than men (mean=18.2 versus 16.4,  $W = 23686, p < .001$ ). In the jointly reporting sample, 55.1% of dependents self-reported pain in the last week while only 40% of parents reported their dependent had pain in the same timeframe. Parents reported more daily pain in girls (17.2%) than boys (5.9%,  $\chi^2(6) = 25.2, p < .001$ ), and indicated that girls were more likely to miss school for their pain (57.4% versus 44.9% of boys,  $\chi^2(4) = 15.7, p < .01$ ). There were no significant self-reported sex differences on the PROMIS Pain Behavior Scale in the joint reporting cohort. In the dependent cohort, 28.9% of parents reported that their dependent experienced pain within the last week, with no significant differences by sex.

**Conclusions:** Findings suggest females on the spectrum may experience more pain that produces a functional impact on their daily life relative to their male peers, at least in adolescence and adulthood. Additional research is needed regarding the frequency and nature of pain in autistic individuals across the lifespan, in particular to understand differences in pain and pain management in autistic women and to elucidate the nature of pain experiences for younger and/or dependent individuals who may not be capable of clearly articulating their pain.

## POSTER SESSION — EPIDEMIOLOGY/POPULATION STUDIES

### Poster 419 - Epidemiology/population studies Posters

**419.001** (Poster) Age at First Maternal Concern about Development and Time to Services Among Children with Autism Spectrum Disorder

**J. Van Dyke<sup>1</sup>, C. DiGuseppi<sup>2</sup>, T. Crume<sup>3</sup>, N. Reyes<sup>4</sup>, A. Alexander<sup>5</sup>, B. Barger<sup>6</sup>, R. Fitzgerald<sup>7</sup>, K. Hightshoe<sup>8</sup>, E. Moody<sup>9</sup>, K. Pazol<sup>10</sup>, C. Robinson Rosenberg<sup>11</sup>, E. Rubenstein<sup>12</sup>, L. Wiggins<sup>13</sup> and S. Rosenberg<sup>8</sup>,** (1)University of Colorado, Aurora, CO, (2)Colorado School of Public Health, University of Colorado Anschutz Medical Campus, Aurora, CO, (3)Epidemiology, University of Colorado Anschutz Medical Campus, Aurora, CO, (4)JFK Partners, University of Colorado Anschutz Medical Campus, Aurora, CO, (5)NCBDDD, Centers for Disease Control and Prevention, Atlanta, GA, (6)Georgia State University, Atlanta, GA, (7)Washington University School of Medicine, St. Louis, MO, (8)University of Colorado Anschutz Medical Campus, Aurora, CO, (9)Wyoming Institute for Disabilities, University of Wyoming, Laramie, WY, (10)Division of Human Development and Disability, Centers for Disease Control and Prevention, National Center on Birth Defects and Developmental Disabilities, Atlanta, GA, (11)University of Colorado / JFK Partners, Aurora, CO, (12)Waisman Center at UW Madison, Madison, WI, (13)Centers for Disease Control and Prevention, Atlanta, GA

**Background:** Early diagnosis and treatment of autism spectrum disorder (ASD) has been shown to improve developmental outcomes. Children from non-white families or families with limited educational attainment are often diagnosed with ASD later than others and tend to have poorer access to services. Some evidence suggests that these disparities might result in part from differences in awareness of developmental milestones or symptoms to be aware of, but research about the relationship between sociodemographic characteristics and age of first maternal concern about child development is inconsistent. Further, factors that delay maternal recognition of developmental problems may also delay initiation of services.

**Objectives:** To explore child and sociodemographic factors potentially related to child age at first maternal concern about development and subsequent time to initiation of services after this first concern among children with ASD.

**Methods:** Data came from the Study to Explore Early Development (SEED), a multi-site case-control study of ASD in preschool aged children in the US. The current study is a cross-sectional analysis of 759 children classified as having ASD after a comprehensive evaluation. Factors associated with age of first maternal concern were investigated using multiple linear regression. Factors associated with time to initiation of services were investigated using a Cox proportional-hazards model.

**Results:** Factors associated with earlier maternal concern about child development were higher maternal parity, the child having at least one chronic condition, more externalizing behaviors of the child, and younger gestational age. Although maternal non-

white race was not associated with earlier concern, it was associated with longer time to initiation of services, along with a higher developmental level and absence of a chronic condition in the child.

Conclusions: Maternal parity, gestational age, and child characteristics, such as behavior and health status influenced age at first maternal concern, which did not vary by race/ethnicity. Maternal non-white race, higher child developmental level, and absence of a chronic condition in the child were associated with later initiation of services. A difference by race in time to initiation of services despite similar age of maternal concern highlights the need to improve access to services among non-white children.

**419.002** (Poster) Are People with Autism over-Represented in Homelessness? - Report from a Prevalence Estimation in the Republic of Ireland.

**M. R. Sweeney<sup>1</sup>**, A. M. Boilson<sup>2</sup> and B. Casey<sup>3</sup>, (1)School of Nursing, Psychotherapy & Community Health, Dublin City University, Dublin, Ireland, (2)School of Nursing & Human Sciences, Dublin City University, Dublin 9, Ireland, (3)School of Nursing, Psychotherapy and Community Health, Dublin City University, Dublin 9, Ireland

---

Background: The prevalence of Autism in the general population in Ireland is estimated to be in the region of 1 - 1.5% (Boilson *et al*, 2016) of the population. Recent research by Churchard *et al*, (2019) estimated the prevalence rate of Autism among a cohort of long-term homeless people in the UK at around 12%. No previous study has examined the prevalence of autism in the homeless population in Ireland.

Objectives: This research was conducted to explore the number of people with autistic traits (as a measure of autism prevalence) among a representative sample of a homeless population, in a defined geographical area of Dublin, Ireland.

Methods: Using the same methodological approach as the UK study, we partnered with one of Ireland's leading not for profit homeless service providers - the Dublin Simon Community. Dublin Simon keyworkers acted as proxy informants for the clients in their caseload and completed researcher administered structured screening interviews on behalf of their entire caseloads of clients, across a representative range of homeless service provision areas - emergency accommodation, supported housing, treatment and recovery. The *Diagnostic Statistical Manual v5 (DSM-5) Autistic Traits in the Homeless Interview* (DATHI) screening instrument was used. Two additional questionnaires were also administered by the researcher which captured demographics, health and behaviour history and client characteristics and needs.

Results: Of the 106 individuals screened by proxy in this study, 3 individuals (2 males and 1 female) screened "present" for autistic traits on the DATHI screening questionnaire, giving a prevalence estimate of 2.8%. A further 7 clients (6 males, 1 female) screened "possibly present" for autistic traits. This gives a combined estimate of 9.4% (95% CI: 5% ± 16% (3 + 7/106) for those who screened "present" and "possibly present".

Conclusions: This study reports a higher autism prevalence estimate than previous Irish studies of autism prevalence in the general population but a lower prevalence estimate than the recent UK study (Churchard *et al*, 2019) in a homeless context. This study supports the emerging evidence that people with autism are overrepresented in the homeless population compared with the housed population. Autism may be a risk factor for entry into homelessness and an added challenge to exiting from homelessness.

**419.003** (Poster) ASD Traits, Social Capital, and Depression Among School-Aged Children

**H. Mori<sup>1</sup>**, M. Adachi<sup>2,3</sup>, M. Takahashi<sup>2,3</sup>, H. Shinkawa<sup>1</sup> and K. Nakamura<sup>1,4</sup>, (1)Research Center for Child Mental Development, Graduate School of Medicine, Hirosaki University, Hirosaki, Japan, (2)Department of Clinical Psychological Science, Hirosaki University, Hirosaki, Japan, (3)Research Center for Child Mental Development, Graduate School of Medicine, Hirosaki University, Hirosaki, Japan, (4)Department of Neuropsychiatry, Graduate School of Medicine, Hirosaki University, Hirosaki, Japan

---

Background:

ASD are approximately 4 times more likely to experience depression (Hudson *et al.*, 2019). Depression in ASD may be associated with severe consequences including suicide attempts or complete suicide. (Cassidy and Rodgers 2017; Richa *et al.* 2014, Magnuson and Constantino 2011). In general population, previous studies have reported that high ASD traits were associated with severer mental health problems (e.g. Lundström *et al.*, 2011), and were more likely to attempt suicide (Pelton and Cassidy, 2017). ASD traits are also associated with a lower school belonging and increase loneliness and lack of social connectedness. However, little has been known about the association between the social environment (referred to as "social capital"), ASD traits, and mental health in a general population sample of school-age.

#### Objectives:

To clarify the associations between social capital, ASD traits, and depression in children with ASD traits.

#### Methods:

We distributed a set of questionnaires to all 9 to 15 year-old children who attend public school in Hirosaki City, Japan.

Data analysis was performed on 6,522 children. Social Capital was measured using the Japanese version of Social Capital Questionnaire-Adolescent Student (SCQ-AS) subscale "School trust and cohesion". ASD traits was measured using ASSQ. Depression was measured using DSRS-C.

#### Results:

ANOVA results showed significant differences in all groups (all  $p < .01$ ). Our findings indicate that a higher level of social capital is associated with lower depressive symptoms even regardless of the level of children's ASD traits (ASD-H\_SC-L vs. ASD-H\_SC-H:  $d = 1.63$  [1.51, 1.74],  $p < .001$ ; ASD-L\_SC-L vs. ASD-L\_SC-H:  $d = 1.48$  [1.37, 1.60],  $p < .001$ ; ASD-L\_SC-H vs. ASD-H\_SC-H  $d = -.187$  [-0.29, -0.09],  $p < .01$ ).

#### Conclusions:

Previous research has shown that children with high ASD traits have a higher probability of exhibiting high depressive symptoms (e.g. Lundström et al., 2011). However, the present study suggests that a high perception of SC may prevent depressive symptoms even in the presence of high ASD traits. The findings suggest that strengthening the level of social capital in school may benefit all students and especially students with high ASD traits. Further research on how strengthening social capital in school in children with high ASD traits should be conducted.

#### **419.004 (Poster)** Association between Prenatal Exposure to Pesticide Residues in the Diet and Child Autism-Related Traits in a High-Risk Cohort

**E. Joyce<sup>1</sup>**, R. J. Schmidt<sup>2</sup>, A. Y. Song<sup>3</sup>, H. E. Volk<sup>4</sup>, L. A. Croen<sup>4</sup>, M. D. Fallin<sup>5</sup>, I. Hertz-Picciotto<sup>5</sup>, C. J. Newschaffer<sup>6</sup>, J. Chavarro<sup>7</sup> and K. Lyall<sup>8</sup>, (1)*Epidemiology and Biostatistics, Drexel University, Philadelphia, PA*, (2)*Public Health Sciences, University of California Davis, Davis, CA*, (3)*Wendy Klag Center for Autism and Developmental Disabilities, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD*, (4)*Division of Research, Kaiser Permanente, Oakland, CA*, (5)*University of California at Davis, Davis, CA*, (6)*College of Health and Human Development, Pennsylvania State University, University Park, PA*, (7)*Departments of Nutrition and Epidemiology, Harvard T.H. Chan School of Public Health, Boston, MA*, (8)*A.J. Drexel Autism Institute, Drexel University, Philadelphia, PA*

**Background:** Prior work has suggested associations between prenatal exposure to several classes of pesticides and autism spectrum disorder (ASD), but results have not been fully consistent, and combined effects across chemicals have not been sufficiently considered. Recent work has developed a cost-efficient measure of diet-based pesticide exposure through residues on fruit and vegetables, the pesticide residue burden score (PRBS), that captures a wider range of pesticides than considered in any single study for associations with neurodevelopment, suggesting it may be a useful metric towards estimating potential combined effects.

**Objectives:** To examine associations between the PRBS and ASD-related traits in our study population.

**Methods:** Participants were drawn from the Early Autism Risk Longitudinal Investigation (EARLI), a high-familial risk cohort that enrolled mothers with a child diagnosed with ASD and followed them through a subsequent pregnancy and that child's early life. Information on food intake was collected through a modified version of a previously validated Food Frequency Questionnaire. ASD-related traits were measured according to the Social Responsiveness Scale (SRS) at 36 months. The PRBS was developed following published methods, using data from the USDA Pesticide Data Program (PDP) to estimate the burden of pesticides for food items across EARLI study years (2009-2012). Food-specific PRBS were multiplied by reported food intake, and combined to create an overall PRBS. Higher PRBS indicates greater contamination. Validity of the PRBS in this cohort was examined by comparing quartiles of the PRBS to available levels of organochlorine pesticides measured in mid-pregnancy samples. Variations of the PRBS tested here included incorporating fatty food sources of organochlorine pesticides (e.g., meat, dairy) and organic intake of foods. Multivariable linear regression models, accounting for maternal body mass index and demographic factors, were used to examine associations between quartiles of the PRBS and SRS scores.

Results: 158 EARLI participants were included. We observed a significant positive trend between measured levels of the organochlorine pesticide p,p'-DDE and PRBS ranks ( $p = 0.04$ ). Counter to our hypothesis, higher PRBS ranks were associated with a reduction of SRS scores, though this relationship was only statistically significant for the PRBS score incorporating organic intake ( $Q4$  vs  $Q1$ ,  $b = -21.49$ , 95% CI:  $(-35.01, -7.98)$ ). Associations with the PRBS differed somewhat when stratifying by overall fruit and vegetable intake, with significant decreases in SRS scores only for those below the median fruit intake. Incorporation of fatty foods into the PRBS yielded results similar to the original PRBS. Results were also similar when adjusting for overall fruit and vegetable intake, or key nutrients with prior associations with ASD, including folic acid and vitamin D.

Conclusions: Results from this high-familial risk study suggested an unexpected inverse association between an index of pesticide residues in the diet and ASD-related traits. Future work should further consider the potential influence of overall healthful eating and other food sources of pesticides, while also seeking to replicate findings and consider whether familial risk may influence these relationships.

**419.005 (Poster)** Association between Prenatal Nutrients and Autism-Related Traits in the EARLI Study Using a Mixtures Approach

**R. Vecchione<sup>1</sup>**, G. B. Hamra<sup>2</sup>, H. E. Volk<sup>3</sup>, M. D. Fallin<sup>3</sup>, L. A. Croen<sup>4</sup>, I. Hertz-Picciotto<sup>5</sup>, C. J. Newschaffer<sup>6</sup>, R. J. Schmidt<sup>7</sup> and K. Lyall<sup>8</sup>, (1)Drexel University, Philadelphia, PA, (2)Epidemiology, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, (3)Wendy Klag Center for Autism and Developmental Disabilities, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, (4)Division of Research, Kaiser Permanente, Oakland, CA, (5)University of California at Davis, Davis, CA, (6)College of Health and Human Development, Pennsylvania State University, University Park, PA, (7)Public Health Sciences, University of California Davis, Davis, CA, (8)A.J. Drexel Autism Institute, Drexel University, Philadelphia, PA

---

**Background:**

Maternal diet during pregnancy is critical to fetal development, as demonstrated by established relationships between folate deficiency and neural tube defects and nutrient deprivation and schizophrenia. Research has also linked certain individual nutrients with autism spectrum disorder (ASD), yet examination of combined effects of nutrients and dietary factors is lacking, despite knowledge of nutrients acting together in pathways.

**Objectives:**

The goal of this work was to utilize Bayesian analyses, capable of estimating combined or “mixture” effects for a large number of correlated variables, to examine the association between prenatal maternal diet in association with ASD-related traits.

**Methods:**

Study participants were drawn from the Early Autism Risk Longitudinal Investigation (EARLI), a high-familial risk cohort that enrolled pregnant mothers who already had a child diagnosed with ASD. Pregnant women were followed until the subsequent child was age 3 years. The Social Responsiveness Scale (SRS), which measures social aspects of ASD, was assessed at 36 months. Nutrient values covering diet since becoming pregnant were determined from dietary information collected during mid-pregnancy using a Food Frequency Questionnaire. Bayesian Kernel Machine Regression (BKMR) was used to examine a range of nutrients involved in immune, one-carbon metabolism, and oxidative stress pathways, and to determine their combined effects in association with raw SRS scores. These included: folic acid and other methyl-donor nutrients, vitamin D, iron, n-3 and n-6 polyunsaturated fatty acids, as well as others. Nutrients values were first standardized using Z scores prior to BKMR.

**Results:**

Results from BKMR were not suggestive of significant mixture effects of a group of a priori-selected nutrients, based on FFQ-based intake covering the first half of pregnancy, on child SRS scores at 36 months. Some potential differences in key nutrients were suggested, including modest increases in SRS scores (indicating greater ASD-related traits) with higher levels of vitamin B12 at mid-pregnancy, and minor decreases in SRS scores with higher levels of iron, vitamin A, and carotenoids, accounting for all other nutrients examined at mid-pregnancy. However, confidence bands were wide in these analyses, and additional adjustment for total calories, maternal age and BMI, and child’s sex, yielded mostly null trends. No significant associations with folic acid specifically were observed. Additional analyses planned include conducting BKMR analyses with foods, rather than nutrients, to capture associations that may more readily translate to usual intake and public health messaging, and examining associations adjusted for potential confounders, and in association with other ASD-related outcomes.

## Conclusions:

Preliminary results from this high-familial risk study did not identify strong mixture effects of nutrients in pathways with suspected relevance to ASD in association with ASD-related traits. Strong novel associations with individual nutrients were not identified with this approach, though modest signals suggest future work should consider these and other nutrients for potential associations with ASD. Because EARLI is a small high-familial risk study, future work should also replicate these analyses in other high familial risk cohorts and in other populations in which the relative contributions of genetic and environmental factors may differ.

**419.006 (Poster)** Association of Maternal Thyroid Hormones with Autism-Related Traits in the EARLI and HOME Studies  
**C. Zhong<sup>1</sup>, J. Braun<sup>2</sup>, A. Chen<sup>3</sup>, Y. Xu<sup>4</sup>, G. B. Hamra<sup>5</sup>, B. Lanphear<sup>6</sup>, K. Yolton<sup>7</sup>, L. A. Croen<sup>8</sup>, M. D. Fallin<sup>9</sup>, I. Hertz-Picciotto<sup>9</sup>, C. J. Newschaffer<sup>10</sup> and K. Lyall<sup>11</sup>. (1)Department of Epidemiology and Biostatistics, Drexel University, Philadelphia, PA, (2)Brown University, Providence, RI, (3)University of Cincinnati College of Medicine, Cincinnati, OH, (4)Cincinnati Children's Hospital Medical Center, Cincinnati, OH, (5)Epidemiology, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, (6)Health Sciences, Simon Fraser University, Burnaby, BC, Canada, (7)Division of Research, Kaiser Permanente, Oakland, CA, (8)Wendy Klag Center for Autism and Developmental Disabilities, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, (9)University of California at Davis, Davis, CA, (10)College of Health and Human Development, Pennsylvania State University, University Park, PA, (11)A.J. Drexel Autism Institute, Drexel University, Philadelphia, PA**

---

## Background:

Thyroid hormones (TH) are essential for neurodevelopment. Previous work examining the link between maternal TH during pregnancy and Autism Spectrum Disorder (ASD) has not yielded consistent findings. Further, few studies have considered associations with quantitatively measured ASD-related traits, which may help elucidate associations for a broader population.

## Objectives:

To examine whether maternal TH during pregnancy are associated with ASD-related traits in two birth cohorts.

## Methods:

Participants were drawn from two prospective pregnancy cohorts: The Early Autism Risk Longitudinal Investigation (EARLI) and the Health Outcomes and Measures of the Environment (HOME) Study. EARLI enrolled pregnant mothers across four US sites who had already had a child with ASD, and HOME enrolled typical pregnant women from the greater Cincinnati, OH area. Maternal TH levels, including thyroid-stimulating hormone (TSH) and free thyroxine (FT4), were measured in mid-pregnancy serum samples using standard immunoassays. ASD-related traits were measured with the Social Responsiveness Scale (SRS) in both cohorts at age 3-8 years. TSH was log-transformed (base e) to meet linear regression assumptions and reduce the influence of outliers, while z-scores were used for FT4 to account for slight differences in distributions across cohorts. In each cohort, quantile regression models were used to examine the association between TH levels and SRS total raw scores, adjusting for maternal and sociodemographic factors. Associations were also examined using linear regression models and stratified by cohort.

## Results:

278 participants (132 from EARLI and 146 from HOME) were included in these analyses. TSH distributions were similar in both cohorts, while FT4 was higher in EARLI compared to HOME. In pooled analyses, quantile regression analyses suggested associations between TH levels and SRS scores for those in the highest quantile of SRS, but not in lower quantiles (25<sup>th</sup> or below; Figure 1). In particular, higher FT4 was significantly associated with increasing SRS scores for those in the highest quantile (adjusted  $\beta$  for 95<sup>th</sup> percentile=10.3, 95%CI=1.5, 19.2). In addition, higher TSH was significantly associated with decreasing SRS scores for those in the same highest quantile (adjusted  $\beta$ =-14.9, 95%CI=-25.3, -4.6). When stratified by cohort, the adjusted association between TSH and SRS remained significant in HOME ( $\beta$ =-20.0, 95%CI=-37.4, -2.6), but not EARLI ( $\beta$ =-3.2, 95%CI=-27.3, 21.0). Analyses using standard linear regression also suggested an association between TSH and SRS scores in the pooled analysis (adjusted  $\beta$ =-5.3, 95%CI=-9.6, -1.0).

## Conclusions:

Results from these prospective pregnancy cohorts suggested that maternal thyroid hormones during pregnancy may be related to children's ASD-related traits. These associations were observed in the highest quantile of SRS scores, suggesting aberrations in

TH influence traits consistent with clinical impairment. Given associations appeared to be driven by the general population cohort, the role of maternal TH may be stronger in those without high genetic liability, or could be related to other factors that differ across these cohorts. Future work should continue to address these relationships, as well as exposure to thyroid disruptors, which may have influenced associations observed here.

**419.007 (Poster) Autism Spectrum Disorder (ASD) in West Africa – a Review**

**M. Bakare<sup>a</sup>, M. Bello-Mojeed<sup>b</sup> and K. M. Munir<sup>c</sup>,** (1)*Federal Neuro-Psychiatric Hospital, Upper Chime, New Haven, Enugu, Enugu State, Nigeria, Enugu, Nigeria,* (2)*Medical, Federal Neuropsychiatric Hospital, Yaba, Nigeria,* (3)*Pediatrics and Psychiatry, University Center for Excellence in Developmental Disabilities (UCEDD), Division of Developmental Medicine, Boston Children Hospital, 300 Longwood Avenue, Boston, MA, USA, Boston, MA*

---

**Background:**

West Africa consists of sixteen (16) countries of Benin, Burkina Faso, Cape Verde, The Gambia, Ghana, Guinea, Guinea-Bissau, Ivory Coast, Liberia, Mali, Mauritania, the Niger, Nigeria, Senegal, Sierra Leone and Togo according to United Nations. We explored research studies on the subject of Autism Spectrum Disorder (ASD) in the region.

**Objectives:**

The review explored history of ASD and looked at various pockets of studies reporting prevalence of ASD in the region. It also explored the characteristic features of West African children with ASD and socio-cultural factors associated with diagnosis and help-seeking behavior. The review offered suggestion on appropriate educational model that should be adopted in the region.

**Methods:**

Literature search was done of research related to ASD coming from West African sub-region using Pubmed, Google Scholar and Google search. Data were extracted from these studies focusing on history, diagnosis, help-seeking behavior, characteristics of children with ASD and peculiar socio-cultural beliefs and practices in the region.

**Results:**

ASD was first reported in West African sub-region in 1972. The prevalence of ASD ranges between 0.8 to 34.5% depending on the population base / environment of the children studied in the region. Period of onset of ASD symptoms coincides with period of high prevalence of childhood infectious diseases with neurological complications in the region. Late diagnosis characterized ASD and help-seeking behavior, which is often tortuous is influenced largely by socio-cultural beliefs and practices in the region. Inclusive education model is suggested for providing intervention for children with ASD in the region.

**Conclusions:**

Further research is needed in the region and more advocacy and capacity development is required to ensure formulation and implementation of appropriate policies.

**419.008 (Poster) Concentrations of Lead, Mercury, Arsenic, Cadmium, Manganese, and Aluminum in the Blood of Pakistani Children with and without Autism Spectrum Disorder and Their Associated Factors**

**M. H. Rahbar<sup>1,2,3</sup>, S. H. Ibrahim<sup>4,5</sup>, S. I. Azam<sup>6</sup>, M. Hessabi<sup>7</sup>, F. Karim<sup>7</sup>, J. Zhang<sup>2,8</sup>, N. Gulzar ali<sup>4</sup> and K. A. Loveland<sup>9</sup>,** (1)*Division of Clinical and Translational Sciences, Department of Internal Medicine, McGovern Medical School, The University of Texas Health Science Center at Houston, Houston, TX,* (2)*Biostatistics/Epidemiology/Research Design (BERD) core, Center for Clinical and Translational Sciences (CCTS), The University of Texas Health Science Center at Houston, Houston, TX,* (3)*Department of Epidemiology, Human Genetics, and Environmental Sciences, School of Public Health, The University of Texas Health Science Center at Houston, Houston, TX,* (4)*Department of Pediatrics and Child Health, Aga Khan University, Karachi, Pakistan,* (5)*Child development and Rehabilitation Centre, Aga Khan University, Karachi, Pakistan,* (6)*Department of Community and Health Sciences, Aga Khan University, Karachi, Pakistan,* (7)*Department of community health sciences, Aga Khan University, Karachi, Pakistan,* (8)*Department of Biostatistics and Data Science, School of Public Health, The University of Texas Health Science Center at Houston, Houston, TX,* (9)*Louis A Faillace, MD, Department of Psychiatry and Behavioral Sciences, McGovern Medical School, The University of Texas Health Science Center at Houston, Houston, TX*

---

**Background:** The prevalence of Autism Spectrum Disorder (ASD) in Pakistan is unknown, but a school-based study reported a prevalence of 1 in 500 for students with special needs that included children with ASD; however, this could be a severe underestimate because many children with ASD are kept from attending school due to social stigma. The etiology of ASD is believed to be multifactorial and researchers believe that ASD is associated with environmental factors, either directly or interactively with genes. Exposure to environmental contaminants greatly contributes to the burden of disease in Pakistan. Elevated blood lead (Pb) concentrations in Pakistani children has been a concern for more than three decades. Studies also reported elevated levels of arsenic (As), manganese (Mn), cadmium (Cd), mercury (Hg), and aluminum (Al) in children and adults in some communities in Pakistan.

**Objectives:** To estimate mean blood concentrations of six metals (Pb, Hg, As, Cd, Mn, Al) and identify associated factors for children with and without ASD in Pakistan.

**Methods:** From an existing database of children already diagnosed with ASD based on the Childhood Autism Rating Scale (CARS) in the Child Development Program at Aga Khan University (AKU) in Karachi, Pakistan, we enrolled 30 children, age 2-12 years old. Children were re-evaluated based on the Urdu-translated versions of Autism Diagnostic Observation Schedule, Second Edition (ADOS-2) and Autism Diagnostic Interview-Revised (ADI-R). For each of 30 ASD cases, we enrolled an age-, and sex-matched typically developing (TD) control child, while maintaining an overall male to female ratio of 4:1. Assessment of the six blood metals concentrations was done using blood samples of 2-3 mL by a CDC-certified Trace Metals Laboratory in Lansing, Michigan, USA. Concentrations below the Limits of Detection (LoD) for each metal were replaced by  $(\text{LoD}/\sqrt{2})$ . The percentage of concentrations below LoD for the six metals are reported in Table 2.

We compared the ASD cases and TD controls groups with respect to distribution of demographics, socioeconomic characteristics, dietary factors, and environmental factors using conditional logistic regression (CLR) models and for blood metal concentrations using univariable and multivariable General Linear Models (GLMs).

**Results:** Mean ages of ASD cases and TD controls were 78.3 and 78.5 months, respectively. ASD cases had lower SES than TD controls. More than half of ASD cases and TD controls (53.3%) reported "Urdu speaking" ethnicity. (Table 1) Geometric mean (GM) blood concentrations of Pb were nearly different between ASD and TD control groups ( $P = 0.05$ ), in the univariable GLM, but when adjusted for four covariates (Table 2), this difference was no longer significant, ( $P = 0.16$ ). For the other 5 metals, the difference was not significant in any of the GLMs. (Table 2).

**Conclusions:** This is the first study that provides information about concentrations of the six metals in the blood of Pakistani children with ASD. The factors associated with higher levels of Pb, Mn, and Al also provide essential information for designing future epidemiologic studies for investigating the role of these six metals in children with ASD in Pakistan.

**419.009 (Poster) COVID-19 and Alterations in Behavioral and Dietary Outcomes in Children with Autism Spectrum Disorder: Disparities By Income and Food Security Status**

**A. A. Panjwani<sup>1,2</sup>, R. L. Bailey<sup>1</sup> and B. Kelleher<sup>2</sup>, (1)Nutrition Science, Purdue University, West Lafayette, IN, (2)Psychological Sciences, Purdue University, West Lafayette, IN**

**Background:** Recent reports demonstrate differential negative impacts of COVID-19 on the autism community; however, specific research is lacking on the impact on behavioral and food-related outcomes among children with autism spectrum disorder (ASD).

**Objectives:** The objective of this study is to investigate the relationship of COVID-19 on overall behavior and specific behaviors, including changes in eating patterns, of children with ASD and their families.

**Methods:** Parents and caregivers (n=200) across the United States participated in an online survey that queried changes in overall behavior, eating behaviors, and specific behavioral domains during the COVID-19 pandemic. Food security was assessed based on a two-question method validated against the United States Department of Agriculture 18-item Household Food Security Survey. Logistic regression was used to assess the associations of moderate-to-large impact on overall behavior and eating behaviors with income and food security status.

**Results:** A majority of respondents reported a moderate to large impact on the child's overall behavior (74%) as well as eating behaviors (57%) due to COVID-19. Increases in specific behaviors were also reported, notably in distractibility (69%), arguing or stubbornness (69%), and hyperactivity (65%). Increased food intake by the child was reported by 42% of respondents while 36% reported decreased intake. Frequency of consumption of meat, seafood, vegetables, and 100% fruit juice decreased overall while frequency of sweets consumption significantly increased. Household food insecurity increased by 8% compared to the past 12

months prior to COVID-19. Stratifying by income level and food security status revealed disparities in the impact on overall behavior, eating behaviors, and most specific behaviors. Compared to a household income  $\geq$ \$100K, an income  $<$ \$50K was associated with an increased risk of moderate to large impact on the child's overall behavior (odds ratio (OR): 4.07, 95% CI: 1.60, 10.38) and eating behaviors (OR: 2.33, 95% CI: 1.02, 5.29). Food insecurity also significantly impacted the risk of moderate to large impacts on overall behavior and eating behaviors (OR: 3.82, 95% CI: 1.95, 7.49, and OR: 2.60, 95% CI: 1.45, 4.67, respectively).

Conclusions: Our findings show a large proportion of caregivers reporting moderate to large changes post-COVID-19 in the behaviors of children with ASD, particularly in families with low income and/or food insecurity. This study highlights the effects of existing disparities on children with ASD and their families during this unprecedented time.

**419.010 (Poster)** Cumulative Incidence of Autism Spectrum Disorders in Tennessee

**K. Rossow<sup>1</sup>, A. Vehorn<sup>2</sup> and Z. Warren<sup>2</sup>, (1)Vanderbilt, Nashville, TN, (2)Vanderbilt University Medical Center, Nashville, TN**

---

Background: The prevalence of Autism Spectrum Disorder (ASD) has significantly increased over time, and the most recent prevalence estimate is 1.85% among 8 year old children. Currently, in the US the CDC reports the prevalence of ASD biannually based on the identification in 8-and 4-year-old children in 11 states using cross sectional methods. However, comprehensive longitudinal data identifying ASD diagnosis across time has not been available for the US with those purporting such estimates usually based on self-report methods. Standard ASD surveillance methods often require time and labor intensive strategies that result in a significant time delay when reporting statistics.

Objectives: Our objective was to utilize electronic health record (EHR) data for patients seen at Vanderbilt University Medical Center (VUMC) to estimate the cumulative incidence of ASD diagnosis over time in children in Tennessee born during 1997-2018.

Methods: Our data source was Vanderbilt's Research Derivative clinical informatic platform which contains the electronic health record (EHR) data for all patients seen at VUMC including ICD codes used at each visit. Children were included as an ASD case if they were born between the years of 1997-2018; had at least one ICD code of ASD; last address in the EHR was listed in TN; and were not listed as deceased in the EHR. Incidence curves were calculated per birth cohort year dividing the number of cases of ASD per year by the total number of same aged-children living in Tennessee in the year of interest.

Results: A model for cumulative incidence curves for children living in Tennessee during birth cohort years 1997-2018 was successfully created using EHR data as shown in the figure. Final incidence estimates for ASD varied by birth cohorts with the lowest incidence of 0.42% in 18 year olds born in 1997/1998 with the highest of 1.01% in 3 and 4 year olds born in 2013/2014. Our methods yielded lower estimates than current CDC estimates. This figure shows an increase in autism incidence over time and across birth cohort years that has not yet flattened. *Importantly*, data for this study were extracted from the EHR over a 6 week period. Quantifying and creating the cumulative incidence curves took less than two weeks.

Conclusions: Utilizing EHR based ASD identification might provide an efficient way to rapidly model ASD incidence. Future directions include linking these methods to statewide educational data and Medicaid data. This strategy could potentially provide a new method to model ASD incidence in real time in a cost effective manner.

**419.011 (Poster)** Developmental Profiles of Children at Risk for Autism Spectrum Disorder at School Entry: A Population-Based Cohort Study in British Columbia, Canada

**A. Ip<sup>1</sup>, T. Oberlander<sup>2</sup>, B. Poon<sup>2</sup>, G. Hanley<sup>2</sup> and M. Guhn<sup>2</sup>, (1)University of British Columbia, Vancouver, BC, CANADA, (2)University of British Columbia, Vancouver, BC, Canada**

---

Background: Children with autism spectrum disorder (ASD) are highly heterogenous in their functional abilities and changes in the definition of ASD over time may be leading to decreased differences among individuals with and without ASD. In British Columbia (BC), the BC Autism Assessment Network (BCAAN) conducts all publicly funded ASD assessments in children. Their clinical database allows us to identify a unique cohort of children with overlapping impairments but differing diagnoses.

Objectives: The purpose of this study was to compare the developmental profiles at school entry of children assessed for ASD using population level linkage data.

**Methods:** This is a retrospective cohort study using administrative datasets of children born in BC from 2000 to 2009. The study sample included 101,739 children in 5 comparison groups: children (1) assessed by BCAAN and diagnosed with ASD (n = 1,583), (2) assessed by BCAAN and not diagnosed with ASD (n = 1,131), (3) not seen by BCAAN but identified by the ministry of education as having ASD (n = 654), (4) identified by the ministry of education as having a special need other than ASD (n = 11,663), and (5) typically developing children (n = 86,708). Developmental profiles were assessed using the Early Development Instrument (EDI), a kindergarten teacher completed measure. The EDI measures 5 core domains: physical health and well-being, social competence, emotional maturity, language and cognitive development, and communication and general knowledge. Scores range from 0 to 10; lower scores represent more vulnerable children. Group differences were examined using one-way ANOVA and Tukey's HSD to adjust for multiple comparisons ( $p < 0.05$  for statistical significance).

**Results:** Overall, children who were assessed for ASD, regardless of diagnosis, had mean domain scores that were lower than children identified by the ministry of education as having a special need and typically developing children. These differences were most prominent in the social competence, emotional maturity, and communication and general knowledge domains. For example, in the social competence domain, children with ASD scored on average 1.75 (95% CI 1.61, 1.88) points lower than children with other special needs, and 3.96 (95% CI 3.84, 4.08) points lower than typically developing children; children assessed for ASD, but not diagnosed with ASD, scored on average 0.89 (95% CI 0.75, 1.04) points lower than children with other special needs, and 3.1 (95% CI 2.96, 3.24) points lower than typically developing children.

**Conclusions:** The results highlight the importance of ongoing monitoring and support of children for whom there are developmental concerns, particularly for ASD. Even when these children are not diagnosed with ASD, they present with an early developmental profile that is distinct from children with other special needs and typically developing children.

**419.012 (Poster)** Disability Eligibility Patterns in Head Start Programs: A Comparison of Puerto Rico and Mainland United States of America

**K. Martinez-Torres<sup>1</sup>** and **S. Camarata<sup>2</sup>**, (1)1215 21st Avenue South Medical Center East, Vanderbilt University, Nashville, TN, (2)Hearing & Speech Sciences; Psychiatry & Behavioral Sciences, Vanderbilt University Medical Center, Nashville, TN

---

**Background:** Population-based research is needed in order to identify eligibility patterns arising from diverse disabilities in diverse communities and countries. However, this has been a difficult process in part arising from challenges in collecting and accessing comparable data that are stable across communities. The Head Start Program, both in the mainland US and in Puerto Rico, is a resource that gathers yearly information service eligibility that can be compared across samples using similar criteria across sites.

**Objectives:** To analyze special education referral patterns for three to five-year-old preschool low-income Head Start populations to better understand eligibility patterns across cultures: mainland USA and Puerto Rico.

**Methods:** Database was retrieved from the Head Start ECKLC enterprise system on three consecutive years (2016-2018) of Program Information Reports, which provided information on enrollment and eligibility classification. We compared the proportions of the two countries' eligibility categories for ID and related eligibilities (e.g., Speech/Language Impairment, Autism Spectrum Disorder, Developmental Delay).

**Results:** Contrary to patterns reported in the literature on Latinx samples in the US, we observed higher incidence of Autism Spectrum Disorder in Puerto Rico when compared to mainland US. But there was a significant discrepancy between Developmental Delay and Speech/Language Impairment, with a much higher identification for Speech/Language Impairment and much lower identification for Developmental Delay in Puerto Rico relative to these categories in the mainland US.

**Conclusions:** Higher incidence of ASD in PR suggests that there might be an increase of awareness and education towards this diagnosis in terms of evaluation and treatment procedures. Differences in Developmental Delay and Speech Impairment could arise from cultural differences in how these typologies are viewed and defined. Expansion of the sample and in depth analysis of cultural impacts, perspectives, and screening methods need to be examined in order to validate speculations herein.

**419.013 (Poster)** Effects of the COVID-19 Pandemic on Parent-Reported Stress and ASD Symptoms in Toddlers in a Community Sample

**N. O. Davis<sup>1</sup>**, **A. Leon Lua<sup>2</sup>**, **L. Knight<sup>2</sup>**, **M. McAllister<sup>2</sup>**, **E. Henderson<sup>2</sup>**, **L. Franz<sup>3</sup>**, **L. Sikich<sup>4</sup>**, **G. Dawson<sup>4</sup>**, **S. N. Compton<sup>2</sup>** and **S. H. Kollins<sup>1</sup>**, (1)Department of Psychiatry and Behavioral Sciences, Duke ADHD Program, Duke University Medical Center, Durham, NC, (2)Duke University Medical Center, Durham, NC, (3)Duke Center for Autism and Brain Development, Department of Psychiatry and Behavioral Sciences, Duke University, Durham, NC, (4)Department of Psychiatry and Behavioral Sciences,

**Background:**

Child behavioral problems and family stress have been reported during the COVID-19 pandemic. To date, studies have not examined the impact of the pandemic on ASD symptoms in very young children. In addition, little is known about the stress of parenting toddlers during the COVID-19 pandemic.

**Objectives:** 1) To compare ASD-related symptoms, other behavior problems, and parenting stress in a cohort of toddlers recruited before the COVID-19 pandemic with a comparable cohort recruited during the pandemic. 2) To explore whether race and ethnicity differentially impacted group differences in these behavioral factors.

**Methods:**

Participants were drawn from a sample of N=1416 toddlers (mean age = 19.9 months) recruited from pediatric clinics as part of a community-based study. The sample was divided into two cohorts based on study enrollment during the same 6-month period (April 1 to October 30) in 2019 (pre-COVID-19 pandemic) and 2020 (during the pandemic). Rates of study participation and enrollment were examined between the cohorts. Parent-reported ASD symptoms were assessed with the Modified Checklist for Autism in Toddlers [M-CHAT] and Autism Spectrum Problems subscale of the Child Behavior Checklist (Aut-CBCL). General behavior problems were assessed on the CBCL Total Problems subscale (Tot-CBCL). Parent stress was examined using the Parental Stress Scale (PSS). Outcomes across the two cohorts and the effects of child race and ethnicity were examined.

**Results:** A lower proportion of eligible families consented to participate during the pandemic (N=142/1481; 9.6%) compared to pre-pandemic (N=803/1480; 54.3%) ( $\chi^2 = 361.1, p < 0.001$ ). Parental stress was significantly higher in the pandemic cohort compared to the pre-pandemic cohort ( $t = 3.8, p < 0.001$ ) for all participants, with particularly higher stress reported for White respondents during the pandemic. No difference was found between the cohorts on the M-CHAT. A nonsignificant increase was observed in the number scores above the M-CHAT cut-off (i.e., score  $\geq 3$ ), and Black children showed statistically insignificant increases in the proportion of clinical cases (8.2% to 14.3%). The cohorts did not differ significantly on the Autism Spectrum Problems scale, but there was a trend for higher scores for Hispanic families during the pandemic ( $p = 0.07$ ). Statistically insignificant cohort differences were found in the proportion of elevated scores (defined as T-score  $> 60$ ) for Black (pre-pandemic 7.6%; pandemic 15.2%) and Hispanic children (pre-pandemic 10.5%; pandemic 16.7%) while White and Non-Hispanic children showed decreases. Lastly, cohorts did not differ in total behavior problems. However, trend-level findings on the Tot-CBCL showed increased problems for non-White versus White children during the COVID-19 pandemic ( $F = 3.73, p = 0.05$ ) and for Hispanic versus non-Hispanic children ( $F = 3.91, p < 0.05$ ).

**Conclusions:**

Higher levels of parenting stress were reported in a cohort of toddlers enrolled during the COVID-19 pandemic compared to pre-pandemic participants. Although ASD symptoms and general problem behaviors did not increase during the pandemic for the full sample, group differences emerged when considering race and ethnicity. Findings suggest possible differential impact of the COVID-19 pandemic on behavioral functioning in toddlers. Future research will examine associations between parenting stress and child behaviors, as well as developmental changes over time between the cohorts.

**419.014 (Poster)** Exploring a Role for Parental Mental Health in Perception and Reports of Pain on Behalf of Children with Autism Spectrum Disorder

**L. P. Grosvenor<sup>1</sup>, D. G. Whitney<sup>2,3</sup>, H. E. Volk<sup>1</sup> and M. D. Fallin<sup>1</sup>,** (1)Wendy Klag Center for Autism and Developmental Disabilities, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, (2)Department of Physical Medicine and Rehabilitation, University of Michigan, Ann Arbor, MI, (3)3Institute for Healthcare Policy and Innovation, University of Michigan, Ann Arbor, MI

---

**Background:** In addition to social communication impairments and repetitive behaviors, children with autism spectrum disorder (ASD) have higher prevalence of pain compared to controls and may experience altered tactile perceptions. However, increased reports of pain may be a function of differences in parental interpretation among children with ASD. Parents of children with ASD experience high rates of stress, depression and anxiety, which may affect how they report pain symptoms on behalf of children. Since pain is a leading cause of morbidity and disability worldwide and may contribute to adverse health outcomes in people with ASD, further work regarding pain experiences in ASD is warranted.

**Objectives:** We sought to explore a relationship between ASD and parental reported child pain, with further consideration of the presence of maternal mental health conditions (MMHCs) as a contextual factor.

**Methods:** Data from 1,423 children with ASD, 46,145 children without ASD and their mothers were used from the combined 2016-2017 National Survey of Children's Health (NSCH). Mothers reported child pain and ASD status and their own mental health status ("Excellent or Very Good," "Good," or "Fair or Poor"). A status of "Fair or Poor" was coded as having MMHCs. Weighted prevalence estimates of ASD, pain and MMHCs were calculated for four levels of one main exposure variable (group 1: No ASD/ No MMHCs (reference group; N= 44,327); group 2: No ASD/Yes MMHCs (N= 1,818); group 3: ASD/No MMHCs (N= 1,277); and group 4: ASD/Yes MMHCs (N= 146)). Logistic regression models were used to explore the relationship between pain and this main exposure variable, adjusting for co-occurring neurological conditions (CNC).

**Results:** Frequent or chronic pain was reported for 8.5% of children without ASD and 14.1% of children with ASD. MMHCs were reported by mothers in 3.9% of children without ASD and 10.3% with ASD. Pain was prevalent in 7.4% [95% CI= 6.9-7.8] of children in group 1, 22.8% [95% CI= 18.7-26.8] of group 2, 16.1% [95% CI= 9.8-22.4] of group 3, and 25.4 % [95% CI= 12.3-35.8] of those in group 4. In a model fully adjusted for CNCs and sociodemographic factors, the odds of pain for group 2 (No ASD/Yes MMHCs ) compared to no ASD and No MMHCs was 3.59 [2.65-4.88], for group 3 (ASD/No MMHCs) was 2.31 [1.21-4.42], and for group 4 (ASD/MMHCs) was 3.86 [1.70-8.78] (Table 1). Tests for contrasts between groups revealed that they did not differ from each other, but each significantly differed from the reference group.

**Conclusions:** Children with and without ASD who had mothers with MHCs had higher odds of pain compared to children with mothers without MHCs. Increased odds did not attenuate as a result of controlling for CNCs, which have been associated with increased pain in children with ASD. Parental MHCs may alter perception and/or reports of pain on behalf of children with and without ASD. Future research should include detailed assessments of parental mental health in order to further explore its role in the experiences of pain and other pathophysiological symptoms present in children with ASD.

#### **419.015 (Poster)** Factors Associated with Knowledge, Attitude, and Practices of Physicians Related to Autism Spectrum Disorder in Romania

**M. H. Rahbar**<sup>1,2,3</sup>, **I. Dobrescu**<sup>4,5</sup>, **S. Gillani**<sup>3</sup>, **M. Hessabi**<sup>2</sup>, **M. Stancu**<sup>4,5</sup> and **F. Rad**<sup>4,5</sup>, (1)Division of Clinical and Translational Sciences, Department of Internal Medicine, McGovern Medical School, The University of Texas Health Science Center at Houston, Houston, TX, (2)Biostatistics/Epidemiology/Research Design (BERD) core, Center for Clinical and Translational Sciences (CCTS), The University of Texas Health Science Center at Houston, Houston, TX, (3)Department of Epidemiology, Human Genetics, and Environmental Sciences, School of Public Health, The University of Texas Health Science Center at Houston, Houston, TX, (4)Child and Adolescent Psychiatry Department, University of Medicine and Pharmacy "Carol Davila", Bucharest, Romania, (5)Child and Adolescent Psychiatry, "Prof. Dr.Alex. Obregia" Psychiatry Hospital, Bucharest, Romania

**Background:** An inadequate level of general knowledge of physicians regarding mental health, including Autism Spectrum Disorder (ASD), could have adverse effects on affected individuals' health and quality of life in a variety of ways. For example, an inadequate level of knowledge of physicians about ASD could further delay its diagnosis and initiation of timely and appropriate interventions, particularly in communities in which mental health is considered a stigma.

**Objectives:** The purpose of this survey is to assess the level of knowledge, attitudes, and practices (KAP) of physicians regarding ASD in Romania and identify their associated factors.

**Methods:** For this cross-sectional survey, investigators at the University of Texas Health Science Center at Houston and "Carol Davila" University of Medicine and Pharmacy (UMF) collaborated to develop a questionnaire by modifying a previously established similar questionnaires used in Pakistan and Turkey, to assess KAP of physicians and specialists regarding ASD in Romania. The Questionnaire was administered to a convenient sample of 383 practicing physicians or specialists recruited from the 2017 National Conference of Family Medicine in Bucharest, Romania. We conducted confirmatory factor analysis that resulted in identifying five composite ASD knowledge sub-scores derived from 12 questions described in Table 1. Using each of these sub-scores as dependent variables in univariable and multivariable General Linear Models, we determined the variables associated KAP related to ASD as well as their potential interactions.

**Results:** Approximately 75% of the responding physicians were female and more than 80% were over the age of 30 years. About 88% of physicians correctly responded that, "impaired social interaction" was necessary for the diagnosis of ASD. The majority (73%-94%) of physicians in Romania have correctly responded to some basic questions regarding knowledge about ASD. We also found that younger physicians (age < 35 years) were more knowledgeable about potential causes of ASD than older physicians, age ≥ 35 years, (adjusted mean sub-scores: 2.70 vs. 2.13,  $P = 0.04$ , adjusted for the "type of medical school attended" and "city where the clinic is located"). The five sub-scores obtained from factor analysis explained about 64% of the variance in

all 12 questions entered into the factor analysis as shown in Table 1. We found a significant interaction between source of ASD knowledge (SAK) and (city where the clinic is located) in relation to knowledge of the physicians' regarding stigma related to ASD. We also found a marginally significant interaction between SAK and completing a master's level training after medical school in relation to knowledge of the physicians' regarding potential causes of ASD ( $P = 0.06$ ). There were no significant interactions in relation to the physician's knowledge of behaviors of children with ASD.

**Conclusions:** Though physicians in Romania have general knowledge about ASD, greater focus is needed on increased awareness of stigma and misconception surrounding ASD, as well as its symptoms and potential causes. Our study also emphasizes the importance of testing for interactions among similar studies, which may help identify associations between ASD knowledge and other covariates that effect physician's knowledge in this area.

**419.016 (Poster) First Trimester Maternal Serum Folate and Child Autism Spectrum Disorder**

*A. M. Iosif<sup>1</sup>, O. Malysheva<sup>2</sup>, M. Caudill<sup>3</sup>, J. E. Deason<sup>4</sup>, K. M. Bakulski<sup>5</sup>, C. J. Newschaffer<sup>6</sup>, I. Hertz-Picciotto<sup>7</sup>, L. A. Croen<sup>8</sup>, M. D. Fallin<sup>9</sup> and R. J. Schmidt<sup>10</sup>, (1)Public Health Sciences, University of California Davis, Davis, CA, (2)Division of Nutritional Sciences, College of Agriculture and Life Sciences, Cornell University, Ithaca, NY, (3)University of Michigan, Ann Arbor, MI, (4)College of Health and Human Development, Pennsylvania State University, University Park, PA, (5)University of California at Davis, Davis, CA, (6)Division of Research, Kaiser Permanente, Oakland, CA, (7)Wendy Klag Center for Autism and Developmental Disabilities, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD*

---

**Background:**

Many studies have reported associations between prenatal supplemental folic acid (FA) intake and reduced risk for autism spectrum disorder (ASD) in the child. Some found a critical window for protection near conception. Although studies of measured maternal serum folate have not shown an association with reduced ASD risk, none measured serum folate metabolites in early pregnancy.

**Objectives:**

We examined maternal first trimester serum folate status in association with the child's later development of ASD.

**Methods:**

In a pooled study of younger siblings of children with autism enrolled in the MARBLES ( $n=75$ ) and EARLI ( $n=24$ ) prospective pregnancy cohorts, serum 5-methyltetrahydrofolate (5-meTHF) and FA were quantified in up to two samples in the first trimester using LC-MS/MS stable-isotope dilution methods. Assay imprecision was calculated using in-house quality-control samples that were included with each extraction batch. ASD was clinically assessed for all children using the Autism Diagnostic Observation Schedule (ADOS) at 3 years old. Typically developing (TD) was defined using an algorithm based on the ADOS and the Mullen Scales of Early Learning at age 3 years. Relative risks for ASD were calculated using a SAS macro, %RELRIK8.

**Results:**

First trimester serum folate metabolites were available for 36 children who were diagnosed with ASD, and 63 TD children. Intra-assay and inter-assay CVs were 1.8% and 1.9% for 5-meTHF; and 4.9 and 8.5% for FA. 91% of the women had elevated 5-meTHF (above 20 ng/ml) and 0 were deficient or possibly deficient.

When examined as continuous exposures, there were no significant associations observed between ASD and averaged first trimester ln-transformed FA (RR= 0.89, 95%CI 0.71, 1.13) or 5-meTHF (RR for 10ng/mL increase=1.10, 95%CI 0.84, 1.43). There was a significant association between higher late first trimester serum 5-meTHF and increased ASD (RR=1.29, 95%CI 1.05, 1.59) that was not observed for early first trimester (**Table 1**). Additionally, when examining first trimester averages as categories given evidence for a U-shaped association with ASD, having less than elevated 5-meTHF (20 ng/ml or less) was associated with borderline significant higher risk for ASD (RR=2.22, 95%CI 0.90, 5.50), and the highest category of 5-meTHF (32 ng/mL or above) was non-significantly associated with higher risk (RR=1.76, 95%CI 0.81, 3.81) compared to having 26-32 ng/mL (**Table 2**).

**Conclusions:**

In this pooled study of high familial risk families, maternal serum folate status in the first trimester was not associated with decreased risk for ASD. There were differences in the directions of associations by timing, in which lower risk was observed for increasing concentrations of both folate metabolites in early first trimester compared to late first trimester. Further, as found in previous studies, we found evidence of a U-shaped association, with non-significantly higher risk associated with the lowest and highest categories of 5-meTHF. Additional, larger studies should confirm these findings especially for the first month of pregnancy and before. Further, population-based cohort studies should assess the generalizability of these findings to families unaffected by autism. Finally, studies in populations without elevated folate should be conducted to investigate associations of deficient serum folate concentrations.

**419.017 (Poster) Higher Than Expected ASD Prevalence in Toms River, New Jersey in 2016**

**W. Zahorodny<sup>1</sup> and J. Shenouda<sup>2</sup>,** (1)*Rutgers New Jersey Medical School, Newark, NJ,* (2)*Pediatrics, Rutgers NJ Medical School, Newark, NJ*

---

### **Background:**

Though accurate information about the prevalence and expression of Autism Spectrum Disorder (ASD) may be useful for planning educational and health services, there is scant information from population-based studies on the prevalence and expression of ASD at the county or local level. ASD prevalence in the New Jersey was 3.1%, nearly double the Autism and Developmental Disabilities Monitoring (ADDM) Network average, during the most recent monitoring period.

### **Objectives:**

Our objective was to provide reliable, population-based, information on ASD prevalence at the school district level in the New Jersey ADDM surveillance region, leading to identification of districts with higher-than-expected and lower-than-expected ASD prevalence.

### **Methods:**

A cross-sectional study was implemented using data from the 2016 New Jersey surveillance site - a multiple source public health monitoring system that analyzes data from educational and health care sources to determine the number of 8-year-old children with ASD in defined populations. In this study, ASD cases were restricted to include children in public education, in 2016. District level denominators were based on public school enrollment data. Wilson score method was used to calculate 95% confidence intervals.

### **Results:**

ASD prevalence across 74 New Jersey districts ranged from 0 to 10.8%. Average prevalence was 3.6%. More than a quarter of the districts had ASD prevalence greater than 4%, including 3 of the 4 largest school districts. Highest ASD prevalence was identified in Toms River, wherein 78 children served by the public school system were identified with ASD (7.3%; 95% CI: 5.9-9.0). Most were boys (n= 66; 85%), from White (Non-Hispanic) (n=60; 77%), middle income families (median household income range \$45,000-\$100,000) (n=70; 90%). Most were born in New Jersey (n=65; 83%). Eighty-eight percent (n=53) with cognitive testing data had a documented Intellectual Quotient (IQ) above 70. Most of the Toms River ASD-confirmed students (n=68; 87%) received special education services during 2016, including (n=29) 38% under an Autism classification, 20% (n=5) under Other Health Impaired and 9% (n=7) under Multiply Disabled classifications. Approximately 13% (n=10) were in general education or received 504 Plan services (n=3). Thirty-seven percent (n=29) of the Toms River ASD-confirmed cases received professional evaluation before 36-months and 45% (n=35) were diagnosed with ASD by 48-months, even though 80% (n=62) had indication of delays before 36 months.

### **Conclusions:**

ASD prevalence in many areas and districts may be higher than indicated by aggregate (state or system-level) estimates. Approximately one in four New Jersey school districts had ASD prevalence greater than 4%, in 2016. In Toms River, New Jersey's largest suburban public school district, 1-in-14 8-year-olds was identified with ASD (7.4%). Higher-than-expected rates of ASD in Toms River and other New Jersey school districts point to the importance of utilizing local-level population-based ASD estimates for the development of strategies to meet the needs of children with ASD and to determine the future needs of adults with ASD. Additional inquiry is needed to identify the factors responsible for higher-than-expected ASD prevalence in New Jersey. Ongoing ASD surveillance by the same method, going forward, is recommended.

**419.018** (Poster) Impact of Belgian COVID-19 Lockdown Restrictions on Autistic Individuals' Behaviors and Their Parents' Quality of Life

**M. Weyland<sup>1</sup>, P. Maes<sup>1</sup>, M. Kissine<sup>1</sup> and P. Defresne<sup>2</sup>,** (1)ACTE — Center of research in Linguistics — ULB Neuroscience Institute, Université libre de Bruxelles, Brussels, Belgium, (2)Fondation SUSAS, Université de Mons, Mons, Belgium

---

**Background:** Due to the rapid spread of the COVID-19 virus, Belgian citizens were required to stay at home between the 18th of March and 10th of May 2020. Belgium's National Security Council only allowed to go out for errands of prime necessity or outdoor physical activity within a limited distance of one's home. There are good reasons to believe that this situation affected families living with an autistic individual. First, work arrangement such as homeworking, financial uncertainty and restriction of movements could add to the challenge in parenting, possibly increasing stress and reducing quality of life. Second, social isolation, changes in routines, closing of schools, restriction of outdoor activities, lack of professional support could increase the amount of behavioral difficulties in autistic individuals.

**Objectives:** The primary aim is to investigate the impact of Belgium's lockdown restrictions on autistic individuals' communicative behaviors and their parents' quality of life. The second aim is to assess the influence of the autistic individual's characteristics, the home characteristics, and the support, resources and implementation of ASD strategies during lockdown on the changes in behaviors and quality of life.

**Methods:** A 125-question on-line survey was shared via LimeSurvey during the second month of lockdown with French-speaking Belgian parents living with an autistic individual. Three main domains were addressed in the questionnaire: family and household characteristics, the autistic individual's characteristics and behaviors, and global quality of life during lockdown. Five-point Likert items (much less than usual/a little less than usual/as usual/a little more than usual/much more than usual) measured the presence of nonfunctional communicative behaviors in the autistic individuals and the changes in their parents' quality of life — higher scores indicating a deterioration and lower scores indicating an improvement.

**Results:** 209 parents completed the survey. Answers on the Likert scales were significantly higher than "as usual" for the autistic individual's nonfunctional socio-communicative ( $t(208) = 10.57, p < .001$ ) and challenging behaviors ( $t(208) = 6.24, p < .001$ ), and for the parents' quality of life ( $t(208) = 10.41, p < .001$ ) and emotional well-being ( $t(251) = 10.54, p < .001$ ) (see Figure 1). Preliminary results indicated that at least two external factors influenced the impact of lockdown on the families. First, there was a significant main effect of the autistic individuals' amount of comorbidities on the presence of nonfunctional socio-communicative ( $F(1,203)=7.49, p=.007$ ) and challenging behaviors ( $F(1,203)=4.09, p=.044$ ), and their parents' emotional well-being ( $F(1,203)=5.86, p=.016$ ). There was also a significant main effect of parents' access to respite care on the presence of nonfunctional socio-communicative ( $F(1,207)=18.88, p < .001$ ) and challenging behaviors ( $F(1,207)=17.12, p < .001$ ), and the parent's quality of life ( $F(1,207)=32.48, p < .001$ ) and emotional well-being ( $F(1,207)=34.98, p < .001$ ).

**Conclusions:** Belgium's governmental lockdown restrictions had a negative impact both on the autistic individuals' communicative behaviors and their parents' global quality of life. Nonfunctional socio-communicative behaviors increased and parents' quality of life declined. Moreover, the impact of lockdown was worse for autistic individuals who have more comorbidities and for parents who could not access some kind of respite care.

**419.019** (Poster) Maternal Prenatal Perceived Stress in Relation to Autism-Related Symptoms at Age Three

**D. H. Hoang<sup>1</sup> and R. J. Schmid<sup>2</sup>,** (1)University of California, Davis, Davis, CA, (2)Public Health Sciences, University of California Davis, Davis, CA

---

**Background:** Maternal exposures during pregnancy have been shown to be associated with elevated risk of ASD in her child. One exposure that warrants more inquiry is prenatal stress. Existing literature has explored the association between maternal prenatal stress and risk of ASD,<sup>1-7</sup> but their methods for measuring stress were either too narrow (i.e., one mass trauma event) or broad (i.e., open-ended recall of events). This will be the first prospective study to consider perceived stress, which accounts for all stressors and how they impact the mother, and ADOS comparison score to determine if there is an association between prenatal stress and later risk of exhibiting ASD-related symptoms. Moreover, a mother's stress during pregnancy may be even more of a concern for her child if she is at high familial risk due to having an older child already diagnosed with ASD.<sup>8</sup> This will also be the first study to examine perceived stress and ASD-related symptoms in a high familial risk population.

**Objectives:** The objective of this study is to examine the association between maternal prenatal perceived stress and the child's ADOS comparison score at age three in a high familial risk cohort.

**Methods:** This prospective cohort study includes 148 high familial risk pregnant women that already have at least one child with ASD and are at an increased risk of having another child with ASD. The exposure of interest was maternal prenatal perceived stress, and the outcome was child Autism Diagnostic Observation Schedule (ADOS) comparison score. Perceived stress was measured during each trimester of pregnancy by using Cohen's Perceived Stress Scale, which is the most widely used psychological instrument to measure perceived stress.<sup>9</sup> The ADOS is the gold-standard assessment for diagnosing autism. Trained psychologists administered the ADOS to every child at age three. The ADOS comparison score, computed through an algorithm, measures the severity of autism-related symptoms. Linear regression models were fitted to determine the relationship between maternal prenatal perceived stress and ADOS comparison score.

**Results:** Findings in the first trimester were not significant. In the second trimester, a one point increase in the mother's prenatal perceived stress score resulted in an 8% increase in the child's ADOS comparison score (*p-value* 0.0244, 95% CI (0.01, 0.15)). In the third trimester, a one point increase in perceived stress score resulted in an 11% increase in the child's ADOS comparison score (*p-value* 0.0006, 95% CI (0.05, 0.17)).

**Conclusions:** This prospective longitudinal study in a high familial risk cohort is the first to explore associations between maternal prenatal perceived stress and the child's ADOS comparison score at three years. Significant findings show that increased perceived stress during pregnancy can lead to higher risk of the child exhibiting autism-related symptoms. These findings are important because understanding prenatal risks can help us design stress interventions and preventative measures that will lead to the optimization of the child's long term health. This is especially true for mothers at high familial risk that have the added stressors from raising at least one other child with ASD.

**419.020 (Poster) Maternal Supplemental Nutrient Mixtures across Pre-Conception and Pregnancy in Relation to Autism Spectrum Disorder in the Child**

**R. J. Schmidt<sup>1</sup>, A. M. Iosif<sup>2</sup>, A. Goodrich<sup>3</sup>, K. M. Bakulski<sup>4</sup>, S. Ozonoff<sup>5</sup>, G. B. Hamra<sup>1</sup> and D. Tancredi<sup>5</sup>,** (1)Public Health Sciences, University of California Davis, Davis, CA, (2)University of Michigan, Ann Arbor, MI, (3)Psychiatry and Behavioral Sciences, University of California at Davis, MIND Institute, Sacramento, CA, (4)Epidemiology, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, (5)UC Davis School of Medicine, Sacramento, CA

---

**Background:**

Maternal pre-pregnancy and prenatal intake of vitamin supplements and certain individual nutrients have been associated with reduced risk for autism spectrum disorder (ASD) in the child. Some found a critical window for protection near conception. Because nutrients are often delivered together in supplements, their intake dose and timing are often correlated. Nutrients also influence overlapping biologic pathways, making nutrient interactions plausible.

**Objectives:**

We used mixtures analysis to examine joint and separate effects of multiple nutrients from supplements mothers reported consuming before and across pregnancy in association with the child's development of ASD.

**Methods:**

In the MARBLES prospective cohort of younger siblings of children with autism, interviews collected information on vitamins and supplements mothers consumed in each month from 6 months before through the end of pregnancy; total average daily intake of many key nutrients was calculated based on supplement brands, frequencies and doses reported in each month.

Children were clinically assessed using the Autism Diagnostic Observation Schedule (ADOS) and the Mullen Scales of Early Learning at 3 years old, and algorithmically classified as typically developing (TD, n=182) or having ASD (n=65).

Bayesian Kernel Machine Regression (BKMR) was used to assess relationships between ASD and maternal supplemental nutrient intake using groupings of 11 nutrients across time points (pre-pregnancy, pregnancy months 1, 2 and 3, trimester 2, and trimester 3) and groupings of time points across nutrients. Group Posterior Inclusion Probabilities (PIPs) were multiplied by conditional PIPs, and all variables with product PIPs > 0.10 were selected for visualization and included in unconditional logistic regression models. Trimmed nutrients were standardized using z-scores prior to BKMR.

**Results:**

When grouped by nutrient, the following had product PIPs > 0.10: calcium in trimester 2, folic acid in months 1 and 2, iron in month 2, vitamin A in months 1 and 2, vitamin C in trimester 3, vitamin E in months 2 and 3, and zinc in trimester 3 (**Figure 1**). Together, these nutrients statistically significantly predicted ASD (C-statistic: 0.70, 95%CI: 0.63, 0.77, p=0.002). Only folic acid in month 1 was statistically significant (OR = 0.32; 95% Confidence Interval (CI): 0.13, 0.79) in the logistic model. When nutrients were grouped by time, the following had product PIPs > 0.10: calcium in trimester 2, folic acid in months 1 and 2, iron in month 1, vitamin C in trimester 3, and vitamin E in months 2 and 3 (**Figure 2**). Together these nutrients statistically significantly predicted ASD (C-statistic: 0.69, 95%CI: 0.62, 0.77, p=0.003). None of these nutrients were statistically significant in the logistic model.

## Conclusions:

This first study to simultaneously evaluate a number of correlated and combined nutrient exposures before and across pregnancy in relation to the child's development of ASD found the strongest evidence for a protective association of supplemental folic acid in month 1. Calcium in trimester 2, folic acid in month 2, vitamin C in trimester 3, and vitamin E in months 2 and 3 and iron in months 1 or 2 also consistently contributed to ASD, with mostly inverse associations.

### 419.021 (Poster) Positive and Negative Impact of Initial Covid-19 Home-Quarantine Period on Children with ASD and Their Families

Dinstein<sup>13</sup>, (1)Department of Cognitive and Brain Sciences, Ben Gurion University, Beer Sheva, Israel, (2)Seymour Fox School of Education, Hebrew University of Jerusalem, Jerusalem, Israel, (3)The Autism Center/ALUT, Pediatrics, Tel Aviv University /Shamir (Assaf Harofeh) Medical Center, Zerifin, Israel, (4)Department of Psychology, Bar-Ilan University, Ramat-Gan, Israel, (5)Child Development Center, Ministry of Health, Beer Sheva, Israel, (6)School of Education, Bar Ilan University, Ramat Gan, Israel, (7)Autism Center, Assaf Harofeh Medical Center, zerifin, Israel, (8)Psychology, Ben Gurion University, Beer Sheva, Israel, (9)Physiology, Ben-Gurion University of the Negev, Beer Sheva, Israel, (10)Public Health, Ben Gurion University, Beer Sheva, Israel, (11)National Autism Research Center, Beer Sheva, Israel, (12)Pediatrics, Sheba Medical Center, Rehovot, ISRAEL, (13)Psychology Department, Ben-Gurion University of the Negev, Beer Sheva, Israel

**Background:** In mid-March 2020, due to the Covid-19 outbreak, the Israeli government imposed an unprecedented nation-wide home-quarantine period for ~6 weeks. During this period all education services, including special education services, were closed and the population was instructed to stay at home. To the best of our knowledge, the impact of home-quarantine on the well-being of children with ASD and their parents has not been assessed to date.

**Objectives:** To assess the impact of the 6-week home-quarantine period on children with ASD and their parents using an online parent questionnaire.

**Methods:** Parents of 268 children with ASD ages 2-18 years old (mean age = 7.6 ± 4.3) completed the questionnaire. The questionnaire included several background questions regarding the child's age, the level of support that the child required before the covid-19 outbreak, and the financial impact of the quarantine. These were followed by 9 questions where parents rated the impact of home-quarantine on their general mood, sleep, family relationships, and parenting skills, as well as 12 questions where parents rated the impact of home-quarantine on the severity of ASD symptoms, anxiety, tantrums, and sleep disturbances of their child. We used one-sample two-tailed t-tests to identify domains where the home-quarantine period had significant positive or negative impact on children with ASD and their parents. We used one-way ANOVA analyses to compare ratings across children with different levels of required support, ages, and sex as well as across families who experienced different levels of income loss during the home-quarantine period.

**Results:** While home-quarantine had a significant negative impact on the mood and sleep of parents (t(265)=-3.2, p=0.002), many reported improvements in the quality of their relationships with spouse (t(250)=4.1, p<0.0001) and child with ASD (t(265)=11.9, p<0.0001), as well as improvements in their parenting skills (t(266)=5.3, p<0.0001). Furthermore, while parents reported an increase in the severity of tantrums (t(263)=-3.3, p=0.0007), anxiety (t(264)=-3.9, p=0.0001), and restricted and repetitive behavior symptoms (t(263)=-3.5, p=0.0006), they also reported improvements in social and communication abilities of their child (t(263)=4.2, p<0.0001). Ratings were significantly lower in families of children with more severe ASD symptoms (F(2, 263)>3.2, p<0.04) and in families that experienced economic hardships (F(3,262)>3.2, p<0.02). There was no difference across ratings of boys and girls with ASD in any of the examined domains.

**Conclusions:** The initial home-quarantine period in Israel created numerous difficulties and challenges for families of children with ASD. Nevertheless, this period also offered a unique opportunity for improving family relationships, developing parenting

skills, and enhancing children's social communication abilities, particularly in families that were not impacted financially and families with children who required relatively low levels of daily support.

**419.022** (Poster) Prenatal Exposure to a Mixture of Persistent Organic Pollutants and Autism-Related Outcomes in Children  
**A. Y. Song<sup>1</sup>**, E. M. Kauffman<sup>2</sup>, K. Lyall<sup>3</sup>, L. Song<sup>4</sup>, L. A. Croen<sup>5</sup>, M. D. Fallin<sup>6</sup>, I. Hertz-Picciotto<sup>1</sup>, R. J. Schmidt<sup>1</sup>, C. J. Newschaffer<sup>1</sup> and H. E. Volk<sup>1</sup>, (1)Wendy Klag Center for Autism and Developmental Disabilities, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, (2)A.J. Drexel Autism Institute, Drexel University, Philadelphia, PA, (3)Division of Research, Kaiser Permanente, Oakland, CA, (4)University of California at Davis, Davis, CA, (5)Public Health Sciences, University of California Davis, Davis, CA, (6)College of Health and Human Development, Pennsylvania State University, University Park, PA

---

**Background:** Persistent organic pollutants (POPs) include compounds that have long-term persistence in the environment and have established adverse effects on neurodevelopmental outcomes. Past studies have examined prenatal exposure to POPs as a potential risk factor for autism spectrum disorder (ASD) and observed associations with specific congeners and/or classes of POPs. However, the findings of previous studies have been inconsistent and many of those studies have not considered the potential for mixture effects of POPs.

**Objectives:** In this study, we sought to examine the association between prenatal exposure to a mixture of POPs and ASD-related quantitative traits in children at high familial risk for ASD, using data collected from the Early Autism Risk Longitudinal Investigation (EARLI).

**Methods:** A total of 155 participants from the EARLI cohort, a high-familial risk cohort that enrolled pregnant mothers with a child diagnosed with ASD, were included in this analysis. Concentrations of 11 polychlorinated biphenyls (PCBs), 4 polybrominated diphenyls (PBDEs), and 2 persistent pesticides (hexachlorobenzene [HCB], 2,2-bis(4-chlorophenyl)-1,1,1-dichloroethene [*p,p'*-DDE]) were measured and imputed in maternal serum samples collected during pregnancy. Adjusted multivariable linear regression models were used to evaluate the independent effects of log-transformed POPs on ASD-related quantitative traits at 36 months, including Social Responsiveness Scale (SRS) scores, Mullen Scales of Early Learning (MSEL) scores, and Vineland Adaptive Behavior Scales version 2 (VABS-II) scores. Higher SRS scores indicate higher ASD-related traits, whereas higher MSEL and VABS scores indicate lower cognitive and adaptive functioning. We further applied weighted quantile sum (WQS) regression model and Bayesian kernel machine regression (BKMR) model to account for correlations among POPs and evaluate the mixture effect of POPs.

**Results:** In models examining chemicals independently, we observed significantly higher SRS scores among subjects exposed to higher log-PBDE47 ( $\beta=2.17$ , 95% CI: 0.08, 4.26 for 1 unit increase) and lower SRS scores among those exposed to higher log-*p,p'*-DDE ( $\beta=-2.97$ , 95% CI: -5.87, -0.07 for 1 unit increase). No significant associations were observed between POPs and MSEL scores. VABS scores were positively associated with PCB170, PCB180, PCB187, and PCB196/203. In mixture analyses, using WQS, we observed a 2.3% decrease in SRS score, a 2.1% increase in MSEL score, and a 4.7% increase in VABS score for one quartile increase in mixed POP index. PCBs were identified as the most important factor contributing to the joint effect of the mixture on ASD-related traits. Results from the BKMR models suggested a positive linear association of PBDE47 and HCB with SRS scores, a negative linear association of PBDE47 and HCB with MSEL and VABS scores, and a suggestive positive overall trend between POP mixture and higher VABS scores.

**Conclusions:** We observed independent associations between PCB180, PBDE47, HCB, and *p,p'*-DDE with ASD-related traits. Contrary to expectation, higher PCBs were associated with higher cognitive functioning. Our mixture analysis showed a degree of consistency across different methods, where we observed an overall positive mixture effect of POPs on cognitive function. Continued exploration and confirmation of our findings in non-high risk cohorts is warranted.

**419.023** (Poster) Prevalence and Characteristics of Autism Spectrum Disorder Among Low Income Children and Adolescents in Wisconsin: Results from a Statewide Population-Based Study

**M. S. Durkin<sup>1</sup>**, O. M. Pokoski<sup>2</sup>, S. Fournier<sup>2</sup> and A. Salinas<sup>3</sup>, (1)Population Health Sciences, University of Wisconsin School of Medicine and Public Health, Madison, WI, (2)Population Health Sciences, University of Wisconsin-Madison, Madison, WI, (3)Waisman Center, University of Wisconsin-Madison, Madison, WI

---

**Background:** Epidemiologic studies of autism spectrum disorder (ASD) in the U.S. have reported persistent socioeconomic and racial disparities, with unexpectedly low prevalence counts for socioeconomically disadvantaged populations. These findings suggest the possibility that low income populations are under-represented in epidemiologic studies that rely on parent reporting and/or recruitment and record review of individuals served by selected healthcare systems and autism treatment services.

**Objectives:** The aims of this study were to (a) describe the prevalence of ASD among children and adolescents (ages 3-21 years) enrolled in Wisconsin's Medicaid program (public insurance program serving low income families and individuals) in 2018; and (b) the sociodemographic characteristics and frequency of co-occurring conditions in this population.

**Methods:** Functional assessment and other data were reviewed for all children and adolescents enrolled in Wisconsin's Medicaid program with International Classification of Disease diagnostic codes for ASD in 2018. The overall prevalence of ASD among children and adolescents enrolled in Medicaid was calculated by dividing the number with Medicaid claims for ASD by the total number of children and adolescents enrolled. 95% confidence intervals were calculated using Wilson's method. Sociodemographic characteristics and the frequency of co-occurring conditions are also described. For a sub-sample of counties included in the Wisconsin Autism and Developmental Disabilities Monitoring (ADDM) Network site, we estimated the percentage of 8 year-old children with ASD and enrolled in Medicaid who would be included in ADDM Network ASD surveillance counts.

**Results:** In 2018, among approximately 446,600 low income children and adolescents in Wisconsin enrolled in Medicaid, 8,769 had been diagnosed with ASD, corresponding to a prevalence of 19.6 (95% confidence interval 19.2, 2.0) per 1,000, or nearly 2% of the population. 38% of low income children and adolescents with ASD diagnoses received long-term care services, and among this population, the ratio of males to females was 3.5:1, the racial/ethnic composition was 72% White, 9% Black, 14% Hispanic, 3% Asian/Pacific Island and 2% American Indian, 95% were residing at home with parents, serious self-injurious behavior was reported for 14.2% and injurious behavior toward others for 31.8%, and 66% had co-occurring psychiatric and/or neurological conditions, with the most frequent being intellectual disability (28.3%), ADHD (25.9%), seizure disorders (10.5%) and mood disorders (5.0%). Within Wisconsin counties included in the ADDM Network ASD surveillance system, we estimate that 25% of 8 year-old children with ASD would not be counted and included in prevalence estimates without review of Medicaid claims and enrollment data.

**Conclusions:** Low income children and adolescents may be under-represented in surveys and public health surveillance systems designed to estimate the prevalence of ASD in the overall population. This study focused specifically on low income children and adolescents receiving services and supports provided by Wisconsin's Medicaid program and found the prevalence of ASD to be comparable to prevalence estimates for higher income populations. The high percentage of low income children and adolescents with ASD who have co-occurring psychiatric and neurological conditions points to the importance of including this population in future public health surveillance of ASD and its impacts.

**419.025 (Poster)** Role of Metabolic Genes (GSTT1, GSTP1, GSTM1) in Blood Mercury Concentrations of Jamaican Children with and without Autism Spectrum Disorder

**Background:** Mercury (Hg) is a toxic metal that exists in elemental, inorganic and organic chemical forms. Exposure to the most toxic organic form of Hg occurs primarily through consumption of fish. Several studies have investigated the possible association between exposure to Hg and autism spectrum disorder (ASD), though findings conflict. These inconsistent findings could be related to potential confounding effects of dietary practices including fish consumption. In addition, there is evidence that single nucleotide polymorphisms (SNPs) in glutathione S-transferase (GST) genes can influence susceptibility to the cytotoxic consequences of Hg due to variation in Hg detoxification capacity.

**Objectives:** We investigated interactive association of three metabolic GST genes (*GSTP1*, *GSTM1*, and *GSTT1*) and ASD in relation to blood Hg concentrations of Jamaican children with and without ASD.

**Methods:** We compared characteristics of 262 children with ASD and 262 typically developing (TD) controls (2-8 years old) using conditional logistic regression models with respect to demographics, socioeconomic status (SES), foods consumed, and genotypes for *GSTP1*, *GSTM1*, and *GSTT1*. In addition, we used multivariable General Linear Models (GLMs) with the log-

transformed blood Hg concentrations as the dependent variable to investigate the interaction between each of the three GST genes and ASD status in relation to blood Hg concentrations. We also adjusted the multivariable GLMs for covariates that have been previously associated with ASD status and blood Hg concentrations. In all GLMs, we also controlled for the potential clustering effect of matched pairs of ASD cases and TD controls.

Results: At the time of enrollment 77.8% of ASD cases and 80.1% of the TD controls were 48 months or older. About 81% of the ASD cases and TD controls were male. Nearly all of the ASD cases (95.5%) and TD controls (97%) were Afro-Caribbean. After adjusting multivariable GLMs for SES, consumption of leafy vegetables, fried plantain, canned fish, and the interaction between *GSTT1* and *GSTP1* (*GSTT1\*GSTP1*), the interaction between *GSTP1* and ASD status was significant in relation to blood Hg concentrations either in a co-dominant or dominant genetic model for *GSTP1* ( $P < 0.001$ ,  $P = 0.006$ , respectively). The genetic variant in *GSTP1* is a SNP that results in an amino acid change at position 105 of the encoded protein (Ile105Val). In the co-dominant model for *GSTP1*, geometric mean (GM) blood Hg concentrations in ASD cases with genotype Ile/Ile were significantly higher than in those with genotype Ile/Val (0.66 vs. 0.43  $\mu\text{g/L}$ ,  $P = 0.01$ ). In contrast, in TD controls with the Ile/Val genotype GM blood Hg concentrations were significantly higher than in those with the Ile/Ile genotype (0.64 vs. 0.43  $\mu\text{g/L}$ ,  $P = 0.03$ ) or the Val/Val genotype (0.64 vs. 0.44  $\mu\text{g/L}$ ,  $P = 0.04$ ).

Conclusions: Findings suggest an interactive association between ASD and *GSTP1* in relation to blood Hg concentrations that is consistent with a possible role for *GSTP1* in detoxification of Hg. Although replication in other populations is warranted, these results support development of targeted interventions focused on dietary and environmental factors that could help to moderate exposure to Hg in Jamaican children.

#### **419.026 (Poster)** Screen Time and Obesity in Children with and without Autism Spectrum Disorder

A. Must<sup>1</sup>, D. Tybor<sup>2</sup>, A. Bowling<sup>3</sup>, M. Eliazziw<sup>1</sup>, T. Kral<sup>4</sup>, S. Magaña<sup>5</sup>, L. Sikich<sup>6</sup>, H. Stanish<sup>7</sup>, L. G. Bandini<sup>8</sup> and C. Curtin<sup>9</sup>, (1)Tufts University School of Medicine, Boston, MA, (2)Public Health and Community Medicine, Tufts University, Boston, MA, (3)School of Health Sciences, Merrimack College, North Andover, MA, (4)University of Pennsylvania School of Nursing, Philadelphia, PA, (5)Steve Hicks School of Social Work, University of Texas at Austin, Austin, TX, (6)Department of Psychiatry and Behavioral Sciences, Duke Center for Autism and Brain Development, Durham, NC, (7)Department of Exercise and Health Sciences, University of Massachusetts- Boston, Boston, MA, (8)Eunice Kennedy Shriver Center, University of Massachusetts Medical School, Worcester, MA, (9)University of Massachusetts Medical School, Waltham, MA

---

#### Background:

Children with autism spectrum disorder (ASD) are more likely to have overweight/obesity compared to children without ASD. Screen time is associated with obesity in typically developing children, but less is known about patterns of screen use in association with obesity in children with ASD.

#### Objectives:

We examined detailed information on screen use in children with and without ASD, using baseline measures from the Adolescent Brain Cognitive Development Study.

#### Methods:

ASD was defined by parental response to “Has your child ever been diagnosed with autism spectrum disorder?” From measured heights and weights, we calculated overweight/obesity using U.S. Centers for Disease Control BMI-for-age percentiles. Researchers surveyed children about daily hours of screen time, which we classified as either “passive” (watching shows/movies/videos/YouTube, gaming on computer/console/phone, or texting on phone/tablet/computer) or “social” (using Facebook/Twitter/Instagram/ Skype/Facetime). More than 2 daily hours of screen time of all types was considered “excessive,” based on American Academic of Pediatrics guidelines.

#### Results:

In 11,875 children aged 10 y (range 9-11), 52% were male, with 52% White, 15% Black, 20% Hispanic, 2% Asian, and 11% other. 2.8% (1 in 38) of boys and 0.5% (1 in 200) of girls had ASD. 32% of children had overweight/obesity. 36% of boys with ASD had overweight/obesity, compared to 32% of boys without ASD (chi-square test,  $p=0.249$ ). 34% of girls with ASD had overweight/obesity, compared to 31% of girls without ASD (chi-square test,  $p=0.69$ ). 79% of children with ASD had excessive screen time on weekdays, compared to 62% of children without ASD (chi-square test,  $p<0.001$ ). 85% of children with ASD had excessive screen time on weekends, compared to 78% of children without ASD (chi-square test,  $p=0.02$ ). On average, boys with

ASD had 7 more hours/week of passive screen time compared to boys without ASD (t- test,  $p<0.001$ ); girls with ASD had 9 more hours/week of passive screen time compared to girls without ASD (t- test,  $p<0.001$ ). In logistic regression models, higher levels of passive screen time were associated with increased risk of overweight/obesity, for both boys and girls: each additional hour of weekly passive screen time was associated with a ~2% increase in risk of overweight/obesity ( $p<0.001$ ). Boys with ASD did not have significantly higher social screen time than boys without ASD (Wilcoxon rank-sum test,  $p=0.55$ ); there also was no difference in social screen time between girls with and without ASD (Wilcoxon rank-sum test,  $p=0.41$ ). There is no evidence that the effect of screen time on overweight/obesity differed between children with and without ASD for boys or girls (interaction term in each model,  $p>0.05$ ).

#### Conclusions:

Screen time – a powerful, modifiable health behavior – is a concern for the health and development of all children. Youth with ASD may be particularly susceptible to the deleterious effects of excessive screen time. Appropriate use of screens is important not just for obesity risk, but for cognitive, behavioral, and other health-related sequelae.

#### **419.027 (Poster)** Service and Support Needs for Families of Children with a Neurodevelopmental Disability in Canada during the COVID-19 Pandemic: Caregivers' Perspectives

**M. Gonzalez<sup>1,2</sup>, A. Yusuf<sup>1,2</sup>, N. J. Wright<sup>3</sup>, M. Steiman<sup>2</sup>, A. Karpur<sup>4</sup>, A. Shih<sup>5</sup>, M. Elsabbagh<sup>1,2</sup> and K. Shikako-Thomas<sup>6</sup>,** (1)Neurology and Neurosurgery, McGill University, Montreal, QC, Canada, (2)Azrieli Center for Autism Research, Montreal Neurological Institute-Hospital, Montreal, QC, Canada, (3)Biostatistics & Health Informatics, Kings College London, London, United Kingdom, (4)Autism Speaks, Princeton, NJ, (5)Autism Speaks, New York, NY, (6)School of Physical and Occupational Therapy, McGill University, Montreal, QC, Canada

---

Background: The COVID-19 pandemic and the public health measures (e.g., closing or modification of support services) taken to manage it have disrupted the lives of Canadian children with disabilities and their families worldwide. The greater healthcare needs and dependency on community-based services of these children make them particularly vulnerable during the pandemic's preventative measures. However, insufficient attention has been paid to documenting service and support needs for this segment of the population during the pandemic. Understanding unmet needs for these families is a first step to informing immediate and long-term supports.

Objectives: To examine the impact of the COVID-19 pandemic on service and support needs for families of children with a neurodevelopmental disability in Canada.

Methods: The Global Report Survey, developed as part of The Global Report on Developmental Delays, Disorders and Disabilities, was designed to document the experiences of caregivers of children with neurodevelopmental conditions during and prior to the COVID-19 pandemic. The online survey was developed, tested, and disseminated in collaboration with caregivers of children with disabilities. Survey questions were based on COVID-19 policy guidance recommendations for persons with disabilities and included topics such as response to the pandemic and access to care and supports. The survey was active from June- July 2020 and collected information from a non-random, convenience sample of caregivers from across Canadian provinces and territories. Descriptive analysis was conducted to illustrate families' needs.

Results: A sample of 883 caregivers of children with disability ranging from 0 to 41 years (57.8% males and 42.1% females) completed the survey. A third of the sample (34%) reported having a child with an autism diagnosis. Close to half of the caregivers who completed the survey indicated that during the pandemic it had been difficult to: get their regular helpers or caregivers to come if they needed them (43%), get help from their family or community for the person with the disability in their home (41.1%), and get schooling (daycare, pre-school, or school) for their child (48%). Almost half reported no access to services in a clinic for their child's physical health (44.4%) or mental health (46.1%). Over a third of caregivers reported having no access to telehealth services for their physical health (35%) or their mental health (34%). Only 30% reported having access to educational plans for schooling their child at home and 21% reported having access to accessible COVID-19 information for their children.

Conclusions: Challenges faced by these families include difficulties: (1) maintaining their formal and informal support networks (regular helpers, family, community), (2) accessing regular or telehealth services for their children or themselves, (3) obtaining educational plans for schooling their children at home, and (4) accessing accessible information for their children. Optimizing access to services and supports during the pandemic is critical to mitigating potential long-term adverse impact on health and wellbeing for these children and their caregivers. Findings will be shared with relevant stakeholders at the local, provincial, and federal levels to inform decisions, policies, and programs to support families' needs.

#### **419.028 (Poster)** Symptom Severity Outcomes of COVID-19 Confinement Among Youth with Autism

### Background:

The 2019 novel coronavirus disease (COVID-19) pandemic is a rapidly evolving global emergency. Shelter-in-place and social distancing orders in response to the COVID-19 outbreak have disrupted routines, removed social outlets, and decreased or eliminated specialized support. While most research has focused on investigating the social and psychological impacts associated with stay-at-home orders in the general population, very little is known regarding mental health outcomes in vulnerable developmental populations. Youth with autism spectrum disorder (ASD) are particularly at increased risk for adverse consequences due to the higher prevalence of depression and anxiety disorders in individuals with the disorder.

### Objectives:

To explore the psychosocial effects on youth with ASD during the COVID-19 outbreak in order to constructively inform responses across communities.

### Methods:

The present study sought to examine the impact of COVID-19 in 56 youth between 10 and 16 years of age ( $n_{ASD} = 25$ ,  $n_{TD} = 31$ ). Participants underwent neuropsychological assessments before the onset of the pandemic including the Wechsler Abbreviated Scale of Intelligence (WASI II), Autism Diagnostic Observation Schedule (ADOS-2), and Behavior Assessment System for Children (BASC-2), used to pre-screen youth for major psychopathology. Measures collected during the enforced lockdown period in South Florida include the Social Psychological Measurements of COVID-19, used to assess parental perceived threat and personal experience of the COVID-19 pandemic, The Perceived Stress Scale for Children (PSS-C), Screen for Child Anxiety and Related Emotional Disorders (SCARED), Mood and Feeling Questionnaire (MFQ) and The Child and the Youth Resilience Measure (CYRM). One-way ANOVAs were performed to examine if there is a significant difference in pre-pandemic and lockdown symptom severity scores between diagnostic groups. Additionally, multiple linear regressions were performed to investigate if any clinical characteristics among children with ASD would predict a greater intensity of anxiety and depressive symptoms following the COVID-19 outbreak. In each regression, the covariates of age, IQ, and SES were entered in the model as fixed effects.

### Results:

Examination of baseline symptom levels of anxiety and depression in youth with ASD, compared with matched controls using the BASC-2 parent rating scales demonstrate significantly elevated depression symptoms for children with ASD (**Figure 1**). Additionally, children with ASD experienced significantly elevated anxiety ( $F(1,54) = 14.42$ ,  $p = 0.003$ ) and depressive symptoms ( $F(1,54) = 7.45$ ,  $p = 0.009$ ) in the context of confinement as compared with their TD peers (**Figure 2**). Pre-pandemic depressive symptoms and perceived parental threat of COVID-19 explain a significant amount of variance in depressive symptoms during lockdown ( $F(2,19) = 25.13$ ,  $p < 0.001$ ).

### Conclusions:

The COVID-19 outbreak has undoubtedly resulted in increased difficulties among ASD individuals. In line with previous research indicating that pre-existing psychological difficulties predict poorer outcomes following lockdown, we provide novel evidence that youth with ASD with depressive symptoms predating the COVID-19 outbreak are more likely to exhibit more severe outcome scores. Among vulnerable populations, youth with ASD are of particular concern for the impact that the COVID-19 outbreak may have on their wellbeing, and thus require special attention.

**419.029** (Poster) The Relationship between Childhood Weight Status and Autism Spectrum Disorder Varies By Age in a Sample of Sibling Dyads

A. Must<sup>1</sup>, A. Bowling<sup>2</sup>, T. Kral<sup>3</sup>, S. Magaña<sup>4</sup>, L. Sikich<sup>5</sup>, H. Stanish<sup>6</sup>, D. Tybor<sup>7</sup>, L. G. Bandini<sup>8</sup>, C. Curtin<sup>9</sup> and M. Eliasziw<sup>1</sup>, (1)Tufts University School of Medicine, Boston, MA, (2)School of Health Sciences, Merrimack College, North Andover, MA, (3)University of Pennsylvania School of Nursing, Philadelphia, PA, (4)Steve Hicks School of Social Work, University of Texas at Austin, Austin, TX, (5)Department of Psychiatry and Behavioral Sciences, Duke Center for Autism and Brain Development, Durham, NC, (6)Department of Exercise and Health Sciences, University of Massachusetts- Boston, Boston, MA, (7)Public

Background:

Several studies, conducted in both clinical and community-based samples, report that children with autism spectrum disorder (ASD) are more likely have overweight or obesity compared to children without ASD. These studies may provide biased estimates because they are limited in their ability to account for potentially important socio-demographic, familial, environmental, and community characteristics that may differ between these two groups of children. Studies of siblings in “simplex” families (i.e., families that include only one offspring with ASD) avoid these potential pitfalls.

Objectives:

The aim of the present study was to estimate the prevalence of overweight/obesity among children with and without ASD across childhood ages from a sample of sibling dyads.

Methods:

The Simon Simplex Collection Version 15.3 was used to create sibling dyads comprising of a child with a clinically confirmed diagnosis of ASD and a full sibling without ASD within the same family, all between the ages of 4-18 years. The full sibling without ASD was chosen to be closest within 5 years of age to the child with ASD. Body mass index (BMI) z-scores and corresponding percentiles were calculated using World Health Organization (WHO) growth references from measured heights and weights. Children who were underweight ( $< 5^{\text{th}}$  percentile) were excluded from the present study. The remaining children were classified as healthy weight ( $\geq 5^{\text{th}}$  to  $< 85^{\text{th}}$  percentile), overweight ( $\geq 85^{\text{th}}$  to  $< 95^{\text{th}}$  percentile) and obese ( $\geq 95^{\text{th}}$  percentile). Prevalence of overweight/obesity ( $\geq 85^{\text{th}}$  percentile) across six age strata was estimated from a log-binomial model using a generalized estimating equations approach to account for the correlation between children with ASD and their full siblings, and to adjust the estimates for age and sex.

Results:

A total of 1608 sibling dyads were available for analysis. The mean (standard deviation) age of the children with and without ASD was 9.3 (3.2) years and 9.2 (3.6) years, respectively ( $p = 0.37$ ). Children with ASD were significantly more likely to be male than their siblings (86% vs 46%,  $p < 0.001$ ). Eighty percent were of white race. Overweight/obesity rates varied significantly across the age strata ( $p < 0.001$ ), with higher rates and larger differences observed between children with ASD and their full siblings at older ages. At 4-7 years, 28% vs 30% ( $p = 0.61$ ) had overweight/obesity?, 7-9 years 36% vs 33% ( $p = 0.37$ ), 9-11 years 46% vs 42% ( $p = 0.38$ ), 11-13 years 50% vs 39% ( $p = 0.031$ ), 13-15 years 49% vs 37% ( $p = 0.056$ ), 15-18 years 48% vs 31% ( $p = 0.031$ ).

Conclusions:

From this unique data resource that accounted for shared family environments by analyzing sibling dyads, the prevalence of overweight/obesity diverged significantly at older ages between children with ASD and their full siblings without ASD. For children with ASD, the prevalence of overweight/obesity leveled off at approximately 50% at 9 years of age but declined for their siblings without ASD, from 42% to 31% from ages 9 through 18 years. Recognizing these age-related differences has important implications for targeting preventive interventions.

**419.030 (Poster)** Understanding Sex-Specific Autism Spectrum Disorder Phenotypes: Total Population Study on Korean School-Aged Children

**H. H. Kim<sup>1</sup>, H. Kim<sup>2</sup>, Y. J. Koh<sup>3</sup>, B. L. Leventhal<sup>1</sup> and Y. S. Kim<sup>1</sup>,** (1)Department of Psychiatry and Behavioral Sciences, University of California San Francisco, San Francisco, CA, (2)Harvard T.H. Chan School of Public Health, Boston, MA, (3)The Korea Institute for Children's Social Development, Rudolph Child Research Center, Seoul, Korea, Republic of (South), (4)Department of Psychiatry and Behavioral Sciences, University of California, San Francisco, San Francisco, CA

---

**Background:** Male:female prevalence in ASD ranges from 2.7:1 to 6:1 and is more pronounced in “clinical populations” ascertained from clinics, disability registries, or special schools. Variable sex ratios suggest possible underdiagnosis of females with ASD due to the sex-specific ASD phenotypes or camouflaging in females. Representative, community cohorts of individuals

diagnosed with ASD including both clinical and “non-clinical” (never received any services) populations can address this concern. Therefore, this study compares clinical presentations in children ascertained from both populations.

**Objectives:** Using a representative, epidemiologically-ascertained populations, we examined current cognitive abilities and ASD symptom severity between males and females diagnosed with ASD, as well as types and ages at initial caregiver concerns during early development.

**Methods:** Using the total population-based ASD prevalence study in Korean school-aged children (Male=158, Female=46), we examined the “clinical” and “non-clinical” ASD populations. We extracted the information from ADI-R (Autism Diagnostic Interview-Revised) questions to determine age of symptom onset, along with qualitative analysis of caregiver responses. We compared mean age of initial concerns, performance IQ from Korean WISC-III, and Leiter International Performance Scale-Revised, domain-level calibrated severity scores (CSS) from Autism Diagnostic Observation Schedule (ADOS), and raw scores from ADI-R, Autism Spectrum Screening Questionnaire (ASSQ), Social Responsiveness Scale (SRS), Behavioral Assessment System for Children-2 (BASC-2) between males and females in clinical and non-clinical populations.

**Results:** While the mean age of initial concerns was younger in females (N=5, 8 months) than males (N=29, 20 months), it was not statistically significant due to the small female sample size in the clinical population ( $p=0.09$ ). In the non-clinical population, there was no significant difference between males (N=129, 40 months) and females (N=41, 43 months) ( $p=0.5$ ). Sex differences in the most common parental concerns in both clinical and non-clinical populations were not significant. Lower performance IQ for clinical population females (44.2) compared to males (68.5) was a trend ( $p=0.08$ ); there were no IQ differences between non-clinical females (92.3) and males (89.5) ( $p=0.5$ ). Phenotypically, clinical population males and females had similar scores for the ADOS, ADI-R, ASSQ, and SRS. However, non-clinical males showed higher ADOS CSS and ADI-R Restricted and Repetitive Behaviors index raw scores than females ( $p<0.01$ ). On the BASC-2, clinical females showed higher somatic problem scores than males ( $p<0.01$ ). Non-clinical females had higher withdrawal problem scores than males ( $p<0.01$ ), while males trended toward higher aggressiveness ( $p=0.02$ ), hyperactivity ( $p=0.07$ ), inattention ( $p=0.05$ ), and conduct problem ( $p=0.08$ ) scores than females.

**Conclusions:** Consistent with previous studies, we found that clinical females were more severely impaired, exhibited earlier initial signs of ASD, and had lower cognitive scores than males. However, non-clinical females were less impaired, had milder ASD symptoms, and showed fewer behavioral problems than males. Results from this small sample suggest that the clinical presentation of females make them less likely to be identified and diagnosed. Future studies in large, diverse communities are necessary to replicate the findings which will inform families, educators, and clinicians for early identification and intervention, especially for females with ASD.

#### Background:

Autism spectrum disorder (ASD) is a heterogeneous condition in both clinical presentation and genetic architecture. There are ~100 known high-impact copy number variations (CNVs) or single genes already associated with ASD, and others still to be found. There are also mounting data of more complex combinations of rare and common genetic variants contributing to baseline susceptibility to ASD. To fully understand the genetic basis of ASD at the level of the individual and/or family, whole-genome sequence (WGS) data are therefore necessary.

#### Objectives:

We aim to: (1) further build a massive WGS and accompanying phenotype data resource from ASD-affected individuals and their family members and make it as openly available for research as possible; and (2) better define the relationships between genotype and clinical expression to further advance clinical management and improve the health of individuals with ASD.

#### Methods: N/A

#### Results:

Firstly, we have developed the Autism Speaks MSSNG project, a controlled-access resource which is available to qualified researchers with a valid ASD-related research question. Hosted on the Google Cloud Platform (GCP), MSSNG can be accessed through a web-based portal or, for advanced users, via GCP interfaces. The latest release of MSSNG, termed DB6, contains 11,359 whole-genome sequences (DB7 coming in 2021). Alignment data (GRCh38/hg38) are available in CRAM format, along with single nucleotide variant (SNV) and indel calls. Additionally, we employed a highly accurate workflow to detect CNVs and have uniquely made these sample-level CNV calls available.

Secondly, we have performed a comprehensive analysis of the MSSNG WGS data, taking into consideration all sizes, types, and frequencies of genetic variants. Along with SNVs, indels and CNVs, we considered tandem repeat expansions, which we recently showed for the first time to be involved in ASD susceptibility, as well as structural variants (SVs) such as inversions and insertions, and mitochondrial mutations. In addition to clinically-relevant rare or *de novo* variants, we assessed common variants risk. Specifically, we calculated a polygenic risk score (PRS) for all individuals of European ancestry in MSSNG using summary statistics from the European iPSYCH association study (p-value threshold  $\leq 0.1$ ) comparing ASD-affected individuals with unaffected relatives. We demonstrated that the average PRS was higher in ASD-affected individuals compared with unaffected individuals ( $p = 1.2E-3$ ,  $R^2 = 0.15\%$ ), and that in ASD-affected individuals not harbouring a clinically significant rare or *de novo* variant, PRS was correlated with the severity of ASD-related traits. To validate any of our genome-wide findings from MSSNG,

we used WGS data from 9,205 ASD-affected individuals and their family members from the Simons Simplex Collection, and tested thousands of controls.

Conclusions:

We contextualize comprehensive rare variant data with PRS scores for the first time to provide a more complete view into the genomic architecture in ASD. The project has also enabled hundreds of deep phenotyping queries and the return of results to specific families. Ongoing functional experiments are underway including the development of induced pluripotent stem cells from individuals carrying variants of interest, integrated epigenetic analyses, and long-read sequencing in families with multiple affected individuals.

**310.002** (Oral) Development and Implementation of a Framework for an Evidence-Based Gene List Relevant to Autism Spectrum Disorder

**O. Rennie<sup>1</sup>, C. Schaaf<sup>2</sup>, N. Hoang<sup>1</sup>, J. Howe<sup>1</sup>, S. W. Scherer<sup>1</sup> and J. Vorstman<sup>1</sup>, (1)The Hospital for Sick Children, Toronto, ON, Canada, (2)Baylor College of Medicine, Houston, TX**

---

**Background:** At present, there is no standardized approach for evaluating a gene's relevance to autism spectrum disorder (ASD). Consequently, substantial variability exists between various proposed lists of "ASD susceptibility/risk" genes. Given the increasing use of genetic testing for patients with ASD and other neurodevelopmental disorders, this limitation hampers uniform interpretation of genetic results. Here, we implement and expand on a systematic framework for the evaluation of ASD susceptibility genes, aimed at developing a comprehensive, transparent, and evidence-based gene list. The approach, first presented in Schaaf *et al.* (2020), was developed by an international team of multi-disciplinary experts and consists of a standardized evaluation of available genetic associations as well as the quality of the presented phenotypic data.

**Objectives:** To implement a multi-disciplinary consensus-based method for the curation of genes putatively associated with ASD risk and to compare concordance and discrepancies between our results and existing classifications.

**Methods:** Briefly, this framework curates published genetic, phenotype, and experimental ASD data. Using the Clinical Genome (ClinGen) Gene-Disease Validity framework as a starting place, points are awarded to each clinical/experimental case. Points are summed across all studies for a given gene, with the total dictating the gene classification (limited, moderate, or definitive relationship to ASD). See PMID: 32317787 for full methodology details. Using this framework, we have thus far evaluated 53 genes with a broadly assumed relevance to ASD. We compared these results with two existing standards: SFARI and ClinGen. Here we report how top scored genes by SFARI (n=42) and ClinGen (n = 11) compared to our method.

**Results:** Of the 53 genes we curated, 22 were definitive, 8 moderate, 22 limited, and one with no evidence. Of the 42 "high confidence" genes scored through SFARI, 20, 6, and 16 were evaluated as definitive, moderate, and limited by our method, respectively. Note that most genes evaluated by the ClinGen ASD/ID expert groups are not curated specifically for ASD, but rather for broader NDD phenotypes or specific syndromes that may or may not include ASD. Of the 11 genes classified as "definitive" by ClinGen for a disorder/syndrome associated with ASD, 7 were definitive, 2 moderate, and 2 limited for ASD by our method. The Venn diagram shows the comparison of the top scored genes using the three methods.

**Conclusions:** We present results from our initial work developing an evidence-based gene list relevant to ASD. Through the initial phases of this process, we provide further evidence illustrating differences that exist regarding reported gene relationships to ASD. Ideally, with continued expansion of our list of genes relevant to ASD and updates as more evidence becomes available, steps could be made to increase consistency across lists of genes used to interrogate the exome/genome in ASD patients. Evidence from our framework will not only increase discussion about this issue in the ASD research community, but ultimately, contribute to a broader agreement on the contribution of different genes to ASD. This will directly feed into genotype-phenotype research, patient care, and interpretation of genetic findings in the clinical sphere.

**310.003** (Oral) Genetic Risk on the Association of Maternal Smoking and Drinking in Pregnancy with Autism Spectrum Disorder

**J. Daniels<sup>1</sup>, K. S. Benke<sup>2</sup>, E. M. Howerton<sup>3</sup>, H. Farzadegan<sup>3</sup>, H. E. Volk<sup>1</sup>, M. D. Fallin<sup>4</sup> and C. Ladd-Acosta<sup>1</sup>, (1)Wendy Klag Center for Autism and Developmental Disabilities, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, (2)Mental Health, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, (3)Epidemiology, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, (4)Bloomberg School of Public Health, Johns Hopkins University, Baltimore, MD**

---

## Background:

Prenatal exposure to maternal smoking and drinking are considered harmful to neurodevelopment but associations with autism spectrum disorder (ASD) risk have been conflicting. Potential explanations for reported discrepancies include potential exposure misclassification, unmeasured confounding, and interaction with genetic background.

## Objectives:

Our main goal was to assess whether the effects of prenatal exposure to smoking or drinking on autism risk differ by underlying genetic variation, at individual loci or in aggregate.

## Methods:

The Study to Explore Early Development (SEED) is a multi-site autism case-control study of children aged 3-5 years. Maternal smoking and alcohol use at any point during pregnancy were ascertained using a telephone-assisted interview and genome-wide genotyping data was measured for a subset of SEED mothers and children using Affymetrix and Illumina genome-wide association study (GWAS) arrays. After data cleaning and imputation, our final genotyping analytic sample consisted of 1139 mothers (489 with an ASD case child and 650 controls) and 987 children (409 ASD cases and 578 controls). For each exposure and single-nucleotide polymorphism (SNP) (considering maternal and child genomes separately), logistic regression models were run, including a term for SNP X exposure interaction while accounting for sex, 10 principal components of ancestry, maternal education, family income, maternal age at birth and parity. In addition to single SNP X exposure tests in mothers and children, we also examined child aggregate genetic risk for autism using polygenic risk scores (ASD-PRS) informed by the largest published GWAS for ASD from the Psychiatric Genetics Consortium-iPSYCH collaboration and using discovery-p-value threshold of 0.10.

## Results:

The frequency of prenatal exposure to smoking and alcohol was 9% and 28.3%, respectively. Child ASD-PRS was significantly associated with ASD risk (adjOR=1.50;  $p=1.03*10^{-3}$ ), but did not modify associations for either exposure (p-value for interaction alcohol=0.33, smoking=0.62). However, we did identify a significant interaction between maternal smoking and maternal genotype at 4 SNPs associated with increased child ASD risk (9:138,599,878 in gene *KCNT1* (adjOR =-13764.45, p-val=  $1.37*10^{-9}$ ); 2:220,667,880 in gene *LINC02832* (adjOR =-14295.63, p-val=  $5.51*10^{-9}$ ); 10:7,141,530 in gene *AL392086.3* (adjOR =-2382.30, p-val=  $1.63*10^{-8}$ ); 6:162,602,454 in gene *PRKN* (adjOR =-1811.68, p-val=  $2.23*10^{-8}$ )). We also identified a significant interaction between maternal alcohol use and maternal genotype at 2 SNPs associated with increased child ASD risk (14:106,078,490 in gene *RP11-731F5.1* (adjOR =11.48, p-val=  $2.59*10^{-9}$ ) and 14:106,647,600 in gene *IGHV1-18*(adjOR =19.11, p-val=  $8.69*10^{-9}$ ))

## Conclusions:

We observed an increased risk for ASD among children with prenatal exposure to smoking or alcohol and whose mothers had a specific genotype at 6 loci (4 smoking and 2 alcohol). Additional larger studies are needed to confirm these findings and to identify additional SNPs our moderately sized sample may be underpowered to detect. Gene-environment interactions, such as those we identified, can help identify subgroups of children at increased risk of ASD.

### **310.004** (Oral) Diversity in Gender Identity and Its Link to Neurocognitive Polygenic Propensity Scores in the SPARK Autism Cohort

**T. R. Thomas<sup>1</sup>, A. Song<sup>2</sup>, J. F. Strang<sup>2</sup> and J. Michaelson<sup>3</sup>, (1)University of Iowa, Iowa City, IA, (2)Center for Autism Spectrum Disorders, Children's National Hospital, Washington, DC, (3)Division of Computational and Molecular Psychiatry, Iowa City, IA**

**Background:** Previous sociological studies have shown there is an enrichment in gender diversity/dysphoria (Hisle-Gorman, et al., 2019) in autistic samples as compared to the general population. Likewise, individuals who are transgender or non-binary (and do not have an autism diagnosis) are more likely to be autistic and have higher rates of autistic traits (Warrier, et al., 2020). Potential genetic factors that might contribute to this increased prevalence have not yet been explored.

**Objectives:** The objective of this analysis is to identify how common genetic variation underlying neurocognitive traits correlates with gender diversity characteristics in a sample of individuals enriched for autism.

**Methods:** The Gender Development Scale (GDS), a 90-item self-report questionnaire that captures multiple dimensions of gender diversity was administered to 818 participants in the SPARK autism cohort (60% with ASD diagnosis, 78% recorded female at birth). Exploratory factor analysis (EFA) was performed with the GDS itemset, and resulting factors were used as phenotypes to test for associations of polygenic propensity. Polygenic propensity scores, corrected for sex, autism diagnosis, and genetic principal components, were calculated for educational attainment, cognitive performance, neuroticism, autism, ADHD, and other neuropsychiatric conditions for 424 participants (45% with ASD diagnosis, 79% recorded female at birth). Statistical association analyses between the quantitative GDS factors and polygenic scores were performed.

**Results:** EFA of the GDS in this sample established five factors explaining 70.5% of the variance (CFI=.98; RMSEA=.07): binary gender diversity, non-binariness, gender neutral style, both maleness and femaleness, and genital dysphoria. Individuals on the autism spectrum were more likely to identify as a gender different from their sex assigned at birth compared to those without autism (OR=13.20, Z=4.97, p<0.0001). Increased levels of gender diversity, as represented by multiple factors from the GDS, were significantly positively correlated with polygenic propensity for educational attainment and cognitive performance.

**Conclusions:** This is the first study to analyze how common genetic variation in an autism cohort correlates with gender diversity characteristics. Using the GDS, we identified five factors expressing different aspects of gender diversity. Our results suggest that genetic factors associated with increased cognitive ability and educational attainment are associated with greater gender diversity. Furthermore, these findings suggest that the autism community is a rich resource for improving our understanding of the biological factors that influence gender identity.

## ORAL SESSION — EPIGENETICS

### Oral 325 - Beyond the Genes...Protein-Protein Interactions and Complex Epigenetics of Autism

#### 325.001 (Oral) Integrative Genomic and Epigenomic Analysis of Autism Spectrum Disorder

A. Starnawska<sup>1,2,3</sup>, C. Søholm Hansen<sup>2</sup>, D. Demontis<sup>1,2,3</sup>, J. Grove<sup>1,2,3</sup>, T. Als<sup>1,2,3</sup>, O. Mors<sup>2,3,4</sup>, A. D. Bøglum<sup>2</sup> and N. H. Staunstrup<sup>1,2,3,4</sup>, (1)Center for Genomics and Personalized Medicine, CGPM, and Center for Integrative Sequencing, iSEQ, Aarhus, Denmark, (2)The Lundbeck Foundation Initiative for Integrative Psychiatric Research, iPSYCH, Aarhus, Denmark, (3)Aarhus University, Aarhus, Denmark, (4)Psychosis Research Unit, Aarhus University Hospital, Aarhus, Denmark

**Background:** Autism Spectrum Disorder (ASD) is a group of complex neurodevelopmental disorders characterized by a pervasive impairment of social and communication skills along with repetitive and restrictive behaviors. ASD affects 1-1.5% of individuals and its risk is influenced by a combination of genetic ( $h^2$  64-91% and  $h^2_{\text{SNP}} = 0.12$ ) and environmental factors. Both genetic variation and multiple environmental exposures alter the epigenetic landscape. DNA methylation, the most studied and best understood epigenetic modification, plays a pivotal role in neuronal development, proper brain functioning, and thereby mental health.

**Objectives:** Identify DNA methylation signatures of ASD at the time of birth and specifically investigate the impact of common genetic ASD risk variants on the newborn epigenome.

**Methods:** DNA methylation levels were quantified at >850,000 loci in the human genome in 2,065 neonatal dried blood spots from the Danish iPSYCH 2012 cohort with the use of Illumina EPIC methylation array. Genotyping data from Illumina PsychChip was available for 2,022 individuals. Three different statistical methodologies were applied to study the role of DNA methylation in molecular aetiology of ASD: 1) epigenome-wide association study (EWAS) of ASD to identify loci with differential methylation between 843 cases and 688 controls; 2) EWAS of ASD polygenic risk score (PRS) (n = 2,022) to identify methylation differences associated with polygenic burden of the disorder; and 3) methylation quantitative trait loci (mQTL) analysis (n = 2,022) for common variants located within the 5 ASD risk loci (Grove et al., 2019) to determine if and where in the human genome they impact epigenetic regulation.

**Results:** ASD EWAS identified 6 differentially methylated positions at p-value <10e-05, with top finding annotated to a gene mapping *MYT1L*. Additionally, 31 differentially methylated regions, with Šidák-adjusted p-value < 0.05, were associated with ASD, mapping to genes crucial for neuron development, neuron differentiation, and synapse formation. EWAS of ASD PRS replicated previous findings where differential DNA methylation at birth was associated with elevated polygenic burden for the disorder and identified additional differentially methylated regions associated with this trait. Further mQTL analyses of common genetic variants located within the 5 ASD GWAS loci confirmed the ASD risk SNPs to impact DNA methylation levels across the genome. Moreover, employing the mQTL approach allowed for improved mapping of impact of ASD risk SNPs on

epigenomic regulation of the neonatal genome in blood and identified new loci associated with the disorder, not indicated by ASD GWAS itself.

**Conclusions:** We identified differential DNA methylation in blood at the time of birth to be associated with ASD diagnosis. Moreover, by combining epigenomic and genomic data to study the molecular aetiology of ASD, we additionally identified differential DNA methylation at the time of birth to be associated with ASD polygenic burden and provided evidence that common ASD risk variants impact neonatal epigenetic landscape, what could modify risk of this neurodevelopmental disorder.

**325.002** (Oral) Protein-Protein Interaction in Autism Spectrum Disorder  
**Z. Z. C. Naing**, University of California, San Francisco, San Francisco, CA

---

**Background:** Autism spectrum disorder (ASD) is a common neurodevelopmental disorder characterized by impaired social and communication skills along with repetitive behaviors, and restrictive interests. In recent years, advances in whole exome sequencing technologies, as well as improved data analysis approaches have led to a better understanding of the genetic architecture of ASD. It is estimated that 30% of ASD cases can be attributed to *de novo* mutations. Focusing on *de novo* mutations and rare variations in ASD-affected families and case-control populations with matched ancestry, 102 high confidence ASD risk genes have been discovered.

**Objectives:** Despite advances in understanding the genetics behind ASD, the mechanisms by which these genes regulate the neurobiology underlying ASD is poorly understood. Mapping protein interactions networks of proteins encoded by ASD risk genes can facilitate the discovery of molecular pathways and disease mechanisms relevant for ASD and in the future lead to next-generation therapeutics. This is highly relevant as proteins do not act alone to carry out their functions, but dictate a multitude of cellular activities that maintain health or diseases through their interaction with other proteins.

**Methods:** To map the protein-protein interactions of ASD risk genes, we transiently transfected 92 affinity tagged constructs of 102 top ASD risk genes in HEK293T cells and performed affinity purifications of these proteins followed by mass spectrometric analysis (AP-MS). To analyze the MS data, we applied a multi-step bioinformatics pipeline combining the AP-MS scoring algorithms SAINT and CompPASS for identification and quantification of high confidence interacting proteins.

**Results:** This analysis resulted in the identification of 887 unique protein interactors, out of which 26 interactors are shared among these 92 ASD risk genes. We observed many of these protein interactors to be a part of stable protein complexes (such as SIN3-HDAC complexes). Moreover, we also observed enrichment of common Gene Ontology (GO) functional annotations among these interactors such as chromatin modification and nuclear transport.

**Conclusions:**

This strengthens the hypothesis that there might be common pathways leading to the disorder. The interaction map of proteins encoded by ASD risk genes can serve as the first step to deduce molecular pathways and cellular processes that might be dysregulated by ASD variants.

**325.003** (Oral) Identification of DNA Methylation Changes in Child Blood Associated with Prenatal Exposure to Infection in the Context of Autism Spectrum Disorder

**E. M. Howerton**<sup>1,2</sup>, **M. Brucato**<sup>1,2</sup>, **Y. Qian**<sup>3</sup>, **J. Daniels**<sup>3</sup>, **A. Y. Song**<sup>3</sup>, **H. Farzadegan**<sup>1</sup>, **K. S. Benke**<sup>2,4</sup>, **H. E. Volk**<sup>2,4</sup>, **L. A. Croen**<sup>1</sup>, **M. D. Fallin**<sup>2,4</sup> and **C. Ladd-Acosta**<sup>1,2</sup>, (1)Epidemiology, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, (2)Wendy Klag Center for Autism and Developmental Disabilities, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, (3)Division of Research, Kaiser Permanente, Oakland, CA, (4)Mental Health, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD

---

**Background:** Prenatal exposure to infection is a well-recognized risk factor for autism spectrum disorder (ASD). There is substantial interest in whether DNA methylation, a type of epigenetic mark, is associated with prenatal exposure to infection because it could provide biologic insights into observed associations or serve as an infection biomarker for studies that did not collect that information.

**Objectives:** We conducted an epigenome-wide association study (EWAS) to identify DNA methylation sites in child peripheral blood associated with prenatal exposure to infection. At specific DNA methylation sites related to exposure, we will also examine whether methylation levels vary by ASD status.

**Methods:** We conducted our analysis using data from the Study to Explore Early Development (SEED), a case-control study of ASD in the United States among children born between 2003 – 2006. Participants were aged 2 – 5 years at the time of enrollment, with an average age of 5 years at the time of blood sample collection. Prenatal exposure to infection was reported by the mother during a telephone-assisted interview, including by trimester. DNA methylation measurements in child peripheral blood were obtained from the Illumina 450K array for ASD cases and population controls, with samples randomized across plates and processing date and rigorous quality control measures applied at the sample and marker levels. The final analytic sample included 898 individuals (409 ASD and 489 controls) and 455,664 probes. We used linear regression models to identify differentially methylated loci associated with exposure to infection in each trimester of pregnancy and in the 3 months prior to conception, while adjusting for 11 surrogate variables to correct for measured and unmeasured confounders.

**Results:** The frequency of any infection during pregnancy was 37%, and 9.6% of mothers experienced an infection during the pre-conception window. We identified three statistically significant loci, all of which were hypomethylated when comparing those exposed to infection to unexposed: one locus in an intergenic region on chromosome 5 associated with maternal infection during the pre-conception window (q-value = 0.002), and two loci associated with maternal infection during trimester 3, one on chromosome 19 (*SHANK1*, q-value = 0.010) and one on chromosome 3 (*IQSECI*, q-value = 0.018). The genes associated with infection in trimester 3, *SHANK1* and *IQSECI*, have both been implicated in neurodevelopment, with rare mutations in *SHANK1* previously identified in ASD. We are currently performing secondary analyses to examine whether these methylation changes are also related to ASD case status and plan to report those results as well.

**Conclusions:** Three loci show differential methylation in child blood associated with maternal infection during trimester 3 or the pre-conception period. The changes we identified warrant further investigation to fully evaluate their potential role in autism etiology or their utility as a biomarker of prenatal exposure to infection, which can advance future epidemiologic studies in ASD.

**Background:** An increasing body of evidence implicates dynamic epigenetic mechanisms to play a crucial role in neuronal development, proper brain functioning, and mediating risk of psychiatric disorders, including autism. Many currently prescribed medications, including anti-psychotic, anti-epileptic and anti-depressant drugs, as well as dietary supplements, like folic acid or vitamin D, have been shown to have lasting effects on the epigenome.

**Objectives:** Since the epigenome is particularly vulnerable to the effect of environmental factors during embryogenesis, when the rate of DNA synthesis is high and the epigenetic marks are being established, we aimed to answer a question if fetal exposure to maternal medication during pregnancy can alter DNA methylation (DNAm) patterns of the child and thereby potentially mediate disease susceptibility after birth.

**Methods:** This study was performed using the MINERVA-iPSYCH case-control sample selected from the Danish iPSYCH 2012 cohort, where neonatal DNAm levels were quantified at >450,000 loci in the human genome by using Illumina's 450K methylation array in 627 autism cases and 633 matched controls. Information on exposure to medication prescribed for 10 common medical conditions during pregnancy: 1) Obesity, metabolic syndrome, hypertension, hyperlipidemia, preeclampsia/eclampsia, 2) Infections, 3) Bacterial infections, 4) Fungal infections, 5) Asthma/chronic obstructive pulmonary disease, 6) Asthma/Premature labor, 7) Allergies, 8) Seizure disorders/epilepsy, 9) Neuropsychiatric disorders, and 10) Autoimmune and inflammatory diseases (excluding diabetes) was obtained for all individuals from the Danish Prescription Registry. In order to identify DNAm changes in newborns exposed *in utero* to different classes of maternal medication we performed 10 epigenome-wide association studies (EWAS), one for each medication class, with DNAm at each tested locus as the outcome variable, exposure to maternal medication as predictive variable, and adjusted the EWAS models for well-established confounders in epigenomic studies (sex, gestational age, blood cell composition, maternal tobacco smoking).

**Results:** Number of individuals exposed to maternal medication varied greatly depending on the medication class tested, with the largest groups of newborns exposed to medication for infections (n = 502), especially bacterial (n = 492), followed by asthma/chronic obstructive pulmonary disease (n = 94) and neuropsychiatric disorders (n = 55). Differential DNAm (p-value <10e-06) was associated with *in utero* exposure to maternal medication during pregnancy in 8 out of 10 performed EWAS analyses. Of specific interest to mental disorders was identification of differential DNAm levels in offspring in the histone deacetylase 4 (*HDAC4*) gene (p-value = 3x10e-07) to be associated with maternal use of neuropsychiatric medication.

**Conclusions:** In this study neonatal differential DNAm in blood was associated with exposure to maternal medication use during pregnancy in a cohort of autism cases and controls for the majority of tested medication classes. We are replicating and will meta-analyze these findings by including methylomic and maternal medication data on additional 2065 newborns (autism/ADHD cases and controls) from the iPSYCH cohort.

## POSTER SESSION — EPIGENETICS

### Poster 420 - Epigenetics Posters

**420.001** (Poster) Alteration in Epigenetic Histone Deacetylase Enzymes in Autism Spectrum Disorder Revealed By In Vivo PET-MRI Neuroimaging

**J. Tseng<sup>1,2</sup>, B. G. Hightower<sup>1</sup>, A. J. Parmar<sup>1</sup>, J. E. Mullett<sup>3</sup>, C. J. McDougale<sup>2,3</sup>, J. M. Hooker<sup>1,2</sup> and N. R. Zurcher<sup>1,2</sup>**, (1)Athinoula A. Martinos Center for Biomedical Imaging, Department of Radiology, Massachusetts General Hospital, Charlestown, MA, (2)Harvard Medical School, Boston, MA, (3)Lurie Center for Autism, Massachusetts General Hospital, Lexington, MA

#### Background:

Prenatal exposure to histone deacetylase (HDAC) inhibitors has led to autism-like behavior in rodent models (Schneider, 2005) and been associated with autism spectrum disorder (ASD) in humans (Christensen, 2013), suggesting that epigenetic HDAC enzymes may play a role in the etiology of ASD. Environmental factors that have been linked to the etiology of ASD (Modabbernia, 2017) also lead to alterations in HDACs (Ferland, 2011; Ramirez, 2008). Postmortem work has shown altered acetylation in ASD-associated genes in children and adults (Sun, 2016), though no study has yet investigated HDAC expression in individuals with ASD *in vivo*.

#### Objectives:

In this pilot study we used positron emission tomography-magnetic resonance imaging (PET-MRI) with [<sup>11</sup>C]Martinostat to determine if HDAC levels are regionally altered in the brain of individuals with ASD. We further investigated whether HDAC expression is associated with behaviors that characterize ASD, including impaired language, social skills and repetitive behaviors.

#### Methods:

Seven participants with ASD (5M/2F, mean age=26.1±6.9years) and seven age- and sex-matched controls (CON) (5M/2F, mean age=26±5.2years) completed a [<sup>11</sup>C]Martinostat PET-MRI scan. Individuals with ASD met diagnosis according to DSM-5 criteria, supported by standard cutoff scores on the Autism Diagnostic Observation Schedule, second edition (ADOS-2) and Autism Diagnostic Interview-Revised (ADI-R), and did not have epilepsy. Controls did not have a first-degree relative with ASD, or a history of a neurological or psychiatric disorder. PET data were collected from 60-90 minutes post-injection of [<sup>11</sup>C]Martinostat. The Aberrant Behavior Checklist (ABC), Social Responsiveness Scale (SRS), and Repetitive Behavior Scale (RBS) were completed by the caretaker and the Peabody Picture Vocabulary Test was administered to the individual with ASD. Whole brain voxelwise analyses were performed using FSL's FEAT (FMRIB software library) with ordinary least squares mixed-effects modeling and age and sex as regressors of non-interest ( $Z > 2.3$ , cluster-corrected  $p = 0.05$ ) to compare [<sup>11</sup>C]Martinostat uptake between the two groups and correlate behavioral scores with [<sup>11</sup>C]Martinostat uptake in ASD.

#### Results:

Higher [<sup>11</sup>C]Martinostat uptake was found in the visual cortex bilaterally in ASD compared to CON. Lower [<sup>11</sup>C]Martinostat uptake was found in the anterior and middle cingulate cortex bilaterally, and right Heschl's gyrus, middle temporal gyrus, globus pallidus, and amygdala in ASD compared to CON. [<sup>11</sup>C]Martinostat uptake correlated positively with the ABC lethargy/social withdrawal subscale in the right orbitofrontal cortex and correlated negatively with the ABC inappropriate speech subscale in the

corticospinal tract and brainstem bilaterally and with the total SRS score in the left frontal white matter in ASD. No other behavioral score correlated with [<sup>11</sup>C]Martinostat uptake in ASD.

Conclusions:

Individuals with ASD showed epigenetic alterations in brain regions associated with socio-cognitive processing and previously implicated in ASD in functional MRI studies (*Patriquin, 2016*). This is the first report of associations between ASD-related behavior and regional HDAC alterations *in vivo*. However, the current sample size is small and [<sup>11</sup>C]Martinostat PET-MRI data from more participants will be needed to determine if HDAC alterations are a common feature in ASD as previously suggested by post mortem work (*Sun, 2016*) and to further understand the association between HDAC levels and ASD-related behavior.

**420.002 (Poster)** Characterization of Screen Exposure in Preschoolers with ASD and Neurotypical Controls and Its Association with Behavioral Problems

*G. Garrido<sup>1</sup>, C. Amigo<sup>2</sup>, G. Lamas<sup>3</sup> and F. Cardoso<sup>1</sup>, (1)Universidad de la República, Montevideo, Uruguay, (2)Clinica de psiquiatria pediátrica Facultad de medicina, UDELAR, Montevideo, Uruguay, (3)Centro Hospitalario Pereira Rossell, Montevideo, Uruguay*

---

Background: Given the ubiquitous screen use since early stages of development, and their parental use as a tool to regulate child behaviour, it is our interest to know the characteristics of electric device use and compare it with American Academy of Pediatrics recommendations in a specific clinical population of preschoolers with Autism Spectrum disorders (ASD) and a healthy control sample paired by age and gender. An emerging literature states that electronic device exposure as a risk factor for autistic-like symptoms, but evidence is inconclusive yet.

Objectives: The objective of the present study is to describe and compare the characteristics of electronic device use in a population of preschoolers with ASD diagnosis. We also aim at identifying possible associations between excessive screen exposure and behavioral and emotional problems.

Methods: Descriptive transversal study. A convenience sample was used, composed by 27 preschoolers with ASD diagnosis who were referred to the outpatient clinic specialized in ASD at Pereira Rossell Hospital, and 54 typically developing controls matched by age and gender. Controls were either hospitalized because of acute disease or consulted in the ER or at different polyclinics. Time of screen exposure, age at first exposure, adequacy according to AAP recommendations were analyzed as independent variables. Bivariate analysis of the aforementioned variables with syndromes and problems according to CBCL 1 1/2- 5 scales were done.

Results: An extended screen exposure and electronic device use was observed in both studied groups. Less than 10 per cent of the total sample had an adequate time of screen exposure according to AAP guidelines. No statistically significant differences were found in the studied variables between clinical and control group. Association between a longer time of exposure and behavioral and clinical syndromes was found in the non clinical group.

Conclusions: Screen device use is widely extended in the preschool population in general. First exposure occurs at early age. Our study could not demonstrate a greater use of electronic devices in children with ASD. Larger studies are required to deepen knowledge in the field. Advice to parents in well child visits regarding a healthy use of electronic devices is necessary.

**420.003 (Poster)** Poor Sperm DNA Quality and DNA Methylation Alterations: Possible Implications in Offspring Susceptibility for ASD.

*S. N. Khan<sup>1</sup>, A. Katiyar<sup>2</sup>, S. Gulati<sup>3</sup> and R. Dada<sup>1</sup>, (1)Laboratory for Molecular Reproduction and Genetics, Anatomy, All India Institute of Medical Sciences, New Delhi, New Delhi, India, (2)Computational Genomics Centre, Division Of Biomedical Informatics, Indian Council Of Medical Research, New Delhi, India, New Delhi, India, (3)Centre of Excellence and Advanced Research for Childhood Neurodevelopmental Disorders, Child Neurology Division, Department of Pediatrics, All India Institute of Medical Sciences, New Delhi, India*

---

Background:

Extensively documented that Advanced paternal age (APA) causes accumulation of Reactive Oxygen Species (ROS), promoting increased seminal oxidative stress, which induces apoptosis and oxidative damage to sperm DNA in the form of DNA fragmentation. Evidence supports that poor quality sperm DNA and epigenetics, specifically DNA methylation alterations, likely

plays a role. In this study we have explored the impact of DNA damage and DNA methylation alterations in mature human sperm obtained from the fathers of children suffering from ASD and its possible association with Autism.

#### Objectives:

We tested for **a)** ROS and DNA Fragmentation Index (DFI) in semen samples of ASD fathers and healthy controls and **b)** the relationship of paternal sperm DNA methylation, examining a cohort of fathers of ASD children with their children and comparative analysis with healthy controls.

Methods: 8IP Elisa was used to estimate ROS levels and DFI estimation was done by Flow cytometry (SCSA Protocol) in 28 samples each, paternal and control semen. We examined genome-wide DNA methylation (DNAm) in paternal semen samples obtained from fathers of children suffering from ASD (Age > 30 years) along with peripheral blood samples of ASD patients (Age 36 months). A case control model of study was followed where unrelated age and gender matched healthy control semen samples and blood samples were taken and compared with ASD fathers and ASD patients respectively, along with blood samples obtained from the siblings of ASD patients as internal healthy control. We analysed methylation data of 32 samples, including thirteen (13) semen samples [Case (N=06)/Control (N=07)] and nineteen (19) peripheral blood samples [Case (N=06)/Control (N=07)/Siblings (N=06)] using the Infinium HumanMethylation850 (EPIC array) an adapted genotyping microarray that covers over 850,000 CpG methylation sites. Methylation data was investigated in ChAMP (Chip Methylation Analysis Pipeline) Bioconductor package. Differentially methylated sites/regions (DMRs) were calculated using limma package in R.

Results: On the basis of beta value ( $\Delta\beta \geq 0.2$ ) and P value ( $< 0.05$ ), we observed thousands of DMRs. The observed data was mapped against the available ASD data bank (SFARI) and 87.08% ASD genes in SFARI database were covered by identified significant methylated genes (beta value  $\pm 0.2$ ) from this study. Significantly methylated genes were further mapped on the Kyoto Encyclopedia of Genes and Genomes (KEGG) database and observed that genes were dominantly associated with developmental processes, synapse formation, sensory motor conduction, inflammatory pathways, innate immunity and cancer, among paternal sperm samples of ASD fathers and ASD patients as compared to healthy controls. It was observed that DFI% was significantly high (p value:  $< 0.0001$ ) in paternal semen (55.00) as compared to healthy controls (23.79.38) and 8IP levels (ROS) were also significantly high (p value  $< 0.0001$ ) in paternal semen ( $156.47 \pm 36.02$ ) as compared to healthy controls ( $84.41 \pm 8.94$ ).

#### Conclusions:

Poor sperm DNA quality associated with advance age impact sperm epigenome. This study suggest that DNA damage are causal of epigenetic differences in paternal sperm which may contribute to autism risk in offspring and also provides an evidence that consistently directional and potentially related epigenetic mechanisms may be operating in ASD.

## POSTER SESSION — ETHICS

### Poster 421 - Ethics Posters

**421.001** (Poster) Use of a Best Practice Alert (BPA) to Increase Diversity within a US-Based Autism Research Cohort  
**G. Duhon**<sup>1,2</sup>, **A. R. Simon**<sup>3</sup>, **D. L. Limon**<sup>1,4</sup>, **G. Marzano**<sup>2,5</sup> and **R. P. Goin-Kochel**<sup>3</sup>, (1)Texas Children's Hospital, Houston, TX, (2)Baylor College of Medicine, Houston, TX, (3)Trinity University, San Antonio, TX, (4)308 W North Temple, Baylor College of Medicine, Salt Lake City, UT, (5)Psychology, Texas Children's Hospital, Houston, TX

**Background:** Effectively recruiting racially and ethnically diverse samples is key to ensuring representative research data and scientific outcomes with broad application. We recently demonstrated that introducing the SPARK study (Simons Foundation Powering Autism Research) for individuals with autism spectrum disorder (ASD) via a Best Practice Alert (BPA) at the point-of-care in select subspecialty practices reached more racially diverse families compared to other recruitment strategies. It is possible that this strategy could further increase sample representativeness when strategically placed in clinic locations that serve racially/economically underrepresented families.

**Objectives:** To (a) examine rates of interest in the SPARK study between families receiving the BPA in *subspecialty practices* versus *select pediatric primary care practices* that serve racially/economically diverse communities; and (b) examine provider responsiveness to the BPA based on patient race and payor status (a surrogate measure of socioeconomic status).

**Methods:** The SPARK team at Texas Children's Hospital (TCH) worked with EPIC support staff to extend the existing SPARK BPA to five Texas Children's Pediatrics (TCP) locations that were selected based on both (a) number of patients with ASD and (b) prevalence of Black/African American and Asian patients served, as these groups were underrepresented at the TCH SPARK site. The BPA contained study information and fired upon chart opening for patients who met the trigger criteria for eligibility. Once a response was recorded (family was reportedly *Interested*, *Enrolled*, or *Declined*), the study team received notification through EPIC and contacted *Interested* and *Enrolled* families. Providers also had a *Dismiss* option that silenced the BPA until the chart opened again. Demographic characteristics, provider information, and BPA responses were exported from EPIC for TCP BPA's first year (10/2019-10/2020) and included subspecialty BPA responses for comparison.

**Results:** During the surveillance period, the BPA fired for 721 and 2,672 unique patients in the TCP and subspecialty practices, respectively. Within the TCP clinics, 340 (47.2%) responded *Interested*, 162 (22.5%) *Declined*, 13 (1.8%) *Enrolled*, and 206 (28.6%) were *Dismissed*; in the subspecialty practices, 867 (32.5%) responded *Interested*, 531 (19.9%) *Declined*, 40 (1.5%) *Enrolled*, and 1,234 (46.2%) were *Dismissed*. See Table 1 for proportions of *Interested* patients in each group by race. For the TCP group, 137/340 (40.3%) non-White patients and 157/340 (46.2%) White patients were *Interested*, respectively; in the subspecialty group, 224/867 (25.8%) of non-White patients and 485/867 (55.9%) of White patients were *Interested*, respectively. Within the TCP group, 114 (15.8%) Medicaid patients and 209 (29.0%) private-insurance patients were *Interested*, respectively. Within the subspecialty BPA, 389 (14.6%) Medicaid patients and 385 (14.1%) private-insurance patients were *Interested*, respectively.

**Conclusions:** Higher proportions of Black/African American and Asian families receiving the TCP BPA versus the subspecialty BPA were interested in SPARK. This suggests that using a BPA in targeted clinical settings can increase outreach about study opportunities to racially diverse communities. Regarding socioeconomic diversity, TCP providers may have introduced the study differently by payor status, potentially introducing bias in who should receive information about study opportunities. Further investigation is needed to understand these lower rates of *Interested* families in the TCPs.

## Family Issues and Stakeholder Experiences

### PANEL SESSION — FAMILY ISSUES AND STAKEHOLDER EXPERIENCES

#### Panel 231 - The Impact of the COVID19 Pandemic on Autism and Other Neurodevelopmental Conditions: Lessons Learned from Studies across the Lifespan

**Panel Chair: Vanessa Bal**, *Graduate School of Applied and Professional Psychology, Rutgers University-New Brunswick, Piscataway, NJ*

**Discussant: Audrey Thurm**, *National Institute of Mental Health, Bethesda, MD*

The COVID-19 pandemic necessitated rapid, dramatic shifts in daily-life across the world. Those with neurodevelopmental conditions (NDC) are assumed to be especially vulnerable to pandemic-related disruptions. Understanding their specific vulnerabilities is critical to effectively respond to immediate and longer-term needs. Accordingly, this panel comprises large-scale studies of the impact of treatment service disruption, and specific adverse effects on a range of behavioral, psychological and/or functional domains in children and adults with ASD and other NDC. Study 1 highlights differences in service loss by age and NDC diagnosis, as well as associations between service loss and increased symptoms and negative parent experiences in individuals with genetic conditions. Study 2 identifies subgroups with differing patterns of risk and resilience among youth with ASD and other NDC from multiple international sites. Study 3 demonstrates an association between employment loss and increases in depressive symptoms in young adults with ASD. Study 4 reports increasing negative impact on services and other domains of daily-life and explores predictors of psychological distress in adults with ASD. These studies provide unique parent and self-reported perspectives that lay critical groundwork to inform service development and supports for individuals with NDC and their families, both now and beyond the pandemic.

**231.001 (Panel)** Impact of COVID-19 Restrictions on Individuals with Intellectual and Developmental Disorders: The Caring through COVID Survey

**C. Hyde<sup>a</sup>, C. DiStefano<sup>a</sup> and S. Jeste<sup>b</sup>**, (1)Semel Institute, UCLA Medical Center, Los Angeles, CA, (2)University of California Los Angeles, Los Angeles, CA, (3)University of California, Los Angeles, Los Angeles, CA

Background: COVID-19 restrictions have greatly impacted individuals with neurodevelopmental disorders (NDD) and their caregivers. CARING through COVID was a national survey of individuals with NDD which examined (1) access to tele-education services following early stay-at-home restrictions, (2) increased behavioral symptoms in children (e.g. increased self-injury, sleep disruption, regression), (3) caregiver accounts of positive and negative personal experiences (e.g. depression, family closeness, fear), and (4) helpful resources for families during the COVID-19 mitigation efforts (Jeste et al., 2020).

Objectives: Examine age, region, and NDD diagnosis-based variation in access to services, increased behavioral symptoms in children, and caregiver accounts of their own experiences following COVID-19 restrictions.

Methods: CARING through COVID was an online survey for caregivers of children (ages 0 to >22 years) with NDDs about their experiences during early stay-at-home restrictions. The survey was administered through Qualtrics between April 15 and May 1, 2020. Participation criteria included having a child with a (1) genetic diagnosis and (2) neurodevelopmental or neurological diagnosis (developmental delay (DD), intellectual disability (ID), autism spectrum disorder (ASD), epilepsy). Respondents (n=650) represented 46 states in the US.

Results: Of all therapeutic and educational services reported at the time of the survey, 64% were discontinued, 32% transitioned to tele-education, and 4% remained in-person. Age was significantly associated with the rate of services lost following COVID restrictions, with adults over 22 years losing an average of 81% of their services, compared to children 1-3 years old who lost an average of 53% of their pre-COVID services. Geographic region was not associated with the rate of services lost, but individuals with an autism diagnosis continued in-person services at a higher rate compared to those without ASD or any other diagnosis ( $p < .001$ ).

76% of parents reported increased symptoms in their children following COVID restrictions. Neither age nor geographic region correlated with the number or type of increased symptoms identified. Compared to individuals without ASD, individuals with ASD were perceived by their parents to have increased anxiety ( $p = .044$ ), regression ( $p = .018$ ), aggression ( $p = .003$ ), and restricted/repetitive behaviors ( $p < .001$ ). No differences were seen among any other NDD diagnosis. Age, NDD diagnosis, and geographic region showed no association with the number or type of parent experiences endorsed. Importantly, the rate of

services lost was significantly associated with the number of increased child symptoms ( $p=.032$ ,  $r=.098$ ,  $r^2=.009$ ), as well as the number of negative parent experiences endorsed ( $p=.036$ ,  $r=.089$ ,  $r^2=.007$ ). Parents who rated the tele-education services they received as more helpful also endorsed fewer increased behavioral symptoms in their children ( $p<.001$ ,  $r=-.221$ ,  $r^2=.048$ ) and fewer negative personal experiences for themselves ( $p=.005$ ,  $r=-.161$ ,  $r^2=.051$ ).

Conclusions: To our knowledge, this is the largest survey of parents and caregivers with neurodevelopmental disorders associated with genetic syndromes. COVID-19 restrictions greatly impacted both caregivers and their children, and with stay-at-home restrictions likely to continue, it is critical to recognize that high-quality, accessible tele-education services may directly benefit not only the health of individuals with NDD but also the wellbeing of their caregivers.

**Background:**

The social, educational, and economic disruptions brought by the COVID-19 pandemic have impacted all segments of the population. Children, especially those with neurodevelopmental conditions, are among the most vulnerable. In response, to systematically assess the specific impact of COVID-19 on this group, we built on the CoRonavIruS health and Impact Survey (CRISIS) effort developed to assess risk and resilience for short- and long-term impact in the general population. Specifically, we adapted CRISIS for autism and related neurodevelopmental conditions (AFAR) by surveying clinically relevant behaviors and

service access. We then formed an international collaboration of 30 institutions across four continents in eight countries willing to longitudinally collect and share CRISIS-AFAR and accompanying deidentified clinical data in previously characterized individuals with neurodevelopmental conditions.

Objectives:

To examine whether homogenous subgroups of individuals could be identified based on their behavior and service changes.

Methods:

To date, we analyzed CRISIS-AFAR data from children (N=870) with a prior clinical neurodevelopmental diagnosis recruited across 10 European and North-American institutions (10.3±3.4 years-old, 80% males, 82% autism; 15% Hispanic). At each site, data collection occurred for 7±1 weeks on a time between May and August 2020, varying by institution. Hierarchical clustering examined 14 features measuring changes in behaviors and service access to determine homogenous subgroups. Specifically, the CRISIS-AFAR surveyed caregiver-reported behaviors in the three months prior to COVID-19 (pre-covid19) and the two weeks prior to the survey completion (current). For each child, changes between these time points were computed across several empirically-derived factors assessing daily-living skills, restrictive-repetitive behaviors, other problem behaviors, use of media for social or non-social purposes, sleep patterns, and time spent outdoors. The COVID-19 impact on medical and psychoeducational services was indexed as the proportion of services lost and modified following the pandemic relative to those previously received. Non-parametric tests characterized subgroups (corrected at  $p < 0.004$ ).

Results:

The optimal clustering solution revealed three subgroups. One subgroup - the *No-change/some-improvement* (55% of the sample) - largely showed no changes (pre-COVID19 to current) across behaviors, except for slightly increased independence in daily-living skills and decreased rates of insomnia. The second subgroup - *No-change/some-worsening* subgroup (39%) - was characterized by no change in most behaviors except for slightly increased insomnia, disruption in sleep routines, and decreased time outdoors. The third subgroup - *Worsening* (6%) - was characterized by worsening across all domains. Notably, the rates of services lost (versus modified) were similar between the *Worsening* and the *No-change/some-improvement* groups which, in turn, was higher than that of the *No-change/some-worsening* group, except for medical services (Figure 1).

Conclusions:

Preliminary analyses revealed a group of children most vulnerable to the adverse impact of the COVID19 pandemic and another, relatively more resilient, albeit in the short-term. Finding that the rates of service loss did not clearly differentiate these two extreme subgroups suggests that additional social and clinical predictors must be examined. By continuing to aggregate CRISIS-AFAR baseline and longitudinal data, as well as previous clinical information, our network will fill this gap.

**231.003 (Panel)** Job Loss Predicts Worsening Depressive Symptoms for Young Adults with Autism: A COVID-19 Natural Experiment

**J. L. Taylor<sup>1</sup>**, R. Adams<sup>2</sup>, F. Pezzimenti<sup>3</sup>, S. Zheng<sup>4</sup> and S. Bishop<sup>5</sup>, (1)Vanderbilt Kennedy Center, Nashville, TN, (2)Cincinnati Children's Hospital Medical Center, Cincinnati, OH, (3)Psychiatry and Behavioral Sciences, Vanderbilt University Medical Center, Nashville, TN, (4)Psychiatry, University of California, San Francisco, San Francisco, CA, (5)University of California San Francisco, San Francisco, CA

**Background:** The COVID-19 pandemic and its associated mitigation strategies have resulted in substantial unemployment and job changes (such as moving to virtual work or reduced hours) among the general population. Rates of change, including job loss, are almost certainly higher for individuals with autism spectrum disorder (ASD), who have greater challenges than adults in the general population obtaining employment and are often the first to lose employment during economic downturns. Though job loss predicts increased risk of depression in the general population, studies have yet to examine this association among individuals with ASD.

**Objectives:** We used a longitudinal design to investigate employment changes for young adults with ASD during the first two months of COVID-19, as well as whether these changes predicted increasing depressive symptoms.

**Methods:** Young adults with ASD were recruited through the Simons Foundation Powering Autism Research for Knowledge (SPARK) research match registry. 315 adults completed an online survey in Mid-March, just days before COVID-19 restrictions

were implemented across the US. Approximately 10 weeks later, 275 of the original sample (87.3% response rate) completed a second online survey. 144 of these adults were employed at Time 1 and were included in the present analyses; they averaged 26.83 years of age (SD = 4.69) with a range of 18 to 35 years. Nearly 50% were male (47.2%, n = 68) and just under 40% (39.6%, n = 57) were living with their parents. Both surveys included measurement of depressive symptoms (Beck Depression Inventory-2). At Time 2, COVID-related employment changes and perceived impact of those changes on well-being were collected. Multiple regression analyses were used to examine associations between employment changes and perceived impact of these changes on Time 2 depressive symptoms, controlling for Time 1 symptoms.

**Results:** Over one-third (37.5%) of young adults who were employed at Time 1 reported employment changes during the first two months of COVID-19. Over 70% of this change was job loss or reductions in hours or pay (“job loss/reduction”); the remaining 30% (n = 16) was comprised of a diverse set of changes including getting a new job, working virtually, changes in duties, increased hours and changes in supports. When controlling for Time 1 depressive symptoms, young adults who experienced job loss/reduction had significantly higher depressive symptoms at Time 2 than those without an employment change,  $B = 3.76$ ,  $SE(B) = 1.82$ ,  $p < .05$ . Amongst those who experienced an employment change, perceived impact of that change also predicted depressive symptoms but in a non-linear fashion. Specifically, those who reported both positive and negative impact of employment changes had increasing depressive symptoms, relative to those who reported no impact of the job change on their well-being,  $B = 2.14$ ,  $SE(B) = 0.85$ ,  $p < .05$  (see Figure 1)

**Conclusions:** COVID-19-related job loss/reduction was common among young adults with ASD and associated with increased depressive symptoms. Mental health interventions or surveillance may need to target all young adults who experience job loss/reduction – not just those who report negative impacts of employment change.

#### **231.004 (Panel) Negative Impact and Predictors of Psychological Distress for Autistic Adults across the Early Weeks of the Pandemic**

*V. H. Bal<sup>1</sup>, E. Wilkinson<sup>1</sup>, C. W. Lehman<sup>2</sup>, J. K. Law<sup>3</sup>, P. Feliciano<sup>4</sup> and W. K. Chung<sup>5</sup>, (1)Graduate School of Applied and Professional Psychology, Rutgers University-New Brunswick, Piscataway, NJ, (2)Simons Foundation, New York, NY, (3)Maryland Center for Developmental Disabilities, Kennedy Krieger Institute, Baltimore, MD, (4)SFARI, Simons Foundation, New York, NY, (5)Department of Pediatrics, Columbia University, New York, NY*

---

**Background:** The COVID-19 pandemic has disrupted lives around the world, yielding a global mental health crisis. While parent-report studies indicate that children with ASD are exhibiting more behavioral challenges (e.g., Colizzi et al., 2020; Nonweiler et al., 2020), no studies have yet reported the pandemic experiences of autistic adults. Self-advocates have cautioned that higher rates of co-occurring psychiatric conditions and difficulties adapting to pandemic-related changes may put autistic adults at even greater risk for adverse mental health effects of the pandemic (denHouting, 2020). A better understanding of autistic adults’ pandemic experiences and mental health during this time is needed to inform development of supports.

**Objectives:** To explore the mental health of autistic adults and identify predictors of change in the early months of the pandemic.

**Methods:** In April 2020, 636 independent adults enrolled in SPARK responded to a survey assessing impact of the pandemic and 396 completed a follow-up survey 7.7-9.7 weeks later (80.3% White; 58.8% female; Mean age=37.4, SD=13.4; range=18.5-74.8 years). Participants self-reported level of impact in six areas (Fig.1) on a scale of 1 (not at all) to 4 (severely) and rated four items assessing depression, anxiety, loneliness and hyperarousal in the past week from 1 (rarely or none of the time, less than 1 day) to 4 (most or all of the time, 5-7 days). Items were added to yield a “total impact” and “psychological distress” score, respectively (higher scores reflect more impact/distress).

**Results:** At T1, psychological distress was high, with an average score of 9.3 (SD=3.2); 54.7% endorsed two or more symptoms for at least 3 days in the past week. Being female, younger and having a previous mental health condition was associated with higher levels of overall impact and distress [Table 1]. Impact, but not hope or psychological distress, showed moderate to large increases over time [Table 1]. Moderate to large increases in severity of impact were observed across most areas, with services showing the greatest increase [Fig.1]. Of 267 adults who reported receiving services in January/February 2020, there was a significant increase in those reporting that COVID negatively impacted their services at T2 (88.8%) compared to T1 (50.6%,  $p < .001$ ); 26.6% (n=71) were not receiving online services at T2. Two-thirds of the sample (n=263) reported needing more supports at T2; counseling/therapy (52.1%) and social supports (40.7%) were the most frequently endorsed areas needed.

Linear regression indicated that higher impact, less hope and being older or female were associated with higher concurrent T1 psychological distress ( $p < .005$ ). In the model predicting T2 psychological distress, increases in total impact, decreases in hope and having unmet support needs at T2 were significant predictors of T2 distress ( $p < .005$ ) controlling for T1 distress levels ( $R^2 = 0.53$ ).

**Conclusions:** These findings document concerningly high levels of psychological distress for autistic adults, which remained stable across the early weeks of the pandemic. A decrease in hope predicted T2 psychological distress, highlighting a possible target area for mental health supports. More attention is needed to ensure that adults are receiving necessary services throughout the pandemic.

## ORAL SESSION — FAMILY ISSUES AND STAKEHOLDER EXPERIENCES

### Oral 311 - Qualitative Understandings of Autistic Individuals, Their Families and Communities

**311.001** (Oral) Sibling and Service Provider Perspectives on Sibling Involvement in the Lives of Adults on the Autism Spectrum  
**E. K. Schmidt<sup>1</sup>, M. Gordillo<sup>2</sup>, M. Getz<sup>3</sup>, G. I. Orsmond<sup>1</sup> and K. Long<sup>3</sup>,** (1)Department of Occupational Therapy, Boston University, Boston, MA, (2)Boston University, Boston, MA, (3)Division of Gastroenterology, Hepatology, and Nutrition, Boston Children's Hospital, Boston, MA

**Background:** Parents often provide support for their adult child on the autism spectrum, but as adults on the autism spectrum age, siblings may become more involved in supporting them. Research about siblings of adults with intellectual disabilities suggests that siblings may take on formal and informal support roles and help plan for the future.<sup>1-5</sup> Yet, limited information is available on siblings' support roles and involvement in the lives of their family member on the autism spectrum specifically. This is important as several characteristics of autism may impact sibling involvement (e.g., ability to express reciprocity, maladaptive behaviors, and the autism-specific adult service systems complexity<sup>6-8</sup>). Further, it is important to consider the perspectives of service providers as they may serve as gatekeepers to inviting and including adult siblings in the care of the adult on the autism spectrum.

**Objectives:** The purposes of this study were to (1) describe perspectives of siblings' involvement in the lives of their family member on the autism spectrum, and (2) explore similarities and differences between siblings' and service providers' perspectives.

**Methods:** Twelve adult siblings and 14 service providers participated in focus groups or interviews in English or Spanish (Table 1). Providers and siblings were asked, "what role do [siblings] play in supporting your client/sibling on the autism spectrum?" Other questions focused on how families determine sibling involvement in future planning. Focus groups and interviews were recorded and transcribed verbatim. Data were systematically coded, stratified by respondent type, and analyzed using applied thematic analysis.<sup>9</sup>

**Results:** Analyses revealed four areas of sibling involvement with their family member on the autism spectrum: (1) encouraging leisure and social activities, (2) promoting independence in self-care, (3) advocacy, and (4) future planning (Table 2). Siblings and service providers had similar perspectives on sibling involvement for the first three themes but reported different views on siblings' level of involvement in future planning. Participants reported that siblings encourage leisure and social activities for their family member on the autism spectrum in community settings (e.g., going to restaurants, movie theaters, and spending time outdoors together). Siblings also encourage independence in self-care activities for their family member more than parents. Finally, siblings act as advocates for their family member by supporting and encouraging the adult on the autism spectrum during medical appointments, individual service plan meetings, and with housing. Providers were less likely, however, to acknowledge siblings' interests and plans for involvement in future planning.

**Conclusions:** Siblings play an important role in supporting their family member on the autism spectrum, and the scope of their support roles often increase over the life course. Yet, our findings suggest a disconnect between siblings' intentions and service providers understanding of the extent to which siblings are positioned to assume support roles for future planning. Service providers tend to underestimate the degree to which siblings intend to be involved in supporting the adult in more formal ways and feel ill-equipped to involve siblings.<sup>10</sup> Service provision for adults on the autism spectrum could be improved with the explicit inclusion of siblings.

**311.002** (Oral) Exploring Leisure Time Use and Impact on Health and Well-Being Among Transition-Age Autistic Youth  
**S. C. Folta<sup>1</sup>, L. G. Bandini<sup>2</sup>, A. Must<sup>3</sup>, J. Pelletier<sup>4</sup>, K. Ryan<sup>2</sup> and C. Curtin<sup>5</sup>,** (1)Tufts University, Boston, MA, (2)Eunice Kennedy Shriver Center, University of Massachusetts Medical School, Worcester, MA, (3)Tufts University School of Medicine, Boston, MA, (4)Boston University, Boston, MA, (5)University of Massachusetts Medical School, Waltham, MA

**Background:** The transition to adulthood has emerged as an important focus for autistic youth, since fewer supports and services exist after they age out of school. Quality of life (QOL) is lower for transition-age autistic youth compared to typically developing counterparts. Leisure-time pursuits have been linked to higher QOL and overall subjective wellbeing, as they provide individuals with opportunities to build relationships, experience positive emotions (e.g., enjoyment, success, affiliation), and acquire new knowledge and skills. Leisure-time activities are also positively associated with health status. Leisure-time has been studied in a limited way in transition-age autistic youth, but prior studies have used parents as respondents.

**Objectives:** The objective of this study was to employ participant-driven photo-elicitation (PDPE) methodology to explore leisure-time use among transition-age autistic youth. We sought to provide insights into supports that can be developed to assist youth in engaging in activities that enhance QOL and promote health.

**Methods:** Youth ages 18-23 years were recruited nationally using purposive sampling through organizations that serve the autistic population and their families as well as universities known to have specific resources for autistic students. Participants took photos of their leisure-time activities over a 7-day period using their own smartphones. They were then interviewed via Zoom using a semi-structured interview guide that was based on the Self-Determination Theory framework and the Iwasaki leisure-time model. Photos were organized and discussed by day. Data were analyzed using directed qualitative content analysis based on the theoretical framework. NVivo (QSR International) was used to assist with coding.

**Results:** Eighteen young autistic adults participated in the study. Playing video games was the most common activity. Other activities were watching television and videos, reading, listening to music, arts (painting, digital art, drawing/sketching/coloring, photography, writing, and needlework), board games, going for walks, and spending time with pets. A major theme was that most youth perceived leisure activities as contributing to their mental health and wellbeing. While most activities were done alone, rather than describing these activities as isolating, youth said they helped with coping with stress. Activities also gave them confidence in overcoming challenges they faced. Most participants mentioned gaining a sense of connection when they were engaged in leisure activities with others who shared common interests. Although many youth participated in some form of physical activity, it was viewed as utilitarian, to promote better health, rather than something that participants enjoyed.

**Conclusions:** Through this research, we gained an understanding of the range of activities that transition-age autistic youth engage in during their leisure time. Overall, this exploratory work suggests that although youth engage in many solitary leisure-time pursuits and spend significant time in front of screens, these activities make positive contributions to their psychological wellbeing. Many youth described purposeful engagement in activities to develop skills, grow emotionally, and manage emotional challenges. These findings suggest that programming in this area might focus less on shifting or expanding upon the types of activities that youth pursue, but instead help ensure that they reap benefits from activities that they already enjoy.

**311.003 (Oral)** Me, My Environment and My Quality of Life: Understanding Autistic Quality of Life Using Photography  
**R. L. Kuzminski<sup>1</sup>, M. Falkmer<sup>2</sup>, S. Phillips<sup>3</sup>, W. Lawson<sup>4</sup>, S. Bolte<sup>5</sup>, S. J. Girdler<sup>6</sup> and B. T. Milbourn<sup>6</sup>,** (1)School of Occupational Therapy, Social Work and Speech Pathology, Cooperative Research Centre for Living with Autism, Long Pocket, QLD, Australia, (2)Curtin University, Bentley, Australia, (3)Curtin University, Perth, Australia, (4)Cooperative Research Centre for Living with Autism (Autism CRC), Brisbane, QLD, Australia, (5)Center of Neurodevelopmental Disorders (KIND), Centre for Psychiatry Research; Department of Women's and Children's Health, Karolinska Institutet, & Stockholm Health Care Services, Region Stockholm, Stockholm, Sweden, (6)School of Occupational Therapy, Social Work and Speech Pathology, Curtin University, Perth, WA, Australia

---

**Background:**

Measuring the quality of life (QoL) of autistic adults is underpinned by the constructs used to define them. Little research has focussed on how autistic adults construct and define their quality of life (QOL) in their everyday lives. Assessments of QoL employed with autistic adults largely assume that the constructs underpinning QoL are the same for all people. Research employing these measures consistently report that autistic adults experience poorer QoL compared to their non-autistic peers. The neurodiversity movement draws attention to autistic individuals' divergent styles of thinking and strengths, including their exceptional memory and pattern recognition abilities, and high levels of attention to detail. The neurodiversity of autistic individuals and their strengths are largely overlooked in traditional QoL constructs.

**Objectives:**

This research aims understand the autistic community's perspective of QoL, employing a Photovoice methodology, with participants portraying what determines and defines their QoL using photos.

## Methods:

Photovoice is a unique and creative approach to co-producing research, capturing meaning and articulating the needs and perspectives of autistic adults through photos. A steering group of five autistic adults developed and refined the research design, materials and assisted in data interpretation. One autistic co-author is a photographer and co-produced the Photovoice resources, upskilling participants in photography techniques.

15 autistic participants from across Australia took part in the Photovoice study, taking up to 20 photos which captured and reflected their perspectives of their QoL. On completion, two focus groups were held with six participants presenting three photos representing their QoL to identify themes as a group. Each of the 15 participants then took part in an individual interview in which they described and identified themes portrayed within their remaining photos with the researcher. The 289 photos and the focus groups and interviews were analysed thematically, primarily identifying participant's reported themes, capturing participants' collective perceptions of their QoL. Additional themes identified during analysis were included and member checked with each participant.

## Results:

Emerging themes embedded within the photos indicate that QoL is nuanced and multifaceted, with "one photo telling a thousand stories". Themes generated from the photos include What I do, What I need, What makes me who I am, What is around me, and What I experience. The photos reflected ingredients of the themes such as passions, socialisation, relationships, physical and mental health and sensory preferences. Following analysis a Photovoice gallery, including a selection of 47 images was co-produced with autistic participants and researchers. This was launched in November 2020 sharing findings, and participant's perspectives, and can be found here: <https://www.youtube.com/watch?v=8H2Arlbe3B0>

## Conclusions:

Co-producing QoL research is critical in ensuring the construct of autistic QoL truly represents autistic adults' experiences. Understanding QoL from the perspective of autistic adults themselves can underpin a conceptualisation of QoL of relevance to the autistic community, which can ultimately be operationalised into measurement tools capable of providing an accurate and meaningful description of the QoL of autistic adults.

### **311.004** (Oral) A Qualitative Study of Police Confidence in Their Work with Autistic Individuals

*A. M. Love<sup>1</sup> and K. Railey<sup>2</sup>, (1)Aspect Research Centre for Autism Practice, Autism Spectrum Australia, Melbourne, VIC, Australia, (2)School of Medicine, Emory University, Atlanta, GA*

---

**Background:** Results from several studies reveal that police officers are often unknowledgeable about autism and report concerns about how to appropriately handle situations involving autistic individuals (Crane et al., 2016; Railey et al., 2019). A recent review of autism and the criminal justice system (Railey et al., 2020) identified training about autism as a critical area of need within the criminal justice system, which is consistent with findings from previous reviews (e.g., King & Murphy, 2014). Bandura (1997) stated that individuals must not only possess appropriate knowledge and skills, but they also need belief in their own capabilities to demonstrate these skills. Police officers' efficacy beliefs can affect whether they will change their behavior and whether they will be motivated to persevere in a new situation. This study explored what contributes to an officers' capability beliefs specific to their work and service delivery to autistic individuals.

**Objectives:** The aim of this study was to understand what makes police officers feel more and less confident when working with autistic individuals in the capacity of their job. Research questions supported each interview question regarding officer confidence.

**Methods:** This study employed a qualitative methodology to analyze the feedback from police officers about their confidence in supporting and working with autistic individuals. Data was extracted from a larger study examining police officer knowledge and self-efficacy for working with autistic individuals, which employed an anonymous survey to explore police officers' self-efficacy (Love et al., 2020). Data were analyzed in Nvivo software by two researchers who independently used the constant-comparative method associated with constructivist grounded theory (CGT; Charmaz, 2014). Participants included 317 police officers who were actively serving in the US and who provided anonymous answers to the following questions: (a) "What makes you feel more confident in your capabilities as a police officer to work with someone with autism?" and (b) "What makes you feel less confident in your capabilities as a police officer to work with someone with autism?"

**Results:** Results from the first question resulted in four thematic categories, including (a) knowledge and training, (b) personal experiences, (c) experiences of fellow officers, and (d) personal characteristics. These themes are consistent with Bandura's (1986) four sources of self-efficacy, and the connection between theory and the results will be discussed. An analysis of responses to the second question, which explored factors that contribute to officers feeling less confident, yielded the following four themes: (a) autistic characteristics, (b) diagnosis concerns, (c) effective training and knowledge, and (d) dynamics of emergency situations.

**Conclusions:** There is current international attention on the autism-specific education and training of first responders. While some police departments are responding to state mandates that require autism training, others are proactively choosing to educate and inform their officers to prevent tragic incidents of misunderstanding. This research utilized the voices of police officers to identify areas of need and themes relating to officer confidence. The findings can be used immediately to improve and inform relationships between first responders and the autistic community.

## POSTER SESSION — FAMILY ISSUES AND STAKEHOLDER EXPERIENCES

### Poster 422 - Family Issues and Stakeholder Experiences Posters

**422.001** (Poster) "Delivered Right to Your Own Home" Stakeholder Perspectives on an at-Home Autism Likelihood Assessment

*C. E. McCormick<sup>1</sup>, A. Pesaladinne<sup>2</sup>, R. A. Mason<sup>3</sup>, H. Crosley<sup>2</sup>, A. Austin<sup>2</sup>, B. Kelleher<sup>4</sup> and A. L. DeMaria<sup>2</sup>, (1)Human Development and Family Studies, Purdue University, West Lafayette, IN, (2)Purdue University, West Lafayette, IN, (3)Educational Studies, Purdue University, West Lafayette, IN, (4)Psychological Sciences, Purdue University, West Lafayette, IN*

**Background:** Autism Spectrum Disorder (autism) has a complex, multifaceted causal pathway. Even within a single individual, multiple factors impact the likelihood of a diagnosis. Biological and environmental impacts have been implicated within the causal pathway; however, we have limited ability to collect and aggregate data from multiple sources of risk for any individual child. An assessment kit allowing families to collect relevant samples at home could enhance the ability to create personalized risk profiles. Input from the patient population is critical for optimal assessment kit design.

**Objectives:** To inform and optimize the development of a remote kit to assess biological and environmental indicators of an autism diagnosis through qualitative interviews with stakeholders.

**Methods:** Participants were six mothers of children with autism and three mothers of children with neurogenetic disorders (1 Prader Willi Syndrome; 2 Down Syndrome). As part of a larger study, mothers completed a 90-minute in-depth semi-structured phone interview that included a description of the potential aspects of the new kit and questions related to their perspectives of such an assessment. Using a grounded theory approach (Salada, 2016), interview transcripts were coded within Nvivo 12 for three categories related to kit development: willingness, concerns, and supports. Second cycle coding identified sub themes for each category and included axial coding across themes.

**Results:** Three themes were identified: Participation, Research Connection, and Design. Overall, participants were willing to collect most samples. Concerns that may impact participation included collection of invasive items (e.g., blood), activities that may result in child non-compliance (e.g., collecting saliva), and amount of work and skill involved with correct collection of samples (e.g., understanding how to collect dirt/dust). Positive impacts on participation were access to direct supports and involvement of healthcare providers for more invasive samples. In relation to the design of the kit, additional supplies (e.g., ice packs) and small sealed containers were important factors for biosamples (e.g., stool). Participants conveyed the importance of clear instructions in multiple formats, including videos. All mothers endorsed having the kits delivered to their homes. Connections to research was a strong theme across all three coding categories. Study goals impacted willingness to participate in sample collection at all and willingness to complete more invasive or time consuming collections. Ethical issues were also raised regarding data storage and usage. Three participants emphasized the importance of receiving research results, including both the main findings of any study and also personalized reports of their own risk status.

**Conclusions:** Overall, parents were willing to collect a myriad of biological and environmental samples in their homes, particularly if the goals of the research align with their own. Child consent and compliance, collection burden, as well as ethical research practices such as data security and storage were the most salient factors related to whether respondents would engage with a home collection kit. These results support the feasibility of this goal and concurrent importance of communication with patient groups before, during, and after research projects to meet community needs and maximize research impact.

**422.002 (Poster)** A Comparison of Non-Latino White and Culturally and Linguistically Diverse Parents' Perceptions of and Experiences with Autism Identification

**P. Chaxiong<sup>1</sup>, J. J. Wolff<sup>2</sup>, R. Vukovic<sup>1</sup> and J. A. Hall-Lande<sup>3</sup>**, (1)Educational Psychology, University of Minnesota, Minneapolis, MN, (2)University of Minnesota, Minneapolis, MN, (3)UCEDD, University of MN, Minneapolis, MN

---

Background:

Although autism spectrum disorder (ASD) can be reliably diagnosed by age two, the average age of diagnosis for children in the U.S is still after age four. For children from underserved, culturally and linguistically diverse (CLD) communities, age of identification can be substantially greater. Thus, efforts to improve disparities in identification are warranted and looking to parents' experiences may inform such efforts. The literature suggests that Non-Latino White (NLW) and CLD parents have different beliefs about ASD and different experiences with the identification process that could influence the course of action parents take-- or are able to take-- to obtain an ASD identification.

Objectives:

To date, few studies have directly compared NLW and CLD parents' perceptions of and experiences with ASD identification. The purpose of this survey study was to examine whether there are differences between NLW and CLD parents in: (1) perceptions of the causes of ASD, identification, and intervention; (2) barriers and facilitators to receiving an ASD identification; and (3) sources parents turn to for ASD information.

Methods:

Eligible participants ( $N = 205$ ) were parents of children with an educational identification and/or clinical diagnosis of ASD and had to be at least 18 years of age and residing in the US at the time of the study. Parents were recruited via ASD-related Facebook groups, email listservs, and community organizations. The link to the Qualtrics® survey was provided in each recruitment method. The CLD group ( $N = 128$ ) consisted of participants who identified as Hispanic/Latino or with a race other than Caucasian. The NLW group ( $N = 77$ ) consisted of participants who identified as Caucasian and non-Hispanic/non-Latino. Chi-square tests were conducted to determine whether there were significant differences in experiences by parent group. The false discovery rate (FDR) approach was used to control for multiple comparisons.

Results:

The results suggest that NLW and CLD parents have substantial differences in perceptions of cause, perceptions of identification, parent-reported barriers to identification, and information sources used but were relatively similar in perceptions of intervention and parent-reported facilitators to identification. Notably, CLD parents in comparison to NLW parents: (a) were significantly less likely to endorse genetics as a cause of ASD; (b) reported more barriers to and negative perceptions of identification; and (c) were significantly less likely to turn to healthcare professionals, other parents of children with ASD, and the internet for ASD information.

Conclusions:

Our findings suggest that NLW and CLD parents have different perceptions of ASD and experiences with the identification process, culminating in different needs. In many ways, our current systems and practices better support the identification of NLW children, potentially contributing to ongoing disparities in identification. Intentional focus on the needs of CLD communities is important for amending current systems and practices to improve disparities in ASD identification.

**422.003 (Poster)** A Developmental Perspective on Family Accommodation in Autism: Preliminary Findings

**S. Wismel<sup>1</sup>, S. Dar<sup>1</sup>, D. A. Zachor<sup>2</sup>, E. Ben-Itzhak<sup>2</sup>, T. Matz Vaisman<sup>1</sup>, E. R. Lebowitz<sup>1</sup> and J. Koller<sup>3</sup>**, (1)The Hebrew University of Jerusalem, Jerusalem, Israel, (2)The Autism Center/ALUT, Pediatrics, Tel Aviv University/Shamir (Assaf Harofeh) Medical Center, Zerifin, Israel, (3)Bruckner Center for Research in Autism, Communication Disorder, Ariel University, Ariel, Israel, (4)Yale Child Study Center, Yale School of Medicine, New Haven, CT, (5)Seymour Fox School of Education, Hebrew University of Jerusalem, Jerusalem, Israel

---

Background: Family accommodation refers to ways in which parents modify their behavior to help a child alleviate distress associated with emotional disorders (e.g. Lebowitz, Scharfstein & Jones, 2014). Such accommodation is common among families

of children with OCD and anxiety disorders, where it is associated with increased symptom severity, lower functioning, and poorer treatment outcomes (e.g. Caporino et al., 2011; Lebowitz, Scharfstein & Jones, 2014).

One study to date has examined family accommodation of repetitive and restrictive behaviors and stereotyped interests (RRBs) in autism. Feldman et al. (2019) found such accommodation to be highly prevalent, positively correlating with symptom severity and negatively correlating with adaptive functioning.

**Objectives:** The current study examines short-term trajectories in the context of family accommodation in autism. The main purpose of the study is to extend the results of the original study by examining the relationship between family accommodation and symptomatology 1-2 years after diagnosis. We aim to examine changes in family accommodation 1-2 years after diagnosis and the association between these changes and parallel shifts in RRBs severity.

**Methods:** Participants include 25 parents of children diagnosed with autism spectrum disorder between the ages 4 and 12.10 years (7 females; mean age = 7.11 years, SD = 2.6), who participated in the original study conducted by Feldman et al. (2019). Parents were invited to participate in an abridged reevaluation, including measures of adaptive behavior (Vineland Adaptive Behavior Scales 2; VABS-2; Sparrow, Balla & Cicchetti, 2005), family accommodation (FAS-RRB; Feldman et al, 2019) and RRBs (RBS-R; Bodfish, Symons, & Lewis, 1998). Data was also collected regarding intervention received and other significant developments during the intervening time.

**Results:** Family accommodation 1-2 years after diagnosis remained highly prevalent, with 68% of parents reporting weekly accommodation and 44% reporting daily accommodation. As in the first study, accommodation positively correlated with RRB severity ( $r_s = .768, p < .01$ ). No significant correlation was found between FAS-RRB total score and the VABS 2. However, the family accommodation sub-category '*participation*' (participating in RRB-related actions) negatively correlated with daily living skills ( $r_s = -.534, p < .01$ ) as measured by VABS 2.

Family accommodation at Time1 significantly positively correlated with family accommodation ( $r_s = .427, p < .05$ ) but not with adaptive behavior skills at T2. The family accommodation '*participation*' sub-category at Time1 negatively correlated with daily living skills at Time2 ( $r_s = -.439, p < .05$ ) as measured by VABS 2. RRB severity at T1 significantly positively correlated with RRB severity in T2 ( $r_s = .413, p < .05$ ) and with family accommodation in T2 ( $r_s = .425, p < .05$ ).

**Conclusions:** These preliminary findings indicate that family accommodation of RRBs is present at time of diagnosis and 1-2 years afterward. Such accommodation, both concurrently and longitudinally, appears to associate with elevated symptomatology and reduced daily living skills. These findings are an important step forward in our understanding of family accommodation in a developmental context. The modest and heterogeneous sample are limitations. Ongoing data collection will allow for confirmation and elucidation of these findings.

**422.004 (Poster)** A Pathway to Understanding: Autistic People's Use of Internet Memes to Illustrate Autistic Experience  
*S. E. Woods, Discover Psychology Services, Lacey, WA*

---

**Background:** Internet memes are replicating units of cultural information (Dawkins, 1976) shared online. They have the power to unite marginalized people (Shifman, 2014) and shape the mindsets and actions of groups (Knobel & Lankshear, 2007). Internet memes are a powerful communication tool among autistic people that has been largely unexplored. The deficit-focused approach to conceptualizing is deficient. Because of the double empathy problem (Milton, 2012), autistic and nonautistic people may have trouble understanding each other. Participation of autistic people in our understanding of autism is a necessity (e.g., Bottema-Beutel et al., 2020; Gillespie-Lynch et al., 2017). Many autistic people have difficulty discussing their own emotional experiences, especially in medical settings (Poquérusse et al., 2018). Autistic people's visual strengths (e.g., Rutherford et al., 2020; Soulieres et al., 2006) and creative use of the internet to overcome obstacles (Kapp, 2020) make memes important for autistic culture. Exploratory research on autistic internet memes offers insight into autistic identity and culture. It provides opportunities for bridging gaps between professional and autistic communities.

**Objectives:** Exploratory research on autistic internet memes offers insight into autistic identity and culture. It provides opportunities for bridging gaps between professional and autistic communities.

**Methods:** A content analysis of autism-related memes (n = 400) from 4 different Facebook pages by and for autistic people was completed. Data were thematically coded (Braun & Clark, 2006), themes were explored, and clinician implications were identified.

Results: Memes included a broad array of content, including comments on nonautistic discourse about autism, affirmations, positive aspects of autistic identity, struggles related to autism (e.g., social interaction, preference for solitude, sensory differences), and related struggles (e.g., executive functioning difficulties, sleep problems, trauma, anxiety). Several important themes were identified. A prominent message was that autistic struggles arise from *differences between autistic and nonautistic preferences and expectations*, as opposed to resulting from basic deficits in autistic people. These included subtle criticism of nonautistic expectations for social interaction and self-deprecating humor. They often included humor derived from the mismatch in styles. This is consistent with the social model of disability and the neurodiversity paradigm. Humor was used to challenge nonautistic conceptualizations of autism. Another prominent theme was *autistic joy*, often illustrated through examples of pleasure and pride associated with autistic experience (e.g., special interests, sensory experiences, direct communication) and admiration of autism by nonautistic people. *Solidarity* among autistic people as a community and within the disability community was also key. Infographics explaining autistic experience in accessible language and images were discovered (e.g., the tendril theory). As a medium, memes legitimize autistic styles of explanation of autistic experience.

Conclusions: Autistic people acknowledge struggle and joy associated with autism powerfully, conveying a wealth of information through memes. The mismatch between professional and autistic experiences has already been established as a barrier to effective intervention and collaboration. Memes offer solutions. Memes offer evocative and memorable illustrations of the social model of disability. Autistic memes could also be useful in assessment and feedback procedures. Dissemination of research to autistic communities through memes may be effective.

**422.005** (Poster) A Winning Lottery Ticket and a Miracle: Parents of Autistic Adults Describe What It Takes to Get Adequate Services

**D. Turnbull<sup>1</sup>** and **M. Lawlor<sup>2</sup>**, (1)University of Southern California, Los Angeles, CA, (2)USC, Los Angeles, CA

---

Background: The social, psychological, and health outcomes for autistic adults are all unacceptably poor. Rates of independent living, education attainment, employment, work satisfaction, and meaningful relationships are not only lower than average, they are lower than for other disability groups (Levy & Perry, 2011). Despite the increased attention paid to autism by research and clinical communities, these outcomes are not improving.

Objectives: The primary aim of this study was to understand the lived experience of autistic adolescents and adults in the community. Working with various stakeholder groups we sought to identify barriers and facilitators to engagement and participation and examine the service ecosystem from the perspective of autistic youth and their families.

Methods: Data presented here is part of a Narrative Phenomenological examination of community engagement of autistic adolescents and young adults. Autistic individuals, their family members, and clinicians participated in semi-structured narrative interviews and “Collective Narrative” group-based interviews to provide their lived-experience. Data was transcribed verbatim and coded thematically. Interviews provide a means of accessing the post-reflective assessment of a leisure engagement and situating the experience in a broader context of the individual and their social environment. Collective Narrative allows for themes and discoveries to be explored at a community level, for stakeholders to offer their interpretation of events, and to find areas of difference and concurrence in the larger group. At each stage, field notes were kept providing important contextual information and a space for reflexive processes.

Results: Services that meet the needs of autistic adults are few and far between, according to parents. Some families struggle to find services or service providers who meet their needs from the time of diagnosis. The struggle to find adequate services increases as children age with nearly all participants expressing dismay by early adulthood. When asked to envision a program to help their child, parents routinely start their answer with, “If I won the lottery,” or “If God granted me a miracle.” Most often this sentiment has been expressed by mothers in the study, who go on to describe services that don’t exist yet but are not extravagant or unscientific. Mothers present realistic and sensible ideas for programs, but their experience of the system has made it clear that winning the lottery is more likely than getting the services their children need.

Conclusions: Adequate services to meet the needs of autistic adults should not require a statistical anomaly like winning the Powerball or a literal act of God. The research and clinical communities must find ways to work together and in partnership with the autistic community to address these critical shortcomings in service availability.

**422.006** (Poster) Access to Interventions and Services for Families of Young Children with Autism Spectrum Disorder

**E. V. Ocampo<sup>1</sup>**, **R. A. Gordon<sup>1</sup>**, **D. Smith<sup>2</sup>**, **J. Budenske<sup>3</sup>** and **A. Wainer<sup>1</sup>**, (1)Department of Psychiatry, Rush University Medical Center, Chicago, IL, (2)Olivet University, Bourbonnais, IL, (3)Rush University Medical Center, Chicago, IL

---

Background: Families of children with autism spectrum disorder (ASD) report significant barriers to accessing and engaging in care, including delayed or foregone care, difficulty receiving referrals, care that is not family-centered, and higher rates of unmet service needs relative to other special health populations (Kogan et al., 2008). Prior research examining service utilization in ASD assessed the number or type of services successfully accessed, with the assumption that underutilization reflects problems with access (Krauss et al., 2003). However, few studies have examined the efforts or attempts made to successfully obtain care.

Objectives: This study aims to identify issues of access to care through examining the number and type of services initially sought versus successfully accessed, with the goal of examining the complexity of service seeking and family experience.

Methods: An online survey was distributed via SPARK Research Match to 324 caregivers of a child with ASD between 18 months and 6 years of age ( $M$  age = 4.01). Caregivers reported the number and types of interventions that were sought and successfully accessed from a list of 13 possible interventions/services. Caregivers reported the ASD-related services their child currently receives and any unmet needs in their child's current programming.

Results: Over 97% of caregivers successfully enrolled in services. On average, caregivers sought between 1.29 to 2.6 different programs per intervention/service category, successfully enrolling in 1.11 to 1.75 programs per category. The most frequently attempted and accessed services include speech/language therapy (93.4% attempted, 97.3% success rate), occupational therapy (87.3% attempted, 92.4% success rate) and behavioral therapy/ABA (73.6% attempted, 72.6% success rate). Caregivers made the most attempts at obtaining behavioral/ABA services ( $M = 2.60$ ,  $SD = 1.91$ ), speech/language therapy ( $M = 2.25$ ,  $SD = 1.42$ ), and occupational therapy ( $M = 1.97$ ,  $SD = 1.38$ ). The most difficult services to access included nutritional counseling (41.9% of caregivers who attempted were unsuccessful), mental health counseling (38.9% of caregivers were unsuccessful), and complimentary or alternative medicine (35% of caregivers were unsuccessful). The greatest reported unmet needs were emotional regulation and anxiety; less than a third of participants requiring support in these areas received it (30.8% for emotional regulation, 28.5% for anxiety).

Conclusions: Families of young children with ASD most frequently seek out and successfully initiate services that are considered central to comprehensive early intervention programs for young children (e.g., speech therapy, occupational therapy and behavioral therapy/ABA). Yet, significant unmet needs remain for this population. In particular, these data suggest that underlying mental health challenges such as emotion regulation and anxiety represent an important area of need, and that services addressing these concerns (e.g., mental health counseling) are challenging to access. These data suggest that understanding the nature of difficulties accessing services (e.g., lack of providers trained in mental health counseling for young children with ASD vs. financial or insurance barriers to enrolling in services) is critical for developing innovative strategies to ensure timely and appropriate care for young children with ASD.

**422.007 (Poster)** Affiliate Stigma, Empowerment, and Self-Esteem Among Serbian Parents of Children with Autism Spectrum Disorder

*M. Čolić and I. Milačić-Vidojević, (1)Special Education Department, University of Hawaii at Manoa, Honolulu, HI, (2)Faculty of Special Education and Rehabilitation, University of Belgrade, Belgrade, Serbia*

---

Background: Concepts of affiliate stigma, empowerment, and self-esteem among parents of children with autism spectrum disorder (ASD) are slowly getting more research attention for the past decade. Yet, these topics remain understudied in Serbia and Southeastern Europe overall. Across different studies, parents of children with ASD have been reporting higher degree of affiliate stigma in comparison to parents of children with other types of disabilities. Findings regarding levels of empowerment and self-esteem among parents of children with ASD and parents of children with different types of disabilities are inconsistent.

Objectives: The aim of the present study is to examine whether parents of children with ASD express greater degree of affiliate stigma and lower levels of empowerment and self-esteem in comparison to the parents of children with physical disabilities (PD). Further, we wanted to explore levels of affiliate stigma, self-esteem, and empowerment among Serbian parents of children with ASD.

Methods: This study is a part of a large project that included a convenience sample of 82 Serbian parents; 40 of children with ASD and 42 of children with PD. The parents were recruited through parental support organizations and public schools from the several cities across the country. We used the Affiliate Stigma Scale (Mak & Cheung, 2008) to measure affiliate stigma (a higher score represents greater stigma level; max = 5), the Family Empowerment Scale (Koren et al., 1992) to examine family empowerment (a higher score represents greater empowerment; max = 5), and the Rosenberg Self-Esteem Scale (Rosenberg, 1965; Rosenberg, 1989) to measure parental self-esteem (a higher score represents greater self-esteem; max = 30).

Results: Results showed that parents of children with ASD ( $M = 1.78$ ,  $SD = 0.508$ ; Min = 14, Max = 30) reported significantly greater degree of affiliate stigma in comparison to parents of children with PD ( $M = 1.46$ ,  $SD = 0.327$ ) ( $t = -3.403$ ,  $df = 66.33$ ,  $p$

= 0.001). No differences between these two groups of parents were found in empowerment and self-esteem. On average, parents of children with ASD reported relatively high level of empowerment (M = 3.98, SD = 0.494), with the highest score on Service System subscale (M = 4.11, SD = 0.452), following by Family subscale (M = 4.06, SD = 0.475), and Community (M = 3.74, SD = 0.761). On average, self-esteem among parents of children with ASD was moderate-to-high (M = 21.28, SD = 4.212; Min = 14, Max = 30).

Conclusions: Based on our results, parents of children with ASD reported a significantly higher level of the affiliate stigma in comparison to parents of children with PD. On average, parents of children with ASD expressed low degree of affiliate stigma, moderate-to-high level of self-esteem, and high level of empowerment. Further research with Serbian parents should include more diverse sample (e.g., parents from rural areas) to examine these constructs, as culture in Serbian smaller cities and rural areas differs from the ones in the larger cities.

**422.008** (Poster) African Americans' Perceptions of Children's Behavior Associated with Autism Spectrum Disorder  
*D. Ashby<sup>1</sup>, F. Jones<sup>2</sup>, A. Lucas-Wright<sup>3</sup>, O. Solomon<sup>4</sup>, A. Deavenport-Saman<sup>1</sup>, D. Vanderbilt<sup>5</sup> and L. Yin<sup>3</sup>, (1)Children's Hospital Los Angeles, Los Angeles, CA, (2)Healthy African American Families, Los Angeles, CA, (3)Charles R. Drew University of Medicine and Science, Los Angeles, CA, (4)University of Southern California, Los Angeles, CA, (5)Children's Hospital Los Angeles/Keck School of Medicine of USC, Los Angeles, CA*

---

Background: Racial disparities in prevalence of Autism Spectrum Disorder (ASD) among White and African American children have been documented since the start of surveillance by the Autism and Developmental Disabilities Monitoring (ADDM) network. Parents from different cultural backgrounds have been shown to differentially interpret similar symptom presentations associated with ASD, which depends upon the salience of missing or delayed behavior in their cultural expectations of normative behavior. Before receiving an Autism Spectrum Disorder (ASD) diagnosis, African American parents report fewer ASD-specific concerns compared to White parents. African American children are also less likely to receive an ASD evaluation prior to age 3. While it has been suggested that African Americans' cultural beliefs about delayed or atypical development may contribute to under-identification of ASD among African American children, research that considers the recognition and interpretation of children's developmental problems by African American parents whose children *do not already have* an ASD diagnosis has been mostly lacking.

Objectives: Our study seeks to understand the socio-cultural factors in the African American community that may contribute to under-identification of African American children with ASD. The insights from this study are anticipated to guide interventions to decrease the timing of ASD diagnosis in the African American community.

Methods: Community-Partnered Participatory Research (CPPR) model is based upon the development of trust and shared knowledge among community members, academic researchers, and health care professionals. CPPR was used to conduct focus groups with 30 African American parents of typically developing children at two Black Churches. Participants watched Centers for Disease Control and Prevention's Autism Case Training videos portraying African American children with ASD and discussed their observations. Parents were uninformed of the diagnosis of the children in the videos. Focus groups were audio-recorded, transcribed and thematically coded using NVivo software. Themes were then mapped onto the Social-Ecological Model (SEM) to illustrate the influences of social environments on perceptions of children's behavior, and to help guide interventions for changes in health outcomes

Results: A total of 30 participants who were between 22 and 85 years of age participated in four focus groups. Most parents identified ASD-specific behaviors as delayed or unusual, but only 10% linked these behaviors with ASD. Developmental delays were seen as normal variants of typical development such as being an only child, or a child of a single parent. Behaviors consistent with ASD, especially lack of joint attention and social-emotional reciprocity were viewed as a sign of the child's intraverted personality rather than a deviation from the norm. Mistrust and concerns that physicians' racial bias may lead to suspicion of child abuse was seen as a barrier to discussing developmental concerns. Racial concordance with physicians was perceived as desirable to facilitate discussion of developmental concerns.

Conclusions: Culturally tailored interventions to educate the African American community about ASD should focus on children's joint attention and social-emotional reciprocity, which were most salient to the parents in our study. Insights from this study are useful for training pediatricians to facilitate trust among African American parents.

**422.009** (Poster) Associations Among Autism Symptom Domains and Facets of Parent Strain  
*S. M. Brunt and M. O. Mazurek, University of Virginia, Charlottesville, VA*

---

Background:

Having a child with an Autism Spectrum Disorder (ASD) diagnosis can pose unique challenges for parents. Parents of children with ASD tend to have higher levels of parenting stress compared to parents of typically developing children (Hayes & Watson, 2013). Aspects of ASD symptomatology such as behavior problems, personal care skills, and sensory issues have been linked to higher caregiver strain (Hand et al., 2018; Khanna et al., 2011). However, discrepancies in findings suggest that the associations may not be stable across developmental periods. Moreover, previous research has not addressed the possibility that different symptom domains might affect different aspects of caregiver strain.

#### Objectives:

The aim of the current study is to investigate the associations between autism symptom domains and facets of caregiver strain, as well as the moderating effect of age on these associations.

#### Methods:

Data was obtained from the Autism Treatment Network Registry Call-Back Study. The sample consisted of 483 male (79.7%) and 123 female (20.3%) children with an ASD diagnosis. Participants ranged in age from 2 to 16.8 years ( $M = 6$ ,  $SD = 3.29$ ).

The frequency and impact of ASD symptoms were measured using the five subdomains of the Autism Impact Measure (AIM; Kanne et al., 2014): Repetitive Behaviors, Communication, Atypical Behaviors, Social Reciprocity, and Peer Interaction. Caregiver strain (CGS) was measured using the three subdomains of the Caregiver Strain Questionnaire (Brannan et al., 1997): objective (disruptions in routines and personal life), subjective externalized (feelings directed toward child such as resentment or embarrassment.) and subjective internalized (negative feelings such as sadness or worry) strain. Multiple regressions were conducted for each subdomain of CGS. Predictors included child age, gender, IQ, AIM subdomains, and interactions between age and AIM subdomains. Standardized betas are reported.

#### Results:

No main effects of age, gender, or IQ were found for any subdomains of CGS. Higher Atypical Behaviors predicted higher objective ( $b = .49, p < .001$ ), externalized ( $b = .35, p < .001$ ), internalized ( $b = .36, p < .001$ ) and global ( $b = .49, p < .001$ ) strain. Repetitive Behaviors were associated with lower externalized ( $b = -.25, p = .001$ ) and lower global strain ( $b = -.13, p = .05$ ). In addition, child age moderated the association between Communication and externalized strain ( $b = .15, p = .04$ ). For younger children, as Communication problems increased, externalized strain decreased, whereas for older children, as Communication problems increased, so did externalized strain.

#### Conclusions:

Results suggest that symptom subdomains are differentially related to parent strain. Moreover, the type of strain experienced varies across symptom domains. Atypical Behaviors was strongly related to all types of strain, suggesting that this domain may weigh heavily on parents. Age moderated the association between Communication and externalized strain; parents may have higher expectations for older children's communication skills compared to younger children whose language skills are still developing. More research is needed to clarify the association between Repetitive Behaviors and externalized and global strain.

#### **422.010** (Poster) Associations Among Child Autism Symptoms and IQ with Mindful Parenting and Parent-Child Relationship Quality in Treatment-Seeking Families

*N. Vashi, J. A. Weiss and Y. M. Bohr, Psychology, York University, Toronto, ON, Canada*

---

**Background:** Parent-child relationship quality and mindful parenting is associated with positive health outcomes in children with developmental disabilities. In children with autism, mindful parenting and positive parent-child relationship quality have each been associated with lower child externalizing problems (Singh et al., 2006; Smith et al., 2008). Studies have demonstrated associations between child characteristics such as autism symptomatology and the parent-child relationship in this population (Haven et al., 2014). Research is needed to examine other child characteristics (e.g., IQ) and family characteristics (e.g., family stressors) which may relate to positive parent-child relationship quality and mindful parenting. It is particularly important to examine these associations within the context of treatment-seeking families, whose children have mental health needs.

**Objectives:** To examine whether child IQ, autism symptoms, and mental health problems, along with family-level characteristics, are related to parenting in families of autistic children.

Methods: Data were collected from 57 parent-child dyads at baseline prior to being involved in cognitive behavioural therapy for child mental health problems. Parents were 29 to 54 years of age (86% Female;  $M = 44.3$  years,  $SD = 5.4$ ), and children were 8 to 13 years of age (79% Male;  $M = 9.9$  years,  $SD = 1.5$ ). Parent-child relationship quality was assessed using the Positive Affect Index (PAI; Bengtson & Schrader, 1982), which provides a total score and two subscale scores: 1) positive affect towards child and 2) positive affect from child. Higher scores reflect more positive relationship quality. Mindful parenting was measured using the Bangor Mindful Parenting Scale (BMPS; Jones et al., 2014), with higher scores reflecting greater mindful parenting. Autism symptomology was assessed using the Social Responsiveness Scale – Second Edition (SRS-2; Constantino & Gruber, 2012), mental health was assessed using the Clinical Global Impression Scale – Severity (CGI-S; Guy, 1976), and IQ was assessed using the Weschler Abbreviated Intelligence Scale – Second Edition (WASI-II; Weschler, 2011). Demographic information (e.g., family income) and the number of family stressors was also assessed.

Results: Correlational analyses revealed that more positive relationship quality was associated with lower autism symptomology ( $r = -.45, p = .001$ ), lower child IQ ( $r = -.32, p = .02$ ), and lower child mental health problems ( $r = -.36, p = .02$ ), while greater mindful parenting was associated with lower autism symptomology ( $r = -.34, p = .01$ ) and lower child IQ ( $r = -.42, p = .002$ ). Neither parenting variable was associated with child gender, age, number of family stressors or family income (all  $p > .05$ ). Results of linear regressions revealed that relationship quality was independently predicted by autism symptomology ( $p = .003$ ) and child IQ ( $p = .01$ ), but not child mental health ( $p = .22$ ). Mindful parenting was independently predicted by autism symptomology ( $p = .002$ ) and child IQ ( $p < .001$ ).

Conclusions: Associations were demonstrated between child characteristics and parent-child relationship quality and mindful parenting in families of autistic children. These protective factors may be addressed in intervention to improve parent-child dynamics, and potentially, child outcomes.

**422.011 (Poster) Autism and the Cultural Imagination: A Critical Analysis of the Cultural Products Sustaining the Use of Behavioral Treatments for Autistics in the United States**

*E. M. Bomgardner, Interdisciplinary and Inclusive Education, Rowan University, Glassboro, NJ*

---

Background: Our cultural imaginings shape disability discourse and the actions taken for and against Autistic bodies. In the United States, Autistic are often subjected to behavioral treatments (Lovaas, 1987; Wolf, Risley, & Mees, 1963). These treatments are perpetuated and reinforced through the medical model of disability (Glynne-Owen, 2010; Shyman, 2016). Through this medical model lens we create cultural products that serve to reinforce the idea that behavioral treatments are justified, desirable, and necessary. Three examples of such cultural products include the visual representation of autism in the media and our communities, the anti-vaccination movement, and the Autism warrior mother trope.

Objectives: I describe how three cultural products (visual representation, the anti-vaccination movement, and the autism warrior mother trope) serve to perpetuate our cultural imaginings of the necessity of behavioral treatments for Autistic bodies. I analyze these cultural products through a critical disability studies (CDS) and disability studies (DS) framework (Grech, 2015; Linton, 2005; Meekosha & Shuttleworth, 2009; Taylor, 2006). Finally, I discuss some of the ways we can shift our cultural imaginings of Autistic bodies in the United States.

Methods: This is a narrative literature review.

Results: Our prominent thinking about autism has been shaped by the clinical experiments of behavioral scientists (Bettleheim, 1967; Kanner, 1943; Lovaas, 1987) and the continued use of behavioral treatments with Autistics have clear economic implications as a lucrative for-profit enterprise (LaRosa, 2018). Cultural products sustain beliefs in behavioral treatment by driving our imaginings of autism as a problem. Visual metaphors like autism puzzle pieces, popular literature, and empirical research create a visual tapestry that paints autism as mysterious, puzzling, interesting, sometimes terrifying, and mostly undesirable (Autism Speaks, 2017; Deggins, 2017; Google Scholar, 2018; Kovach, 2015). Dr. Andrew Wakefield (1998) wrote a now redacted study that powerfully created a connection between vaccines and autism and cemented a strong and on-going anti-vaccination (anti-vaxxer) movement that continues to grow today (Hayden, 2018; Rozbicki, 2016). Finally, the autism warrior mother trope was born from mothers' long and complicated history with autism (Sousa, 2011) and helps sustain a drive in many mothers to fix their child's autism. From Bettleheim (1967) comparing autism mothers to Nazi camp guards, to blaming refrigerator mothers for causing their child's autism (Douglas, 2013) to Jenny McCarthy's personal memoir on warrior mothers (2008) the vision of mothers as modern warriors fighting against autism will most likely thrive for years to come.

Conclusions: To begin shifting our cultural imaginings of autism, Autistic self-advocates, Autistic researchers, and parent advocates are powerful and necessary voices (Dawson, 2009; Milton, 2014; Perry, 2018). It is also necessary that marginalized Autistic voices such as people of color and transgender autistics are amplified in autism discourse (Brown, Ashkenazy &

Onaiwu, 2017). There are Autistic authors speaking back against behavioral treatments in academic research (Kupferstein, 2018) and in online spaces (Hode, 2012; Mohler, 2018, Kronstein, 2018, Sequenzia, 2015). Critically analyzing the cultural products we consume about autism could begin to shift our cultural imaginings about the desirability of behavioral treatments.

**422.012** (Poster) Autistic People's Experiences of the First UK-Wide Lockdown and Lessons for Conducting Research during and after the COVID-19 Pandemic

*A. X. Realpe<sup>1</sup>, N. Mills<sup>1</sup>, L. Beasant<sup>1</sup>, S. Douglas<sup>2</sup>, L. Kenny<sup>3</sup> and D. Rai<sup>4</sup>, (1)Bristol Medical School, University of Bristol, Bristol, United Kingdom, (2)Bristol, United Kingdom, (3)Centre for Research in Autism and Education (CRAE), London, United Kingdom of Great Britain and Northern Ireland, (4)Population Health Sciences, Bristol Medical School, Centre for Academic Mental Health, Bristol, United Kingdom*

---

Background: Following a rapid rise in COVID-19 cases, a set of nationwide public health restrictions including limits on social mixing, business closures and guidance to maintain social distance and wear face coverings (hereafter, COVID-19 lockdown) were in force on the UK from March 2020. Anxiety and depression highly co-occur in autism and autistic people are at heightened risk of potential adverse mental health due to the COVID-19 lockdown. Furthermore, the impact of current and future public health measures on autistic people's willingness to take part in autism research remains unknown.

Objectives:

- Understand autistic people's experiences of the COVID-19 lockdown and how it impacted their daily lives.
- Describe how the pandemic may affect future research participation among autistic people.
- Identify adaptations required to research processes to facilitate research participation during and after the pandemic.

Methods: Participants were autistic adults who expressed an interest in participating in a separate study about the autistic people's views about randomised controlled trials following advertising via the UK charity Autistica and social media. Interviews were conducted remotely and were transcribed verbatim. Two authors conducted thematic analysis and met regularly to refine their codes and discuss disagreements. Transcripts were analysed from an inductive perspective where themes were created within a contextualist framework of critical realism.

Results:

The sample included 31 autistic adults (14 males, 15 females, and 2 non-binary people). Most people (77%) had higher education qualifications and half (51%) were employed. We organised findings in four overarching themes: i) positive aspects of lockdown; ii) challenges of lockdown; iii) concerns and hopes about the lifting of restrictions; and iv) views on research engagement and participation. Participants identified positive aspects of lockdown such as enjoying the lack of social pressures and using their well-developed skills for dealing with uncertainty. Autistic people shared challenges of adjusting to lockdown, for example, due to the rapid change in daily routines. While participants were hopeful about the freedom gained from easing restrictions, they were concerned about the inconsistent communication and application of rules during the transition out of lockdown which may serve to exacerbate already rising mental health issues among autistic people. The participants viewed research participation and engagement with increased relevance during the pandemic and welcomed efforts to conduct research using online methods of communication. Although not deterred from participating in-person, they would need more assurance derived from rigorous rationale and stricter safety protocols.

Conclusions: The COVID-19 lockdown had a varied effect in the lives and routines of autistic people evidenced in their mixed experiences that included seeing opportunities and facing challenges. However, healthcare providers and researchers need to be mindful of rising mental health issues during the pandemic, especially for people who were already vulnerable. Apart from the challenges, the findings suggest that the pandemic may have offered opportunities for innovation in research processes (e.g., wider use of remote methods of consent and data collection) enabling more autistic people to engage with research and making studies more inclusive.

**422.013** (Poster) Bedtime Resistance and Parent Stress in Families of Children with Autism

*R. Finlayson<sup>1</sup>, A. M. Estes<sup>2</sup>, J. Munson<sup>3</sup> and G. Dawson<sup>4</sup>, (1)College of Education, University of Washington, Seattle, WA, (2)Speech and Hearing Sciences, University of Washington, Seattle, WA, (3)Psychiatry & Behavioral Sciences, University of Washington, Seattle, WA, (4)Department of Psychiatry and Behavioral Sciences, Duke Center for Autism and Brain Development, Durham, NC*

---

Background:

Sleep problems are reported in as many as 80% of children with autism spectrum disorders, and occur at significantly higher rates than in typically developing populations. Children's sleep problems also impact the sleep and general wellbeing of family members. This is of particular concern as parents of children with autism already demonstrate higher rates of stress than parents of both typically developing children and children with other developmental disabilities, suggesting that families of children with autism and sleep problems may be at particular risk for psychological distress. It is as yet unknown if parent stress is in part accounted for by child sleep problems, and in particular which domains of sleep problems might uniquely predict this stress. Identifying specific sleep concerns that contribute to parent stress may have implications for developing cost-effective and feasible interventions to improve child sleep, parent stress, and related child and family outcomes.

#### Objectives:

To identify the relationship between subscales on the Child Sleep Habit Questionnaire (CSHQ) and parent stress in families of children with Autism Spectrum Disorders, controlling for child irritability, autism symptom severity, and participation in a comprehensive intervention for toddlers with autism (the Early Start Denver Model) .

#### Methods:

Drawing from a cohort of children with diagnoses of ASD ( $N = 33$ ), initially recruited for a study assessing the effects of an intervention for toddlers with ASD and followed longitudinally through age 6 (Dawson et al., 2010; Estes et al, 2015), we analyzed the relationships between parent stress (Questionnaire on Resources and Stress) and child sleep problems (Child Sleep Habits Questionnaire; 8 subscales, 1 total score), controlling for child's level of autism symptoms (Autism Diagnostic Observation Schedule), child irritability (Aberrant Behavior Checklist-Community), and participation in the Early Start Denver Model (intervention vs control group).

#### Results:

CSHQ subscales Bedtime Resistance (BR) and Sleep Anxiety (SA) were significantly correlated with parent stress. No other CSHQ subscale or total score were significantly correlated. BR and SA were highly intercorrelated. BR was chosen for further analysis; SA yielded similar results. Bedtime resistance was uniquely predictive of parent stress holding ASD symptom severity, and child irritability constant. Participation in the ESDM treatment did not uniquely predict parent stress.

#### Conclusions:

Bedtime resistance uniquely predicted a proportion of parent stress, even when controlling for child irritability and ASD symptom severity in children with ASD. Behavioral interventions to address bedtime resistance may have cumulative positive effects; improving child sleep, reducing parent stress, and improving related challenges for families. Targeted intervention to address bedtime resistance may be a cost-effective, feasible, and acceptable pathway to improve outcomes for children with ASD and their families.

#### **422.015 (Poster) Caregiver Experience with Telebaby: A Telehealth Intervention Designed for Caregivers of Infants with Early Signs of Autism Spectrum Disorder (ASD)**

**R. S. John<sup>1</sup>, M. R. Talbott<sup>2</sup>, S. J. Rogers<sup>3</sup> and S. Dufek<sup>4</sup>, (1)UCD MIND Institute, Sacramento, CA, (2)Psychiatry and Behavioral Sciences, University of California at Davis MIND Institute, Sacramento, CA, (3)Department of Psychiatry and Behavioral Sciences, The Medical Investigation of Neurodevelopmental Disorders (MIND) Institute, UC Davis School of Medicine, University of California Davis, Sacramento, CA, (4)Psychiatry, University of California, Davis, Sacramento, CA**

**Background:** Service providers face multiple challenges delivering timely and appropriate care to infants exhibiting early signs of autism spectrum disorder (ASD). Barriers such as lack of local service providers with specialized training and lack of access to infants and their caregivers in their natural environments limit the ease and efficiency of treatment provision. The use of telehealth technology to serve families who are concerned about ASD symptoms in their infants is a promising solution (Machalicek et al., 2010; McDuffie et al., 2013; Oakes et al., 2015).

**Objectives:** Characterize caregiver experience with TeleBaby, a telehealth intervention designed for caregivers of infants with early signs of ASD.

**Methods:** Six infants (6-12 months of age) exhibiting early signs of ASD and their primary caregivers participated in this study. Treatment sessions occurred three times per week for one month for a total of 12 sessions. Caregiver coaches introduced three

treatment techniques (Step into the Spotlight, Imitation, Talking to Baby) to the caregiver and allowed for caregiver practice with immediate reflection and planning. One final treatment session was conducted after a 1-month follow-up period. Session attendance was closely tracked and caregivers participated in an exit interview in order to obtain information about caregiver perspective around acceptability of and satisfaction with the TeleBaby intervention. Caregivers had never encountered the interviewer before, and the interviewer was blind to the caregiver's and infant's level of progress throughout the course of the project. The interviewer asked a set of questions in a semi-structured format (initial questions were predetermined but the interviewer asked follow-up questions as needed). Interview questions were concerned with the caregivers' experience in their local service system and the research study. Once interviews were completed they were transcribed by research assistants blind to the purpose of the study and coded for common themes.

**Results:** Session attendance rate was high (96%) with minimal rescheduling throughout the course of treatment. Participating caregivers reported frustration with their local service providers (e.g., practitioners often dismissed caregiver concerns, adopted a "wait and see" approach, lacked capacity or experience to serve infants with high likelihood of developing ASD). All caregivers reported high acceptability and satisfaction regarding the telemedicine-delivered TeleBaby intervention. They reported minimal difficulties managing the technology components required for telemedicine visits and appreciated the liberal rescheduling policy when their infants were having an occasional off day. Caregivers found the TeleBaby intervention techniques easy to implement and particularly enjoyed the live coaching component. Very specific feedback about all aspects of the Telebaby approach will be reported. Overall, all caregivers emphasized that they would not hesitate to participate in the intervention again and would recommend the intervention to others.

**Conclusions:** As more information is becoming available about symptoms of ASD in infants, an increasing number of families are seeking help from practitioners. Telemedicine-delivered intervention approaches such as TeleBaby can give service providers valuable intervention options that allow coaching in the natural environment, reduce the need for clinic and caregiver resources such as clinic space and travel time, and make scheduling/rescheduling fairly easy.

**422.016 (Poster)** Caregiver Perspective on the Psychosocial and Behavioral Impact of COVID-19 on Children with ASD in the United States

*L. Hewitson and P. Sachdev, The Johnson Center for Child Health and Development, Austin, TX*

---

**Background:** Children with ASD are particularly vulnerable to the disruptions caused by the COVID-19 pandemic. With the loss of school and private therapy services, establishing routines and maintaining structure within the home environment has been extremely challenging.

**Objectives:** The aim of this study was to conduct a parent/caregiver survey to assess the psychosocial and behavioral impact of COVID-19 on children with ASD in the United States to understand family support needs.

**Methods:** An anonymous parent/caregiver survey was conducted online between June and August 2020. All demographic and clinical variables were summarized using frequencies and percentages for categorical variables. Logistic regression was conducted to examine the associations of ASD individuals' socio-demographic or clinical characteristics with the parents' ability to manage their child's behaviors following the COVID-19 outbreak.

**Results:** Data from 700 complete survey responses were included representing 555 (79.2%) male and 138 (19.7%) female children. The mean±SEM age of responders' children was 10±4.68 years. There were 534 (76.3%) children with at least 1 sibling. Of these, 96/534 (17.9%) had an ASD diagnosis. The majority of caregivers completing the survey were married/cohabitating, highly educated, and reported an annual household income above \$75,000. ASD comorbid conditions were prevalent (500/700; 71.4%), with anxiety (65%), ADD/ADHD (58.2%), and sensory processing disorder (56.8%) frequently reported. Around 15% of children were non-verbal, while 42% had fluent language.

Behavior problems were present in 573 (81.9%) children before the outbreak of COVID-19. Out of these children, 218/573 (31.1%) were receiving ABA therapy, and 190/573 (27.1%) were receiving pharmacological interventions. There were 98 (14%) parents reporting that they or another family member were concerned for their safety due to their child's behavior, and 24 (3.4%) children were taken to the Emergency Room due to behavioral concerns. Many parents reported difficulties in managing their child's structured on-line school activities (72.4%) and free time (69.7%) during the lockdown. Parents also reported more difficulties in managing their child's behaviors (57.6%), therapies (57.6%), and sleep schedule (47.7%), while challenges in managing meals/dietary needs (27%) and medications (8.6%) were less of a concern. Several factors significantly affected the parents' ability to manage their child's behaviors post COVID, including: level of language ( $p=0.038$ ), difficulty in falling asleep ( $p=0.018$ ), and being under the care of a neuropsychiatrist/psychologist due to behavioral concerns ( $p=0.000$ ; Table 1).

Finally, 480 (68.5%) parents reported that they needed behavioral support for their child, whether center-based (16.4%), home-based (38.4%), or web-based (13.7%) during the lockdown. In preparation for the start of the new school year, 371 (53%) parents were planning to send their child to school for in-person learning, 96 (13.7%) would opt for remote learning, while 125 (17.9%) would opt for a combination of in-person/remote learning.

**Conclusions:** Parents/caregivers reported that the COVID-19 pandemic had a wide-ranging impact on their child/family. Escalating behaviors and changes to structures and routines affected the parents' ability to manage their child's day-to-day activities, and a large proportion of parents felt that behavioral support in or out of the home would have been a helpful intervention.

#### **422.018 (Poster) Challenging Behavior in ASD and Its Effects on Family**

**G. M. Kuravackel<sup>1</sup>, E. A. Roth<sup>2</sup>, H. A. Cooley-Cook<sup>3</sup>, M. Kong<sup>4</sup> and Q. Xu<sup>5</sup>,** (1)University of Louisville School of Medicine, Louisville, KY, (2)Spalding University, Indianapolis, IN, (3)Kentucky Autism Training Center, University of Louisville, Louisville, KY, (4)Bioinformatics and Biostatistics, University of Louisville, Louisville, KY, (5)Biostatistics, University of Louisville, Louisville, KY

---

#### Background:

Caring for children with Autism Spectrum Disorder (ASD) has the potential to influence the health and well-being of all family members. Conflicting data exists on the psychological and emotional functioning of siblings of children with ASD. Some studies indicate average functioning and advanced psychological well-being (Dempsey, Llorens, Brewton, Mulchandani, & Goin-Kochel, 2012; Macks & Reeve, 2007). On the other hand, a recent meta-analysis of typically developing siblings of individuals with ASD, results from 69 independent samples indicated that ASD-Sibs have significantly more negative outcomes than comparison groups overall. Specific areas of functioning in which ASD-Sibs fared worse include internalizing behavior problems, psychological functioning, beliefs, social functioning, and the sibling relationship functioning (Shivers, Jackson and McGregor, 2019).

#### Objectives:

To assess the relationship between multiple demographic characteristics and the behavioral symptoms of the sibling with ASD and the participant's anxiety symptoms, quality of life, and psychological functioning.

#### Methods:

Research participants included 50 siblings of children diagnosed with ASD. The participants were selected via recruitment flyers. Inclusionary criterion included having a biological sibling with ASD, living with sibling, and between the ages of eight and 18. Exclusionary criteria included the participant experiencing any known developmental disorders. Measures included:

1. Demographic Questionnaire to assess family composition, total income, parent reported stress on a 6 point scale and other relevant variables
2. Child behavior checklist (CBCL, school-age): represents a 112-item questionnaire assessing a child's symptomology, as defined by the DSM-5.
3. Aberrant Behavior Checklist (ABC): represents a 58-item questionnaire assessing problem behaviors of children and adults with ASD and other developmental disabilities
4. KINDL: assesses children and adolescents' perception of their own quality of life.
5. Screen for childhood anxiety related emotional disorders (SCARED): represents a 41-item questionnaire assessing a child's anxiety.

The parents completed the Demographic Questionnaire, the ABC on their child with ASD, and the CBCL on their participating child. The participating child completed the SCARED and KINDL.

#### Results:

Using the Mann-Whitney *U* test for continuous variables and Fisher's exact test for categorical variables, results showed that parent reported stress correlated significantly with higher parent ratings on the ABC measures (Total and sum of each domain: Irritability; lethargy; Stereotype and Hyperactivity) of the sibling with ASD and higher scores of the participant on the CBCL

total T score. Parent stress was higher when the CBCL total T score was higher than the median of 54 as compared to when the CBCL total T score was lower than the median ( $p$ -value=0.014).

#### Conclusions:

While there is much variability observed in sibling literature, the impact of problem behavior in children with ASD can impact family functioning including sibling and parent emotional health. While much attention is focused on the child with ASD and their intervention, the sibling often ignored. This study clearly indicates the need for a family based approach to intervention that takes into account the emotional well-being of the entire family, their access to supports and resources to mitigate the adverse effects of behavior problems in ASD that can take a considerable toll.

**422.019** (Poster) Child Social and Executive Function Problems Relate to Caregiver Sense of Self-Efficacy and Strain in Autism  
**J. V. Smith<sup>1</sup>**, A. Verbalis<sup>2</sup>, A. C. Armour<sup>2</sup>, E. Burlinson<sup>1</sup>, R. Handsman<sup>2</sup>, A. B. Ratto<sup>2</sup>, B. J. Anthony<sup>3</sup>, L. Anthony<sup>3</sup> and L. Kenworthy<sup>2</sup>, (1)Center for Autism Spectrum Disorders, Children's National Hospital, Rockville, MD, (2)Center for Autism Spectrum Disorders, Children's National Hospital, Washington, DC, (3)University of Colorado, Denver, Aurora, CO

---

#### Background:

Caregivers of children with Autism Spectrum Disorder (ASD) experience many challenges. ASD has been associated with increased caregiver strain/stress and decreased self-perceived competence in caregiver/parenting abilities (i.e., caregiver self-efficacy). Deficits in both executive and social functioning associated with ASD may affect caregiver stress/strain and caregiver self-efficacy.

#### Objectives:

The present study has the following aims:

- Examine the relationship between caregiver strain and child executive dysfunction and social deficits.
- Examine the relationship between caregiver self-efficacy and child executive dysfunction and social deficits.

#### Methods:

Participants included caregivers (i.e., parents/guardians) of children with ASD ( $N = 32$ ) from a school-based executive function (EF) intervention study. Caregivers' children were primarily male (75%), between the ages of 8 and 12 ( $M = 9.54$ ) with  $FSIQ \geq 70$ , with a research diagnosis of ASD, and teacher-reported flexibility problems in the classroom. Caregivers were majority female (84.4%); caregiver age, race, and ethnicity were not available. Caregiver strain was assessed through the Caregiver Strain Questionnaire-Short Form 7, a 7-item self-report questionnaire assessing child-related caregiver strain through a 6-point Likert scale; higher composite scores indicate greater strain (CSQ-SF7; Brannan, Athay, & de Andrade, 2012), and caregiver self-efficacy was measured through the Family Empowerment Scale, Competence subscale (FES: Koren, DeChillo, & Friesen, 1992; Singh et al., 1995). Child EF was measured by caregiver report on the Behavior Rating Inventory of Executive Function (BRIEF-2; Gioia et al., 2015), which includes three indices: Behavior (BRI), Emotion (ERI), and Cognitive (CRI) Regulation. Finally, social deficits were assessed via the social problems scale of the Child Behavior Checklist (CBCL; Achenbach & Rescorla, 2001).

#### Results:

Caregiver strain was moderately correlated with child age ( $r = .377, p = .033$ ) and behavior regulation (BRI) ( $r = .441, p = .012$ ), and highly correlated with emotion regulation (ERI) ( $r = .701, p = .000$ ), and social problems ( $r = .508, p = .003$ ) (Table 1). A simple linear regression performed to predict caregiver strain was significant ( $R^2 = .539, p < .001$ ), and the results indicated that child emotion regulation (ERI) was the lone significant predictor of caregiver strain ( $b = .825, t(32) = 3.473, p < .005$ ). All Variance Inflation Factors (VIF) were below 3.5.

Results indicated that a significant relationship exists between caregiver self-efficacy and child's social problems, ( $r = -.373, p = .042$ ).

#### Conclusions:

Our results indicate that child EF and social deficits are differentially related to caregiver well-being, such that that child emotion regulation problems are strongly related to caregiver strain, and 2) the child social problems are related to caregiver self-efficacy. These findings provide crucial focal points for tailored interventions for caregivers of autistic children. Highly stressed caregivers likely need supports for supporting children's emotional dysregulation, while those with low self-efficacy may need supports to better understand and accept their child's social interaction differences. Future studies should incorporate additional reporters and measures. Overall, better understanding the relationship between caregiver self-efficacy and strain sharpens the lens through which interventionists view and create interventions for those with ASD.

**422.020 (Poster) Comparing Patient Experience with Longitudinal Autism Care Via Virtual and in-Person Visits**

**J. Reken<sup>1</sup>, N. Buranova<sup>2</sup>, K. Sohl<sup>3</sup> and A. Ohler<sup>4</sup>,** (1)Child Health, University of Missouri, Columbia, MO, (2)Special Education, University of Missouri, Columbia, MO, (3)Department of Child Health, University of Missouri, School of Medicine, Columbia, MO, (4)Statistics, University of Missouri, Columbia, MO

---

**Background:**

Individuals with autism spectrum disorder (ASD) experience barriers to specialty medical care for their longitudinal needs. Telemedicine visits can reduce barriers like time off work, travel costs and missed school, yet implementation has been minimal. The COVID-19 pandemic necessitated conversion of traditional in-person autism medical visits to telehealth appointments. Current literature reports experiences from various specialties using telehealth. While telehealth is presumed to remove barriers to care for more remote patients and allow for similar visit experiences this is the first study to examine this in a cohort of patients with autism spectrum disorder receiving longitudinal specialty medical care

**Objectives:**

- Evaluate patient experience of receiving longitudinal autism medical care via virtual visits during the COVID19 pandemic to in-person visits
- Analyze variables impacting satisfaction with virtual visits across study participants
- Assess barriers to in-person visits compared to virtual visits

**Methods:**

Patients seen for longitudinal ASD follow up via telemedicine at a University-based Autism Center during the global pandemic (March 2020-August 2020) who also received in-person longitudinal medical care within the past 24 months were invited to participate in the study. All participants received care from the same physician at both types of visits. Eligible participants received an anonymous, REDCap survey consisting of 25 questions, with a combination of Likert scale questions regarding telehealth perceptions and multiple response questions regarding barriers and benefits. 87 participants were eligible to participate. A nominal incentive was provided for participant's time for survey completion.

**Results:**

Response rate was 44% among eligible participants with descriptive statistical analysis illustrating the average patient age as 12 years old, with a range of 3 years old to 26 years old, respondents had an average continuity of care of 7 years, ranging from 1-15. Respondents reported fast and reliable internet access from their location (79%), easy to understand instructions for the telehealth visit (87%), and no technical difficulties during the appointment (84%). The majority of patients participated in the virtual visits through video conference (89%) via a computer or tablet (81%). Most respondents (89.19%) reported benefits to telehealth, including less disruption in daily schedule, less travel expense and less time away from school. In patients who reported barriers to in-person visits, the most commonly reported barriers to visits were disruption in daily schedule (21.62%) lack of time (18.92%) and other (21.62%). The overall results suggest the two groups (positive vs poor experience) are not distinctly different in the ability to access telehealth, connectivity, internet quality, or perceived barriers to in-person visits. Lastly, the distance traveled to the appointment was associated with certain barriers and benefits among participants of the study.

**Conclusions:**

Longitudinal autism medical care is an essential component of comprehensive care for individuals with autism spectrum disorder. COVID-19 pandemic required abrupt changes to care delivery models to maintain healthcare access for individuals with chronic

conditions like autism. This study highlights the acceptability of virtual visits for patients with ASD to receive longitudinal care and supports the vital role for alternative visit types to continue beyond the COVID19 era.

**422.021 (Poster)** Development of the Self-Assessment of Autistic Traits, a New Self-Report Scale Centered in the Autistic Experience

*N. Nadwodny<sup>1</sup>, J. Bascom<sup>2</sup>, S. daVanport<sup>3</sup>, J. F. Strang<sup>1</sup>, L. Anthony<sup>4</sup>, A. B. Ratto<sup>1</sup>, G. L. Wallace<sup>5</sup>, A. Verbalis<sup>1</sup>, C. E. Pugliese<sup>1</sup>, A. Song<sup>1</sup>, K. A. Pelphrey<sup>6</sup> and L. Kenworthy<sup>1</sup>, (1)Center for Autism Spectrum Disorders, Children's National Hospital, Washington, DC, (2)Autistic Self-Advocacy Network, Washington, DC, (3)Autistic Women & Nonbinary Network, Lincoln, NE, (4)University of Colorado, Denver, Aurora, CO, (5)The George Washington University, Washington, DC, (6)University of Virginia, Charlottesville, VA*

---

**Background:**

Current gold standard tools for identifying and characterizing autism have been critiqued for their lack of specificity and sensitivity, especially in older, higher IQ, and non-male individuals (e.g., Lai, Lombardo, Auyeung, Chakrabarti, & Baron-Cohen, 2015). Information from autistic people about their inner experience of autism represents an untapped resource for enhancing phenotyping tools.

**Objectives:**

To develop a self-report autism trait questionnaire for adolescents and adults using a Community-Based Participatory Research (CBPR) approach, in which autistic self-advocates lead a team of non-autistic clinicians and researchers (Nicolaidis et al., 2020).

**Methods:**

A team of two autistic co-investigators and eight non-autistic clinical researchers employed a novel measure development procedure designed to center item generation and selection in the personal experience of autistic people. Ground rules were set for team meetings similar to the ASPIRE CBPR process (Nicolaidis, Raymaker et al., 2011, 2019). The autistic co-investigators compiled a list of internet documents written by autistic people that are regarded as seminal in the autistic community for their definitions of the autistic experience. The clinician-researchers extracted themes and descriptors of the autistic experience from the documents which were discussed and translated into 52 items. These items were refined in a two-stage modified Delphi procedure (Waggoner, Carline, & Durning, 2016). The international expert Delphi panel was comprised of 22 autistic adults (ages 25-62 years) that was diverse in terms of ethnicity (n=12 White, n=4 Black, n=4 Asian, n=2 Multiracial, n=1 unreported), gender (n=10 female, n=8 male, n=2 agender, n=2 nonbinary/genderqueer, n=1 exploring, n=1 gender fluid, n=1 "complicated"), and gender diversity status (n=6 self-identified as gender diverse), where participants could endorse more than one classification/identity within each category. The Delphi experts were asked to accept or reject and suggest improvements for each of the 52 descriptors generated by the team. The quantitative data was tabulated and used to prioritize item inclusion, and suggestions for improving items or additional items were addressed with the full research team. This resulted in a comprehensive list of 84 items. In the second step of the Delphi, 19 of the original 22 experts gave feedback on whether or not each of the 84 items was an 'essential' component of the autistic experience. 26 items were eliminated because less than 70% of the Delphi experts deemed them 'essential', resulting in 58 iteratively revised descriptors of autism.

**Results:**

This process resulted in the Self-Assessment of Autistic Traits presented in a format and language that is consistent with common autistic thinking styles, increasing accessibility for respondents. The iterative, team intensive process led to an item pool that addresses aspects of autism that are not captured with current diagnostic or phenotyping tools, such as autistic inertia and changes in abilities outside of early childhood. Many traits that are typically pathologized are presented in a positive manner more in line with how autistic people commonly describe them.

**Conclusions:**

Participatory research techniques with autistic partners leading researchers and clinicians in the development of new assessment tools yields a measure which introduces understudied components of the autistic experience.

**422.022 (Poster)** Engaging Community Stakeholders in Qatar to Develop Support Programs for Young Adults with Autism

*A. B. Ratto<sup>1</sup>, S. I. Habayeb<sup>2</sup>, S. T. Al-Harashsheh<sup>3</sup>, C. E. Pugliese<sup>1</sup>, A. Verbalis<sup>1</sup> and N. Nadwodny<sup>1</sup>, (1)Center for Autism Spectrum Disorders, Children's National Hospital, Washington, DC, (2)Catholic University of America, Washington, DC, (3)World Innovation Summit for Health, Doha, Qatar*

---

**Background:** Autism services in Qatar are expanding rapidly, but focus primarily on diagnosis and treatment of young children (Alshaban et al., 2017). The shortage of qualified autism providers and minimal opportunities for autistic youth to participate in school, work, and community (Qoronfleh et al., 2019) have led to a growing population of autistic youth transitioning to adulthood, many with co-occurring intellectual disability, who have substantial unmet needs for behavioral support and instruction in critical life skills. There are growing calls for supports for autistic adolescents and young adults. Consideration of local, stakeholder-driven priorities and values is critical to the success of these support programs, particularly given the integral role of families in adult support services (Jeon et al., 2005).

**Objectives:** Identify the priorities for support programming for autistic adolescents and young adults in Qatar, with particular focus on respite care, utilizing family and stakeholder input

**Methods:**

Researchers from Children's National (Washington, DC) collaborated with researchers and community leaders from the Qatar Foundation and World Innovation Summit for Health (Doha, Qatar) to evaluate perspectives regarding adults supports, including respite care, with families of autistic people (n=11) and providers/ community stakeholders (n=20). Participants were recruited via electronic media, flyers, and word-of-mouth, by leveraging existing networks (e.g., schools, clinics, family support groups). Participants responded via brief questionnaires (focusing on respite care) and/or focus groups (covering broader adult support services), conducted separately with providers, in English, and families, in both English and Arabic. Most providers were non-Qatari (90%, n=18) and had advanced degrees (95%, n=19). Most had several years of experience working with individuals with autism (M=15.8, SD=10.28). Relatively few providers specialized in adults (20%, n=4). Most family members were non-Qatari (54.54%, n=6), with children ages 5-31 years (M=16.82, SD=7.21). Families were evenly divided in language preferences between Arabic (n=6) and English (n=5). All family participants were mothers. Qualitative analysis of focus groups was conducted using inductive thematic analysis.

**Results:** The team generated 5 codes encompassing 22 subcodes, then used inductive thematic analysis, which identified four themes: 1) the need for trust and reliability in providers and systems 2) the importance of quality of life 3) the desire for meaningful inclusion of autistic individuals in their communities and 4) challenges navigating services systems. As reflected in the themes, stakeholders emphasized opportunities for autistic adults to develop their skills and make significant community contributions, in addition to valuing respite care. On questionnaires, families endorsed reducing stress (54.55%, n=6), attending to personal business (e.g., work, medical appointments, social activities) (45.56%, n=5), and increasing their ability to care for their child (45.56%, n=5) as motivators for seeking respite. Extensive prior experience in autism was endorsed as critical for trusting respite care providers (72.72%, n=8).

**Conclusions:** Families in Qatar endorsed clear interest in services for young adults with autism, with a focus on opportunities for learning, building purpose, and being actively included in communities. This study highlights the value of including both provider and family expertise in developing new service models.

**422.023 (Poster) Examining Sibling Relationships Among Children on the Autism Spectrum: Clinical Characteristics of Autism and Links with Sibling Status and Rivalry**

*C. Liu<sup>1</sup>, A. J. McVey<sup>1</sup>, A. Zaidman-Zait<sup>1</sup>, P. Mirenda<sup>1</sup>, T. Bennett<sup>1</sup>, E. Duku<sup>1</sup>, M. Elsabbagh<sup>5</sup>, S. Georgiades<sup>6</sup>, I. M. Smith<sup>7</sup>, P. Szatmari<sup>8</sup>, W. J. Ungar<sup>9</sup>, T. Vaillancourt<sup>10</sup>, C. Waddell<sup>11</sup>, L. Zwaigenbaum<sup>12</sup> and C. M. Kerns<sup>1</sup>, (1)University of British Columbia, Vancouver, BC, Canada, (2)Tel-Aviv University, Tel-Aviv, Israel, (3)Offord Centre for Child Studies, McMaster University, Hamilton, ON, CANADA, (4)Offord Centre for Child Studies, McMaster University, Hamilton, ON, Canada, (5)Neurology and Neurosurgery, McGill University, Montreal, QC, Canada, (6)McMaster Autism Research Team, McMaster University, Hamilton, ON, Canada, (7)Dalhousie University / IWK Health Centre, Halifax, NS, CANADA, (8)The Hospital for Sick Children, Toronto, ON, Canada, (9)The Hospital for Sick Children Research Institute, Toronto, ON, Canada, (10)University of Ottawa, Ottawa, ON, Canada, (11)Simon Fraser University, Vancouver, BC, Canada, (12)University of Alberta, Edmonton, AB, Canada*

---

**Background:** Research suggests that having a sibling is a more consistent predictor of well-being in children on the autism spectrum when the quality of the sibling relationship is considered (Walton & Ingersoll, 2015; Tomeny et al., 2017). Little is known, however, about how the varied clinical characteristics of autism spectrum disorder relate to sibling relationship quality. Autism symptoms, behavioural difficulties, and communication ability have been associated with peer and parental relationships,

but investigations of their link with sibling relationship quality, particularly sibling rivalry (i.e., parental differential treatment) and relative status (i.e., sibling leadership and support of one another) are lacking.

**Objectives:** To examine how autism symptoms, behavioural difficulties, and communication ability relate to sibling status and rivalry for children on the autism spectrum. We hypothesized that greater autism symptoms would be associated with lesser status and more rivalry. We expected an interaction between behavioural difficulties and communication ability for rivalry and status, such that rivalry would be higher among children with lesser communication ability and more behavioural difficulties whose multiple challenges may demand more parental attention; we expected relative status would be lower among these children as they may be less dominant over their siblings.

**Methods:** Data from a subsample of children on the autism spectrum ( $n = 92$ ) were drawn from Time 8 of an ongoing longitudinal study, the *Pathways in ASD* study. Assessments of autism symptom symptoms (*Autism Diagnostic Observation Schedule Calibrated Severity Score [ADOS CSS]*; Gotham et al., 2009), behavioural difficulties (*Child Behaviour Checklist Total Problems [CBCL-TP]*; Achenbach and Rescorla, 2001), and communication ability (*Vineland Adaptive Behaviour Scale, 2<sup>nd</sup> Edition Communication Subscale [VABS-II-C]*; Sparrow et al., 2005) were included. To investigate interaction effects, a median split based on the *VABS-II-C* was applied to group the autistic children by communication ability. The parent-reported *Sibling Relationship Questionnaire (SRQ)* measured domains of sibling relationship quality: *Relative Status* and *Rivalry*. Hierarchical multiple regressions, controlling for child assigned sex at birth and birth order, tested hypotheses.

**Results:** Autism symptoms (*ADOS CSS*) were not significantly associated with *SRQ Relative Status* ( $b = 0.08, p = 0.46$ ) or *Rivalry* ( $b = -0.06, p = 0.61$ ). There was a significant interaction between behavioural difficulties (*CBCL-TP*) and communication ability (*VABS-II-C*) for *Rivalry*, but not *Relative Status* (Table 1). Sibling rivalry was more strongly associated with behavioural problems in the group with lower communication ability (Figure 1).

**Conclusions:** Unexpectedly, the predictor variables were unrelated to sibling status, suggesting that these factors may not play a role in this aspect of sibling relationships for children on the autism spectrum. Autism symptoms were not associated with sibling status or rivalry. In line with our hypothesis, however, we found an interplay between children's behaviour and communication abilities, such that behavioural difficulties enhanced rivalry for when those children also had communication difficulties. It may be that siblings compete more with these children for their parents' attention. Overall, our findings underscore the importance of considering the clinical characteristics that may be associated with the sibling relationships of children on the autism spectrum.

**422.025 (Poster)** Experiences of Uruguayan Individuals with ASD and Their Families , during COVID-19 Pandemic. **G. Garrido<sup>1</sup>, M. Montenegro<sup>2</sup>, C. Amigo<sup>3</sup>, C. Nava<sup>4</sup>, N. Barrios<sup>5</sup>, A. Rosoli<sup>6</sup>, S. H. Cukier<sup>7</sup>, R. A. Garcia<sup>8</sup>, C. S. Paula<sup>9</sup>, J. M. Suárez<sup>10</sup>, M. Segura<sup>11</sup>, D. Valdez<sup>12</sup> and A. Rattazzi<sup>1</sup>.** (1)Universidad de la Republica, Montevideo, Uruguay, (2)University of Texas Rio Grande Valley, Edinburg, TX, (3)Clinica de psiquiatria pediátrica Facultad de medicina, UDELAR, Montevideo, Uruguay, (4)Psychological Science, University of Texas Rio Grande Valley, Edinburg, TX, (5)Fleni, Capital Federal, ARGENTINA, (6)Projects, Organización Estados Iberoamericanos, Santo Domingo, Dominican Republic, (7)PANAACEA, Buenos Aires, Argentina, (8)Clinica Las Condes, Santiago, Chile., Santiago, CHILE, (9)Developmental Disorder Program, Universidade Presbiteriana Mackenzie, São Paulo, Brazil, (10)Clínica de psiquiatria pediátrica, Facultad de medicina, Universidad de la Republica, Montevideo, Uruguay, (11)Facultad de medicina, Montevideo, Uruguay, (12)Universidad de Buenos Aires- FLACSO, Buenos Aires, Argentina

**Background:** As the world reels with a worldwide pandemic due to the rapid spread of the virus COVID-19, children with autism spectrum disorder (ASD) experience a plethora of adjustments. The suspension of services and shelter in place has created added issues to an already vulnerable community. National Emergency state was declared by the Uruguayan government on March 13 th, with the consequent shut down of schools and restricted access to health care centers. Confinement was voluntary with a significant adherence of the population. Changes and unknown circumstances can be particularly difficult for children with ASD who benefit from routine and structure. The present study attempted to understand changing patterns for children with ASD and their families, and possible relationships between screen time, behavioral and emotional changes, and treatment changes.

**Objectives:** To explore the new reality of children with ASD in terms of treatment, screen time and behavioral and emotional changes. To explore the relationship between these variables.

**Methods:** A total of 259 caregivers of children and adults with ASD in Uruguay completed an anonymous online survey. The survey was comprehensive and explored sociodemographic information about the individual with ASD, changes experienced during the pandemic including treatment changes, screen time utilization, and behavioral and emotional changes. A descriptive inferential analysis was conducted to understand modifications experienced by individuals with ASD and their families. Chi-

square tests of independence were conducted to understand relationships between treatment changes, screen time, and behavioral and emotional changes. The study has the approval of the research ethics committee.

Results: Response rate was 7,5/100.000 inhabitants. Total sample consisted of caregivers of 215 male children and 44 females. During the pandemic, 23.9% of children found their treatment suspended, while 64.5% received services either by phone or through a videoconference platform. Interestingly, 74.5% saw an increase in screen time. Regarding changes in behaviors and emotions, 44% of children experienced difficulty sleeping, 59.6% experienced difficulty concentrating and paying attention, 53.5% changes in eating (either less or more than before), 63.9% became more irritable, 48.8% increased their wandering, and 47.6% of children experienced mood changes. Chi-square tests of independence were performed to understand relationship between variables and treatment during the pandemic. Significant relationships existed between treatment during the pandemic and eating changes  $\chi^2(5, N = 259) = 11.793, p = .038$ , and mood changes  $\chi^2(5, N = 259) = 12.490, p = .029$ . Screen time utilization was related with: sleep changes  $\chi^2(16, N = 259) = 49.416, p = 0.028$ , difficulty concentrating and paying attention  $\chi^2(16, N = 259) = 46.589, p = 0.000$ , eating changes  $\chi^2(16, N = 259) = 26.906, p = 0.043$ , irritability  $\chi^2(16, N = 259) = 26.884, p = 0.043$ , and behavioral dysfunction  $\chi^2(4, N = 259) = 9.961, p = 0.041$ .

Conclusions: Changes due to life modifications by the pandemic situation had an impact in different areas of autistic individuals. We hypothesize that increased screen time could be moderating the relationship between treatment and behavioral and emotional changes in children during the pandemic.

**422.026 (Poster)** Exploring Psychological Distress and Burden Among Informal Caregivers of Children with Autism Spectrum Disorder in Ghana, West Africa

**P. Ekremet<sup>1</sup>, M. Bello-Mojee<sup>2</sup>, Y. Adeniyi<sup>3</sup>, O. Omigbodun<sup>3</sup>, J. Akinyemi<sup>3</sup> and K. Kusi-Mensah<sup>4</sup>,** (1)Accra Psychiatric Hospital, Accra, Ghana, (2)Medical, Federal Neuropsychiatric Hospital, Yaba, Nigeria, (3)University of Ibadan, Ibadan, Nigeria, (4)Komfo Anokye Teaching Hospital, Kumasi, Ghana

---

Background: Caring for children with autism spectrum disorder (ASD) can be a particularly challenging task for carers and other family members especially in a resource restricted country like Ghana. Globally, there have been reports of increased psychiatric morbidity and burden among caregivers children with ASD. Limited studies in this area have been done in Africa and more specifically Ghana.

Objectives: This study determined the prevalence and predictors of psychiatric morbidity and level of burden among informal caregivers of children with ASD attending the outpatient clinics of selected hospitals in Ghana.

Methods: The study was a cross sectional survey among sixty one informal caregivers of children with DSM-V diagnosis of ASD attending the outpatient clinics of three selected hospitals in Ghana: Komfo Anokye Teaching Hospital Psychiatry clinic, Accra Psychiatric Hospital and Pantang Psychiatric Hospital. The instruments used for data collection were sociodemographic and clinical questionnaire, the 12-Item General Health Questionnaire (GHQ-12) and the Zarit Burden Interview (ZBI). Data was analysed using statistical package for social sciences.

Results: Sixty one (61) caregivers participated in the study. The mean age of children was  $10.64 \pm 5.15$  years, with male predominance (73.8%). The mean age of the informal caregivers was  $43.53 \text{ years} \pm 8.97$ ; mostly female gender (80%). The prevalence of psychiatric morbidity among the caregivers was 45.9% and 36.1% of them had a high level of burden of care. Factors significantly associated with psychiatric morbidity and a high burden were the child's birth order and unemployment status of the caregiver. On multiple linear regression with adjustment for age, predictor of high burden was found to be the employment status of the caregiver (adjusted OR=7.69, 95% CI 1.71-34.68,  $p = 0.008$ ) while predictor of psychiatric morbidity was caring for a child who was either a second or third born as compared to caring for a first born child (unadjusted OR= 4.03, 95% CI 1.28-12.62,  $p = 0.017$ ).

Conclusions: Psychiatric morbidity and burden are highly prevalent among informal caregivers of children with autism in Ghana. There is an urgent need to incorporate mental health screening for caregivers of children with ASD into routine care of their children. The findings are implicated in the inclusion of caregiver outcome in the management of persons with autism in Africa.

**422.027 (Poster)** Families Facing COVID: The Association between Perceived Vulnerability for Contracting COVID-19, and Suspected or Confirmed Cases of COVID-19 and Caregiver Mental Health

**H. O'Brien<sup>1</sup>, J. A. Weiss<sup>2</sup>, C. M. Kerns<sup>3</sup> and C. McMorris<sup>4</sup>,** (1)University of Calgary, Calgary, AB, Canada, (2)Psychology, York University, Toronto, ON, Canada, (3)University of British Columbia, Vancouver, BC, Canada, (4)Department of Paediatrics, University of Calgary, Calgary, AB, Canada

---

**Background:** Individuals with neurodevelopmental conditions, including autism, are disproportionately impacted by COVID-19. For example, the fatality rate for COVID-19 is significantly higher for people with intellectual and developmental disabilities compared to other individuals, demonstrating the vulnerability in this population (Turk, 2020). Many caregivers of children with autism report high levels of stress and poor quality of life, and unfortunately COVID-19 can exacerbate these negative outcomes. Contributing factors for caregiver distress during COVID-19 may include financial strain, loss of supports/services for their child, and a fear of themselves or their child contracting the disease. It is natural for these caregivers to worry about their child's vulnerability in relation to contracting COVID-19, along with a heightened risk for other physical health issues (Goines, 2010). To date, no study has examined the link between COVID-19 related concerns and caregiver stress in caregivers of autistic children and youth.

**Objectives:** To fill this gap, the present study aimed to 1) describe how families have experienced COVID-19; and 2) determine how perceived vulnerability for contracting COVID-19 is related to caregiver well-being and stress.

**Methods:** 625 caregivers of individuals with autism participated in this large Canadian study, by completing an online questionnaire between June and July 2020. Caregiver stress was measured using the Perceived Stress Scale (PSS), and physical health was assessed through self-reported symptoms and diagnoses, including questions of perceived vulnerability of contracting COVID-19. Correlations examined associations between caregivers perceived stress, and physical health.

**Results:** Caregivers were primarily female (60%) and married or common law (89%). Over half of respondents reported moderate levels of stress (85%), and high anxiety (68%), with a small proportion of caregivers reporting high levels of stress (9%). Just under half of caregivers reported themselves being high risk or vulnerable to contracting COVID-19 and/or developing severe complications, while 41% of caregivers indicated their child was at high risk or vulnerable to contracting COVID-19. Very few (2%) reported having a confirmed case of COVID-19, while slightly higher (6%) reported a suspected but not confirmed case of COVID-19. Of these 51 individuals who had suspected or confirmed case of COVID-19, the majority of symptoms (96%) were reported as mild to moderate, with few reporting severe symptoms (4%). Preliminary results show a significant association between feelings of vulnerability for both the parent ( $p<.001$ ) and child ( $p<.001$ ) and total score of perceived stress scale. However, no association between reporting of a confirmed positive COVID-19 and parental stress, nor between either a confirmed or suspected COVID-19 case in the caregivers extended family or close friend.

**Conclusions:** As expected, caregivers of children with autism are experiencing increased levels of stress during COVID-19. Perceived vulnerability of contracting the virus is related to caregiver stress, but caregiver stress was not related to confirmed cases of COVID-19 in the family. Findings highlight the how the fear of COVID-19 can impact caregiver mental health and quality of life. Future research must focus on supporting caregivers of children with autism, especially as COVID factors may exacerbate stress levels.

**422.028 (Poster) Family Perceptions of Access to Healthcare Services for Autistic Young Adults Who Receive State Developmental Disability Services**

**A. Roux<sup>1</sup>, J. Rast<sup>1</sup> and L. Shea<sup>2</sup>, (1)A.J. Drexel Autism Institute, Drexel University, Philadelphia, PA, (2)A.J. Drexel Autism Institute, Philadelphia, PA**

---

**Background:**

Preventive health care is vital for autistic young adults (YA) given high prevalence of co-occurring health and psychiatric conditions and early mortality. Approximately 87% of autistic YAs live with family – a higher rate than peers with other disabilities. Adults with developmental disabilities (DD) who live with family are the least likely to receive preventive health care compared adults with DDs in other settings. No published studies have examined the intersectionality between age, race/ethnicity, household income and complexity of health needs in regard to healthcare access for autistic adults.

**Objectives:**

This study examined prevalence and factors of consistent healthcare access among autistic YA (ages 18-25 years) who lived with family and received DD services. We compared autistic YA to autistic adults (26+ years) versus YA and adults with mental, behavioral, and other developmental disabilities (MBDDs).

**Methods:**

We analyzed data from the National Core Indicator's Adult Family Survey of families of state DD service users ages 18 and older who lived with the respondent and received at least one direct service in addition to service coordination. We used bivariate

analyses and multivariable logistic regression to examine family report of whether the individual with a disability was able to always access healthcare when needed and the role of sociodemographic and complex health needs in predicting consistent care.

#### Results:

Approximately 70% of autistic YAs had consistent access to health care when needed, similar to autistic adults but lower rates than those with MBDD. Odds of consistent healthcare access were higher among autistic YA who were Black (OR=3.27,  $p<.001$ ) or who lived in a rural area (OR=1.65,  $p<.05$ ), and lower among those with co-occurring health conditions (OR=.67,  $p<.05$ ) or who needed extensive personal care supports (OR=.66,  $p<.05$ ). Additionally, only 55% of families of autistic YAs felt that the primary care doctor understood needs related to their family member's disability – similar to families of autistic adults – both significantly lower rates than families of MBDD peers.

#### Conclusions:

Nearly one-third of autistic YA who lived with family and receive state DD services had difficulty consistently accessing needed health care, echoing findings of lower rates of preventive care among DD service users who lived with family. Upstream preventive care is critical for addressing high rates of chronic, poorly managed health conditions and increased hospitalizations in adults on the spectrum. Although state DD services are typically funded through Medicaid waivers to reduce unmet health needs, it is unclear how waivers differentially prioritize, require or support medical care unless the individual is enrolled in a managed care program. Additional research is needed to determine whether participation in Medicaid managed care may explain increased access to consistent healthcare among minority YA and other subgroups. Additional innovations in Medicaid waivers could help improve access to care for YA who live with family, including additional supports for families who often must coordinate care despite inadequate preparation for healthcare transition. Other policy recommendations include improved surveillance of healthcare services in this population.

#### **422.029 (Poster) Gender Differences in Perceived Stigma Among Latino Caregivers**

**M. Montenegro<sup>1</sup>, M. M. Abdul-Chani<sup>2</sup>, A. Ramirez<sup>1</sup>, D. Valdez<sup>3</sup>, A. Rosoli<sup>4</sup>, G. Garrido<sup>5</sup>, S. H. Cukier<sup>6</sup>, C. S. Paula<sup>7</sup>, R. A. Garcia<sup>8</sup>, A. Rattazzi<sup>9</sup> and C. Nava<sup>9</sup>.** (1)University of Texas Rio Grande Valley, Edinburg, TX, (2)Psychology, The University of Alabama at Birmingham, Birmingham, AL, (3)Universidad de Buenos Aires- FLACSO, Buenos Aires, Argentina, (4)Projects, Organizacion Estados Iberoamericanos, Santo Domingo, Dominican Republic, (5)Universidad de la República, Montevideo, Uruguay, (6)PANAACEA, Buenos Aires, Argentina, (7)Developmental Disorder Program, Universidade Presbiteriana Mackenzie, São Paulo, Brazil, (8)Clinica Las Condes, Santiago, Chile., Santiago, CHILE, (9)Psychological Science, University of Texas Rio Grande Valley, Edinburg, TX

Background: Current literature has rarely explored the effect of stigma in Latino populations with Autism Spectrum Disorder (ASD), and much of the available research has been conducted in the U.S., hindering generalization to the diverse, global Latino population. Gender is one of the most studied variables in ASD research. Yet, in terms of the role of gender on perceived stigma among diverse populations, no up-to-date research could be identified. Cultural and societal norms shape the different gender roles, and that could extend to the way ASD is experienced among females and their families.

Objectives: The present study explored the relationship between gender and perceived stigma among caregivers of children and adults with ASD in Latin America and provide a cross-cultural account of ASD.

Methods: A total of 2,817 caregivers of children and adults with ASD from six Latin American countries completed an anonymous online survey. Caregivers completed a survey that besides asking sociodemographic and clinical information about the individual with ASD, asked about perceived stigma. Participants answered to four statements targeting stigma which included helplessness, worry, discrimination, and negative impact of ASD. A combined variable of all four statements was created to assess gender differences in terms of agreement to all statements. A descriptive inferential analysis was calculated to understand caregivers' experience with perceived stigma.

Results: For the combined variable "Perceived Stigma," 59.9% of caregivers experienced some form of perceived stigma. Caregivers of female children reported a 7.7% higher agreement to having experienced perceived stigma. In addition, there were statistical differences when considering gender ( $\chi^2=8.203$ ,  $p=0.004$ ) age group ( $\chi^2=7.857$ ,  $p=0.049$ ), and country of residence ( $\chi^2=57.932$ ,  $p=0.000$ ). Caregivers of females (66.3%), pre-school aged children (63.2%), and those from Brazil (67.2%) reported the highest rate of "Perceived stigma"

Conclusions: Caregivers of female children with ASD in Latin America might have a difficult time when attempting to help their children navigate in a society with strong-held pre-determined cultural norms. When observing stigma within a social-cognitive

approach, especially considering Latino/a cultures placed value on societal norms, a distinctive picture emerges. It is possible that Latinos/as importance placed on the roles of *marianismo*, *machismo*, and *familismo* could be influencing stigma. Specially, the role of women in terms of *marianismo*, the idea of females having to endure suffering with dignity and being nurturing and self-sacrificing. This in combination with *machismo*, the notion that males are stronger, and *familismo*, loyalty to family connections, could place females with a mental disorders in a position with a different set of hardships when going against cultural norms. This multi-cultural inclusion allows for a better understanding of the experience among Latino caregivers' concerning perceived ASD stigma, which may ultimately improve access to services and better advocacy programs for Latino individuals and their children with ASD.

**422.030** (Poster) How Do You Talk about Autism?: Label Preferences within the North American Autism Community  
*Z. M. Sargent, A. J. Lampi, K. M. Stockwell and V. K. Jaswal, University of Virginia, Charlottesville, VA*

---

#### Background:

Understanding the terminology preferences of autism community members is an important step towards avoiding ableist language (Bottema-Beutel et al., 2020). For example, “person-first” language (i.e., “person with autism”) is common in scientific and popular discourse, but many Autistic self-advocates have criticized this in favor of “identity-first” language (i.e., “Autistic person”; Sinclair, 1999).

Given ongoing debates about the use of person-first versus identity-first language in publishing (Vivanti, 2020), documented differences in how these labels are perceived by Autistic and non-Autistic people (Kenny et al., 2015), and the potential that person-first labels may increase the stigma associated with autism (Gernsbacher, 2017), it is important to gain a widespread understanding of the terminology used and preferred by members of the autism community. Surveys of autism terminology preferences have been conducted in the UK (Kenny et al., 2015) and Australia (Bury et al., 2020), but to our knowledge, there have been no large-scale efforts to study this question in North America.

#### Objectives:

We conducted a large survey to investigate autism terminology preferences of people with a connection to autism in North America.

#### Methods:

In consultation with Autistic adults, we developed an online survey asking participants to indicate which terms they use, how likeable and offensive these terms are, and how they would rank them (from the label they like the most to the label they like the least). Free-text boxes allowed participants to explain their preferences.

The survey was distributed through national autism organizations and local chapters across the US and Canada, as well as on social media. 785 North American adults completed the survey (608 self-identified or with an autism diagnosis, 177 with a different connection to autism).

#### Results:

The results demonstrate widely-shared attitudes as well as notable variability. As Figure 1 shows, respondents overwhelmingly preferred using identity-first terms such as “Autistic” and “Autistic person” vs. other terms, including “person with autism.” However, respondents who were not Autistic said that they would use the term “person with autism” more often than Autistic respondents did (34% vs. 17%, respectively).

The rankings in Figure 2 demonstrate a similar pattern. When participants were asked to rank 10 possible labels, the most common top choices were “Autistic” (67%) and “Autistic person” (38%). However, variability in participants’ preferences can be seen as well: For instance, “Person with autism” was the last choice for 26% of Autistic participants and 13% of non-Autistic participants. But it was also the top choice for 3% of Autistic participants and 17% of non-Autistic participants. Analyses of participant liking of terms, perceptions of term offensiveness, and perceptions of term utility are ongoing.

#### Conclusions:

Consistent with previous studies (Bury et al., 2020; Kenny et al., 2016), the terms “Autistic” and “Autistic person” were most preferred by adults in the autism community, although there is considerable diversity of opinion as well. Efforts should be made to defer to Autistic individuals’ preferences, but the patterns described here suggest that identity-first language is preferable for widespread communications among the North American Autistic community.

**422.031 (Poster)** How Does a Participatory Mentorship Program for Autistic University Students Function during a Pandemic? **K. Gillespie-Lynch<sup>1</sup>**, B. Kofner<sup>2</sup>, E. Ilyes<sup>3</sup>, J. Delos Santos<sup>4</sup>, C. Frka<sup>5</sup>, M. Armstrong<sup>6</sup>, E. Yamakado<sup>7</sup>, S. Shevchuk<sup>8</sup>, A. Riccio<sup>9</sup>, S. K. Kapp<sup>10</sup>, J. DeNigris<sup>12</sup>, (1)Department of Psychology, College of Staten Island; CUNY Graduate Center, Brooklyn, NY, (2)CUNY, NY, NY, (3)Graduate Center; CUNY, Brooklyn, NY, (4)Hunter College, City University of New York, New York, NY, (5)CSI, Staten Island, NY, (6)Washington University of St. Louis, St. Louis, MO, (7)Washington University of St Louis, St. Louis, MO, (8)College of Staten Island, CUNY, Staten Island, NY, (9)Department of Psychology, The Graduate Center, City University of New York (CUNY), New York, NY, (10)Department of Psychology, University of Portsmouth, Portsmouth, United Kingdom, (11)CUNY School of Professional Studies, New York, NY, (12)Psychology & Counseling, Fairleigh Dickinson University, Madison, NJ

---

**Background:** As autistic students increasingly enter college, they often exhibit academic strengths (Bakker et al., 2019) yet face social, executive functioning and self-advocacy challenges (Accardo et al., 2019). Supports for autistic students are often neither evidence-based nor informed by their perspectives (Barnhill, 2016). Although promising programs have emerged (Kudder & Accardo, 2018), prior research has *not* provided sufficient opportunities for neurodivergent students to guide program development. Obviously, the transition to online education in response to COVID-19 has been very stressful for many students. However, online education can also provide unique opportunities to work together to develop supports.

**Objectives:** Describe the process through which a *participatory* mentorship program (in which neurodivergent students play leadership roles in developing, delivering, and evaluating programming) transitioned from in-person to online.

**Methods:**

Our no-cost program is designed for autistic students but open to those with other disabilities. Although our goal since program inception was for the program to be participatory, becoming truly participatory took time. Seventeen students/alumni with disabilities (12 autistic) have become mentors thus far.

Students choose to attend an hour per week of one-on-one mentorship, group meetings, or both. Group curriculum is selected/developed based on assessments and group discussions.

In the Spring of 2020, group meetings were led by a doctoral student once a week. In the Fall of 2020, group meetings, offered twice a week, include a Creative Exploration Group where students share and discuss their art (led by a neurodivergent life/executive coach) and a structured Skills Development group (led by two autistic graduate students who guide discussions about autism, executive functioning, social relationships, and media literacy).

Mentees can complete assessments for gift cards, but are under no obligation to provide data. In 2020, we conducted assessments with a smaller set of students than usually participate in assessments (those who were interested in doing assessments completely virtually). In the Spring, 14 students completed pre-tests and 10 completed post-tests. In the Fall, 10 students completed pre-tests.

**Results:** In the Spring of 2020, we observed improvements in self-esteem from the beginning ( $M = 75.9$ ) to the end ( $M = 92.4$ ) of the term ( $p = .04$ ). Although no other changes were statistically significant (likely due to low power), numeric improvements (on the range of 10 points or more on a scale of 100) were observed across a number of domains including self-advocacy, public speaking (the virtual group meetings involved multiple opportunities for students to practice speaking about their interests, hopes, and concerns), planning, communication, self-regulation, and job skills. All students but one reported that they were very satisfied with group meetings. This student was somewhat satisfied, the second highest rating. All students who attended one-on-one mentorship reported that they were very satisfied with mentorship.

**Conclusions:** By collaborating with neurodivergent students, we have developed a program that has proven quite resilient to moving online during the pandemic. Students have gained valuable skills as mentors, researchers, and public speakers. Students have weathered stressful events together and discussed difficult topics, including differences in political opinions, in constructive ways.

**422.032** (Poster) I Can Actually Do It without Any Help or Someone Watching over Me All the Time and Giving Me Constant Instruction..? Autistic Adolescents' Accounts of Using Video Game and Online Networking While Gaming  
**G. Pavlopoulou<sup>1</sup>, C. Usher<sup>2</sup> and A. Pearson<sup>3</sup>,** (1)Department of Psychology and Human Development, Institute of Education, UCL, London, United Kingdom, (2)Department of Psychology and Human Development, University of Bedfordshire, London, United Kingdom, (3)University of Sunderland, Sunderland, United Kingdom

---

**Background:** Despite evidence suggesting social media and video game play use are popular recreational activities that co-occur during online play time, the interaction between the two and its impact on an individual's well-being, to account for the growing inclusion of social networking within video game design, is virtually unknown for autistic online users who have been presented as unhealthy users.

**Objectives:** The present study aimed to facilitate our understanding of the motivators, functions and the emotions associated with recreational activities that include online gaming and networking while gaming.

**Methods:** A mixed methods design was used to establish the background profile of the autistic teenagers using quantitative data (severity of autism, sensory profile, medical history, loneliness scale and online motivation questionnaire). To achieve a wealthy and comprehensive understanding, one-to-one semi structured interviews were also employed to capture the detailed perspectives of the autistic adolescents.

**Results:** The male teenagers were aged 13–15 years ( $M = 13.75$  years,  $SD = 0.60$ ). Majority of teenagers identified as White (92%), with one identifying as Black. All 12 participants reported moderate to high levels of motivation for online gaming on all factors of motives. The most prevalent among the motives was Recreation ( $M = 4.00$ ,  $SD = 0.67$ ) which included enjoyment and entertainment as reasons for engaging in game play. Escape also featured as a prominent motive ( $M = 3.98$ ,  $SD = 0.57$ ) where being able to forget about daily hassles and real life were scored highly. Social ( $M = 2.54$ ,  $SD = 0.68$ ) and Skill Development ( $M = 2.54$ ,  $SD = 0.49$ ), although still a moderately high motivator, were reported as the least prominent motives by participants. Specifically, gaming for company or to sharpen senses were not seen as important motivators for gaming by participants. Themes analysis revealed the following themes; (i) Perceived benefits of video gaming and networking (sense of agency, cultivating positive emotions, adding a sense of achievement, manageable challenge and self reward to daily life), (ii) Perceived functions of video gaming and networking (escapism from a hostile world, prevention of low mood and anxiety), (iii) Perceived motivations of video game and networking (experience of a different life that is not possible, opportunities to feel connected with others), (iv) Perceived consequences of video gaming and networking (parental conflicts, postponing other self-care activities, neglecting school-related work)

**Conclusions:** The themes highlight that the online gaming experience provides a rich source of satisfaction for autistic teenagers. Video games provide an uncomplicated space to express themselves and a rich source of fulfilment from situations that are often not satisfied in their real world. This study reaffirms the importance of acquiring autistic CYP's unique perspective to fully understand their personal lived experiences and the implications to their well-being. Further research needs to unfold elements which have not been given the necessary attention in existing literature in order to appreciate the autistic teenagers' experience of using video games and online networking while playing games and capture the depth and breadth of what it means to be an autistic young person online.

**422.033** (Poster) Impact of a Sibling Support Group on Relationship Quality and Siblings' Knowledge of Autism Spectrum Disorder (ASD)

**J. M. Wolf<sup>1</sup>, M. Coffman<sup>2</sup>, N. Kelso<sup>3</sup>, M. L. Braconnier<sup>4</sup> and J. McPartland<sup>1</sup>,** (1)Child Study Center, Yale University School of Medicine, New Haven, CT, (2)Virginia Tech, Blacksburg, VA, (3)University of Maryland, College Park, College Park, MD, (4)Psychology, St. John's University, Queens, NY

---

**Background:** Siblings of children with ASD have a unique lived experience. The literature regarding the impact of this experience on their psychological wellbeing has been mixed, with some studies reporting increased adjustment difficulties (Shivers et al., 2018), and others finding that siblings are well-adjusted (Dempsey et al., 2011). Likewise, studies investigating the quality of sibling relationships when one child has ASD have highlighted both positive and negative aspects of the relationship (Kaminsky & Dewey, 2001). Finally, Glasberg (2000) found that siblings acquire delayed knowledge about the nature of autism.

Support groups for siblings of children with disabilities (e.g. Sibshops; Meyer & Vadasy, 1994) have been developed to address these needs. However, research investigating their impact is limited, with studies yielding mixed results with regard to improvements in unaffected siblings' psychological wellbeing (Tudor & Lerner, 2015). There is some evidence that psychoeducational groups improve siblings' knowledge about ASD (Brouzos et al., 2017). Few studies have investigated the impact of sibling support groups on sibling relationship quality.

**Objectives:** To evaluate the effectiveness of a sibling support group in improving the quality of sibling relationships and siblings' knowledge of ASD.

**Methods:** Nine 10-week sibling support groups for unaffected siblings of children with ASD were conducted across two sites (Yale Child Study Center and Virginia Tech Center for Autism Research). Support groups were based on the Sibshop model (Meyer & Vadasy, 1994), with additional activities targeting knowledge of autism and coping with stress. Participants (N=41) ranged in age from 6 to 17 (M=9.86, SD=2.86), although groups were composed of similarly aged children to ensure matched developmental level. The Sibling Relationship Questionnaire (SRQ), Parent- and Self-Report forms (Slomkowski et al., 2001) and the Satisfaction with the Sibling Relationship Questionnaire (SSRQ; McHale & Gamble, 1989) were administered pre- and post-group to assess the quality of the sibling relationship. Participants were also interviewed pre- and post-group with the Concepts of Autism Protocol (CAP; Glasberg, 2000) to assess their knowledge of the nature of ASD and its implications on their siblings' lives. Interviews were coded by raters blind to pre/post timepoint, utilizing the Developmental Conceptions of Autism Category System (Glasberg, 2000).

**Results:** On the SSRQ, siblings self-reported significant improvement in their overall satisfaction in the sibling relationship ( $p=.008$ ). On the SRQ, parents reported a significant reduction in negative behaviors within the sibling relationship, both by the sibling with ASD ( $p=.026$ ) and by the unaffected sibling ( $p=.007$ ), while no changes were found in positive behaviors or in siblings' self-reported ratings. On the CAP, siblings showed significant improvements in their knowledge about ASD ( $p<.001$ ), but no change in their understanding of its implications.

**Conclusions:** The sibling support group was effective in improving participants' overall satisfaction in their relationship with their sibling with ASD, in reducing negative behaviors, and in improving knowledge of autism. It will be important to replicate these findings through a randomly controlled trial with a larger sample size. These findings highlight the value of including sibling support groups within service provision for families affected by ASD.

**422.034 (Poster)** Influence of Parental Experience on ASD Knowledge and Identification: A Mixed Methods Approach  
**C. H. Morgan<sup>1</sup>, M. M. Abdul-Chani<sup>1</sup> and S. E. O'Kelley<sup>2</sup>,** (1)Psychology, The University of Alabama at Birmingham, Birmingham, AL, (2)The University of Alabama at Birmingham, Birmingham, AL

---

**Background:** Knowledge about child development is essential to positive child outcomes and parenting skills and is influenced by many factors, such as number of children raised. Limited research exists regarding the relation between parental experience and autism spectrum disorder (ASD) knowledge or identification.

**Objectives:** The current study examines how parenting experience relates to self-report ASD knowledge and recognition of ASD symptomology.

**Methods:** A total of 211 participants ( $M_{age}=33.08$ ,  $SD=8.74$ ; 89.2%=White; 54.0%=Non-Hispanic; 52.8%=Female) completed an online study. Procedures included a demographics questionnaire, random assignment to a vignette depicting characteristics and symptoms of ASD without mentioning the diagnosis, an attention check, and mixed-method intervention-seeking measures addressing level of concern and action to seek treatment. Qualitative responses were coded as 0 being "No Recognition" and 1 being "ASD recognition" (defined as any ASD terminology). Participants completed the Autism Knowledge Questionnaire (ASK-Q) evaluating ASD knowledge. Parenting experience was defined as the number of children reported in the demographics questionnaire.

**Results:** Correlations and binary logistic regression models examined sex, ASD knowledge, and parenting experience in predicting ASD recognition. 57.1% of the sample were parents (a majority had 1-3 children) and 34% recognized ASD. See Table 1 for bivariate correlations.

Sex, ASD Knowledge, and parenting experience significantly predicted ASD recognition,  $\chi^2(5)=33.88$ ,  $p<.01$ . The model explained 20.0% (Nagelkerke  $R^2$ ) of the variance in ASD recognition and correctly classified 70.0% of cases. ASD knowledge significantly contributed to predicting ASD recognition (Wald( $df=1,211$ )=20.94,  $p<.01$ ).

The second model included the interaction between ASD knowledge and parenting experience and it also significantly predicted ASD recognition,  $\chi^2(5)=34.15$ ,  $p<.01$ . Similar to model 1, 21.0% (Nagelkerke  $R^2$ ) of the variance in ASD recognition is explained and 69.0% cases are correctly classified. ASD knowledge also significantly contributed to predicting ASD recognition (Wald( $df=1,211$ )=9.61,  $p<.01$ ).

Conclusions: Sex was related to ASD recognition and ASD knowledge, potentially due to cultural effects in which women and mothers are the primary caregivers and thus are more experienced with child development. Self-report ASD knowledge was related to ASD recognition, suggesting individuals applied learned ASD knowledge to the vignettes when recognizing concern and determining need for evaluation. Individuals may rely on this knowledge in real-world situations (e.g., observing their own child) to make similar decisions.

The finding that parenting experience did not uniquely predict ASD recognition is concerning because parent knowledge about child development is important in fostering healthy child outcomes. Some participants (both parents and non-parents) confused ASD symptoms for misbehavior and attention-seeking, demonstrating concern about social development/skills, without clear identification of ASD features. Previous research supports a similar lack of ASD knowledge in parents of typically developing children. Together, these findings support a gap in parenting education on ASD. Identifying gaps in parenting knowledge is significant for child outcomes because they may carry implications for future parent interactions with pediatricians, teachers, and other healthcare professionals. These findings support the need for improved parent education on child development patterns and ASD.

**422.035 (Poster)** Investigating Mental Health in Autistic Children and Young People during the COVID-19 Pandemic: Preliminary Findings from the Astar Cohort

**F. Mguith<sup>1</sup>, M. Palmer<sup>1</sup>, S. Chandler<sup>1</sup>, V. Slonims<sup>2</sup>, A. Pickles<sup>1</sup>, M. Knapp<sup>3</sup>, S. Scott<sup>1</sup>, T. Charman<sup>1</sup> and E. Simonoff<sup>1</sup>,** (1)King's College London, Institute of Psychiatry, Psychology and Neuroscience, London, United Kingdom, (2)Guy's & St Thomas' NHS Foundation Trust (Evelina Children's Hospital), London, United Kingdom, (3)PSSRU, LSE, London, United Kingdom

---

**Background:** The COVID-19 pandemic has had widespread impact on daily life for all and the effects on children and mental health are areas of concern (Holmes et al., 2020). Autistic children may experience the effects of the pandemic differently to the general population. They already have substantially increased rates of mental health disorders (Simonoff et al., 2008) and 10-15% display challenging behaviours that mean they cannot attend mainstream schools and participate in family and community life in the typical ways. While they are a highly vulnerable group, we have limited understanding of how the pandemic is affecting them, who is most severely affected and how best to target limited community-based interventions to those most in need.

**Objectives:** We surveyed the ASTAR cohort to explore the interplay between pre-existing vulnerabilities measured at earlier timepoints and the additional stressors of COVID-19 on autistic children and their families.

**Methods:** The ASTAR cohort ( $N=83$ ) were involved in a pilot evaluation of group-based parenting interventions that aimed to reduce disruptive behaviour and anxiety amongst 4–8 year olds (ISRCTN91411078, as part of the Improving Autism Mental Health project [IAMHealth], [www.iamhealthkcl.net](http://www.iamhealthkcl.net)). Participation criteria were designed to be as inclusive as possible. No exclusion for IQ or levels of disruptive behaviour/anxiety was used to screen into the study. During the COVID-19 pandemic (children aged 6:0–11:10 years), we administered a brief parent-report survey to understand the child's emotional and behavioural experiences. The survey also covers other pandemic-related factors such as infection and self-isolation experiences, and changes in education, family life and parental employment. The survey is being used with another autism cohort (QUEST) and with clinical populations in 8 countries, allowing for comparison across the studies. Semi-structured interviews with 18 purposefully sampled parents of verbal ( $n=9$ ) and minimally verbal ( $n=9$ ) autistic children explored a variety of experiences in detail and factors that promote resilience.

**Results:** Sixty-seven parents (94% mothers) of autistic children (48% verbal, 52% minimally verbal; 84% male) split across mainstream (58%) and specialist education (42%) participated. Non-participating families did not differ from participating families in relation to: child age, verbal ability, gender and education provision, nor parental employment or household income. Figure 1 displays the parent-reported impacts on the child's relationships and education. Most reported a change in education arrangements even though government stipulation was for education to remain in person for children with special educational needs. The impact on relationships varied, with a large proportion of parents reporting parent-child, sibling and friendship relationships had not changed. Table 2 shows initial themes from the qualitative interviews. Both positive and negative impacts were felt across all key domains of child development. Access to appropriate services and supports was a key challenge for families. Further thematic analysis of the interviews, and regression analyses exploring whether pre-existing vulnerabilities measured at earlier timepoints predict COVID-19 outcomes will be completed.

**Conclusions:** The COVID-19 pandemic has had widespread impact on all of society. Understanding the impact on autistic children and who are most severely affected is important for care planning.

**422.036** (Poster) Learning from COVID-19: Barriers and Facilitators to Coping with Routine Disruption in Autistic Children with Complex Support Needs

*D. Osmanaj<sup>a</sup>, A. Roestorf<sup>b</sup> and A. Lambrechts<sup>c</sup>, (1)Psychology, City, University of London, London, United Kingdom, (2)Psychology, University of Stirling, Stirling, Scotland, United Kingdom*

---

**Background:**

The COVID-19 pandemic has created a major, worldwide disruption to people's daily lives. In March 2020, the UK imposed a nationwide lockdown with specific public health guidelines, including restricted freedom of movement, reduced access to non-COVID-related services, and isolation/shielding of 'at risk' groups, including those on the autism spectrum. Autistic people are expected to have experienced disproportionately increased anxiety, distress and other mental health difficulties as a result of changes to their daily routines. In addition to a tendency to engage in insistence on sameness behaviours, autistic individuals are more susceptible to intolerance of uncertainty - a major contributor to heightened anxiety in autism (Wigham et al., 2015). The radical changes to daily routines alongside high levels of uncertainty around COVID-19 are likely to have adversely affected autistic people's well-being and mental health. Amongst the autistic community, children with complex support needs are especially reliant on access to educational, health and social care services and were particularly vulnerable to restricted access to support during lockdown.

**Objectives:**

This study aimed to capture the factors that acted as barriers or facilitators to coping with the first COVID-19 UK lockdown (March 23<sup>rd</sup> to May 10<sup>th</sup> 2020) from the perspective of parents of autistic children with complex support needs.

**Methods:**

Nine parents of autistic children attending Special Education Needs Schools were interviewed about their child's experience of the first month of the UK lockdown. The International Classification of Functioning, Disability and Health (Bölte et al., 2014) was used as a framework to design semi-structured interviews to identify personal and environmental factors that were either helpful or detrimental to adapting to the lockdown. Topics included changes to routine, sleeping and eating patterns, access to resources and support, and child- and parent-led coping strategies and behaviours. A thematic analysis was conducted to identify overarching themes.

**Results:**

Findings indicated that disruption to children's routines often elicited delayed challenging behaviours: children coped well with short-term changes but struggled with long-term disruptions. Verbal ability played an important role in children's ability to cope: more proficient children were able to understand the situation, which led to greater tolerance in the short-term, but increased anxiety and disproportionate preoccupation with COVID-19 in the longer term.

In terms of coping strategies, parents generally chose to limit potential distress and conflict by minimising the demands on the child, and facilitating a child-led daily schedule. From the child's perspective, coping strategies consisted of identifying and staying within a self-defined 'safe space', and substituting former activities (school, friends/relatives, in-person activities) with others (TV, parent, online activities).

Availability of resources, particularly support networks (school and family) and space (opportunities for sensory or physical activity) also positively contributed to the child's (and parent's) ability to cope.

**Conclusions:**

The current study provides valuable insights to support autistic children with complex needs and their families as we continue to experience successive levels of disruption from the COVID-19 pandemic. These insights also provide the foundation to better support autistic people with complex needs through major disruptions in the longer term.

**422.037** (Poster) Learning from the Experts: Evaluating a Participatory Autism and Universal Design Training for University Teaching Staff

---

Background: Autistic students in higher education settings often possess academic strengths coupled with difficulties with social interaction, self-advocacy, executive functioning, mental health, and stigma (Accardo et al., 2019; Sturm & Kasari, 2019). This highlights a mismatch between autistic students' needs and traditionally academically-focused higher education accommodations. Limited autism understanding among staff and peers may exacerbate challenges faced by autistic students (Cage & Howes, 2020), but online training can increase autism understanding among peers (Gillespie-Lynch et al., 2015). In this study, autistic and non-autistic scholars developed an online training program for university staff, to improve their understanding and appreciation of autism and Universal Design (UD; teaching strategies designed to be accessible and engaging for diverse learners).

Objectives:

1. To examine hypothesized predictors of reduced autism appreciation and less positive attitudes toward UD at pre-test: male gender, heightened social dominance orientation (SDO), and being in a STEM field.
2. To assess whether online training about autism and effective strategies for engaging diverse students improves staff understanding and appreciation of autism and Universal Design.

Methods: University teaching staff completed the following online: a pre-test survey, two training modules (about autism and UD, respectively), a post-test survey, and a follow-up survey a month after post-test. Ninety participants (mean age = 41.7; 25.7% male, 22.8% STEM disciplines) completed pre-tests and seventy have completed post-tests thus far. Measures included an autism knowledge scale ( $\alpha = .89$ ), an adapted social distance scale, focusing on autism appreciation (e.g. "I would welcome the opportunity to have an autistic colleague";  $\alpha = .90$ ), a measure of positive attitudes toward UD (Lombardi et al., 2015;  $\alpha = .87$ ), confidence in understanding UD, and a SDO measure (Ho et al., 2012).

Results:

In regression analyses, male gender ( $\beta = -.40$ ;  $p < .001$ ), heightened SDO ( $\beta = -.21$ ;  $p = .02$ ), and reduced autism knowledge ( $\beta = .20$ ;  $p = .002$ ), but not being in a STEM field ( $\beta = -.09$ ;  $p = .31$ ), predicted reduced pre-test autism appreciation. Only greater autism knowledge ( $\beta = .28$ ;  $p = .008$ ) was associated with more positive attitudes toward UD. Confidence in one's understanding of UD was lower among faculty in STEM fields ( $\beta = -.28$ ;  $p = .007$ ).

Repeated-measures ANOVAs ( $n = 70$ ) revealed improvements in autism knowledge ( $p < .001$ ,  $\eta^2 = .16$ ), autism appreciation ( $p = .001$ ,  $\eta^2 = .17$ ), attitudes toward UD ( $p = .015$ ,  $\eta^2 = .08$ ), and confidence in UD understanding ( $p < .001$ ,  $\eta^2 = .73$ ) associated with training.

Conclusions: Substantial variation in autism appreciation and attitudes toward UD was apparent among faculty who completed the training. Being male, believing that inequality is just, and lower pre-test autism knowledge predicted less pre-test autism appreciation and more reluctance to use UD to reach diverse students. Being in a STEM field was *not* associated with attitudes but was associated with reduced confidence in one's understanding of UD. Preliminary evidence supports the efficacy of our training in improving knowledge and attitudes. Full results will be presented at the INSAR conference; data completion is due December 2020. Once this study is complete, training materials will be made available open-access.

**422.038 (Poster)** Lived Experiences of Families As Youth with Autism and Mental Health Concerns Transition to Adulthood  
**D. B. Nicholas<sup>1</sup>, W. Mitchell<sup>2</sup> and J. Ciesielski<sup>2</sup>**, (1)University of Calgary, Edmonton, AB, Canada, (2)University of Calgary, Calgary, AB, Canada

---

Background:

In Canada, within a given year 20% of our population will experience a mental illness and this increases to 50% over the lifespan (<https://www.mentalhealthcommission.ca>) with over 70% of adults with mental illness developing symptoms in childhood or

adolescence (Government of Canada, 2006). For youth with autism the figures for mental illness are four or five times higher than youth in the general population (Toskia, Hastings, Emerson, Lancaster & Berridge, 2011). These individuals and their families face challenges accessing appropriate and unified care, often encountering multiple barriers within and between systems of care. As a result, participation in their communities is curtailed limiting their social inclusion.

#### Objectives:

As part of a larger initiative, this study explored the lived experience of families supporting youth with autism (ASD) and mental health (MH) concerns as they transition to adulthood. Social connectedness and awareness of mental health services within their communities and how these aligned with the support needs of the youth were explored.

#### Methods:

A questionnaire and interview based on a semi-structured interview guide were administered. Quantitative and NVivo-based qualitative analyses, respectively, were used. Interview analysis (the focus in this presentation) consisted of 1) line-by-line coding, 2) review of codes for textual linkages both within and across transcripts and 3) examination of the emerging categorization of codes in yielding themes. Interrater review of data by leaders in the ASD and MH field verified themes.

#### Results:

Ten parents of youth with autism and mental health concerns were interviewed. The youths' age ranged from 10-26 years. Comorbid MH concerns included anxiety, depression, emotional dysregulations, Oppositional Defiance Disorder, Obsessive Compulsive Disorder, conduct disorder and psychosis. The majority of parents indicated little support from family/friends/neighbours when they needed it and were overwhelmed. They were concerned about their child's behaviours and the safety of their child, their family and the broader community. Many shared that they were uncomfortable seeking supports for their child or themselves because they don't 'fit' within the system and their community, and that this struggle has been exacerbated as their youth transitions to adulthood.

Parents were more familiar with, and had accessed services from, autism service providers more so than MH services. When supports to address complex behaviours and MH concerns had been found, the most significant barrier to access were youth's unwillingness to engage. In refusing counselling and other related programming, prior negative experiences were commonly cited as a deterrent.

Despite limited services (40% had no or less than an hour of support/week) and limited youth engagement, parents recognized strengths in their youth (i.e., independence, developing interests, success in school/employment) and themselves (i.e., advocacy, developing coping and innovation).

#### Conclusions:

These findings suggest that earlier experiences with services may pave a path, suggesting the need for early engagement and supports that are generative for children and youth. Support to parents in navigating services and strategy development are desired and needed. Clinical and program implications will be offered.

**422.039** (Poster) Marital Status of Parents Raising Individuals with Autism Spectrum Disorder (ASD) from Age 2 to 25  
*N. Bahri<sup>1</sup>, K. Sierrett<sup>2</sup> and C. Lord<sup>2</sup>, (1)UCLA, Los Angeles, CA, (2)University of California, Los Angeles, Los Angeles, CA*

---

Background: Previous estimates of divorce in families raising a child with ASD have hovered around from 25% (Hartley et al., 2010; Baeza-Velasco et al., 2013) with an 80% figure that was much cited, but never supported (Freedman et al., 2012). Consensus suggests the risk of divorce in parents of children with ASD remains high into their child's early adulthood (Hartley et al., 2010). In addition, there is limited information about the factors that contribute to divorces in families of autistic individuals at different points of development.

Objectives: In this study, we describe changes in marital status and predictors, both child and family factors, of divorce over a 20-year period among parents of a longitudinal sample of 247 individuals with ASD (n = 192) and other developmental disabilities (n = 55).

Methods: Participants included parents of 247 individuals, in a longitudinal study, initially referred for ASD and other developmental delays. Kaplan-Meier survival curves were fit to determine the risk of divorce over time in the sample as a whole. Cox proportional-hazards models were then fit separately for both child (Gender, Birth Order, ADOS CSS Social Affect and RRB scores, ASD Diagnosis, Highest Verbal IQ and Vineland Daily Living Scores) and family factors (Mother's Age, Level of Education, Race and total number of children) to determine which factors affected the risk of divorce in the sample. Variables with statistically significant regression coefficients were combined into a final model.

Results: Approximately 36% of individuals with ASD experienced a parental divorce at some point in their life in our sample by age 25. Two peaks emerged for more frequent divorces: when children were under age 5 and between ages 10 and 15 (see Figure 1). Higher daily living skills in the children reduced the risk for divorce ( $b=-.025$ ,  $se=.012$ ,  $p=.04$ ); while families where the oldest sibling had autism were at higher risk for experiencing a divorce than only children ( $b=.81$ ,  $se=.36$ ,  $p=.02$ ), with other birth orders in between. Risk of divorce was significantly higher for parents with a high school education or less ( $b=0.83$ ,  $se=.29$ ,  $p=.004$ ). An increase in mother's age at child's birth reduced the risk for divorce ( $b=.06$ ,  $se=.02$ ,  $p=.009$ ). The overall rate of individuals experiencing a divorce is about 22% for those without an ASD diagnosis and 35% for those with an ASD diagnosis.

Conclusions: The results suggest that divorce in families of children with ASD remains high through early childhood into early adulthood as suggested earlier (Hartley et al., 2010). Understanding the factors that contribute to these changes in marital status may help us better support families across time.

#### **422.040 (Poster)** Moving from Participants to Engaged Collaborators: Designing and Piloting a Stakeholder Developed Research Consultation Model

A. Wainer<sup>1</sup>, K. M. Walton<sup>2</sup>, M. Beard<sup>3</sup>, A. R. Borowy<sup>2</sup>, R. A. Gordon<sup>1</sup> and S. Petrill<sup>3</sup>, (1)Department of Psychiatry, Rush University Medical Center, Chicago, IL, (2)Nisonger Center, The Ohio State University, Columbus, OH, (3)Department of Psychology, The Ohio State University, Columbus, OH

Background: Approaching stakeholders as engaged collaborators in the research process represents a significant, yet necessary shift in the field in order to better align early intervention research with the values, goals and needs of the stakeholder community. Although there are existing models for stakeholder engagement in research activities, none had been developed specifically by members of the autism stakeholder community.

Objectives: Given the unique needs and perspectives of the ASD community, the goal of this work was to collaboratively develop and pilot a model for stakeholder engagement across different stages of early intervention for ASD-related research.

Methods: Project STEER (Stakeholders Engaged in Early Intervention Research) represents an effort to develop a sustainable model that puts stakeholders at the center of autism spectrum disorder (ASD) early intervention research and is driven by 10 adults with ASD, 10 parents of children with ASD, and 10 community-based clinicians/policy makers in Columbus, Ohio and Chicago, Illinois. Project STEER has used a Participatory Action Research approach, focused on collaborative reflection and systematic data collection, to create and pilot strategies for stakeholder engagement across different stages of the research process. We began with a series of discussion and engagement activities to identify when and in what way stakeholders could collaborate in the research process. Project STEER members provided feedback on a draft stakeholder consultation model. The first half of the consultation model was then piloted with a sub-group of STEER stakeholders. Acceptability and feasibility data were collected after each opportunity for stakeholder engagement across the early stages of research.

Results: Project STEER members identified specific times within the research process that would be particularly critical for stakeholder engagement including: active involvement in the development of project aims, recruitment materials, data collection and interpretation, and dissemination strategies. It was emphasized that opportunities for flexible participation and a range of communication strategies (e.g., taking a survey vs. attending a meeting) were necessary to ensure engagement from the broad and representative stakeholder community. The draft consultation model included stakeholder engagement in (1) creating research questions and study aims, (2) study population and demographics, and (3) recruitment and participant materials including informed consent. Identified engagement activities included group Zoom calls, online surveys, and interactive activities (e.g., creating a social media post for study recruitment). Stakeholders rated the Zoom calls, online surveys and interactive activities as acceptable and feasible.

Conclusions: This work offers a first step in identifying creative strategies for stakeholders to be considered as partners, rather than simply participants, in the early intervention research process. Importantly, additional efforts are planned to pilot the second half of the stakeholder consultation model, including (4) data analysis/interpretation and (5) dissemination strategies (planned for

Winter 2021). As stakeholders have led the development of this model, we expect that the final result will be a more acceptable, engaging and sustainable model for stakeholders to serve as active collaborators in research.

**422.041 (Poster) Parent Perspectives on Use of Cannabis in Children with Autism Spectrum Disorder**

**R. Lane<sup>1</sup>, B. B. Maddox<sup>2</sup> and A. Bennett<sup>3</sup>,** (1)*Developmental and Behavioral Pediatrics, Children's Hospital of Philadelphia, Philadelphia, PA,* (2)*Psychiatry, UNC TEACCH Autism Program, Chapel Hill, NC,* (3)*Children's Hospital of Philadelphia, Philadelphia, PA*

---

**Background:** As the prevalence of autism spectrum disorder (ASD) continues to rise, so has interest in the identification of effective treatments. While there are some evidence-based pharmacologic treatments for ASD, many parents turn to alternative therapies with anecdotal support and popularity through social media. Children with ASD are reported to receive complementary and alternative medicine interventions at rates much higher than the general population. There has been an increasing interest in the use of cannabis as more states are passing legislature to approve use both recreationally and in certain health conditions such as ASD. Parents are often reluctant to talk about these alternative treatment options with their child's medical providers, leading to decreased opportunities for parents and providers to engage in shared decision making.

**Objectives:** The primary objective of this study is to determine the different reasons parents have for considering cannabis treatment for their child with ASD and what additional personal beliefs and outside information helped inform those decisions. A secondary objective is to determine parental knowledge of cannabis risks and benefits and the relationship between that knowledge and other factors reported to influence decisions about cannabis use in a child with ASD.

**Methods:** We completed semi-structured interviews with 21 parents of children with ASD. We asked open-ended questions about perspectives regarding cannabis use for youth with ASD as well as potential symptom targets. Parents were also asked where they would look for more information regarding cannabis use in ASD as well as comfort with speaking with their child's medical provider. All interviews were audio-recorded and professionally transcribed. Transcriptions were coded using a systematic approach to generate codes and identify themes. Prior to the interview, each participant completed a survey collecting demographic information, rating of child's level of impairment, as well as current and past medication history. This information will be used to look for any associations with identified themes.

**Results:** All respondents were biological parents, age 27-52 years, with 33% having a graduate/professional degree. Most children were male (N=18), age 18 months-10 years, and 38% were rated by parents as requiring substantial support related to symptoms of ASD. Based on preliminary findings, participants reported limited prior knowledge of cannabis use in children with ASD and cited the internet and social media groups as sources of information to further their knowledge. Many parents remarked that cannabis was appealing as a treatment option because they felt it was a more "natural" option compared to conventional medications and less likely to lead to dependence or negative long-term consequences. Many participants felt comfortable asking their child's doctors about cannabis.

**Conclusions:** While many studies have previously looked at parental attitudes toward complementary and alternative treatments for children with ASD, this is one of the first to ask explicitly about cannabis use. As medical and recreational use of cannabis gains legalization, more parents may be interested in it as a treatment option. The results of this project will help clinicians better understand the factors driving parental decision-making in using cannabis for children with ASD.

**422.042 (Poster) Parent Stress Affects Their Responses to Children's Negative Emotions in ASD Families**

**T. N. Worley<sup>1</sup>, A. Rovane<sup>2</sup> and R. Hock<sup>1</sup>,** (1)*University of South Carolina, Columbia, SC,* (2)*Psychology, University of South Carolina, Columbia, SC*

---

**Background:** Researchers have found that child ASD symptoms can place a substantial strain on the family system. These parents and caregivers present significantly higher stress levels and lower wellbeing than those of parents of children with other disorders or whom are typically developing. Research has demonstrated the deleterious impact of parent stress on child behaviors and outcomes. However, more research is needed to understand the mechanisms of this impact. One likely mechanism is the way parents respond to their child's expression of negative emotions. Literature in this area distinguishes between supportive (i.e., emotion-focused, problem-focused, and expressive encouragement), unsupportive (i.e., distressed and punitive), and distressed parenting responses styles. This study is one the first to examine the relationship between parents' stress level and their style of responding to negative emotions by children with ASD.

**Objectives:** The present study aims to understand the influence of parent stress on their responses to negative emotions and behaviors in children with ASD. We hypothesize that greater parent stress levels will be associated with more unsupportive and distressed responses, and fewer supportive responses.

**Methods:** Participants are 28 primary caregivers of children with ASD who were recruited for a larger study on family patterns in ASD. The Parenting Stress Scale is an 18-item measure that indicates stress related to parenting. The Coping with Children's Negative Emotions Scale consists of 12 scenarios in which youth may experience negative emotion. Parents identify how they would respond to each scenario using six responses which they are to rate on a 7-point Likert-scale regarding their likelihood of responding that way. We ran descriptive statistics on each parenting response style, and we conducted linear regression models to better understand relations between parent stress and responses to negative child emotion.

**Results:** Parents reported higher rates of supportive response styles, including emotion-focused ( $M = 5.75, SD = .69$ ), problem-focused ( $M = 5.67, SD = .69$ ) and expressive encouragement ( $M = 5.23, SD = .98$ ), compared to unsupportive or distressed styles. Heightened parent stress levels were associated with increased frequency of distressed responses to child emotion ( $B = .04, p < .01$ ). However, the relationships between stress level and the use of supportive or unsupportive responses were not statistically insignificant ( $p > .05$ ).

**Conclusions:** Our findings indicated that while parents reported using more supportive response styles, higher parent stress levels predicted a more distressed pattern of responding to negative child emotions. It is likely that increased parent stress impacts their choice of parenting behavior during their child's heightened emotional moments. The effect may be more pronounced in distressed parenting responses, over supportive and unsupportive parenting responses. These findings suggest that future studies should aim to support parents of children with ASD and provide them with tools of stress management in order to improve their parenting as well as to improve the parent-child relationship.

**422.043 (Poster)** Parent-Child Integrated Music Program Supports Parent Well-Being in Families of Young Children with and without ASD

*T. Liu<sup>1</sup>, L. Booke<sup>2</sup> and M. D. Lense<sup>1</sup>, (1)Vanderbilt University Medical Center, Nashville, TN, (2)In Tune Music and Wellness, Nashville, TN*

---

**Background:** There is increasing recognition of the need to consider parent and family well-being when evaluating programs for young children with ASD, including consideration of how to support family involvement in community activities. Community music activities may provide an ecologically valid setting to support both children with ASD and their parents. Social musical experiences play an important role in parent-child interactions and early childhood peer interactions. Musical experiences promote prosocial behavior, emotional well-being, and social connection in children and adults. A limited but emerging body of research also shows support for the use of musical activities and music therapy to promote children with ASD's social communication skills. However, little research has examined the impact of music programs on parents of children with ASD.

**Objectives:** To examine changes in parents' affect and sense of connection to others during their participation in an integrated parent-child weekly music class program.

**Methods:** Thirty-three children with ASD (27 male,  $M=43.8$  months) and thirty TD children (17 male,  $M=37.0$  months) and their parents participated in an integrated twelve-week music program that embedded parent training and peer interaction in shared musical activities. At the start and end of their first, middle, and last session, parents completed the Positive and Negative Affect Schedule (PANAS) to measure their affect in the moment and the Inclusion of Other in the Self (IOS) scale to measure their connection to their child and to other class members. Children's engagement states were coded from videos of each child's first and last sessions. Mixed-models were used to examine changes in parent affect, connectedness to others, and children's engagement throughout the program.

**Results:** Parents' PANAS positive affect scores significantly increased and PANAS negative affect scores significantly decreased within sessions (i.e., from start to end of a given class),  $p's < 0.01$ . Parents' IOS connection scores to other class members significantly increased within sessions,  $p < 0.001$ , and parents reported greater connectedness to other class members at the middle and last session versus the first session,  $p < 0.001$ . Parents' sense of connectedness to their own child did not change, likely due to high baseline ratings of connectedness. Parent ratings did not differ by diagnostic group for any measure. While children's active engagement during classes increased over the sessions,  $p < 0.001$ , it was not associated with parent affect or connectedness ratings.

**Conclusions:** Participating in an integrated parent-child music class was associated with increased positive and decreased negative affect for parents of children with and without ASD, as well as an increased sense of connection to other class members. These findings are consistent with studies of musical experiences in other populations (e.g., parents of infants). The positive impact of program participation for parents, which was not related to children's class engagement, may reflect parents' direct participation in social musical activities, as well as broader involvement in shared parenting experiences. By creating positive emotional experiences and increasing connections to others, community or therapeutic music programs may be a viable context for supporting family well-being in families of children with and without ASD.

**422.044 (Poster)** Parent-Reported Behavioral Changes during the COVID-19 Pandemic in Children with Autism Versus Other Conditions

**A. Yusuf<sup>1,2</sup>, N. J. Wright<sup>1</sup>, M. Steiman<sup>2</sup>, A. Karpur<sup>1</sup>, A. Shih<sup>3</sup>, M. Elsabbagh<sup>1,2</sup> and K. Shikako-Thomas<sup>4</sup>,** (1)Neurology and Neurosurgery, McGill University, Montreal, QC, Canada, (2)Azrieli Center for Autism Research, Montreal Neurological Institute-Hospital, Montreal, QC, Canada, (3)Biostatistics & Health Informatics, Kings College London, London, United Kingdom, (4)Autism Speaks, Princeton, NJ, (5)Autism Speaks, New York, NY, (6)School of Physical and Occupational Therapy, McGill University, Montreal, QC, Canada

---

**Background:**

Following the declaration of the COVID-19 pandemic in March 2020, numerous countries imposed intensive measures to manage the outbreak, namely social distancing and confinement. There is evidence of negative impact of these measures on children, including increased anxiety and depression (Xie et al. 2020) and behaviour difficulties (Orgilés et al. 2020). Paradoxically, positive impacts following a previous outbreak have been documented, e.g. increased family and social support and more attention to self-care activities, all of which negatively correlate with post-traumatic stress (Lau et al. 2006). These findings suggest a pattern of resilience in response to stressful events. Currently, little is known about the impact of the COVID-19 pandemic on the functioning of children with autism.

**Objectives:**

We examined parent-reported behavioural changes during the COVID-19 pandemic and assessed whether the changes differed in children with autism versus other conditions.

**Methods:**

In close collaboration with stakeholders following a Participatory Action Research approach, we integrated COVID-19 guidance recommendations for persons with disabilities from WHO and UNICEF into an online survey, which was originally developed as part of the *UNICEF-WHO Global Report on Developmental Delays, Disorders, and Disabilities* to describe current practices and resources available to these populations. The online survey was available from June 11 - July 21, 2020, resulting in a convenience sample of caregivers across provinces and territories in Canada. This study focused on parent-reported changes on 12 domains of functioning (Table 1). Each domain was rated as either 'worsening', 'no change', or 'improving.' We conducted multinomial regressions to assess the extent to which condition (autism versus other conditions) predicted parent-reported behavioural changes on each domain.

**Results:**

Out of n=883, 35% of respondents identified as caregivers of a child with autism. Improvement in at least one domain of functioning was reported by 65.8% of parents. No change in functioning was the most frequently endorsed response averaged across all domains (50%), followed by worsening (31%). The domain most frequently endorsed as improved was daily living skills (25%), followed by health problems (20%), and diet/eating difficulties (19%). We found that individuals are more likely to report worsening than improvement on the following domains if they are caregivers of children with autism rather than caregivers of children with other conditions (Table 1): mental health, diet/eating, social interaction, repetitive behaviours, safety concerns, sensory issues, and education compared to caregivers of children with other conditions. There were no significant differences in likelihood to report worsening compared to improvement on other domains between caregivers of children with autism and those of children with other conditions.

**Conclusions:**

Some parents reported improvement in some functioning suggesting evidence of resilience from the COVID-19 pandemic among children with autism and other conditions. However, evidence of worsening of functioning was also concerning, with parents of children with autism being more likely to rate their children as showing worsening of functioning compared to parents of children with other conditions. Future studies examining predictors of resilience are needed to tailor support for all families with a child with autism and other conditions.

**422.045 (Poster)** Parental Distress and Parenting Quality in Families of Children with ASD: Evidence for Potential Compartmentalization

A. Preston<sup>1</sup>, J. K. Baker<sup>2</sup>, R. M. Fenning<sup>3</sup>, H. A. McGregor<sup>1</sup>, C. M. Sanner<sup>1</sup>, N. Chan<sup>4</sup> and C. L. Neece<sup>1</sup>, (1)Psychology, Loma Linda University, Loma Linda, CA, (2)Center for Autism; Dept. of Child & Adolescent Studies, California State University, Fullerton, Fullerton, CA, (3)Center for Autism, Child and Adolescent Studies, California State University, Fullerton, Fullerton, CA, (4)Department of Psychology, Loma Linda University, Loma Linda, CA

---

**Background:** Parents of children with autism spectrum disorder (ASD) report increased levels of stress and mental health challenges (Hayes & Watson, 2013). Parent well-being is generally considered a key contributor to parenting behavior (Belsky, 1984); however, parents of children with ASD often appear to provide similar quality parenting despite higher personal distress (e.g., Baker et al., 2010). This apparent contradiction may be explained by an increased ability of parents of children with ASD to compartmentalize their parenting, buffering spillover from their own emotional state.

**Objectives:** The current study examined the compartmentalization hypothesis by testing whether associations between parental distress and positive parenting were lower and/or less consistent for families of children with ASD as compared to those of children with neurotypical development (TD).

**Methods:** The sample consisted of 73 preschool children with ASD and 55 children with TD (age 2-5 years) and their primary caregivers (12% fathers). The groups with ASD/TD differed on child gender (78%/46% male), caregiver race/ethnicity (32%/56% Caucasian, non-Hispanic), and caregiver education (TD higher), so each of these were controlled in regressions. Parents completed measures relating to their stress (PSI-PD), depression (CES-D), and emotion dysregulation (DERS). Parents also reported on their positive parenting (APQ), and warmth was coded from the Five-Minute-Speech-Sample interview (FMSS).

**Results:** Status groups differed on every parenting and distress variable of interest, with TD families exhibiting healthier levels on all factors with the exception of caregiver depression, for which the group with ASD reported significantly lower levels,  $t = 3.94, p < .001$ . Families of children with TD demonstrated significant associations between parent distress and parenting for five of six correlations tested. In contrast, none of the correlations were significant for families of children with ASD, with many close to zero or in the opposite direction (Table 1). Hierarchical regressions controlling for potential confounds and main effects revealed a significant interaction between status group and a parent distress composite in the prediction of reported positive parenting,  $\beta = .36, t = 2.29, p = .024$ , such that parent distress only predicted lower positive parenting in families of children with TD,  $t = -2.08, p = .040$  (slope for ASD:  $t = 1.04, p = .30$ ; Figure 1). The interaction in a binary logistic regression predicting parental warmth did not reach significance ( $p = .10$ ). Given significant associations between group status and several demographic variables, the latter were substituted for group status as moderators and none were significant.

**Conclusions:** Data provide evidence for compartmentalization in that associations between parent distress and positive parenting were consistently lower and non-significant for families of children with ASD as compared to the TD group. These findings suggest that parents of children with ASD may be more able to buffer potential spillover from their own distress to their positive parenting. Additional resilience may be suggested by lower depression scores among the caregivers of the preschoolers with ASD. Further investigation into potential contributors to the lower positive parenting scores for families of children with ASD is required, including consideration of child characteristics.

#### 422.046 (Poster) Parental Quality of Life and Child's Community Participation in Young Children with Autism Spectrum Disorder in Singapore

R. Aishworiya<sup>1</sup>, S. C. Chong<sup>2</sup>, K. Mulay<sup>2</sup>, T. S. Lim<sup>2</sup>, J. Kiing<sup>2</sup> and Y. Q. Kang<sup>2</sup>, (1)Paediatrics, National University Health System, Singapore, Singapore, (2)National University Hospital, Singapore, Singapore

---

**Background:** Parents of children with autism spectrum disorder (ASD) tend to experience greater parenting stress and psychological ill-effects than parents of typically developing children. Quality of Life (QoL) of parents is increasingly recognized as a critical outcome measure in the management of children with ASD. Identifying specific child factors, which can impact parental QoL, can facilitate targeted intervention strategies

**Objectives:**

The primary aim of this study was to describe the QoL of parents of young children with ASD in Singapore and their child's community participation. The secondary aim was to identify associations, if any, between the child's community participation, severity of ASD symptoms and parental QoL.

**Methods:**

This was a cross-sectional study conducted at a tertiary developmental pediatric centre in Singapore from September to December 2019. Inclusion criteria was 1. Parent with a child with ASD aged between 5 and 8 years, and 2. Child diagnosis of ASD following clinical evaluation by a developmental pediatrician or formal psychological evaluation with the Autism Diagnostic Observation Schedule. Parents completed the Quality of Life in Autism Questionnaire (QoLA), parent version. The QoLA contains 2 subscales: part A measures parental self-rated QoL (score range 28-140, higher scores denote greater perceived QoL); part B measures perceived problems due to child's ASD-related behaviors (score range 20-100, higher scores denote fewer perceived problems due to behavior). Parents also answered questions on the frequency of their child's community participation. Descriptive statistics and T- tests were used to analyze data.

#### Results:

Parents of 48 children (72.9% males) with ASD completed the study; the mean age of children was 74.8 months (SD 23.9). The majority (67%) of children attended less than 1 social event per month and more than half (55%) attended less than 1 community event per month. The mean QoLA part A score in the cohort was 100.3 (SD 16.1); this was significantly higher for our cohort compared to other international cohorts of children with ASD (Table 1). The mean QoLA part B score was 39.6 (SD 16.4); this was significantly lower for our cohort compared to international cohorts and denotes higher perceived problems with the child's ASD-related behaviors. (Table 1) There was no significant association between parent-reported QoLA part A, QoLA part B and community participation scores.

#### Conclusions:

Self-reported QoL of parents with children with ASD in our cohort appears to be high despite children having greater problematic behaviors. Although community participation of children was sub-optimal, this was not associated with poorer parental QoL. Other child and parental factors that may contribute to QoL such as parental resilience and mental health should be explored in further research.

#### **422.047 (Poster) Predictors of Parent Activation in Caregivers of Children with ASD Using PAM-DD**

*Y. Yu<sup>1</sup>, L. A. Ruble<sup>2</sup>, J. H. McGrew<sup>3</sup> and D. S. Murray<sup>4</sup>, (1)UC Davis MIND institute, Sacramento, CA, (2)Special Education, Ball State University, Muncie, IN, (3)Psychology, Indiana University - Purdue University Indianapolis, Indianapolis, IN, (4)Autism Speaks, Boston, MA*

Background: Patient activation (PA) refers to one's beliefs, knowledge, ability, and persistence to manage one's care (Hibbard et al., 2004). Importantly, PA has been shown to be related to medical and behavioral health outcomes (Hibbard & Greene, 2013). The concept has been extended to activation in parents of children with chronic health and mental conditions, including neurodevelopmental disabilities. For example, a study using a Parent Activation Measure for Developmental Disability (PAM-DD), indicated positive associations between parent activation and service satisfaction and youth outcomes, and lower caregiver stress (Crossman et al., 2020). However, there is limited research on activation in parents of children with autism spectrum disorder (ASD).

Objectives: To fill the gap, we examined child and family characteristics related to parent activation using the PAM-DD.

Methods: This study utilizes secondary data analysis of the Registry Call Back Assessment (RCBA) study, which was a longitudinal substudy of the Autism Treatment Network (ATN) Registry study (Murray et al., 2016). Participants completed a series of measures at RCBA visit 1 and visit 2, including Vineland-II, Child Behavior Checklist, Aberrant Behavior Checklist, Pediatric Quality of Life Inventory, Children's Sleep Habits Questionnaire, Caregiver Strain Questionnaire, PAM-DD, parent and child characteristics.

#### Results:

A total of 658 families completed the measures at first visit, and 407 families completed a second visit. Child participants' average age at study enrollment was 72 months (SD = 39.40). Most child participants were male (80%), White (77%), non-Hispanic (86%), and used public insurance (63%). About half of caregiver participants had college or greater education (49%), and annual incomes of \$50,000 or more (48%). Cross-sectionally, at time 1, greater parent activation was related to lower levels of child sleep issues ( $r = -.11$ ), irritability ( $r = -.12$ ), lethargy ( $r = -.08$ ), internalizing ( $r = -.16$ ) and externalizing behaviors in child participants ( $r = -.21$ ), parental concerns ( $r = -.12$ ), and caregiver strain ( $r = -.19$ ) and higher levels of peds quality of life ( $r = .15$ ) and child adaptive behaviors ( $r = .10$ ),  $p < .05$ .

Longitudinally, greater parent activation at time 2 was related to several time 1 measures: older child age at registry ( $r = .11$ ), lower levels of child sleep problems ( $r = -.14$ ), hyperactivity ( $r = -.13$ ), internalizing ( $r = -.23$ ) and externalizing behaviors ( $r = -.21$ ) in child participants, and caregiver strain ( $r = -.22$ ), and higher levels of child quality of life at time 1 ( $r = .13$ ),  $p < .05$ . In a multivariable model, older child age at initial registry ( $\beta = .12$ ) and lower levels of caregiver strain at Visit 1 ( $\beta = -.15$ ),  $p < .05$ , were related to higher levels of parent activation level at Visit 2,  $R^2 = .097$ ,  $F(7, 319) = 4.88$ ,  $p < .001$ .

Conclusions: Overall, both child and caregiver characteristics were related to parent activation. Child symptom severity and problem behaviors (e.g., externalizing behaviors) and sleep issues and caregiver strain negatively impacted caregivers' activation level. On the other hand, higher levels of adaptive behaviors and quality of life may help increase activation in parents of children with ASD.

**422.048 (Poster)** Predictors of Resilience in Parents of Children with Autism Spectrum Disorder (ASD)

**J. M. Schwartzman<sup>1</sup>**, M. E. Millan<sup>2</sup> and G. W. Gengoux<sup>2</sup>, (1)Psychiatry and Behavioral Sciences, Vanderbilt University Medical Center, Nashville, TN, (2)Psychiatry and Behavioral Sciences, Stanford University School of Medicine, Stanford, CA

---

Background: Parents of children with Autism Spectrum Disorder (ASD) experience elevated stress. Research indicates an inverse relationship between stress and resilience such that higher resilience is associated with lower perceived stress, suggesting that resilience could be a promising treatment target. Preliminary efficacy data from autism-adapted resilience intervention are also promising. However, identifying predictors of resilience among parents of children with ASD requires continued investigation.

Objectives: The primary objective of this study is to examine the amount of variance in resilience scores explained by four blocks of variables (e.g., parent variables, child/parenting variables, social supports, and mental health practices) that may be related to resilience. A secondary aim was to examine the strength of individual variables within blocks in predicting resilience.

Methods: Fifty parents (15 males, 35 females, mean age = 40.5 years) of children with ASD (4:0-10:11 years) rated resilience on the Connor-Davidson Resilience Scale (CD-RISC). At the same timepoint, parents completed additional questionnaires, which were categorized into four blocks of predictors: (a) parent variables (e.g., internalizing symptoms, broad autism phenotype traits), (b) child/parenting variables (e.g., parenting stress, child problem behaviors, child social impairment), (c) social supports (e.g., degree of engagement in religion, number of close relationships), and (d) positive mental health practices (e.g., acceptance, mindfulness, optimism, self-compassion). All variables were continuous, apart from religious practice which was ordinal (0 = no religious practice, 1 = a little, 2 = some, 3 = regular practice). The regression model included the four blocks of predictors to identify the amount of variance in CD-RISC scores explained by each block. Additionally, the adjusted beta values for all predictors within each block were examined to identify significant predictors of CD-RISC scores.

Results: Regression analyses demonstrated that three of the four blocks – parent variables, social support, and mental health practices – accounted for 76% of the total variance in CD-RISC scores ( $R^2 = 0.76$ ,  $p < 0.01$ ; see Table 1). Specifically, the block of parent variables accounted for 46% of the variance ( $R^2 = 0.46$ ,  $p < 0.05$ ), social support accounted for an additional 7% of the variance ( $\Delta R^2 = 0.07$ ,  $p < 0.05$ ), and mental health practices accounted for another 22% ( $\Delta R^2 = 0.22$ ,  $p < 0.05$ ). The contribution of child/parenting variables was not significant ( $\Delta R^2 = 0.01$ ,  $p > 0.10$ ). Within the four blocks, four individual variables were significant predictors of CD-RISC scores: anxiety ( $\beta = -0.49$ ,  $p < 0.01$ ), engagement in religious practice ( $\beta = 0.38$ ,  $p < 0.05$ ), optimism ( $\beta = 0.34$ ,  $p < 0.05$ ), and self-compassion ( $\beta = 0.45$ ,  $p < 0.01$ ). In essence, higher parent resilience in this sample was associated with greater engagement in religious practices, higher optimism and self-compassion, and lower anxiety.

Conclusions: Findings indicate that certain factors – anxiety, religious practices, optimism, and self-compassion – may be particularly important in understanding resilience among parents of children with ASD. This may suggest potential treatment targets for resilience interventions. Continued investigations with larger samples and among parents of older children are needed to expand the present findings.

**422.049 (Poster)** Provider Perspectives on Usual Care and Ndbi Models within an Early Intervention System

**K. Pickard<sup>1,2</sup>**, H. Mellman<sup>2</sup>, K. M. Frost<sup>3</sup>, J. Reaven<sup>2</sup> and B. R. Ingersoll<sup>1</sup>, (1)Emory University School of Medicine, Atlanta, GA, (2)JFK Partners, University of Colorado Anschutz Medical Campus, Aurora, CO, (3)Psychology, Michigan State University, East Lansing, MI

---

Background: Naturalistic, Developmental, and Behavioral Interventions (NDBIs) are evidence-based interventions for young children with ASD. There has been growing interest in translating NDBIs into the Early Intervention (EI) system to better serve young children with ASD in addition to those who have an increased chance of having ASD. In order to do so, it is also important to understand the intervention practices that young children with ASD and social communication delays already receive within

this system. To date, research has yet to examine the existing use of both manualized NDBI programs and broader NDBI strategies by EI providers. This is a gap that limits our understanding of “usual care” for children being served within the EI system and the more naturalistic capacity for the EI system to serve these children.

**Objectives:** The goals of the current study were to understand provider perspectives on how young children with ASD or social communication delays are currently served within the EI system, and how best to translate NDBI programs and strategies within this system. Specifically, this study examined: 1) provider-reported use of both manualized NDBI programs and broader NDBI strategies; 2) factors that impact the use of NDBI programs and strategies within the EI system; and 3) methods to increase the delivery of NDBI programs and strategies within this system of care.

**Methods:** Eighty-eight EI providers participated in this study. Providers were recruited if they were currently serving a child under 36-months who either had a medical diagnosis of ASD or whom they suspected had an increased likelihood of having ASD. All providers completed a measure of NDBI program and strategy use (Frost et al., 2020). Thirty-three providers also participated in a supplemental focus group. Focus groups were semi-structured and included EI providers within the same county. An iterative approach grounded in content analysis was used to analyze qualitative data.

**Results:** Providers reported relatively high competence in supporting young children with social communication delays but greater variability in the ways in which they deliver this support. Although a handful of EI providers had received training in a manualized NDBI program, the vast majority of providers described using broader NDBI strategies that were not encompassed by a manualized framework. Importantly, even providers trained in manualized NDBI programs underscored feeling the need to adapt these models by blending the terminology and strategies from different programs, and by following the caregivers’ lead in the types of strategies taught. Participating EI providers almost unanimously described that their training in NDBI programs and/or strategies was impacted by system-level factors, such as their county’s service delivery model.

**Conclusions:** This study provides insight into usual care for young children with an increased chance of having ASD who are served within the EI system. Overall, it provides important information about the inherent strengths and limitations of EI providers and systems, and foundational next steps to support the translation of early interventions that are both evidence-based and appropriately flexible to meet the needs of the EI system.

#### **422.050 (Poster) Psychological Impact of COVID-19 Pandemic in Italian Families of Children with Neurodevelopmental Disorder**

*N. Mazzoni, A. Bentenuto, M. Giannotti, P. Venuti and S. De Falco, Department of Psychology and Cognitive Science, University of Trento, Rovereto, Italy*

---

**Background:** The restrictive measures imposed to control the COVID-19 pandemic have produced drastic changes in families' lifestyle and habits. Research on the psychological impact of the COVID-19 pandemic highlighted negative effects on the general population and, particularly, on parents (Wang et al., 2020; Zhang et al., 2020). Changes in daily routines and sudden decrease of support from educational and therapeutic environments may have strongly impacted children with NDD and their families (Nonweiler, et. al.2020). However, little empirical evidence exists about this issue.

**Objectives:** In this study, we investigated parental and child adjustment in Italian families of children with NDD and typical developing (TD) children during lockdown.

**Methods:** A total of 164 parents participated to an anonymous online survey, 82 parents of children with neurodevelopmental disabilities (NDD) and 82 parents of typically developing children (TD), matched for: parental gender, child gender, family SES, living area at the time of survey completion, child age. In the NDD group, 59% of children (N=49) had a diagnosis of Autism Spectrum Disorder and 41% of other neurodevelopmental disorders (N =33). The survey included questions about sociodemographic information, ad-hoc questions about family’s organisation in relation to COVID-19 outbreak, parental stress (10 items from the Parental Stress Scale - PSS, Berry and Jones, 1995), coparenting (brief form of the Coparenting Relationship Scale - CRS, Feinberg et al., 2012) and child externalising behaviour (*hyperactivity/inattention* and *conduct problems* scales from the Strengths and Difficulties Questionnaire - SDQ Goodman et al., 2001). For PSS, CRS, and SDQ participants were asked to respond to each item twice: firstly, with reference to the lockdown period (“Now”); secondly, with reference to the month just before the lockdown’s beginning (“Before”).

**Results:** In both groups, we found increased parental stress ( $F(1,162)=15.03, p<0.001, \eta^2=.085$ ) and child externalising behaviour ( $F(1,162)=23.59, p<0.001, \eta^2=.127$ ) during the lockdown compared to before. Moreover, child externalising behaviour were higher in children with NDD compared to children with TD, both during and before the lockdown ( $F(1,162)=10.53, p= 0.001, \eta^2=.061$ ). In the NDD group the increase of child externalising behaviour was predicted by the decrease in provided therapy. No significant changes between pre and during lockdown were found in coparenting, in either

groups. However, the quality of coparenting acted as moderator between the time spent with the child and level of parental stress during the lockdown, differently in the two groups (*NDD*: significant when coparenting was low:  $\beta = 2.86$ ,  $p = .016$ ; *TD*: significant when coparenting was high:  $\beta = 2.41$ ,  $p = .027$ ).

Conclusions: Our results pointed out the role of good coparenting relationship for limiting parental stress during pandemic home confinement, and highlighted the importance to ensure continuity in therapies for children with *NDD* (e.g. telehealth) during home confinement and to provide psychological support for parents.

**422.051 (Poster)** Resiliency Intervention for Siblings of Children with ASD

**K. Kuhlthau<sup>1</sup>**, L. A. Fell<sup>2</sup>, L. Traeger<sup>3</sup>, C. M. Luberto<sup>4</sup>, B. Goshe<sup>5</sup>, D. A. Iannuzzi<sup>6</sup>, G. K. Perez<sup>7</sup> and E. Park<sup>1</sup>, (1)Massachusetts General Hospital, Boston, MA, (2)Division of Academic Pediatrics, MGH, Boston, MA, (3)Psychiatry, Massachusetts General Hospital, Boston, MA, (4)Health Policy Research Center at Mongon Institute, Mass General Hospital, Boston, MA, (5)Psychiatry, Mass General Hospital, Boston, MA, (6)125 Nashua Street, MassGeneral Hospital, Boston, MA, (7)Health Policy Research Center at Mongon Institute, Mass General Hospital/Harvard Medical School, Boston, MA

---

Background:

Neurotypical siblings (NT sibs) of individuals with autism spectrum disorder (ASD) are at elevated risk for stress, emotional, and adjustment problems. Resiliency is the ability to cope and adapt when faced with stressful events, Thus, interventions to enhance resiliency might be particularly beneficial to NT sibs.

Objectives:

We conducted a randomized waitlist-controlled pilot trial to examine the feasibility, acceptability, and preliminary efficacy of an adapted virtual mind-body resiliency group intervention for NT sibs of individuals with ASD.

Methods:

We modified an existing resiliency intervention (the Stress Management and Resiliency Training-Relaxation Response Resiliency Program [SMART-3RP]) by incorporating results from formative qualitative research with NT sibs and parents of individuals with autism and feedback from youth advisors. From May to July 2020, we randomly assigned teens (aged 14-17) to immediate intervention vs. waitlist control. The intervention included 8 group sessions delivered by a study clinician via a video conferencing platform. We measured feasibility based on enrollment and group attendance rates; acceptability was based on post treatment survey responses. We explored group differences in pre-post changes in 1) stress coping (Measure of Current Status-A) and 2) resiliency (Current Experiences Scale) using independent samples t-tests and effect size calculations.

Results:

We enrolled 40/52 (77%) eligible teens and randomly assigned them to the intervention (n=20) and control (n=20) conditions. 18/20 (90%) of intervention participants attended at least 7 of the 8 sessions. Among 19/20 (95%) of intervention participants who completed the post treatment survey, 79% reported practicing relaxation response exercises at least “a few times a week,” and 77% found the program sessions to be at least “somewhat helpful.” Post-treatment, the intervention group showed greater improvements than the control group in stress coping ( $d=0.60$ ) and resiliency ( $d=0.24$ ).

Conclusions:

Findings from our wait-list controlled pilot trial showed promising feasibility, acceptability, and preliminary efficacy of the modified SMART-3RP program, delivered virtually for NT sibs of individuals with ASD. Small to medium effect sizes for improvements in stress coping and resilience support further testing the modified SMART-3RP for teen siblings in a larger efficacy trial.

**422.052 (Poster)** Rethinking Stakeholder Roles in ASC Early Interventions: The Development of a Stakeholder Driven Early Intervention Research Agenda

A. Wainer<sup>1</sup>, R. A. Gordon<sup>1</sup>, A. R. Borowy<sup>2</sup> and K. M. Walton<sup>2</sup>, (1)Department of Psychiatry, Rush University Medical Center, Chicago, IL, (2)Nisonger Center, The Ohio State University, Columbus, OH

---

**Background:** Multiple types of early interventions (EI) are available for children with autism spectrum conditions (ASC); yet, data about how to select, prioritize, and individualize different intervention approaches for a particular child is absent. Further, there is a clear mismatch between the range of outcomes studied in research, and the outcomes/values described by stakeholders like adults with ASC, caregivers and clinicians. This may reflect the fact that stakeholders have rarely been engaged in discussions about which outcomes and measurement approaches should be used in EI research.

**Objectives:** A goal of this project, referred to as Project STEER (Stakeholders Engaged in Early Intervention Research), is to develop a stakeholder-driven research agenda. It is expected that this agenda will help ensure better alignment between research questions that are of value to the community and those that are studied by researchers.

**Methods:** Project STEER has used a Participatory Action Research approach to develop a research agenda that reflects strategies, measurement, and outcomes relevant to ASC EI stakeholder goals and priorities. Our participatory action approach uses collaborative reflection and systematic data collection to mobilize specific actions (Baum, MacDougall, & Smith, 2006); this approach has been particularly well-suited for the current project aims given that a lack of collaboration, focus and clearly defined next steps have hampered prior attempts to create a meaningful research agenda in this area. Project STEER stakeholders include 10 adults with ASC, 10 parents of children with ASC, and 10 community-based clinicians/policy makers in Columbus, Ohio and Chicago, Illinois. Project STEER has successfully engaged these stakeholders in facilitated group meetings to collectively define problems with current approaches to identifying and measuring EI outcomes and jointly identify recommendations that put stakeholder-driven perspectives at the center of the EI research agenda.

**Results:** Project STEER has developed 3 core components of a stakeholder research agenda: Guiding Principles, Research Priorities, and Systems Implications. The Guiding Principles emphasize critical perspectives such as a need to include autistic voices in research and to ensure accessibility of research findings to the stakeholder community. Stakeholder generated Research Priorities focus on developing and testing strategies for better family support, more coordinated and cohesive service delivery systems, understanding quality of life for the child and family, and intervention approaches and treatment targets that account for the heterogeneity of ASC. Finally, Systems Implications highlight the need for continued efforts at the policy and systems levels to ensure that findings in research have direct and lasting impacts on children with ASD and their families.

**Conclusions:** Project STEER represents a critical step forward in realigning the research questions and approaches considered and used by researchers with the goals and priorities of stakeholders. The first phase of the project has allowed for identification of topics that stakeholders believe should be at the center of scientific endeavors. Now we are validating this research agenda using an online survey to engage a broader range of stakeholders across the country. The finalized Project STEER agenda will be disseminated broadly across lay, scientific and policy-focused outlets.

**422.053 (Poster) Self-Determination As Perceived By Autistic Adolescents and Their Parents: A Mixed-Methods Approach**  
**R. Handsman<sup>1</sup>, J. R. Linde<sup>2</sup>, B. B. Maddox<sup>3</sup>, L. Kenworthy<sup>1</sup> and C. E. Pugliese<sup>1</sup>,** (1)Center for Autism Spectrum Disorders, Children's National Hospital, Washington, DC, (2)Georgetown University, Washington, DC, (3)Psychiatry, UNC TEACCH Autism Program, Chapel Hill, NC

---

**Background:** Adolescence is a critical period of transition for autistic youth. Mandated school supports end after graduation, and teens are increasingly required to self-advocate. Self-determination (SD) skills (e.g., problem-solving, goal setting, self-advocacy) are linked to positive adult outcomes including friendships, living independently, and employment opportunities. SD has been under-explored in autistic youth with average or above intellectual abilities, including how parents and teens perceive teens' SD abilities, opportunities to practice SD, and focus of goals.

**Objectives:**

- To quantitatively examine the differences between parent and autistic youth self-report of SD skills and opportunities to practice SD.
- To describe the types of goals teens choose to work towards and compare youth and parent perspectives on current goals and progress attaining them using qualitative data.

**Methods:** Participants were 42 dyads consisting of diploma-track autistic high school students and their parents. Students were 14-20 years old (M=16.3, SD=1.3) with FSIQ $\geq$ 80 (M=104.5, SD=15.4), who met DSM-5 criteria for ASD supported by the SCQ and/or ADOS-2. Teens and their parents completed the American Institutes for Research Self-Determination Scale (AIR-SDS). The AIR-SDS measures overall SD skills (e.g., I/My child set their own goals to satisfy wants or needs) and opportunities to practice SD at home and at school. Bivariate correlations and Paired-samples t-tests examined the relationship between parent- and self-report of SD skills and practice opportunities. The AIR-SDS also asks respondents to report on current goals (e.g., Give

an example of a goal you/your child is working on now). These open-ended responses were coded by two raters (inter-rater reliability=86%, with a 3<sup>rd</sup> coder resolving discrepancies) using a priori categories (see Figure 1). The next phase of analysis involves a thematic analysis of the open-ended responses to better understand the differences between parent and self-report of goals.

**Results:** Correlations found no significant associations between parent and self-report of SD skills or opportunities to practice SD at home or school ( $p=.804-.924$ ). T-tests highlighted that both respondents reported similar opportunities to practice SD at home ( $p=.393$ ), though teens rated their SD skills higher than parents ( $t=6.28, p<.01$ ) and perceived fewer opportunities to practice skills at school ( $t=-2.70, p<.01$ ). The majority of respondents (42%) in both groups identified that teens were working on academic goals related to high school work or graduation. However, the next largest category was daily living skills for parents and leisure for youth. When further investigating this relationship, we found that only 28% of parent-teen dyad's goals matched. Preliminary themes from the open-ended responses highlight important ways that autistic adolescents and their parents differ in establishing and evaluating goals.

**Conclusions:** Results indicate differences in how teens and parents perceive youth SD skills and opportunities to practice SD. Although parents and youth both prioritized academic related goals, the lack of cohesion between the content of these goals emphasizes the discrepancy between parent and self-report of SD. Therefore, youth may face difficulties in getting support at home for goals that parents are unaware of. Collaboration between parents and their children could help to improve outcomes during this transition period.

#### 422.054 (Poster) Stress and Resilient Coping in Caregivers of Autistic People during the COVID-19 Pandemic

**K. A. Friesen<sup>1</sup>, J. A. Weiss<sup>2</sup>, S. J. Howe<sup>1</sup>, C. M. Kerns<sup>3</sup> and C. McMorris<sup>4</sup>,** (1)University of Calgary, Calgary, AB, Canada, (2)Psychology, York University, Toronto, ON, Canada, (3)University of British Columbia, Vancouver, BC, Canada, (4)Department of Paediatrics, University of Calgary, Calgary, AB, Canada

**Background:** A large number of caregivers of autistic people experience mental health problems, including stress and anxiety, while at the same time can cope effectively and make positive gains. Mental health difficulties in caregivers of autistic people likely reflect a combination of factors, including situational stressors, child and family characteristics, and adaptive coping. The impact of various disruptions due to COVID-19 has the potential to present considerable additional challenges over and above those typically experienced by caregivers of autistic people, and may lead to health and safety-related concerns (i.e., fear of infection), disruptions to work and/or income, lack of access to services and supports, adoption of multiple roles (e.g., caregiver and educator), and social isolation. The purpose of this study was to better understand the impact of child and family factors and COVID-19-related disruptions and difficulties on caregiver mental health (i.e., perceived stress), as well as the role of resilient coping in this association.

**Objectives:** The objectives of the present study were: (1) To characterize caregiver stress during COVID-19, (2) To identify contributing factors of caregiver stress, and (3) To model the relation between contributing factors (i.e., demographic factors and difficulties and disruptions associated with COVID-19), resilient coping, and caregiver stress. To carry out the objectives of the study we tested three hypotheses: (1) Caregivers of autistic children would report high levels of perceived stress, (2) Caregiver stress would be significantly associated with demographic variables (e.g., number of children with autism in the home, age of the child, autism severity, etc.) and difficulties and disruptions associated with COVID-19, and (3) Caregiver resilient coping would contribute a statistically significant amount of variance in caregiver perceived stress after accounting for demographic variables and difficulties and disruptions associated with COVID-19.

**Methods:** 620 caregivers of autistic individuals participated in this Canadian study. Caregivers completed an online questionnaire between June and July 2020 that included demographic information, disruptions and difficulties due to COVID-19, perceived stress, and resilient coping.

**Results:** Majority of caregivers (98%) reported experiencing some degree of disruption and difficulty as a result of COVID-19, with more than half of respondents reporting moderate levels of stress (85%). Caregiver stress was significantly associated with a number of demographic factors, as well as difficulties and disruptions as a result of COVID-19. As predicted, caregiver resilient coping contributed a statistically significant amount of variance in caregiver perceived stress after accounting for demographic variables and difficulties and disruptions associated with COVID-19. However, a large proportion of variance remains unaccounted for in this model and future research is necessary.

**Conclusions:** As expected, caregivers of autistic individuals continue to experience elevated levels of stress and anxiety during COVID-19. The tendency to cope with stress in an adaptive manner represents one of the many important factors to consider in

supporting these families. Future research is needed to better understand mental health in caregivers and families of autistic people as a result of the COVID-19 pandemic.

**422.055** (Poster) Stress, Coping, and Quality of Life in Parental Caregivers of Individuals with Autism Spectrum Disorder  
*D. M. Turnage, College of Nursing, University of Central Florida, Orlando, FL*

---

**Background:** Parental caregivers of children with Autism Spectrum Disorder (ASD) are exposed to stressors associated with the daily care of raising a child with a developmental disability, which may negatively impact parental quality of life (QOL).

**Objectives:** The specific aim of this study was to examine the relationships between demographic factors, stress, and coping among parental caregivers of children with ASD to determine whether predictors of QOL exist.

**Methods:** This study was descriptive, and an electronic survey was distributed to Florida parents of children, age 3-21 years old, diagnosed with ASD. The survey measured parent-reported demographic factors, severity of the diagnosis of ASD in the child, parental stress, coping, and QOL. Data were analyzed using multiple regression.

**Results:** Study findings suggest that, in parental caregivers of children with ASD in Florida (N = 152) daily stressors, coping self-efficacy, and household income were predictors for physical QOL; daily stressors and coping self-efficacy were predictors of psychological QOL, and coping-self efficacy, household income, and severity of the diagnosis of the child were predictors for environmental QOL.

**Conclusions:** Coping self-efficacy and improved income can positively improve QOL, while severity of the diagnosis of ASD and daily stressors can negatively impact QOL. Clinically, nurses with a better understanding of the parental stress and coping in parents of children with ASD can better recommend tailored resources to improve QOL. Policies to support financial help for families may also improve QOL. Future research should focus on interventions to improve coping-self efficacy.

**422.057** (Poster) The ASD Parent Perspective: Examining Parent Gender As a Moderator in the Relationship between Child Behavior Problems, ASD Symptom Severity, and Parent Stress.  
*C. Noble and T. Du Rocher Schudlich, Psychology, Western Washington University, Bellingham, WA*

---

**Background:**

Parents of children with autism spectrum disorder (ASD) experience a great amount of stress. Over 90% of children with ASD are diagnosed with a co-morbid disorder such as anxiety or conduct problems. Evidence indicates that parent stress is associated with ASD severity and behavior problems. However, there are gaps in the literature examining these associations in fathers and whether these associations differ across mothers and fathers.

**Objectives:**

The current study addressed the gaps and inconsistencies in the literature by examining whether ASD symptom severity and associated behavior problems predicted parent stress, as well as by assessing whether parent gender moderates the relationships between child behavior problems, ASD symptom severity, and parent stress. It was hypothesized that child behavior problems would significantly predict increased stress levels for mothers, whereas ASD symptom severity would significantly predict increased stress for fathers.

**Methods:**

We recruited 244 parents of children ages 3-5 diagnosed with ASD within the last 8-12 months via Facebook and flyers emailed to Autism clinics throughout the United States with a link to Qualtrics. Parents completed the Child Behavior Checklist (1.5-5yrs) to assess their child's behavior problems as well as the Gilliam Autism Rating Scale (3rd edition) to assess their child's ASD severity. Parents also completed the Parenting Stress Index-Short Form (4th Edition) to assess their stress levels.

**Results:**

Hierarchical regressions examined ASD symptom severity and the child's behavior problems as predictors of parent stress. Multiple linear regressions examined whether associations between child behavior problems, ASD symptom severity and parent

stress varied as a function of parent gender (see Table 1). We followed up significant interactions with simple slopes analyses. Behavior problems (CBCL total) significantly predicted parent stress; however, there was not a statistically significant difference in this relationship between mothers and fathers. Additionally, ASD symptom severity was significantly associated with parent stress and parent gender also moderated the association between symptom severity and parent stress. ASD symptom severity was significantly associated with greater stress for both fathers,  $t(1,236) = 4.968, p < .001$ , and for mothers,  $t(1,236) = 2.203, p = .029$ . However, simple slope analyses indicated a greater magnitude of this association for fathers (see Figure 1).

#### Conclusions:

Consistent with previous studies, both ASD symptom severity and behavior problems were significantly associated with parent stress. Additionally, there was a greater association between ASD symptom severity and parent stress for fathers compared to mothers, which is inconsistent with previous literature and with our hypotheses. The fathering vulnerability hypothesis describes fathers as more susceptible to stress within the home because fathers often rely on the mother to help define their role in the family, so stressful situations that impact both parents would provide a greater risk to the father's stress. Previous studies reported that mothers are typically the primary caregiver and thus more often exposed to their child's behaviors. However, in our study most fathers identified as the primary caregiver (92.7%). In combination with the fathering vulnerability hypothesis, this could possibly explain this unique finding. Clinical implications will be discussed.

**422.058 (Poster)** The Development of an Autistic-Led Research Agenda for Autistic Women and Girls in Australia  
**R. Grove<sup>1</sup>, H. Clapham<sup>2</sup>, S. Gurrin<sup>2</sup>, G. Hall<sup>1</sup> and T. Moodie<sup>2</sup>,** (1)University of Technology Sydney, Sydney, NSW, Australia,  
(2)University of Technology Sydney Autistic Advisory Board, Sydney, NSW, Australia

---

**Background:** Autism has historically been understood as a male disorder. However, recent evidence suggests that autistic women are being missed or misdiagnosed (Rutherford et al., 2016). Autistic girls and women experience unique challenges, including specific physical health issues (Mademtzi et al., 2018). Autistic girls and women also report 'masking' or 'camouflaging' their autistic traits in order to fit in (Lai et al., 2017). This effort has a significant impact on their wellbeing, and has been associated with an increase in mental health problems and suicide (Cassidy et al., 2018). The majority of autism research has been conducted with males. In addition, the research agenda has predominantly been set by researchers rather than the autistic community. Participatory research practices allow for effective translation of research outcomes, and ensure that research is relevant and beneficial for the community it aims to help (Long et al., 2017). While there have been increases in participatory research in autism, there has been no research that specifically focuses on developing a research agenda with the community of autistic women and girls. This is important given their unique needs and risk factors.

**Objectives:** This project aimed to utilise participatory research practices to develop an autistic-led research agenda for autistic girls and women in Australia.

**Methods:** An advisory group of autistic women from a range of backgrounds was recruited to develop and drive the project. Qualitative interviews were conducted with autistic girls (aged 7 and above) and autistic women (aged 18 and above). Participants included cis, trans, non-binary and gender diverse individuals who had a formal diagnosis of autism, or self-identified as autistic. All participants were interviewed by an autistic woman, and were asked questions about their needs and support systems, their strengths, as well as what research for autistic women and girls should focus on.

**Results:** The qualitative interviews were analysed using thematic analysis to identify the main themes or areas that are important for autistic women and girls. These themes were then used to develop an autistic-led research agenda for autistic girls and women.

**Conclusions:** This is the first project that outlines the development of an autistic-led research agenda for autistic girls and women in Australia. The research priorities identified will result in outcomes that are directly relevant for the autistic community. This will significantly improve our understanding of the specific needs and challenges identified by autistic girls and women themselves. In turn, this will allow for the provision of appropriate supports and services to better support autistic women and girls.

**422.059 (Poster)** The Developmental Process of Parent Advocacy for Black Families of Children on the Autism Spectrum: Semi-Structured Interviews of Black Autism Parents Serving As Peer Coaches.  
**E. Morgan, MIND Institute, UC Davis, Sacramento, CA**

---

**Abstract:** In this exploratory study, the qualitative method of Portraiture (Lawrence-Lightfoot & Davis, 1997) is used to recognize the characteristics associated with parent advocacy in Black mothers of children on the autism spectrum across three states: California, Pennsylvania, and New York. This study used liberating methodologies to co-construct portrait narratives of six mothers to illustrate the resources they used to navigate service-delivery systems (e.g., early intervention, special education) after their child's diagnosis and discuss how those resources contributed to their advocacy skills. The preliminary results of this study found: (1) Black mothers discuss using internal resources (i.e., non-dominant cultural capital) to navigate service-delivery systems after their child's diagnosis (Yosso, 2005). (2) Black mothers describe disseminating advocacy strategies to parents they coach.

**Background:** Black children are diagnosed with ASD 1.6-5 years posterior to White children (Mandell et al., 2009), and are also three times more likely misdiagnosed (Mandell et al., 2007). Even when controlling for socioeconomic status and education, families of Black autistic children are less knowledgeable about evidence-based autism intervention services and advocacy (Longtin & Principe, 2016). Despite these obstacles, there are Black mothers that advocate for diagnosis and intervention for their own and other children in their communities.

**Objectives:** This study aims to demonstrate the use of qualitative, liberating methodologies to illustrate the resources Black mothers of children on the autism spectrum used to navigate service-delivery systems after their child's diagnosis and discuss how those resources contributed to their advocacy skills (Lawrence-Lightfoot & Davis, 1997; Watson, 2019).

**Methods:** We used the methods of a qualitative phenomenological framework, Portraiture, to analyze the interviews (Lawrence-Lightfoot & Davis, 1997; Lawrence-Lightfoot 2005). Portraiture methods are like ethnography, but distinct in the approach and level of engagement that the portraitist takes part in data collection. During the analysis of the data, the lead author who is also a Black mother of a child on the autism spectrum engaged with the peer coach mothers in the process of co-construction of a portrait of "successful advocacy". During each interview, field notes of key ideas and non-verbal communication were taken to use during analysis; we used open-coding techniques (Glaser & Strauss, 1967; Tavory & Timmermans, 2009) and analytic memoing. Narratives for each mother were written based on their collective and object-interviews, open coding, analysis of memoing and journal writing.

**Results:** A common theme of the powerful roles that the maternal grandmothers played in providing emotional support and advocacy modeling was salient. These mothers never felt alone because they had both their families and key community partners (e.g., doctors, interventionist, teachers), who served as cultural brokers and built the trust to help when they needed it most. The preliminary analysis has implications on approaches that schools can use to create culturally sensitive interactions with Black families of children with ASD.

**Conclusions:** This work attempts to expand the knowledge of ASD families with intersectional identities (race, gender) by focusing on their assets, rather than deficits, creating a portrait of advocacy and resilience for us to learn from.

**422.060 (Poster)** The Experiences of Affiliate Stigma, Social Support, and Stress Among Mothers of Children on the Autism Spectrum

*L. Lipovenko<sup>1</sup>, J. Brier<sup>2</sup>, R. L. Fischbach<sup>3</sup>, B. C. Lyman<sup>4</sup> and S. L. Armstrong<sup>5</sup>, (1)Ezra Medical Center, Brooklyn, NY, (2)Queens College, Queens, NY, (3)Columbia University, Manhattan, NY, (4)Autism Spectrum Diagnostics and Consulting, Doylestown, PA, (5)La Salle University, Philadelphia, PA*

---

**Background:**

Autism Spectrum Disorder (ASD) is a pervasive neurodevelopmental disorder, characterized by deficits in social interactions, communication, and restricted and repetitive behaviors (APA, 2013). Parents of children with ASD often experience affiliate stigma as a result of the parent and the child being the target of negative judgments and comments from, friends, family, and the general public. Sleep duration and relationship status of the parents have been shown to lead to increased stress and internalization of affiliate stigma (Lovell & Wetherell, 2018). Parent-directed stigma, child-directed stigma and related stress are associated with adverse outcomes in the parents of children with ASD, such as increased negative interactions with family members, depressive symptoms, decreased psychological wellbeing, feelings of isolation, and decreased employment (Mak & Kwok 2010; Mickelson, 2001, Kinnear et al, 2016).

**Objectives:**

Our study investigated whether

- an increase in both mother-directed and child-directed affiliate stigma would result in an increase in maternal stress.
- a mother's level of social support would be negatively related to feelings of maternal stress.
- social support would mediate the relationship between both child-directed stigma and mother-directed stigma and maternal stress.

Methods:

#### Participants

62 mothers of a child/adolescent (ages 4-20) with a diagnosis of: ASD, PDD-NOS, or Asperger's syndrome.

93.5% were biological mothers

Average age: 44 years-old (SD: 7.1)

Race: 88.7% Caucasian

#### Measures

Demographics Questionnaire

Child's Autism related behaviors

The Child-Directed Stigma Scale

Perceived Stigma Scale

Multidimensional Scale of Perceived Social Support

Questionnaire on Resources and Stress

#### Procedure

Participants were recruited through clinics, schools, and social service agencies serving individuals with ASD. Participants completed measures online using Qualtrics. A hierarchical multiple regression analysis was performed to understand the unique contribution of all significant variables on maternal stress. To test for the role of social support as a mediator, we performed a simple mediation analysis with percentile bootstrap confidence intervals.

Results:

Results of a hierarchical multiple regression analysis revealed

- That social support has a strong negative relationship with maternal stress ( $\beta = -.457, p < .001$ )
- That even after controlling for child's autism-related behaviors, both mother-directed stigma and child-directed stigma are positively related to maternal stress ( $R^2 = .54$ ).
- Percentile bootstrap confidence intervals based on 5,000 samples separately assessed the indirect effects of stigma directed at mothers and on child on maternal stress through social support and did not contain zero (.0418 to .6613) and (.0060 to .5487) respectively.

Conclusions:

We found that mothers who perceived stigma directed at themselves or their child with ASD reported increased stress levels and that this relationship was significant even after accounting for other sources of maternal stress, such as, autism-related behavior and social support.

We also found a negative relationship between social support and maternal stress, even after controlling for autism-related behaviors and both types of stigma. Mothers who experienced lower levels of social support reported increased stress and this accounted for 20% of the variance in maternal stress. These findings highlight the importance of ensuring that mothers have adequate social support as well as helping them cope with the deleterious effects of stigma.

**422.061 (Poster)** The Factors Predicting Poor Mental and Physical Health in Parents of Children with Autism Spectrum Disorder (ASD): Data from 2016 -2018 National Survey of Children's Health (NSCH)

*J. Lee<sup>1</sup> and B. Barger<sup>2</sup>, (1)School of Nursing, Georgia State University, Atlanta, GA, (2)Georgia State University, Atlanta, GA*

---

**Background:** Growing evidence suggests that parents of children with autism spectrum disorder (ASD) are at risk for poor mental and physical health. While child behavior problems and parenting stress have been identified as significant factors associated with poor mental health in parents of children with ASD, the relative contributions of other child and parent characteristics remain unclear. In addition, the majority of published studies exclude fathers, use small clinical samples, and focus solely on mental health.

**Objectives:** The purpose of this study was to determine the factors predicting poor mental and physical health in parents of children with ASD using a nationally representative large sample.

**Methods:** Using population-based cross-sectional survey data from the 2016 - 2018 National Survey of Children's Health (NSCH), this secondary data analysis examined selected child (sleep problems [ $\leq 8$  hours], behavior problems, and autism severity) and parental (caregiving stress, coping, emotional support, amount of time providing care, amount of time coordinating care, and out of pocket cost for healthcare) characteristics as predictors of mental and physical health in 2,270 parents (mothers = 1,594, fathers =676) of children (4 to 17 years) with ASD. Multivariate logistic regression was used to determine predictors of poor mental and physical health in mothers and fathers of children with ASD while controlling for sociodemographic covariates.

**Results:** The mean age of mothers, fathers, and children with ASD were 42.43 7.94 years, 46.15 8.29 years, and 11.25 years respectively. For *mothers* of children with ASD, reporting moderate to severe child behavior problems (OR = 4.60, 95% CI [1.36-15.53]) and spending 1-4 hours per week coordinating care had significantly poorer mental health compared to those mothers spending no time coordinating care (OR = 4.90, 95% CI [1.11-21.58]). For mothers physical health, those reporting moderate to severe child behavior problems (OR = 4.94, 95% CI [1.26-19.40]) and spending 1-4 hours per week coordinating care had significantly poorer physical health compared to those reporting no time spent coordinating care (OR = 3.99, 95% CI [1.07-14.91]). For *fathers* of children with ASD, greater perceived caregiving stress (OR = 3.00, 95% CI [1.37-6.58]) and spending 5+ hours per week providing care compared to no time spent providing care (OR = 12.68, 95% CI [1.42->100.0]) were significantly associated with poorer mental health; only greater perceived caregiving stress (OR = 2.96, 95% CI [1.48-5.92]) was associated with fathers' poorer physical health.

**Conclusions:** For parents of children with ASD, child behavior problems were significant predictors of poor mental and physical health for mothers while perceived caregiving stress was associated with of father's poor mental and physical health. To address both parent's needs, targeted interventions focused on addressing child behavior problems and reducing caregiving stress may result in improved mental and physical health of both parents of children with ASD.

**422.062 (Poster)** The Impact of Uncertainty on the Everyday Lives of Autistic Children and Their Families

*J. Goodwin<sup>1</sup>, P. Rob<sup>1</sup>, M. Freeston<sup>2</sup>, D. Garland<sup>3</sup>, V. Grahame<sup>3</sup>, A. Kernohan<sup>1</sup>, M. Labus<sup>1</sup>, M. R. Osborne<sup>5</sup>, J. R. ---

**Background:**

Anxiety is common in autistic children and approximately 50% of autistic children experience high anxiety. One key mechanism underlying anxiety is intolerance of uncertainty, which is a tendency to react negatively on an emotional, cognitive, and behavioural level to uncertain situations. Understanding the types of uncertain situations that cause difficulties for autistic children, their responses to those situations, and how intolerance of uncertainty impacts on family life is critical to the development of appropriate anxiety interventions.

## Objectives:

The study aimed to provide a descriptive, thematic analysis of the impact of uncertainty on the daily lives of autistic children and their families.

## Methods:

Fifty families were recruited to the study through clinical services in the North East of England. The children were aged 6 – 16 years, had a diagnosis of autism, and were experiencing anxiety related to uncertainty. Data were collected as part of a randomised pilot trial of a parent group-based intervention aimed at increasing tolerance to uncertainty in autistic young people: Coping with Uncertainty in Everyday Situation (CUES©). Parents completed a semi-structured interview during which they a) identified two everyday uncertain situations that were challenging for their autistic child, b) described their child's reactions to these situations, and c) described the impact on the child and the wider family. The data from the semi-structured interviews were then analysed thematically.

## Results:

Across the 100 uncertain situations from 50 parents, the most commonly identified were school-related situations: uncertainties included changes in routine, different teachers, getting answers wrong, getting in trouble, what to do at break time, and tests. Thematic analysis revealed five main themes that described how anxiety related to uncertainty increased restricted and repetitive behaviours such as physical mannerisms, inflexibility, and repetitive questions. Parents also reported that children often missed out on opportunities for enjoyment, friendship, education and had low self-image and low mood. Difficulties with uncertainty affected family life, with parents accommodating their child's anxieties around uncertainty through reassurance, changes to routines and avoidance of specific people, places, or activities.

## Conclusions:

This is the first study that has explored the types of uncertain situations that cause difficulties for autistic children and how these difficulties impacted on the daily lives of them and their families. It provides insight into a wide range of everyday uncertain situations that can be challenging. These are situations that occur in typical daily life and cause increased distress, worry, frustration and anger, lowered mood and self-image. Uncertainty may lead to missed opportunities for learning and fun, whilst also impacting on parental energy and wellbeing. Interventions to increase autistic children's ability to cope with everyday uncertain situations could improve quality of life for autistic children and their families.

**422.063** (Poster) The Mental Health of Young People with ASD during the COVID-19 Pandemic: Data from the QUEST Cohort  
**S. Chandler<sup>1</sup>, I. Yorke<sup>1</sup>, V. Carter Leno<sup>1</sup>, M. Palmer<sup>1</sup>, T. Charman<sup>2</sup> and E. Simonoff<sup>1</sup>, (1)King's College London, Institute of Psychiatry, Psychology and Neuroscience, London, United Kingdom, (2)Department of Psychology, Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, United Kingdom**

---

Background: Understanding the impact of the COVID-19 pandemic on the mental health of children and young people has been identified as a key priority for mental health science (Holmes et al., 2020). Autistic young people (YP) present a particularly vulnerable group as we know they already have substantially increased rates of mental health disorders, compared to the general population (Simonoff, et al., 2008). Further, they may experience the effects of the pandemic differently to the general population; and some autistic young people may be more severely impacted than others. Understanding how the pandemic affects young people with autism will enable professionals to target limited community-based interventions to those most in need.

Objectives: Using a longitudinal sample with three previous timepoints, this study aims to identify which young people with autism and their families are most adversely affected by the pandemic, and in what ways.

Methods: Participants were part of the QUEST cohort, a community-based sample of young people diagnosed with autism in early childhood. At time 1 (age 4-9 years, n=277) data was collected on ASD severity, other emotional and behavioural problems, IQ, and psychiatric diagnoses. At time 2 (age 11-15 years, n=211) data was collected on adaptive functioning, mental health and behavioural problems, parenting style and family functioning. At time 3 (age 13-17 years, n=214) data was collected on psychiatric diagnoses, health economics and service use. During the COVID-19 pandemic (time 4, age 16-20 years), we administered a brief parent-report survey to explore changes in emotional and behavioural experiences during the pandemic. A parallel self-report version was also included for those YP judged by parents as being able to complete it. The parent-report survey is also being used with another ASD cohort (ASTAR), and with clinical populations in 8 countries, allowing for cross-study comparisons.

Results: Sample characteristics are provided in Table 1. At the time of writing, the COVID-19 survey was completed by 108 families (51% of eligible sample). Non-participating families did not differ from participating families in terms of the YP's ASD severity, IQ or ethnicity (all  $p > .2$ ). The majority of participating of families (73%) reported a change in their child's education arrangements since the start of the pandemic, with almost half (45%) currently only attending school/college remotely; despite government stipulation that face-to-face education should be made available to students with special educational needs. Figure 1 summarizes parents' reports of YP mental health during the pandemic. Responses were varied, but almost half (49%) reported that their YP was sad/depressed/unhappy; a similar proportion (50%) reported that their YP was moderately/very worried. Regression analyses will examine how this data relates to behavioural and mental health data collected at earlier timepoints; and whether any individual, family or wider background factors are associated with the level of impact experienced by families during the pandemic.

Conclusions: This study reports on the mental health of a well-characterised cohort of autistic YP during the COVID-19 pandemic. Understanding how earlier vulnerabilities relate to current mental health and other outcomes will have important implications for service planning.

**422.064 (Poster)** The Relation of ASD Symptom Severity to Parental Expressed Emotion, Affiliate Stigma, and Typically-Developing Sibling Internalizing Behavior

**A. H. Brinkman<sup>1</sup>, T. D. Barry<sup>2</sup> and R. A. Lindsey<sup>1</sup>,** (1)Washington State University, Pullman, WA, (2)Psychology, Washington State University, Pullman, WA

---

Background: Caregivers of children with ASD experience greater stress, psychopathology, and social isolation than caregivers of typically-developing (TD) children or those with other disorders. They also may be more likely to experience expressed emotion (EE), which is characterized by criticism/hostility and emotional overinvolvement toward their child, as well as affiliate stigma (e.g., marginalization, devaluation, discrimination), as a result of having a child with ASD (Romero-Gonzales et al., 2018). TD siblings of children with ASD often experience more negative functioning than siblings of individuals without a developmental disorder (Shivers et al., 2019).

Objectives: The current study examined the relation between ASD symptom severity, parental EE (criticism and emotional overinvolvement), parental affiliate stigma (affective, behavioral, and cognitive), and TD sibling internalizing behaviors using correlational and hierarchical regression analyses. It was hypothesized that ASD symptom severity in the child with ASD would be significantly related to all parental and TD sibling variables; that affiliate stigma would be significantly related to EE and TD sibling internalizing behaviors; and that EE would be significantly related to TD internalizing behaviors.

Methods: Data from a larger completed study was used that included 120 caregivers of a child with ASD, with 55 of the caregivers also having at least one TD child. Caregivers completed a demographic questionnaire and measures assessing their own affiliate stigma and EE as well as ASD symptom severity of their child with ASD and behavior of their TD child. Demographic variables were correlated with criterion variables to determine covariates. Caregiver sex was included as a covariate in subsequent analyses examining emotional overinvolvement and TD sibling internalizing behaviors. Hierarchical regressions were also used to understand the unique contribution of affiliate stigma in predicting parent and sibling criterion variables.

Results: Table 1 shows intercorrelations (zero-order or partial, if accounting for caregiver sex) among all variables of interest. ASD symptom severity was significantly positively correlated with all components of parental affiliate stigma, parental criticism, emotional overinvolvement, and TD sibling internalizing behaviors (Table 1). All components of parental affiliate stigma were significantly positively correlated with criticism, emotional overinvolvement, and TD sibling internalizing behaviors. Hierarchical regressions indicated affiliate stigma predicted criticism and emotional overinvolvement above and beyond ASD symptom severity and caregiver sex (Table 2). Criticism and emotional overinvolvement did not predict unique variance in TD sibling internalizing behavior beyond ASD symptom severity and caregiver sex ( $\Delta R^2 = .001, p = .79$ ).

Conclusions: Findings suggest that families with children with more severe symptoms of ASD may experience greater levels of affiliate stigma and EE and that these two constructs are predictors of different areas of family functioning. As such, these may be vital areas of intervention when working in a clinical setting. Limitations of the current study included self-report data, limited diversity in the sample, use of cross-sectional data, and reduced sample size for TD siblings, which may have reduced power to detect unique variance in predicting internalizing behaviors. Future research will help further understand how affiliate stigma and expressed emotion affect families of children with ASD.

**422.065 (Poster)** Trends in U.S. Autism Research Funding: Interagency Autism Coordinating Committee Autism Research Portfolio Analysis Report

S. Daniels<sup>1</sup>, O. Celestin<sup>2</sup>, J. Rava<sup>3</sup> and K. Ferrara<sup>4</sup>, (1)National Institute of Mental Health (NIMH), Rockville, MD, (2)OARC, NIH/NIMH, Bethesda, MD, (3)National Institute of Mental Health, Office of Autism Research Coordination (OARC), Rockville, MD, (4)National Institute of Mental Health (NIMH), ROCKVILLE, MD

---

**Background:** The Office of Autism Research Coordination (OARC) of the U.S. National Institutes of Health (NIH) will present findings from the upcoming *2017-2018 Interagency Autism Coordinating Committee (IACC) Autism Research Portfolio Analysis Report* that describes autism research investments made by both government and private funders.

OARC/NIH coordinates and manages the IACC, a federal advisory committee composed of federal officials and public stakeholders. The Committee was established by Congress to coordinate federal agency activities and to provide advice to the Secretary of Health and Human Services related to autism spectrum disorder (ASD). The IACC's *Strategic Plan* provides a framework to guide the efforts of U.S. federal agencies and partner organizations. OARC conducts an annual portfolio analysis of U.S. research projects to help guide the IACC's strategic planning efforts and inform the IACC of progress toward implementation of the *Strategic Plan*. The *Portfolio Analysis* is also used by agencies and organizations to better understand trends in ASD research funding.

**Objectives:** OARC will present findings from its *2017-2018 IACC ASD Research Portfolio Analysis Report*, which provides information on autism research investments made by U.S. federal and private funders of ASD research. This report will be the first to assess the composition of research projects that are investigating racial and ethnic disparities in ASD as well as a comprehensive analysis of the cross-cutting objective on the topic of ASD in females.

**Methods:** Data including project description, institution, and funding amount were collected from U.S. government and non-government funders of autism research. All projects included in the *Portfolio Analysis* were coded according to the seven research questions and 23 objectives outlined in the *2016-2017 IACC Strategic Plan*. Each of the questions in the *Strategic Plan* address general topic areas that are represented as community-focused questions (e.g., How can I recognize the signs of ASD, and why is early detection so important?). Each question includes three to four objectives; there is also one cross-cutting objective that focuses on ASD in females. The data were analyzed in several ways to provide information on the types of research being funded and the research topic areas supported by each funder.

**Results:** OARC collected U.S. ASD research project data for 2017 and 2018 and aligned research projects with the 23 objectives in the *Strategic Plan*. The analysis provides an overview of the distribution of research projects and funding across the seven *Strategic Plan* Question areas, analysis of projects across multiple scientific subcategories, a breakdown of federal and non-federal funders' contributions to ASD research investments, geographical distribution of research projects, and trends in research funding over time. The data provide information on the degree to which the objectives and budget recommendations described in the *IACC Strategic Plan* are being met. These data will be made available to the public through the Autism Research Database on the IACC website: <https://iacc.hhs.gov/funding/data/>.

**Conclusions:** These analyses of ASD research funding provide a broad overview of the autism research landscape in the U.S. and the roles of government and non-government funders in supporting ASD research.

**422.066 (Poster)** Understanding Existing Involvement with Community-Based ASD Care Systems for Children from Linguistically Diverse Families within a Family Navigation Model

A. Miceli<sup>1</sup>, A. Lavanderos<sup>1</sup>, N. Harris<sup>1</sup>, A. S. Weitlauf<sup>1</sup>, E. Davis<sup>1</sup>, M. West<sup>1</sup> and Z. Warren<sup>2</sup>, (1)Vanderbilt Kennedy Center, Vanderbilt University Medical Center, Nashville, TN, (2)Vanderbilt University Medical Center, Nashville, TN

---

**Background:** Children and families from diverse ethnic and linguistic backgrounds face numerous barriers to receiving assessment for autism spectrum disorder (ASD) and subsequent access to services. Our team is engaged in ongoing work to develop a statewide Family Navigation Network that partners with community providers to assess families' connections to community resources and build competence to access supports. As part of this ongoing work, we have focused on expanding diverse language resources and engaging in targeted community conversations to understand barriers to navigating care systems. To better understand the existing state of service connection and utilization amongst families referred for Family Navigation by providers, the present study examined baseline service utilization at time of Navigation referral across racial, ethnic, and linguistic groups.

**Objectives:** To identify existing disparities and improve care coordination, this study examined differences in baseline engagement with community systems of care across racial, ethnic, and linguistic groups for children under age five who come from medically underserved populations and who have or are at risk for ASD.

**Methods:** Families were referred for Navigation by a community primary care provider or early interventionist. For each family, the navigator asked about family knowledge of or engagement with 6 core service categories identified by the study team as best practice for young children at developmental risk (See Table 1). Navigators logged this information into a REDCap database to communicate back to the referring care team. Out of 626 participating families, 583 selected English as their primary language; 30 selected Spanish; 8 selected Arabic; and 5 selected Other.

**Results:** Services of interest were early intervention, speech therapy, and occupational therapy. Mean age at point of referral was 33.1 months for English-speaking (ES) children and 39.6 months for non-English speaking (NES) children. When looking at children  $\leq 35$  months and  $\geq 36$  months who were already involved in state Part C and school services respectively at first point of contact, 66.3% of ES children were enrolled in Part C services compared to 52.6% of NES children; 10% of ES children were receiving school system services versus 16.7% of NES children. Only 26.2% of ES families were not currently enrolled in services compared to 46.5% of NES families. When asked about speech therapy, 28.6% of ES families indicated current involvement compared to 18.6% of NES families. When asked about occupational therapy, 19.9% of ES families indicated current involvement compared to 9.3% of NES families.

**Conclusions:** Conversations with families revealed differences in utilization of services between ES and NES families. NES families were overall less likely to be involved with services than ES families, although they were slightly more likely to be involved in school services. This identifies a target for provider education and pre-referral navigation, since a formal psychological evaluation is often not necessary for children to receive Part C services. Future research will continue to expand family navigation services to further broaden equal access to and enrollment in services for children with or at risk for ASD.

**422.067 (Poster)** Use of Stakeholder Focus Groups to Develop Content and Structure of a New Measure of Social Communication for Young Children with Autism Spectrum Disorder

*K. M. Walton<sup>1</sup>, A. R. Borowy<sup>1</sup> and C. Taylor<sup>2</sup>, (1)Nisonger Center, The Ohio State University, Columbus, OH, (2)The Ohio State University, Columbus, OH*

---

**Background:** Children with autism spectrum disorder (ASD) show pervasive, often severe deficits in social communication that are a major target of early intervention programs. Sensitively and efficiently tracking both long- and short-term change in early social communication skills is essential in both research and community settings. However, current measures of social communication in ASD suffer from limited sensitivity to change, incomplete content coverage, and high burden of administration (Anagnostou et al., 2015).

**Objectives:** As part of a larger effort to develop a new parent- and teacher-report measure of social communication in young children with ASD, this study aimed to identify key social communication domains, skills, and behaviors considered most important to parents, teachers, and experts.

**Methods:** Twenty-one parents, nine teachers, and fourteen expert clinicians participated in a total of seven focus groups regarding their perceptions of social communication challenges and needs in young children (ages 2-6) with ASD. Thematic analysis was used to analyze focus group transcripts and extract themes and subthemes from the groups.

**Results:** Participants identified challenges with expressive language, receptive language, and social skills. In addition, they noted important differences in social behaviors across contexts and partners, and described ways in which communication challenges and emotion regulation problems compounded and interacted with one another. Respondents also identified strategies for supporting and building social communication skills. Sub-themes included content regarding differences in interactions with adults vs. peers, key deficits in use of expressive communication in flexible and functional ways, and difficulties with understanding and responding to others' emotions.

**Conclusions:** Parents, teachers, and experts identified a number of key concerns with social communication in young children with ASD. Some identified areas of concern (e.g., interaction between communication and emotion regulation deficits; differences in communication capacities and strategies across settings) are not well represented on existing measures of social communication intended for use in this population. As development and validation of this new measure of social communication continues, focus group content will be integrated during the item development process, including addition of items in areas tapping key areas of divergence between focus group themes and current measure content. This strategy is consistent with best practices in development of patient-reported outcome measures (Food and Drug Administration, 2009) and will likely result in a

measure with increased relevance and sensitivity to changes in key areas of social communication related concerns for parents and teachers.

**422.068 (Poster)** Use of Technology in Autistic Children and Adolescents during COVID-19 Lockdown

**J. Desrosiers<sup>1</sup>, K. Sotelo<sup>2</sup>, A. Ethier<sup>2</sup>, I. Soulières<sup>3</sup> and C. Jacques<sup>2</sup>,** (1)University of Montreal, Montreal, QC, Canada, (2)University of Quebec in Outaouais, Gatineau, QC, Canada, (3)Département de Psychologie, Université du Québec à Montréal, Montréal, QC, Canada

---

**Background:** Due to COVID-19, Quebec temporary closed school activities (March 16 to August 28) and social services (March 16 to May 6). Autistic children were left facing many challenges, such as coping on their own with pandemic-related stress. The literature suggests that autistic children and adolescents have a great interest in technological tools, such as televisions, computers, smartphones, electronic tablets, and video games (Morrison et al., 2018). That said, there is an interest in knowing whether this population uses technological tools as a coping method in the context of the COVID-19 lockdown.

**Objectives:** To explore the impact of technological tools use on families with autistic children or teenagers (hereinafter “children”) during the lockdown in Quebec due to COVID-19.

**Methods:** One hundred and nine parents of autistic children (2.5–18 years old) completed the French-language version of the *Questionnaire on the Needs of Children and Adolescents with Autism and their Families during the COVID-19 Pandemic*, an anonymous online survey. Fifty-six autistic children (5.75–18 years old) completed a sub-section of the survey, which was intended for them. The survey included multiple-choice and open-ended questions. For both sections (parents and children), descriptive analyses and independent *t*-tests were carried out using SPSS software, and thematic analyses were conducted for the open-ended questions.

**Results:** When autistic children were asked what contributed to their well-being during the lockdown period, the most common answer was electronic devices. Indeed, almost the entire sample (94.6%;  $n = 52$ ) reported that the use of electronics gave them a sense of well-being. Two thirds of the parents (67%;  $n = 73$ ) had implemented larger access to technologies to accommodate their children. Access to electronics was also the third item out of 15 identified by the parents as helping their children to cope. Along with *establishing a routine* (67%) and *reducing school responsibilities* (46.6%), 41.3% ( $n = 45$ ) of the parents indicated that *access to electronics* made their child's adjustment easier. There was a significant difference between older children's parents ( $M = 11.42$  years old,  $SD = 3.83$ ) and younger children's parents ( $M = 9.82$  years old,  $SD = 4.16$ ; *t*-test:  $t(107) = 2.00$ ,  $p = .049$ ) regarding free access to technologies. Parents of older children ( $M = 11.76$  years old,  $SD = 3.40$ ) were significantly more likely than parents of younger children ( $M = 10.28$  years old,  $SD = 4.28$ , *t*-test:  $t(107) = 2.00$ ,  $p = .048$ ) to consider that access to technology facilitated their child's adaptation.

**Conclusions:** This study shows that technological tools have played an important role for autistic children during the COVID-19 lockdown. For some of parents, technologies helped their child to cope with the lockdown. The positive integration of technologies in daily lives of autistic children should be better understood.

**422.069 (Poster)** Vaccine Hesitancy and Beliefs about Causes of Children's Developmental Disorders Among Parents of Children Awaiting Developmental/Behavioral Evaluation

**R. P. Goin-Kochel<sup>1,2</sup>, K. L. Ahmed<sup>1</sup>, J. H. Smith<sup>1,2</sup>, J. Cervantes<sup>1,2</sup>, D. Godwin<sup>1,2</sup>, L. N. Berry<sup>1,2</sup> and R. H. Fein<sup>1,2</sup>,** (1)Baylor College of Medicine, Houston, TX, (2)Texas Children's Hospital, Houston, TX

---

**Background:** Although recent data show that children with autism spectrum disorder (ASD) are well vaccinated for childhood vaccines recommended during the first two years of life, parents of children with ASD are among those most at risk for becoming vaccine hesitant (i.e., having concerns about vaccines that may lead to delay/refusal of one or more vaccines) compared to other parent groups, including parents of children with non-ASD developmental delays. However, little is known about the onset/timing of their vaccine concerns and the potential influence of the ASD diagnosis, itself.

**Objectives:** To characterize vaccine hesitancy, parents' beliefs about causes of children's developmental disorders, and factors associated with vaccine hesitancy among parents of children currently on a clinic waitlist for developmental/behavioral evaluation.

**Methods:** Data were collected from 138 caregivers (91.4% female) whose children were awaiting behavioral/developmental evaluation. Participants completed a questionnaire about information/services families seek while they await diagnostic evaluation, the *Parent Attitudes About Childhood Vaccines* questionnaire (PACV; measure of vaccine hesitancy), the *Revised*

*Illness Perception Questionnaire* (IPQ-R; measure of attributions about children's diagnoses and etiological beliefs), and provided demographic information.

**Results:** Overall, 48/118 parents (40.7%) were vaccine hesitant (PACV score  $\geq 50$ ) and 17/83 (20.5%) agreed with vaccines as a cause for their child's developmental difficulties; 66/136 (48.5%) children had received a prior ASD diagnosis and 59/136 (43.4%) had not. Vaccine hesitancy did not differ between parents of children +/- a prior ASD diagnosis. However, those reporting a prior ASD diagnosis were significantly more likely to be seeking information about ASD compared to those without a prior ASD diagnosis ( $p < .01$ ); a similar trend was observed for vaccine-hesitant parents (VHPs) compared to non-hesitant parents ( $p < .06$ ). Proportions of parents endorsing various causes did not differ between those with children +/- a prior ASD diagnosis. Yet, VHPs were significantly less likely to endorse genetics as a cause ( $p < .02$ ) and more likely to endorse diet/eating habits ( $p < .001$ ), environmental pollution ( $p < .04$ ), and vaccines ( $p < .02$ ) as causes. Characterizing participants by both *hesitancy status* and *beliefs about vaccines as a cause for developmental difficulties*, 35/83 (42.2%) were not hesitant and disagreed with vaccines as a cause, 15/83 (18.1%) were not hesitant but agreed with/were unsure about vaccines as a cause, 21/83 (25.3%) were hesitant and agreed with/were unsure about vaccines as a cause, and 12/83 (14.5%) were vaccine hesitant but disagreed with vaccines as a cause.

**Conclusions:** The prevalence of vaccine hesitancy in this sample was high, suggesting that concerns about vaccines may develop prior to a formal diagnosis. That the prevalence of vaccine hesitancy and proportions of parents endorsing various causes did not differ between groups +/- a prior ASD diagnosis could indicate that the question of autism is not resolved for the former. This may explain their continued pursuit of diagnostic services and suggest that information seeking largely follows receipt/acceptance of a diagnosis, which may subsequently influence beliefs about causes of ASD/developmental delays. This information could inform the design and timing of preemptive, tailored educational strategies around both vaccines and causes of children's developmental disabilities.

**422.070 (Poster) Websites: Supports for Autistics and Their Families during the COVID-19 Pandemic**

**W. Mitchell<sup>1</sup>, R. Zulla<sup>2</sup>, D. B. Nicholas<sup>3</sup>, E. Onofrychuk<sup>3</sup> and S. Samborn<sup>1</sup>,** (1)University of Calgary, Calgary, AB, Canada, (2)School of Public Health, University of Alberta, Edmonton, AB, Canada, (3)University of Calgary, Edmonton, AB, Canada

Background:

The COVID-19 pandemic has had a worldwide impact. In Canada, findings from a recent Canadian Mental Health Association survey demonstrate increased mental health concerns, such as feeling anxious and worried, having trouble coping and having suicidal thoughts, since the start of the outbreak. These struggles are likely amplified for vulnerable groups like persons with autism given the disruption to routines, elimination or reduction in services, and uncertainty regarding future supports and services. In this public-health crisis, web-based support offering information and resources specific to autism during the pandemic may help families manage the various strains associated with the pandemic by offering ways to navigate and cope.

Objectives:

- To determine what information/resources were accessed by autistics and their families during the first 6 months of the pandemic and the perceived impact of that information/resources on autistics and their families.
- To conduct an environmental scan and review that identifies what organizations have developed information/ resource websites addressing the needs of autistics during COVID-19.

Methods:

For the first objective 19 parents and/self-advocates engaged in focus groups. The evaluation was based on interpretive description to understand what was needed and deemed important in terms of support/resources for autistics and their families during the pandemic. For the second objective a scoping review was conducted using Google Advanced Search. Thirty websites met inclusion criteria and were evaluated according to content, topics, features, searchability and general impressions.

Results:

Learnings from focus groups indicated that parents have sought information on how to 'educate' their children when schools and community venues are closed, how to manage stress – their child's and their own, and how to access funds to support their child during the pandemic. Website features that were notably important included the availability of government funding and information related to current needs like how to encourage your child to wear a mask in public. Website searchability and accessibility features were of importance to self-advocates and parents. A review of websites focused on COVID-19 and autism

revealed that sites included a combination of unique content and links (ranging from 1 – 200) to other websites. Websites tended to address multiple topics (health and well-being, government programs/supports, education, mental health), and a number of the websites included social media links to help people connect with one another. Gaps noted: (i) websites were focused primarily on children and adults, but not adolescent/young adults, (ii) websites predominantly offered information in a textual format and did not include accessibility features, (iii) websites searchability functions were often limited, and (vi) the majority of websites failed to include dates, making it challenging for users to determine the currency, relevance and accuracy of information.

#### Conclusions:

Findings invite considerations for how websites can provide information and resources to families; namely, whether information offered can be comprehensive and inclusive to all autistics and their families. Findings will inform the breadth of information needs and effective methods for sharing information.

#### **422.071 (Poster) What Happens after the Coach Leaves? Examining the Changes in Parenting Stress in Caregivers of Toddlers with ASD before and after the Withdrawal of Clinical Support**

**L. M. Chiang<sup>1</sup>, W. I. Shih<sup>2</sup>, A. Gulsrud<sup>1</sup> and C. Kasari<sup>2</sup>, (1)UCLA Semel Institute for Neuroscience & Human Behavior, Los Angeles, CA, (2)University of California, Los Angeles, Los Angeles, CA**

---

#### Background:

Parenting stress negatively impacts both parental and child outcomes (Neece et al., 2010) and potentially counteracts the effectiveness of early interventions (Osborne et al., 2008). It is imperative to employ interventions that target both child and parent outcomes to yield holistic and sustainable treatment effects for children with ASD and their families. As raising children with ASD comes with unique challenges, parenting stress needs to be teased out into subdomains of sources of stress and further examined at the subdomain level since there are stressors from all aspects of the caregivers' environment that could contribute to the overall experienced stress.

#### Objectives:

To extend previous work by Kasari et al. (2015) and to investigate how different aspects of parent-related stress changed over the active treatment course and after the clinical support had been withdrawn, between the two treatment groups that received either a short-term, caregiver-mediated intervention (i.e., JASPER; Kasari et al., 2015) or a parent education intervention (PEI; Brereton & Tonge, 2005).

#### Methods:

This study includes 86 toddlers with ASD and their primary caregivers ( $M_{age} = 31.5$  months), randomized to receive either one of two types of intervention as part of an RCT trial (Kasari et al., 2015). The Parenting Stress Index (PSI; Loyd & Abidin, 1985) was administered at entry, exit, 3-month and 6-month follow-ups. Linear mixed-effect models were utilized to examine which of the seven parent-related subdomains changed over time by treatment group, specifically before and after the clinical support was withdrawn. Chronological age, Mullen Scale of Early Learning (MSEL; Mullen, 1995) score, and Autism Diagnostic Observation Schedule (ADOS; Lord et al., 1999) score were accounted for in the statistical models.

#### Results:

Significant time effect was found on the Competence score for both treatment groups [ $F(1,73)=9.75, p=.003$ ] from entry to exit, indicating improvement, though no significant difference in treatment effect was found between the groups over time [ $F(1,73)=1.74, p=.19$ ]. Four subdomains reflected significantly worsened stress, from exit to 3-month and 6-month follow-ups: Isolation [ $F(2,137)=2.77, p=.03$ ]; Role Restriction [ $F(2,136)=5.41, p=.006$ ]; Depression [ $F(2, 134)= 2.35, p=.02$ ]; Spouse Relationship [ $F(2,137)=4.24, p=.02$ ]. Overall, no significant group-by-time interactions were observed— both groups experienced similar levels of deteriorated psychological well-being after the clinical attention was withdrawn.

#### Conclusions:

Though no overall reduction of stress in the parent domain over time was found in the original study (Kasari et al., 2015), our analysis indicates changes do manifest at the level of subdomains, under the parent domain of PSI, especially after the clinical support ended. Both treatment formats afforded the participants an increased sense of competence at exit, but both groups

reported continually worsening stress related to isolation, depression, role restriction, and spousal relationship, through six months after the clinical attention had ceased. Providing booster sessions as follow-ups after parents exit the study may aid such transitional period, and delivering the sessions in telehealth format could conserve clinical resources (Shire et al., 2015). Lastly, one should look beyond the immediate post-treatment effect to evaluate whether an intervention yields sustainable benefits for both parents and their children with ASD.

**422.072 (Poster) When Should You Tell Your Child They Are Autistic? Insights from a Participatory Study with Autistic University Students**

*B. Kofner<sup>1</sup>, T. Oredipe<sup>2</sup>, A. Riccio<sup>3</sup>, E. Cage<sup>4</sup>, S. K. Kapp<sup>5</sup>, P. Dwyer<sup>6</sup>, J. Vincent<sup>7</sup>, J. Delos Santos<sup>8</sup> and K. ---

**Background:** Prior literature has explored parental experiences with their child's autism diagnosis (Crane et al., 2019). However, very little is known about how the process of learning one is autistic impacts development. Learning about one's autism through open dialogue with parents may have positive impacts on self-perception and autism understanding (Riccio et al., 2020). Previous research has identified benefits of early disclosure for other conditions (Goodwin et al., 2015) and anecdotal evidence suggests similar benefits for autistic people (Jones, 2001), but no prior studies have evaluated if earlier discovery that one is autistic is associated with better adult outcomes.

**Objectives:**

To examine how the timing of learning one is autistic influences adult well-being, Quality of Life (QoL), and perceptions of autism.

**Hypothesis a:** Autistic adults who learned about their autism earlier in life will have higher well-being and QoL than those who learned later.

**Hypothesis b:** Learning one is autistic earlier will be associated with more positive perspectives on autism.

**Methods:** Autistic university students ( $N=84$ ,  $M(\text{age})=23.93$ , 50.0% male, 63.3% White, 78.3% undergraduates) participated in an online survey developed by a team of autistic and non-autistic scholars. They answered questions like: "How old were you when you first learned you were autistic?", "How did you feel when you learned you were autistic?", "How do you feel about autism now?" Responses were coded to establish reliability and summarize patterns.

**Results:**

Separate regressions predicting QoL and well-being from the age of participants' discovery of their autism diagnosis, gender, current age, academic level, and self-reported autistic traits revealed that learning one is autistic earlier in life ( $p < .001$ ), lower traits ( $p < .001$ ), being older ( $p = .02$ ) and being a graduate student ( $p = .04$ ) were associated with heightened QoL. Learning one is autistic earlier in life, being older, and lower traits were also associated with heightened well-being ( $ps \leq .001$ ).

Participants learned they were autistic in varied ways: 46.8% from clinicians, 38.3% from parents, and 18.1% found out on their own. Learning from clinicians was associated with heightened camouflaging in adulthood.

Most participants described experiencing positive feelings when they first learned they were autistic (Table 1) and about their autism now. Contrary to hypotheses, people who learned they were autistic *later* in life described *more* positive emotions, such as relief, than those who learned earlier ( $p < .001$ ). Although numerically more participants described autism positively concurrently (63.5%) than when they learned they were autistic (54.1%), this was not significant ( $p = .32$ ). Positive current feelings about autism were associated with less camouflaging and more connection to an autism community ( $ps < .003$ ).

**Conclusions:** These findings suggest that learning about one's autism diagnosis early in development lays a foundation for thriving in adulthood. However, learning one is autistic later in development was associated with more positive viewpoints about autism itself. These findings echo participants' recommendations highlighting the importance of considering not only age but

also developmental factors when deciding when to tell someone about their autism diagnosis.

**422.073 (Poster)** Who Knows You Best: Adult Self-Report Vs. Sibling Report Vs. Parent Report

**O. Ward, S. R. Dufresne and E. T. Crehan, Eliot-Pearson Department of Child Study & Human Development, Tufts University, Medford, MA**

---

**Background:** The practice of relying solely on parent report in Autism Spectrum Disorder (ASD) is being re-examined (Bishop & Seltzer, 2012; Mazefsky et al., 2011; Ozsivadjian et al., 2014). Though parents are able to provide insight into the lives of their child, parent report has limitations. Autistic self-report and sibling report provide alternatives to parent report. Through exploring self-report and sibling report, researchers would help amplify autistic voices and provide alternatives when parent report is inaccessible. In this pilot study, we explore how different perspectives impact reporting on special domains in ASD.

**Objectives:** Illustrate how adult self-report and sibling report compare to parent-report measures for autism specific domains.

**Methods:** Nine family triads consisting of an autistic adult, a sibling, and a parent participated. Participants completed questionnaires relating to special domains of ASD. Internalizing symptoms domain included Beck's Anxiety Inventory (BAI; Beck & Steer, 1993) and Beck's Depression Inventory (BDI; Beck, Steer, & Brown, 1996). Restricted and repetitive behaviors (RRBs) domain contained Social Responsiveness Scale (SRS-2-SR; Constantino, 2012) subdomain SRS-RRB and Family Accommodation Scale for Restricted and Repetitive Behaviors (FAS-RRB; Feldman et al., 2019). Social skills domain contained SRS-2-SR subdomains communication, awareness, and motivation as well as Theory of Mind Inventory (ToMI; Hutchins, Prelock, & Bonazinga, 2012). Adaptive functioning domain included SRS-Cognition (SRS-2-SR, Constantino, 2012). Pearson correlational coefficients were conducted between family member dyads.

**Results:** For internalizing symptoms, the BDI self-report was significantly correlated with sibling report  $r(9)=-.79, p<.05$ . For RRBs, SRS-RRB sibling report was significantly correlated with parent report  $r(9)=.94, p<.01$ . Within the social skills domain, SRS-Communication  $r(9)=1.00, p<.01$  and SRS-Motivation  $r(9)=.90, p<.01$  parent report was significantly correlated with sibling report. SRS-Awareness  $r(9)=-.86, p<.01$  self-report was significantly negatively correlated with sibling report. Across early  $r(9)=.67, p<.05$ , basic  $r(9)=.70, p<.05$ , and advanced  $r(9)=.70, p<.05$  TOMI self-report was significantly correlated with parent report. Basic  $r(9)=.73, p<.05$  and advanced  $r(9)=.75, p<.05$  TOMI self-report was significantly correlated with sibling report, while the advanced  $r(9)=.67, p<.05$  TOMI sibling report was only significantly correlated with parent report. For adaptive functioning, SRS-Cognition  $r(9)=.90, p<.01$  parent report was significantly correlated with sibling report.

**Conclusions:** There is much to be learned from examining a variety of perspectives in reporting measures for ASD. Exploring self-report measures allows researchers and clinicians to focus on the needs and desires of autistic adults. Sibling reports provide valuable, varied insight into the autistic adult while growing our understanding and utilization of sibling's perspectives for when parent report is not available. Based on this pilot study, sibling report of internalizing symptoms appears more consistent with self-report compared to parents. However, for RRBs, parent report correlated with self-report more often, indicating that parents may be more consistent reporters. Future exploration into online socialization of autistic adults is imperative to help researchers understand why parents and siblings were not correlated with self-report in social domains. The goal of this study was not to establish who is "most accurate," but to explore ways for researchers and clinicians to make mindful decisions about where and how information is collected.

**422.074 (Poster)** Young Adult and Caregiver Perspectives on Emerging Adulthood in Autism Spectrum Disorder

**E. B. Clarke, R. Elias and C. Lord, University of California, Los Angeles, Los Angeles, CA**

---

**Background:** As increasing numbers of individuals with ASD enter adulthood or receive diagnoses in adulthood, it has become increasingly important for autism researchers to seek direct input from individuals on the spectrum and their families. Arnett (2000) outlined a theoretical framework for emerging adulthood that could have important implications for understanding adult outcomes in autism spectrum disorder (ASD). Some individuals with autism will experience the fluidity in identity and autonomy described by the Arnett's framework, but may be less likely to experience normative adult outcomes such as marriage, steady employment, and parenthood than their typical peers. In contrast, many individuals with ASD will need extensive support throughout their lives, but the societal expectations associated with emerging adulthood still influence the experiences of high-need adults with ASD and their families. An in-depth investigation of the ways in which the experiences of young adults with ASD are different from and similar to Arnett's descriptions of emerging adulthood could be significant to both our understanding of adulthood in ASD and of emerging adulthood as a unique developmental stage.

**Objectives:** To understand how individuals with ASD and their caregivers conceptualize the developmental transition to emerging adulthood, and to identify ways in which this mirrors and contrasts with the transition to emerging adulthood in typical development.

**Methods:** Fifteen semi-structured interviews were completed with participants from a well-characterized longitudinal study of autism. Five interviews were conducted with adults with ASD, five interviews with parents of adults with ASD without intellectual disability, and five interviews with parents of adults with ASD with intellectual disability. In addition to the qualitative data collected for this study, data on participants' IQ, autism severity, and adaptive behavior in adulthood have also been collected (Table 1). Trained coders analyzed interviews using the constant comparative method to examine commonalities and discrepancies between interviews and inductively identify themes.

**Results:** Initial coding identified several emergent themes that parallel normative emerging adulthood, including the desire for meaningful daily activities and social and romantic relationships. However, the majority of the identified themes appear to diverge from normative emerging adulthood. Many of the participants with autism noted that the transition to adulthood forced them to reexamine the personal significance of their autistic identities. Both adults and parents identified access to services such as Social Security and vocational rehabilitation as a significant concern in emerging adulthood. Additionally, parents noted that emerging adulthood was accompanied by a new caregiving challenge of continuing to provide support for their child with ASD whilst simultaneously finding ways to foster increased independence. Additional coding will continue to identify similarities and contrasts between Arnett's theory of emerging adulthood and participants' interview responses.

**Conclusions:** Emerging adulthood is a key period that has been well-characterized in typical development. By qualitatively examining the experiences of adults with ASD and their families during this developmental period, this study enriches our understanding of 1) how Arnett's theory of emerging adulthood relates to nonnormative development and 2) the significance of the transition to adulthood for individuals on the spectrum.

**422.075 (Poster)** "Increasing Awareness of Regional Center Services for Autism Spectrum Disorders in the African American Community: A Faith-Based, Community-Partnered Participatory Research (CPPR) Approach"

*F. Jones<sup>1</sup>, A. Lucas-Wright<sup>2</sup>, G. A. Green<sup>3</sup>, H. Owens<sup>4</sup>, A. Jones<sup>5</sup>, Z. Masongsong<sup>6</sup> and O. Solomon<sup>7</sup>, (1)Healthy African American Families, Los Angeles, CA, (2)Charles R. Drew University of Medicine and Science, Los Angeles, CA, (3)UCLA Department of AA Studies, EASE Project team/ARCS Project/ UCEDD Children's Hospital LA, LOS ANGELES, CA, (4)CHILDREN'S HOSPITAL LOS ANGELES, LOS ANGELES, CA, (5)Suite 105 4305 Degnan Blvd, HEALTHY AFRICAN AMERICAN FAMILIES, Los Angeles, CA, (6)Healthy African American Families, II, LOS ANGELES, CA, (7)University of Southern California, Los Angeles, CA*

**Background:** California Department of Developmental Services (DDS) administers the Lanterman Services Act and the Early Intervention Services Act for individuals with developmental disabilities, independent of socio-economic status or other characteristics. Significant racial and ethnic disparities, however, exist in expenditures for services across most Regional Centers (RC). African American/Black (AA/B) individuals comprise 8.9% (28,371) of the DDS-served population. South Central Los Angeles Regional Center (SCLARC) serves the largest percentage of AA/Bs with developmental disabilities among all RCs. For 2018/19, SCLARC reported per-capita Purchase of Services (PoS) expenditures were \$27,997 for AA/Bs and \$60,487 for Whites. Within the AA/B community, faith centers have provided education and promoted influential health initiatives, including for Autism Spectrum Disorder (ASD), independent of individuals' religious beliefs.

**Objectives:** Decrease PoS disparities in the AA/B community by raising awareness of ASD and underutilization of services. Engage faith centers to support AA/B families in accessing information about RC services and developing skills for self-advocacy.

**Methods:** The Community-Partnered Participatory Research (CPPR) model guided the partnership among Healthy African American Families II (HAAF), the University Center for Excellence in Developmental Disabilities (UCEDD) and three African American faith centers. Four Community Health Advisors (CHA) received four 3-hour trainings on ASD and RC services. Forty-nine AA/B parents/caregivers with a family member with ASD receiving RC services participated in twelve focus group/instructional sessions to determine perceived barriers to services. Participants received information about RC services and their rights to appeal, and set goals for services to acquire from the RC. CHAs followed up monthly with participants by phone for three months to help families achieve their goals. Focus group transcripts were thematically analyzed using NVivo software. Pre- and post-surveys with CHAs and participants were also analyzed.

**Results:** Pre-focus group, 44.8% of the participants indicated level 5 or less awareness of RC services (1=unaware, 10=perfectly aware). Post-focus group, 87.8% of participants indicated level 6 or greater. On a similar scale of self-efficacy, pre-focus group,

50% indicated a confidence level of 5 or less. Post-focus group, 71% indicated level 6 or greater. Upon study completion, 80% of participants met their goals for RC services. Both the CHAs and the parents/caregivers reported high levels of satisfaction with the program. Based on the thematic analysis of focus group transcripts, the main barriers to equitable access to RC services are: (1) inequity in access to information about services, and (2) parents' perceptions of RC personnel as disrespectful and judgmental, especially when there is disagreement. We developed a manual for training CHAs to use culturally and linguistically appropriate strategies to support AA/B families in advocating for RC services.

Conclusions: Partnering with faith centers is an effective approach to raising awareness about ASD, navigating and accessing RC services, advocacy strategies, and resources in the AA/B community. The CHAs provided a safe environment for families to share challenges, hear how others dealt with similar issues, and receive mutual support. Culturally tailored training for RC personnel is essential to close the disparity in PoS.

## Gastrointestinal (GI)

### POSTER SESSION — GASTROINTESTINAL (GI)

#### Poster 423 - Gastrointestinal (GI) Posters

**423.001** (Poster) Altered Gut Microbiota in Youth with Autism Spectrum Disorder Associated with the Severity of Social Deficits and Executive Dysfunctions.

*Y. C. Chen, Graduate Institute of Clinical Medicine, College of Medicine, National Taiwan University, Taipei, Taiwan*

**Background:** Autism spectrum disorder (ASD) is a common neurodevelopmental disorder in Taiwan and worldwide (prevalence rate, ASD, 1%), presenting clinically and genetically heterogeneous disorder with early onset at childhood lasting to adulthood without biological treatment. Moreover, the role of the microbiome in neuropsychiatric disorders has been highlighted to modulate the behavioral impairments.<sup>1-4</sup> However, the discrepancies between studies might bias via differences in sample number, methodology, and variability include differences in unknown environmental factors, such as diet. Though evidence suggested decreasing gut microbiota dysbiosis also decreased core symptoms. Their underlying pathogenesis remains unclear.<sup>5-8</sup>

**Objectives:** Hence, we aim to identify the direct associations between the gut microbiome and behavioral impairments are needed in ASD, discovering the underlying mechanism of how gut microbiota dysbiosis modulated the clinical symptoms.

**Methods:** The sample consisted of 114 youths from age 6 to 25 years old, including 82 males with a clinical diagnosis of ASD (age= 16.16 ) according to the DSM-5 criteria from National Taiwan University Hospital, Taiwan, and 31 typically developing control males (TDC) (age=13.19 5.29), without other neuropsychiatric disorders. The ASD diagnosis was confirmed by ADI-R and ADOS. All stool samples were analyzed by 16s metagenome sequencing. The clinical and executive functions were measured by the social responsiveness scale (SRS) and behavior rating inventory of executive function (BRIEF) simultaneously. In the statistical analysis via QIIME2 and R, the significance level is the FDR-corrected q value <0.05.

**Results:** There were no differences between alpha diversity of species richness estimates (Chao1 and ACE and diversity indices (Shannon and Simpson). The significant group differences in weighted- Unifrac beta diversity which ASD youth had higher variability of microbial communities than TDC. Three microbiotas, parabacteroides sp Marseille P3236, Campylobacter jejuni, and Streptococcus paprauberis, were significantly higher in TDC than ASD. The top 2 distinct microbial community components have explained the 67.4% social impairments and 52.3% executive dysfunctions.

#### **Conclusions:**

These findings support a connection between metabolism, social impairments and executive dysfunction and may advance the discovery and development of molecular biomarkers for ASD.

**423.003** (Poster) Comparative Analysis of Gut Microbiota between Children with Autism Spectrum Disorder and Typically Developing Children: A PCR and Metagenomic Approach

*S. Gulati<sup>1</sup>, S. V. Aparna<sup>2</sup>, H. M. Rashmi<sup>3</sup>, V. Sondhi<sup>4</sup> and S. Grover<sup>1</sup>, (1)Centre of Excellence and Advanced Research for Childhood Neurodevelopmental Disorders, Child Neurology Division, Department of Pediatrics, All India Institute of Medical Sciences, New Delhi, India, (2)College of Dairy Science and Technology Kerala Veterinary and Animal Science University,, Thrissur, Kerala, India, India, (3)Dairy Microbiology Division, ICAR- National Dairy Research Institute., Karnal, Haryana, India, India, (4)Child Neurology Division, Department of Pediatrics, All India Institute of Medical Sciences, New Delhi, New Delhi, India*

**Background:** Autism spectrum disorders (ASD) is an umbrella term that incorporates a set of neurodevelopmental disorders previously referred to as autistic disorder, Asperger's syndrome, pervasive developmental disorder not otherwise specified, and childhood disintegrative disorders. Several emerging studies have identified an imbalanced composition of the intestinal microbiota in ASD individuals, often reported under the controversial term "dysbiosis." However, the characterization of a distinctive ASD microbial pattern is still unclear.

**Objectives:** This study analyzed the comparative abundance of major gut microflora between children with ASD and typically developing (TD) children.

**Methods:** All children between 3 to 15 years with ASD presenting to a tertiary care center in India were eligible for the study. The control population included the TD siblings of ASD patients. Fecal specimens were collected in the homes of the participants by their parents. Fecal specimens were shipped to the laboratory on the same day, where each specimen was frozen at  $-80^{\circ}\text{C}$  until DNA extraction. Relative and Absolute qPCR, as well as 16S rRNA diversity using High throughput Sequencing (HTS) of metagenomic DNA analysis, was carried out for studying the comparative abundance of the targeted microbiota.

**Results:** Twenty-four children were enrolled in the study; six were excluded due to inadequacy of stool sample, and eighteen children (all boys, median age=7.5 years) were included for final analysis. These included 12 children with ASD and six TD siblings of ASD patients. The DNA concentration from fecal samples of TD children was in the range of 157.19 and 187.54ng/ $\mu\text{l}$ , and the corresponding figures in related ASD children were 226.49 and 205.54 ng/ $\mu\text{l}$ , respectively. From the Quantitative Insights Into Microbial Ecology analysis, out of 178154 and 195285 processed reads from TD siblings and related ASD children, 168851 and 186985 sequence reads were identified as 16S rRNA sequences in TD siblings and related ASD children, respectively. In the metagenomic analysis, comparative analyses of gut microbial composition at the phylum level revealed the predominance of Firmicutes (60.83 %), followed by Actinobacteria (18.39%), Proteobacteria (12.28%), and Bacteroidetes (8.47%) in ASD children. In contrast, the composition of Firmicutes, Actinobacteria, Proteobacteria, Bacteroidetes in TD siblings were 77.71%, 13.84%, 1.08%, and 7.05%, respectively.

**Conclusions:** There was decreased gut bacterial diversity in the gut microflora of children with ASD. The phylum *Firmicutes* was significantly less, and the phylum *Bacteroidetes* was significantly more in children with ASD as compared to TD siblings. Also, *Clostridium perfringens* was significantly higher in the gut microbiota of children with ASD. These results suggest that gut-microbiota-based disease analysis can predict the novel connection between gut microbes and ASD and may play a role in revealing the pathogenesis of ASD.

#### **423.004 (Poster) Genetic Liability to Autism and Inflammatory Bowel Disease: Is There Evidence for a Shared Genetic Aetiology?**

**A. Sadik<sup>1</sup>, C. Dardani<sup>2</sup>, P. Pagoni<sup>3</sup>, E. Stergiakouli<sup>3</sup>, R. Gardner<sup>4</sup>, G. Davey Smith<sup>5</sup>, S. Sullivan<sup>6</sup>, S. Zammit<sup>6</sup>, G. M. Khandaker<sup>7</sup>, H. J. Jones<sup>2</sup> and D. Rai<sup>2</sup>,** (1)Avon and Wiltshire Mental Health Partnership NHS Trust, Bath, United Kingdom, (2)Population Health Sciences, Bristol Medical School, Centre for Academic Mental Health, Bristol, United Kingdom, (3)MRC Integrative Epidemiology Unit, Bristol Medical School, University of Bristol, Bristol, United Kingdom, (4)Karolinska Institutet, Stockholm, Sweden, (5)Population Health Sciences, Bristol Medical School, MRC Integrative Epidemiology Unit, Bristol, United Kingdom, (6)Division of Psychological Medicine and Clinical Neurosciences, Cardiff University, Cardiff, United Kingdom, (7)University of Cambridge, Cambridge, United Kingdom

**Background:** Observational studies suggest that people with autism are at increased risk of gastrointestinal conditions, while a family history of gastrointestinal conditions seems to be associated with increased risk of autism in offspring. The reasons underlying these associations are currently unknown.

**Objectives:** We evaluated whether there is evidence for a shared genetic aetiology between autism and inflammatory bowel disease (IBD) or the major IBD subtypes: Crohn's disease and ulcerative colitis.

**Methods:** Publicly available summary statistics from the largest genome-wide association study (GWAS) were identified for autism (Grove et al., 2019, N=46,350), IBD (de Lange et al., 2017, N=59,957), Crohn's disease (de Lange et al., N=40,266) and ulcerative colitis (de Lange et al., N=45,975). Three different analyses were carried out. Firstly, linkage disequilibrium (LD)-score regression was used to estimate genetic correlations between autism and each gastrointestinal condition. Secondly, two-sample Mendelian randomisation (MR) was used to estimate causal effects of genetic liability to autism on risk of each gastrointestinal condition, and vice versa. Finally, in order to further interrogate findings, polygenic risk scores (PRSs) were generated using individual-level data from the Avon Longitudinal Study of Parents and Children (ALSPAC) cohort (available N=7,505). These were regressed on a composite measure of autistic traits in ALSPAC, an autism mean factor score previously described by Steer et al., 2010

**Results:** There was limited evidence to suggest a genetic correlation between autism and IBD ( $r_g = -0.07$ ; 95%CI: -0.15 to 0.02,  $p = 0.158$ ), as well as limited evidence for an effect of genetic liability to ASD on risk of IBD (ORMR= 0.91; 95%CI: 0.76 to 1.1,  $p = 0.323$ ). However, there was evidence indicating that genetic liability to ulcerative colitis was causally linked to increased risk of autism (ORMR= 1.03; 95%CI: 1.01 to 1.06,  $p = 0.017$ ). PRS analyses in ALSPAC suggested that higher maternal polygenic risk for ulcerative colitis and Crohn's disease was associated with a higher autism factor mean score in the offspring (ulcerative colitis:  $\beta_{PRS} = 0.02$ ; 95%CI: 0.00 to 0.05,  $p = 0.025$ ; Crohn's disease:  $\beta_{PRS} = 0.03$ ; 95%CI: 0.01 to 0.05,  $p = 0.004$ ). In contrast, there was limited evidence to suggest an association between offspring polygenic risk for each gastrointestinal condition and autism factor mean score.

Conclusions: Our findings suggest that genetic liability to ulcerative colitis increases the risk of autism. In our ALSPAC analyses, maternal PRSs, but not offspring PRSs, for both Crohn's disease and ulcerative colitis were associated with autism traits in offspring. Our findings suggest a causal link and a polygenic association between genetic liability to IBD subtypes and risk of ASD. These may be of maternal origin. Further work is needed to investigate the potential mechanisms, such as intra-uterine effects and inflammatory pathways, that may underly the associations.

**423.005** (Poster) Haploinsufficiency of CHD8 Leads to Distinctive Gastrointestinal Deficits and Gut-Brain Axis Abnormalities  
*I. Chaterjee, D. Getselter and E. Elliott, Medicine, Bar Ilan University, Safed, Israel*

---

**Background:** Many individuals diagnosed with autism spectrum disorders report gastrointestinal abnormalities, that may range from constipation to gut reflux. Treatment of these abnormalities are proposed as an important step in improving quality of life. It is not clear what are the role of these gastrointestinal symptoms in the presentation of the core behavioral phenotypes of autism. Mutations in CHD8 is one of the leading genetic factors in the etiology of autism, and individuals with mutations in CHD8 report gastrointestinal difficulties. This suggests that the genetic etiology of autism may be directly related to gut function and the gut-brain axis.

**Objectives:** We aimed to characterize how CHD8 haploinsufficiency affects gut function, including gut permeability, proper gut development, and microbiome regulation. Further, we aim to understand if CHD8 abnormalities in the gut may play a role in the behavioral symptomology of autism.

**Methods:** First, we performed characterization of the gut epithelial function (gut permeability analysis), gut morphology, and gene expression (RNA-seq) in the CHD8 haploinsufficient mouse model. This was followed by whole-throughput analysis of the microbiome (16S sequencing). Furthermore, in a separate model, we induced haploinsufficiency of CHD8 specifically in gut epithelial cells (using villin-cre/floxed CHD8 system) and have characterized the behavioral phenotype in these mice.

**Results:** CHD8 haploinsufficient mice display an increase in gut permeability. In parallel, these mice display a decrease in mucus layer width and goblet cells (mucus producing cells) in the small intestine. Gene expression analysis revealed that 900 genes are differentially expressed specifically in gut epithelial cells of these mice (in comparison to only 10 that are differentially expressed in neurons). Downregulated genes are enriched for genes involved in tuft cell function (important for gut permeability) and upregulated genes are involved in inflammatory response and anti-microbial response. Microbiome analysis revealed an increase in overall microbiome load (increase in total amounts of bacteria), and an increase in alpha diversity of microbiome in CHD8 haploinsufficient mice. Knockout of CHD8 specifically in gut epithelial cells induced some behavioral changes that are similar to those seen in a full body CHD8 haploinsufficiency.

**Conclusions:** Our data suggests that autism-associated gene CHD8 has an important role in regulating gut function through several mechanisms, including proper development of gut cells and regulation of microbiome. Furthermore, the gut-specific CHD8 knockout model gives preliminary evidence that gut phenotypes play a direct role in behavioral changes seen in autism. These findings are a significant step forward in understanding the interplay between genetic etiology, autistic behavior, and the gut-brain axis.

**423.007** (Poster) Mapping the Mucosal Microbiome in Gastrointestinal Biopsy Specimens from Children with ASD: A Pilot Study  
*K. Reeves<sup>1</sup>, A. Krigsman<sup>2</sup> and S. J. Walker<sup>3</sup>, (1)Int Med-Molecular Medicine, Wake Forest University Health Sciences, Winston Salem, NC, (2)Pediatric Gastroenterology Resources of New York and Texas, Austin, TX, (3)Wake Forest Institute for Regenerative Medicine, Winston Salem, NC*

---

**Background:** Microbial dysbiosis is a common finding in children with autism spectrum disorder (ASD), particularly in children with chronic gastrointestinal (GI) symptoms. There is evidence to suggest that the fecal microbiome may not accurately reflect the mucosal microbiome and that these differences may have important consequences when trying to understand the impact of dysbiosis on the host's physiology. Moreover, it is known that the gut luminal microbiome composition varies with anatomic location, suggesting that dysbiosis may sometimes be localized to a specific region of the lower GI tract rather than being pan-colonic.

**Objectives:** The objective of this pilot study was to use unbiased methods to map the mucosal microbiome, in multiple sites within the lower GI tract, from children with ASD and chronic GI symptoms. To our knowledge, this is the first study in GI-symptomatic children with ASD to specifically evaluate the microbiome in multiple locations throughout the lower GI tract

**Methods:** The study samples were comprised of three individual mucosal biopsy specimens (from: (1) terminal ileum, (2) transverse colon, and (3) rectum) taken from five GI-symptomatic children (ages 6 years – 9 years) with ASD who were undergoing clinically-indicated ileocolonoscopy. Shotgun metagenomic sequencing was performed to identify and quantify microorganisms in each biopsy specimen, and results from the taxonomic profiling were subsequently merged to estimate similarities and differences among the samples.

**Results:** Microbial diversity differed between the three different regions of the lower GI tract of five children with ASD and chronic GI symptoms. **Figure 1** highlights the microbial diversity identified within the three different GI regions from the five individuals (top: bar graphs) and the variability of microbial composition between each sample (bottom: principal component analysis (PCA) plot). In comparison to the transverse colon and rectum, the microbial composition within the terminal ileum was less diverse and displayed a higher level of similarity across the five individuals.

**Conclusions:** Results from this pilot study demonstrate feasibility of our proposed approach - we acquired robust sequence data from biopsies that were previously collected and stored in RNAlater. In addition, even with this small sample size, we were able to identify species-specific differences within and across the samples collected from three different regions of the GI tract of five children with ASD and chronic GI symptoms.

**423.008 (Poster)** Molecular Co-Expression Analysis Identifies Dysregulated Ion Transport As a Potential Mechanism for Right-Sided Colonic Hypomotility in Children with Autism

R. Kumar<sup>1</sup>, A. Krigsman<sup>2</sup>, E. Koukos<sup>1</sup>, T. Simon<sup>1</sup> and S. J. Walker<sup>1</sup>, (1)Wake Forest Institute for Regenerative Medicine, Winston Salem, NC, (2)Pediatric Gastroenterology Resources of New York and Texas, Austin, TX

---

**Background:** Gastrointestinal (GI) symptoms are more common in children with autism spectrum disorder (ASD) compared to typically developing (TD) children. Of the GI symptoms most commonly observed in children with ASD, chronic constipation is reported by parents to be especially problematic. In children with ASD who have sought medical assistance for chronic constipation on a background of colonic inflammation, two clinical trends (phenotypes) were observed based on the children's response to anti-inflammatory therapy: (1) patients who experience remission from constipation while undergoing anti-inflammatory therapy (*fast responders*), and (2) patients who experience recurrent right-side fecal loading while undergoing anti-inflammatory therapy (*slow responders*). In an earlier study we showed that total gene expression derived from right colon biopsies of 35 patients (15 *fast responders*, 20 *slow responders*), distinguished the fast responders from slow responders.

**Objectives:** The objective of this study is to further characterize the two ASD subgroups through microRNA (miRNA) and total gene (mRNA) co-expression analysis to identify potential molecular regulators of the atypical constipation phenotype.

**Methods:** In the original pilot study, hierarchical clustering of the right colon gene expression profiles from 35 patients resulted in two distinct clusters; the separation was based largely on clinical phenotype (*fast* vs *slow* responder; **Figure 1** – left panel). In this follow-up study, miRNA expression profiles were assessed for 12 of the 35 original right colon biopsies (6 *fast responders*, 6 *slow responders*) and analyzed together with mRNA profiles. Total RNA was quantified using NanoDrop and miRNA expression was assessed based on ~800 known miRNAs using NanoString nCounter SPRINT protocol. Differential expression of miRNA in fast vs. slow responders was determined using nSolver software and miRNA-mRNA co-expression was evaluated using Ingenuity Pathway Analysis (IPA).

**Results:** We identified 12 differentially expressed miRNAs ( $p=0.05$ ; **Figure 1** - right panel) and ~1500 differentially expressed transcripts (DETs) ( $p=0.01$ ) between slow vs fast responders. The mRNA comparison revealed decreases in expression of genes involved in  $Ca^{2+}$  and  $Na^{+}$  transport, smooth muscle cell generation, and smooth muscle contraction in patients exhibiting the slow responder phenotype. The co-expression analysis revealed a downregulation of gene(s) involved in inositol phosphate metabolism (e.g. CDC25A) and a concomitant increase in miR-125b-5p, which is known to impact CDC25A expression, in the slow responder group. Furthermore, a decrease in miRNA let-7a-5p, which has also been experimentally observed to target genes involved in inositol phosphate metabolism (e.g. CDC25A, CDIPT), was associated with a concomitant decrease of both CDC25A and CDIPT.

**Conclusions:**

A central finding of the miRNA-mRNA co-expression analysis was a downregulation of transcripts coding for ion channels and transport in the smooth muscle in slow responders compared to fast responders. Since smooth muscle contractility in the GI tract is integral to colonic motility, this observed decrease in factors necessary for smooth muscle cell contractility suggests a potential mechanism for the persistent hypomotility, even following treatment for gastrointestinal inflammation, observed in slow responders.

**423.009 (Poster)** Prevalence of Gastrointestinal Symptoms Among Individuals with ASD, with and without Co-Occurring Intellectual Disability

**C. B. Hologue**<sup>1,2,3</sup>, **P. Danika**<sup>1,4</sup>, **R. Reetzke**<sup>1,4</sup>, **J. S. Hong**<sup>1,4</sup>, **L. Kalb**<sup>1,2,3</sup> and **R. Landa**<sup>1,4</sup>, (1)Center for Autism and Related Disorders, Kennedy Krieger Institute, Baltimore, MD, (2)Department of Mental Health, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, (3)Department of Neuropsychology, Kennedy Krieger Institute, Baltimore, MD, (4)Department of Psychiatry and Behavioral Sciences, Johns Hopkins University School of Medicine, Baltimore, MD

---

**Background:**

While gastrointestinal (GI) symptoms are known to be highly prevalent among children with autism spectrum disorder (ASD), prior research has not assessed whether co-occurring intellectual disability (ID) influences the parental reporting of these symptoms.

**Objectives:**

To examine differences in the parental certainty and odds of reporting GI signs and symptoms among children with ASD with and without ID.

**Methods:**

Participants were 209 children and adolescents with a clinical diagnosis of ASD (6-18 years, mean =10.7, SD=3.5), assessed at an urban, outpatient ASD specialty clinic. Diagnosis of ASD and ID were determined by a licensed physician or psychologist based on the DSM-IV-TR or -5. At diagnostic intake, parents were asked to endorse whether, in the past 3 months, their child had experienced or displayed a range of signs or symptoms related to GI problems on custom medical form. Response options were yes, no, or unsure. First, we assessed whether having ASD with ID (relative to ASD without ID) was associated with parental certainty regarding the presence or absence of GI signs or symptoms (i.e., responses of yes and no were considered 'certain' and responses of unsure were considered 'uncertain'). Next, multivariate logistic regression models assessed the association between ID and each GI sign or symptom while adjusting for child sex, age, race, and parental education. Each model excluded children whose parents were uncertain regarding presence or absence of that particular GI symptom or sign. Given the relatively small sample of children with ASD with ID, p-values < 0.10 were considered statistically significant.

**Results:**

161 (77%) did not have ID, whereas 48 (23%) had ID. Parents of children with ASD and ID reported higher levels of uncertainty regarding the presence or absence of GI signs and symptoms; significant differences were observed for abdominal pain, nausea, bloating, and other GI symptoms (p<0.10, Table 1). Among children whose parents were certain about the presence or absence of symptoms, having co-occurring ID was associated with significantly higher odds of bloating and other GI symptoms (p<0.10, Table 2), after adjusting for potential demographic confounders. Other symptoms were not statistically different between the groups, though the group with ID reported greater abdominal pain, constipation, diarrhea, spitting up, and regurgitating food, whereas the group without ID tended to have more of nausea, tilting head to side and arching back, and refusal of foods (Table 2).

**Conclusions:**

Parents of children with ASD and ID reported more uncertainty regarding the presence or absence of GI signs and symptoms, relative to parents of children with ASD only. GI symptoms may be elevated among children with ASD and ID, though this relatively small sample size and the challenges of ascertaining these symptoms in children hinders this inference. Further research is needed to improve the accurate identification of GI symptoms among children with co-occurring ID.

**423.011 (Poster)** Study of the Gut Microbiome Profile in Children with Autism Spectrum Disorder and Their Unaffected Siblings.

**S. S. F. Gau**, Department of Psychiatry, National Taiwan University Hospital & College of Medicine, Taipei, Taiwan

---

**Background:** Autism spectrum disorder (ASD) is a highly clinically and genetically heterogeneous neurodevelopmental disorder with characteristic behavioral manifestations including impaired social communication and restricted, repetitive behavior. Up to now, there has been no FDA approved drugs for its core behavioral symptoms. The youth with ASD often display gastrointestinal

(GI) dysfunction and altered gut microbiome compositions compared with their healthy biological unaffected siblings in the same family, who shared similar environmental conditions.<sup>1</sup> The metabolome directly or indirectly is affected through chemical transformation by the trillions of gut microbes, the microbiome, which has been proposed to modulate complex behaviors; such proposed environmental endophenotype of ASD may integrate with genetic risks to impact behavioral endpoints through the actions of small molecules produced in tissues outside the brain.<sup>2,3</sup>

**Objectives:** We aim to present a comprehensive comparison of extensively identified metabolism mechanisms in human feces from cohorts of matched ASD, unaffected siblings, and typically developing control youths.

**Methods:** A total of 190 samples were assessed, including 103 ASD youth (M:F=99:4, age= 17.32±4.52), 43 unaffected siblings (M:F=23:16, age= 14.51±6.21) and 32 healthy controls (all males, age= 15.67±3.21). All the samples were analyzed with 16s metagenome sequencing, and along with the social responsiveness scale (SRS) score and school function via Social Adjustment Inventory for Children and Adolescents simultaneously. The statistical analysis was done via QIIME2 and R, with the significance level being the FDR-corrected q value <0.05.

**Results:** The gut microbiome of unaffected siblings contained a higher relative abundance of Streptococcaceae as well as Aerococcaceae (family level) than the ASD and control groups. The ratios of Prevotella/Bacteroides (P/B) and Firmicutes/Bacteroidetes (F/B) were significantly lower in both youths with ASD and their unaffected siblings. Further, through the linear discriminant analysis effect size method, we have identified the three-group difference of microbial community, which were majorly in class level of C. bacilli, such as planococcaceae, lactobacillales, and bacillaceae. There were significant correlations between the altered gut microbiome, the severity of social deficits, and impaired school functions in youths with ASD and their siblings.

**Conclusions:** We identified many differential levels of microbiotas among the ASD, unaffected siblings, and control groups. These microbiotas correlate with clinical behavioral and functional scores. These findings support the emerging concept of healthy distal gut microflora in the development of neural systems. Moreover, our findings provide the insights that altered microbiome, as one of the possible etiologies of ASD, may be identified via the comparison between ASD probands and their healthy, unaffected siblings, who might be at risk of ASD.

**423.012 (Poster)** The Directional Relationship between Internalizing Symptoms and Gastrointestinal Problems in Autism Spectrum Disorder

**K. Gynegrowski, Marist, Poughkeepsie, NY**

---

**Background:** Autism Spectrum Disorder (ASD) is characterized by impairments in social communication and restricted or repetitive behaviors and interests. Individuals with ASD experience co-occurring gastrointestinal (GI) problems and internalizing symptoms such as anxiety and depression. For example, children with greater constipation and abdominal pain display greater symptom severity on measures of irritability, anxiety, stereotypy, and social withdrawal when compared to children with no GI symptoms. However, there is minimal research on the directional relationship of these conditions.

**Objectives:** This study aimed to analyze the direction of the relationship between GI problems and internalizing symptoms in individuals with ASD.

**Methods:** The sample for this study included 2,444 individuals with ASD who had been seen at the Thompson Center for Autism and Neurodevelopmental Disorders, part of a multi-site system of autism centers specializing in ASD diagnosis and treatment. Participants ranged greatly in age from 1 to 54 years old (M = 7.33, SD = 5.71). Caregivers answered four dichotomous questions on whether their child had any past or present GI problems: constipation, diarrhea, nausea or vomiting, or stomachaches, stomach pain, or reflux. Caregivers reported on specific dietary traits (e.g., picky eating, milk aversion), and the sum of dietary problems served as a covariate in subsequent analyses. Caregivers also reported the use of any medications, and a dichotomous variable was created where 0 = no GI medications, and 1 = at least one GI medication. Three specific internalizing symptoms, withdrawn/depressed, somatic complaints, and anxious/depressed, were measured by The Child Behavior Checklist (CBCL). The CBCL is a psychometrically sound parent-report measure assessing internalizing and externalizing symptoms, with items rated on a 3-point scale. To test the relationship among GI problems and internalizing symptoms, we ran a structural equation modeling analysis to compare fit statistics across four models: unrelated, with GI problems and internalizing symptoms as independent variables; unidirectional, with GI problems predicting internalizing symptoms; unidirectional, with internalizing symptoms predicting GI problems; and bidirectional, with GI problems and internalizing symptoms correlated. Internalizing symptoms were always represented as a latent, unobserved construct with the three observed CBCL variables, and GI problems were represented as a dichotomous dummy-coded variable. Each model included GI medications, the total number of medications, age, gender, verbal IQ, nonverbal IQ, full scale IQ, total dietary issues, household income, and the number of dependents in the household as exogenous, correlated, covariates. The models were evaluated for relative and absolute model fit

using a chi-square ( $\chi^2$ ) goodness of fit statistic, a Comparative Fit Index (CFI), and a Root Mean Square Error of Approximation (RMSEA).

Results: The best-fitting model was unidirectional, wherein internalizing symptoms led to GI problems.

Conclusions: Results suggest that individuals with ASD who struggle to express internal emotions may show GI symptoms in response. Better knowledge about the relationship and progression of these co-occurring conditions would be useful in developing treatment plans. Research might identify subgroups of individuals with ASD at risk for anxiety-triggered GI issues that could benefit from very different interventions, aside from GI medications.

## PANEL DISCUSSION — IMMUNOLOGY

### Panel 212 - Microbiota and Immune Signaling in Neurodevelopmental Disorders

**Panel Chair: Jane A. Foster**, *Department of Psychiatry & Behavioural Neurosciences, McMaster University, Hamilton, ON, Canada*

**Discussant: Tamar Gur**, *Ohio State University, Columbus, OH*

Trillions of microbes cover the surfaces of our bodies and inhabit our gastrointestinal tract. In the past decade, research efforts examining the role of the microbiome in mental health have moved to the forefront of neuroscience and psychiatry. Our increasing knowledge on pathways and involved mediators along the gut-brain axis has revolutionized our understanding of brain-body interaction. Intestinal bacteria act along the gut-brain axis in part by modifying the immune response. On the other side, bacteria produce neuroactive mediators and can modulate neuronal function, plasticity and behavior. Understanding the influence of microbiota-brain axis on brain function and behaviour is at the forefront of neuroscience research and microbiota-brain is essential to normal and healthy brain development. This session will highlight recent work in animal models examining the importance the brain's innate immune cell in neurodevelopmental disorders and will explore recent work examining the potential of microbiota-targeted therapies in autism.

**212.001 (Panel Discussion)** The Role of Bidirectional Communication between Gut Bacteria and T Cells in Neurodevelopment  
*J. A. Foster, Department of Psychiatry & Behavioural Neurosciences, McMaster University, Hamilton, ON, Canada*

#### Background

Researchers in psychiatry and neuroscience are increasingly recognizing the importance of gut-brain communication in mental health. Based on a foundation of animal studies demonstrating the vital role for microbiota-brain communication in brain development, behavior, and brain function over the life span, clinical studies have started to consider the microbiome in psychiatric disorders. Work to date by our group and others suggest that microbiota-immune-brain signaling is an important pathway that influences brain structure, gene expression of stress-related and plasticity-related genes, stress-reactivity, and behaviour.

#### Objectives

In mice, this study examined the importance of peripheral T cells in the maturation of the microbiome and neurodevelopment.

#### Methods

T cell receptor deficient mice ( $TCR\beta^{-/-}\delta^{-/-}$ ) and C57BL/6 mice were bred in house. Mice were exposed to immune challenge with lipopolysaccharide (LPS) at postnatal day (P) 3 and maternal separation at P9 (16 h overnight). Behavioural assessment of growth and development as well as behaviour (righting reflex, ultrasonic vocalizations in response to brief maternal separation, open field, sociability and grooming).

At P24, fecal samples were collected. Microbiota composition was determined by amplifying the 16S rRNA gene variable 3 (v3) region and then sequenced using the Illumina MiSeq platform data analyzed using DADA2, a Bioconductor pipeline. Alpha and Beta diversity analyses were conducted using the phyloseq package in the R software.

#### Results

Loss of T cells resulted in a delay in the development of the right reflex, increase vocalizations at P7, increase activity and exploratory behaviour at P17, and increased self-grooming. Genotype differences were evident in microbiota composition between  $TCR\beta^{-/-}\delta^{-/-}$  and C57BL/6 mice.  $TCR\beta^{-/-}\delta^{-/-}$  mice were found to have significantly lower alpha diversity than C57BL/6 mice (Shannon:  $p < 0.05$ ). Samples were found to cluster by mouse strain in PCoA plot with bray-curtis (PERMANOVA:  $p < 0.001$ ). Relative abundance at both the phylum and genus level of taxa revealed significant differences between strains. Ongoing analyses examines the relationship between specific immune related taxa and behaviour.

## Conclusions

These findings show the important relationship between the immune system and gut microbiota. By understanding the relationship and influence between the immune system and gut microbiota, we can further begin to understand microbiome-immune-brain signaling pathways and its relation to behavior in early development.

**212.002** (*Panel Discussion*) Microglial P2Y<sub>12</sub>R in Sex-Biased ASD-like Behavioral Phenotypes  
*U. Eyo, Neuroscience, University of Virginia, Charlottesville, VA*

---

**Background:** Autism spectrum disorder (ASD) refers to a group of heterogeneous neurodevelopmental disorders with hallmarks of aberrant social, communication and repetitive behaviors. ASD occurs in 1 in 59 children and is diagnosed more frequently in boys over girls. However, boys and girls present with different behaviors when diagnosed. Of interest, there is mounting evidence for the hypothesis of a dysregulated immune system in ASD. Moreover, pre-clinical models of ASD, often focus on male phenotypes and ignore female phenotypes despite a growing incidence of ASD diagnosis in girls. This raises the need for the development of adequate pre-clinical mouse models that better recapitulate sex-biased behaviors in ASD. Microglia represent the primary brain-resident immune cell and orchestrate brain wiring. Microglial phenotypes have been repeatedly reported to be altered in ASD and specifically manipulating microglia is sufficient to generate ASD-like phenotypes in mice. Moreover, a growing body of literature indicates sex differences in microglia raising possibilities for microglial dysfunction as a factor in regulating sex differences in neurodevelopmental disorders such as ASD. Among microglial genes, the *p2ry12* gene which encodes the P2RY<sub>12</sub> purinergic receptors has emerged as a signature gene for microglial identity.

**Objectives:** The objectives of this project are three-fold. First, we sought to test the possibility of developing a pre-clinical mouse model that adequately re-capitulates sex different behaviors of human ASD in mice. Second, we sought to do this specifically targeting microglia with the hypothesis that microglial dysfunction could elicit sex-biased ASD-like behaviors in mice. Finally, having developed such a model we will attempt to determine the underlying circuits that are dysregulated in this model.

**Methods:** To test the possibility that microglial dysfunction could elicit ASD-like behaviors in mice, we studied mice lacking P2RY<sub>12</sub>. We hypothesized that lacking the functions of a notable microglial homeostatic gene would perturb microglial function and facilitate the development of sex-biased ASD-like phenotypes. We therefore performed various ASD-relevant behavioral tests in wildtype and P2RY<sub>12</sub><sup>-/-</sup> mice of both sexes. We also undertook some cFos immunohistochemistry to assess neuronal activity in relevant brain regions.

**Results:** Our findings indicate sex-biased ASD-like phenotypes in P2RY<sub>12</sub><sup>-/-</sup> male and female mice that mirror behaviors in human boys and girls with ASD. Moreover, we are beginning to observe different neuronal activity patterns between wildtype and mutant mice and are exploring these differences.

**Conclusions:** We are developing a pre-clinical mouse model that can mimic the human condition of ASD-like behaviors in a sex-biased manner by mutating a signature microglial gene. We are attempting to validate this model with other behaviors and determine the underlying circuit and neurobiological mechanisms that precipitate these ASD-like sex differences that we hope can be used to further understand the human condition.

**212.003** (*Panel Discussion*) Gut-Derived Metabolites in Autism Spectrum Disorder and Mouse Models of Behavior  
*S. K. Mazmanian, Division of Biology & Biological Engineering, California Institute of Technology, Pasadena, CA*

---

## Background

The gut microbiome has been associated with effects on the brain, such as modifying risk-taking behaviors and hyperactivity, impacting learning and memory, modulating expression of neurotransmitters, and affecting brain myelination patterns in mice. Recent studies have reported that the gut microbiome, and certain microbial metabolites, are altered in individuals with autism spectrum disorder (ASD).

## Objectives

We sought to translate into humans our preclinical findings that specific gut microbial molecules are dysregulated in mouse models of neurodevelopment, research that is supported by several clinical studies identifying metabolic imbalances in feces and circulation of individuals with ASD. The objective of this study was to take the first steps in testing whether targeting the gut microbiome is a safe and effective option to modulate complex behaviors in humans.

## Methods

We previously reported that the microbial metabolite 4-ethylphenyl sulfate (4EPS) was elevated in a mouse model of neurodevelopment and in a large cohort of ASD individuals. In new unpublished work, engineered bacteria that selectively produce 4EPS in the gut of mice led to changes in brain activity, functional and structural connectivity in brain regions linked to emotional behavior, as well as gene expression signatures of altered oligodendrocyte function. Indeed, production of 4EPS by the microbiome is associated with increased proportions of immature oligodendrocytes in mice and, accordingly, decreased myelination of neuronal axons in the brain. Furthermore, mice exposed to 4EPS display anxiety-like behaviors, reduced social activity and decreased vocalization. These findings reveal that 4EPS can impact the function of oligodendrocytes in the brain and modulate complex behaviors in mice, and suggest that microbial metabolites may be associated with neurodevelopmental disorders in humans.

ASD is defined by core symptomatic behaviors involving delayed or reduced social communication and repetition of familiar traits. Additional features of ASD may include social anxiety, irritability/aggression, altered sensory integration, and GI symptoms. A pilot human study was designed to explore if AB-2004, an oral gut-restricted sequestrant reduces systemic levels of specific bacterial metabolites that are elevated in ASD. Primary endpoints are safety and tolerability. Additionally, metabolites were measured in the blood and urine of study participants, behavioral assessment tools implemented at baseline and end of treatment, as GI symptoms evaluated.

## Results

In an open-label Phase 1b/2a clinical trial with 26 adolescent ASD participants, we confirm safety and tolerability of AB-2004, with little to no adverse events reported. Using metabolomic analysis, we validate reduction of key gut-derived metabolites in urine and blood after 8 weeks of treatment. Importantly, drug therapy was associated with improvements in multiple behavioral domains, most significantly in anxiety and irritability, as measured by the aberrant behavioral checklist and other assessment instruments. GI symptoms were reduced based on standardized functional assessment tools. Preliminary fMRI data suggest that oral AB-2004 affects connectivity between specific brain regions implicated in autism.

## Conclusions

These early findings require replication in larger placebo-controlled trials to test the hypothesis that targeting the gut microbiome may represent a new approach to addressing the core and non-core symptoms of ASD.

**212.004** (*Panel Discussion*) Microbiota Transfer Therapy for Autism: Microbiome and Metabolites Changes  
**R. Krajmalnik-Brown** and **J. Adams**, Arizona State University, Tempe, AZ

---

**Background:** Recent studies in human cohorts and mouse models have shown a link between gut microbiota and autism.

**Objectives:** To investigate the link between gut microbiota and autism by modifying the gut microbiota through a Microbiota Transfer Therapy

**Methods:** An open-label phase 1 study with a follow-up at 2 years post-treatment was conducted. The treatment involved 2 weeks of oral vancomycin, a bowel cleanse, and 7-8 weeks of microbiota transplant. Fecal microbiota was profiled before, after treatment and at follow up by 16S rRNA gene amplicon sequencing, and metabolites were assessed in blood and fecal samples.

**Results:** Gastro-intestinal symptoms and behavior improved significantly, and most improvements remained two years after treatment. The microbiota and metabolites changed with treatment. Beneficial gut microbial changes were sustained 2 years after treatment. We identified important metabolic changes also.

**Conclusions:** MTT is a promising therapy for treating GI disorders for autism. Using a multi-omic approach we are looking at microbes, pathways, genes, and metabolites, which likely lead to the trial's success and can lead to biomarkers or targets for treatment.

**212.005** (*Panel Discussion*) Microbiota Transfer Therapy for Autism: GI and ASD Outcomes  
**J. Adams** and **R. Krajmalnik-Brown**, Arizona State University, Tempe, AZ

---

Background: Gastrointestinal problems including chronic constipation, diarrhea, and/or abdominal pain are common in children and adults with ASD, and are resistant to standard treatments.

Objectives: Investigate a novel method of treatment, Microbiota Transfer Therapy

Methods: An open-label phase 1 study with a follow-up at 2 years post-treatment was conducted. The treatment involved 2 weeks of oral vancomycin, a bowel cleanse, and 7-8 weeks of microbiota transplant.

Results: At the end of treatment there was an 80% reduction in GI symptoms, and a 23% reduction in autism symptoms. At a 2 year follow-up, most of the GI improvements remained (59% reduction compared to baseline), and there was a 47% reduction in ASD symptoms. Five factors in the early medical history of the children with ASD were different compared to controls, and likely contributed to the GI symptoms.

Conclusions: MTT is a promising therapy for treating GI disorders for autism, and randomized double-blind placebo-controlled studies are warranted to further investigate this treatment.

## POSTER SESSION — IMMUNOLOGY

### Poster 424 - Immunology Posters

**424.001** (Poster) Inflammatory Pathways to Autism: Exploring Causality within a Two-Sample Mendelian Randomization Framework

*C. Dardani<sup>1</sup>, J. Robinson<sup>2</sup>, A. Sadik<sup>3</sup>, P. Pagoni<sup>4</sup>, J. Zheng<sup>5</sup>, E. Stergiakouli<sup>6</sup>, R. Gardner<sup>7</sup>, J. Grove<sup>8</sup>, T. iPSYCH ASD Working Group<sup>9</sup>, G. Davey Smith<sup>1</sup>, S. Sullivan<sup>1</sup>, B. Leppert<sup>1</sup>, H. J. Jones<sup>1</sup>, S. Zammit<sup>6</sup>, G. M. Khandaker<sup>9</sup> and D. Rai<sup>1</sup>, (1)Population Health Sciences, Bristol Medical School, Centre for Academic Mental Health, Bristol, United Kingdom, (2)MRC Integrative Epidemiology Unit, Bristol Medical School, University of Bristol, Bristol, United Kingdom, (3)Avon and Wiltshire Mental Health Partnership NHS Trust, Bath, United Kingdom, (4)Karolinska Institutet, Stockholm, Sweden, (5)Aarhus University, Aarhus, Denmark, (6)Denmark, (7)Population Health Sciences, Bristol Medical School, MRC Integrative Epidemiology Unit, Bristol, United Kingdom, (8)Division of Psychological Medicine and Clinical Neurosciences, Cardiff University, Cardiff, United Kingdom, (9)University of Cambridge, Cambridge, United Kingdom*

Background: Inflammation and immune system activation have been proposed to have a key role in autism aetiopathogenesis. There is increasing observational evidence suggesting atypical levels of circulating cytokines in blood plasma and serum of autistic children, as well as associations with core autism-related behaviours. However, inferring a causal role of circulating cytokines in autism has been limited, as the majority of evidence so far has been based on studies with small and selected samples.

Objectives: In 18,381 autism cases and 27,969 controls from the Psychiatric Genetics Consortium and the iPSYCH, we tested the hypothesis that two-major categories of cytokines, implicated in birth complications and secreted by T-helper cells (Th1 and Th2), could be causally linked to autism risk.

Methods: Based on the cytokine categories of interest, we focused on interferon-gamma (IFN-g) as the main Th1 cytokine, and interleukins 4, 5, 10 and 13 (IL4, IL5, IL10, IL13) as the main Th2. We additionally tested macrophage secreted cytokines (tumour necrosis factor alpha; TNF-a, IL1, IL6). We used Mendelian randomization (MR), an approach that utilizes common genetic variants as proxies for risk factors and allows the estimation of their causal effects on outcomes of interest. Within this framework, we selected genetic variants associated with cytokine levels from available genome-wide association studies (Sun et al., 2018, N= 3,301; Ahola-Oli et al., 2017, N= 7,681; Sliz et al., 2019; N= 8,280) and extracted effect sizes and standard errors from the latest available autism GWAS (Grove et al, 2019, N= 46,350) to generate causal effect estimates. In order to further interrogate our findings, we selected brain tissue expression quantitative trait loci (eQTLs) from the largest brain tissue eQTL meta-analysis to date (Qi et al., 2018, N= 1,194) and examined whether changes in gene expression levels of the inflammatory markers of interest might affect autism risk. Finally, analyses were repeated using a subsample of the autism GWAS excluding all intellectual disabilities cases.

Results: We found evidence consistent with a causal effect of genetically predicted levels of IFN-gR (OR= 1.15; 95%CI: 1.03, 1.29), IL-4R (OR= 0.81; 95%CI: 0.66, 0.98; p= 0.03), IL-10 (OR= 0.8; 95%CI: 0.65, 0.98; p= 0.03), IL-13 (OR= 0.8; 95%CI: 0.65, 0.98; p= 0.03) and IL-13R (OR= 1.16; 95%CI: 1.01, 1.33; p= 0.03) on risk of autism. Brain eQTL MR analyses suggested that increased expression of IFN-gR gene in brain tissue was linked to autism risk (OR= 1.15; 95%CI: 1.03, 1.27; p=0.009).

Findings were consistent after repeating our analyses using the autism GWAS subsample excluding intellectual disability cases. There was limited evidence to suggest a causal effect of genetically proxied macrophages secreted cytokines on autism risk.

Conclusions: Present findings are consistent with a potentially causal role of Th1 and Th2 family of cytokines on risk of autism, especially IFN- $\gamma$ , IL4R, IL10, IL13. This information may advance the biological processes underlying the origins of autism and further research focusing on these pathways is warranted.

**424.002 (Poster)** Prevalence of Celiac Disease in a Large Cohort of Italian Children with Autism Spectrum Disorders  
**M. Prosperi<sup>1,2</sup>, E. Brunori<sup>1</sup>, A. Cosenza<sup>1</sup>, R. Tancredi<sup>2</sup>, F. Muratori<sup>1,2</sup> and S. Calderoni<sup>1,2</sup>**, (1)IRCCS Fondazione Stella Maris, Calambrone (Pisa), Italy, (2)Department of Clinical and Experimental Medicine, University of Pisa, Pisa, Italy, (3)IRCCS Stella Maris Foundation, Pisa, Italy

---

Background: Recent studies suggest that a sort of immune system dysregulation might be present in Autism Spectrum Disorder (ASD), supporting the proposal that the immunity system may be involved in various ways in ASD. Some studies have found an association between celiac disease (CD) and ASD, while others hypothesized a random link. To date, studies assessing the prevalence of CD in subjects with ASD provide controversial results.

Objectives: This investigation aims to evaluate the prevalence of celiac disease (CD) in a large sample of school-aged children with Autism Spectrum Disorder (ASD), as well as to characterize their clinical profile.

Methods: Medical records of 405 children with ASD aged 5-11 years (mean age: 86 months; SD: 22 months) referred to a tertiary care university hospital were reviewed: among them, 362 had carried out a serological screening for CD.

Results: Nine patients with positive CD serology were identified, eight of which satisfied the criteria for CD diagnosis. The estimated CD prevalence in ASD children was 2.18% (95% CI, 0.8-3.7), which was not statistically different from that of an Italian population -matched for age range- considered as a control group (1.58%;  $p=0.36$ ). Three out of the eight ASD patients with CD did not have any symptoms suggestive of CD.

Conclusions: Our findings did not show a higher prevalence of CD in ASD subjects than in the control pediatric population but could suggest the utility of routine CD screening, given the frequent atypical clinical presentation in this population.

**424.003 (Poster)** Serological Test for Maternal Autoantibody Related Autism  
**A. Ramirez-Celis<sup>1</sup>, M. Becker<sup>2</sup>, M. Nuño<sup>1</sup>, J. Schauer<sup>3</sup>, N. Aghaepour<sup>2</sup> and J. Van de Water<sup>3</sup>**, (1)UC Davis, Davis, CA, (2)Stanford University, Stanford, CA, (3)MIND Institute, University of California, Davis, Davis, CA

---

Background: Autism spectrum disorder (ASD) is a behavioral disorder that is estimated to affect 1 in 59 children in the USA, and the incidence seems to be on the rise, making it a public health concern. However, biomarkers that accurately predict ASD risk remain unavailable. We previously reported a sub-type of ASD known as maternal autoantibody related autism (MAR-ASD), which is driven by maternal autoantibodies reactive to proteins present in the developing brain. We then identified eight proteins that are the target of the ASD-specific maternal autoantibodies as CRMP1, CRMP2, GDA, NSE, LDHA, LDHB, STIP1, and YBOX.

Objectives: This project aimed to create and validate a robust serological assay to determine ASD-specific maternal autoantibody patterns against the eight previously identified proteins, and to determine the relationship of these reactivity patterns with an ASD diagnosis in the offspring, using machine learning (ML) subgroup discovery techniques.

Methods: This retrospective-case-control-study used plasma samples obtained from mothers whose children were enrolled in the CHARGE (Childhood Autism Risks from Genetics and Environment) study. This project included a total of 780 maternal samples: 450 from mothers of children diagnosed with ASD and 342 control mothers of neurotypically developing children (TD). The participants provided written consent and fulfilled the recruitment and eligibility criteria. Autoantibody reactivity of maternal plasma samples against protein antigens was determined by Enzyme-Linked Immunosorbent Assay (ELISA) using commercially available proteins. To detect high-precision ASD indicator patterns, we used subgroup analysis and exceptional model mining ML methods. In addition, we used the least absolute shrinkage and selection operator (LASSO) ordinal logistic regression model to determine important autoantibody-antigen combinations that describe the ADOS severity score.

Results: We found maternal autoantibody reactivity to single antigens was not correlated with ASD diagnosis since we observed reactivity to at least one antigen in both groups (ASD=134, 65% and TD= 96 57%;  $p= 0.1108$ ). However, we identified several specific patterns of reactivity composed of 2 or more antigens that were present only on the ASD group. The most abundant ASD-specific patterns were CRMP1 + GDA (ASD= 19, TD= 0, OR 31.04,  $p<0.0001$ ), CRMP1 + CRMP2 (ASD= 16, TD= 0, OR 26.08,  $p= 0.0005$ ), NSE + STIP1 (ASD= 14, TD= 0, OR 22.82,  $p= 0.0001$ ) and CRMP2 + STIP1 (ASD= 9, TD= 0, OR 14.78,  $p= 0.0064$ ). We also found that autoantibody reactivity to CRMP1 increases the odds by 2.3 times of presenting with a higher ADOS severity score (OR 2.3; 95% CI: 1.358- 3.987,  $p= 0.0021$ ).

Conclusions: This is the first report that identifies, with 100% accuracy, patterns of maternal autoantibody reactivity associated with a subtype of autism known as MAR-ASD, which accounts for up to 18% of total ASD cases in our current study. This ELISA is a novel serological test that, after substantial clinical validation, has potential for use as a risk assessment test for women at high risk of having a child with autism. Additionally, this work provides support for a better understanding regarding the etiology of this subtype of autism.

## International and Cross-Cultural Perspectives

### PANEL SESSION — INTERNATIONAL AND CROSS-CULTURAL PERSPECTIVES

#### Panel 225 - Cultural Perspectives on Families' Experience of Autism and Autism Services

**Panel Chair:** *Adrienne Perry, Psychology, York University, Toronto, ON, Canada*

**Discussant:** *Joachim Nyoni, Education, Lusaka, Zambia*

Although there is a considerable body of research on families of children with autism, it is based primarily (though not exclusively) on middle-class, white, American or European samples and has tended to focus on negative aspects (such as parenting stress) and service system inadequacies. Although more recent research includes examination of positive aspects as well as challenges families face, the perspectives of families from other countries and of immigrant families are conspicuously absent. This set of studies focuses on the experience of families of children with autism who are either living in other countries (Zambia and Taiwan) or who are immigrants to Canada (one study of a heterogeneous group of immigrants, the other of South Asians specifically). Using quantitative and/or qualitative methods, we explore the perspectives of parents from other countries and cultures, including their understanding of the diagnosis, their experience of stress and coping, positive and negative family impacts, how culture influences these experiences, and their perspectives on autism supports and services. The results have important implications for future research and clinical practice with diverse families. We hope this panel will also challenge some assumptions, change some attitudes towards families from different backgrounds, and promote greater diversity awareness generally.

**225.001 (Panel)** Exploring Diagnosis and Treatment from the Perspective of Zambian Mothers

**B. Zapparoli<sup>1</sup>** and **A. Perry<sup>2</sup>**, (1)*Clinical Neuropsychology, Boston Children's Hospital, Boston, MA*, (2)*Psychology, York University, Toronto, ON, Canada*

**Background:** Parents of children with autism and developmental disabilities (DD) in low-income countries such as Zambia are underrepresented in research despite the impact that having a child with autism/DD can have on a family. Women and girls overwhelmingly shoulder the responsibility for family caregiving and experience greater stress, reduced opportunity for employment, and often end up caring for others even in their own advanced age (Mckenzie et al., 2013). Research suggests that Zambian parents experience unique frustrations that are likely to increase their stress, including increased rates of poverty, marital strain, social stigma, and a need for more institutional-level supports and services (Chiluba & Moyo, 2017; Nyoni & Serpell, 2012; Mung'omba, 2008; Trani & Loeb, 2012).

**Objectives:** This project is part of a larger mixed-methods study examining factors contributing to parenting stress in Zambian parents of children with autism/DD. This presentation will focus on the experiences of Zambian parents with regards to obtaining a diagnosis, understanding their child's condition, and obtaining services for their child.

**Methods:** Interviews were conducted with 15 Zambian mothers using a semi-structured interview guide. A focus group was then conducted with 10 caregivers, who were invited to share their opinions about the results of the earlier quantitative survey and interview-based study and to expand or provide context to enrich our interpretation of the findings. The interviews and focus group discussion were audio recorded and then transcribed verbatim. An inductive approach was used to analyze the data.

**Results:** Parents reported varied experiences of the diagnostic process. Notably, a number of parents did not know their child's diagnosis or did not understand what the diagnostic label meant. Misunderstandings about the etiology of DD in the broader community reportedly contributed to increased social stigma and marital strain. For example, some mothers reported being blamed for their child's disability and felt that this contributed to infidelity or abandonment by their spouses. Lack of access to information about their children's conditions, and lack of access to services and interventions were frequently described as sources of stress. Financial difficulties played a role in limiting parents' access to services and interventions; however, services were limited even for parents who had the means to afford them. Interventions and support for children with DD were mainly obtained through non-governmental organizations (NGOs), hospitals, and schools. Parents often complained about the quality of services received through public hospitals and mainstream schools, while private hospitals and schools for children with special needs/special education teachers were often praised.

**Conclusions:** The results highlight challenges and provide direction for improvements. At a broader systemic level, the results indicate that increasing knowledge and training about autism and DD amongst healthcare providers and teachers would improve the supports available to Zambian mothers. Additionally, removing barriers to accessing healthcare and special education

services is necessary. Increasing knowledge and sensitivity about DD in Zambian society at large is also essential to improving the experiences of Zambian children and their families.

**225.002 (Panel) Exploring Knowledge, Attitudes, and Practices of Autism Treatment in Taiwan**

**H. S. Ho<sup>1</sup>, A. Perry<sup>2</sup> and H. T. Wang<sup>3</sup>, (1)York University, Markham, ON, Canada, (2)Psychology, York University, Toronto, ON, Canada, (3)National Taiwan Normal University, Taipei, Taiwan**

---

**Background:** Although numerous autism interventions exist, only a small subset is considered to be evidence-based such as interventions based on applied behavior analysis (ABA). However, parents often choose non-evidence-based approaches for a variety of reasons. Research suggests that treatment selection is based on a variety of child, parent, and intervention factors, although most of this research has been conducted in Western countries. Cultural factors influence every aspect of parents' experience of the autism diagnosis, such as the perceived seriousness of the disorder and the types of treatment or intervention services selected. Little is known about the perspectives of parents of children with autism from other countries, such as Taiwan.

**Objectives:** This present exploratory study focused on examining the knowledge and attitudes of parents in Taiwan, identifying the types of evidence-based and non-evidence-based treatments they were currently using or had previously used for their children with autism, and examining predictors of ABA-based intervention specifically.

**Methods:** Using a mixed methods sequential explanatory design, this project was conducted in two phases, with a quantitative survey followed by qualitative interviews (Creswell et al., 2003; Ivankova et al., 2006). In phase 1, a survey was used to examine the knowledge of and attitudes towards autism and ABA-based services, as well as to explore the service utilization patterns of a sample of 147 parents of children with autism in Taiwan. Children were aged 8 on average and had been diagnosed by psychiatrists and were screened using the SCQ for the study. In phase 2, semi-structured interviews were conducted with key informants to clarify and elaborate on the quantitative results obtained in phase 1.

**Results:** 76% of the parents had high scores on the autism knowledge scale. Parents in this sample were generally positive about their child's future (86%). In terms of autism treatments, the most frequent treatments used were: occupational therapy (80%), speech therapy (67%), and physiotherapy (52%), which were publically funded. Factors parents considered when selecting interventions included: distance (83%), cost (69%), and recommendations from medical professionals (69%) and school/other professionals (56%). Very few parents (8%) reported currently using ABA-based intervention and an additional 20% had previously used it. Binomial logistic regression was used to examine the relative strength of predictors of ABA-based service use (currently or previously). Knowledge of ABA was significantly related to the selection of ABA-based services ( $p = .002$ ), controlling for other parent characteristics (e.g., education) and child characteristics (e.g., severity),  $X^2(7) = 15.284, p < 0.001$ . In phase 2 of the study, specific factors contributing to this ABA knowledge gap were identified at the parent level, at the intervention level, and at the systems level.

**Conclusions:** Although parents in this sample had a good understanding of autism and a positive outlook regarding the diagnosis, the use of ABA-based intervention was low and various barriers in the selection of autism treatments were identified. The findings underscore the importance of providing timely knowledge about evidence-based interventions so that parents can make informed decisions.

**225.003 (Panel) Experience of Canadian Immigrant Families of Children with Autism**

**T. Kuan<sup>1</sup>, O. Weiss<sup>2</sup> and A. Perry<sup>3</sup>, (1)York University, Toronto, ON, Canada, (2)Children & Youth Division, Surrey Place, Toronto, ON, Canada, (3)Psychology, York University, Toronto, ON, Canada**

---

**Background:** Parents of children with autism spectrum disorder (ASD) experience major impacts on the family but much of the literature focuses on the negative impact. The Perry Model of Stress (Perry, 2004) provides a different approach to conceptualizing the experiences of parents, positing that stressors (child characteristics and other life stressors), resources (individual and family system resources) and supports (informal social support and formal supports and services) must be considered in understanding both negative and positive family impacts of having a child with ASD. Clinical wisdom suggests that negative impacts may be particularly felt by immigrant families. However, there is a lack of literature exploring the impact of having a child with ASD in immigrant populations.

**Objectives:** This exploratory study aims to investigate whether there are differences in how Canadian-born versus immigrant parents are negatively and positively impacted by having a child with ASD and how potential differences in the stressors, resources and supports relate to immigration status.

**Methods:** This study is a secondary analysis of survey data collected from parents of children with ASD ( $n = 163$ ) receiving services at a public agency located in Toronto, Canada (a very ethnically diverse city) for another study unrelated to immigration status. Constructs included in the survey included positive and negative impact (Trute & Hiebert-Murphy, 2002) as well as various resources and supports in the Perry (2004) model. In this community sample, 70 parents (43%) were immigrants to Canada from 37 different countries with a majority from East Asia, Eastern Europe and South Asia. They ranged in age from 24 to 61, 85% were 2-parent families and there was a wide range of SES. Children (80% male) ranged in age from 3 to 18 ( $M = 9.17$ ;  $SD = 3.62$ ) and all had a diagnosis of ASD from community professionals.

**Results:** Independent samples  $t$ -tests were conducted to compare groups and showed no differences between immigrants and Canadian-born parents for either positive or negative impacts on the family ( $t(158) = 1.41, p = .161$ ;  $t(158) = -1.28, p = .202$ ). Scores for the resources and supports were generally similar in the two groups and the only significant differences indicated more optimal scores in the immigrant sample, contrary to expectation. Specifically, immigrant parents had higher positive coping ( $t(158) = 2.43, p = .016, d = .39$ ), higher satisfaction with formal services ( $t(158) = 2.24, p = .026, d = .36$ ) and higher social support satisfaction ( $t(158) = 2.85, p = .005, d = .45$ ), in spite of the fact that their children had lower adaptive skills ( $t(158) = -2.86, p = .006, d = .46$ ).

**Conclusions:** These findings indicate that there is more similarity than difference between these two samples and that immigrant families do not necessarily report more adverse impacts. Further analyses using hierarchical linear regression are underway (and will be reported at INSAR) to explore whether these differences predict positive and negative impacts differentially in Canadian-born and immigrant parents.

**225.004 (Panel) Experiences of South Asian Immigrant and Canadian-Born Mothers**

N. Luthra<sup>1</sup> and A. Perry<sup>2</sup>, (1)McMaster Children's Hospital, Hamilton, ON, Canada, (2)Psychology, York University, Toronto, ON, Canada

---

**Background:** The Perry (2004) model of stress suggests that mothers experience both negative and positive impacts of raising a child with a Developmental Disability (DD) such as Autism Spectrum Disorder (ASD) as they deal with stressors with the help of personal and family resources as well as social supports and services (Hastings & Taunt, 2002; Luthra, Perry & Minnes, 2014). However, these variables can vary across cultures due to differences in culturally acceptable developmental timetable, conceptualization of disability, its causes, treatments, and implications for the family (Harry, 2002; Welterlin & LaRue, 2007). Immigrant mothers' conceptualization may differ based on their culture and may alter as they acculturate to a more western understanding of disability (Daley, 2004; Mandell & Novak, 2005). There is some research in Canada about immigrant mothers' experience with services and barriers they encounter on their journey (Khanlou & Haque, 2013), however there is a scarcity of literature specifically examining positive impact in South Asian immigrant mothers of children with autism/DD (Gabel, 2004; Ravindran & Myers, 2013).

**Objectives:** This study used the Perry (2004) model of stress to explore these main questions:

1) Is there a significant difference between the two groups on positive and/or negative impact? 2) Are there differences in any of the *stressor* (child's age, adaptive skills, maladaptive behaviors, financial burden and other life stressors), *personal* (self-efficacy, mental health, coping) and *family* resources (family hardiness, marital satisfaction), formal and informal sources of *support* variables? 3) Are there different predictors of positive impact in the two groups?

**Methods:** A correlational embedded mixed method design (Creswell et al., 2003) was used. Quantitative questionnaire data completed by 56 Canadian and 51 South Asian immigrant mothers of children with a DD served as the primary data and qualitative themes from semi-structured interviews with a sub-sample of mothers from both groups as secondary data. South Asian immigrant mothers were from India, Pakistan, Bangladesh, Sri Lanka, and Afghanistan, spoke 11 languages besides English, and had been in Canada for average 13.5 years. About 75-80% children in both groups were male and over 80% had ASD (by parent report).

**Results:** Interestingly, the South Asian group reported significantly higher positive impact ( $t = -2.43, p = .017, d = .48$ ) relative to Canadian-born mothers. They also reported higher positive coping ( $t = -3.97, p < .001, d = .78$ ) and greater helpfulness of social supports ( $t = -2.80, p = .006, d = .54$ ), but also higher negative coping ( $t = -2.30, p = .023, d = .46$ ) and greater mental health issues ( $t = 2.71, p = .008, d = .53$ ). Their children were reported to have significantly lower adaptive skills ( $t = 3.73, p < .001, d = .72$ ). Predictors of positive impact for Canadian-born mothers were child's age, positive coping and family hardiness and for South Asian mothers were mother's mental health and positive coping.

**Conclusions:** There was considerable similarity between Canadian-born and South Asian immigrant mothers, but some key differences. It is important for service providers to be cognizant of these differences, and provide culturally sensitive services to immigrant mothers. Clinical implications will be discussed in detail in the presentation, along with supportive qualitative themes.

## ORAL SESSION — INTERNATIONAL AND CROSS-CULTURAL PERSPECTIVES

### Oral 326 - Impacts on Families and Individuals

**326.001** (Oral) An Intersectional Analysis of the Experiences of Parents Raising Children with Autism and Other Developmental Disorders in Ethiopia

**B. T. Tekola<sup>1</sup>**, **M. Kinfe<sup>2</sup>**, **F. Girma<sup>2</sup>**, **C. Hanlon<sup>3</sup>** and **R. A. Hoekstra<sup>1</sup>**, (1)Department of Psychology, King's College London, London, United Kingdom, (2)Department of Psychiatry, School of Medicine, College of Health Sciences, Addis Ababa University, Addis Ababa, Ethiopia, (3)Addis Ababa University and King's College London, Addis Ababa, Ethiopia

**Background:** The experiences of parents raising children with autism and other developmental disorders (DD) have been widely researched, though most of this research comes from Western, high-income countries. In comparison, little is known about the lived experience of parents of children with DD in low-and middle-income countries (LMIC) in general, and in Africa in particular.

**Objectives:** We aimed to explore the experiences of parents raising a child with DD in urban and rural Ethiopia. Specifically, we explored how stigma interacted with poverty, single parenthood and DD in shaping the experiences of the parents in our study, using intersectionality.

**Methods:** Participants comprised nine parents of a child with DD in Addis Ababa and nine parents from the rural town of Butajira (4 fathers; 14 mothers). Their children with DD (6 primary autism diagnosis; 12 intellectual disability) were aged 4-9 years. All participants completed an in-depth semi-structured interview. Data were analysed using thematic analysis.

**Results:** Four themes were developed: “recognising and responding to delays or differences in the child’s development”, “negotiating the social world”, “experiencing multiple and intersecting struggles”, and “remaining positive and hopeful”. Stigma pervaded all themes. Culture shaped the types of delays or differences in their child’s development that parents noticed early and the kinds of support they sought. Despite stigma and lack of understanding from others, not all parents were withdrawn from family relationships and social life completely and permanently. Most parents were facing multiple struggles such as lack of appropriate services for their child with DD and financial difficulties, but often their experiences varied based on, among other things, where they lived (urban or rural) and their socio-economic status. For single mothers, the challenges that come with raising a child with DD were experienced on top of the acute financial difficulties they were facing. Most of the time they worried about how to survive: how to feed their family, fulfil basic needs and pay house rent. The intersection of single parenthood, poverty, stigma and DD also left single mothers and their children in our study without a means of livelihood. Parents, especially mothers who were primarily responsible for the daily care of their child with DD, prioritized the needs of their child with DD by foregoing family relationships, social life, their work and their religion. Spiritual beliefs, the many sacrifices that they made and their commitments to care for their child enhanced and maintained parents’ hope and meaning of life.

**Conclusions:** This study highlights the varied experiences of parents raising a child with DD in Ethiopia. Our findings suggest that poverty, single parenthood, stigma and DD interacted with one another to shape the experiences of some parents raising a child with DD in urban and rural Ethiopia. Despite diversity, parents raising a child with DD in urban and rural Ethiopia also shared experiences in terms of ongoing struggle, sacrifice and hope. Interventions aiming to support families with children with DD in low-resource settings like Ethiopia should include a focus on stigma, single parenthood and poverty reduction.

**326.002** (Oral) Depression Among Latinx Mothers of Children with ASD: Did a Culturally Tailored Parent Psychoeducation Intervention Show Positive Effects on Maternal Depressive Symptoms?

**W. Zeng<sup>1</sup>**, **S. Magaña<sup>1</sup>**, **K. Lopez<sup>2</sup>** and **W. A. Machalicek<sup>3</sup>**, (1)Steve Hicks School of Social Work, University of Texas at Austin, Austin, TX, (2)Arizona State University, Phoenix, AZ, (3)University of Oregon, Springfield, OR

**Background:**

Mothers of children with ASD have higher rates of negative mental health outcomes including depression (Vasilopoulou & Nisbet, 2016). There are very few empirical studies on the emotional experiences of Latinx parents of children with ASD and how intervention can improve issues with their mental health. Parents Taking Action (PTA) is a culturally tailored parent

education intervention that was developed to address service disparities faced by Latinx families of children with ASD. Parents received 14-session home-based education program from peer-leaders who were trained on the content and intervention protocol. A two-site (Illinois and California) randomized waitlist-control trial was conducted and data were collected at three time-points: baseline (T1), four-month (T2), and eight-month post baseline (T3).

**Objectives:** The purpose of this study is to assess the intervention's longer-term effects on Latina mothers' depressive symptoms across the three time-points.

**Methods:**

The participants were 91 (intervention n=39, control n=52) Latinx mothers of children with ASD aged 8 years or younger, who completed all three assessments using the Center for Epidemiologic Studies Depression Scale (CES-D). Total CES-D scores were calculated for all participants. We assess the intervention effects across time-points by conducting repeated measures analysis of covariance (ANCOVA) models for total CES-D scores from T1 to T3. Maternal education was controlled for as it was the only significant between-group demographic variable. We also analyzed differences in intervention effects by site by running OLS regression models at eight months.

**Results:**

Overall, the mothers were 37 years old and were primarily foreign born (90%). The differences in baseline CES-D scores between the intervention and control groups were not significant ( $t=1.19$ ,  $p=.24$ ). The intervention group mothers' average total CES-D scores decreased by 5.3 points (T1=17.6, T2=13.1, T3=12.3) while the control group mothers remained essentially unchanged (T1=14.9, T2=14.9, T3=14.2) across the three time-points. Our ANCOVA models also showed that there were significant intervention effects ( $F_{[1, 88]}=4.38$ ,  $p=.04$ ) even after maternal education was accounted for. There were no significant treatment differences across the two study sites.

**Conclusions:**

The intervention group mothers at both sites reported significantly lower depressive symptoms scores eight-months post baseline compared to the control. The findings of this RCT study suggest that the content, structure, and delivery mode of PTA contributed to the decrease in depressive symptoms from baseline to eight-month post baseline. The findings also indicate that the culturally tailored parent education program could be employed to improve mental health outcomes of Latinx parents of children with ASD.

**326.003 (Oral)** Impact of Covid-19 on the Experiences of Parents and Family Carers of Autistic Children and Young People in the UK

**G. Pavlopoulou**<sup>1,2</sup>, **R. Wood**<sup>3</sup> and **C. Papadopoulos**<sup>4</sup>, (1)Department of Psychology and Human Development, Institute of Education, UCL, London, United Kingdom, (2)Anna Freud Centre/UCL Brain Sciences, London, United Kingdom, (3)School of Education and Communities, University of East London, London, United Kingdom, (4)University of Bedfordshire, London, United Kingdom

**Background:** The outbreak of Covid-19 has triggered profound changes to the life of family carers of autistic children and young people (CYP), including a switch to online teaching, restricted access to services and family support due to social distancing measures and changes to home routines.

**Objectives:** This study examined how the coronavirus pandemic, the Coronavirus Act (2020) and the lockdown impacted on families of autistic CYP in the UK, particularly in relation to their caregiving experiences and wellbeing.

**Methods:** Ethical approval was provided to run an anonymous qualitative survey between 1st and 30th April 2020. The survey was co-produced with three parents of autistic children, one of whom is autistic. 449 participants completed the survey: 401 mothers, 35 fathers and 13 carers (including siblings). All lived in the UK and cared for at least one autistic CYP. 41% of the autistic CYP were diagnosed with co-

occurring conditions such as a learning disability, anxiety, ADHD and dyspraxia. 82% of the participants were identified as white, 18% of the participants identified with an ethnic minority background including Arab, Persian, Black, Asian, or mixed.

Results: Thematic Analysis was used to analyse survey data. Five key themes were identified within the dataset: (i) A sense of familiarity, (ii) New struggles (iii) New opportunities and unexpected freedoms, (iv) Personal accounts on mental health and (v) Re-imagining the future, returning to pre-covid normal is not enough. According to our findings 86% of family carers think that the needs of autistic people and their families have not been adequately addressed during Covid-19, 46% of family carers stated that they consider their autistic children or themselves to be at higher risk for Covid-19 than the general population. 70% of family carers report that their daily routines have changed. Importantly, many participants did not want to return to the pre-Covid world. 58% of family carers still had access to at least one type of specialist support. However, this was not always timely nor sufficient.

Conclusions: This is the first study to examine the experiences, perspectives and needs of parents raising an autistic during a world pandemic. Importantly, this study also established priorities for future research and analysed caregiver's 'wish list' for future service and support provision. This knowledge, produced by parent's first-hand accounts, may help researchers gain a better understanding on the potential stressors and/or facilitator factors experienced during this challenging period. A particularly big impact of Covid-19 has been the removal of respite and the lack of a support scheme specific to the needs of working family carers. Our data show that services can still adapt and support families, so planning and consideration into service delivery methods that can remotely support disabled people and their families need further planning. Enforced changes to daily routines have often been stressful for autistic CYP and their families, particularly if they have not received support. Moving forward, transitions and changes (which will continue to occur) need to be as clearly communicated in advance as possible so planning can more effectively take place.

**326.004** *(Oral)* Understanding Barriers to Good Mental Health for Autistic People during the COVID-19 Pandemic  
*I. Dale<sup>1</sup>, H. Judge<sup>2</sup> and D. May<sup>3</sup>, (1)The National Autistic Society, Sheffield, United Kingdom, (2)National Autistic Society, London, United Kingdom, (3)National Autistic Society, London, United Kingdom of Great Britain and Northern Ireland*

---

Background:

Autistic people are more likely to experience mental health problems (Lai et al, 2019). Autistic people consistently report mental health as a key life challenge and a priority for research (Roche et al, 2020). The COVID-19 pandemic has led to drastic changes of circumstances and routines for many autistic people, with potentially serious consequences for their mental health and wellbeing. The pandemic has also compromised support services for many autistic people.

Objectives:

The aim of the research was to inform a mental health programme being developed by a national autism charity in partnership with a national mental health charity. Firstly to identify information and support needs which could be addressed during the pandemic. Secondly to identify issues on which to base a campaign for more and better autism specific mental health support. Thirdly to identify sub-groups of the autism community affected disproportionately by the pandemic.

Methods:

A national, open access, online survey was conducted in two waves. The survey was co-designed with autistic people and publicised via social media, email and the website of the charity. The first fieldwork wave in June and July 2020 focused on the impact of the pandemic. The second wave in the autumn focused on anxiety and depression and the therapies respondents had accessed. 579 autistic people and 514 family members completed both waves. A further 2,466 autistic people and 2,538 families completed one wave only, resulting in an overall achieved sample of 6,097.

Results:

Among autistic people, the most frequently reported worries were their mental health, what will happen after lockdown, and their friends or family contracting COVID-19. The most commonly report difficulties caused by the pandemic were in buying food and necessities, anxiety becoming harder to manage, and getting less mental health support. Autistic respondents identifying as female or non-binary were more likely to report worries. People with high support needs, and their families, more frequently reported negative impacts. Spending time outside, using video calls or the phone to talk to friends and family, and doing exercise were most likely to be reported as helpful in coping. Counselling, Cognitive Behavioural Therapy (CBT) and mindfulness were the therapies respondents were most likely to say had made helped with anxiety or depression, though a minority of respondents

reported that CBT had made things worse. Among respondents completing both waves, negative impacts were reported less often in the second survey, possibly reflecting an easing of lockdown restrictions.

#### Conclusions:

This was the largest such survey within its national setting. Consistent with anecdotal reports, a minority of respondents reported mood, anxiety levels or behaviour were improved during the lockdown, due to fewer work, education or social pressures. However, overall, autistic people's mental health and wellbeing, already less satisfactory than that of the rest of the population, has deteriorated further as a result of the pandemic. Furthermore their ability to access support has been compromised. However this can be at least partially remedied by the provision of online information, adoption of coping strategies, and access to talking therapies.

## POSTER SESSION — INTERNATIONAL AND CROSS-CULTURAL PERSPECTIVES

### Poster 425 - International and Cross-Cultural Perspectives Posters

**425.001** (Poster) "I Was Confused... and Still Am" Barriers Impacting the Help-Seeking Pathway for an Autism Diagnosis in Urban North India - a Mixed Methods Study

**S. Bhavnani<sup>1</sup>**, G. Lockwood Estrin<sup>2</sup>, R. Arora<sup>1</sup>, D. Kumar<sup>3</sup>, M. Kakra<sup>3</sup>, M. Juneja<sup>4</sup>, S. Gulati<sup>5</sup>, V. Patel<sup>6</sup> and G. Divan<sup>1</sup>, (1)Child Development Group, Sangath, New Delhi, India, (2)Centre for Brain and Cognitive Development, Birkbeck University of London, London, United Kingdom, (3)Sangath, New Delhi, India, (4)Maulana Azad Medical College, New Delhi, India, (5)Centre of Excellence and Advanced Research for Childhood Neurodevelopmental Disorders, Child Neurology Division, Department of Pediatrics, All India Institute of Medical Sciences, New Delhi, India, (6)Department of Global Health and Social Medicine, Harvard Medical School, Boston, MA

**Background:** The importance of timely recognition of autism in young children and referral to effective interventions is widely recognised. In most countries, especially low and middle-income countries (LAMIC) such as India, there is a long delay between when parents recognise developmental or behavioural concerns in their child and obtain an autism diagnosis. There is thus a need to build on the evidence base of the contextual barriers that prolong the help-seeking pathway followed by families of children with autism in India in order to identify opportunities that can facilitate the provision of an autism diagnosis and access to available interventions at a younger age.

**Objectives:** The objective of this study was to explore 1) the extent to which the nature of parental concerns and prior knowledge of developmental disorders impact the time between symptom recognition and autism diagnosis, and 2) the contextual family, societal and health-system related factors that impede the autism help-seeking pathway.

**Methods:** A mixed methods study design was employed. Case-registers of 84 participants were accessed and data was extracted on the sex of the child and types of presenting concerns. The impact of these on the age of the child at initial parental concern and diagnosis and time taken for diagnosis was quantitatively explored. Semi-structured in-depth interviews were conducted with parents or primary caregivers of 20 children with autism. The interviews explored the nature of initial parental concerns and parents' experience of obtaining an autism diagnosis for their child, including who they consulted, the advice they received and the action they took along each step of the help-seeking pathway

**Results:** Children were approximately 2.5 years old when parents recognised developmental or behavioural concerns, and 4 years old when they were diagnosed with autism. Social communication difficulties and lack of language were the most common presenting concerns by parents, being recognised more often in girls than boys. Comorbidities such as seizures or physical health conditions were prioritised over autism-related concerns such that these children obtained a diagnosis later than those who did not have comorbidities. A lack of awareness of age-appropriate attainment of child developmental milestones, and neurodevelopmental disorders like autism, was apparent in the community as well as health professionals. Parents who sought advice from family members and general physicians would often be advised to 'wait and watch' their child, as they would 'catch-up' in their development. The disempowerment of mothers in taking decisions for their child's health, and often a lack of any social support, also contributed to delayed diagnoses.

**Conclusions:** The pathway to an autism diagnosis was found to be a complex and arduous one. We triangulate our quantitative and qualitative findings to make recommendations of potential actions that can be taken at various stages within the help-seeking pathway to minimize its length. These include increasing awareness of age-appropriate milestones amongst the community and health professionals and harnessing the potential of existing cadres of non-specialist health workers by equipping them with scalable tools for developmental monitoring of young children.

**425.002** (Poster) A Comparison of Parenting Stress and Resilience in Parents of Children with Autism between India and the UK: A Qualitative Analysis  
*F. M. Kodakkadan<sup>1</sup>, E. M. Lee<sup>2</sup>, J. Lambie<sup>2</sup> and S. D. Stagg<sup>1</sup>, (1)Anglia Ruskin University, Cambridge, United Kingdom, (2)School of Psychology and Sport Science, Anglia Ruskin University, Cambridge, United Kingdom*

---

**Background:** Raising a child with Autism Spectrum Disorder (ASD) involves unique and specific cultural challenges that are often not considered in research (Spong, 2019). To effectively address the psychological needs of parents of children with ASD, as part of any intervention program, it is necessary to identify and understand the socio-cultural factors that contribute to parenting stress and resilience. While questionnaires may identify similar levels of stress in different populations, the causes of stress may be significantly different and go unacknowledged. Cultural differences mean families define stress differently, need different resources and build resilience in different ways. Our study reports qualitative data from Indian and UK parents based on the Double ABCX framework of McCubbin and Patterson (1983). The analysed transcripts help to illustrate some unique cultural elements that contribute to stress and resilience.

**Objectives:** To compare the experiences of stress and resilience in parents of children with ASD in India and the UK. To improve understanding of how cultural factors may lead to improved methods for culturally adapted interventions.

**Methods:** Semi-structured telephonic interviews were conducted with 30 parents who have a child diagnosed with ASD (15 from India, 15 from the UK) and were transcribed verbatim. Transcripts were analysed using thematic analysis.

**Results:** Several themes emerged from the analysis. Both Indian and UK parents explained that their stressors ranged from child-related factors (severity of autism symptoms) to financial and family level challenges. Indian parents utilised a combination of cultural and religious-based explanation (for example, attributing their child disability to 'Karma') to make sense of their child's autism diagnosis. The role of religion and superstition was unique to the Indian context. A lack of general awareness of disability issues in Indian culture also served to place pressure on parents. Parenting stress was more prominent among Indian parents in our research. Indian parents reported difficulty in accessing appropriate resources, and they referenced a general lack of formal and informal support networks related to autism. As a resource for coping with stress, Indian parents reported using a blend of technology (internet), traditional forms of medicine (Ayurveda) and spiritual support (seeking help from spiritual healers). Additionally, one clear difference between parents in both countries was that the Indian parents, especially mothers, faced blame for giving birth to a disabled child and the quality of parenting was also linked to their child's autism.

**Conclusions:** Severity of autism, financial and family pressures were common factors to both parental groups. However, there were substantial differences in the nature and the experience of stress. Our research suggests that using traditional questionnaires may not uncover the culturally specific nature and diversify of stress and resilience experienced by parents with autistic children. The findings allow us to fill out the lived experiences behind the framework. Our findings give a clear indication of why Indian parents may be reluctant to seek help for their children or even seek a diagnosis. We hope our findings will help practitioners to understand the unique needs of parents from diverse cultures and provide appropriate culturally sensitive support.

**425.003** (Poster) A Lost Year? Art, Creativity and Strengths in Autism during covid19 Lockdown.  
*C. D'Agostino<sup>1</sup>, L. Echenique<sup>2</sup>, N. Galetta<sup>3</sup>, N. Santamaria<sup>4</sup>, V. De Chiara<sup>5</sup> and A. Larroulet<sup>6</sup>, (1)Universidad Caece, Mujeres TEA, Yoenfoco, Buenos Aires, Argentina, (2)Grupo Cidep, Mujeres TEA, Buenos Aires, Argentina, (3)Private practice, Buenos Aires, Argentina, (4)Motivatea, Buenos Aires, Argentina, (5)CTA, Buenos Aires, Argentina, (6)Socializarte, Buenos Aires, Argentina*

---

**Background:**

Art, creativity, special abilities and strengths in ASD are rarely addressed in research and practice. During Covid-19 our country was in lockdown for 8 months with only online resources. We organized a social media online contest and exhibition for individuals with ASD to promote art and creativity. 138 participants from 15 provinces sent 6000 pictures during 5 months that were exhibited online. 100 ASD organizations from the country donated and sent a small price to participants to their homes so every participant had a reward.

**Objectives:**

**Objectives:** The aim of the study was to explore the time and motivation of individuals with ASD to create and show art and creativity during lock down with and online survey, the profile of strengths and special abilities and to explore the importance and role of them during pandemic and normal times.

## Methods:

An online survey based on the state of the art of strengths and creativity in ASD was administered after 8 months lockdown project. The survey had quantitative variables, multiple choice and likert scales. Preliminary statistic data was processed in this pilot exploratory descriptive study with SPSS. The sample were 100 parents (N 100), 92% mothers, reporting on 100 of participants with ASD from ranging from 4 to 34 years of whom 64 were male and 36 were female, and less than half of the sample also presented intellectual disability (39%).

## Results:

Reported favorite art activity for was painting (70%) drawing (53%) collage (34%) photography (27%), music (23%) and sculpture (23%). Reported strengths were excellent memory (69%), detail focus (50%) creativity (45%) Hiper-focus or flow (46%) Visual processing (34%) perfect pitch in music (33%) systematization (27%) and synesthesia (7%).

Almost all families reported having more quality time with their son/daughters (89%). The ASD individuals also had more time for art and creativity activities (90%) with high motivation for creating (73%) and for showing their work online (73%). More than half of the sample discovered new interest and skills (57%).

Measuring how challenging lockdown was in a likert scale (1 very difficult/ 5 easier than regular life) families reported that as parents was difficult but they got used to it (2, 41%) and, 16% reported that was easier than normal life (5). For their son/daughter results were similar (49%)- 2- difficult but they got used to it-, and for some- 5- easier than normal life (20%).

When asked about the importance of art, creativity and special interests during pandemic times (1- indispensable, 5 not important) families reported they were indispensable 40% and very important 49%, 11% important, and in normal times 31% reported indispensable, and 63% very important, 6% important. All the sample reported that they needed more spaces and opportunities to develop their skills in their communities.

## Conclusions:

Results suggests that strengths, art and creativity played an important role for individuals with ASD and their families during lockdown, and future efforts might be needed to shed light in the unique role of them in challenging and not challenging times.

**425.004 (Poster)** A Mixed-Method Evaluation of Feasibility, Acceptability and Initial Efficacy of the Who- Caregivers Skills Training (CST) Pilot in India.

**K. Sengupta<sup>1</sup>, S. Ghosh<sup>2</sup>, D. Sanghvi<sup>3</sup>, S. Mahadik<sup>4</sup> and T. W. CST Team<sup>4</sup>, (1)Ummeed Child Development Center, Mumbai, Maharashtra, INDIA, (2)Research Insights and Innovation, Population Health & Safety, Seattle, WA, (3)Ummeed Child Development Center, Mumbai, India, (4)Department of Mental Health and Substance Abuse, World Health Organization, Geneva, Switzerland**

**Background:** There exists a significant gap in the availability and access to early intervention in ASD across low and middle-income countries(LMICs). Training non-professionals to facilitate evidence-based parent-mediated interventions that are culturally acceptable, accessible and diagnosis-agnostic to circumvent challenges in early detection and affiliate stigma, can bridge the service gap. The World Health Organization-Caregivers Skills Training program(WHO-CST), which meets these criteria, is undergoing various field-testing stages in over 35 countries.

**Objectives:** To report on the acceptability, feasibility and initial efficacy of the WHO-CST pilot program delivered by non-specialist facilitators in Mumbai, India.

**Methods:** The WHO-CST program was translated into Hindi and adapted to the local context, based on feedback from various stakeholder groups. Master-Trainers trained in the intervention, in turn, trained non-specialist facilitators to deliver CST at two sites in Mumbai. 22 primary caregivers (parents) of children with communication delays (ASD=20 and non-ASD=2) volunteered to participate in a quasi-experimental pre-post study. The intervention consisted of nine center-based group-sessions and three individualized home-visits per family. The content based on naturalistic-developmental-behavioral and positive behavior support principles included sessions on building engagement, communication, daily living activities, addressing challenging behaviors, and enhancing parental well-being.

A mixed-methods explanatory design was used to evaluate program acceptability, feasibility and efficacy. Quantitative metrics of feasibility included caregiver attendance, fidelity, and adherence to CST strategies. Metrics of efficacy included measures of parental stress, self-efficacy and child outcomes in social-communication skills, collected at baseline and completion of intervention. Pre-post change was assessed using Wilcoxon signed-rank test. Program acceptability, feasibility and effectiveness were also assessed using focus groups with caregivers. Data from the qualitative data were transcribed and analyzed by two independent coders using principles of inductive thematic analysis.

Results: The program was found to be feasible. All caregivers who enrolled completed the program. Caregiver fidelity scores increased from baseline (Md= 0.57) to end of intervention (Md= 2.58),  $z = -3.05$ ,  $p < 0.01$ ,  $r = 0.65$ . Parents engaged with their children for an average of 4.29 times a week during the program, the average duration of engagement per session being 10-15 minutes. On metrics of efficacy, parent showed significant improvement in levels of self-reported distress on the PSI-SF ( $z = -2.42$ ,  $p < 0.05$ ,  $r = 0.51$ ). Child social-communication outcomes as measured on the Social-Communication Checklist also showed significant improvement ( $z = 3.66$ ,  $p < 0.001$ ,  $r = 0.78$ ).

The findings from the quantitative data were supported by data from qualitative interviews. Parents found multiple aspects of the program helpful and feasible, including didactics, demonstrations, peer-discussions, and home-visits. Parents reported *new learnings* from participating in the program, such as understanding child's level of functioning, setting appropriate goals, and learning new strategies that led to *changes in parenting style* (more child-led, focus on play routines and ADLs), improvement in *self-efficacy*, and *changes in children's developmental skills* (language, engagement, behaviors, independence). Further, parents perceived an overall *positive impact* (stress reduction and well-being).

Conclusions: The WHO-CST intervention was found acceptable and feasible, with both content and process considered relevant and effective by caregivers who participated in the pilot in India. Further studies are warranted to evaluate impact at scale

**425.005 (Poster)** Adaptation of a Parent Mediated Communication Intervention for Autism for Virtual Delivery in Response to the Pandemic Lockdown, in New Delhi, India

**S. Lakhera<sup>a</sup>**, S. Guha Roy<sup>a</sup>, L. Naithani<sup>a</sup>, P. Sangwan<sup>a</sup>, Z. Azar<sup>a</sup>, S. Menon<sup>a</sup>, V. Patel<sup>b</sup>, V. Vajaratkar<sup>c</sup>, C. A. Taylor<sup>d</sup>, J. Green<sup>e</sup> and G. Divan<sup>f</sup>, (1)Sangath, New Delhi, India, (2)Department of Global Health and Social Medicine, Harvard Medical School, Boston, MA, (3)University of Manchester, Manchester, United Kingdom, (4)University of Manchester, Manchester, United Kingdom of Great Britain and Northern Ireland, (5)Child Development Group, Sangath, New Delhi, India

Background: The unexpected outbreak of COVID-19 pandemic led to the complete restriction on movement as the response by the government of India. As a result, the home based delivery of a social-communication parent mediated intervention for children with autism, PASS Plus, delivered through non-specialist counsellors, being delivered in the Communication-centered Parent mediated intervention for Autism Spectrum Disorders in South Asia (COMPASS) trial was also suspended. For providing continued intervention services to the families, PASS Plus was adapted for remote delivery through virtual sessions on practice cases with a view to re-establishing delivery in the trial.

Objectives: In the present study we describe the adaptation of PASS Plus for virtual delivery and the barriers and facilitators impacting its acceptability and feasibility.

Methods: The experiences of virtual delivery across 50 cases are described. Two thirds of the parent-child dyads (n=34) were already engaged through home based, face-to-face delivery while others were recruited after establishment of movement restrictions (n=16); these latter families received complete virtual delivery. Verbal consent was requested for virtual delivery from all 50 cases. The steps of adaptation included i) introduction of additional modules to support digital literacy for families and counsellors ii) development of virtual supervision methodologies iii) documentation of barriers and facilitators in intervention delivery by counsellors v) establishing mitigating strategies to overcome barriers .

Results: Of the total participants(n=34) receiving intervention before suspension of face to face delivery due to the COVID-19 pandemic, half of them (n=17) agreed to virtual delivery. The barriers to virtual delivery for families included i) personal reasons: for example a preference for face to face sessions (n=4), concern over misuse of video shared digitally for intervention delivery (n=1), lack of space at home (n=1) and lack of time for sessions(n=2) ii) technology related reasons: for example poor internet connectivity (n=1), absence of a smartphone (n=2) or low digital literacy for using smartphone(n=1) iii) participants not contactable (n=3) iv) Financial concern primarily of a lack of money for data services (n=2). These factors were considered when adapting the intervention for virtual delivery and approaching the new participants(n=16) for complete virtual delivery. Preparatory sessions were introduced to support building digital skills of families around the use of smartphones. The barriers faced by counsellors were mostly around technical skills(use of smartphone and apps) that were supported via enhanced training.

Conclusions: Our experience suggests that virtual delivery of a home delivery based, communication-centered and parent-mediated intervention for children with autism can be successfully achieved through adaptation considering the service provider and user barriers. Training and support for building digital skills of the non-specialist counsellors can also add to effectiveness of the virtual intervention delivery. We have observed that not being able to reach out to families with restricted digital access is a major drawback of virtual sessions, which extends the digital divide for already vulnerable families.

**425.006 (Poster)** Assessing Autism Knowledge and Stigma across the Global Landscape Using the ASK-Q  
*A. J. Harrison<sup>1</sup>, A. de Bildt<sup>2</sup>, L. Yu<sup>3</sup>, N. Naqvi<sup>4</sup>, A. K. Smir<sup>5</sup>, H. Low<sup>6</sup>, C. Yang<sup>7</sup> and S. Saade<sup>8</sup>, (1)Educational Psychology, University of Georgia, Athens, GA, (2)Department of Child and Adolescent Psychiatry, University Medical Center Groningen, University of Groningen, Groningen, Netherlands, (3)School of Psychology, South China Normal University, Guangzhou, China, (4)Iona College, New Rochelle, NY, (5)Accare Child and Adolescent Psychiatry or University of Groningen, Groningen, Netherlands, (6)Universiti Sains Malaysia, Penang, Malaysia, (7)East China Normal University, Shanghai, China, (8)Psychology, Université du Québec à Montréal, Montreal, QC, Canada*

---

### **Background:**

Substantial variability exists with regard to ASD service provision around the world. Providing more equitable care for all individuals with ASD is an important emerging public health concern. Service disparities observed in many low- and middle-income countries may be driven, in part, by limited knowledge of ASD; however, measurement limitations have made it difficult to quantify autism knowledge across countries. As a result, the autism stigma and knowledge questionnaire (ASK-Q) was developed as a cross-culturally sensitive, comprehensive assessment tool to measure the nature and extent of ASD knowledge. This instrument has been requested for use in 26 countries, but limited information exists about measure performance across regions and patterns of knowledge variability across countries and demographic groups.

**Objectives:** The current study aims to first examine whether the autism stigma and knowledge questionnaire (ASK-Q), is suitable for use across the global contexts by examining the basic psychometric properties of the instruments in a large, trans-continental sample. The secondary aim of this study is to use one common measure (ASK-Q) to quantify different patterns of autism knowledge and stigma across different countries and demographics.

**Methods:** The current study compiled data from 4207 participants collected using adapted versions of the ASK-Q administered in seven different countries (China, Canada, Tanzania, France, the United Kingdom, the Netherlands, and Romania), representing four different continents. The ASK-Q is a 49-item questionnaire, with dichotomous (agree/disagree) response options. The measure is comprised of 3 knowledge subdomains (Etiology, Diagnosis, Treatment) and a stigma subscale that contains items also loading onto one of the knowledge domains. Participating research sites also included some demographic data about participants including gender, role in participating in study, occupation, age, and education level.

### **Results:**

In spite of the measure being administered in five different languages, the ASK-Q demonstrated strong overall internal reliability ( $\alpha = .91$ ). The measure subscales had more variability in terms of internal consistency: Etiology subscale  $\alpha = .79$ , Treatment subscale  $\alpha = .64$ , Diagnosis subscale  $\alpha = .79$ , and Stigma subscale  $\alpha = .60$ ). The examination of cross-country differences in autism knowledge revealed a significant difference in total knowledge scores,  $F(4052) = 325.90, p < .0001$ . Post hoc results revealed that significantly higher knowledge levels in French Canada compared to most of the other examined countries (UK, France, China, the Netherlands). Conversely, participants in China demonstrated significantly less overall knowledge compared to all other countries assessed.

### **Conclusions:**

Results reveal that the total ASK-Q score demonstrates strong internal consistency across countries and identifies meaningful differences in knowledge across countries. Although, ASK-Q subscales followed similar cross-country trends to the overall score and will be examined in more detail in the conference proceeding, scale subdomains do not perform reliably across cultural contexts. This indicates the need for an item level analysis of the measure and perhaps minor revision to ensure psychometric strength across countries. Follow up analyses will also include data from Laos and Lithuania and will control for occupation and other sociodemographic variables to better understand patterns of autism knowledge.

**425.007 (Poster)** Autistic Identity and the Experience of Disability: Related Concepts with Various Meanings  
*I. Courcy<sup>1</sup>, N. Jeanneret<sup>2</sup>, V. Caron<sup>2</sup>, A. M. Nader<sup>1</sup>, M. Giroux<sup>2</sup>, L. Guerrero<sup>2</sup>, M. Ouimet<sup>2</sup>, B. Forgeot d'Arc<sup>1</sup> and I. Soulieres<sup>2</sup>, (1)Département de Sociologie, Université du Québec à Montréal, Montréal, QC, Canada, (2)CIUSSS Nord-de-l'Île-de-Montréal,*

Montréal, QC, Canada, (3)Département de Psychologie, Université du Québec à Montréal, Montréal, QC, Canada, (4)Département de Psychiatrie, Université de Montréal, Montréal, QC, Canada, (5)Aut'Créatifs, Montréal, QC, Canada, (6)Neurodiversité, Montréal, QC, Canada

---

Background: Identity refers to the way an individual sees themselves and is perceived by others with regard to their characteristics (personal identity) and those they share with the groups to which they belong (social identity). The Neurodiversity and Disability rights movements can offer conceptual tools to represent oneself, advocate for more social justice and create a sense of belonging in these communities. However, not all autistic people identify with them.

Objectives: Analyze the use and the meanings related to autistic and disability identities according to autistic individuals.

Methods: 460 adults (18-74 years old,  $\mu=35.5$  SD=11.6) from France, Belgium, Switzerland, Senegal and Quebec (Canada) were joined *via* an online questionnaire. A majority had received a diagnosis of autism (69%) and 31% were self-diagnosed. Gender identity: female (58%), male (22%), other identities (e.g. autigender, genderqueer, neurogender, trans, xenogender) (22%).

They were asked: “*Is autism an aspect of your identity?*” and “*Do you consider yourself disabled or having disabilities?*”. Respondents had to choose among multiple answers and specify in their own words. A qualitative content analysis was performed to identify emerging categories and compare the coders’ interpretations. We had parity between autistic and non-autistic coders.

Results: Autism is a part of identity for the majority, with importance ranging from “a lot” (43%) to “extremely” (32%). Considering autism as part of one’s identity (in varying degrees) did not differ significantly by country, age, gender or (self-)diagnosis. Ten categories about autism were identified: “an integral part of who I am”, “only part of my identity among others”, “a neurological functioning”, “explains my ways of acting or behaving”, “a strength”, “associated to difficulties in my life”, “I use camouflage to hide my true self”, “diagnosis makes sense of my impression of alienation in the social world”, “the prism through which I experience the world”, “associated to a community”.

Regarding disability, 27% consider themselves disabled and one in five did “not know”. Men (44%), participants from Quebec (52%) and those for whom autism is not part of their identity or to a lesser extent (60%) are more likely to not consider themselves disabled compared to others ( $p < .001$ ). Twelve ideas about the experience of disability were identified: “it’s invisible”, “depends on the person’s autonomy”, “I have also a health problem or a chronic disease”, “my hypersensitivities are a disability”, “I had difficulties in relationships or social situations”, “sometimes I feel disabled, sometimes not”, “a social disadvantage in terms of employment and economic security”, “society and environment are not adapted to me”, “I experience discrimination”, “I deviate from normalcy in my ways of being, behaving or moving”, “I adapt, pretend, have strategies”, “an administrative category”.

Conclusions: Identity is a complex and multifaceted process. This study shows that autistic identity and experience of disability are mobilized to varying degrees and with various meanings at the intersection with other affiliations such as gender. Clinicians and stakeholders must be sensitive to the diversity of identities and their cultural meanings within the autistic community and not consider autism as a monolithic identifier.

**425.008** (Poster) Behavioral Treatment and Response Intervention Received By Children with Autism in Ethiopia  
*W. A. Zeleke, Counseling, Psychology and Special Education, Duquesne University, Pittsburgh, PA*

---

Background: Although autism spectrum disorders (ASDs) are a global occurrence, information on provision of services, and effectiveness of treatments in Ethiopia is scant. It is well-documented in the literature that early identification coupled with access to mental health, behavioral, and educational intervention services for children with ASDs are crucial to promoting child development and quality of life. As in most developing countries, educational materials regarding the type of intervention required for children with autism in Ethiopia are still underdeveloped. Specifically, there is no documentation regarding the use of standardized diagnostic instruments, how autism interventions are selected and implemented, or whether well-researched evidence-based educational curriculum and behavioral protocols designed for children with autism are used. Given the few studies directly or relatedly documenting autism intervention and its effectiveness in Ethiopia, the results from this study can help to establish a culturally-competent response to intervention procedure manual for assessing treatment outcomes and promotion of evidence-based practices in Ethiopia.

Objectives: This study aimed to examine the effectiveness of behavioral treatment and outcome response to intervention received by children with autism in Ethiopia.

**Methods:** This mixed method study used both qualitative and quantitative approach to collect data. Data were collected from the two primary organizations that provide services to children with autism (n=120) in the capital city, addressing the following questions: (a) What behavioral treatments are used? (b) Under what conditions are they effective? (c) What intervention responses/outcomes are considered most effective in the Ethiopian context?

**Results:** Even though most children enrolled in these centers don't have a formal diagnosis, 90.01% of them had SCQ scores above the clinical cutoff, which is the score recommended for distinguishing pervasive developmental disorder from other psychiatric disorders in children. No significant difference found in the "autism- positive" response rate between male and female students. The qualitative analysis result shows that participant centers have an existing practice of assessment to effective intervention, which starts from the process of intervention selection and development. Interventions are designed to influence symptoms, in this case, communication, social, emotional, and behavioral symptoms experienced by children with ASDs. The identification and utilization of interventions are informed by existing research and literature but are shaped more by the cultural context and by intuitive approaches to providing services for children with ASDs. Neither center is following a specific intervention response manual, and that there is no written guideline or manual related to assessing the outcomes of intervention. There is clearly a need for such guidelines, particularly written in the local languages. However, the interview and FGD results show that they already have a process and procedure that seems easily fit to the response to intervention framework (RTI).

**Conclusions:** Teacher-training colleges and institutions of higher education in the developing world should be supported in their efforts to provide sufficient training for individuals entering these fields, so that children with ASDs and other special needs can be served in humane and adequate ways that foster their optimal development.

**425.010 (Poster)** Characterizing the Diagnosis and Service Odyssey in Texas: Results from a Needs Assessment Survey  
*S. Vanegas<sup>1</sup>, S. Magaña<sup>2</sup> and W. Zeng<sup>2</sup>, (1)School of Social Work, Texas State University, San Marcos, TX, (2)Steve Hicks School of Social Work, University of Texas at Austin, Austin, TX*

---

**Background:** Understanding the experience of ASD across diverse families is essential as it helps shape the advancement of education and health care systems and policies. However, research suggests that the experience of ASD can be highly dependent on the context and environment in which the child and family reside (Fountain et al., 2011). Texas is a diverse state, comprised of over 50% of racial/ethnic minorities. Yet, little is known about the journey individuals with ASD and their families undergo to access diagnostic assessments, services, and supports in Texas. A needs assessment survey was conducted in Texas to capture and understand the experience of ASD in Texas.

**Objectives:** The current study's objectives were to investigate the status of ASD diagnostic and treatment services and supports in Texas to identify critical areas for community engagement, research focus, and service development.

**Methods:** A survey was created and disseminated across Texas, United States, to understand the barriers, challenges, and experiences of diverse families of children with ASD. The survey included closed- and open-ended questions directed to parents or primary caregivers of children and youth with ASD (Age 0 to 22 years). The survey was available online (Qualtrics) and available in paper format with postage-paid envelopes for return to the researchers. The surveys were available in English and Spanish. The survey was distributed across community events, parent support groups, clinical service providers, and online research directories. In this study, we present data for completed surveys ( $n = 144$ ).

**Results:** The sample reflects the experience of primarily White (40.3%) and Latino (40.3%) families. On average, families reported 2.43 years between parents' first concern to the age when their child received an ASD diagnosis. A linear regression analysis was conducted to identify significant factors in a child's first ASD diagnosis. Factors included in the model were the child's race/ethnicity, ASD severity, age of first concern, age when reporting concerns, the number of professionals visited prior to a diagnosis, parent nativity, parent education, and household income. The linear regression model was significant,  $R^2 = 0.50$ ,  $F(8, 119) = 14.85$ ,  $p < .001$ . Further inspection identified ASD severity ( $p = .035$ ) and the age when reporting concerns ( $p < .001$ ) as significant predictors in the model. These results suggest that children with greater support needs and earlier engagement with a health professional about developmental concerns have a younger age of ASD diagnosis. Additional analyses will examine child, family, and community-level demographic characteristics on the professional responses with an ASD diagnosis, community views of ASD, and ASD treatments and services.

**Conclusions:** The needs assessment survey results highlight the importance of parents and primary caregivers in sharing their concerns with health care professionals. Additional analyses will identify other key areas to target in developing research and service projects to alleviate disparities in access to diagnosis, treatments, and support for all Texas families. This model can be adapted for other communities to ensure that researchers and providers are responsive to the community.

**425.011 (Poster)** Comparison of Familial and General Public' Autism Knowledge and Stigma: Building Family Foundation for Autism Advocacy in China

*B. Lai, X. Mao, X. Chen and L. Yu, School of Psychology, South China Normal University, Guangzhou, China*

---

**Background:** Service provision for autistic individuals in China has been historically underdeveloped, despite the overall economic and societal growth of this country. One of the barriers to diagnosis, intervention and education opportunities that has been identified is the widespread misconceptions and high stigma about autism in the general public assessed by the ASK-Q (Yu et al., 2020). This finding highlighted the need for not only policy-level measures but also community-level experts and advocates for disseminating autism science and eliminating stigma.

**Objectives:** The current study utilized the standardized ASK-Q instrument to compare autism knowledge and stigma between family members living with autism and non-family members in the public in China. The aim was to investigate whether family members have greater scientific understanding of autism relative to the general public, a pattern seen with parents of children with other neurodevelopmental disorders (e.g., ADHD; West et al., 2005). The results were expected to recognize family members as candidates to effectively penetrate the public in raising awareness and advocacy.

**Methods:** A nation-wide survey was conducted online with 1,251 participants in China (mean age = 32 years, range = 18 ~ 88 years) including 200 family members of autistic individuals and 1051 non-family members. Cutoff scores for knowledge adequacy and stigma rejection (>13 for diagnosis/symptoms, >10 for etiology, >10 for treatment, and >4 for not endorsing stigma) were used to obtain the numbers of individuals with higher and lower knowledge in each category within each group. Chi-squared tests were performed to evaluate the degree of knowledge gap between- and within-group.

**Results:** The participants who responded as having familial relations with autistic people included first-degree (parents, sibling) and second-degree (cousins, uncles) relatives. The family members as a group demonstrated significantly higher autism knowledge than the general public in all categories (disagnosis,  $\chi^2=38.275, p<0.001$ ; etiology,  $\chi^2=61.517, p<0.001$ ; treatment,  $\chi^2=47.558, p<0.001$ ) and lower stigma (stigma,  $\chi^2=69.449, p<0.001$ ). The percentages of adequate knowledge were 85.5%, 93.5%, and 84.5% in the family group, and 37.1%, 65.84%, and 58.8% in the non-family public. Only 11% of family members indicated autism stigma endorsement whereas 42.1% of nonfamily did so. Nonfamily females had significantly higher knowledge and lower stigma than nonfamily males ( $p<0.001$ ), while there was no gender disparity within family members.

**Conclusions:** The current study directly compared family members living with autism against the general public and provided new information for the construct and demographics of the societal misconceptions and stigma beliefs about autism in China. The results indicated drastic disparities between the two groups that family members of autistic individuals have unequivocal knowledge advantages over the lay community. The pattern suggested considerable improvement in autism awareness among families, whereas the extremely low knowledge in the lay community remain profound barriers to service scale expansion and quality improvement. We emphasize that families living with autism should take advantage of their roles as both community participants and knowledge experts to actively facilitate autism science flow to the lay community and advocate for systematic changes of autism service and integration in China.

**425.012 (Poster)** Cross-Cultural Adaptation and Psychometric Properties of Participatory Autism Stigma and Knowledge Scales for Use in Brazil

*A. Gabriela Rocha Araujo<sup>1</sup>, R. Zanon<sup>2</sup>, M. Aparecida da Silva<sup>1</sup> and K. Gillespie-Lynch<sup>3</sup>, (1)Federal University of São João del-Rei, São João del-Rei, Brazil, (2)Federal University of Rio Grande do Sul, Porto Alegre, Brazil, (3)Department of Psychology, College of Staten Island; CUNY Graduate Center, Brooklyn, NY*

---

**Background:** In Brazil, people with Autism Spectrum Disorder (ASD) have some laws that promote their inclusion in basic and superior education (Lei nº 12.764/2012; Lei nº 9.394/1996; Lei nº 13.146/ 2015). Due to these laws, ASD is the third most common disability among students enrolled in primary schools and the fourth most common among students in college in Brazil (Instituto Nacional de Estudos e Pesquisas Educacionais Anísio Teixeira [INEP], 2019). The country frames inclusion as one way all students can experience basic rights of education without discrimination. But, neurotypical people sometimes do not understand some behaviors associated with autism and can demonstrate stigma toward people with ASD. Some studies show that when knowledge about ASD increases, the level of stigma decreases (Allport, 1954; Foster & Hill, 2018). In Brazil, we do not have any available instrument to evaluate stigma about autism, and instruments measuring knowledge are scarce (Nunes, Souza, & Giunco, 2009; Penido et al. 2016), and do not include autistic people in their development.

**Objectives:** The aim of this research was to cross-culturally adapt and to investigate the psychometric properties of a Participatory Autism Knowledge Scale and a Participatory Stigma Scale, both developed in collaboration with autistic students and scholars.

**Methods:** The adaptation of both scales followed recommendations in the literature (Borsa, Damásio, & Bandeira), following six steps: 1) translation and cross-cultural adaptation; 2) synthesis of versions; 3) evaluation by judges in Brazil (one with expertise in psychometrics, 1 autistic person, and 13 university students); 4) back-translation; 5) feedback from one of the original authors of the scales and 6) pilot-study (9 university students). Several items were modified during the scales' adaptation process, which became known as Escala de Atitudes em Relação à Pessoa com Autismo (EARPA) e Escala de Conhecimento para uso no Autismo (ECAT). This psychometric study was performed after the adaptation process and had 532 Brazilian participants. They were mostly college students (81.4%,  $n=433$ ) and females (74.6%,  $n=397$ ).

**Results:** Results show that EARPA is a unidimensional instrument while ECAT has a multidimensional structure. Moreover, preliminary results indicate that the stigma scale has very satisfactory fit indexes ( $\chi^2 = 1873.75$ ,  $df = 36$ ;  $p < 0.001$ ; RMSEA = 0.078; CFI = 0.968; TLI = 0.957) and that the items presented adequate factorial loadings. The factor's composite reliability, as well as the McDonald's Omega, were also adequate, indicating the instrument's accuracy. For ECAT, fit indexes were also satisfactory for a four-dimension structure ( $\chi^2 = 577.06$ ;  $df = 249$ ;  $p = 0.000$ ; RMSEA = 0.051; CFI = 0.966; TLI = 0.952), with almost all items having satisfactory factorial loadings with the dimensions. The factor's composite reliability was satisfactory ( $> 0.70$ ) for three of the dimensions.

**Conclusions:** The inclusion of several steps in the cross-cultural adaptation process accumulates evidence of content validity and internal consistency for both scales in the Brazilian context. The instruments show suitability to Brazilian samples and could be used in the future for evaluating and improving stigma and knowledge in different cultural contexts.

**425.013 (Poster)** Cross-Cultural Adaptation of Routine Autism and Developmental Scoring Measures: A Feasibility Study from a South-African Cohort

**P. E. Springer<sup>1</sup>**, E. Loth<sup>2</sup>, M. Potter<sup>3</sup>, W. L. Mackay<sup>3</sup>, P. Smit<sup>3</sup>, H. J. Odendaal<sup>4</sup> and D. Murphy<sup>2</sup>, (1)Department of Paediatrics and Child Health, Stellenbosch University, Cape Town, South Africa, (2)Department of Forensic and Neurodevelopmental Sciences, Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, United Kingdom, (3)Stellenbosch University, Cape Town, South Africa, (4)Department of Obstetrics and Gynaecology, Stellenbosch University, Cape Town, South Africa

**Background:** Research into specific biomarkers for autism spectrum disorders (ASD) in Africa is limited. The Biomarkers of Neurodevelopmental Outcome (BONO) study aims to validate early 'risk' or 'stratification' markers for ASD that are currently identified in Western European cohorts. However many assessment measures have not been validated in low- and middle-income countries. We plan to follow up 4500 school-aged children from two lower socioeconomic residential areas in Cape Town, South Africa, whose mothers were enrolled antenatally in the Safe Passage Study. Participants will undergo broad (screening) and deep phenotyping to detect autism symptoms, cognitive development, and emotional and behavioural difficulties. We report the results of the feasibility study that was implemented to allow for careful consideration of cultural and socioeconomic diversity when selecting measures, so as to prevent bias.

**Objectives:** The aims of the feasibility study were to ascertain comprehensibility, suitability and cultural appropriateness of assessment measures.

**Methods:** One hundred children aged 4-12 years were recruited from March to October 2019. Measures included the Social Communication Questionnaire (SCQ), Childhood Autism Rating Scales (CARS), Strengths and Difficulties Questionnaire (SDQ), and selected subscales of the Mullen Scales of Early Learning (MSEL) and Wechsler Abbreviated Scales of Intelligence-3rd edition (WASI). Questionnaires were translated into Afrikaans, and we applied recommended cut-off scores. We ascertained comprehensibility, suitability and cultural appropriateness of all measures and tested symptom frequency in the cohort.

**Results:**

The SCQ and CARS results showed a similar distribution. The frequency of children who scored around cut-off was comparable with Western studies. The same two children performed above cut-off on both measures. Both questionnaires were well understood although some caregivers over-reported on specific items.

The SDQ was well received although the frequency of emotional, social, conduct and hyperkinetic symptoms was elevated with 19.6% of children having an SDQ total score classified as "abnormal", 18.4% "borderline" with 62% in the "normal" range.

The MSEL results were skewed towards low performance. The majority of children performed below age expectations, with approximately a third having severe difficulties. For the receptive language subscale, only 9% scored within the average range, 46.3% were below average, and 34.1% scored very low. In contrast to the MSEL, the WASI verbal (VIQ) and performance

subscales, including full-scale (IQ) estimates, were normally distributed. However, VIQ and full-scale IQ scores were shifted approximately 25 points and 17 points respectively below Western IQ distributions.

**Conclusions:** The findings of the feasibility study justified some practical adjustment to the protocol. We adjusted for over-reporting on the SCQ and CARS by reassuring caregivers that we expected a negative response for most questions. We hypothesised that lack of learning opportunities, cultural and psychosocial factors may have affected performance on MSEL and WASI assessments. We therefore added the Vinelands Adaptive Behaviour Scales-3 to provide more relevant information on the child's everyday functioning and social interaction. Minor changes included word substitutions with colloquial versions, but no further adaptations were made. In conclusion, a feasibility study is vital to inform research design when using standardized Western instruments in a different sociocultural context.

**425.014 (Poster)** Determining Future Directions for Parent Education & Training Programmes in Autism Spectrum Disorder  
**J. J. S. Dawson-Squibb<sup>1</sup>** and **P. J. de Vries<sup>2</sup>**, (1)Division of Child & Adolescent Psychiatry, University of Cape Town, Cape Town, South Africa, (2)Centre for Autism Research in Africa, Division of Child & Adolescent Psychiatry, University of Cape Town, Cape Town, South Africa

---

**Background:**

The World Health Organization has recognised Autism Spectrum Disorder (ASD) as a public health concern and have recommended access to appropriate assessment and interventions. Psychoeducation and parent support soon after diagnosis are considered global best practice. Parent Education & Training (PET) programmes provide education, skills and support to parents. Despite the high need for PET there has been limited research in this field and few programmes are available, particularly in low- and middle-income countries (LMIC).

**Objectives:**

To determine future directions for Parent Education & Training programmes in low-resource environments by 1) evaluating the broader evidence-base of PET; 2) conducting a comparative feasibility study of two PET programme in South Africa.

**Methods:**

A scoping review of all peer-reviewed publications outside the USA was conducted. Two reviewers independently searched seven key databases for titles and abstracts. Four reviewers extracted data with a focus on descriptive characteristics of PET programmes, research methodologies and implementation factors. A mixed-methods quality appraisal of publications was performed. A comparative feasibility study of two PET programmes in a low resource setting was also conducted. EarlyBird/EarlyBird Plus (EB/EBP), a UK developed 12-week programme was compared to Autism Cares (AC), a locally developed 5-day programme. A mixed method, quasi-experimental design was used to collect pre, post, and 3-month follow-up data. Measures included standardised and custom-designed quantitative outcome measures and qualitative semi-structured interview data. A multi-stakeholder group used an ASD PET evaluation framework to compare the programmes.

**Results:**

A total of 37 publications were found in the scoping review. These described a highly diverse range of PET programmes across 20 countries. Programmes varied significantly in their goals, modalities and length. A broad range of outcomes measures were used. Quality appraisal rated only 27% of studies to have met all the methodological quality criteria. Factors relevant to implementation such as manualisation, fidelity and cost were commented on infrequently.

In the comparative feasibility study eighteen parents participated in the EB/EBP programmes and eleven in Autism Cares. Strong parental acceptability for both programmes was found along with the need for some adaptations to the local context. Limited efficacy testing showed positive changes for parental stress, knowledge of ASD and changes in child, more so for EB/EBP. The multi-stakeholder group judged EB/EBP as most suitable for next-step research citing factors relating to implementation including scalability and sustainability.

**Conclusions:**

Our findings contributed to the limited evidence-base for ASD PET in low-resource environments and highlighted the need for global collaboration in this area. We propose the following five recommendations for future directions of PET programmes: 1)

expansion of local PET research in different settings; 2) creation of standardised outcomes for PET through involvement of global stakeholders; 3) dissemination of PET findings and lobbying of potential funders; 4) setting up of a global PET network; 5) caution around implementation of PET programme without a robust evidence-base that includes intervention outcomes as well as implementation outcome data.

**425.015** (Poster) Developing a Cost of Illness Inventory Questionnaire for Children with Autism in India

**D. Chaudhary<sup>1</sup>, G. Shields<sup>2</sup>, B. Bhat<sup>3</sup>, T. Verghis<sup>3</sup>, R. Roy<sup>4</sup>, D. Kumar<sup>4</sup>, M. Kakra<sup>4</sup>, V. Vajaratkar<sup>4</sup>, G. Lall<sup>5</sup>, S. Pandey<sup>4</sup>, S. Johri<sup>1</sup>, S. Gulati<sup>1</sup>, M. Juneja<sup>3</sup>, J. Green<sup>6</sup>, L. Davies<sup>2</sup> and G. Divan<sup>7</sup>.** (1)Sangath, New Delhi, India, (2)University of Manchester, Manchester, United Kingdom, (3)Sangath, Goa, India, (4)Centre of Excellence and Advanced Research for Childhood Neurodevelopmental Disorders, Child Neurology Division, Department of Pediatrics, All India Institute of Medical Sciences, New Delhi, India, (5)Maulana Azad Medical College, New Delhi, India, (6)University of Manchester, Manchester, United Kingdom of Great Britain and Northern Ireland, (7)Child Development Group, Sangath, New Delhi, India

---

Background:

The economic burden of autism is likely to be substantial; with costs attributed to healthcare, education, productivity losses, informal care and respite care, as well as others. In India, approximately, 2 million children aged 2-9 years have autism. Despite this, there is currently limited evidence on the cost of illness in India. Given the economic costs of autism determined in high income contexts, there is a need to understand these costs to inform the identification of effective and cost-effective interventions. The Communication-centred Parent-mediated treatment for Autism Spectrum disorder in South Asia (COMPASS) project is conducting a randomized controlled trial, to evaluate the effectiveness and cost-effectiveness of a parent-mediated intervention for autism in New Delhi, India [ISRCTN ID: 21454676].

Objectives:

This research aimed to produce a comprehensive cost of illness inventory (COII) suitable for children with autism in South Asia (India).

Methods:

A structured and iterative design process was followed including literature reviews, interviews with caregivers, pilot testing and translation. The first stage of development included in-depth caregiver interviews (n=15), literature reviews and a desk review of existing tools from other settings. This allowed the first draft version of the COII to be developed. Across the development of the COII thirty-two families were involved in the design and piloting of the tool; the majority (88%) of these families had a child with autism. Prior to pilot testing the COII was forward translated (from English to Hindi) and back translated. Each stage of the process of development of the COMPASS COII resulted in the further refinement of the tool.

Results:

COII development took place from November 2018 to October 2019. Pretesting was conducted with four families, and the first draft developing from this process was administered to six families. Iterative modifications resulted in a second draft, which was tested on twelve families and finalised. The final COII is hosted by REDCap Cloud and is a bilingual instrument (Hindi and English). Domains covered in the COII include education, childcare, relocation, healthcare contacts (outpatient, inpatient, medical emergencies, investigations and medication), religious retreats and rituals, specialist equipment's, workshops and training, special diet, support and care, certification, occupational adjustments and government rebates/schemes. Contextual complementary health approaches are also captured. Though it is very comprehensive, administration and completion of the COII was determined to be feasible, with it taking around 35 minutes to complete by trained researchers.

Conclusions:

The COMPASS COII was developed using experiences gathered from an iterative process in a metropolitan area within the context of one low- and middle-income country setting, India. Compared to COII tools used for children with autism in high-income country settings, additional domains were required, such as complimentary medication (homeopathy) and the need to record out-of-pocket expenses in a system with a virtual absence of health insurance coverage. The COII will allow future research to define the cost of illness of autism in India and will support relevant economic evaluations. Understanding the process of developing the questionnaire will help researchers working in LMICs.

**425.016** (Poster) Development of Attention Control in Autism: Results from a Community-Based Project in Delhi, India

**G. Lockwood Estrin<sup>1</sup>, L. Mason<sup>2</sup>, R. Arora<sup>3</sup>, S. Bhavnani<sup>3</sup>, J. Dasgupta<sup>3</sup>, G. Divan<sup>3</sup>, S. Gulati<sup>4</sup>, V. Patel<sup>5</sup>, T. Johnson<sup>2</sup>,** (1)Centre for Brain and Cognitive Development, Birkbeck University of London, London, United Kingdom, (2)Centre for Brain and Cognitive Development, Birkbeck, University of London, London, United Kingdom, (3)Child Development Group, Sangath, New Delhi, India, (4)Centre of Excellence and Advanced Research for Childhood Neurodevelopmental Disorders, Child Neurology Division, Department of Pediatrics, All India Institute of Medical Sciences, New Delhi, India, (5)Department of Global Health and Social Medicine, Harvard Medical School, Boston, MA

---

#### Background:

The ability to inhibit and flexibly shift visual attention develops across early childhood. Alterations in its development have been implicated in Autism Spectrum Disorder (ASD); reduced inhibitory control has been found in autistic compared to neurotypical groups. The antisaccade task has been used to measure attention control, and to assess a child's ability to learn to inhibit and anticipate saccades related to visual cues, both within and between blocks of trials.

However, the majority of our knowledge of attention control results from samples in high-income countries (HICs). We need to expand our research to investigate abilities in children beyond these limited settings, and specifically in low and middle income countries (LMICs). This is particularly important because socioeconomic factors are associated with the development of children's executive functioning.

To make such research accessible to different populations, we need to conduct this work within the community, close to people's home or to their health facility. Eye-tracking technology offers an advantage over other methods, due to its availability of relatively low-cost and portable devices, as well providing objective markers.

#### Objectives:

We aimed to assess attention control and learning using eye-tracking in children aged 3-5 years with and without ASD in a community LMIC setting, specifically New Delhi, India.

#### Methods:

Three groups of children were assessed within community or healthcare facility settings in the Delhi/NCR region, India: children meeting their developmental milestones (NT), children with a diagnosis of Autism Spectrum Disorder (ASD), and children with a diagnosis of Intellectual Disability (ID). Data was analysed from 104 participants (n=32 NT group; n=46 ASD group; n=26 ID group). There were no differences in age at assessment between groups (mean age:  $4.42 \pm 1.17$  years). The number and latency of prosaccades (looks towards a peripheral distractor stimulus appearing on the screen) and antisaccades (an anticipatory look in the direction of the target stimulus appearing on the opposite side of the screen) were calculated offline. Generalized Estimating Equation (GEE) was utilised to analyse data.

#### Results:

Preliminary results demonstrate that the number of prosaccades decreased and antisaccades increased within and across blocks, which was indicative of children learning to inhibit saccades towards the distractor, and to anticipate looking towards the target stimulus. The clinical groups (ASD, ID) demonstrated reduced learning compared to the NT group within blocks. However, across the four blocks of trials, the ASD and ID group continued to learn at an increased rate than that of the NT group. No differences were found between the ASD and ID groups.

#### Conclusions:

These results suggest that the clinical groups may have a reduced rate of learning in the shorter term, but the learning process continues for a longer time than the NT group, although does not reach NT levels over the course of the trial. However, this task did not discriminate between the two clinical groups (ASD, ID). This study investigated attention control in pre-school children in a community LMIC setting, showing its feasibility and the need for additional research in this population.

**425.017 (Poster)** Diagnostic Process and Barriers Among Asian American Parents of Children with Autism and Other Developmental Disabilities

**I. Kim<sup>1</sup>, S. Dababnah<sup>2</sup> and Y. Wang<sup>3</sup>,** (1)School of Social Work, Tulane University, New Orleans, LA, (2)University of Maryland, Baltimore, Baltimore, MD, (3)Social of Social Work, University of Maryland, Baltimore, Baltimore, MD

---

**Background:** Early diagnosis and intervention are beneficial not only for children with autism and other developmental disabilities (DDs), but also for caregivers' well-being (Giarelli & Fisher, 2016). However, multiple studies highlight racial and ethnic disparities in DD health care and service use, including in diagnosis and early intervention (Dababnah et al., 2018; Magaña et al., 2016). Yet, while the literature focused on historically underserved communities is growing, there is little known about Asian children with DDs and their families about diagnosis.

**Objectives:** This study aims to describe how Asian American (AA) parents of children with DDs navigate services to obtain a diagnosis for their children.

**Methods:** We developed a survey that includes items about diagnostic processes and barriers. The survey was professionally translated into four languages: Korean, Japanese, Mandarin, and Vietnamese. Participants were eligible to complete the survey if they 1) lived in Maryland; 2) identified as Asian or AA; 3) and were a parent or other primary caregiver of a child 18 years or younger with autism or another DD. Between October 2019-July 2020, 73 AA parents completed the survey online and in-person. About half of the parents who participated were Chinese; the remaining participants were Korean, Indian, Japanese, Vietnamese, Filipino, or Bangladeshi. Their children had autism (58%), Attention Deficit Hyperactivity Disorder, a developmental delay, an intellectual disability, Down syndrome, or Cerebral Palsy. We used descriptive statistics to summarize our findings.

**Results:** Nearly three-fourths of the parents reported having concerns about their children's development pre-diagnosis and discussing their concerns with a healthcare professional. Respondents had early concerns (average of 28 months). In response to parents' concerns, some professionals conducted a developmental screener (32%), but notable percentages of participants reported the professional responded by telling the parent it was too early to identify developmental concerns (29%), the child's developmental was typical (17%), or the child would "grow out of it" (14%). There is an average 12-month gap between noticing developmental delays and getting a diagnosis for their child. Parents encountered many barriers to obtaining a diagnosis for their child, including trouble understanding how the healthcare system worked (62%) and stigma related to disabilities (19%). 36% of the respondents said that language interpreters were unavailable when needed and 41% reported interpreters did not help them to understand what the professionals were saying. 72% also said the diagnostic process caused family stress.

**Conclusions:** To our knowledge, this was the first study to understand diagnosis process and barriers of AA parents raising children with autism and other DDs. The majority of parents reported they trusted their providers' advice, yet experienced delays in obtaining a timely developmental evaluation. Thus, providers should listen to parents' concerns and act quickly to refer children for evaluations. In particular, providers should be aware that cultural and language barriers might make it more difficult for providers to recognize developmental delays or understand parents' concerns; or for parents to navigate the healthcare system, coordinate care, or overcome disability-related stigma.

**425.018 (Poster)** Does the Desire to Dominate People and Nature Contribute to Cross-Cultural Variations in Autism Stigma? **K. Gillespie-Lynch<sup>1</sup>, B. Bockstal Fieulaine<sup>2</sup>, S. Saade<sup>3</sup>, E. Cappe<sup>4</sup>, N. Daou<sup>5</sup>, B. Kofner<sup>6</sup>, R. Obeid<sup>7</sup>, G. Y. H. Lam<sup>8</sup> and J. MacCormack<sup>9</sup>**, (1)Department of Psychology, College of Staten Island; CUNY Graduate Center, Brooklyn, NY, (2)Département de Psychologie, Université Reims Champagne Ardenne, Reims, France, (3)Psychology, Université du Québec à Montréal, Montreal, QC, Canada, (4)Université de Paris, Boulogne-Billancourt, France, (5)McNeese State University, Lake Charles, LA, (6)CUNY, NY, NY, (7)Department of Psychological Sciences, Case Western Reserve University, New York, NY, (8)Department of Educational and Psychological Studies, University of South Florida, Tampa, FL, (9)University of Lethbridge, Lethbridge, AB, Canada

**Background:** Stigma reduces the well-being of autistic people (Robertson, 2010). Given that stigma arises when an individual "falls short" of culturally-defined norms (Goffman, 1963), it is not surprising that autism stigma varies across cultures (Obeid et al., 2015). Heightened acceptance of inequality and racism are associated with autism stigma (Gillespie-Lynch et al., 2019; Obeid et al., 2020). Stigma may reflect a general desire to dominate; autism stigma (lacking appreciation for neurodiversity) may be intertwined with seeking to dominate nature (lacking appreciation for biodiversity). Indeed, the term neurodiversity was inspired by the desire to expand biodiversity to include neurological diversity (Singer 2017).

**Objectives:** To identify factors that contribute to autism stigma in three multicultural countries: the US, with high levels of autism resources but access inequalities (apparent across countries), Lebanon, with very limited resources, and France, where questionable autism interventions, such as psychoanalysis or "packing" are more common. We hypothesized that stigma would be higher in Lebanon and France than the US. We expected heightened social dominance orientation (SDO) and reduced biodiversity appreciation to predict stigma.

**Methods:** Undergraduates from the Parisian region ( $n = 85$ ), Beirut ( $n = 156$ ), Midwest ( $n = 201$ ), South ( $n = 404$ ), and Northeast US ( $n = 555$ ) participated in an online survey that assessed: demographics, stigma (social distance;  $\alpha$  France = .86;  $\alpha$  Lebanon =

.84;  $\alpha$  US = .89), autism knowledge ( $\alpha$  France = .70;  $\alpha$  Lebanon = .75;  $\alpha$  US = .86), biodiversity appreciation, SDO, Culture Value Orientation, and social desirability bias.

#### Results:

Although autism knowledge measures often exhibit sub-par internal consistency, the participatory autism knowledge scale exhibited satisfactory internal consistency across countries. Unexpectedly, autism knowledge was highest in France, followed by the US, and Lebanon ( $ps < .001$ ). Biodiversity appreciation was lowest and SDO highest among students in the US, followed by Lebanon, and France ( $ps < .005$ ).

French students were less likely to attribute autism to heredity or preternatural causes and more likely to index environmental causes than participants in the US and Lebanon ( $ps < .001$ ).

A regression revealed that being French ( $B = .16$ ) or from Lebanon ( $B = .07$ ), being male ( $B = .08$ ), heightened SDO ( $B = .14$ ), and vertical individualism ( $B = .12$ ), and reduced horizontal collectivism ( $B = -.14$ ) and biodiversity appreciation ( $B = -.08$ ) were associated with heightened autism stigma ( $ps < .007$ ). Heightened autism knowledge ( $B = -.26$ ), more pleasant past experiences with autism ( $B = -.15$ ), having worked with autistic people ( $B = -.06$ ), and more social desirability bias ( $B = -.06$ ) were associated with reduced stigma ( $ps < .02$ ).

Conclusions: These findings suggest that autism stigma and disrespect of biodiversity arise from a broader belief that those who are in power (e.g., “neurotypical humans” when compared to “neurodivergent” humans or humans in general when compared to other animals) deserve their privileges. By recognizing common causes shared by different social justice movements, we can work together to ameliorate stigma and combat environmental degradation by teaching the value of interdependence and respect for diverse ways of being.

#### **425.019** (Poster) Effects of Internet-Based Online Modules on Behavioral Principles for Parents of Children with ASD

**J. D. Lee<sup>1</sup>** and **H. Meadan<sup>2</sup>**, (1)Special Education, University of Illinois, Champaign, IL, (2)University of Illinois, Champaign, IL 61820, IL

---

#### Background:

Many children with autism and other developmental disabilities have deficits or delays in social-emotional or communication skills, which might lead to challenging behaviors as communicative attempts (Dunlap & Fox, 2011). It is also reported to have a significant impact on others who experience the child’s challenging behaviors daily, such as parents. Parents of children who exhibit challenging behaviors report that these behaviors have negative effects on family’s stress, social isolation, and well-being (Meadan et al., 2010). Therefore, parents’ roles become very significant in a child's development especially when a child has a disability and exhibits challenging behaviors (Lopez-Liria et al., 2020). However, when parents are uncertain of what a correct response is to a child’s challenging behaviors, it can significantly increase their stress (Bearss et al., 2018) and could result in parent-child interactions that are coercive in nature (McIntyre, 2013). Parents who live in areas with severe service disparity, such as South Korea, report heightened financial hardships of paying for services such as applied behavior analysis (ABA) due to the limited number of professionals available.

#### Objectives:

In order to mitigate service disparity in Korea, we developed and evaluated the effectiveness of the Challenging Behavior Online Modules (CBOM) with parents of children with ASD/DD who exhibit challenging behaviors in Korea on increasing their knowledge in behavioral principle, positive parenting practice, and decrease in parental stress. We also collected qualitative social validity data to examine feasibility and acceptability.

#### Methods:

In this randomized controlled trial, a total of 88 participants in intervention and waitlist control groups completed the study. More than half of the participants reported having children with ASD (54.5%,  $n = 48$ ). CBOM is consisted of six online video modules that are approximately 11 minutes long. Participants in the intervention group were given access to the modules for three weeks. Dependent variables include researcher-developed Parent Knowledge Assessment (PKA), Parenting Young Children (PARYC; McEachern et al., 2012), and Korean-Parenting Stress Index (K-PSI-4-SF; Chung et al., 2019). We conducted repeated-measures ANOVA analyses, treating time and treatment conditions as fixed factors. If the interaction effect was significant, Tukey’s test for post hoc analysis was performed to further investigate the mean differences.

## Results:

Significant interaction effects of Group  $\times$  Time were found across all measures, with no preexisting differences between the two groups at pretest, which indicate that the changes are likely due to treatment alone. Large effect sizes (2.29 and .75) were found for PKA and PARYC, respectively, and relatively small (.32) effect size was found for K-PSI-4-SF. Social validity data also supplement the quantitative findings. Parents spoke highly of the acceptability, satisfaction, and effectiveness of the modules, and shared that such modules would be very helpful to parents in Korea where ABA service disparity is pronounced.

## Conclusions:

While the CBOM was found to be effective in promoting positive changes in Korean parents, future study should examine how to better tailor the CBOM and to develop more online resources to meet the individual needs of diverse parents.

### **425.020** (Poster) Evaluation of the Program Parents Taking Action for Parents of Pre/Adolescents with Autism Spectrum Disorder in Colombia

*M. Garcia<sup>1</sup> and F. Balcazar<sup>2</sup>, (1)UIC, Chicago, IL, (2)University of Illinois at Chicago, Chicago, IL*

---

**Background:** The prevalence of Autism Spectrum Disorder (ASD) has been increasing in the last decades around the world. In Colombia, there is not a clear statistic about the prevalence of ASD, but it is estimated that 16% of the population under 15 years old has some type of developmental disability. In addition, disability in Colombia is still considered a taboo and it has a strong stigma that prevents people with disabilities from fully participating in the community. Unfortunately, the lack of research and information about supports for families of children/pre/adolescents with ASD limits the understanding of how ASD is approached and what services and supports are available for this population. This project includes a curriculum for Colombian parents of pre/adolescents with ASD which includes topics of puberty, sexuality, and adolescence development

**Objectives:** This research project evaluates the effectiveness of the program Parents Taking Action (PTA) in Bogota, Colombia. This program aims to increase parent empowerment, at the family level, by increasing aspects such as self-efficacy, knowledge, goal attainment, and use of new strategies/skills.

**Methods:** this study used a quasi-experimental pretest-posttest design with multiple replications and follow-up. This research design included two intervention groups and one control group. In addition, the program included 4 weekly sessions; each session was three hours long and included the topics of the curriculum, active learning activities and discussions. The program includes 9 modules, and it is designed to provide parents with a space to practice strategies, learn from others and set goals.

**Results:** the PTA program was offered to 38 Colombian parents of pre/adolescents with ASD between the ages of 10-17 in the city of Bogota. This study showed that there were significant gains in the pre-post analysis in all three groups for levels of empowerment, knowledge, self-efficacy, and use of strategies. Also, the difference between intervention groups and the control group was significant in all dimensions (knowledge  $p < 0.000$ ; use of strategies  $p < 0.001$ ; empowerment  $p < 0.005$ ; and self-efficacy  $p < 0.000$ ).

**Conclusions:** the results of this study show that the program Parents Taking Action is effective in terms of increasing knowledge, use of strategies, self-efficacy, and empowerment in relation to the topics related to puberty, adolescence and sexuality for parents of pre/adolescents with ASD. Also, the findings also indicated that parents are not only acquiring knowledge, but they are also applying the knowledge and strategies with their children. This is also significant as their empowerment and self-efficacy increased after receiving the program. The program had a high impact in the Colombian participants as the information is scarce and parents do not have resources to be informed about the complicated developmental stage of pre/adolescence. Finally, the program is an effective tool for community organizations and health providers to provide extra support to these families during their youth's stage of puberty and pre/adolescence.

### **425.021** (Poster) Examining Beliefs about the Causes of Autism in Kenya: What Have People Been Told and What Do They Personally Believe?

*C. Messina<sup>1</sup>, L. Chen<sup>2</sup>, J. Mathaga<sup>3</sup>, J. Muiruri<sup>4</sup>, N. Daou<sup>5</sup>, D. S. Smith<sup>6</sup> and K. Gillespie-Lynch<sup>7</sup>, (1)Emory University, Atlanta, GA, (2)College of Staten Island, Staten Island, NY, (3)Arthur's Dream Autism Trust (ADAT Foundation), Nairobi, Kenya, (4)Kenya Autism Alliance, Nairobi, Kenya, (5)McNeese State University, Lake Charles, LA, (6)College of Staten Island, CUNY, Staten Island, NY, (7)Department of Psychology, College of Staten Island; CUNY Graduate Center, Brooklyn, NY*

---

Background: Although autism affects people at similar rates globally, reliable information about autism and evidence-based supports are far from equally distributed (Hahler & Elsabbagh, 2015). Autism resources remain particularly scarce in Kenya (Riccio, 2011). In one of the only prior studies about autism in Kenya, parents and educators reported experiencing stigma and pronounced challenges accessing care (Gona et al., 2015). They expressed misconceptions about autism, including that it is caused by witchcraft. Although an important first step, Gona's research did not distinguish between what participants personally believed and what they had been told by others.

Objectives:

To examine if people in Kenya describe the etiology of autism similarly or differently from what they have been told by community members.

To determine if misconceptions about autism were more common among parents or educators.

Methods: In collaboration with the Kenya Autism Alliance and autistic university students, we adapted a training which had been associated with improved knowledge and/or stigma among college students and educators internationally. We delivered two half-day long trainings in Nairobi and Mombasa. Ninety-eight people attended the training, 74 (34% parents, 37% educators) provided complete data. We adapted two knowledge measures to address strengths as well as challenges and align with the cultural context. We measured stigma with a social distance scale. Nine open-ended questions assessed access to care, personal, and community conceptions of autism. Answers to two questions, "What have you been told causes autism by others?" and "Please share what you yourself think causes autism?", were coded after independent coders obtained reliability.

Results:

When asked what they had been told causes autism by others, participants most commonly had heard that autism is attributable to biomedical causes (40.7%; e.g., genetics), followed by issues with parents (35.8%; e.g., what the mother consumed during pregnancy), environmental toxins (28.4%; e.g., vaccines), and preternatural forces (27.2%; e.g., witchcraft; Table 1).

When asked what they themselves believe causes autism, participants overwhelmingly indicated biomedical causes (78.1%), followed by toxins (43.9%) and issues with parents (40.2%; Table 2). They almost never personally endorsed preternatural causes (2.5%).

Chi square tests revealed that participants were more likely than their community members to attribute autism to biomedical causes and less likely to endorse preternatural causes ( $p < .001$ ). However, they did not differ from community members in attributing autism to parents or vaccines ( $p > .60$ ).

Parents (26%) were more likely to attribute autism to vaccines than teachers (4%;  $p = .04$ ). Teachers (33%) were more likely to attribute autism to parents than parents (4%;  $p = .02$ ).

Conclusions: Participants in Kenya received a mix of accurate information and misinformation about autism from community members. They successfully rejected some misconceptions (e.g., preternatural causes) while accepting others (e.g., that autism is caused by vaccines). To better understand perspectives on autism in different cultures, it is important to distinguish between what people have been told by community members and what they themselves believe.

**425.022** (Poster) Experiences, Opportunities and Challenges of Autistic Students in Higher Education in Singapore: A Qualitative Analysis

*E. Lim<sup>1</sup>, S. Wong<sup>1</sup> and I. Magiati<sup>2</sup>, (1)National University of Singapore, Singapore, Singapore, (2)Dept. of Psychology, National University of Singapore, Singapore, Singapore*

---

Background:

Autistic people are entering higher education (HE) in increasing numbers. Research on understanding their experiences and support needs has only emerged in the last few years and was predominantly conducted in Western countries, with only two exceptions to date (one study each from Japan and Israel). Supporting autistic people in education is a top research priority for autistic people, but autism research in Singapore and in most Asian countries has largely focused on early, primary or secondary school education, rather than higher education. To the best of our knowledge, the present study is the first in Singapore and the

third outside of Western countries to explore the experiences, perspectives, opportunities, challenges, and needs of autistic HE students.

#### Objectives:

The present study adopted a qualitative and exploratory approach, aiming to understand the experiences, opportunities and challenges faced by autistic HE students in Singapore's local polytechnics and universities. The present study also sought to find out the availability and efficacy of supports available to autistic students from transition into HE to transition out of HE and into employment. These findings could contribute to improving and strengthening relevant supports to better enable autistic students to fulfil their potential in HE.

#### Methods:

20 autistic students (aged 21-29; 15 males) and 22 non-autistic students (aged 20-30; 8 males) who either supported or worked with autistic peers during classes or assignments provided anonymous responses to online open-ended survey questions which were transcribed and thematically coded.

#### Results:

Figure 1 summarizes the themes that emerged. Similar to students in other countries, our surveyed autistic HE students had unique, diverse experiences that ranged from highly enjoyable to highly challenging—some excelled academically, while some faced difficulties; some made friends while others struggled to form connections. Autistic students indicated that having a comprehensive transition plan generally made entering HE easier, and that receiving support from others was usually beneficial. Non-autistic students, however, either felt ill equipped to understand, engage with, or support autistic peers or were unwilling to due to negative perceptions of autistic people. Two findings, namely that autistic students in Singapore did not spontaneously refer to mental health difficulties, and that non-autistic students often engaged in “othering” their autistic peers, may pertain more specifically to the educational and sociocultural context of Singapore. Both autistic and non-autistic students noted the presence of deep-rooted stigma about neurodevelopmental/mental health conditions in their country's HE settings —this could deter disclosure, in turn hindering autistic students from receiving reasonable accommodations.

#### Conclusions:

More flexible, individualised supports need to be developed and existing supports refined, in tandem with improving non-autistic peers' knowledge of and attitudes towards autistic people. Future research directions include expanding the literature base in Asian countries by obtaining perspectives from other stakeholders (especially faculty and families) and examining factors that predict successful and positive HE experiences. Lastly, inclusivity cannot be limited to the HE context, and changes need to be made on a societal level to address underlying stigma (e.g. in primary and secondary school, in the workforce).

**425.023 (Poster)** Exploring the Use of the ASK-Q As a Baseline and Outcome Measure in Face to Face and Virtual (mobile phone) Autism Knowledge Trainings in Tanzania

*N. Naqvi<sup>1</sup>, M. Ricci<sup>1</sup>, L. Konak<sup>1</sup> and A. Martinage<sup>2</sup>, (1)Iona College, New Rochelle, NY, (2)OMPACO, Lexington, MA*

---

**Background:** ASD is prevalent globally, but there is variability in the awareness of ASD depending on the country. In Tanzania, educators and clinicians report reduced awareness of ASD in the community and few training opportunities and resources. A U.S based non-profit has provided free trainings on ASD to teachers and clinicians in Tanzania using in-person and virtual formats. Both have their advantages. In-person trainings can be tailored specifically to a particular audience and provides opportunity for discourse and networking. Virtual trainings can reach a larger audience and raise awareness throughout the country.

**Objectives:** Analysis of the Autism Stigma Knowledge Questionnaire (ASK-Q) as a baseline and outcome measure of autism knowledge to assess effectiveness of in-person and virtual autism knowledge trainings among Tanzanian educators.

**Methods:** The studies used a pre-post methodology with the ASK-Q. Content was identical across in-person and virtual trainings and incorporated different topic areas including, etiology, assessment and communication. Information was presented in English and Swahili. The in-person training was delivered in July 2018 in Mwanza, Tanzania and lasted three days. Of the 39 recruited participants, 34 (17 males and 17 females;  $M_{age} = 40.29$ ,  $SD_{age} = 8.50$ ) successfully completed the study. The virtual trainings were launched in July 2018 and July 2019, were available for free for six months after the start date, and were accessible to participants on any mobile device (phone or tablet) with internet access. Sample sizes were 84 (52 females and 29 males,

majority age (39.3%) over 39 years) and 179 (74 females, 104 males, majority age (27%) between 20-24 years) for the 2018 and 2019 virtual trainings respectively. Both trainings included end-of-module quizzes. The 2019 training modified the ASK-Q post-test administration by embedding all post-test questions into the end-of-module quizzes.

**Results:** Pre-post-test comparison for the in-person training was significant,  $t(34) = 5.12, p < .001$ . (pretest mean = 36.09 (SD= 3.80; posttest mean = 39.63 SD= 2.52). Cronbach alpha (.460) for the measure at pre-test was lower than expected, most likely due to the small (n=34) sample size. Cronbach alpha on the ASK-Q was higher for the 2019 virtual training (.657) compared to 2018 (.542). Pre-post comparisons were not significant for either virtual training (2018 pretest mean=35.92, SD=3.56; post-test mean 36.14, SD=4.57; 2019 pretest mean=38.90, SD=5.01, post-test mean=38.27, SD=5.11). Participant completion for in-person training was 87%, completion rate for the 2018 and 2019 virtual trainings was 41% and 39 % respectively. Results from the end of module quizzes for the virtual trainings ranged from 73-96% for both years.

**Conclusions:** Positive outcomes using a pre-post-test methodology did not translate to the virtual format, despite the improved reliability of the ASK-Q in the virtual trainings. Reasons could be the high participant baseline scores in the virtual trainings and significantly lower completion rates for these trainings. Considerations need to be given to the viability of a pre-post-test methodology in the virtual space, particularly when participants access content via their mobile devices. Future applications of these virtual trainings should consider alternative methods to capture participant learning.

**425.024 (Poster)** From Engagement to Competency: Making Disability Naïve Frontline Health Workers Competent to Deliver an Evidence Based Autism Intervention in New Delhi, India

**L. Naithani<sup>1</sup>, P. Sangwan<sup>1</sup>, S. Guha Roy<sup>1</sup>, S. Lakhera<sup>1</sup>, Z. Azar<sup>1</sup>, S. Menon<sup>1</sup>, D. Kumar<sup>1</sup>, M. Kakra<sup>1</sup>, G. Lall<sup>1</sup>, S. Pandey<sup>1</sup>, S. Johri<sup>1</sup>, R. Roy<sup>1</sup>, V. Vajaratkar<sup>1</sup>, C. A. Taylor<sup>2</sup>, V. Patel<sup>3</sup>, J. Green<sup>4</sup> and G. Divan<sup>5</sup>, (1)Sangath, New Delhi, India, (2)University of Manchester, Manchester, United Kingdom, (3)Department of Global Health and Social Medicine, Harvard Medical School, Boston, MA, (4)University of Manchester, Manchester, United Kingdom of Great Britain and Northern Ireland, (5)Child Development Group, Sangath, New Delhi, India**

**Background:** The Communication-centred Parent-mediated treatment for Autism Spectrum Disorder in South Asia (COMPASS) program is an ongoing randomized control trial being conducted in India. It is evaluating the effectiveness and cost-effectiveness of delivering an evidence-based intervention PASS Plus (Parent-mediated treatment for Autism Spectrum Disorder in South Asia Plus), an adaptation and expansion of the Preschool Autism Communication Therapy (PACT), to families of children with autism. The estimated prevalence of children with autism in India, aged 2 to 9 years, is over five million and the paucity of specialist care makes access to interventions difficult for most families. To address this issue, COMPASS is using the task-sharing approach by training non-specialists to deliver the intervention to families in their homes using video feedback. These non-specialists work within a supportive supervision framework in the project. COMPASS is engaging and training health system workers called the Accredited Social Health Activists (ASHAs). ASHAs are embedded within the Ministry of Health and Family Welfare, and each is linked to a Public Urban Health Centre (PUHC) under the Delhi State Health Mission. The primary role of ASHAs is to mobilize their communities to avail services related to maternal and child health care

**Objectives:** To describe the processes and experiences of an autism intervention delivery project and its interaction with the health system in a state of India, as a model to inform the future scalability of early interventions for neurodevelopmental disorders through the process of task-sharing.

**Methods:** The present study describes the process followed to support autism naïve non-specialists to become competent at delivering a complex autism intervention. It included the following steps i) engagement, ii) recruitment, iii) training iv) internship and v) competency evaluation. The engagement process introduced the ASHAs to the organisation, autism and the COMPASS program, and their potential roles within it. The recruitment process comprised telephonic screening followed by in-person interviews to gauge capabilities of ASHAs specific to project requirements. The shortlisted ASHAs received a 7-day classroom training followed by an internship period with practice cases. Finally, competency assessments, comprising a test of knowledge and skills through role-plays, was administered.

**Results:** The COMPASS team approached 23 PUHCs across seven districts of Delhi and met with 408 ASHAs across 24 engagement meetings. On follow-up calls, 188 ASHAs reconfirmed their willingness to join the program. Telephonic screening was conducted with 127 ASHAs and 72 ASHAs were selected for in-person interviews, 45 ASHAs attended. 33 ASHAs were shortlisted for training, 24 ASHAs commenced training and 18 ASHAs completed the 7-days training. 15 ASHAs entered the internship and 8 ASHAs achieved competency in intervention delivery

**Conclusions:** There was a significant attrition along the pathway to having a competent non-specialist frontline worker deliver a complex autism intervention. These reasons included low digital literacy, a lack of family support and a requirement for improved remuneration. The lessons learnt from this process can inform health systems on possibility of developing a cadre of

disability specific health workers who can deliver evidence-based interventions for neurodevelopmental disorders under supervision.

**425.026** (Poster) Impact of COVID-19 and Lockdown on People with ASD and Their Families in Latin America  
**D. Valdez**<sup>1</sup>, **C. Nava**<sup>2</sup>, **A. Rattazzi**<sup>3</sup>, **S. H. Cukier**<sup>4</sup>, **N. Barrios**<sup>5</sup>, **C. S. Paula**<sup>6</sup>, **A. Rosoli**<sup>7</sup>, **G. Perez Liz**<sup>8</sup>, **R. A. Garcia**<sup>9</sup> and **G. Garrido**<sup>9</sup>, (1)Universidad de Buenos Aires- FLACSO, Buenos Aires, Argentina, (2)Psychological Science, University of Texas Rio Grande Valley, Edinburg, TX, (3)PANAACEA, Buenos Aires, Argentina, (4)Fleni, Capital Federal, ARGENTINA, (5)Developmental Disorder Program, Universidade Presbiteriana Mackenzie, São Paulo, Brazil, (6)Projects, Organizacion Estados Iberoamericanos, Santo Domingo, Dominican Republic, (7)A.J. Drexel Autism Institute, Drexel University, Philadelphia, PA, (8)Clínica Las Condes, Santiago, Chile., Santiago, CHILE, (9)Universidad de la República, Montevideo, Uruguay

---

#### Background:

There is a worldwide emergency because of the COVID-19 outbreak. Challenges related to quarantine and lockdown are an added burden to those already experienced by families with a member on the spectrum living in low and middle-income countries. Approximately 6 million individuals with autism live in Latin America. These countries share cultural heritage with Europe mixed with cultures of native aboriginal communities of America or Africa. Health disparities are present for the poorest and most vulnerable populations (women, children, and aboriginals). As a new risk factor, the COVID-19 affects the already scarce services for individuals on the spectrum, telehealth adaptations, family dynamics, and up to an unknown degree, the outcomes of individuals with ASD.

#### Objectives:

Describe the impact of the COVID-19 lockdown on people with ASD and their families in Latin America in relation to any changes in feeding and sleep habits, anxiety and behavior. Analyze the impact of the pandemic on the services, taking into account the different types of treatment and schooling, their possible discontinuity, the telehealth intervention and its scope and limitations.

#### Methods:

1826 families from Argentina, Brazil, Chile, Mexico, Peru, the Dominican Republic, Uruguay, and Venezuela participated in this multicentric study. Caregivers completed an online survey designed by Red Espectro Autista Latinoamérica (REAL). Questions inquired about changes in education, services and support, behaviors, outings, adaptations for educational and health services before and during the pandemic.

#### Results:

Right before the lockdown, 26.9% of the participants were receiving speech therapy, 19.6% medication, 19.5% occupational therapy, 17.6% school support, and 15.5% behavioral therapy. Overall, 30% of the treatments were suspended either due to centers closure or by health providers' decisions. 40% of the families have received services through telehealth. Participants reported sleep disturbances (40.8%), eating problems (45.4%), irritability (64.8%), "aggressive" behaviors (hitting, pinching, biting and shoving) (35.5%), wandering (46.6%), anxiety (59.1%) mood disturbances (46%) and setbacks (60%). The majority of participants reported an increase in screen use outside of educational use (80%) and behavioral improvement when they were allowed to go out of the house (50%). Most families (75%) shifted to remote learning.

#### Conclusions:

Sleep problems increase at the same level as attention problems, hyperactivity, dysfunctional behaviors and irritability/aggressiveness. Anxiety increased markedly. Parents mention a task overload due to telehealth interventions and the lack of experience of professionals with technology. Caregivers identified some advantages for remote services, such as lower stress level by not traveling and avoiding the demands of social interaction outside the household. Many families say they have been able to learn more about their children's treatment goals and strategies. This should help us to rethink the relationships between families and professionals and include families in therapeutic proposals. Socioeconomic inequalities and the technological gap are evident. The current global crisis should serve as an opportunity to promote changes in the health and education systems, providing sufficient support with a more ecological, inclusive and autism-friendly perspective.

**425.027 (Poster)** Impact of COVID-19 on Children with Autism and Parents: A Preliminary Investigation into a School Sample in Mainland China

*L. Sun<sup>1</sup>, X. Cao<sup>2</sup>, M. Li<sup>3</sup>, R. Chen<sup>3</sup> and H. Schertz<sup>1</sup>, (1)Indiana University, Bloomington, IN, (2)Renyu School for Children with Special Needs, Fujian, China, (3)School of Labor and Human Resources, Renmin University of China, Beijing, China*

---

**Background:** Earlier in 2020 China instituted a nationwide lockdown after the outbreak of a novel coronavirus (COVID-19). The isolation has not only disrupted people's routine life but also afflicted mental distress on individuals under quarantine. Children with autism and their families are among the most vulnerable populations that experience COVID-19-related challenges.

**Objectives:** To understand the impact of COVID-19 on children with autism and parents to inform our teaching and parent support post-COVID-19 to better meet the needs of the students and families.

**Methods:** A survey was developed with input from parents and non-autism researchers. The survey assesses the impact of COVID-19 on children with autism and their parents with respect to parents' implementation of home-based interventions. The survey, published on the survey platform [www.wjx.cn](http://www.wjx.cn), was distributed to online parent groups. Respondents were asked to consent before answering the survey. IRB was waived because the survey did not collect identifiable information and the collected information was analyzed as secondary data. Fifty-six parents participated and 54 responses were valid. Descriptive statistics (Table 1) and qualitative analysis (Table 2) were used to analyze the results.

**Results:** Parent-reported impacts of COVID-19 on children with autism included discontinuation of schooling, limited (social) opportunities, less generalization of learned skills to non-home contexts, and skill regression. Parents reported intensified behavioral issues in children, including mood swings, self-stimulation, and less compliance with the home-based intervention plan. These behavioral irregularities resulted in parent caregiving difficulties. Although 36 parents reported implementing home-based intervention and adapting its content, schedule, and intensity, only four parents preferred this configuration. Reasons for parents' preferences for school-based intervention (Table 2) aligned with their reported challenges moving to home-based interventions.

Thirty-one parents reported receiving support from professionals, peer parents, community resources, or family members. For others, the biggest challenges were social isolation and a lack of means to provide home-based intervention. Parents expressed needs for (1) professional support for intervention strategies, remote consultation, and home visit services; (2) child care for respite and within-family division of labor in caring for the child; (3) financial support for childcare; (4) information about autism; and (5) emotional support for combatting loneliness, opportunities to share feelings, and peer support.

Twenty-two parents expressed interest in how parents from other countries implemented intervention and accessed supports for parent mental well-being during the pandemic. These parents expressed resilience in their beliefs in (1) patience and quality time with the child; (2) reasonable expectations; (3) self-discipline and endurance; and (4) coordination of childcare responsibilities among family members.

**Conclusions:** The impact of COVID-19 on both children with autism and parents was evident from this sample of parents. Parents reported lockdown-related challenges for children and themselves related to gaps in family support opportunities. Implications for schools are the need for parent supports to empower them for a larger role in supporting child learning during the pandemic.

**425.028 (Poster)** Impact of Lockdown Due to COVID-19 on People with ASD and Their Families in Argentina.

*C. Montiel-Nava<sup>1</sup>, D. Valdez<sup>2</sup>, A. Wilches<sup>3</sup>, A. Rattazzi<sup>4</sup>, S. H. Cukier<sup>5</sup>, N. Barrios<sup>6</sup>, G. Garrido<sup>6</sup>, C. S. Paula<sup>7</sup>, A. Rosoli<sup>8</sup>, G. Perez Liz<sup>9</sup>, R. A. Garcia<sup>10</sup> and M. Nunez<sup>11</sup>, (1)La Universidad del Zulia, Gainesville, GA, (2)Universidad de Buenos Aires-FLACSO, Buenos Aires, Argentina, (3)FLACSO, Buenos Aires, Argentina, (4)PANAACEA, Buenos Aires, Argentina, (5)Fleni, Capital Federal, ARGENTINA, (6)Universidad de la República, Montevideo, Uruguay, (7)Developmental Disorder Program, Universidade Presbiteriana Mackenzie, São Paulo, Brazil, (8)Projects, Organizacion Estados Iberoamericanos, Santo Domingo, Dominican Republic, (9)A.J. Drexel Autism Institute, Drexel University, Philadelphia, PA, (10)Clínica Las Condes, Santiago, Chile., Santiago, CHILE, (11)Faculty of Psychology, Universidad Autonoma de Madrid, Madrid, Spain*

---

Background:

Argentina is among the countries most affected by COVID-19, with 2,737 infected for every 100,000 inhabitants. For children, adolescents and adults with ASD and their families, facing a situation of confinement is challenging. In order to understand the

challenges they face, it is crucial to understand their socio-economic and cultural context. Argentina shares cultural heritage with Europe mixed with cultures of native aboriginal communities of America. 40.9% of the population is in poverty. Inequity in health systems is common for the poorest and most vulnerable populations (women, children, aborigines). Research and health provision is significantly under-resourced.

#### Objectives:

Describe the impact of the COVID-19 lockdown on people with ASD in Argentina in relation to any changes in feeding and sleep habits, anxiety and behavior. Analyze the impact of the pandemic on the services, taking into account the different types of treatment and schooling, their possible discontinuity, the telematic intervention and its scope and limitations.

#### Methods:

834 participants (81% caregivers, 16% therapists, 3% people with ASD) from Argentina participated in this study through an online survey designed by Red Espectro Autista Latinoamérica (REAL). The survey enquired about 8 aspects, as follows: Place of residence, Pre and post-pandemic schooling, Situation at home, Treatments and supports at the time of the start of the pandemic, Behavioral changes from home isolation, Leaving the home, Treatments and Supports during the pandemic, Main concerns during quarantine.

#### Results:

When the pandemic started, 56% of people with ASD received speech therapy, 19% medication, 41% occupational therapy, 35% school support, and 65% behavioral therapy. 24% of the treatments are completely suspended due to the closure of centers (30%) or by a health provider (27%). 43% of the families have received counseling through video calls and 18% only by telephone. When faced with the need for help, 59% call to therapists. Sleep problems (46%), eating problems (40%), irritability (63%), aggressiveness (35%), dysfunctional behaviors (52%), wandering (47%), anxiety (63%) and setbacks (65%) are reported. 56% have difficulties understanding why they cannot leave their home. Behaviors improve in 44% of people when outings began. For most families (80%), schooling was done remotely during the pandemic. 78% of people with ASD increased the use of screens outside of educational use.

#### Conclusions:

It seems that for individuals on the spectrum, staying at home and the changes in services delivery (from face to face to remote) impacted behaviors. The most-reported difficulties were irritability and anxiety, although sleep and eating problems were also present in a significant proportion of the sample. The technology gap and lack of internet penetrance in the country might have contributed to the disruption of services and support for families during the home for shelter period. An abrupt and drastic change as the one provoked by health measures during COVID-19 will disrupt individuals' routines and activities, which in individuals with autism would be a source of anxiety and disturbance.

#### **425.029** (Poster) Impact of Lockdown Due to COVID-19 on People with ASD and Their Families in Peru.

*S. Manrique<sup>1</sup>, D. Valdez<sup>2</sup>, A. Rattazzi<sup>3</sup>, G. Garrido<sup>4</sup>, S. H. Cukier<sup>5</sup>, N. Barríos<sup>6</sup>, A. Rosoli<sup>6</sup>, C. S. Paula<sup>7</sup>, R. A. Garcia<sup>8</sup>, G. Perez Liz<sup>9</sup> and C. Nava<sup>10</sup>, (1)CPAL, Peru., Lima, Peru, (2)Universidad de Buenos Aires- FLACSO, Buenos Aires, Argentina, (3)PANAACEA, Buenos Aires, Argentina, (4)Universidad de la República, Montevideo, Uruguay, (5)Fleni, Capital Federal, ARGENTINA, (6)Projects, Organizacion Estados Iberoamericanos, Santo Domingo, Dominican Republic, (7)Developmental Disorder Program, Universidade Presbiteriana Mackenzie, São Paulo, Brazil, (8)Clínica Las Condes, Santiago, Chile., (9)A.J. Drexel Autism Institute, Drexel University, Philadelphia, PA, (10)Psychological Science, University of Texas Rio Grande Valley, Edinburg, TX*

#### Background:

Peru is among the countries most affected by COVID-19, with 2,860 infected for every 100,000 inhabitants. For children, adolescents and adults with ASD and their families, facing this situation of confinement is very difficult. To understand the challenges of families of people with ASD, it is crucial to understand their socio-economic and cultural context. Peru has 30% of the population of African American aboriginal origin. One in every 4 children is in poverty. Inequity in health systems is common for the poorest and most vulnerable populations (women, children, and aborigines). There is not enough research and health professionals available in the area of autism.

#### Objectives:

Describe the impact of the confinement due to COVID-19 the pandemic in people with ASD in Peru in relation to food, sleep, anxiety and behavior. Analyze the impact of the pandemic on services, taking into account the different types of treatment and schooling, its possible discontinuity, telematic intervention, its scope and limitations.

#### Methods:

In this exploratory study, 110 people - including therapists, families and people with ASD - from Peru participated through an online survey designed by Red Espectro Autista Latinoamérica. The survey enquired about 8 aspects, as follows: Place of residence, Pre and post-pandemic schooling, Situation at home, Treatments and supports at the time of the start of the pandemic, Behavioral changes from home isolation, Leaving the home, Treatments and Supports during the pandemic, Main concerns during quarantine.

#### Results:

When the pandemic started, 46% of the people with ASD received speech therapy, 6% medication, 16% occupational therapy, 21% school support, 23% behavioral therapy. 30% of the treatments are totally suspended due to the closure of centers (27%) or by health provider (12%). 32% of the families have received advice through video calls and 16% only by telephone. 17% of the families took care of the therapies. Faced with the need for help, 72% turn to therapists. Sleep problems (36%), eating problems (26%), attention (55%), irritability (55%), aggressiveness (26%), ambulation (35%), anxiety (40%) and setbacks (56%) are reported. Behaviors improve in 36% of people when outings began. For most families (73%), schooling was done remotely during the pandemic. 87% of people with ASD increased the use of screens outside of educational use.

#### Conclusions:

The increase in irritability, attention problems and anxiety levels are high in this situation. Most families have requested remote help from therapists. Parents mention the overload of tasks due to tele-treatment at home during confinement and the lack of experience of professionals with technology. Socioeconomic inequalities and the technological gap are evident. The advantages are lower stress level by not traveling and avoiding the demands of social interaction. Many families say that they have been able to learn more about their children's treatment. This should promote the inclusion of families in therapeutic proposals. The current global crisis should serve as an opportunity to make changes in the health and education systems, providing support to families and people with ASD with a more ecological, inclusive and autism-friendly perspective.

#### **425.030** (Poster) Impact of the COVID-19 Lockdown in Malaysia: An Examination of the Psychological Wellbeing of Parent-Child Dyads and Child Behaviour in Families with and without Children on the Autism Spectrum

**H. X. Fong<sup>1</sup>**, K. Cornish<sup>2</sup>, H. Kirk<sup>2</sup>, K. Ilias<sup>3</sup>, M. F. Shaikh<sup>4</sup> and K. J. Golden<sup>1,4</sup>, (1)Department of Psychology, Jeffrey Cheah School of Medicine and Health Sciences, Monash University Malaysia, Bandar Sunway, Malaysia, (2)Turner Institute for Brain and Mental Health, School of Psychological Sciences, Monash University, Melbourne, VIC, Australia, (3)Department of Basic Sciences, Faculty of Health Sciences, Universiti Teknologi MARA, Puncak Alam, Selangor, Malaysia, (4)Neuropharmacology Research Strength, Jeffrey Cheah School of Medicine and Health Sciences, Monash University Malaysia, Bandar Sunway, Malaysia

#### Background:

Responding to the COVID-19 pandemic, the Malaysian government implemented rapidly changing, multi-stage nationwide lockdowns since March 2020 with ambiguous protocols that provided little recognition or support for families of children on the autism spectrum. Of concern, home confinements, school closures, and related uncertainties may negatively impact families of children on the autism spectrum disproportionately, piled on top of existing stressors resulting from the poor infrastructure to support these families in Malaysia (a culturally-diverse, developing South-East Asian country).

#### Objectives:

The current exploratory research is part of a broader mixed-methods, longitudinal project examining the impact of the COVID-19 pandemic on families. The current quantitative research aimed to (a) examine parent-reported changes in behaviour and psychological distress of children formally diagnosed with an autism spectrum condition (ASC) pre-lockdown and mid-lockdown in Malaysia, compared to a control group of typically developing (TD) peers and (b) examine the changes in psychological distress and wellbeing of parents pre-lockdown and mid-lockdown between ASC and TD groups.

#### Methods:

The children's ages ranged between 5 to 17 years. The sample included 72 ASC parent-child dyads ( $M_{childage}=109.05$  months,  $SD_{childage}=35.58$  months; 75% boys;  $T$ -scores  $\geq 60$  on the Social Responsiveness Scale-2 [SRS-2];  $M_{parentage}=38.3$  years,  $SD_{parentage}=5.62$  years) and 62 aged-match TD parent-child dyads ( $M_{childage}=104.68$  months,  $SD_{childage}=33.78$  months, 58.1% boys;  $T$ -scores  $< 60$  on the SRS-2;  $M_{parentage}=37.8$  years,  $SD_{parentage}=5.93$  years). The primary caregiver completed an online survey including the following: demographic and diagnostic information; SRS-2; Conners' Parent Rating Scales-3 (CPRS-3; *Inattention, Hyperactivity/Impulsivity, Global Index, Anxiety, and Depression subscales*); Perceived Stress Scale-Child (PSSC); Perceived Stress Scale-Adult (PSSA); DASS-21 *Depression and Anxiety* subscales; and Scale of Positive and Negative Experience (SPANE) based on their experience pre-lockdown and mid-lockdown (March 18th to June 9th) in Malaysia.

#### Results:

There were no significant gender differences (boys/girls) in all the child scales. The 2 (diagnosis [ASC, TD])  $\times$  2 (lockdown [pre-lockdown, mid-lockdown]) mixed-model ANOVAs revealed main effects of lockdown on **child's behaviour** [CPRS-3 *Inattention* ( $F(1,130)=12.41, p<.001, \eta_p^2=.09$ ); CPRS-3 *Hyperactivity/Impulsivity* ( $F(1,130)=7.14, p<.001, \eta_p^2=.05$ ); CPRS-3 *Global Index* ( $F(1,131)=14.80, p<.001, \eta_p^2=.10$ )], **child's psychological distress** [CPRS-3 *Anxiety* ( $F(1,132)=16.46, p<.001, \eta_p^2=.11$ ); CPRS *Depression* ( $F(1,131)=6.97, p<.01, \eta_p^2=.05$ ); PSSC ( $F(1,130)=10.02, p<.001, \eta_p^2=.07$ )] as well as **parent's psychological distress** [PSSA ( $F(1,129)=6.81, p<.001, \eta_p^2=.05$ ); DASS-21:*Depression* ( $F(1,129)=8.18, p<.001, \eta_p^2=.06$ ); DASS-21:*Anxiety* ( $F(1,129)=7.82, p<.001, \eta_p^2=.06$ )], and **parent's wellbeing** [SPANE ( $F(1,130)=12.33, p<.001, \eta_p^2=.09$ )]. There was a main effect of diagnosis in all child and parent variables; however, there was no significant interaction effect between diagnosis and lockdown (see Table 1). Among the ASC group, no significant pre-lockdown and mid-lockdown changes were found in SRS-2 total or five subscales scores ( $t$ -tests;  $ps>.05$ ).

#### Conclusions:

The results provide preliminary evidence indicating negative effects of the Malaysian lockdown on both children on the autism spectrum and TD children, as well as their parents. Parents of both groups reported more behavioural concerns and higher psychological distress among their children, as well as higher personal psychological distress and poorer wellbeing mid-lockdown. These quantitative results will be triangulated with the qualitative interview data to provide a holistic understanding of the impact of the pandemic, informing translational policy and practice recommendations.

#### 425.031 (Poster) Inland Southern California: A Service Desert for Individuals with Autism Spectrum Disorder (ASD) and Their Families: Descriptive Analyses of Unmet Service Needs

*M. R. Ledoux<sup>1</sup>, A. Losh<sup>2</sup>, E. Veytsman<sup>2</sup> and J. Blacher<sup>1</sup>, (1)Graduate School of Education, University of California, Riverside, Riverside, CA, (2)Graduate School of Education, University of California Riverside, Riverside, CA*

**Background:** Children with autism spectrum disorder (ASD) need specialized services to support their academic, behavioral, and social wellbeing. Early intervention, reliant upon early diagnosis, promotes positive outcomes. However, large regions exist in which families face substantial barriers to timely assessment and intervention services, leading to geographical pockets of underserved families. One such area is the Inland Empire (IE) region of Southern California, where services are sparse and many families fall into at-risk groups for later age of diagnosis (e.g., Hispanic or Latinx). This study aims to examine the assessment and service needs of families with children with ASD in order to identify areas for improvement and inform future development of services in the IE region.

**Objectives:** 1) What are the assessment and evaluation needs of children with ASD and their families in the IE? 2) What are the intervention and healthcare needs of children with ASD and their families in the IE?

**Methods:** An online survey was developed and distributed to parents ( $n = 55$ ) of children with ASD, medical practitioners ( $n = 15$ ), and service providers ( $n = 20$ ) in the IE region ( $N = 90$ ). Parents were asked open- and close-ended questions about the diagnosis process, accessing services, perceptions of service needs, and satisfaction with different aspects of the service delivery system. Practitioners and service providers were asked open- and close-ended questions about their comfort providing services to individuals with ASD, training in ASD, and perceptions of service needs. Likert scale survey items were analyzed using descriptive statistics, and open-ended responses were coded qualitatively using a conventional content analysis approach to assess the specific needs of families of children with ASD in the IE region.

**Results:** Only 12% ( $n = 11$ ) of the total participants agreed that the intervention needs of individuals with ASD are currently being met. For parents, only 24% ( $n = 13$ ) agreed that the assessment needs of individuals with ASD are currently being met. Many parents reported a long latency between diagnosis and treatment (e.g., 36% indicated six months or more;  $n = 12$ ). Additionally, the vast majority of parents (78%;  $n = 43$ ) reported that they wished their child was receiving additional services.

Qualitative analyses of open-ended responses provided insight from parents, medical practitioners, and service providers regarding how to improve the service delivery system for children with ASD in the IE (e.g., increased coordination of care, timely access to evaluations, individualized services; see Tables 1 and 2).

**Conclusions:** Results captured the need for increased services in the IE region, as reported by parents, medical practitioners, and service providers. Parents indicated the need for increased access to comprehensive assessment and effective interventions for their children with ASD. These results, in particular the themes that emerged from qualitative analyses, may inform service providers, medical professionals, and policymakers in the IE as to how to improve the service delivery system (e.g., increase both quantity and quality of services, providing ASD-specific training to providers), in hopes of better supporting individuals with ASD and their families.

#### **425.032 (Poster) Knowledge of Evidence-Based Practices in Chinese Parents of Individuals with ASD**

*M. Y. S. Bak<sup>1</sup>, Y. Yang<sup>2</sup>, M. L. Hugh<sup>3</sup>, A. Reilly<sup>4</sup> and H. Abas<sup>1</sup>, (1)Educational Psychology, University of Minnesota, Minneapolis, MN, (2)School of Education Science, Lingnan Normal University, Zhanjiang, China, (3)Psychiatry & Behavioral Sciences, University of Washington, Seattle, WA, (4)College of Liberal Arts, University of Minnesota, Minneapolis, MN*

---

#### **Background:**

Parent knowledge and involvement are strong predictors for positive intervention outcomes. For parent-professional partnerships to be successful in planning and using interventions for children with autism spectrum disorder (ASD), parents must have knowledge to advocate for valid and effective interventions. Although researchers have investigated other stake holders' knowledge of evidence-based practices (EBPs) such as special education teachers and clinicians, there is very little research on parents' knowledge and perception of the importance of EBPs for their children with ASD. Moreover, there is even less research on how EBPs have been translated or disseminated in international communities not within the English-speaking, Western population.

In order to provide appropriate support for parents of children with ASD in all communities, we need more information on the current knowledge of EBPs and identify possible barriers that may affect parental involvement.

#### **Objectives:**

This study aims to identify some Chinese parents' knowledge of EBPs for individuals with ASD; factors influencing their agreement with an intervention proposed by a clinician/teacher; and external sources, if any, they use to inform their decision about treatment options for their child with ASD.

#### **Methods:**

We distributed an internet survey to a convenience sample of Chinese parents of children with ASD in the Guangdong province. The survey results were aggregated for descriptive statistics.

#### **Results:**

Preliminary results from 87 Chinese parents with children with ASD showed that 58.6% of the participants had no knowledge of what EBPs were and an additional 29.7% of the participants had heard of EBPs but not sure what they were. Familiarity with each EBP collected from the 2020 NCAEP report (Steinbrenner et al., 2020) ranged from 44% (Sensory Integration) to 14.3% (Time Delay) and usage of each EBP ranged from 45.3% (Music-Mediated) to 11.9% (Time Delay). When asked if they suggest or ask about an intervention to their primary service provider, 67.9% said "no" because they did not have knowledge (50.88%), were afraid of making an error (31.58%), or did not want to jeopardize the relationship (17.54%). We also asked types of service received, history of parent training, qualitative information on external sources (e.g., internet sources), and how parents assessed trustworthiness of a source, among others. Results from more participants and other questions will be available. Demographics of preliminary participants are available in the supplemental image.

#### **Conclusions:**

Although all participants expressed the desire to learn more about ASD and interventions, parents chose external sources rather than their primary service providers to gain information on interventions. Given that participants who answer survey questions

voluntarily are more likely to be active about their child's education compared to the general population, these results amplify the need for service and education providers to increase parent involvement and training. In addition, we must facilitate dissemination of research into communities that do not use English as a primary language. Languages and cultures differ but it is universal that effective collaborative efforts between parents and service providers can promote positive developmental outcomes for individuals with ASD.

**425.033 (Poster) Learning from Autistic People How to Assess and Reduce Autism Stigma**

**K. Gillespie-Lynch<sup>1</sup>, S. Saade<sup>2</sup>, R. Obeid<sup>3</sup>, J. Bailey Bisson<sup>4</sup>, B. Kofner<sup>5</sup>, N. Tricarico<sup>6</sup>, A. J. Harrison<sup>7</sup>, N. Daou<sup>8</sup> and W. Pinkava<sup>8</sup>,**  
(1)Department of Psychology, College of Staten Island; CUNY Graduate Center, Brooklyn, NY, (2)Psychology, Université du Québec à Montréal, Montreal, QC, Canada, (3)Department of Psychological Sciences, Case Western Reserve University, New York, NY, (4)Clemson University, Clemson, SC, (5)CUNY, NY, NY, (6)College of Staten Island, City University of New York, Staten Island, NY, (7)Educational Psychology, University of Georgia, Athens, GA, (8)McNeese State University, Lake Charles, LA

Background: Autistic university students often experience academic strengths coupled with social difficulties (Sturm & Kasari, 2019), including stigma. Online trainings have been used to improve autism stigma internationally (Obeid et al., 2015). However, prior research has not included autistic students in the process of developing trainings to improve understanding. In this study, autistic university students played a leading role in developing and evaluating a participatory autism training.

**Objectives:**

- 1) Determine if a participatory autism training (developed in collaboration with autistic university students) is more effective than a non-participatory training.
- 2) Evaluate if social distance scales inadvertently contribute to stigma.

**Methods:**

Four autistic university students helped adapt an autism training by making concepts/assessments more accessible/engaging and by adding videos highlighting their perspectives. A non-participatory training was developed by non-autistic educators. After pilot assessments, we matched the trainings in length and interactivity, pre-registered this research, and conducted an initial evaluation in NYC. The initial evaluation revealed improvements in explicit and implicit stigma associated with both trainings. Students described the IAT as tedious, so we removed it prior to the current multi-site evaluation wherein university students from NYC ( $n = 614$ ), Cleveland ( $n = 203$ ), and Beirut ( $n = 250$ ) completed a pre-test, were randomized to one of the trainings, and completed a post-test. Assessments included a participatory autism knowledge scale ( $\alpha = .84$ ), social distance scale ( $\alpha = .88$ ), and a scale assessing attitudes toward inclusion ( $\alpha = .67$ ).

Due to concerns raised by an autistic self-advocate on Twitter that social distance scales may “other” autistic people, we conducted a follow-up study. Sixty students were randomly assigned to either a social distance scale or an autism appreciation-focused scale (e.g., “I would welcome the opportunity to have an autistic boss”) followed by semantic differentials assessing perceived similarity of autistic people to oneself and others, an IAT, the participatory training, and post-test.

**Results:**

Three mixed models with country and training type as between-subjects factors, social desirability as a covariate, autism knowledge, stigma, and attitudes toward inclusion as outcomes revealed improvements with training in knowledge, stigma, and attitudes toward inclusion ( $ps < .001$ ). Interactions between improvements and training type ( $ps < .001$ ) and country ( $ps < .001$ ) were observed in all models. Follow-up analyses revealed greater improvements following the participatory than non-participatory training and for students in Lebanon relative to the US. Social desirability bias influenced, but did not account for, improvements in stigma and attitudes toward inclusion.

In the follow-up study, perceived similarity of autistic people to oneself and others was numerically *higher* following the social distance than the acceptance-oriented scale. Improvements following the participatory training were again observed.

Conclusions: This research provides empirical support for the oft cited, but rarely tested, benefits of involving autistic people in research about autism. Not only was the participatory training more effective than the non-participatory training, the participatory

knowledge measure exhibited better internal consistency than most measures developed without autistic input. Findings also suggest that assessing social distance does not contribute to the “othering” of autistic people.

**425.034** (Poster) Mealtime Behaviors and Parents Strategies in Children with Autism Spectrum Disorders  
**S. Suswaram**, *Speech Language Hearing: Sciences and Disorders, University of Kansas, Lawrence, KS*

---

Background:

An estimate of 2 million individuals in India have Autism Spectrum Disorder (ASD; Krishnamurthy, 2008), and approximately 50%-90% exhibit feeding difficulties (Kodak & Piazza, 2008). Feeding difficulties in children results in slower weight gain (Siddiqi et al., 2019), inadequate nutrition intake (Attlee et al., 2015), sleep disturbances (Prosperi et al., 2017), and increases problem behaviors (Johnson et al., 2014). Feeding behaviors vary across culture, specifically, feeding behaviors in India differ from Western cultures, yet, literature on feeding difficulties in ASD from Indian context remains limited (Padmanabhan & Shroff, 2020). For increasing knowledge on feeding difficulties and concurrent parent strategies used for overcoming feeding difficulties, the current study surveyed parents of children with ASD in South India.

Objectives:

To differentiate feeding difficulties, mealtime disruptive behaviors, and parent strategies between children with ASD with and without feeding difficulties.

Methods:

Primary caretakers of children with ASD, between the age of 2 and 10 years, without other neurodevelopmental disabilities or other developmental delays participated in the survey (N = 70). Participants responded to 39 questions divided into 2 subcategories, demographic information and feeding behaviors. Using parent ratings of their child's feeding difficulties, the survey responses were divided into children with feeding difficulties (n = 42) and those without. Feeding difficulties, mealtime disruptive behavior and parent strategies were compared between the two groups using chi-square test and Kruskal Wallis H test.

Results:

All children had delayed communication abilities and attended speech and language therapy but did not receive feeding interventions. Parents of 42 children (60%) reported normal feeding behaviors and 28 shared their child had feeding difficulties (40%). The number of feeding difficulties between the two groups did not significantly differ. However, the two groups significantly differed on the number of strategies used by the parents, ( $\chi^2(1, N = 70) = 7.457, p = .006$ ). Chi-square test revealed the two groups significantly differed on the use of “distractions during mealtimes”,  $\chi^2(1, N = 70) = 5.59, p = .016$ , “Allowing child to sip fluids between feeds”,  $\chi^2(1, N = 70) = 5.105, p = .024$ , “feeding child only when they request”,  $\chi^2(1, N = 70) = 8.491, p = .006$ . The groups also significantly differed on the total number of mealtime disruptive behaviors, ( $\chi^2(1, N = 70) = 11.396, p = .001$ ). Chi-square test revealed the two groups significantly differed on “spitting food”,  $\chi^2(1, N = 70) = 9.076, p = .003$ , “crying and screaming”,  $\chi^2(1, N = 70) = 3.673, p = .050$ , “holding food in the mouth for an extended period”,  $\chi^2(1, N = 70) = 10.048, p = .002$ .

Conclusions:

The two groups differed on mealtime behaviors but exhibited similar feeding difficulties. Children with feeding difficulties exhibited more mealtime disruptive behaviors than the other. Parent of children with feeding difficulties used more strategies than other group. Mealtime disruptive behavior might concern parents more than feeding difficulties in their children. Future research should focus on parent concerns and feeding-based interventions access barriers.

**425.035** (Poster) Mental Health and Social Support of Caregivers of Children and Adolescents with ASD and Other Developmental Disorders during COVID-19 Pandemic  
**C. Wang**, *Department of Social Psychology, Nankai University, Tianjin, China*

---

Background:

Previous findings have demonstrated that parents of children with autism spectrum disorder (ASD) and other developmental disorders such as attention-deficit/hyperactivity disorder (ADHD), language delay, intelligent disability, etc., experience higher levels of parenting stress, anxiety and depression that are associated with negative outcomes for families.

Objectives:

The present study aims to investigate the caregivers' mental health and the mediating role of social support in the relationship between symptoms severity and parenting stress during COVID-19.

Methods:

During 20 March to 8 April, 1932 caregivers of children and adolescents with ASD and other developmental disorders from 31 provincial-level administrative units in China were enrolled to fill in a sociodemographic questionnaire, Depression, Anxiety and Stress Scale (DASS21, Lovibond & Lovibond, 1995) and Social Support Rating Scale (SSRS, Xiao, 1993). 70.91% of their children were diagnosed with ASD, 13.25% ADHD, 36.80% language delay, 35.27% had intelligent disabilities and 6.99% other developmental disorders. The disability severity symptoms and behavioral problems of their children were also collected.

Results:

The results showed that 46.01% of the caregivers had depression, 44.67% had anxiety and 44.62% had stress during COVID-19 pandemic. Fathers were found to get more subjective support than mothers ( $P < 0.05$ ). Caregivers who had the highest educational attainment had the most social support ( $P = 0.01$ ). People who had the more household income had the significantly lower level of depression and anxiety ( $P < 0.05$ ). Their employment status during COVID-19 was found significantly related with their depression, anxiety, stress and social support ( $P < 0.05$ ).

Conclusions:

The findings showed that quite a lot of caregivers experienced mental health problems during COVID-19 and it also illustrated the need to promote their engagement in functional social support and the application of behavioral strategies with their children to help them to reduce the impact of stress, anxiety and depression affected by the COVID-19.

**425.036** (*Poster*) Parental Perceptions of Children's Autistic Traits in British and Minority Egyptian/Sudanese Communities in the UK

*E. Genovesi, P. Ullmer, L. Bhatti, P. Meyer, P. Memon, D. Panchani, M. Rafla, M. Welford, B. Tekola Gebru and R. A. Hoekstra, Department of Psychology, King's College London, London, United Kingdom*

---

Background: Most autism research is conducted in White participants in high-income Western countries. A few studies have reported that culture influences autism detection and interpretation of symptoms, but these have mainly been conducted in families of children with autism. However, views held in families who have no previous experience of raising a child with autism are important to understand the potential reasons why autism symptoms may not be recognised in the community.

Objectives: This study explored how UK-based Egyptian/Sudanese and British parents of typically developing children perceive atypical development relevant to autism and autistic traits, with the aim to uncover potential differences between the two cultural groups and factors that could affect reporting of autistic-like behaviours.

Methods: Participants were 19 mothers self-identifying as British and 19 mothers and 1 father self-identifying as Egyptian/Sudanese. Participants covered all age ranges from 18-29 to 70-74, but the majority were aged 30-49. Their children's ages varied from infancy to adulthood. We collected qualitative data through focus group discussions (FGDs) and individual cognitive interviews (CIs), to achieve methodological triangulation. We conducted 3 FGDs for each cultural group, 12 CIs in the British group and 8 CIs in the Egyptian/Sudanese group. FGDs explored autism symptoms and atypical child development. CIs focused on 10 items describing a variety of autistic traits, drawn from a widely used screening tool, the *Autism-spectrum Quotient: Children's version* (AQ-Child). Data from the two communities were analysed collectively using template analyses; subsequently, comparisons were made between the British and the Egyptian/Sudanese groups within themes.

Results: Three overarching themes were developed (template available in the Figure): 1) Value judgements of traits and behaviours, whereby participants' perspectives on children's development seemed influenced by their considerations on whether behaviours relevant to autism were desirable and important for development, or inappropriate; 2) Considerations of differences

between children, including comparisons with peers or siblings, discussions of age and developmental milestones and comments on personality traits; 3) Problematic interpretations of the wording of autistic traits descriptions in the AQ-Child, including difficulties in understanding some items, and ambiguity of wording. Cross-cultural comparisons suggested subtle differences between British and Egyptian/Sudanese parents' interpretations and value judgements of traits relevant to autism. British participants referred to age expectations and comparisons with other children more often than the Egyptian/Sudanese group, suggesting that there may be cultural differences in parents' thought process when evaluating children's development. However, overall within-group variability appeared larger than cross-cultural differences. In particular, when discussing desirability of traits, British participants suggested that older and working-class parents may have tighter boundaries than younger and middle-class families in what they consider appropriate behaviour for children.

Conclusions: Cultural differences and within-community factors, such as socioeconomic status and age, may influence the way in which parents of typically developing children perceive and report on children's development relevant to autism. Our findings can inform the adaptation and implementation of screening and diagnostic tools in multi-cultural settings, to promote better recognition of autism symptoms in diverse communities, where autism tends to be underdiagnosed.

**425.037 (Poster)** Parental Perspectives on the Impact of COVID-19 on Their Young Children with Autism Spectrum Disorder and Themselves - a Preliminary Study from India

**D. Nair<sup>1</sup>, P. Vaidhyathan<sup>2</sup>, S. Nagesh<sup>1</sup>, N. Dadlani<sup>1</sup>, D. Swaminathan<sup>2</sup> and S. S. Meera<sup>2</sup>, (1)Latika Roy Foundation, Dehradun, India, (2)National Institute of Mental Health and Neurosciences, Bangalore, India**

---

Background:

COVID -19 has impacted individuals in ways like never before. It's impact on families of children with Autism Spectrum Disorder (ASD) and the children themselves, has resulted in a sense of anxiety and panic among parents/caregivers. Many countries, including India, have gone through an extended period of lockdown which has shifted lifestyle significantly, causing disruptions especially for children with ASD, for whom routines play an important role. Parents of these children have taken over the roles of teachers and therapists in addition to their usual roles of parenting, employment and managing homes creating significant influences on the nature of their interactions. In addition, developmental and educational services that children with ASD receive have now moved to a predominantly virtual mode.

Objectives:

This study aimed to understand the impact of COVID-19 on young children with ASD and their parents during the lockdown, from a region near the Himalayan foothills, India

Methods:

A total of 10 families of children with ASD attending an intervention center participated in two semi-structured focus group discussions (FGD) (n=5/group). This was conducted with the parents via Zoom, in order to explore the study objective in open dialogue (~2hours/FGD). The study was led by two investigators using a set of predetermined probes. Audio recordings were transcribed by hand and coded to extract significant themes. All 10 children attended the same intervention center in-person before the pandemic that included physio (PT), occupational, speech-language (SLT) and behaviour therapy, and moved to virtual mode during the pandemic.

Results:

Mean (SD) age of children whose parents contributed to the study was 62.7 (10.53) months; range: 48-84mo. The FGD consisted predominantly of mothers (90%). All families belonged to lower-middle SES. Other socio-demographic variables across the 2 FGDs were similar (e.g. education, religion etc.). All families spoke Hindi. Pre-COVID children spent ~ 3hours, 5days per week at the intervention center. However, during the lockdown, there was a significant drop in time spent (virtual) with staff of the intervention center - children attended ~ 1 hour per day for 5 days a week. A total of 10 themes emerged from the FGD: these included positive, negative and mixed experiences. Positive themes included improved (a)communication skills and, (b)play routines attributed to increased time spent with the child(ren). Negative themes included (a)enhanced parental stress, (b)change in child's behaviour e.g. increased aggression attributed to being home-bound, altered routines and lack of in-person intervention/presence of limited virtual intervention sessions, (c)increase in restrictive repetitive behaviours and, (d)worsening of academic skills. Families provided mixed responses in areas of (a)social- emotional abilities, (b)attention and (c)compliance to virtual therapy (PT, SLT)/classroom activities during COVID-19.

## Conclusions:

Given that virtual mode of learning may stay on, parents will continue to be mediators between therapists and teachers, and their child. Care must be taken to make parents feel sufficiently empowered and motivated. This study provides a preliminary framework to develop a more comprehensive model for virtual learning that may help ameliorate parental stress and concerns that were repeatedly brought out through the FGDs.

### **425.038** (Poster) Pilot Study to Improve Access to Early Intervention for Autism in Africa

**L. Franz<sup>1</sup>, M. Viljoen<sup>2</sup>, N. Shabalala<sup>2</sup>, N. Seris<sup>2</sup>, M. Ndlovu<sup>2</sup>, A. Reider<sup>3</sup>, E. L. Turner<sup>4</sup>, R. Simmons<sup>4</sup> and P. J. de Vries<sup>2</sup>,** (1)Duke Center for Autism and Brain Development, Department of Psychiatry and Behavioral Sciences, Duke University, Durham, NC, (2)Centre for Autism Research in Africa, Division of Child & Adolescent Psychiatry, University of Cape Town, Cape Town, South Africa, (3)Duke Global Health Institute, Duke University, Durham, NC, (4)Department of Biostatistics and Bioinformatics, Duke University, Durham, NC

---

**Background:** By 2050 Africa will be home to 2 in 5 of the world's children. This demographic shift highlights the importance of developing feasible, contextually appropriate early ASD intervention, that can be integrated into existing systems of care. Naturalistic Developmental Behavioral Intervention (NDBI) is a class of early intervention emerging as best practice. Caregivers can be coached in NDBI strategies, which they incorporate into caregiver-child routines. Non-specialist-delivered NDBI caregiver coaching is a key implementation strategy and responsive to low resource environments.

**Objectives:** Community-Early Start Denver Model (C-ESDM) are web-based open access materials, designed to support families in low-resource settings learn NDBI strategies. In our South African study, we adapted a C-ESDM coaching approach for non-specialists and assessed implementation and caregiver-child outcomes. We utilized the apprenticeship model for lay counselor supervision in mental health for ongoing non-specialist support.

**Methods:** Implementation and clinical data from an ongoing longitudinal pre-post study with one study arm will be presented. A qualitative process evaluation was conducted following a pre-pilot of the adapted NDBI coaching approach to identify preliminary implementation determinants. Mean change (post-pre) and 95% confidence intervals were calculated for each outcome to assess the effect of the caregiver coaching.

**Results:** C-ESDM adaptations for non-specialist delivery are documented using the Wiltsey-Stirman framework. Barriers of intervention delivery were identified and adaptations made prior to the pilot study. Data from 10 caregiver-child dyads is included in the abstract. The average (SD) child age was 53 (8.75) months and caregivers were mothers (n=4, 40%), fathers (4, 40%), and grandmothers (2, 20%). Nine children (90%) received ADOS Module 1, and 1 received Module 2; with mean ADOS comparison scores of 6.5 (SD=1.58). Data offers early indications that caregivers can implement NDBI strategies when coached by non-specialists. After 12 sessions ESDM caregiver fidelity mean scores increased from 2.93 (SD=.33) to 3.73 (SD=.31). Furthermore 3/5 Joint Engagement Rating Inventory (JERI) caregiver items showed significant improvement after 12 sessions: Following in on a child's focus (mean change: 1.7, 95% C.I. 0.63 – 2.77), Language facilitation (1.6, 95% C.I. 0.33 – 2.87), and Communication temptations (1.1, 95% C.I. 0.06 – 2.14). Pilot data also shows growth in child social communication - indicated by increases in Vineland Adaptive Behavior Scales, 3rd Edition (VABS-3) Communication (mean change: 7.5, 95% C.I. 2.2 – 12.9) and Socialization Subscale Standard Score (6.4, 95% C.I. 0.4 – 12.4), and Griffiths III Language/Communication (0.05, 95% C.I. 0.03 – 0.07) and Personal, Social, Emotional Developmental Quotients (0.03, 95% C.I. 0.00 – 0.06). Furthermore, caregiver sense of competency increased by 4.7 points after 12 coaching sessions (95% C.I. -1.6 – 10.0).

**Conclusions:** South Africa, a multi-cultural nation marked by stark disparities, provides a unique opportunity to assess feasibility and impact of a scalable intervention, in an environment with significant contextual challenges. This study is timely given growing recognition of the importance of early ASD intervention, emerging policies in low and middle income countries that provide a framework on which to build intervention services, and global programs that support child developmental needs.

### **425.039** (Poster) Predictors of Parenting Stress in Malaysian Mothers and Fathers with and without Children on the Autism Spectrum: Parental Sleep and Depression, Family Functioning, and Child Autism Symptoms and Behavioral Concerns

**K. J. Golden<sup>1,2,3</sup>, K. Ilias<sup>2,4</sup>, M. Park<sup>2,5</sup> and K. Cornish<sup>6</sup>,** (1)Neuropharmacology Research Strength, Jeffrey Cheah School of Medicine and Health Sciences, Monash University Malaysia, Bandar Sunway, Malaysia, (2)Department of Psychology, Jeffrey Cheah School of Medicine and Health Sciences, Monash University Malaysia, Bandar Sunway, Malaysia, (3)Global Asia in the 21st Century (GA21), Monash University Malaysia, Bandar Sunway, Malaysia, (4)Department of Basic Sciences, Faculty of Health Sciences, Universiti Teknologi MARA, Puncak Alam, Selangor, Malaysia, (5)Department of Psychology, School of Social Sciences, Nottingham Trent University, Nottingham, United Kingdom, (6)Turner Institute for Brain and Mental Health, School of Psychological Sciences, Monash University, Melbourne, VIC, Australia

---

Background: Past research highlighted that parenting stress may be experienced differently by mothers and fathers and depends on multiple factors; however, problematically, research with fathers of children on the autism spectrum has been limited globally and locally. Although awareness and acceptance of autism and neurodiversity has been slowly increasing in recent years in South-East Asia, there remains a dearth of local scientific research on the experiences of parents of children on the autism spectrum in Malaysia. The predictors of stress for parents in Malaysia (and their related support needs) may be unique from other Western countries, given the significant lack of resources and support available to help these families and the presence of ongoing stigmas. Research in this region is urgently needed to better understand the needs of diverse families, so that support, services, and policies can be better tailored to their holistic needs and be relevant to their cultures.

Objectives: The current cross-sectional quantitative study examined in a hard-copy survey self-reported parent and child predictors of parenting stress in Malaysian mothers and fathers of primary school-age children (5 to 13 years) on the autism spectrum (ASC), and in an age-matched comparison group of parents/children with typical development (TD). This quantitative survey study was a part of a broader, longitudinal, mixed-methods project that followed a grounded theory approach, adopting Charmaz's social constructivist perspective design.

Methods: Participants included ASC parent-child dyads (69 mothers, 52 fathers;  $M_{\text{parentage}}=38.8, SD=4.87$ ;  $M_{\text{childage}}=7.8, SD=1.86$ ) and TD parent-child dyads (65 mothers, 43 fathers;  $M_{\text{parentage}}=38.7, SD=5.22$ ;  $M_{\text{childage}}=8.43, SD=1.95$ ). All children on the autism spectrum were formally diagnosed with a DSM-IV/DSM-5 autism spectrum disorder. Furthermore, the Social Responsive Scale-2 (SRS-2) was utilized as an additional inclusion/exclusion criteria, with T-scores equal to or  $>60$  used as inclusion criteria for the ASC group and exclusion criteria for the TD group. Measures included: Demographic/family/diagnostic information; SRS-2; Parenting Stress Index Short-Form (PSI-SF); Depression subscale of Depression, Anxiety and Stress Scale (DASS-21); General Functioning Subscale of the Family Assessment Device (GF-FAD); Pittsburgh Sleep Quality Index (PSQI); and Developmental Behavior Checklist (DBC-Parent).

Results: Mothers and fathers in both groups reported comparable parenting stress levels with no significant gender differences in parental stress emerging for the total PSI-SF score and subscale scores (PSI-SF-PD, PSI-SF-DC, PSI-SF-PCDI). Parents of children on the autism spectrum reported significantly more parenting stress (total and subscale scores) and depressive symptoms as well as poorer sleep quality and family functioning than parents of TD children ( $ps < .001$ ). In the ASC group, higher autism symptom severity (specifically, higher social communication/interaction symptoms; SRS-2 Social Communication Interaction Index), higher maternal depressive symptoms, poorer family functioning, and poorer maternal sleep quality (total PSQI score) predicted maternal stress. Higher child behavioral concerns predicted paternal stress in both the ASC and TD groups.

Conclusions: The project concluded with numerous workshops and meetings, discussing recommendations with participants, professionals, and community/government stakeholders. The findings highlight the need to develop programs and supports for wellbeing across the family system. Furthermore, there remains a need to increase awareness and better support understandings of neurodiversity in the region.

#### **425.040** (Poster) Socio-Economic Profiles in a Large European Multinational Autism Study

**T. Del Bianco<sup>1</sup>**, G. Lockwood Estrin<sup>1</sup>, L. Mason<sup>2</sup>, J. Tillmann<sup>3</sup>, T. Charman<sup>4</sup>, E. Loth<sup>5</sup>, J. K. Buitelaar<sup>6</sup>, D. Murphy<sup>7</sup>, M. Johnson<sup>7</sup>, E. J. Jones<sup>8</sup> and L. G. EU-AIMS<sup>8</sup>, (1)Centre for Brain and Cognitive Development, Birkbeck University of London, London, United Kingdom, (2)Centre for Brain and Cognitive Development, Birkbeck, University of London, London, United Kingdom, (3)Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, United Kingdom, (4)Department of Psychology, Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, United Kingdom, (5)Department of Forensic and Neurodevelopmental Sciences, Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, United Kingdom, (6)Department of Cognitive Neuroscience, Donders Institute for Brain, Cognition and Behaviour, Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands, (7)Department of Psychology, University of Cambridge, Cambridge, United Kingdom, (8)EU-AIMS Organization, London, United Kingdom

Background: Social attention (SA) has been studied in-depth as a potential biomarker of autism - with autistic individuals showing reduced attention to social stimuli - and eye-tracking has been a favoured approach due to its objective measurement. Recent studies have revealed differences in SA with varying Socioeconomic Scores (SES), however, very little focus has been placed on SES in autism studies. The large multi-national autism biomarker study, *LEAP*, provides a timely opportunity to fully explore SES and its relationship with SA across a large sample at multiple sites.

Objectives: We aim to outline representation biases and disparities by describing this population in terms of demographics (e.g. income, education, ethnicity), and examine the SES effect on a candidate biomarker - the attention to faces in a social scene of autistic participants vs control - and its interaction with SES.

Methods: 764 individuals volunteered to participate in the LEAP study, and 418 autistic (females: 114, average age=16.5, SD=5.8, average IQ=116.2, SD=20.2) and 195 controls (females: 60, average age=14.4, SD=4.8, average IQ=116.2, SD=21.1) had available demographic data. Questionnaires included categories (e.g., range of family income), or short answers (e.g., occupation). We calculated the Four Factors Index (FFI) - a composite indicator of SES - as the average of the weighted sum of parental education and occupation, and the percentages/averages by group for each indicator and the FFI (available for N=494). Eye-movements while watching a social scene (multiple photographs of people) for 20 seconds were recorded as part of a composite eye-tracking session. SA was estimated by extracting the average percentage looking time (PLT) to the face for each participant, and investigated with a mixed model including group by site interacting with FFI as predictors, and random intercepts by participant, site and stimulus.

Results: By far, the greatest proportion of participants were white and native to the country of the site, with London showing the greatest diversity, but similarly to other sites, less diversity than population census data. On average, the control group earned more in the higher income range, and more frequently completed tertiary education (Fig. 1A). Fathers employed as directors were twice as common in the control group, that also reported a higher number of children per household. The FFI (Fig. 1B) demonstrated that the sample was not exclusively high SES, but did not include the lowest range; the autistic group had a lower median and minimum FFI across sites. PLT in the autistic group was significantly affected by FFI in the London site, with higher SES associated with lower overall SA ( $\beta=-0.08\%$ ,  $SE=0.03$ ,  $p\text{-value}=0.001$ , Fig. 1C).

Conclusions: Our preliminary results suggest representation imbalance in ethnicity and origin, and undersampling of participants of lower SES. With respect to SA in autism, preliminary evidence suggests that PLT is confounded by SES. These results highlight the importance of including diverse populations and fully describing the samples in autism research.

**425.041 (Poster) The Bamboo Ceiling: A Preliminary Exploration of Autism Spectrum Condition in AAPI Girls**

**K. G. Tena<sup>1</sup>, M. L. Cola<sup>1</sup>, A. S. Russell<sup>2</sup>, V. Petrulla<sup>2</sup> and J. Parish-Morris<sup>1</sup>, (1)Center for Autism Research, Children's Hospital of Philadelphia, Philadelphia, PA, (2)Florida International University, Miami, FL**

Background: Asian Americans comprise the fastest-growing racial/ethnic subgroup in the United States<sup>1</sup>, but little is known about autism spectrum condition (ASC) in the Asian American Pacific Islander (AAPI) cultural context. It is widely understood that people of color face systemic challenges when accessing ASC supports, with factors such as maternal race/ethnicity and language spoken at home affecting when a child enters intervention services<sup>2</sup>. Similarly, extant research suggests that girls are diagnosed with ASC less often than boys<sup>4</sup> even when their symptoms are equally severe<sup>3</sup>. This may be due, in part, to insufficient understanding of the way ASC manifests in girls. Importantly, almost nothing is known about how the intersecting factors of race and sex influence ASC detection, diagnosis, and treatment. Autistic girls and boys present distinct symptom profiles in a variety of domains, such as language<sup>6-12</sup> – but prior studies are limited by significant White overrepresentation<sup>13</sup>. Culturally informed research on ASC that considers gendered societal expectations is vital for improving diagnostic methods and providing personalized supports in cultural subgroups in which autism is often stigmatized, misdiagnosed, or undiagnosed.

Objectives: Review prior research on the presentation of ASC in Asian American girls and explore the intersection of culture and gender on the way ASC is perceived and treated in this population.

Methods: A literature search was conducted in PsycInfo, PubMed, ERIC, and Google Scholar, with search terms “autis\*” AND “Asian” AND (“female” OR “girl”). The resulting set of references was augmented with additional materials identified from other sources, including reference lists of included works.

Results: Results of a broad, exploratory literature review revealed significant research gaps in our understanding of ASC in AAPI girls and women, with very few papers focused on the female autism phenotype in these groups. The past 20 years have seen a growing number of papers that explore “the female autism phenotype” in ASC, but few if any had sufficient numbers of AAPI participants to examine differences by race/cultural background. Of papers focused on non-Western “Asian” populations, most were Chinese-focused samples<sup>12</sup>, reinforcing the perception of “Asian” as a monolith. Importantly, few studies collected data on key cultural factors (e.g., religious background, first language, first- or second-generation immigrant status, enculturation, residence in an ethnic enclave neighborhood) that would enable researchers to parse the influence of culture and culturally-specific gendered expectations on ASC.

Conclusions: ASC is poorly understood in girls, and the ways that (anti-Asian) racism and perceived cultural and gender norms<sup>14</sup> interact to erect barriers to diagnosis and services have largely been unexamined by the field. Designing studies that disentangle these complicated interacting effects could inform personalized, culturally relevant treatments and policies. Multi-level changes are needed to improve the experiences of AAPI girls with ASC, likely incorporating family- and community-focused approaches. Finally, research on Asian American subpopulations is important for designing targeted governmental programs, such as

language assistance for mental health and disabilities support. This suite of approaches will move us closer to developing best practices to support AAPI communities.

**425.042** (Poster) The COVID 19 Crisis and the Support of the Program Parents Taking Action for Parents of Pre/Adolescents with Autism Spectrum Disorder in Colombia

*M. Garcia<sup>a</sup> and F. Balcazar<sup>a</sup>, (1)UIC, Chicago, IL, (2)University of Illinois at Chicago, Chicago, IL*

---

Background: the current crisis related to the COVID 19 has impacted every country and every population around the world. The most vulnerable populations have not been an exception, and in fact, they have dealt with significant challenges in terms of their economic situation, their employment status, access to health care services, and social connections. In Colombia, this crisis has struck families of children with disabilities in many aspects too. Specifically, families of children with Autism Spectrum Disorder (ASD) have dealt with changes in the routines of their children, such as schooling, eating habits, therapies, and extracurricular activities, and this have triggered difficult behaviors and situations that they were not prepared for. In addition, pre/adolescents with ASD have extra challenges in terms of the management of their emotions and mental health, sexual inappropriate behaviors, and adapting to new routines. The program Parents Taking Actions, that was initially designed to be “in person,” was modified to a hybrid model in which 50% of the program was online and 50% in person. This educational program covers topics of pre/adolescence, puberty and sexuality and the management of these topics.

Objectives: this study aims to show the impact of the program Parents Taking Action (PTA) during the crisis of the COVID 19 and how strategies provided in this program helped parents to support their children in the transitions related to school, habits, therapies and overall routines. This program also aimed to increase overall empowerment and self-efficacy of parents.

Methods: using semi-structured phone interviews, Colombian parents of pre/adolescents with ASD were asked questions related to the challenges that their family was going through, and the changes in behavior that their children were experiencing. The interviews also included questions about how the PTA program provided knowledge and support for them to manage these challenges and changes in the routine, and how empowered they felt after receiving the program. Each interview had an average duration of 40 minutes.

Results: in this study, 11 Colombian parents of preadolescents between 10 and 17 years old participated in the interviews. They reported that the program helped them feel empowered to manage the new challenges that the COVID 19 crisis brought to their homes. Through a deductive qualitative analysis, data showed that the information, resources, and strategies taught in the program were important tools for parents to deal with difficult situations, such as changes in their children’s overall routines, lack of contact with the exterior world (public transportation, therapy location, etc.), virtual school, increases of inappropriate sexual behaviors, increases in difficult behaviors, and overall mental health challenges.

Conclusions: the program Parents Taking Action, provided knowledge, resources, and tools for parents to manage difficult situations related to the changes related to the COVID 19 confinement, as well as challenges related to puberty and sexuality, and behaviors that their children experience during this transition. Therefore, the program is an effective tool for community organizations and health providers to offer extra supports to these families during their children’s stage of puberty and pre/adolescence.

**425.043** (Poster) The First Years Inventory for Spain: An Linguistic and Conceptual Analysis of Translation Methods  
*R. Palomo<sup>a</sup>, R. Campos<sup>a</sup>, M. DuBay<sup>a</sup>, M. Zamora<sup>a</sup>, A. Watkins<sup>a</sup>, P. Melero<sup>a</sup> and C. Nieto<sup>a</sup>, (1)Universidad Complutense de Madrid, Madrid, Spain, (2)Department of Basic Psychology, Universidad Autónoma de Madrid, Madrid, Spain, (3)University of North Carolina, Chapel Hill, NC, (4)Autismo Sevilla, Sevilla, Spain, (5)Abbeywood Community School, Bristol, United Kingdom, (6)Valencia Montessori School, Valencia, Spain*

---

Background:

Early identification of autism spectrum disorder (ASD) is imperative for access to early intervention. The *First Years Inventory v3.1* (FYIv3.1; Baranek et al., 2013) is designed to detect behavioral symptoms of ASD around one year of age, demonstrating good psychometrics properties (Chen et al., 2019). In Spain, there is a lack of validated ASD screening tools for children under 18 months of age. The goal of this project is to translate and culturally adapt the FYIv3.1 with a Spanish population.

Sufficient translations are equivalent to the original version linguistically, conceptually, and psychometrically, so that the instrument measures the same latent variables in the new population (Beaton et al., 2000). A rigorous cultural adaptation approach is required to achieve this equivalence, including multiple translators, quality assurance measures, and pre-testing (DuBay et al, 2019). Insufficient translation and cultural adaptation methods may result in psychometric differences between

language versions, possibly resulting in poor quality assessments (Soto et al., 2015). More information is needed regarding which specific methods are effective for identifying and addressing which threats to equivalence.

#### Objectives:

This project presents and describes the translation and cultural adaptation process for the FYIv3.1, highlighting difficulties identified during the process. We will qualitatively and quantitatively analyze the challenges identified during the 1) forward translation and 2) pre-testing phases, describing which threats to equivalence were identified and addressed during each step in the process, with the goal of informing future translation teams.

#### Methods:

Four Spanish translators, strategically selected for their background and expertise, independently translated the FYIv3.1 to Spanish. Translations were collaboratively synthesized into a single draft. This draft will go through several rounds of pre-testing with 20 target population members (Spanish parents of children 8-16mo across a range of demographic groups). During pre-testing, a cognitive interview format reveals item interpretations and cognitive processes of participants, exposing conflicts between original FYIv3.1 items and their translations. A final version will be developed based on qualitative and quantitative data from throughout the process.

#### Results:

Preliminary results suggest that during the forward translation, semantic and/or grammatical agreement between the translators was absent or minimal for half of the items. A third of all items required conceptual modifications to maintain construct equivalence between translations. Preliminary pre-testing results indicate that at least 15% of items were misinterpreted by participants. Semantic difficulties related to conceptual complexity were observed in 60% of these items. Items describing RRBIs were frequently difficult for participants to understand. We found a limited correlation between items presenting difficulty in the forward translation as compared to pre-testing. A complete linguistic analysis with specific examples will be included.

#### Conclusions:

These results demonstrate both the complexity of the forward translation process and the potential misinterpretations by target population members, highlighting the need to directly confirm a translation's equivalence during the translation process. This evidence reveals the specific methods that effectively identify and address relevant threats to equivalence between versions, which will inform future translation work for similar ASD assessment tools.

**425.044** (Poster) The Impact of the Lockdown Due to COVID-19 on ASD People in Argentina: A First Person Point of View. M. Nunez<sup>1</sup>, D. Valdez<sup>2</sup>, A. Wilches<sup>3</sup>, A. Rattazzi<sup>4</sup>, S. H. Cukier<sup>5</sup>, N. Barrios<sup>6</sup>, C. S. Paula<sup>7</sup>, G. Garrido<sup>8</sup>, A. Rosoli<sup>9</sup>, G. Perez Liz<sup>10</sup>, R. A. Garcia<sup>10</sup> and C. Nava<sup>11</sup>, (1)Faculty of Psychology, Universidad Autonoma de Madrid, Madrid, Spain, (2)Universidad de Buenos Aires- FLACSO, Buenos Aires, Argentina, (3)FLACSO, Buenos Aires, Argentina, (4)PANAACEA, Buenos Aires, Argentina, (5)Fleni, Capital Federal, ARGENTINA, (6)Developmental Disorder Program, Universidade Presbiteriana Mackenzie, São Paulo, Brazil, (7)Universidad de la República, Montevideo, Uruguay, (8)Projects, Organizacion Estados Iberoamericanos, Santo Domingo, Dominican Republic, (9)A.J. Drexel Autism Institute, Drexel University, Philadelphia, PA, (10)Clínica Las Condes, Santiago, Chile., Santiago, CHILE, (11)Psychological Science, University of Texas Rio Grande Valley, Edinburg, TX

---

#### Background:

Argentina has been severely affected by COVID-19, with 2,737 infected for every 100,000 inhabitants; the country had a severe five months lockdown. This situation may be particularly challenging for people with ASD. In order to understand how people with ASD have experienced the lockdown it is paramount to count with their own testimony first hand, rather than simply rely on the view of their families or the professionals working with them; their testimony must also be placed within their socio-economic, cultural context and health provision context.

#### Objectives:

Describe the impact of the COVID-19 lockdown on people with ASD in Argentina from their own perspective in relation to: (1) any changes in feeding and sleep habits, anxiety and behavior and (2) the different types of treatment and schooling, their possible discontinuity, the telematic intervention and its scope and limitations.

#### Methods:

Twenty-seven ASD people (15 men and 12 women) took part in an online survey of the network REAL (Red Espectro Autista Latinoamérica). Participants are on the high-functioning end of the spectrum, including 60% with an Asperger Syndrome diagnosis; 56% had a degree in higher education. The survey enquired about 8 aspects, as follows: Place of residence, Pre- and post-lockdown schooling, Situation in the household, Treatment and support at the time of the start of the pandemic, Behavioral changes from home isolation, Outings, Treatment and support during the pandemic, Main concerns during quarantine.

#### Results:

Before the lockdown, most participants were receiving some type of therapy/treatment, as follows: 22% reported psychoanalytic therapy, 22% medication treatment, 15%, behavioral therapy and 8%. During the lockdown, 15% of the participants had their treatment totally suspended due to the closure of either the therapy centers (26%) or the health-service providers (26%). Forty-two percent of participants report to have received some counselling through video-calls, and 19% over the phone. When in need of help, 44% of participants report to resource to a therapist. Sixteen percent report not to have needed any help. The main problems experienced during the lockdown include: sleep disturbances (55%), feeding problems (54%), concentration difficulties and irritability (54%), mood alterations (69%), aggressivity (19%), wandering (32%), anxiety (74%), therapeutic setbacks (81%). Additionally, participants reported difficulties in understanding why they could not leave the house (26%) and an increased concern to become ill (41%). During the lockdown, 78% acknowledges to have increased the use of electronic devices outside their educational use. As for the perceived improvements, 52% of participants report a behavioral improvement when the outings began.

#### Conclusions:

Results indicate that the lockdown experienced by Argentinian high-functioning ASD adolescents and adults has put a considerable strain on their daily habits, mood and emotional welfare and their therapeutic support and progress. Further analysis on the relationship between the different aspects reported are in progress. Nevertheless, these descriptive findings provide an initial step into understanding the impact that the lockdown in people with ASD within a socio-economic and cultural context where research and health provision in ASD is significantly under-resourced.

#### 425.045 (Poster) The Importance of Socio-Cultural Context on the Quality of Life of Autistic Adults: A Comparison between France and Quebec

*V. Caron<sup>1</sup>, N. Jeanneret<sup>2,3</sup>, M. Giroux<sup>4</sup>, L. Guerrero<sup>5</sup>, M. Ouimet<sup>6</sup>, B. Forgeot d'Arc<sup>6</sup>, I. Soulieres<sup>1</sup> and I. Courcy<sup>3</sup>, (1)Département de Psychologie, Université du Québec à Montréal, Montréal, QC, Canada, (2)CIUSSS Nord-de-l'Île-de-Montréal, Montréal, QC, Canada, (3)Département de Sociologie, Université du Québec à Montréal, Montréal, QC, Canada, (4)Aut'Créatifs, Montréal, QC, Canada, (5)Neurodiversité, Montréal, QC, Canada, (6)Département de Psychiatrie, Université de Montréal, Montréal, QC, CANADA*

**Background:** Quality of life (QoL) is a multidimensional concept based on a person's subjective assessment of the positive and negative aspects of their life in several areas related to physical and psychological health, environment, and social interactions. Many studies reported a poorer QoL in autistic individuals as compared to typical individuals. Scientific literature is inconsistent in terms of what predicts QoL. Since QoL is indissociable from sociocultural context, the factors associated with QoL might differ between France and Quebec.

**Objectives:** This research aims to explore whether the socio-cultural context 1-has an effect on quality of life of autistic individuals, and 2- moderates the association between autism-specific quality of life and socio-demographic and health characteristics.

**Methods:** An online survey was developed in collaboration with autistic expert collaborators. In this survey, QoL was measured by the autism-specific quality of life scale (ASQoL), which was developed to cover what matters most in terms of QoL according to autistic people. Autistic traits were self-evaluated using the short version of the Autism Spectrum Quotient (AQ). Physical health conditions, mental health diagnosis and sociodemographic parameters were also assessed.

**Results:** 226 participants living in Quebec and 204 living in France took part in the study. A majority of participants (Quebec 79%, France 59%) had received a formal diagnosis of autism and the others were self-diagnosed. On average, participants from Quebec reported significantly better QoL, as measured by the ASQoL ( $M = 2.92$ ,  $SD = 0.71$ ), than participants from France ( $M = 2.50$ ,  $SD = 0.67$ ),  $t(428) = -6.324$ ,  $p < .001$ . According to a general model ( $R^2$  adjusted = 27.7%), it appears that living in Quebec is a positive predictor of QoL in autistic individuals, standardized  $\beta = 0.204$ ,  $p < .001$ . In Quebec, experiencing violence whether verbal, physical, on the Internet or elsewhere, because they are autistic (referred to as specific violence), having chronic pain, having a high school diploma or less, and having anxiety disorders all significantly predicted a lower quality of life. In France, negative predictors of QoL in autistic individuals were having an AQ score of 6 or higher, experiencing specific violence, having mood, bipolar or depressive disorders. Still in France, positive predictors of QoL were being employed, being male and having a university degree.

**Conclusions:** In this research, most predictors of QoL (measured with ASQoL) are different in France and in Quebec suggesting that sociocultural context does influence autism-specific QoL. This confirms the importance of taking into account the sociocultural context when investigating QoL and its predictors in autism. Social representations of autism in the given population (in this case Quebec or France) might influence QoL. However, further studies are needed to explore such possible differences between France and Quebec and to explore whether they indeed influence the QoL of autistic adults. As for specific violence, it emerges as an equally or even more important predictor of autism-specific QoL than medical conditions or mental health diagnosis, demonstrating the importance of addressing specific violence and implementing programs to reduce its prevalence.

## Interventions - Non-pharmacologic - Infant, Toddler, and Preschool

### PANEL SESSION — INTERVENTIONS - NON-PHARMACOLOGIC - INFANT, TODDLER, AND PRESCHOOL

#### Panel 216 - The State of Autism Intervention Research for Young Children

**Panel Chair:** Micheal Sandbank, *The University of Texas at Austin, Austin, TX*

This panel highlights findings from several recent (published and in-progress) systematic reviews and meta-analyses of nonpharmacological intervention research involving autistic children. The first presenter will summarize new findings about the effectiveness of common intervention approaches (i.e., behavioral, developmental, naturalistic developmental behavioral interventions [NDBIs]) for supporting development in this population, taken from a comprehensive meta-analysis known as Project AIM (Autism Intervention Meta-analysis; Sandbank et al., 2020), as well as the extent to which intervention effectiveness varies by different intervention parameters, such as implementer and intensity. The second presenter will highlight findings from secondary analyses of this data examining participant characteristics that may differentially influence intervention effectiveness for supporting development in important domains (i.e., play, language, adaptive behavior, etc.). The third presenter will review findings regarding the quality of studies supporting different intervention approaches, and report new findings in trends in quality indicators over time in this literature. The final presenter will discuss ethical issues that continue to pervade autism early childhood intervention research, namely the prevalence of undisclosed conflicts of interest (COIs), in both group and single-case design studies. Each presenter will highlight questions that remain unanswered, and options for improving the quality and utility of future research.

**216.001** (Panel) *The Influence of Intensity and Implementer on Intervention Effectiveness*

*M. Sandbank<sup>1</sup>, S. Crowley<sup>2</sup>, K. Bottema-Beutel<sup>3</sup> and T. G. Woynarowski<sup>3</sup>, (1)The University of Texas at Austin, Austin, TX, (2)Lynch School of Education, Boston College, Chestnut Hill, MA, (3)Department of Hearing and Speech Sciences, Vanderbilt University Medical Center, Nashville, TN*

**Background:** Although relatively rare a decade ago, the number of group studies testing interventions for young autistic children has dramatically increased (French & Kennedy, 2018). These studies represent a diverse set of intervention approaches designed to support a wide range of outcomes. A scoping systematic review and meta-analysis recently summarized available group studies of interventions for autistic children up to age 8, reporting results in a manner that permitted comparison of summary effects within intervention approach and outcome type (Sandbank et al., 2020). However, even within intervention approach, varied intervention parameters (i.e., implementer, intensity) may differentially influence intervention effectiveness, and this influence may even vary by outcome domain. Understanding how intervention parameters influence intervention effectiveness can facilitate intervention refinement to encourage the development of maximally effective therapies.

**Objectives:** The purpose of this study was to identify whether intervention implementer (e.g., caregiver, clinician, both working in concert) and cumulative intervention intensity (i.e., intervention dose x frequency x duration) significantly moderated intervention effects on key outcomes (i.e., adaptive behavior, cognition, core features of autism, language, and play).

**Methods:** Using data from the main meta-analysis (Project AIM; Sandbank et al., 2020), which features effects for 1615 outcomes extracted from 150 reports of 130 studies representing 6,240 participants, we tested the influence of intervention implementer and cumulative intensity using a series of meta-regression models conducted within subsets of data from each outcome domain (i.e., adaptive behavior, cognition, core features of autism, language, and play), relying on robust variance estimation to control for the intercorrelation of outcomes within studies. We also separately examined whether cumulative intensity moderated effects of behavioral interventions, developmental interventions, and NDBIs.

**Results:** For adaptive and cognitive outcomes, intervention effects were significantly larger for interventions implemented by clinicians alone relative to those implemented by caregivers and clinicians combined or caregivers alone. For outcomes derived from measures of the core features of autism (e.g., ADOS, CARS, etc.), intervention effects were significantly moderated by implementer and cumulative intensity, though our confidence in these results is low due to the prevalence of poorly-designed studies in this subset of data. Intervention effects on language outcomes were significantly moderated by intervention implementer, favoring interventions implemented by clinicians alone or by clinicians and caregivers working in concert, compared to interventions implemented by caregivers alone. Intervention effects on play outcomes were not moderated by any intervention parameters. When examining the influence of intensity within subsets of data from studies of behavioral, developmental, and NDBI interventions, we found no evidence to support the notion that cumulative intervention intensity influences the effectiveness of these intervention approaches.

**Conclusions:** Interventions — specifically those that support adaptive behavior, language, and cognition — may be more effective when delivered directly by clinicians, or by caregivers working in concert with clinicians. At present, there is little evidence to support the notion that a greater number of intervention hours is uniformly associated with greater improvements (compared to low-intensity interventions), regardless of intervention approach. Studies which embed systematic, randomized comparisons of these parameters are needed.

**216.002 (Panel) Participant Characteristics That Influence the Effectiveness of Intervention**

*T. G. Woynaroski<sup>1</sup>, M. Sandbank<sup>2</sup>, K. Bottema-Beutel<sup>1</sup> and S. Crowley<sup>3</sup>, (1)Department of Hearing and Speech Sciences, Vanderbilt University Medical Center, Nashville, TN, (2)The University of Texas at Austin, Austin, TX, (3)Lynch School of Education, Boston College, Chestnut Hill, MA*

---

**Background:** Intervention is widely recommended as important for supporting development in young autistic children (Boyd et al., 2010), but evidence suggests it may be differentially effective depending on individual child attributes. Scholars have routinely asserted that intervention is more effective when delivered at an early age (e.g., below 4 years), although evidence supporting this assertion is mixed. Other potentially important child attributes that may influence intervention effectiveness include biological sex, language ability at intervention onset, and level of autism-related challenges.

**Objectives:** The purpose of this study was to examine the extent to which the summary effects of interventions on a variety of outcomes were significantly influenced by specific participant characteristics (i.e., age, sex, level of autism-related challenges, language ability) in early childhood.

**Methods:** Participant characteristics were coded as part of the main meta-analysis (Project AIM; Sandbank et al., 2020). Age was coded as the sample mean age in months at study entry. Sex was coded as the percentage of males in the sample. Level of autism-related challenges was categorized as either high or moderate based on sample means on diagnostic measures of autism characteristics. Language ability was coded as the sample mean language age equivalent in months when reported. Meta-regression models tested whether participant characteristics significantly moderated intervention effects on each outcome that was sufficiently represented across group design studies (i.e., adaptive behavior, cognition, core features of autism, language, and play).

**Results:** For cognitive outcomes and language outcomes, intervention effects were significantly larger for participant samples with higher mean participant entry-level language age. Intervention effects on play outcomes, adaptive outcomes, and measures of the core features of autism were not moderated by any participant characteristics.

**Conclusions:** Language ability at intervention onset may influence the effectiveness of therapies for supporting language and cognitive development, providing a developmental foundation upon which intervention can more effectively build. We did not find evidence that intervention effectiveness differed by participant sex or level of autism-related challenges at pre-treatment. However, true moderating effects of these child attributes may have been obscured by restricted range for the percentage of samples that were male, and by underrepresentation of samples with high levels of autism-related challenges. Notably, we failed to find evidence to support the notion that younger children make greater improvements compared to children that begin intervention at a later age. Although multiple studies attest that very young children can benefit from intervention, these results suggest that advancing age (up to 8 years) does not meaningfully limit intervention effectiveness.

**216.003 (Panel) The Quality of Studies in Autism Early Childhood Intervention Research**

*S. Crowley<sup>1</sup>, M. Sandbank<sup>2</sup>, K. Bottema-Beutel<sup>1</sup> and T. G. Woynaroski<sup>3</sup>, (1)Lynch School of Education, Boston College, Chestnut Hill, MA, (2)The University of Texas at Austin, Austin, TX, (3)Department of Hearing and Speech Sciences, Vanderbilt University Medical Center, Nashville, TN*

---

**Background:** Although the number of randomized controlled trials testing the effectiveness of interventions for young autistic children has precipitously increased in the last decade, the overall quality of this evidence base remains relatively poor. A previous study (Sandbank et al., 2020) reported the proportion of outcomes from studies of each intervention approach that were subject to threats posed by selection bias, detection bias, reliance on caregiver report for outcome assessment, and high levels of attrition. While some intervention approaches (i.e., developmental, NDBI) boasted relatively high proportions of outcomes that were immune to such threats, studies of other approaches (i.e., behavioral) had high proportions of outcomes that were plagued by selection bias, detection bias, and reliance on caregiver report. In order to assess the state and progress of autism early childhood intervention research, a report is needed which details the prevalence of these threats in the literature over time.

**Objectives:** Our aim was to derive statistics for various quality indicators of group design studies, disaggregated by year, allowing us to identify trends in study quality over time.

**Methods:** Using data from the main meta-analysis (Project AIM; Sandbank et al., 2020), we computed the number and percentage of outcomes from studies published each year from 1989 to 2017 (year of search) which were rated as having low, high, or unclear risk of selection bias, detection bias, and attrition bias, and which were derived from caregiver report.

**Results:** Although the percentage of outcomes from studies that employed randomization increased steadily over time, it was frequently less than 70%, even over the last decade. The percentage of outcomes rated as having low risk of attrition bias ranged from 53 - 100%. Although initially high, this percentage has decreased in recent years, potentially due to increases in sample sizes and better reporting standards. A substantial percentage of outcomes were derived from caregiver report, comprising as much as 90% of outcomes in early years when few studies were published. In the last decade, this percentage has remained relatively stable, ranging from approximately a quarter to half of all outcomes in studies published each year. Similarly, an ever larger portion of outcomes were subject to high detection bias each year (approximately half to three quarters). In most years, even in the past decade, the number of outcomes threatened by detection bias exceeded the number of outcomes that were not.

**Conclusions:** Data indicate that poor study quality, across several indicators, has persisted over time for group design intervention studies for young autistic children. This is unfortunate, as low quality studies increase bias, and may lead to the implementation of inefficacious support strategies. We argue that autism researchers and practitioners should be cognizant of these quality concerns when interpreting the existing evidence base for autism intervention research. Additionally, funding agencies should prioritize intervention research that utilizes high quality study designs, with the aim of increasing the availability of reliable evidence in this area.

**216.004 (Panel) Ethical Concerns in Autism Research: Pervasive Undisclosed Conflicts of Interest**  
*K. Bottema-Beutel and S. Crowley, Lynch School of Education, Boston College, Chestnut Hill, MA*

---

**Background:** An ethical concern that has only recently received attention in autism intervention literature is conflicts of interest (COIs). COIs occur in circumstances when researchers stand to potentially gain from their study findings. COIs can introduce bias into the research process through questionable research practices, poor quality designs, and inappropriate interpretation of data. Researchers may then claim positive effects for ineffective interventions. A recent study showed COIs were relatively prevalent, and often undisclosed in group-design autism intervention literature (Bottema-Beutel et al., 2020). However, this report arguably under-represented applied behavior analysis (ABA) research, because ABA studies often use single-case designs. Recent reviews of ABA research have suggested that study quality is generally poor in some subfields of ABA (Bottema-Beutel & Crowley, 2020; Reichow, Barton, & Maggin, 2018), and COIs could potentially contribute to this state of affairs. Because ABA services are routinely provided to autistic children (Xu et al., 2019), this is an important area of investigation.

**Objectives:** In this study, we focus on COIs related to researcher employment as a clinical provider or a training consultant to other providers. We focus on these COIs because they are identifiable even when researchers do not disclose them, and because financial incentives unambiguously constitute COIs. We sought to determine: (a) the proportion of articles with authors with a clinical/training consultancy COI, (b) the proportion of articles with authors who had clinical and/or training COIs that omitted to disclose these roles as COIs in the manuscript, (c) the proportion of articles with authors who had clinical and/or training COIs that erroneously declared in the manuscript that the authors had no COIs, and (d) whether COI omissions were in violation of journal policies.

**Methods:** We tallied author COIs in articles published over a one-year period that tested, commented on, or reviewed autism intervention strategies, extracted from eight journals devoted to publishing ABA research. We located undisclosed COIs via web searches.

**Results:** Of the 180 studies that met inclusion criteria, we found that 84% had at least one author with a clinical/training consultancy COI, but that they were disclosed as COIs in only 2% of studies. Additionally, 87% of studies with statements claiming the authors did not have COIs were authored by researchers found to have clinical/training consultancy COIs. See Table 1 for additional details. Five of the eight journals we examined had policies requiring disclosure of COIs related to employment; clear violations were evident in four of these five journals.

**Conclusions:** Undisclosed COIs are pervasive across both studies of broader autism-focused interventions and, as evidenced by the current investigation, studies of ABA autism interventions. These COIs can introduce researcher bias, and could at least partially account for persistent poor quality research in this area. We recommend that journals hold researchers accountable for failing to disclose COIs and/or falsely claiming that they do not hold such COIs. Further, researchers must extend efforts to ensure that COIs do not influence study findings, through strategies such as partitioning researchers who hold COIs from data collection and interpretation.

**426.001** (Poster) 1-2-3. First Play, Second Engage, Third Communicate: A Potential Sequential Mediation Model for Preschoolers with ASD

*W. I. Shih<sup>1</sup>, Y. C. Chang<sup>2</sup>, S. Y. Shire<sup>3</sup> and C. Kasari<sup>1</sup>, (1)University of California, Los Angeles, Los Angeles, CA, (2)Special Education and Counseling, California State University, Los Angeles, Los Angeles, CA, (3)University of Oregon, Eugene, OR*

**Background:**

Social engagement and communication are core developmental challenges for children with ASDs and a focus in early intervention (Mundy et al., 1990; Kasari et al., 2006). Gains in joint engagement (JE) and social communication (joint attention-JA) have been linked to better language outcomes (Kasari et al., 2008; Jones et al., 2006), and JE shows promise as a potential treatment mechanism (Shih et al., 2017). However, many young children with ASD spend very limited time in JE, creating a cumulative deficit in early language learning opportunities JE requires a shared referent which is often a shared activity. Developing play skills may facilitate more opportunities to share an activity. Therefore, increasing play skills may promote JE. However, this sequential mediation process where play skills and JE together act as the mechanism of change in early intervention has yet to be explored.

**Objectives:**

This study (1) examines the mediating effect of play diversity on JE and JA in the context of an early intervention: Joint Attention, Symbolic Play, Engagement, and Regulation (JASPER: Kasari et al., 2008; Lawton & Kasari, 2012) delivered by teachers, and (2) explores the sequential mediation effect of play diversity on JA after accounting for JE.

**Methods:**

**Participants.** 66 children were 50 months old (SD=6.47) and 83% were male. Children ranged in developmental level (Mullen Scales of Early Learning) at entry (range: 11.00–57.67 months; M=35.41 months). Parents reported children as 29% Caucasian, 14% African American, 23% Hispanic, 15% Asian, and 20% Other/Mixed.

**Intervention.** Teachers received two weeks of in-vivo JASPER training from the research team. JASPER teachers delivered the intervention for 30 minutes/day for 10-weeks, while waitlist teachers continued their regular school curriculum.

**Measures.** Ten-minute teacher-child interactions were video-recorded and coded at entry and exit. Children's JE (time coordinating the adult and shared activity) and spontaneous JA skills (eye contact, gestures, language) were coded by reliable assessors blinded to time and condition.

The number of unique spontaneous play types (play diversity) were coded (Lifter & Bloom, 1989).

**Results:**

Linear mixed models were used to explore the mediating effect of play diversity on JE and JA in JASPER intervention.

Increased play diversity is associated with increased JE ( $p < 0.001$ ) and JA ( $p = 0.005$ ). Further, significant treatment differences were found between JASPER and Waitlist from entry to exit in total play diversity ( $p < 0.001$ ), JA ( $p = 0.02$ ), and JE ( $p = 0.019$ ) where JASPER children made significantly greater improvement.

Part-1 (Figure-1): Play diversity is a significant mediator of JASPER intervention on JE ( $p = 0.002$ ) and JA ( $p = 0.047$ ).

Part-2 (Figure-2): A significant indirect effect of JASPER intervention on JA was observed ( $p < 0.001$ ) suggesting that JASPER intervention increased JE through increased play diversity and resulted in increased JA.

Conclusions:

Joint attention is a core deficit of ASD, and improving outcomes may depend on improving play skill as one way to increase joint engagement. By helping children increase their range of play skills, we can facilitate gains in JE, a critical factor to foster development in core social communication challenges.

**426.002 (Poster)** A Comparison of Change Trajectories in Parent Sensitivity and Responsivity across Different Intervention Approaches

**S. F. Vejnaska<sup>1</sup>**, A. C. Stahmer<sup>2</sup>, P. Yoder<sup>3</sup>, A. M. Estes<sup>3</sup> and S. J. Rogers<sup>4</sup>, (1)UC Davis MIND Institute, University of California, Davis, Sacramento, CA, (2)Department of Special Education, Vanderbilt University, Nashville, TN, (3)Speech and Hearing Sciences, University of Washington, Seattle, WA, (4)Psychiatry and Behavioral Sciences, University of California MIND Institute, Sacramento, CA

---

Background: Multiple intervention approaches including parent participation are evidence-based practices in autism spectrum disorder (ASD; Schreibman et al., 2015). Structured behavioral interventions, such as Discrete Trial Training (DTT; Lovaas, 1987), are based on applied behavioral analysis (ABA). DTT emphasizes the provision of learning opportunities by utilizing antecedent and consequence strategies to enhance child learning with limited attention to the caregiver/child relationship. More recently, interventions such as the Early Start Denver Model (ESDM; Rogers & Dawson, 2010) blend the learning principles of ABA with relational strategies based on developmental science (e.g., developing sensitive and responsive interactions; Ingersoll et al., 2010). Developmental studies examining the effect of helping parents increase sensitive and responsive parenting behaviors that fit their child's learning needs link increases in these behaviors to more positive outcomes for children with ASD (Gulsrud et al., 2016; Rogers et al., 2014; Siller et al., 2013), but little attention has been paid to how these behaviors vary as a function of intervention approach.

Objectives: Compare change trajectories in sensitive/responsive interactions facilitated by different parent coaching interventions.

Methods: Data were collected as part of a randomized treatment study comparing DTT and ESDM. Participants in the parent study included toddlers with ASD and their primary caregivers. Over the year-long intervention, parents received coaching in parent ESDM or behavior management in the DTT condition. 83 children completed the study (42 DTT, 41 ESDM). Children were, on average, white (53%) males (75%), and 25 months old at entry (range 12-30). Video recordings of parent-child interaction during home toy play were collected monthly for 12 months. This study compares the quality of the parent-child interaction from months 1, 4, 8, and 12 using the Parenting Interactions with Children: Checklist of Observations Linked to Outcomes (PICCOLO; Roggman et al., 2013), a checklist of 29 observable developmentally supportive parenting behaviors in four domains—Affection, Responsiveness, Encouragement, and Teaching. Repeated measures, random effects models will be used to model change over time in parent sensitivity/responsivity. Secondary analyses will assess the four sub-domain scores as outcomes to probe specific areas that might explain any overall difference. With 83 parents, assuming a two-sided test and alpha = 0.05, we will have 80% power to detect a difference in slope as small as 0.25 standard deviations, assuming the correlation between the repeat assessments is at least 0.2.

Results: PICCOLO coding is almost complete (90% completed at submission). Comparison of preliminary video data from the ESDM condition (128 observations) and DTT condition (128 observations) found statistically significant differences in overall parent behavior between the ESDM dyads ( $M=45.59$ ,  $SD=7.46$ ) and the DTT dyads ( $M=43.03$ ,  $SD=4.45$ )  $F(1, 254)=11.07$ ,  $p=0.001$ , with parents participating in the ESDM condition showing greater supportive parenting behaviors. Final analyses will examine change over time across groups.

Conclusions: Comparing the learning patterns of parents coached in different intervention strategies will lead to a greater understanding of how best to support parents of children with ASD. This information can be used to streamline parent coaching strategies.

**426.003 (Poster)** A Nimble Model of Care: Adapting the Social ABCs Parent-Mediated Toddler Intervention for Group-Based and Virtual Delivery

**J. A. Brian<sup>1</sup>**, I. M. Smith<sup>2</sup>, L. Zwaigenbaum<sup>3</sup>, A. Solish<sup>4</sup>, K. Bernardi<sup>5</sup>, I. Roth<sup>6</sup>, S. Daoud<sup>6</sup>, E. M. Dowds<sup>7</sup>, S. Jilderda<sup>8</sup>, S. Macwilliam<sup>9</sup>, K. Perry<sup>1</sup> and S. E. Bryson<sup>10</sup>, (1)Holland Bloorview Kids Rehabilitation Hospital, Toronto, ON, Canada, (2)Dalhousie University / IWK Health Centre, Halifax, NS, CANADA, (3)University of Alberta, Edmonton, AB, Canada, (4)Holland Bloorview Kids Rehab, Toronto, ON, Canada, (5)Autism Research Centre, Holland Bloorview Kids Rehab, Toronto, ON, Canada, (6)Holland Bloorview, Toronto, ON, Canada, (7)Autism Research Centre, Holland Bloorview Kids Rehabilitation

Background: Informed by two decades of infant sibling research, our team developed a 12-week, parent-mediated, naturalistic developmental behavioural intervention (NDBI) for toddlers. The *Social ABCs*<sup>1</sup> combines didactic teaching (supported by a parent manual) and individual in-vivo parent coaching, yielding parent implementation fidelity and gains in toddlers' social communication<sup>2</sup>.

Objectives: To improve efficiency of the program and increase access, we adapted the model to **Group-based** didactic teaching and 1:1 coaching in-clinic (vs. home), over 6 (vs. 12) weeks (Phase I). In response to the Covid-19 pandemic we modified the model for virtual delivery (Phase II).

Methods: Phase I: 45 families participated in the in-person Group model (ages: 21-35 months;  $M=30.6$ ; 39 boys). Phase II: 39 families participated in the virtual Group model (ages: 18-36 months;  $M=30.1$ ; 26 boys); 16 enrolled as waitlist controls 6 weeks prior to beginning the program. Data were collected at baseline and week 6 for all participants via videotaped parent-child interactions and parent questionnaires. "Pre-baseline" data were collected for waitlist controls.

Results: Preliminary analyses are reported. Formal comparisons across phases and studies will be conducted once all data are available (Dec/20).

Phase I: Paired samples t-tests revealed significant increases in toddlers' responsivity and parents' fidelity;  $p$ 's  $<.001$ , with gains that appear comparable to those in the original model (Fig.1). Parents reported improved toddler language (words understood/spoken; *MacArthur-Bates Communicative Development Inventories*;  $p$ 's  $<.001$ ), reduced autism symptoms (*Autism Parent Screen for Infants*<sup>3</sup>;  $p <.001$ ), and high satisfaction (33.1 out of 35). Unique to the Group model was decreased parenting stress;  $p <.001$  (Fig.2).

Phase II: Outcomes appear commensurate with the *in-person* Group model for implementation fidelity ( $p =.009$ ; Figure 1a), autism symptoms ( $p =.004$ ), child language skills ( $p$ 's  $=.003$ ,  $.018$ , respectively; words understood/spoken), and satisfaction (32.5/35). We failed to show reduced parenting stress;  $p =.10$  (but note that baseline stress was marginally higher than in Phase I;  $p =.10$ ). Video-coded toddler behaviour from this phase will be available for INSAR.

Conclusions: *Group Social ABCs* is a promising, innovative and cost-efficient way to intervene at the first signs of concern. Moreover, the virtual adaptation appears to yield parent fidelity and child gains commensurate with the in-person version. Parenting stress may not improve in the virtual model, perhaps due to the absence of a key active ingredient (e.g., interpersonal interaction). It also remains possible that the pandemic may be a major driver in increasing overall stress, overshadowing any potential reduction in stress that might otherwise have occurred with the virtual model. Nonetheless, the virtual model holds promise as an effective way to serve families who are harder to reach by traditional methods, both during and beyond the pandemic.

Background: Core symptoms of Autism Spectrum Disorder (ASD) impact on the child 's interplay with parents, inducing maladaptive interactive circuits that need to be restored in order to guarantee effective emotional exchanges (Kasari et al. 2010; Adamson et al. 2010). Recent findings strengthened the importance of involving caregivers during the intervention in order to increase dyadic levels of syntonzation and to extend the acquisition of competencies also in naturalistic contexts (Oono IP et al.

2013; Parsons et al. 2017). However, the evaluation of treatment response is mainly focused on child outcomes, demonstrating the improvements on both child's social engagement and cognitive development (Tiede et al. 2019), often without deepening dyadic and caregivers' variables associated with the response.

**Objectives:** In line with this, we want to investigate longitudinal trajectories of dyadic affective quality and play skills abilities during an intervention with parent involvement. Further, we want to identify which parental and child characteristics and behaviors might be associated with changes in the dyadic competences.

**Methods:** In order to assess the affective quality within the dyad the Emotional Availability Scales (EAS, Biringen et al. 2008) were used to codify ten minutes video-recorded interactions between 29 preschool children and their caregiver. On the same interaction's sequences, the Play code (O'Reilly & Bornstein, 1993) was employed in order to assess the levels of both child and caregiver's exploratory and symbolic play. These measures were also applied after 11 months of an early intensive intervention that provides parent involvement into the therapy room (at least 2 h per week).

**Results:** Results revealed that mothers increased affective quality ( $V(28) = 13$ ;  $p = 0.002$ ;  $r^2 = 0.596$ ;  $BF = 25.097$ ) and awareness ( $V(28) = 0$ ;  $p = 0.026$ ;  $r^2 = 0.454$ ;  $BF = 2.952$ ) in understanding the signals produced by the child. They also seem to structure activities with the child more adequately, ( $V(28) = 0$ ;  $p < 0.0001$ ;  $r^2 = 0.892$ ;  $BF > 100$ ) showing less intrusive behaviors ( $V(28) = 0$ ;  $p < 0.0001$ ;  $r^2 = 0.886$ ;  $BF > 100$ ). The children, in turn, were more responsive ( $V(28) = 21.5$ ;  $p < 0.001$ ;  $r^2 = 0.716$ ;  $BF > 100$ ), more involving ( $V(28) = 0$ ;  $p = 0.002$ ;  $r^2 = 0.613$ ;  $BF = 24.648$ ) and they showed more complex and symbolic strategies of symbolic play ( $V(27) = 79$ ;  $p = 0.0255$ ;  $r^2 = 0.392$ ;  $BF = 3.449$ ). Further, linear mixed effect models revealed that mothers' structuring abilities were linked to their perception of having a difficult child ( $b=0.016$ ;  $t(24)=2.255$ ;  $p=0.034$ ), and their non-intrusiveness skills seemed to be influenced by child's language ability ( $b=0.008$ ;  $t(50)=2.677$ ;  $p=0.010$ ).

**Conclusions:**

From a theoretical perspective this study may enhance knowledge about child and caregiver variables that impact on dyadic outcomes, and help the identification of important target areas to be addressed during intervention. From a clinical standpoint, our results suggest that parental based intervention may support and facilitate improvements and dyadic synchronization in both children and caregiver's affective quality and cognitive abilities.

**426.005 (Poster)** An Umbrella Review and a Meta-Analysis of Pivotal Response Treatment in Autism Spectrum Disorder  
*A. Y. Hardan<sup>1</sup> and M. Uljarevic<sup>2</sup>, (1)Psychiatry & Behavioral Sciences, Stanford University, Stanford, CA, (2)Department of Psychiatry and Behavioral Sciences, School of Medicine, Stanford University, Stanford, CA*

---

**Background:** A number of single-subject, small N, non-randomized group-based and more recently randomized controlled trial (RCT) studies have suggested that Pivotal Response Training (PRT) outcomes are quite promising in certain symptom and functional domains. Given the increased adoption of PRT in clinical practice, it is important to systematically appraise existing evidence and achieve current consensus on the effectiveness of PRT for specific outcomes. It is also crucial to identify the limitations of the current PRT treatment literature and highlight crucial areas for future improvements.

**Objectives:** To provide a comprehensive appraisal of the current evidence on the effectiveness of PRT for individuals with autism spectrum disorder (ASD) through an umbrella review of previous systematic examination of the literature and meta-analytic synthesis of all available PRT RCTs.

**Methods:** PsycINFO, Medline, Embase, Cochrane Central Register of Controlled Trials, ERIC and Linguistics and Language Behavior Abstracts were searched for published articles available through May 2020. Review methodology adhered to the steps described in the Preferred Reporting Items for Systematic reviews and Meta-Analyses (PRISMA) statement.

**Results:** Six systematic reviews were identified, two with meta-analytic components and four providing a descriptive summary of the findings. Identified reviews varied widely in terms of their aims, outcomes, and designs which precluded a unified and consistent set of conclusions and recommendations. Nine RCTs were identified. Eight of nine identified RCTs reported at least one language and communication-related outcome. Statistically significant effects of PRT for a range of language and communication skills were identified across a majority of identified RCTs. Although some of the identified PRT RCT studies also examined a range of non-language targets behaviors including other core features such as social interaction and associated behaviors and adaptive functioning, a small number of overlapping measures precluded robust effect size estimations for these outcomes. Therefore, evidence for positive treatment effects of PRT on outcome measures assessing non-language domains was less robust and or specific. This systematic review has identified several key limitations that should be addressed in future research. More specifically, future studies will need to (i) include more comprehensive treatment targets, in particular adaptive

functioning, a generalization of treatment effects and longer-term (12-months or longer) outcomes, (ii) use more objective outcome measures, (iii) measure of parental well-being, and (iv) improve trial methodology by adopting factorial and adaptive treatment designs while implementing more advanced individual difference analytical strategies that would enable the identification of subgroups of children who respond well to PRT and understand the profile of treatment responders.

**Conclusions:** Overall, both previous systematic reviews and new meta-analysis of the RCTs suggest that PRT shows promise for improving language and communication. This review has identified several key methodological and design improvements that are needed to enable our field to fully capitalize on the potential of RCT designs and establish not only overall treatment efficacy but also detailed profiles of treatment responders in order to provide evidence-based guidance for clinicians on what works for whom and why.

**426.006 (Poster) Champion: Caregiver Administered Holistic Autism Management Program for Individualised and Optimal Nurturing: Comparison between Weekly and Six-Weekly Follow-up Training Sessions : A Randomised Trial**  
*M. Juneja<sup>1</sup>, S. Sairam<sup>2</sup>, R. Jain<sup>3</sup> and D. Mishra<sup>3</sup>, (1)Maulana Azad Medical College, New Delhi, India, (2)Maya Clinic, Ghaziabad, India, (3)Pediatrics, Maulana Azad Medical College and Lok Nayak Hospital, New Delhi, India*

---

**Background:** Recent estimated prevalence of ASD in India ranges from 0.15% to 1.01% in various studies, depending on the screening method used, and the areas surveyed. However, this increase in prevalence has not been accompanied by a corresponding growth in the availability of evidence-based intervention services, resulting in high levels of unmet service needs for individuals with ASD and their families. In such resource constrained settings, parent-mediated interventions may be an effective alternative, and the general consensus is that parents, who receive appropriate training, gain skills in the delivery of interventions, thus improving joint attention, social communication and behaviours of their children with ASD.

**Objectives:** To compare the efficacy of caregiver administered intervention program with weekly training sessions versus a program with six-weekly training sessions for children with autism

**Methods:** A standardized parent-administered intervention program was developed for children with Autism including a self-designed culturally appropriate comprehensive checklist of skills to be taught in various domains including social-emotional, receptive and expressive language, play skills, daily living skills and pre-academics.

90 children with Autism Spectrum Disorder, aged 2-6 years were enrolled. At baseline, all participants were administered standardized tools/ checklists for evaluation of IQ/DQ (Leiters/ DP-3), Autism severity (CARS), adaptive functioning (VABS-2), behavioral problems (Aberrant Behavior Checklist) and language levels (Receptive Expressive Emergent Language Scale/ Linguistic Profile Test), followed by the designed checklist to assess the functional levels and the skills to be taught. Parents were psycho-educated regarding Autism, and were given hands-on training for administering the intervention. Patients were randomized into weekly and 6-weekly follow-up groups using stratified block randomisation using random block sizes. Parents were asked to follow the intervention program for at least 4 hours per day at home.

The children were evaluated every 12 weeks using the checklist, to check for the skills achieved, and to set new goals. At the end of 1 year study period, all assessments were repeated, to check the efficacy of the program.

**Results:** Of the 90 children enrolled, 46 were in the weekly follow-up group and 44 in 6-weekly follow-up group. Both the groups were comparable with respect to baseline characteristics. 7 children were lost to follow-up first group and 20 in second group. The baseline characteristics of the children lost to follow-up were similar to those who completed the study.

On comparing final scores with baseline values, there was statistically significant improvement in all parameters including IQ/DQ, Adaptive behavior, language (receptive and expressive) and behavioral problems in both the groups. There was a mean increase of 16.33 points IQ/DQ in the weekly group, and 21.5 points in the 6-weekly group. The CARS score decreased by 4.58 points in weekly vs 3.8 in 6-weekly group. There was no significant difference in the changes observed between groups.

**Conclusions:**

This study reaffirms that parent-administered intervention programs are effective in management of young children with Autism Spectrum Disorder in resource-limited setting, with both 6-weekly and 1-weekly intervention protocols having similar efficacy. However, frequent contact with parents may be necessary to ensure compliance with therapy.

**426.007 (Poster)** Comparative Outcomes of Young Minimally Verbal and Verbal Autistic Children Following Receipt of Group-Based Early Start Denver Model (G-ESDM)

**C. Dissanayake<sup>1</sup>** and **R. H. Cliffe<sup>2</sup>**, (1)Olga Tennison Autism Research Centre, La Trobe University, Melbourne, VIC, Australia, (2)Olga Tennison Research Centre, BUNDOORA, VIC, Australia

---

**Background:** Little research has examined developmental outcomes following intervention of young minimally verbal autistic children compared to their more verbal peers. As approximately 30% of autistic children remain minimally verbal (defined as having a very small repertoire of spoken words - < 20 functional words - or fixed phrases that are used communicatively), and few develop spoken language after the age of five, it is important to understand the very early developmental trajectories of minimally verbal children in order to target interventions for those with the greatest need.

**Objectives:** The aim in this study was to compare the early developmental trajectories of minimally verbal and verbal autistic children who accessed a G-ESDM intervention program for a period of one year.

**Methods:** Data from 141 children (78% male) diagnosed with Autism Spectrum Disorder who participated in a G-ESDM program within an early learning and care centre in Australia was used to address the study aim. Children had a mean age of 34.21 months (Range: 13 - 64 m) at entry into intervention and 45.39 months (Range: 24 - 72 m) at the one-year follow-up. The Autism Diagnostic Observation Schedule was used to confirm diagnoses at entry into intervention. The Mullen Scales of Early Learning was administered at entry and one-year following, and parents completed the Vineland Adaptive Behaviour Scales (VABS) and the Social Communication Questionnaire (SCQ) at both time points.

**Results:** Given their young age, 89 children (63%) were classified as minimally verbal at baseline which reduced significantly to 52 (37%) at follow-up. Children's developmental trajectories were examined as a function of their verbal status at *exit* using 2 (Group: Minimally Verbal; Verbal) x 2 (Time: Baseline; Follow-up) repeated measures ANOVAs, revealing near identical trajectories with no group differences on verbal and non-verbal DQ. Both groups also made equivalent and significant gains in verbal and non-verbal DQ following one year of the G-ESDM intervention. This pattern of findings was repeated with the VABS, with a significant increase in scores over time. Similarly, no group differences were evident on the SCQ at entry and follow-up, with both groups showing significantly reduced scores following one-year of intervention.

**Conclusions:** Autistic children who remained minimally verbal at exit had similar developmental trajectories to their verbal peers when examined from entry to one-year follow-up within a group-based early intervention program. The findings were consistent across the developmental measures used here, including when children's social communication abilities as reported by parents were considered over time. The gains in both verbal and non-verbal developmental quotients is encouraging with both groups showing equivalent leaning outcomes having received the G-ESDM. This finding is particularly important as older minimally verbal autistic children have previously been found to make minimal gains following intervention. Our study, which focused on very young children, found that the G-ESDM is equally suitable for all autistic children despite their verbal ability at entry into intervention. It is possible that the G-ESDM is ideally suited to young minimally verbal children. Further research is required to examine this hypothesis.

**426.008 (Poster)** Developmental Outcomes for Young Children with Autism Participating in the Parent-Implemented Early Start Denver Model Whose Parents Received Mindfulness Based Stress Reduction

**N. A. Broderick<sup>1</sup>**, **Z. Warren<sup>2</sup>**, **J. C. Slaughter<sup>3</sup>**, **A. Nicholson<sup>4</sup>**, **A. Stainbrook<sup>5</sup>**, **J. L. Taylor<sup>6</sup>**, **C. G. Santulli<sup>8</sup>**, (1)Pediatrics, Vanderbilt University Medical Center - Treatment and Research Institute for Autism Spectrum Disorder, Nashville, TN, (2)Vanderbilt University Medical Center, Nashville, TN, (3)Biostatistics, Vanderbilt University Medical Center, Nashville, TN, (4)Vanderbilt University, Pleasant View, TN, (5)Vanderbilt University Medical Center- Treatment and Research Institute for Autism Spectrum Disorder, Nashville, TN, (6)Vanderbilt Kennedy Center, Nashville, TN, (7)Vanderbilt University, Nashville, TN, (8)Vanderbilt Kennedy Center, Vanderbilt University Medical Center, Nashville, TN, (9)East Tennessee State University, Johnson City, TN

---

**Background:** Although low-intensity parent-mediated interventions for young children with or at-risk of Autism Spectrum Disorder (ASD) have gained momentum, [1-3], evidence of their impact on child outcomes remains unclear [4, 5]. Offering targeted parent training in strategies to support children with ASD may give parents the skills to support their children during naturalistic, everyday interactions [1, 2, 6-8]. However, little is known about whether directly treating parental distress as part of an early intervention protocol has positive impacts on young children with ASD.

**Objectives:** In a randomized controlled trial of P-ESDM with and without MBSR for parents, [9] we found that parents who received MBSR reported reduced parental distress and increase mindfulness. In this work, we examine overall group impacts of P-ESDM on longitudinal child outcomes and between-group differences in child outcomes.

Methods: Participants included 63 children with ASD less than 36 months of age and a primary caregiver. All children received 12 sessions of weekly P-ESDM. Half of their parents were randomized to also participate in 6 sessions of MBSR. Developmental outcomes related to autism symptoms (ADOS-2 severity scores), cognitive skills (MSEL, Early Learning Composite and raw domain scores), and ratings of communication and socialization (VABS-II standardized domain scores) were assessed at baseline (T1), immediately post-treatment (T2; 3 months), and at end of study (T3; 6 months.)

Results: Group means were compared at each timepoint. No significant differences emerged on any variables. Groups were then combined to evaluate the impact of P-ESDM participation. From T2-T3, but not T1-T2, ADOS-2 scores significantly decreased (-.94 points,  $p < .001$ ) and MSEL Early Learning Composite scores (3.94 points,  $p < .001$ ) significantly increased. Both groups significantly improved on raw scores of MSEL domains from T1-T2 and T2-T3, which may be consistent with maturation. Standardized VABS-2 Communication scores improved from T1-T2 (6.48 points,  $p < .001$ ) but not T2-T3, whereas VABS-2 Socialization scores remained stable across timepoints.

Conclusions: Parental involvement in a stress reduction program did not directly impact commonly used measures of developmental outcomes for young children with ASD. Across groups, children showed modest improvements in autism severity as well as cognitive and adaptive skills. Although statistically significant, the clinical significance of these changes is less clear. Additionally, the lack of a control group makes it difficult to understand the impact of maturation. Our previous work [9] demonstrated that directly supporting parents positively impacted aspects of parental wellbeing. This study demonstrates that adding parental treatment did not negatively impact child progress, supporting comprehensive early intervention programs that address needs of the entire family.

**426.009 (Poster)** Does Early Intervention Improve Long-Term Outcomes in Children with Autism Spectrum Disorder? an 8-Year Follow-up of a Randomized Controlled Trial of a Preschool-Based Social Communication Intervention

A. Kaale<sup>1,2</sup>, M. W. Fagerland<sup>3</sup>, K. Larsen<sup>4</sup>, O. A. Andreassen<sup>5</sup>, T. Nærland<sup>6</sup> and L. Smith<sup>7</sup>, (1)Department of Special Needs Education, University of Oslo, Oslo, Norway, (2)Norwegian Centre of Expertise for Neurodevelopmental Disorders and Hypersomnias, Oslo University Hospital, Oslo, Norway, (3)Oslo Centre for Biostatistics & Epidemiology, Oslo University Hospital, Oslo, Norway, (4)Division of Pediatric and Adolescent Medicine, Regional Resource Centre for Autism, ADHD, Tourette's Syndrome and Narcolepsy, Oslo University Hospital, Oslo, Norway, (5)NORMENT, KG Jebsen Centre for Psychosis Research, Institute of Clinical Medicine, University of Oslo, Oslo, Norway, (6)National Center of Competence for Rare Disorders and Disabilities, Oslo University Hospital, Oslo, Norway, (7)Department of Psychology, University of Oslo, Oslo, Norway

Background: There is little knowledge about the long-term (> 2 years) effects of interventions provided for children with autism spectrum disorder (ASD) during the preschool years.

Objectives: This study reports on the 8-year follow-up data from a randomized controlled trial (RCT) of a short-term (8 weeks) preschool-based social-communication intervention (adaptation of JASPER) for 2-4-year old children with ASD that was documented as being effective at intervention-end and 1-year follow-up.

Methods: All children from the original trial were invited to participate in the 8-year follow-up study. Video-recordings of 10-minutes of parent-child and teacher-child interaction were collected at several time points (four times during the preschool-age and once at 8-year follow-up). The recordings were blind-coded for primary outcomes; child initiation of joint attention (IJA<sub>parents</sub> and IJA<sub>teachers</sub>) and duration of joint engagement between child and interaction partner (JEng<sub>parents</sub> and JEng<sub>teachers</sub>). Secondary outcomes of expressive and receptive language were assessed by blinded testers using the Expressive Vocabulary Test (EVT) and Peabody Picture Vocabulary Test (PPVT). Intention-to-treat analyses were performed using linear mixed models fitted to each of the outcomes.

Results: Fifty-one (83.6%) ( $M_{age} = 13.2$  years, [ $SD_{age} = 1.1$ ], 82.4 % boys) of the 61 children from the original trial (29 [85.3%] of 34 assigned to the social-communication intervention in addition to treatment as usual (TAU), and 22 [81.5%] of 27 assigned to TAU only) participated in the 8-year follow-up. No significant group differences were identified in gains from baseline to 8-year follow-up on either of the social-communication or language outcomes (Table). The increase in IJA<sub>parents</sub> was 1.61 (95% CI: -1.57, 4.79) for the intervention group and 0.86 (95% CI: -2.52, 4.25) for the control group [mean group difference 0.75 (-3.90, 5.39);  $p=0.75$ ], while the increase in IJA<sub>teachers</sub> was 3.71 (95% CI: 1.08, 6.34) for the intervention group and 0.69 (95% CI: -2.26, 3.64) for the control group [mean group difference was 3.02 (-0.93, 6.97);  $p=0.13$ ]. Additionally, the increase in EVT raw scores was 35.8 (95% CI: 27.0, 44.7) for the intervention group and 30.3 (95% CI: 20.4, 40.2) for the control group [mean group difference was 5.5 (-7.8, 18.8);  $p=0.42$ ].

Conclusions: This study adds to the knowledge of long-term effects of early intervention for children with ASD. The findings suggest that despite identified effects of the preschool-based social-communication intervention at treatment-end and 1-year

follow-up, the intervention did not have long-term effects on children's social-communication and language skills. Thus, in contrast to specialist-delivered intervention (Kasari et al., 2014), and more comprehensive parent-mediated intervention (Pickles et al., 2016), the short-term preschool-based intervention was not evidenced to produce similar positive long-term effects on core social-communication skills and language. Possibly, measures (e.g. more training of teachers, longer duration of the intervention, booster sessions) may be taken to strengthen long-term impact.

**426.011 (Poster)** Early Childhood Services and Adaptive Behavior Outcomes for Young Children with Autism and Other Developmental Delays

**E. Pompan<sup>1</sup>, J. Safer-Lichtenstein<sup>1</sup> and L. L. McIntyre<sup>2</sup>.** (1)University of Oregon, Eugene, OR, (2)Special Education and Clinical Sciences, University of Oregon, Eugene, OR

---

**Background:** Interventions delivered in early childhood result in improved, long-term adaptive behavior outcomes for children with autism spectrum disorder (ASD; Estes et al., 2015). Although ASD symptoms emerge before age two (Zwaigenbaum et al., 2015), delays in diagnosis have been associated with family demographics (Mandell et al., 2005), primary care referral practices and wait time for evaluations (Monteiro et al., 2016, 2019). The majority of parents report delays in speech, language, and developmental milestones as their earliest concerns regarding their child's development (Chawarska et al., 2006), which may influence eligibility for early childhood services prior to diagnosis.

**Objectives:** This study aims to characterize the impact of early intervention services on school-age adaptive behavior for a community sample of young children with speech or language delays (SLD), ASD and other developmental delays and disabilities (DD).

**Methods:** Participants included caregivers of young children ( $M=37$  months,  $SD=4.65$ ) classified as having SLDs ( $n=77$ ), ASD ( $n=21$ ) or other DDs ( $n=43$ ) who were recruited in the Northwestern United States. They were enrolled in a longitudinal, caregiver-directed intervention trial during which they reported on their child's receipt of direct interventions at five timepoints until age five ( $M=59$ ,  $SD=4.57$ ; R01 HD059838; PI, L. L. McIntyre). *Vineland Adaptive Behavior Scales, Second Edition* (Sparrow et al., 2005) interviews of child adaptive behavior were conducted at ages three and five. Raw scores were used to account for within-subject change. A hierarchical linear regression evaluated whether early childhood interventions accounted for unique variance in adaptive behavior at age five, controlling for adaptive behavior at age three and randomized study intervention condition. Intervention variables included cumulative number of sessions of evidence-based interventions (EBI; behavioral, speech, occupational, and physical therapy) and the proportion of timepoints enrolled in preschool or early childhood special education (ECE-SPED).

**Results:** Age, number of EBI sessions, and enrollment in preschool or ECE-SPED did not differ based on child diagnosis. Children with SLDs had higher adaptive behavior compared to ASD and other DDs at age three ( $F(2,137)=6.34$ ,  $p=.002$ ) and five ( $F(2,137)=13.588$ ,  $p<.001$ ). Hierarchical linear regression results indicate the total model, including diagnosis, EBIs and preschool and ECE-SPED utilization, accounted for 38.4% of variance in adaptive behavior at age five, with EBI services significantly accounting for 5.4% unique variance in outcome ( $R^2=.384$ ,  $F(2,131)$ ,  $p=.004$ ).

**Conclusions:** Findings suggest that, in the current sample, children's EBI service utilization did not vary as a function of diagnosis. Best practices in early intervention suggest that services should be individualized and sufficient in their intensity, particularly for children who have significant social, communication, and behavioral support needs (McIntyre & Zemantic, 2017). Findings from the present study also underscore that more service utilization during the early childhood period is associated with better adaptive behavior at school entry, providing additional support for the well-established finding that "early" is better (National Research Council, 2001). Future research should include more sophisticated characterization of service utilization, including indices of quality, fidelity, and engagement, as well as investigations of service utilization as influenced by geographical differences.

**426.012 (Poster)** Early Echoic Imitation Predicts Reduction in Autism Symptomatology: A Retrospective Analysis of Toddlers from an Early Intervention Treatment Center

**P. Vietze<sup>1</sup>, L. E. Lax<sup>2</sup>, S. Khawar<sup>3</sup>, A. Yanchik<sup>4</sup>, G. Irshad<sup>5</sup>, M. Grazioli<sup>5</sup> and C. Tilson<sup>6</sup>.** (1)Psychology, Montclair State University, Montclair, NJ, (2)Administration, CARES, NEW YORK, NY, (3)Department of Psychology, Montclair State University, Montclair, NJ, (4)PSYCHOLOGY, Montclair State University, Montclair, NJ, (5)PSYCHOLOGY, Montclair State University, Plainfield, NJ, (6)Helping Hands Inc, NEW YORK, NY

---

**Background:**

According to the American Psychiatric Association (2013), the main characteristics of Autism Spectrum Disorder (ASD) include challenges in social interaction and communication skills. Lack of typical speech is a key factor affecting the severity of ASD (Matson, Kozlowski, & Matson, 2012). Many children with autism remain nonverbal and fail to gain language unless intervention is introduced to them (Rice, Warren, & Betz, 2005). In this regard, evidence-based treatment is essential to reduce language delays in children with ASD because their symptoms are complex and set them apart from typical children (Luyster, Lopez, & Lord, 2007). Skinner (1957) proposed that echoic behavior was essential for the development of language and communication skills.

#### Objectives:

The current study was conducted to answer the following question: why do only some children improve as a result of ABA? One possible answer is that the children who improve may have different behavioral capacities, like vocal imitation. The current study tested whether vocal imitation skills at baseline predicted reduction in ASD symptoms with ABA intervention. It was hypothesized that echoic behavior skills reduce the severity of ASD symptoms.

#### Methods:

Participants in this study included 143 children ranging in age from 21-40 months at onset of intervention. Their families had a variety of first languages: English (52%), Chinese (29%), Spanish (17%). Children were enrolled in a Center-Based ABA program in which they received DTT, NET, or both. Prior to enrollment, the children were tested using the Bayley Scales of Infant and Toddler Development-3rd Edition (BSID), the Childhood Autism Rating Scale-2nd Edition (CARS-2), and the Verbal Behavior Milestones Assessment and Placement Program (VBMAPP). Prior to leaving the program, the children were retested.

The children were classified according to reduction in symptoms of ASD upon leaving the program. Thus, 5 groups resulted according to the amount of symptom reduction. These groups were examined for the level of vocal imitation they displayed when entering the program (See Table 1).

#### Results:

These 5 groups were examined retrospectively for the level of echoic vocal behavior, non-echoic vocal behavior and motor imitation they displayed when they entered the program using mixed between groups (5) by repeated measures (2) ANOVAs. Echoic behavior was compared to vocal behavior and it was found that the children who had the greatest reduction in symptoms of ASD showed the highest level of pre-intervention echoic behavior and the largest difference between echoic behavior and non-echoic vocal behavior. These results held for the three groups with the largest reduction in symptoms for ASD See Figure 1. The results show that neither early motor imitation nor non-echoic vocal behavior predict reductions in ASD symptoms in toddlers while early echoic (vocal) imitation did predict reductions in symptoms of ASD.

#### Conclusions:

The findings suggest that early intervention should focus on increasing echoic behavior in toddlers showing early signs of ASD. Absence of speech and language in toddlers is often seen as an early sign of Autism Spectrum Disorder (ASD). Vocal imitation is regarded as a necessary condition for the development of language.

#### **426.013** (Poster) Early Intervention for Autistic Children: Incorporating the Perspectives of Autistic Adults

**K. M. Penner<sup>1</sup>, R. K. Schuck<sup>2</sup>, P. Dwyer<sup>3</sup>, Z. J. Williams<sup>4</sup>, A. Jevtic<sup>1</sup> and M. Wang<sup>1</sup>,** (1)Gevirtz Graduate School of Education, University of California, Santa Barbara, Santa Barbara, CA, (2)Psychiatry and Behavioral Sciences, San Jose State University, Palo Alto, CA, (3)Department of Psychology, University of California, Davis, Davis, CA, (4)Medical Scientist Training Program, Vanderbilt University School of Medicine, Nashville, TN

Background: While behavioral interventions for autistic children are widely used, a number of autistic adults have spoken out against them. These individuals report trauma as a result of interventions that they feel have emphasized “normalization” and compliance over acceptance and quality of life. Naturalistic Developmental Behavioral Interventions (NDBIs) were developed to combat some issues with earlier interventions, such as use of aversives, and offer a strengths-based approach, emphasizing child choice and naturalistic learning opportunities. However, most intervention research has been conducted without soliciting autistic perspectives, and there is far less evidence to suggest that autistic people themselves find behavioral intervention models acceptable or effective.

**Objectives:** This study aimed to elicit autistic adults' perspectives of common intervention goals, the core components of NDBIs, and the role that autistic individuals should take in informing intervention practices.

**Methods:** Preliminary data include 33 autistic adults (16 F, 10 M, 6 Non-binary, 1 unknown) who were recruited online to take a 26-item survey about intervention goals, strategies, and decision-making factors. Ten statements identified common skill acquisition goals (e.g. building communication skills); nine statements described common behavior reduction goals (e.g. reducing motor/vocal stimming, reducing noncompliance, reducing self-injury); five statements described core components of NDBIs (e.g. using natural settings, incorporating the child's interests); and two statements discussed autistic people's involvement in intervention decisions. Participants were asked to rate their agreement with each statement on a scale from 1=*Strongly Disagree* to 6=*Strongly Agree*. Mean item ratings were examined for each item set, with scores above 3.5 indicating agreement and scores below 3.5 indicating disagreement. Participants were able to expand upon their answers in a textbox; thematic analysis will be used to analyze these data. Data collection is ongoing, with several hundred participants expected, and generalized linear mixed models will be used to analyze ordinal item responses.

**Results:** The overall mean score for statements describing skill acquisition goals was 4.47 ( $SD=1.13$ ). In contrast, the mean score for statements describing behavior reduction goals was 3.28 ( $SD=1.12$ ); when excluding the statements about reducing dangerous behaviors ( $M=5.44, SD=0.58$ ), the mean score was 2.66 ( $SD=1.35$ ). Statements describing NDBI strategies were found to be slightly agreeable ( $M=4.19, SD=0.77$ ). Finally, participants generally supported statements about autistic involvement in intervention decision-making ( $M=5.38, SD=0.83$ ).

**Conclusions:** These preliminary data highlight which aspects of intervention are and are not viewed favorably by autistic adults. Overall, participants viewed involvement of autistic individuals and skill acquisition goals favorably. On the other hand, behavior reduction targets (with the exception of reducing dangerous behaviors) were rated negatively. Overall, participants slightly agreed with the use of NDBI intervention strategies. The present study reveals both agreement and disagreement between autistic adults and practitioners. Bringing interventions more in line with goals that are important to the autistic community could help to bridge the gap between the clinical/academic community and the autistic individuals they seek to serve.

**426.014 (Poster)** Early Reading Comprehension Intervention for Preschoolers with ASD and Hyperlexia  
*D. Macdonald, G. Luk and E. M. Quintin, Educational & Counselling Psychology, McGill University, Montreal, QC, Canada*

---

**Background:**

Children with combined autism spectrum disorder (ASD) and hyperlexia (HPL) demonstrate advanced word reading skills at a very young age, alongside an associated deficit in reading comprehension. A number of these children also exhibit impaired oral language skills. Taken together, oral language and reading comprehension challenges can have a cascading negative effect on social skills and academic success. Given the documented social and academic challenges for children with ASD, it is critical that early interventions target the integral components of academic success, such as oral language and reading comprehension. Yet, support for reading comprehension at the preschool level or even in the early primary grades is lacking for young children with ASD and hyperlexia (ASD+HPL). To address this gap, we developed a preschool oral language and reading comprehension intervention using written word-, phrase- and sentence-picture matching tasks on an iPad tablet supported by parents at home.

**Objectives:**

To evaluate a novel, parent-supported, tablet-based intervention application aiming to improve oral and reading comprehension skills, at the word-, phrase- and sentence-level, for preschool children with ASD+HPL as compared to typically developing (TD) preschoolers and those with ASD without hyperlexia (ASD-HPL).

**Methods:**

English-speaking preschoolers ( $N=30$ ) with ASD+HPL ( $N=8$ ), ASD-HPL ( $N=7$ ) and TD preschoolers ( $N=15$ ) participated in the study. Children's reading comprehension and oral language skills were evaluated at three timepoints using the Passage Comprehension subtest of the Woodcock Johnson Test of Achievement – 4<sup>th</sup> edition and the Oral and Written Language Scales - 2<sup>nd</sup> Edition – Listening Comprehension Scale (receptive language) and Oral Expression Scale (expressive language). Time 1 assessment occurred six weeks prior to the beginning of intervention. From Time 1 to Time 2, parents were instructed to conduct their typical activities with their child. Time 2 assessments occurred right before the 6-week intervention period during which time children used an experimenter-designed, tablet-based application for 15 minutes daily, five days a week at home supported by their parents. Time 3 assessment occurred after the 6-week intervention. Treatment fidelity was monitored to ensure compliance.

## Results:

Findings revealed that, although there was no significant difference between the groups for reading comprehension scores at Time 1, reading comprehension scores significantly improved for the group with ASD+HPL from Time 1-3 ( $p=.001$ ) and Time 2-3,  $p=.018$ , but not from Time 1-2 ( $p=.382$ ) as compared to the other groups. Gains were also found for receptive language from Time 1-3 ( $p<.001$ ) and Time 2-3 ( $p=.002$ ), but not for Time 1-2 ( $p=.929$ ) for all three groups. No gains were noted for expressive oral language skills for all groups.

Conclusions: Word-picture matching is a successful early intervention to improve both reading comprehension and receptive language for preschoolers with ASD+HPL and receptive language skills for all preschoolers. Findings suggest that interventions aiming to improve reading comprehension for preschoolers with ASD+HPL can begin at the first signs of reading ability, rather than waiting until later primary school. This represents a paradigm shift in current curriculum delivery. Finally, parents can also successfully implement this intervention at home with minimal training while awaiting public services.

**426.015** (Poster) Effect of Project Impact on Joint Attention in Children with ASD: A Randomized Controlled Trial  
**S. Van der Paelt, P. Warreyn, A. Piatti and H. Roeyers, Department of Experimental-Clinical and Health Psychology, Ghent University, Ghent, Belgium**

---

Background: Children with autism spectrum disorder (ASD) show deficits in joint attention skills (Charman, 2003). Joint attention plays an important role in early development, given its associations with language and other social communication skills (e.g. Nowell, Watson, & Craig, 2020). Project ImPACT (Ingersoll & Dvortcsak, 2010) is a parent-implemented intervention, focusing on social communication in children with ASD. One of the intervention targets is the increase of social engagement (including joint attention) through the use of interactive and behavioural strategies during daily routines. Previous studies have shown positive effects on language and communication in parent-child interaction in children with ASD (e.g., Ingersoll & Wainer, 2013; Stadnick et al., 2015).

Objectives: The goal of the present study was to test the effect of Project ImPACT in a community setting on the joint attention skills of children with ASD in interaction with a researcher.

## Methods:

Participants: 41 children between 22 and 51 months (five girls) were recruited through services for home guidance for children with ASD. Participants were randomly assigned to either an ImPACT intervention group ( $n = 20$ ) or a treatment as usual (TAU) condition ( $n = 21$ ). Mean age in the ImPACT and TAU groups were 36 and 35 months respectively.

Intervention: Parents of children in the ImPACT group received 18 weekly individual training sessions. Parents in the TAU condition received regular home guidance, with a frequency of one session every 2-3 weeks, mainly targeting daily living skills.

Procedure: Joint attention skills were assessed with the Early Social Communication Scales (ESCS; Mundy et al., 2003) before and after receiving Project ImPACT or after a similar time interval in the TAU group ( $M = 6$  months in both groups). There was a follow-up assessment 12 weeks after the post-test. Follow-up data was missing for 4 children. Administrators and coders were blind for group assignment. We computed the total number of initiations of joint attention (by means of eye contact, pointing, showing, language or a combination; IJAtotal) and the total number of joint attention bids with eye contact (IJAEC).

Results: Data were analysed by computing a linear mixed effect model in R with restricted maximum likelihood (REML) estimates of the parameters. For IJAtotal there was no time\*group interaction at posttest,  $t(73.35) = 0.23, p = .82$  or at follow-up  $t(74.80) = 1.17, p = .25$ . For IJAEC there was also no significant time\*group interaction at posttest  $t(74.11) = -0.16, p = .88$ . There was however a significant time\*group interaction, favouring the ImPACT group at follow-up,  $t(75.20) = 2.15, p = .035$ . See Figure.

Conclusions: Project ImPACT does not seem to have a differential effect on the total number of initiations of joint attention, compared to TAU. However, children who received Project ImPACT showed an improvement in the number of joint attention bids that were combined with eye contact at follow-up, whereas TAU children showed no sustained improvement in this skill. This shows that Project ImPACT mainly influences the quality of joint attention and helps to sustain this skill after parent training has ended.

**426.016** (Poster) Effectiveness of a Parent-Implemented SCERTS Model-Based Intervention for Toddlers with Autism Spectrum Disorders

*M. Suh<sup>1</sup> and S. Lee<sup>2</sup>, (1)Ewha Womans University, Seoul, Korea, The Republic of, (2)Special Education, Ewha woman's Univ., Seoul, Korea, Republic of (South)*

---

Background: SCERTS has been developed to disseminate NDBI intervention systems through parent implementation at home in collaboration with professionals. In SCERTS model, parents work with professionals to assess children and then choose a set of individual techniques they think will be the most beneficial for their children. Parents help conduct the initial assessment, set intervention goals and play a central part in implementing the teaching support and techniques

Objectives: The purpose of this study is to investigate the effectiveness of parent-implemented SCERTS Model-based intervention for toddlers 23-33 months old with ASD and their parents, ensuring the procedure used to support and engage the parents in home settings where intervention is provided

Methods: A home-based experimental group involving 9 toddlers and their parents was formed investigating the efficacy of a parent-delivered intervention compared to the control group. Parents in the experimental group received two parent education sessions on the characteristics of toddlers with ASD and the developmental features of infants and toddlers.

Results: Results showed that there were statistically significant differences in the degree of change in toddlers' joint attention skills, functional play skills, and parenting efficacy between the two groups. The experimental group showed improvement in both initiating joint attention and responding to joint attention skills

Conclusions: This study provide an initial basis for parent-implemented intervention using SCERTS Model in the family routines as the context for early intervention services for children with ASD. The results of this study is an extension of previous at-home parent-implemented intervention by demonstrating feasibility with younger children, using a limited number of sessions.

**426.017** (Poster) Effectiveness of Responsivity Intervention Strategies on Prelinguistic and Language Skills of Children with ASD: A Meta-Analysis of Randomized Controlled Trials

*J. McDaniel<sup>1</sup>, L. Black<sup>2</sup>, M. Murphy<sup>2</sup>, J. Rangel<sup>3</sup>, M. Friedrichs<sup>3</sup>, N. Brady<sup>2</sup> and S. F. Warren<sup>4</sup>, (1)Life Span Institute, University of Kansas, Lawrence, KS, (2)University of Kansas, Lawrence, KS, (3)University of Kansas Medical Center, Kansas City, KS, (4)Speech-Language-Hearing: Sciences and Disorders, University of Kansas, Lawrence, KS*

---

Background: Investigations of the effectiveness of communication and language interventions vary across multiple facets and have yielded widely varying results. One organizational approach to synthesizing prior results is to evaluate the effectiveness of interventions that include specific intervention components to identify active ingredients. Interventionists can then implement these essential strategies.

Objectives: This systematic review and meta-analysis aims to describe the current state of the literature for the role of responsivity intervention strategies (i.e., support turn-taking conversations through responding systematically to children's vocalizations and communicative attempts, following the child's lead, and providing targeted input) to influence the direction of future research studies and clinical practice. Multiple converging theories provide theoretical support for responsivity intervention strategies. Research questions: Is the mean effect size for interventions that use responsivity strategies on prelinguistic and/or language skills in children with ASD greater than zero for randomized controlled trials (RCTs)? Does the mean effect size vary by interventionist, length of intervention, proximal versus distal outcome, context-bound versus generalized characteristic outcome, risk for correlated measurement error (CME), or publication status? What percentage of included studies exhibit low, moderate, and high risk of bias?

Methods: We conducted a systematic review to identify records of RCTs of children with ASD comparing an intervention that used responsivity intervention techniques to one that did not. Reports had to include prelinguistic and/or language outcomes.

Results: Of 5671 reports screened, 45 reports from 33 RCTs met inclusion criteria (single case research design studies [ $n = 91$ ] presented at a later date) and included 293 relevant effect sizes. The mean treatment group sample size was 26.7 (range: 5-82) and mean age of 42.1 months (range: 20.6-110.7 months). RQ1: The mean standardized group difference using robust variance estimation with random effects is  $g = .37$ , 95% CI [0.22, 0.52]. The Galbraith plot (Figure 1) and  $\tau^2$  value (0.18) indicate substantial heterogeneity. RQ2: Context-bound outcomes exhibited a larger mean effect size (mean  $ES = 0.47$ ) than generalized or possibly context-bound behaviors combined (mean  $ES = 0.25$ ). No other moderator analyses yielded significant results. Of note, the mean effect size was greater than zero for effect sizes at-risk for CME (mean  $ES = 0.39$ ), but not for those free from

CME risk (mean  $ES = 0.14$ ). Although a publication bias was not detected via the moderator analysis, the Egger's test suggests publication bias against small studies with negative results (Figure 2). RQ3: Twenty-five studies were coded at overall high risk versus seven at moderate risk and one at low risk. A primary reason for studies being high risk was risk for CME.

Conclusions: We identified a significant, positive mean effect size for interventions that include responsivity strategies increasing prelinguistic and language skills in children with ASD compared with randomly assigned control conditions. Context-bound outcomes exhibiting a larger mean effect size than generalized or possibly context-bound behaviors. The majority of studies exhibited overall high risk for bias. Future directions include testing of additional putative moderators to explain heterogeneity and synthesizing single case research design studies.

**426.018 (Poster)** Effectiveness of World Health Organization Caregiver Skills Training Programme for Families of Children with Developmental Disorders or Delays in Taiwan: The First Year at Implementation Stage

**M. N. Hsiao**<sup>1,2</sup>, **W. T. Soong**<sup>1,3,4</sup>, **Y. N. Chiu**<sup>1,3</sup>, **W. C. Tsai**<sup>1,3</sup>, **H. Y. Lin**<sup>3</sup>, **S. C. Li**<sup>1</sup>, **G. J. Seng**<sup>1,6</sup>, **T. J. Liu**<sup>7</sup>, **H. M. Chen**<sup>7,8</sup>, **A. Shih**<sup>9</sup>, **Y. C. Chang**<sup>10</sup> and **T. W. CST Team**<sup>11</sup>, (1)Department of Psychiatry, National Taiwan University Hospital, Taipei, Taiwan, (2)School of Occupational Therapy, College of Medicine, National Taiwan University, Taipei, Taiwan, (3)Department of Psychiatry, College of Medicine, National Taiwan University, Taipei, Taiwan, (4)St. Joseph's Hospital, Yunlin, Taiwan, (5)Department of Psychiatry, University of Toronto, Toronto, ON, Canada, (6)Graduate Institute of Brain and Mind Sciences, National Taiwan University, Taipei, Taiwan, (7)Foundation for Autistic Children and Adults in Taiwan, Taipei, Taiwan, (8)Department of Special Education, National Taipei University of Education, Taipei, Taiwan, (9)Autism Speaks, New York, NY, (10)Special Education and Counseling, California State University, Los Angeles, Los Angeles, CA, (11)Department of Mental Health and Substance Abuse, World Health Organization, Geneva, Switzerland

Background: Though several effective early intervention models for autism spectrum disorder (ASD) were developed, many children with ASD can't get them where resources are limited. Caregiver Skills Training Programme for Family of Children with Developmental Disorders or Delays (CST), developed by World Health Organization (WHO) and Autism Speaks (AS) for the resource gap, just meets the huge needs of children with ASD globally. Taiwan CST team already presented the adaptations and results of their pilot study to show CST's effectiveness in an international meeting, and started implementation stage in 2019.

Objectives: This study aimed to examine the effectiveness of CST-Taiwan in the first year of the post-pilot stage.

Methods: The CST-Taiwan consists of a combination of nine group sessions for caregivers, three individual sessions for home visiting, and seven phone follow-ups in five months, executed by 2 facilitators (FT) fully trained and under the supervision of Master Trainers (MT). We analyzed data of 35 families (most of them having children with ASD) enrolled from 7 sites, including northern/southern Taiwan and an offshore island, with parent-reported questionnaires before and after intervention. Paired t-test was used to evaluate the parenting skills and confidence of the caregivers with the Caregiver Skills Training Test for Caregivers, and the adaptive function and health problems of their children with the Autism Treatment Evaluation Checklist (ATEC) and Adaptive Behavior Assessment System (ABAS-II).

Results: The result showed that the intervention outcomes of caregivers' skills and confidence were facilitated significantly (knowledge  $t=6.72, p<0.001$ ; confidence  $t=7.37, p<0.001$ ; empowerment  $t=4.83, p<0.001$ ) and children's symptoms and adaptive function were also improved significantly (concept  $t=4.94, p<0.001$ ; social cognition  $t=3.53, p=0.001$ ; functional skill  $t=5.42, p<0.001$ ; motor  $t=2.76, p=0.010$ ; speech communication  $t=3.56, p=0.001$ ; sensory/cognitive awareness  $t=3.10, p=0.004$ ; health/physical behavior  $t=-3.20, p=0.003$ ).

Conclusions: The results revealed that CST-Taiwan continued to show its effectiveness for the first year of the implementation stage, and many children with ASD and their caregivers got significant benefit from it. It is suggested that CST-Taiwan is worthy of being adopted as a nationwide policy in Taiwan.

**426.019 (Poster)** From Clinic Room to Zoom: Deploying an Evidence-Based Parent-Mediated Intervention in the Community before and during the Pandemic

**S. Netzer**<sup>1</sup>, **T. Graucher**<sup>1</sup>, **L. Levi**<sup>1</sup>, **N. Rudko**<sup>1</sup> and **J. Koller**<sup>1</sup>, (1)The Hebrew University of Jerusalem, Jerusalem, Israel, (2)Seymour Fox School of Education, Hebrew University of Jerusalem, Jerusalem, Israel

Background: The Research Units in Behavioral Intervention (RUBI) protocol is an evidence-based, parent-mediated intervention (PMI) for young children (4-8 years old) with autism and disruptive behaviors (e.g. Bearss et al., 2015). PMIs engage parents as agents of change and their effectiveness for children with autism has a solid evidence base (e.g. Pickles et al., 2016).

The initial goal for this study was to examine the efficacy of RUBI in a community-implemented, group format with Jewish and Arab Israeli families. With the onset of the Covid-19 pandemic, in-person groups shifted to online delivery, and all subsequent groups have been virtual. While logistically challenging, this shift allows us to examine the efficacy of the intervention virtually and affords us the ability to directly compare between in-person and virtual groups.

**Objectives:** In addition to examining the efficacy of RUBI in a community-delivered, group format, the current study seeks to elucidate the differences or similarities between in-person and virtual groups, with focus on immediate and short-term (2-month) follow up when possible, and to examine outcome predictors in both modalities.

**Methods:** The RUBI protocol was delivered to 60 families of children with a recognized diagnosis of autism between the ages of 4-8 in a group format. Of these families, 34 participated in-person and 28 did so virtually. The intervention is a 12-week, structured protocol. Data collection took place at week 1 and 12, with follow-up data collection one and two-months afterward. Primary outcome measures were the parent-report Aberrant Behavior Checklist (ABC; Aman, Singh, Stewart, & Field, 1985a, b), and the Home Situations Questionnaire (HSQ; Barkley and Murphy 1998). Secondary outcomes were parent stress, assessed with the Parenting Stress Index-Short Version (PSI-SR; Abidin, 1990) and repetitive behaviors, assessed with the Repetitive Behavior Scale-Revised (RBS-R; Bodfish, Symons, & Lewis, 1998).

**Results:** Results indicated significant reduction of DBs in in-person groups ( $p=0.003$ ). ABC total score indicated slightly reduced efficacy in virtual groups ( $p=0.15$ ), although the Irritability sub-scale was significant (virtual:  $p=0.012$ ). Gains following the intervention were maintained in in-person groups for two months following the intervention, with no significant regression at two-month follow-up ( $p=0.46$ ). Follow-up data for virtual groups is currently being collected.

Secondary outcome measures indicated reduced parenting stress in in-person groups (PSI Total;  $p=0.002$ ), with specific subscales indicating improvement in virtual groups (Defensive Responding:  $p=0.002$ ; Parental Distress:  $p=0.007$ ).

Child improvement in the in-person and virtual groups was predicted by child- and not parent-characteristics (e.g. PSI). Higher ABC-TOTAL scores prior to the intervention were associated with greater improvement (in-person:  $p=0.001$ ,  $r=0.59$ , virtual:  $p=0.004$ ,  $r=0.54$ ). In virtual groups, symptom severity predicted outcome as well (RBS-R; in-person:  $p=0.09$ ,  $r=0.28$ , virtual:  $p=0.002$ ,  $r=0.58$ )

**Conclusions:** This study points to the efficacy of RUBI in a group, community-implemented version as well as when delivered virtually, albeit with slightly reduced significance. Reduction in DBs following the intervention maintained for two months in in-person groups, and higher DBs at intervention onset predicted positive outcomes. Further study with a larger sample, particularly of the virtual group, is necessary, as is longer-term follow-up.

**426.020 (Poster) Implementation of the Group-Esdm in a Childcare Setting Serving Under-Resourced Communities**  
**A. Zitter<sup>a</sup>, V. David<sup>b</sup>, L. A. Vismara<sup>c</sup> and G. Vivanti<sup>d</sup>, (1)A.J. Drexel Autism Institute, Drexel University, Philadelphia, PA, (2)So Love Autistic Center, Philadelphia, PA, (3)Independent Consultant, Sacramento, CA**

**Background:** Despite advances in early intervention research, many children with ASD do not have access to effective treatments, especially in under-resourced communities serving low-income families. The Group Early Start Denver Model (G-ESDM; Vivanti et al., 2017) is an early intervention approach based on the adaptation of the Early Start Denver Model (ESDM; Rogers & Dawson, 2010) for delivery within educational group settings such as daycares and preschools. Studies have shown that providing G-ESDM during childcare hours has the potential to maximize efficiency and promote positive treatment outcomes without disrupting parents' workforce participation (Vivanti et al., 2014; Sinai-Gavrilov et al., 2020). However, despite this initial evidence, there is limited knowledge about the feasibility and effectiveness of implementing this intervention in US childcare settings that specifically serve under-resourced communities.

**Objectives:** The current study examines feasibility and implementation indicators of delivering the G-ESDM at the So Love Autistic Center, a US community childcare setting serving under-resourced communities, as well as preliminary indicators of effectiveness.

**Methods:** We used a community-partnered participatory approach (Jones & Wells, 2007) and the RE-AIM Implementation Science Framework (Glasgow, Vogt, & Boles, 1999) to design, implement and evaluate the delivery of the G-ESDM at So Love Autistic Center. Five male children (ages 32-41 months) with a confirmed ASD diagnosis received G-ESDM daily at So Love Autistic Center for approximately 6 months. The intervention was administered by trained staff members under the supervision of certified ESDM trainers. Following the RE-AIM implementation framework, we collected survey measures of perceived acceptability and feasibility of implementation ("adoption"), projected sustainability of implementing G-ESDM after the study's

conclusion (“maintenance”), characteristics of the families who signed up for the program (“reach”) as well as fidelity of implementation using the G-ESDM fidelity tools (“implementation”). Changes in pre and post age equivalence scores on the Mullen Scale of Early Learning (MSEL; Mullen, 1995) and Vineland Adaptive Behavioral Scale-2<sup>nd</sup> Edition (VABS-II; Sparrow et al., 2016) were analyzed to assess preliminary indicators of effectiveness of the intervention in this setting (“effectiveness”).

Results: Demographic data indicated that the study successfully reached the target population of children with ASD from under-resourced communities who may have limited access to care (“reach”). Changes in age equivalence scores on the VABS-II (Figure 1) and MSEL (Figure 2) revealed that most children who received G-ESDM achieved measurable progress in communication, socialization, visual reception and fine motor skills. These results provide preliminary indication that G-ESDM may be effective when integrated in this type of setting (“effectiveness”). Responses on the staff survey indicated a high level of feasibility and acceptability of the intervention (“adoption”) along with intent to continue treatment after the conclusion of the study (“maintenance”). Monitoring of fidelity indicated that staff members were able to integrate the G-ESDM techniques at an acceptable level of fidelity, between 60-88%, across fidelity items following targeted training and supervision (“implementation”).

Conclusions: Findings across all RE-AIM framework domains indicate that incorporating G-ESDM into the daycare setting can be feasible, successfully implemented, and potentially beneficial for children and their families in under-resourced communities.

#### 426.021 (Poster) Interventions for Children on the Autism Spectrum: A Systematic Umbrella Review

**H. Waddington**<sup>1,2</sup>, **K. Varcin**<sup>2,3</sup>, **R. Sulek**<sup>2,3</sup>, **C. A. Bent**<sup>2,4</sup>, **J. Ashburner**<sup>5</sup>, **V. Eapen**<sup>6</sup>, **E. ---

**Background:** Having access to effective intervention during childhood is an important element of the intervention pathway for children on the autism spectrum, providing an opportunity to support early development and promote longer-term quality of life. There are a large number of interventions available within clinical practice, which vary in their theoretical orientation and practical application. However, no previous review has provided a systematic evaluation and synthesis of the evidence for autism interventions across different intervention types. The clear gap in synthesized knowledge has created substantial clinical confusion, and the proliferation of interventions with a questionable evidence base.

**Objectives:** To conduct an umbrella review which synthesises the scientific evidence for the therapeutic (and other) effects of interventions for children on the autism spectrum aged 0-12 years.

**Methods:** The umbrella review was conducted according to the procedures outlined in the Joanna Briggs Institute manual for evidence synthesis and the PRISMA Reporting Guidelines. The review protocol was pre-registered (PROSPERO; Open Science Framework) and focused on systematic reviews that included at least one randomised controlled trial or controlled clinical trial of an intervention designed for use with children aged 0-12 years. Interventions were grouped into nine different theoretically-derived intervention categories: behavioural, developmental, naturalistic developmental behavioural (NDBI), sensory-based, technology-based, animal-assisted, cognitive behaviour therapy (CBT), Treatment and Education of Autistic and related Communication-handicapped Children (TEACCH), and ‘other’ interventions. A systematic and reproducible method was used to collate and synthesise data from the systematic review into a matrix showing evidence for the effects of a given intervention on a wide range of child and family outcomes.

**Results:** The systematic search of 10 academic databases and grey literature (years 2010-2020) yielded 58 eligible systematic reviews, representing 1,787 unique studies. The systematic reviews were of variable quality, and only 4 met all ‘high quality’ indicators. The 58 systematic reviews provided data on at least 111 different practices across the nine intervention categories.

There was evidence for positive effects on a range of child and family outcomes for behavioural interventions, developmental interventions, NDBIs, technology-based interventions, and CBT. Within these categories, the intervention effect on outcomes was variable (null, positive) across intervention practices. Positive intervention effects for sensory-based interventions were reported for certain intervention practices only, and in those cases, positive effects were limited to select child and family outcomes. A mix of inconsistent and null intervention effects on child outcomes were reported for both TEACCH and animal-

assisted interventions. There was either null or inconsistent evidence that child characteristics (age, cognitive ability, communication skills) or intervention characteristics (e.g., intensity, delivery mechanism) moderate intervention effects. Minimal information was provided on adverse effects.

**Conclusions:** This review provides the most comprehensive synthesis to date of the effects of different autism interventions, and represents an important step forward in evidence-based practice for children on the autism spectrum. The findings yield clear conclusions that will inform clinical and policy decision making regarding the most appropriate and evidence-based supports for children on the autism spectrum and their families.

**426.022 (Poster)** Investigate the Parent Learned Specific Skills during 10 Weeks Parent Early Start Denver Model Training Program

*S. F. Fan, Taipei Medical University Hospital, Taipei, Taiwan*

---

**Background:**

Parent implemented-early start Denver model (P-ESDM) program have been indicated effectiveness in various culture (Rogers et al., 2012; Estes et al., 2014; Zhou et al., 2018; Fan & Tseng., 2020). Parent have been coached using several strategies in P-ESDM program to help Autism spectrum kids to communicate and learn in everyday activities. One study figure out the specific result (Waddington et al., 2019) from western culture background, however, no study to figure out what the specific skill they learn more correlate with children improved from Asian culture perspective.

**Objectives:**

Since we know the culture play a different roles in parenting. The first aims to analysis which domain-general ESDM strategies parent learned correlated with the children's communication improved. The second purpose we also expect that how domain-specific strategies parent learned with individual.

**Methods:**

Six parent-child were recruited. Children's average age is around 27m (SD is 9.3) to conduct the P-ESDM. The main-caregivers are all mothers. All the kids were assessed cognitive/language domains by Mullen scales of early learning , social-interaction domain by Screening Tool for Autism in Toddlers & Young Children (STAT) and Childhood Autism Rating Scale–Second Edition (CARS-2) inventory, and ESDM curriculum to build up individual 10 treatment goals for next 10 weeks. P-ESDM was conducted by a certified ESDM therapist and certified ESDM Parent Coach. And follow up assessment was different therapist whose was a clinical psychologist. Parent stress status from parent stress inventory-forth edition (PSI-4), parenting sense of competence scale (PSCS) and board autism phenotype (BAP) were also measured. Communication and interaction goal score (1-6) are as target to measure with Parent each week fidelity via correlation analyse.

**Results:**

Each child improved their communication and interaction ability from standard assessment result. The parent get less parenting stress after 10 weeks. Each group of families can get different levels of ESDM skills at the end of the course compared to the baseline before intervention; similarly, we measure the communication goals and interaction of young children can be high correlated with parental ESDM strategies and skills.

**Conclusions:**

In conclusion, we could find the general skills most improved parenting skills was multiple varied communicative functions, the parent learn the skill apply to the different daily routine to facilitate the interaction and create the opportunities of receptive and expressive communication. Similarly, some skills are highly correlated with children's progress in different parent styles which will be highly correlated with the abilities that parents have acquired previously. The overall examining parent use specific intervention skills are similar to previous studies. This suggest that parent training should tailor and adapt the current abilities and needs.

**426.023 (Poster)** Linking Social Communication and Disruptive Behaviour in Parent-Mediated Interventions for Toddlers with ASD

Background:

Autism Spectrum Disorder (ASD) is a neurodevelopmental disorder characterized by impaired social-communication and restricted repetitive interests and patterns of behaviour. Furthermore, children with ASD frequently experience behavioural challenges. These disruptive behaviours (e.g., aggression, non-compliance) have a significant impact on learning acquisition and social relationships. Much research has been devoted to understanding how parents can reduce children's challenging behaviour and many parent training programs have been developed to target both parents' skills and children's responses to their parents (Kaminski & Claussen, 2017). For children with ASD, a recent meta-analysis supported the use of parent training for disruptive behaviours and found it to be as effective as parent training for children with disruptive behaviour but no ASD diagnosis (Postorino et al., 2017).

Objectives:

This study expands on research from a randomized control trial (RCT) of a manualized parent-mediated intervention. This intervention primarily targeted functional social communication and positive affect sharing for toddlers with confirmed or suspected ASD. This program also contained many parenting strategies used in the treatment of disruptive behaviour. As such, the current study aimed to: (1) assess whether children receiving the intervention showed decreases in disruptive behaviour following the intervention, and (2) examine the relationship between social communication skills and disruptive behaviour.

Methods:

This study utilized a subset of families who participated in the intervention RCT through a large rehabilitation hospital in Toronto, Canada. The sample consisted of thirty-two toddlers ( $n = 32$ ; age range: 16 to 30 months). In the RCT, continuous 10-minute video clips of parent-child interactions were taken at baseline, post-training, and follow-up. In this study, a video-coding scheme was adapted from the Dyadic Parent-Child Interaction Coding System (D-PICS; Eyberg & Robinson) and used to code the child's disruptive behaviour at each time point.

Results: Analyses were conducted using generalized estimating equations (GEE) as the majority of disruptive behaviour variables did not meet the assumption of normality. Preliminary analyses indicated that toddlers in the treatment group demonstrated significant decreases in refusal behaviours (e.g., going limp in parental hold, moving parents' hand off of toy to regain control) between baseline ( $M = 7.11$ ,  $SD = 1.54$ ) and follow-up (i.e., 24 weeks after baseline;  $M = 2.44$ ,  $SD = 1.04$ ;  $p = .029$ ). In comparison, toddlers in the control group did not demonstrate a decrease between baseline ( $M = 4.71$ ,  $SD = .99$ ) and follow-up ( $M = 4.61$ ,  $SD = 1.40$ ;  $p = .95$ ). Additional analyses exploring the relationship between social communication skills will be available at the time of the conference.

Conclusions: These findings suggest that this parent-mediated intervention has positive effects on both toddlers' social communication and non-compliant behaviours. There are several possible reasons for the decrease in disruptive behaviours, including increased parent-child synchrony, which may lead to a reduction in refusal behaviours, as well as an increased ability for the child to communicate their wants and needs to their parents, resulting in less parental uncertainty. Further analyses will substantially increase our understanding of the reciprocal relationship between communication and challenging behaviours.

**426.024 (Poster)** Micro-Analysis Reveals Increased Parent-Child Positive Affect in Severely Impaired Children Receiving the Esdm

*Y. Sinai<sup>1</sup>, T. Gev<sup>1,2</sup>, I. Gordon<sup>1,3</sup>, I. Mor Snir<sup>2</sup>, G. Vivanti<sup>4</sup> and O. Golan<sup>1,2</sup>, (1)Department of Psychology, Bar-Ilan University, Ramat-Gan, Israel, (2)Association for Children at Risk, Givat-Shmuel, Israel, (3)The Gonda Brain Research Center, Bar-Ilan University, Ramat-Gan, Israel, (4)A.J. Drexel Autism Institute, Drexel University, Philadelphia, PA*

---

Background: Shared positive affect (SPA) is a key element of parent-child interaction, which is related to favorable developmental outcomes. Children with autism and their parents tend to show less SPA compared to other populations. SPA is a pivotal component in Naturalistic Behavioral Developmental Interventions (NDBI), one of which is the Early Start Denver Model (ESDM). The ESDM highlights the importance of the interaction partner's positive affect as a way of increasing the reward value of social engagement.

**Objectives:** The current study aimed to assess changes in SPA among children with ASD and their parents following a preschool-based ESDM program with regular parental involvement and training, compared to a the commonly used Multidisciplinary-Integrative Intervention (MDI).

**Methods:** Thirty children receiving PB-ESDM (7 girls) and their parents (4 fathers) and 23 receiving MDI (2 girls, 4 fathers) participated in the current study. Groups were comparable on age, SES and DQ. Overall adaptive behavior levels at pre-intervention were higher in the PB-ESDM group and were therefore entered as a covariate in the analysis.

Children in both groups received the intervention during their 44 weekly hours preschool time, over an 8-month period. The PB-ESDM included two weekly ESDM sessions and one weekly hour of a parent-child joint intervention, in which therapists provided modelling and coached parents on the delivery of ESDM techniques. Parents were encouraged to increase shared positive affect by using strategies such as exaggerated facial expressions, gestures and voice, creating enjoyable sensory-social routines and following the child's lead. MDI consisted of a combination of methods from several approaches such as Floortime™, TEACCH and applied behavioral analysis. Parents of children from the MDI group attended bi-weekly parent counseling sessions with the child's case manager in which various issues were discussed, as initiated by the parent.

Parent-child free-play interactions were video-recorded pre and post intervention. These interactions were then microanalytically coded using the Observer XT software, providing a continuous moment-to-moment measure of overall SPA observed during the interaction. SPA was defined as a period of time in which both child and parent demonstrated positive affect. Children's adaptive functioning was parent-reported using the Vineland Adaptive Behavior Scales, 2<sup>nd</sup> Ed.

**Results:** An interaction effect between group (PB-ESDM/MDI), pre-intervention adaptive behavior functioning (high/low – above/below median), and time (pre/post intervention) was found on dyads' SPA. Post-hoc analysis revealed that dyads from the PB-ESDM group whose children had lower pre-intervention adaptive functioning demonstrated a significant increase in SPA, compared to the dyads from the MDI group, and dyads from the PB-ESDM with higher pre-intervention adaptive functioning (Figure 1).

**Conclusions:** The current findings demonstrate the effect parental involvement in ESDM has on parent-child SPA, especially among children with poorer pre-intervention adaptive functioning. Engagement in dyadic routines characterized by shared positive affect has the potential of extending children's learning opportunities. Furthermore, our findings suggest that SPA may serve as a sensitive treatment outcome measure for children with lower pre-intervention functioning levels, who often show no significant changes on standardized measures. The study's modest sample and non-randomized design are noted as limitations.

**426.026 (Poster)** Outcomes of a Short-Term Low-Intensity Early Start Denver Model Implemented in the Taiwanese Public Health System: 6-Month Follow-up

**C. H. Chiang<sup>1</sup>, T. L. Lin<sup>1</sup>, S. Y. Ho<sup>2</sup>, H. C. Wu<sup>3</sup> and C. C. Wong<sup>2</sup>,** (1)Department of Psychology, National Chengchi University, Taipei City, Taiwan, (2)Child Developmental Assessment & Intervention Center, Zhongxing Branch of Taipei City Hospital, Taipei City, Taiwan, (3)Department of Rehabilitation, Taipei Tzu Chi Hospital, Buddhist Tzu Chi Medical Foundation, New Taipei City, Taiwan

**Background:** Early Start Denver Model (ESDM) is one kind of Naturalistic Developmental Behavioral Interventions for young children with autism spectrum disorder (ASD). In the past nearly 10 years, most of the ESDM studies were reported in the west, how to implement ESDM in the Chinese culture such as Taiwan and merged into Taiwanese public health system is an open issue.

**Objectives:** The purposes of this study was to examine 6-month follow-up after implementing the ESDM intervention based on Taiwanese public health policy for young children with ASD in the Greater Taipei area in Taiwan.

**Methods:** A case control study was conducted. A total of 42 children with ASD aged between 25 and 46 months were recruited. A multidiscipline team included child psychiatrists and clinical psychologists based on DSM-5 diagnosis of ASD. The ESDM intervention group (N = 21, mean age = 33.23 months) matched to the control group who got community-intervention (N = 21, mean age = 35.14 months) on chronological age, overall development quotient (DQ) and sex. Children in ESDM intervention group received 9 hours per week of one-on-one ESDM intervention in clinical settings for 24 weeks. Children's outcome measures were administered at pre and post intervention, comprising the cognitive ability, language, adaptive behaviors and symptom severity assessed by the Mullen Scales of Early Learning, Mandarin-Chinese Communicative Development Inventory (MCDI), Adaptive Behavior Assessment System (2<sup>nd</sup> Edition, ABAS-II), and Autism Diagnostic Observation Scales (ADOS), respectively.

**Results:** The results indicated that from pre- to post- intervention, children with ASD in ESDM group showed significantly improvements in nonverbal cognitive ability, verbal cognitive ability, overall cognitive ability, vocabulary production, mean length of utterance and general adaptive behaviors ( $p < .01$ ). The improvements in nonverbal cognitive ability and overall cognitive ability were greater than the children with ASD in control group. However, when following up at 6 months, there was no significant improvements in ESDM group from post-intervention to 6-month follow-up, and there was no significantly difference in improvements between the two groups.

**Conclusions:** This study was the first finding to support the implementation of ESDM in Taiwan. The results suggested that a short-term and low intensity of ESDM intervention directly delivered by a multidisciplinary team in clinical settings may be a promising treatment for young children with ASD. However, the positive effects could not be maintained for 6 months. Relative factors such as child's and parental characteristics influencing long-term effectiveness might be clarified.

**426.027 (Poster) PACE Coaching: Training Community Providers to Support Parents of Toddlers at Risk for ASD**  
*P. Colozzo, School of Audiology and Speech Sciences, University of British Columbia, Vancouver, BC, Canada*

---

**Background:** There is growing evidence to support the efficacy of parent-delivered intervention based on the Early Start Denver Model (ESDM; Estes et al., 2013; Rogers et al., 2012, 2018). In most ESDM studies, parents are coached in academic settings by graduate-level clinicians who are certified in ESDM. There is a need to train community-based providers to provide parent coaching in order to make this support more widely available.

**Objectives:** The coach training phase of the PACE Coaching project was designed to develop, implement, and evaluate the effectiveness of an adapted version of ESDM training for community providers.

**Methods:** Thirty-nine community providers in 15 child development centres were nominated by their Executive Directors to be trained as parent coaches. All training was provided by three master trainers who are certified ESDM parent coaches and reside locally. Trainees were all women ( $M$  age = 44 years); 66.7% completed college or University undergraduate programs and 33.3% completed graduate degrees. In consultation with ESDM authors, the PACE Coaching team created a coach training approach that consisted of two phases. In the first phase (PACE1), trainees attended an intensive, 3-day workshop and then practiced the social-communication intervention strategies they learned with a toddler in their agency for 12-13 weeks. In the second phase (PACE2), they attended a second 3-day workshop and then practiced the parent coaching strategies they learned with a parent and child in their agency for 16-20 weeks. Mentored practice was delivered remotely via a secure portal that enabled face-to-face conferencing and video recording. Trainees tracked the time spent on various tasks during training, and trainers evaluated coaches' skills following PACE1 and at project completion using checklist tools that were adapted from ESDM training.

**Results:** Twenty-seven trainees completed all training over a 10-month period. Half of withdrawals occurred because of caseload demands that interfered with participation. Post-workshop practice required a mean of 29.5 hours following each workshop; trainees with graduate degrees required significantly less time than those with undergraduate degrees in PACE2 practice. Post-PACE1, trainee skills for working with a young child improved from a baseline mean of 69.1% to a mean of 83.3%, with no significant difference between undergraduate and graduate coaches. At project completion, master trainers observed a final coaching session for each family and completed a coaching skills checklist; inter-observer agreement was 90.8%. The mean score for graduate coaches (83.9%) was significantly higher ( $p < .05$ ) than the mean for undergraduate coaches (66.9%); however, no significant correlations were found between groups for checklist scores or for either parent or child outcome measures.

**Conclusions:** Results suggest that PACE Coaching can be successfully used to train community providers to coach parents in an adapted version of parent-implemented ESDM. Opportunities provided for hands-on practice during the workshops and the remote mentoring provided during post-workshop practice and coaching periods were essential for building coach confidence and for skill development in all areas.

**426.028 (Poster) Parent Therapeutic Factors in Mental Health Treatment for Autistic Children: A Qualitative Analysis**  
*V. Chan (Ting) and J. A. Weiss, Psychology, York University, Toronto, ON, Canada*

---

**Background:** Many autistic children and youth experience mental health problems, and cognitive behaviour therapy (CBT) is considered an effective treatment for many (van Steensel & Bögels, 2015). Parents are particularly involved in psychotherapy for autistic children because of the core deficits associated with autism (Reaven et al., 2009), even being asked to attend and assist with therapy sessions (Reaven & Hepburn, 2003). There has yet to be a conceptual framework to identify the variables that contribute to successful parent therapeutic involvement in children's psychotherapy.

**Objectives:** This study aimed to develop a conceptual framework of successful parent therapeutic involvement in CBT for autistic children, and the factors that lead to it.

**Methods:** Seventeen therapists (94% female) and 11 mothers participated in individual semi-structured interviews. All participants were involved in one of two randomized controlled trials of CBT for children ages 8-13 with autism. In the CBT program, parents attended all 10 weekly sessions with their child, and were involved in activities during and outside of session time. Data collection and coding for the current study occurred in overlapping phases, and sample size was determined by theoretical saturation (Corbin & Strauss, 2008). Interview questions included initial open-ended, intermediate, and ending questions (Charmaz, 2006). Reflective memos were recorded immediately following each interview. Interviews were transcribed verbatim, and coding occurred in three overlapping phases: open, axial, and selective (Corbin & Strauss, 2008). To enhance methodological rigor, we employed applied analyst triangulation, constant comparative coding, and member checking.

**Results:** “Very involved/helpful” parents were committed, engaged, supportive, and mindful. The level of parent involvement varied among families. As depicted in the conceptual framework (see Figure 1), the extent of parent involvement considered helpful may depend on child factors (e.g., age, developmental level, temperament), the parent-child relationship, parent factors (e.g., mental health, attitudes, previous experiences with therapy), and family factors (e.g., other children, spousal support, financial resources). The specific ways parents might contribute to the therapeutic process were grouped into five main roles: 1) **logistical coordinator** (e.g., scheduling sessions, organizing materials, arranging transportation), 2) **co-facilitator** (e.g., helping to facilitate session activities, providing information about the child, helping with skill generalization), 3) **coach and cheerleader** (e.g., praising and encouraging the child, helping the child with emotion regulation), 4) **companion and teammate** (e.g., helping the child feel safe, participating in activities with the child), and 5) **complementary helper** -- bridging the gap between the child’s capacity and what is expected of them within the therapeutic context (e.g., being attuned to the child’s needs, helping the child build a relationship with the therapist, managing child behavioural or attention problems).

**Conclusions:** Parents can serve many different roles in helping their child to benefit from CBT and enhance skill maintenance following the end of therapy. Autistic children may benefit from parent involvement in therapy because parents can complement the child’s needs and enable their full participation in the therapeutic context. This is the first study to empirically investigate how parents of autistic children contribute to the therapeutic process in child psychotherapy.

**426.029 (Poster)** Perceptions of Brazilian Parents and Clinicians of a Low-Cost Parent-Mediated Intervention for Autistic Children

**P. Godoy<sup>1</sup>, E. Shephard<sup>2</sup>, J. Green<sup>3</sup>, L. McWilliams<sup>4</sup> and H. Brentani<sup>5</sup>,** (1)Universidade de Sao Paulo (USP), Sao Paulo, Brazil, (2)Institute of Psychiatry, Psychology and Neuroscience, King’s College London, London, United Kingdom of Great Britain and Northern Ireland, (3)University of Manchester, Manchester, United Kingdom of Great Britain and Northern Ireland, (4)The University of Manchester, Manchester, United Kingdom, (5)Clinical Hospital, São Paulo, Brazil

**Background:** Effective support and treatment for autistic individuals is lacking in Brazil. Few centres offer services and those that do are limited in therapeutic options and geographical location. Effective, low-resource interventions for autism are therefore urgently needed in Brazil. Paediatric Autism Communication Therapy (PACT) is a low-resource, evidence-based parent-mediated social-communication intervention and may be useful for this scenario.

**Objectives:** As part of a larger implementation study, we aimed to assess the acceptability of introducing PACT for young autistic children (aged 2-10 years) in Brazil.

**Methods:** Qualitative methods were used to explore parental and clinicians’ perceptions concerning the acceptability of PACT in Brazil. The original PACT protocol includes fortnightly home or clinic sessions with therapists, who support parents in learning strategies to adapt their communication style to their child’s social-communication difficulties using video-feedback of parent-child play interactions. Between sessions with the therapist, parents are asked to practice the strategies with the child at home every day for 30 minutes. Eighteen parents of 2-10 year-old autistic children were recruited from publicly accessible child mental health clinics, and 20 clinicians (psychologists, speech therapists, occupational therapists) who work therapeutically with autistic children were recruited from national clinics offering assessment and/or treatment services for autism. After a detailed explanation about PACT, semi-structured, in-depth-interviews about the intervention and its potential use in Brazil were conducted with the 18 parents and 20 clinicians. Interviews were conducted individually and by telephone due to the COVID-19 pandemic. Interview data were analyzed separately for parents and clinicians using thematic analysis according to Braun & Clarke’s (2006) six stages. In addition, parents completed the validated Brazilian “Communicative Difficulties Questionnaire”, which assesses difficulties parents experience in communicating with their autistic child, to quantitatively evaluate the need for a therapy focused on improving parent-child social communication in Brazil.

Results: All parents and clinicians had favorable opinions about the feasibility and effectiveness of a parent-mediated intervention that would be conducted mainly in the home. This included viewing PACT as an intervention that could result in improvements in social-communication development in the child's daily life, providing parents with the skills to support their child's development, and the low-cost nature of the intervention. However, most parents and clinicians also raised possible obstacles concerning the effective use of PACT in Brazil. These related to cramped and noisy home environments, which would complicate implementation of the intervention strategies by parents, and clinician reports of difficulties engaging Brazilian parents in therapy. Finally, the results of the questionnaire revealed that all parents would like to have more information about how to communicate better with their child and most reported difficulties in communicating with their autistic child.

Conclusions: The current findings support the acceptability and utility of PACT for Brazil, and highlight where adaptations to the original protocol are required before assessment in feasibility research.

**426.030 (Poster)** Pivotal Response Treatment (PRT) with Parent Group Training for Young Children with Autism Spectrum Disorder: A Mixed-Methods Approach

**M. W. P. De Korte<sup>1,2</sup>, M. Van Dongen - Boomsma<sup>1</sup>, I. J. Servatius-Oosterling<sup>1</sup>, S. Kaijdoe<sup>1</sup>, J. K. Buitelaar<sup>1,3</sup> and W. G. Staal<sup>1,2,4</sup>,** (1)Karakter Child and Adolescent Psychiatry University Center, Nijmegen, Netherlands, (2)Radboud University Medical Center, Donders Institute for Brain, Cognition and Behaviour, Department of Cognitive Neuroscience, Nijmegen, Netherlands, (3)Department of Cognitive Neuroscience, Donders Institute for Brain, Cognition and Behaviour, Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands, (4)Institute for Brain and Cognition, Leiden University, Leiden, Netherlands

---

Background: Pivotal Response Treatment (PRT) is a promising intervention addressing core symptoms of children with autism spectrum disorder (ASD), with parent involvement as key component (Koegel & Koegel, 2006). Parent group delivered PRT is suggested to be an effective treatment model for young children with ASD, but currently the evidence is limited and little attention has been paid to the involvement of multiple important contexts (e.g. home, school, family) of the child. It is also unclear how parents experience these type of intervention models and which facilitators and barriers are identified. Insight in the efficacy and perceived experiences of parent group delivered PRT are needed to optimize treatment outcome of young children with ASD and their family.

Objectives: The current study aims to explore a 14-week protocol of PRT parent group training (PRT-PG), complemented with individual parent-child sessions and involvement of teachers and other child care providers, for young children with ASD and their parents.

Methods: A mixed methods approach was conducted to explore the efficacy and feasibility of PRT-PG. Participants included 20 children aged 2-6 years old with ASD (90% boys; mean age = 4.92, SD= 1.07) and their parents. Social-communicative skills and collateral gains (e.g. adaptive functioning, clinical global functioning, parenting stress) were assessed with parent- and clinician- rated questionnaires and semi-structured observations at baseline and after 14 weeks of intervention. Semi-structured interviews ( $n=15$ ) were conducted at endpoint to understand parents perspectives on facilitators and barriers and perceived effects of PRT-PG. Coding was based on Grounded Theory (Glaser & Strauss, 2017).

Results: As presented in table 1, quantitative analyses showed a significant increase in spontaneous initiations during a semi-structured therapist-child interaction ( $p = .004$ ,  $d = 0.86$ ) together with widespread gains in clinical global functioning as measured with the CGI-severity score (CGI-S;  $p = 0.01$ ,  $d = 0.69$ ) and the CGI-Improvement score (CGI-I; 80% of the participants improved). No significant improvement on parent-rated general social-communicative skills (i.e. SRS-2; Social Responsiveness Scale- Second Edition) was observed. Preliminary qualitative analyses of interviews suggest the following facilitators and barriers; treatment format (e.g. combination of parent group, individual sessions and other contexts), role of PRT therapist (e.g. therapeutic alliance), contextual factors (e.g. time investment), and individual participant characteristics (e.g. child's age). Parental effects included awareness, insight and acceptance of their child's and own behavior, along with raised feelings of competence. Subsequently, parents mentioned improved family cohesion. Perceived child's gains were mentioned on functional and social questions, eye contact and emotion-regulation. Further analyses will be performed and presented.

Conclusions: These exploratory findings suggest feasibility and efficacy of the PRT parent group training on child's social-communicative skills and global functioning. Also, the complementary addition of individual sessions and multiple contexts of the young child with ASD seem to contribute to a patient-tailored approach. Implication of findings and future research will be discussed.

**426.031 (Poster)** Pivotal Response Treatment: Perspectives of Autistic Adults

R. K. Schuck<sup>1</sup>, K. M. Penner<sup>1</sup>, P. Dwyer<sup>2</sup>, Z. J. Williams<sup>3</sup>, A. Jevtic<sup>1</sup> and M. Wang<sup>1</sup>, (1)Gevirtz Graduate School of Education, University of California, Santa Barbara, Santa Barbara, CA, (2)Department of Psychology, University of California, Davis, Davis, CA, (3)Medical Scientist Training Program, Vanderbilt University School of Medicine, Nashville, TN

---

**Background:** While behavioral interventions for autistic children are evidence-based and widely viewed by clinicians as best practice, many autistic adults have spoken out against them. Some individuals report trauma as a result of interventions that they feel have been designed to suppress autistic characteristics. Recently developed Naturalistic Developmental Behavioral Interventions (NDBIs), however, aim to offer a more accepting approach by emphasizing child motivation and naturalistic, child-initiated learning opportunities. Nevertheless, research has yet to explore autistic perspectives on NDBIs.

**Objectives:** This study aimed to learn more about how autistic adults view a common NDBI, Pivotal Response Treatment (PRT).

**Methods:** Thirty-five autistic adults (16 F, 10 M, 6 Non-binary, 3 unknown) were recruited to take an online survey that included 5 short video clips of children receiving PRT. Participants were not informed of the intervention type. All videos were judged to meet PRT fidelity. Four videos included children who verbally responded correctly to prompts and who were subsequently reinforced. One video showed an interventionist providing a nonverbal child with a challenging verbal task in which they were unsuccessful and reinforcement was withheld. After each video, participants were asked to rate to what degree they agreed that they (1) found the intervention acceptable and (2) would suggest the intervention for others (1=Strongly Disagree; 6=Strongly Agree). Participants could also type feedback regarding each video into a textbox. To preliminarily analyze data, descriptive statistics were used to evaluate quantitative responses, and thematic analysis was employed to analyze open-ended responses. Recruitment is ongoing and full data will be presented at INSAR.

**Results:** The overall mean scores of all 5 videos were 4.29 ( $SD=1.00$ ) for acceptance and 3.90 ( $SD=1.12$ ) for suggesting. Mean acceptance scores for individual videos ranged from 3.29-4.80 and mean suggestion scores ranged from 2.91-4.54. Themes from the open-ended responses to the highest-rated video included: *child positivity/happiness* ( $n=18$ ); *uncertainty regarding intervention purpose* ( $n=4$ ); and *intervention-related complaints* ( $n=3$ ). Themes from the lowest-rated video (the video in which the interventionist contingently withheld reinforcement) were: *attempts should be reinforced* ( $n=15$ ); *disconnect between child and interventionist* ( $n=5$ ); and *the intervention was acceptable* ( $n=5$ ). Many comments from all videos indicated that intervention choices should be tailored to the individual child.

**Conclusions:** This study provides an initial glimpse into how autistic adults view PRT, a prominent NDBI used with young autistic children. On average, participants found the video clips mildly acceptable and varied as to whether or not they would recommend the intervention to others. This suggests that PRT may be more acceptable than prior iterations of behavioral intervention, though certain commonly-used strategies such as withholding reinforcement may be viewed poorly. Negative comments highlight areas that clinicians should always be attuned to, including sensory issues, appropriateness of physical contact, and appropriateness of pushing for more differentiated language in nonverbal children. This line of research has the capacity to strengthen NDBIs and bring them more in line with the ideals of autism acceptance and promotion of quality of life.

#### 426.032 (Poster) Play Diversity and Complexity in Diverse Young Children with Autism

Y. C. Chang<sup>1</sup>, S. Y. Shire<sup>2</sup>, W. I. Shih<sup>3</sup> and C. Kasari<sup>3</sup>, (1)Special Education and Counseling, California State University, Los Angeles, Los Angeles, CA, (2)University of Oregon, Eugene, OR, (3)University of California, Los Angeles, Los Angeles, CA

---

**Background:** There are many evidence-based interventions for children with autism. It is important to examine for whom these interventions are most tailored for to maximize optimal outcomes (Schreibman et al., 2011). Play skills are often rote and repetitive for children with autism compared to their neurotypical peers (Jarrold et al., 1996). It is a critical skill for children's development that has been associated with gains in other developmental domains, (Pierucci et al., 2015), including social communication skills (e.g., joint attention).

**Objectives:** The study will 1) examine whether changes in play skills are associated with changes in other developmental skills after participation in intervention and 2) identify potential moderators of the treatment on changes in play skills in a diverse sample of children with autism.

**Methods:** Participants included 174 children with ASD ( $M=46.72$  months;  $SD=.5$  months) from four different studies. Eighty-six percent of the sample was male and 75% reported ethnic minority backgrounds.

Ninety-three children in the sample participated in a play-based social communication intervention, Joint Attention, Symbolic, Engagement, and Regulation (JASPER; Kasari et al., 2006) that took place in community settings. Eighty-one children received treatment as usual.

*Mullen Scales of Early Learning* (Mullen, 1995) was used to measure visual reception, fine motor, receptive language, and expressive language. Children's mental age (MA) scores were calculated by averaging the age equivalent scores of the four domains ( $M=26.34$  months,  $SD=10.99$  months).

*Structured Play Assessment* (Ungerer & Sigman, 1981) was used to measure children's spontaneous play acts. The number of different spontaneous play types and their frequency were coded by raters blinded to condition and time for 16 levels of play ranging from indiscriminant to thematic play (Lifter & Bloom, 1989). Play diversity was the total number of different play acts. Play complexity was defined as the child's mastered play level ( $\geq 2$  different play acts at a specific play level with an overall frequency of  $\geq 5$  acts).

*Early Social-Communication Scales* (Mundy et al., 2003) was used to measure children's spontaneous initiations of joint attention (IJA) and behavior regulation (IBR).

**Results:** Regression analyses were conducted to examine the association of changes in play with mental age and IJA. Children who received JASPER made significant gains from entry to exit in total play diversity associated with increases in MA ( $p=0.005$ ) and expressive language ( $p=0.007$ ) from entry to exit. Increase in play complexity was not significantly associated with increases in MA from entry to exit.

Moderation: Entry IJA moderated the effect of treatment on play diversity ( $p<0.001$ ) and approached significance for play complexity ( $p=0.078$ ). Children with greater IJA had greater improvement in play diversity and complexity if they received JASPER.

**Conclusions:** Children receiving an intervention that specifically targets play development (JASPER), improve significantly in play diversity on independent evaluations, and play gains are associated with improved communication and cognition on a standardized test. Children with more IJA to begin with make more progress, suggesting an important moderator of outcomes. Results also suggest that IJA and play diversity are important targets of developmental outcomes in early interventions.

#### **426.033** (Poster) Preliminary Evaluation to Implement Who Caregiver Skill Training Program in Mainland China – a Pilot Study

**B. Chen<sup>1</sup>, H. Deng<sup>2</sup>, X. Zou<sup>3</sup>, H. Zhu<sup>1</sup> and T. W. CST Team<sup>4</sup>,** (1)Child Development and Behavior Center, Third Affiliated Hospital of SUN YAT-SEN University, Guangzhou, China, (2)Child Developmental & Behavior Center, Third Affiliated Hospital of SUN YAT-SEN University, Guangzhou, China, Guangzhou, Guangdong, China, (3)The Third Affiliated Hospital of Sun Yat-Sen University, Guangzhou, China, (4)Department of Mental Health and Substance Abuse, World Health Organization, Geneva, Switzerland

Background: Limited provision of evidence-based behavioral intervention resources is one of the main difficulties faced by children with autism and their families in main-land China. The CST (Caregiver Skills Training) program, developed and promoted by the World Health Organization (WHO), aims to train non-professionals to become guides (FT), fully mobilize local primary health care and community resources, provide more targeted services for families with autistic children, and provide core parenting skills guidance that is easy to impart and operable under the framework of effective intervention strategies.

Objectives: To implement WHO-CST program to families with autism child in main-land China, for promoting caregiver's knowledge and skills, improving parental efficacy, and promoting children's adaptive skills as well as their participation in family life and social activities.

Methods: This pilot study was conducted in one group ( $n=24$ ) in Dongguan urban area. It's delivered by non-specialist facilitators under two specialists' on-site supervision in all group sessions and home visits. Caregiver Involvement and attendance rates, Autism Stigma & Knowledge Questionnaire (ASK-Q), Clinical Global Impressions (CGI), primary target behavior, and fidelity rating data were collected. Pre-program and post-program focus group discussions with caregivers and trainee facilitators were conducted accordingly.

Results: We are here to report the preliminary outcomes of CST in the pilot stage. A total of 24 families with 2-9 years old autistic children were recruited in the Dongguan area, among which has 20 males and 4 females, and their average age is  $5.16 \pm 2.25$  years. Our results showed that at the checkpoint of the second home visit, their parenting knowledge and skills were significantly improved ( $t = 2.89, P < 0.05$ ), and parental efficacy was significantly improved ( $t = 2.13, P < 0.05$ ) comparing to the first home visit. At their third home visit, the child's Clinical Global Impressions (CGI) score was significantly improved ( $t = 2.12, P < 0.05$ ), and the severity for primarily concerned target behavior was significantly decreased ( $t_1=-6.04, P_1<0.05; t_2=-5.56, P_2<0.05$ ). Our result also indicated that the trend of increasing children participated in family and community activities at the endpoint of CST; however, the difference was not yet statistically significant ( $P = 0.06$ ).

Conclusions: WHO-CST program is easily accepted by caregivers of children with autism in main-land China. From this small sample exploratory pilot study, we found that the CST project has good effects on improving caregivers' knowledge and skills, improving parents' sense of efficacy, improving the overall clinical impression of children, and reduce target behavior parents are most concerned about. On-site supervision provided by the specialist for trainee facilitators (non-specialist) to deliver CST for at least one round may help improve their confidence and feasibility. Further research needs to address the high fidelity requirement in adult-child interaction and conduct a full scale of RCT for the efficacy study.

**426.034 (Poster)** Probiotic Intervention May Benefit Preschool Children with Autism Spectrum Disorder Via Gut-Brain Axis  
**Y. W. Liu<sup>1</sup>, Y. H. Huang<sup>2,3</sup> and H. J. Chen<sup>3,4</sup>,** (1)Institute of Biochemistry and Molecular Biology, National Yang-Ming University, Taipei, Taiwan, (2)Department of Psychiatry, MacKay Memorial Hospital, Taipei, Taiwan, (3)Department of Medicine, MacKay Medical College, New Taipei City, Taiwan, (4)Division of Pediatric Neurology, Department of Pediatrics, MacKay Children's Hospital, Taipei, Taiwan

---

Background: Restricted, repetitive patterns of behavior, interests, or activities and persistent deficits in social communication and social interaction are diagnostic criteria for autism. For preschool children with autism spectrum disorder, early intervention is important to improve the behavioral and communication disorders for the accommodation to the following school time. *Lactobacillus plantarum* PS128 (PS128) showed beneficial effects on boys (aged 7-15) with autism spectrum disorder (ASD; ACTRN12616001002471) and younger subjects benefit more from PS128.

Objectives: We carried out a trial investigating the effects of probiotic *Lactobacillus plantarum* PS128 on preschool children (NCT03982290). Our hypothesis is probiotic may be beneficial to children with ASD by improving the gastrointestinal and nervous system functions via gut-brain axis.

Methods: This study is a 2-stage, randomized, double-blind, placebo-controlled trial. Preschool children, aged 2.5-6 years old, fulfilled the inclusion criteria were recruited. At stage 1, the subjects received either probiotic or placebo for 8 weeks. And then all subjects received probiotic for a further 8 weeks. Several questionnaires were used as outcome measurement, including Achenbach System of Empirically Based Assessment-The Child Behavior Checklist (ASEBA), Attention-Deficit/Hyperactivity Disorder Test (ADHDT), Childhood Asperger Syndrome Test (CAST), Penn Interactive Peer Play Scale, (PIPPS), and Social Interaction Assessment Scale.

Results: Seventy six subjects (69 boys and 7 girls) with average age of  $53.78 \pm 14.43$  week-old finished participating this 2-stage trial. No adverse effect was reported neither in probiotic group (33 boys and 4 girls) nor in placebo group (36 boys and 3 girls). At week 8, improvement in anxiety, internal problems and total score of ASEBA were observed in subjects of probiotic group but not of placebo group. At week 16, improvement in ASEBA-total T score, ADHDT-inattention, and PIPPS-Play were observed in both probiotic and placebo group, suggesting the probiotic have positive impacts on subjects mainly on the behaviors. The results of PIPPS showed that subjects in probiotic group showed less play disturbance and more play interaction. To compare the outcomes of baseline, week 8 and week 16, the results showed that 16-week probiotic consumption showed beneficial effects on ASD subjects accumulatively.

Conclusions: Our results showed that the intervention with probiotic benefits preschool children with ASD in behaviors and social interaction. The possible mechanisms may be targeting the gut-brain axis by the psychobiotic, *Lactobacillus plantarum* PS128.

**426.035 (Poster)** Restricted and Repetitive Behaviors, Problem Behaviors, and Outcomes of the PEERS® for Preschoolers Program

**L. Antezana<sup>1</sup>, J. Albright<sup>1</sup>, A. Scarpa<sup>1</sup>, J. A. Richey<sup>2</sup>, E. A. Laugeson<sup>3</sup> and R. S. Factor<sup>1</sup>,** (1)Virginia Polytechnic Institute and State University, Blacksburg, VA, (2)Virginia Tech, Blacksburg, VA, (3)UCLA Semel Institute for Neuroscience and Human Behavior, Los Angeles, CA

---

Background: Restricted and repetitive behaviors (RRB) are a core symptom domain in autism spectrum disorder (ASD) and may impact treatment outcomes. Considering the links between RRB and problem behaviors (i.e., internalizing problems; Factor et al., 2016; Muskett et al., 2019), RRB may play an important role on outcomes of social skill interventions. Moreover, changes in RRB may be a secondary outcome of social skills treatment as social impairments and RRB are intertwined in ASD. Emerging work on the PEERS® for Preschoolers (P4P) Program has demonstrated promising results for young children (Laugeson et al., 2016). As early reciprocal social interactions have been posited to have cascading effects on later social outcomes (Chevallier et al., 2012), understanding RRB on P4P outcomes may elucidate potential mechanisms in treatment trajectories.

**Objectives:** We aimed to examine (1) changes in RRB and problem behavior as secondary outcomes of P4P, and (2) whether RRB impacted social skills and problem behaviors at post-treatment and follow-up. We hypothesized that P4P would produce reliable change within-subjects, and that RRB would predict problem behaviors following treatment.

**Methods:** Twenty-two caregiver/child dyads (13 boys; 77.3% Caucasian) completed P4P groups (6 groups), consisting of 16 1.5-hour group sessions. One hour included separate child/caregiver didactics and 30 minutes were for caregiver-coached play. Children were required to be fluent in English, meet ADOS-2 criteria for ASD, have an  $IQ \geq 70$ , be toilet trained, and able to tolerate a group setting. The SRS-2 was used to examine RRB. SSIS was used to measure Social Skills and Problem Behaviors.

**Results:** Reliable change indices (RCI) were calculated for each child and linear regressions were used to examine RRB on outcomes. On the SSIS Problem Behaviors, RCIs revealed 100% of children demonstrated significant improvement from pre-treatment to post-treatment and 46.15% of children showed improvement at follow-up. On the SRS-2 RRB subscale, 25% of children demonstrated significant improvement from pre-treatment to post-treatment and 31.25% of children demonstrated significant improvement at follow-up.

Pre-treatment SRS-2 RRB subscale was used to predict post-treatment and follow-up SSIS Social Skills and Problem Behaviors. Pre-treatment RRB did not predict social skills at post-treatment,  $p > .19$ . Lower pre-treatment RRB significantly predicted lower problem behaviors at post-treatment,  $\beta = .49$ ,  $t = 2.49$ ,  $p = .02$ , and accounted for 24% of the variance in post-treatment problem behaviors,  $R^2 = 0.24$ ,  $F(1, 20) = 6.20$ ,  $p = .02$ . No significant effects were found for pre-treatment RRB on social skills or problem behaviors at follow-up,  $ps > .28$ .

**Conclusions:** This study allowed for the examination of RRB on child problem behaviors and social skill outcomes. Treatment response indicated that 25% of children showed RRB improvements that increased to 31% at follow-up, and 100% showed problem behavior improvements that decreased to 45% at follow-up. Additionally, rigidity that underlies RRB may play an important role on changes in problem behavior at post-treatment. Future work using larger samples is needed to support this link and to further elucidate the role of specific types of RRB (i.e., insistence on sameness) on treatment outcomes.

**426.036 (Poster) Social Skills, Parenting Styles, and Family Functioning in the PEERS® for Preschoolers Program**  
**R. S. Factor<sup>1,2,3</sup>, H. Rea<sup>1</sup>, A. V. Dahiya-Singh<sup>1,3</sup>, J. Albright<sup>1,3</sup>, T. H. Ollendick<sup>1</sup>, E. A. Laugeson<sup>2</sup> and A. Scarpa<sup>1,3</sup>,** (1)Virginia Polytechnic Institute and State University, Blacksburg, VA, (2)UCLA Semel Institute for Neuroscience and Human Behavior, Los Angeles, CA, (3)Virginia Tech Autism Clinic & Center for Autism Research, Blacksburg, VA, (4)Center for Human Development and Disability, University of Washington, Seattle, WA

---

**Background:** Social impairments are evident early in Autism Spectrum Disorder (ASD) and tend to worsen (Rao, Beidel, & Murray, 2008). Despite emphasis on early intervention, few evidence-based interventions explicitly address social skills in preschool-aged children with ASD and none actively integrate caregivers (Reichow, Steiner, & Volkmar, 2012). Increase in caregiver-administered interventions and calls to compare child gains with family effects (Lord & Bishop, 2010) necessitate further investigation of how interventions impact family functioning and relationships. The PEERS® program is an evidence-based caregiver-assisted social skills program (Laugeson & Frankel, 2010), recently extended for preschoolers with ASD. Studying child social skills and caregiver and family unit functioning in the context of P4P fills this need.

**Objectives:** This study seeks to analyze improvements in child social skills, caregiver parenting style, and family functioning in the context of P4P compared to baseline in order to take a more holistic view in evaluating the intervention.

**Methods:** Fifteen caregiver/child dyads (11 boys; 66.7% Caucasian) from 4 to 7-years ( $M = 4.87$ ;  $SD = 1.25$ ) participated in four P4P groups (16 1.5 hour sessions twice per week). One hour included separate child/caregiver didactics while the last 30 minutes involved caregiver-coached play. Children were required to have an ASD diagnosis, meet ASD criteria on the ADOS-2, be fluent in English, have an IQ greater than 70, be toilet trained, and able to tolerate a group setting. Measures included the Social Skills Monitoring Form (SSM; measuring child's skill acquisition and at-home practice of social skills), the Parenting Scale (PS, measuring parenting style), and the Confusion, Hubbub, and Order Scale (CHAOS; measuring home environmental confusion), all administered at baselines, each session, post-treatment, and at follow-up.

**Results:** A nonconcurrent multiple baseline design allowed for analysis of changes in child, caregiver, and family variables and Simulation Modeling Analysis (SMA) allowed for examination of slope of symptom change in mean scores of each group between baseline, treatment, and post-treatment/follow-up for all domains. Results suggested mean changes in social skills for Group 3 ( $r = .53$ ;  $p = .035$ ) and all groups demonstrated significant slopes for slopes 2 (flat baseline, increasing treatment), 4 (increasing from baseline throughout treatment), and 5 (increasing during baseline, return to pre-treatment level at initiation of treatment, then increasing throughout treatment). For PS, mean changes were observed for Group 4 ( $r = -0.60$ ;  $p = .017$ ) and

demonstrated significant slopes for slope 2, 3 (increasing baseline, flat treatment), 4, and 5. No significant changes were observed across any groups for family chaos.

**Conclusions:** This novel study allowed for the examination of caregiver, child, and family outcomes within the context of a social skills intervention for preschoolers with ASD. Results directly support the use of P4P, especially regarding child social skill and parenting style improvement, as indicated by improvements from baseline. Family chaos was not impacted. Future work will allow further understanding of specific effectiveness of caregiver-assisted social skills on treatment implementation.

**426.037 (Poster) Stay with Me: The Role of Child-Therapist Interactive Variables and Interpersonal Synchrony in Early Ndbi Treatment Response.**

**G. Bertamini**<sup>1,2</sup>, S. Perzollì<sup>1</sup>, A. Bentenuto<sup>1</sup>, E. Paolizzi<sup>1</sup>, P. Venuti<sup>1</sup> and C. Furlanello<sup>3</sup>, (1)Department of Psychology and Cognitive Science, University of Trento, Rovereto, Italy, (2)Bruno Kessler Foundation (FBK), Trento, Italy, (3)HK3 Lab, Milan, Italy

---

### **Background:**

Naturalistic Developmental Behavioral Interventions (NDBI) for Autism Spectrum Disorder (ASD) have been supported by research and highlight the role of interpersonal aspects and interactive quality of child-therapist interplay (Tiede et al., 2019). However, there is a need for process measures able to objectively investigate the role of these variables in longitudinal changes (Fuller et al., 2020).

### **Objectives:**

Quantitatively measuring child-therapist interaction may help in explaining part of the high interindividual variability that emerges from efficacy studies (Wetherby, 2018), as well as identifying specific features that may impact on treatment response.

### **Methods:**

We set up a longitudinal exploratory design on a sample of n=25 children with ASD that underwent early intensive NDBI intervention. Children have been assessed pre- and post- intervention, after about 12 months.

We applied an observational coding system designed by ODFLab on 20-minutes segments of n=50 video-recorded sessions of intervention to quantitatively evaluate interpersonal aspects of child-therapist interaction pre- and post- treatment.

The code is bidirectional and allows to study frequencies, proportions, durations, latencies and the computation of indexes measuring the rate of success of different types of therapist initiatives (e.g. therapist proposals), child's intentionality and engagement levels. Treatment outcomes have been measured through the Griffiths Mental Development Scales (GMDS) and the Autism Diagnostic Observation Schedule (ADOS-2). We investigated longitudinal changes and fitted a linear regression model to investigate the role of interactive variables in treatment response, measured with the learning rate provided by the GMDS (Klintwall et al., 2013). Finally, we applied a preliminary cluster analysis on the interactions considering a 3-dimensional space (proportion of therapists initiatives, child's engagement, latency to initiate the exchange).

### **Results:**

Children showed significant gains in general development ( $t(23)=-2.37$ ,  $p=0.03$ ,  $BF=2.18$ ), especially in the language subscale ( $V=48.5$ ,  $p=0.007$ ,  $BF=19.57$ ), and in symptoms severity ( $t(23)=4.73$ ,  $p<0.0001$ ,  $BF=294.57$ ). Further, children's engagement level increased significantly over time ( $V=24$ ,  $p=0.005$ ,  $BF=16.25$ ).

The regression model ( $F(3,44)=5.751$ ,  $p=0.002$ ,  $BF=18.52$ ,  $adj-R^2=0.23$ ) has been fitted with the therapist's success rate ( $b=0.84$ ,  $p=0.02$ ), the proportion of therapist's initiatives with respect to child's intentionality signals or proposals ( $b=-0.52$ ,  $p=0.03$ ) and the frequency of child's dysregulation episodes ( $b=-0.04$ ,  $p=0.04$ ).

The cluster analysis identified two clusters of interactions characterized by significantly different therapist's success rates ( $t(46)=2.15$ ,  $p=0.04$ ,  $BF=1.57$ ) and durations of the exchanges ( $t(46)=5.12$ ,  $p<0.002$ ,  $BF=185.55$ ). Interestingly, the clusters significantly differed in terms of learning rate ( $t(38.197)=3.012$ ,  $p=0.005$ ,  $BF=9.86$ ).

### **Conclusions:**

These preliminary results may highlight interactive features that impact on treatment response. Quantitatively measuring these variables during ASD intervention may eventually help in disclosing optimal and individualized strategies to maximize response. This study will expand these preliminary findings by adding a mid-point to better investigate response trajectories. It will further exploit more sophisticated computational techniques like hierarchical density-based clustering (HDBScan) for longitudinal analysis, dimensionality reduction (UMAP) and techniques to identify the best number of clusters. Finally, deep learning techniques (i.e. OpenPose) for behavioral imaging and body motion tracking will be applied to employ automatic, quantitative and non-invasive measures of interpersonal synchrony (i.e. Dynamic Time Warping) for time series analysis.

**426.038 (Poster)** The Effects of Brief Parent Coaching in Pivotal Response Treatment on Minimally Verbal Preschoolers with Autism Spectrum Disorder

**T. Hamodat<sup>1</sup>**, H. E. Flanagan<sup>2</sup>, D. J. Chitty<sup>3</sup> and I. M. Smith<sup>4</sup>, (1)Psychology & Neuroscience, Dalhousie University, Halifax, NS, Canada, (2)IWK Health Centre, Halifax, NS, Canada, (3)IWK Health Centre, Halifax, NS, CANADA, (4)Dalhousie University / IWK Health Centre, Halifax, NS, CANADA

---

**Background:** Minimally verbal children with autism spectrum disorder are typically considered hardest to treat. Few studies have looked at the effectiveness of naturalistic developmental behavioural interventions, such as Pivotal Response Treatment (PRT), for this population. Nova Scotia's public Early Intensive Behavioural Intervention program (EIBI) uses the PRT model. In a child's first week, parents receive PRT coaching for two hours a day for four consecutive days.

**Objectives:** Study objectives are to identify whether: 1) parents trained in PRT reach treatment fidelity after brief coaching; and 2) parents' post-coaching PRT fidelity is associated with their children's immediate- and long-term communication and socialization gains.

**Methods:** Caregivers of 39 children (27 mothers, 10 fathers, 1 grandfather, and 1 aunt) were included in analyses. Children were aged 4 to 5 years ( $M = 4.8$ ,  $SD = .19$ ) and were eligible if they were nonverbal (38%), used only single words (21%), or used two-word combinations (41%).

We assessed parents' ability to provide developmentally appropriate language opportunities with shared control (frequency count). We also assessed the quality of language opportunities: whether parents followed their child's lead, attained appropriate attention, and were contingent (interval recording). Child outcomes were measured by determining (1) frequency of initiations and percentage of correct responding to parent-provided language opportunities pre-and post-training and (2) age-equivalent scores on the Communication and Socialization domains of the Vineland-II at EIBI start and exit (an approximately 10-month long, intensive treatment beginning right after training).

**Results:** The number of language opportunities parents provided to their children significantly increased after coaching ( $t(38) = 8.02$ ,  $p < .001$ ). Parents also improved in their ability to attain children's attention when providing language opportunities ( $t(38) = 7.43$ ,  $p < .001$ ) as well as being contingent with correct responding ( $t(38) = 9.71$ ,  $p < .001$ ). Parents followed their children's lead well before coaching, and maintained this skill ( $t(38) = 1.22$ ,  $p = .23$ ). At post-coaching, 31% of parents met full criteria for PRT fidelity.

During parent training, there were immediate mean gains in children's responding to language opportunities ( $t(38) = 5.13$ ,  $p < .001$ ), but not in frequency of initiations ( $t(38) = 0.06$ ,  $p = .95$ ). In the 10 months following parent training, children made important gains on Vineland outcomes ( $p \leq .03$ ). Preliminary analyses suggest that parent gains in fidelity are associated with some child outcomes. For example, increases in developmentally appropriate language opportunities parents provided post-coaching were significantly associated with gains in initiations by their children ( $r = .21$ ,  $p = .02$ ).

**Conclusions:** Parents of minimally verbal preschoolers made important gains in implementation of PRT strategies with brief coaching. However, additional coaching would be needed for many families to meet intervention fidelity. Children showed immediate gains in correct responding to language opportunities. Importantly, parent gains in fidelity were associated with child gains in frequency of verbal initiations. Further analyses will examine the impact on children's outcomes of their parents' effectiveness in implementing PRT strategies throughout the course of EIBI. Parent coaching may be helpful in maximizing benefits from clinician-delivered intervention for this group of children.

**426.039 (Poster)** The PACE Coaching Cost Analysis: An Incremental Analysis Comparing the Costs of Parent Coaching to Assessment and Monitoring in Toddlers at Risk for ASD

*W. J. Ungar, The Hospital for Sick Children Research Institute, Toronto, ON, Canada*

---

**Background:** A parent coaching intervention based on the principles of naturalistic developmental behavioural interventions (NDBIs) may offer benefits to toddlers with suspected autism spectrum disorder (ASD) but the costs are not well understood.

**Objectives:** The study objectives were to: a) determine the costs of a parent coaching (PC) intervention and b) to measure the incremental costs of PC compared to assessment and monitoring (A&M) in families with a child at risk for ASD aged 15-36 months, from public payer and societal perspectives.

**Methods:** The cost of the intervention included coach training costs and costs associated with intervention delivery. Training time related to attending workshops (39 trainees) and for labour and travel for three master trainers was collected. During intervention, time allocated to direct coaching, telephone follow-up, session preparation, administrative tasks, and master trainer support was recorded for each family receiving coaching. Costs for training and intervention delivery were calculated by multiplying hours reported for each activity by hourly wages. Eligible families of children at risk for ASD were randomized to receive PC or A&M services for 6 months. Families completed a detailed resource use questionnaire at baseline and post-6 months, reporting use of behavioural, educational, health, social, and other services. Out-of-pocket costs and productivity (time) losses were also reported. Each cost item was mapped to a public payer (Ministry of Children and Family Development or Ministry of Health). Costs were calculated by multiplying volumes of resource use by unit prices obtained from public sources. The societal perspective included all public payer costs, out-of-pockets costs, and time losses monetized using average national wages. An incremental analysis compared the mean cost per family in the PC group to the A&M group by major cost category.

**Results:** The mean training cost per coach was CAD\$11,822. The mean cost per family for intervention delivery was CAD\$3,118 for coaching and CAD\$2,056 for master trainer support, for a total intervention cost of CAD\$5,174 per family. At baseline, a majority of families in both groups reported receiving services from a speech language pathologist, occupational therapist, and health professional. Most families (>60%) also reported time losses related to caring for their child. During the 6 months of coaching, PC families greatly reduced their use of speech language pathologist and occupational therapist services compared to controls, but reported more time losses. The mean cost per family to the MCFD public payer was CAD\$199 ( $SD=358$ ) in the PC group compared to CAD \$923 ( $SD=760$ ) in the control group. When the intervention costs were factored in, the net cost to the MCFD was CAD\$4,350 per family (95% confidence interval 3587, 5,149).

**Conclusions:** While PC families used fewer public services, intervention costs resulted in a net cost to the public payer. Policy decision makers should consider these additional costs in terms of added benefits to families to inform investment in coaching interventions for toddlers with suspected ASD. Investments in coach training and parent coaching are likely to yield long-term benefits for both service providers and families of young at-risk children.

**426.040 (Poster)** The PACE Coaching Project for Toddlers at Risk for Autism: Understanding Implementation

*V. R. Smith, Educational Psychology, University of Alberta, Edmonton, AB, CANADA*

---

**Background:** One of the major translational gaps in the research community is how to go about implementing evidence-based practices in community settings.

**Objectives:** The objective of this arm of the study was to identify promising practices that will optimize future implementation of a community-based parent coaching model, particularly in relation to achieving and maintaining high quality coaching (i.e., effective implementation) for families of children at risk for autism across diverse communities in BC.

**Methods:** Interview data were collected with project participants in 15 child development centres across the province prior to, during, and toward the end of the project. Interviews were transcribed and coded deductively using NVivo 12, according to constructs included in the Consolidated Framework for Implementation Research (CFIR; Damschroder, Aron, Keith, Kirsh, Alexander, & Lowery, 2009). The CFIR provides a menu of 36 constructs across five key domains: Intervention Characteristics, Inner Setting, Outer Setting, Characteristics of Individuals, and Process of Engaging Participation and Conducting the Implementation. Research team members independently coded the transcripts and then met regularly to review codes, discuss differences, and refine definitions of CFIR constructs to fit the PACE Coaching implementation context. This process was followed by construction of case summaries and ratings of each CFIR construct as negative, positive, neutral, mixed, or missing with regard to implementation. Transcripts were also coded inductively, to develop themes that might influence challenges or successful future implementation of the model.

**Results:** PACE Coaching program characteristics that positively influenced implementation included evidence of strength and quality, relative advantage of the program, and program design quality and packaging. Characteristics that negatively influenced implementation included intervention source, adaptability, complexity, and cost. Limited community networking was a deterrent to recruitment, while participants' deep understanding of families' needs and resources contributed to success. The processes of implementing coach training positively contributed to implementation. Participants described the coach training as "top tier," "superb," and "hands down, the best training I have ever had." Themes that emerged from the implementation experience included: (a) an opportunity for "working differently" including reflective practice, data driven decision making, and family empowerment; (b) meeting the needs of individual children and families is paramount; (c) the importance of moving beyond how to implement PACE Coaching with children at risk for autism to implementing PACE Coaching with other young children with developmental needs; (d) imagining implementation ownership and the intention to sustain what has been started; and (e) recognition of the tension between commitments to serve families and to participate in a research project.

**Conclusions:** Numerous common and unique community and agency factors contributed to project outcomes. Future implementation considerations include the need to accommodate a broader range of children and families, develop strategies to increase coach efficiency and create a community of coaching practice within each agency, address funding and staffing challenges, and expand the use of technology to engage in remote coaching and outreach activities.

**426.041 (Poster)** The PACE Coaching Randomized Controlled Trial  
*P. Mirenda, University of British Columbia, Vancouver, BC, Canada*

---

**Background:** Previous research has demonstrated the effectiveness of interventions based on the Early Start Denver Model (ESDM) for children with autism spectrum disorder (ASD). Half of the studies were conducted in community settings using quasi-experimental designs. There is a need to assess the effectiveness of community-based ESDM using a more rigorous randomized controlled trial (RCT) and to examine its effectiveness for toddlers at risk for ASD.

**Objectives:** The study objective was to measure the effectiveness of a parent-implemented version of ESDM for toddlers identified at risk for ASD.

**Methods:** Sixty-four parents/caregivers of children ages 15-36 months who screened positive on the Modified Checklist for Autism in Toddlers-Revised with Follow-up participated in a hybrid, modified intent-to-treat RCT. Thirty-two families were assigned to the parent coaching (PC) group and 30 were assigned to the Assess & Monitor (A&M) group. All parents were provided with resources designed for parents of at-risk children, including a book and access to four online modules. They could also receive any locally-available services, with the exception of speech-language therapy for the PC group. In addition, a coach trained in the project provided PC parents with 1 hour/week of parent coaching plus a brief telephone follow-up for 24 weeks. Professionals at each site were trained to administer child cognitive and language measures and measures of parent stress, quality of life, and satisfaction at Time 1 (T1) and post-intervention (Time 2, T2). At both time points, they also recorded brief parent-child interactions corresponding to four scenes from the *Communication Play Protocol* (Adamson & Bakeman, 2016), using toys provided by the project. Videos were scored by the research team using an adapted version of the *Joint Engagement Rating Inventory* (JERI; Adamson et al., 2018).

**Results:** Forty-nine families (24 PC and 25 A&M) completed the study; withdrawals were primarily due to adverse family circumstances. PC families received a mean of 7.35 hours/month of service (including parent coaching), and A&M families received a mean of 6.47 hours/month. Repeated measures ANOVAS indicated no significant change over time ( $p > .05$ ) from T1-T2 for either group on the child cognitive measure or the parent stress measure. For both groups, there were significant gains over time ( $p < .05$ ) for words produced by the child. In addition, significant gains ( $p < .05$ ) in favour of the PC group were found for words understood by the child, parent quality of life, parent intervention satisfaction, and parent self-assessment of skills learned in the study. JERI scores indicated parent and child improvements from T1 to T2 for both groups, with trends toward larger effect size trends for the PC group across six out of seven scores. At study completion, 52% of children had received an ASD diagnosis, 11% had not, and 37% were waiting for a diagnostic assessment.

**Conclusions:** Although children and parents in both groups showed gains over time on some measures, overall results suggest the effectiveness of a community-based parent coaching intervention for toddlers at risk for ASD.

**426.042 (Poster)** The Relationship between Child's Play Level and Use of Parent Strategies in Preschoolers with Limited Language

**M. Tafolla Magana<sup>1</sup>, K. Sterrett<sup>1</sup>, J. Yang<sup>2</sup>, C. K. Toolan<sup>1</sup> and C. Kasari<sup>1</sup>,** (1)University of California, Los Angeles, Los Angeles, CA, (2)Department of Psychiatry and Biobehavioral Sciences, UCLA, Los Angeles, CA

---

**Background:** There are a number of active ingredients of effective parent-implemented early interventions. These generally have focused on parent responsiveness (Mahoney & Powell, 1988), parental ability to synchronize with the child (Green et al., 2015), and pacing of their interactions (Gulsrud et al., 2015). Parent-mediated interventions can improve parent's use of strategies, which leads to improvements in social communication skills in children with ASD (Kasari et al., 2015; Wetherby et al., 2014). However, there is great heterogeneity among parents and children with ASD. Especially for children with ASD who are responding slowly to early interventions, the child's initial abilities in play skills may correspond to parent strategy use and provide useful information for treatment targets.

**Objectives:** Investigate the correspondence between children's play abilities and parent strategy use in preschool aged children with ASD with limited spoken language abilities.

**Methods:** This study is a secondary data analysis of baseline data from 153 preschoolers with ASD (M<sub>Age</sub> = 45.08 months, SD = 5.54, 85.5% Males, 37% White, N<sub>VIQ</sub> = 55.56) using limited language (<30 functional words at baseline) enrolled in a randomized social communication intervention trial. Parent strategies and child's mastered play levels (simple, combination, pre-symbolic, and symbolic) were coded from a 10-minute parent-child free play interaction (Lifter et al., 1993). Parents were rated on their use of environmental arrangement (EA), prompting, pacing, and responsiveness strategies using a 5-point Likert scale. Higher ratings indicate more fluent and more appropriate strategy use. We used Kruskal-Wallis tests to determine if baseline parent strategy usage differed by child's mastered play level, followed up with post-hoc pairwise Wilcoxon tests as necessary. The next step was to fit an ordinal logistic regression controlling for N<sub>VIQ</sub>.

**Results:** There was no difference in quality of parent pacing or responsiveness based on child play level. There was a significant relationship between play level and parent EA ( $p = .05$ ), driven by lower quality strategy use in parents of children with mastered simple play compared to combination play ( $p = .03$ ). There was a trend towards significance for parent prompting ( $p = .12$ ), driven by lower quality prompting strategies in parents of children who mastered simple play vs. pre-symbolic play ( $p = .055$ ).

The probability of parents using higher quality EA strategies remained significant for those whose children mastered combination play compared to simple play ( $p = .03$ ) when controlling for N<sub>VIQ</sub>. Children's N<sub>VIQ</sub> was associated with higher quality parent prompting ( $p = .01$ ) and pacing ( $p = .05$ ), with higher N<sub>VIQ</sub> related to higher strategy use. No relationship was found between mastered play level and either pacing or prompting.

**Conclusions:** It may be easier for parents to use higher quality EA strategies if their children are playing at more developmentally complex levels and parents are more likely to use higher quality prompting and pacing strategies if their children have higher cognitive abilities. These findings indicate that certain parent strategies at baseline may be affected by different child characteristics. This is a first step in identifying the types of dyads that may need individualized support in implementing core strategies for early parent-mediated interventions, especially for children who are minimally verbal.

**426.044 (Poster)** Treating Disruptive Behavior in Children with ASD: Bridging Implementation of the Rubi Parent Training Program from Research to Practice

**D. M. Tagavi<sup>1</sup>, H. Rea<sup>2</sup>, K. P. Ahlers<sup>3</sup>, G. Haidar<sup>4</sup>, K. Paszek<sup>5</sup> and K. Bearss<sup>3</sup>,** (1)University of California, Santa Barbara, Santa Barbara, CA, (2)Center for Human Development and Disability, University of Washington, Seattle, WA, (3)Psychiatry and Behavioral Sciences, University of Washington, Seattle, WA, (4)University of Washington, Seattle, WA, (5)SDSU Center for Autism and Developmental Disorders, San Diego State University, San Diego, CA

---

**Background:** Disruptive behaviors are among the most common and impactful challenges in children with autism spectrum disorder (Carroll et al., 2014). Up to half of children with ASD exhibit disruptive behaviors, such as tantrums, defiance, and aggression, and these behaviors have been associated with significant impairment across multiple domains of functioning (Brown et al., 2019; Mazurek et al., 2013; Simonoff et al., 2008). Research Units in Behavioral Interventions (RUBI) is a low-intensity, manualized intervention for parents of children with ASD and co-occurring disruptive behavior. Although the results of three large scale trials have shown RUBI to significantly decrease child disruptive behavior, RUBI has yet to be implemented and tested in a community setting (Bearss et al., 2015).

**Objectives:** This study examined the preliminary effectiveness of the RUBI parent-training intervention delivered in a community setting on behavioral problems in children with ASD.

**Methods:** Participants were 29 children (ages 2-12) with ASD, who were referred for treatment for disruptive behaviors, and their parents. Participants in this sample were more diverse than in previous trials in terms of age, race/ethnicity, and IQ. Parents received twelve sessions of RUBI on average, which were delivered by both doctoral-level and graduate student clinicians. Pre- and post- levels of disruptive behavior were measured via the Aberrant Behavior Checklist (ABC) and the Home Situations Questionnaire (HSQ; Aman et al., 1985; Altepeter et al., 1989). Additionally, treatment drop-out rates were examined as a preliminary measure of feasibility.

**Results:** Dependent samples t-tests were conducted to determine the difference in parent-reported disruptive behaviors and behavioral noncompliance before and after participating in RUBI in a community care setting. Results indicated that parent ratings of challenging behavior across three out of five domains on the ABC (Irritability, Agitation, & Crying  $t(28)=5.34, p < .001$ ; Hyperactivity  $t(28)=2.20, p = .46$ ; Inappropriate Speech  $t(28)=2.45, p = .02$ ) and noncompliance as rated by the HSQ ( $t(28)=5.62, p < .001$ ) significantly decreased following intervention. Results for ABC domains of Lethargy and Social Withdrawal were not significant. Levels of disruptive behavior post-intervention were similar to results presented in initial RCTs. Additionally, 84% of parents completed the intervention, compared with 89% in the RCT, indicating adequate feasibility of RUBI in a clinical setting.

**Conclusions:** Findings support the preliminary effectiveness and feasibility of RUBI in a community setting. This investigation was the first to examine a parent-training intervention for disruptive behaviors developed specifically for children with ASD in community care, which could help expand the reach of RUBI throughout the country. Future directions include randomized-controlled implementation studies of RUBI in community care and other settings.

**426.045 (Poster)** Treatment Experiences Prior to World Health Organization's Caregiver Skills Training Programme May Moderate Outcomes

**G. J. Seng<sup>1,2</sup>, W. T. Soong<sup>3</sup>, Y. N. Chiu<sup>1</sup>, W. C. Tsai<sup>1</sup>, H. Y. Lin<sup>1,4,5</sup>, S. C. Li<sup>1</sup>, M. N. Hsiao<sup>1,6</sup>, T. J. Liu<sup>1</sup>, H. M. Chen<sup>1</sup>, A. Shih<sup>8</sup>, Y. C. Chang<sup>9</sup> and T. W. CST Team<sup>10</sup>,** (1)Department of Psychiatry, National Taiwan University Hospital, Taipei, Taiwan, (2)Graduate Institute of Brain and Mind Sciences, National Taiwan University, Taipei, Taiwan, (3)Department of Psychiatry, College of Medicine, National Taiwan University, Taipei, Taiwan, (4)Department of Psychiatry, National Taiwan University Hospital & College of Medicine, Taipei, Taiwan, (5)Department of Psychiatry, University of Toronto, Toronto, ON, Canada, (6)School of Occupational Therapy, College of Medicine, National Taiwan University, Taipei, Taiwan, (7)Foundation for Autistic Children and Adults in Taiwan, Taipei, Taiwan, (8)Autism Speaks, New York, NY, (9)Special Education and Counseling, California State University, Los Angeles, Los Angeles, CA, (10)Department of Mental Health and Substance Abuse, World Health Organization, Geneva, Switzerland

**Background:**

Caregiver Skills Training Programme for Children with Developmental delays (CST), developed by World Health Organization (WHO) and Autism Speaks (AS) for the resource gap, intend to meet the huge needs globally, including children with Autism Spectrum Disorder (ASD) and their families. Taiwan CST team have presented the adaptations and results of their pilot study to show CST's effectiveness in an international meeting, and started implementation stage in 2019. As a parent-mediated intervention, a range of individual and family factors may influence the outcomes.

**Objectives:**

The aim of this study is to analyze the effectiveness of CST-Taiwan and some key child and caregiver factors which may have influence on outcomes of CST-Taiwan.

**Methods:**

Forty-four families (most of them having children with ASD) were recruited from the pilot and implementation stage of CST-Taiwan. The demographic data of caregivers, including age, sex, education level and family income as well as treatment prior to the intervention, were collected. Caregiver outcomes assessed by WHO caregiver skills test and child outcomes assessed by Autism Treatment Evaluation Checklist were collected before and after the intervention. Paired-t test were applied to examine the effectiveness of the intervention. Linear regression model was used to examine the impact of child/caregiver factors on changes made by the intervention. The covariates were child age, caregiver age, caregiver sex, caregiver education level, family income and treatment prior to the intervention.

#### Results:

All indices of caregiver and child outcomes showed significant differences between pre- and post- intervention (knowledge  $t=-3.45$ ,  $p=0.001$ ; confidence  $t=-7.41$ ,  $p<0.001$ ; empowerment  $t=-4.67$ ,  $p<0.001$ ; communication  $t=-3.14$ ,  $p=0.003$ ; sociability  $t=3.74$ ,  $p=0.001$ ; sensory/cognitive awareness  $t=-2.13$ ,  $p=0.039$ ; health/physical behaviors  $t=2.42$ ,  $p=0.02$ ). Although no examined covariates showed significant effect on the outcome variables, however, treatment prior to intervention showed its effect on communication at a trend level ( $F=4.12$ ,  $p=0.050$ ).

#### Conclusions:

CST-Taiwan significantly improved the caregivers' knowledge and confidence on skills and empowered the family. The program also showed promise in improving children's communication, sociability, cognition and health/physical behaviors. The treatment experiences prior to CST intervention may have positive impact on the improvement of the communication but only at a trend level.

## Interventions - Non-pharmacologic - School-Age, Adolescent, Adult

### PANEL SESSION — INTERVENTIONS - NON-PHARMACOLOGIC - SCHOOL-AGE, ADOLESCENT, ADULT

#### Panel 213 - Promoting Pre-Employment Skills in Autistic Transition Age Youth

**Panel Chair:** Kari Sherwood, *School of Social Work, University of Michigan, Ann Arbor, MI, Department of Psychology, University of Michigan, Ann Arbor, MI, School of Social Work, University of Michigan, Ann Arbor, MI, Department of Psychology, University of Michigan, Ann Arbor, MI*

**Discussant:** Denise Juliano-Bult, *National Institute of Mental Health, Bethesda, MD*

Vocational experiences are associated with quality of life in adulthood. Despite the growing population of adolescents and adults with autism spectrum disorder, only 32% of autistic young adults obtain a job the first two years after high school. Transition-age autistic individuals experience difficulties in both obtaining and sustaining employment. Few research studies have examined skills and interventions focused on promoting skills essential for employment. This panel will focus on topics related to pre-employment skills and interventions in autistic transition-age youth, including executive function, social cognition, job interview skills, implementation of interventions in schools, and longitudinal employment outcomes.

**213.001 (Panel) Transition Age Youth (TAY) Success RCT Feasibility Study Targeting Executive Functioning and Social Cognitive Skills to Improve Outcomes**

*M. Baker-Ericzen<sup>1</sup>, A. Tran<sup>2</sup>, K. Scarvie<sup>1</sup>, B. Kraemer<sup>3</sup>, L. Brookman-Frazee<sup>4</sup> and C. Sax<sup>5</sup>, (1)Rady Children's Hospital San Diego, San Diego, CA, (2)Child and Adolescent Services Research, Rady Children's Hospital, San Diego, CA, (3)Special Education, San Diego State University, San Diego, CA, (4)Psychiatry, UC San Diego, La Jolla, CA, (5)College of Education, San Diego State University, San Diego, CA*

**Background:** Over 50,000 students with autism are completing High School (HS) yearly and more than 50% of these youth are not employed or attending college within 2 years afterwards. Devastatingly, these rates are higher than any other disability and continue years later with 50% unemployed and 70% without higher education even though they may be intellectually capable. Autistic individuals will be adults for significantly greater time compared to childhood yet there are far fewer intervention studies targeting teens and young adults. Autistic TAY are in need of functional cognitive and social skills necessary for positive livelihood; those with these skills demonstrate increased vocational and educational outcomes.

**Objectives:** This study tested through a pilot RCT an adapted, public school-based intervention teaching executive functioning (EF) and social cognitive and communication (SCC) skills required for self-determination, independence and attainment of post-secondary outcomes. TAY SUCCESS is a manualized group program delivered in HS and transition educational settings for autistic TAY. Multiple outcomes were assessed (ratings and performance scales) across informants (self, parent, teacher) and satisfaction.

**Methods:** A total of 31 teen/adults ( $\mu = 17.55$  SD=1.91 yrs; 13-21 yrs) participated. The participants were male (84%), race/ethnically diverse (48% Hispanic, 13% black/AA, 13% Asian, 19% Native American/Hawaiian/PI), 32% teens (<18 yrs), 55% in High School and 44% in transition program. The TAY SUCCESS curriculum was delivered over 7.5 months with ~90minutes active group sessions. The curriculum teaches cognitive enhancement, social cognitive and social communication strategies through 27 chapters including targeting executive functioning (EF) skills of prospective memory, working memory, sustaining attention, shifting attention, cognitive flexibility, problem-solving, inhibition, goal-oriented thinking and behaviors and contextual awareness. Social cognitive and communication skills targeted perspective-taking, social observations and evaluations, gaining social knowledge, social adaptation, decision-making, exchanging help, compliments & feedback, self-advocacy, social networking and social media usage. Pre and post assessments include a full battery of assessments on EF, SCC, adaptive living, MH, self-determination, self-efficacy, educational & employment outcomes and satisfaction.

**Results:** Analyses consisted of calculating Intent-to-treat ANCOVAs (Group) by (Time). Findings reveal significant differences by group on cognitive skills by informant report- BRIEF-2/A Inhibit  $p=.01$ , Working Memory  $p=.03$ , Plan/Organize  $p=.01$ , Task Monitor  $p=.03$ , and GEC  $p=.01$  and performance- DKEFS Inhibition,  $p=.02$ , sorting,  $p=.01$ , and sorting description,  $p=.01$ . Significant differences between intervention and control were also found for social cognitive and communication skills by informant report- SRS-2 SOC,  $p=.01$ , SCL,  $p=.00$  and Total Score,  $p=.03$  and performance-SSPA ranging from  $p=.04$  to  $p=.00$ . Adaptive living parent report revealed significance (scheduling,  $p=.04$  and attending activities,  $p=.01$ ) and educational outcomes measures rated by self and teachers ranging ( $p=.01$  to  $p=.03$ ). (Refer to Figures 1-3). No significant differences between groups

on self-efficacy, self-determination or work motivation or skills. All informants rated high satisfaction and indicated positive feasibility and accessibility.

**Conclusions:** This study demonstrates that TAY SUCCESS intervention is feasible and acceptable within public school settings and positively impacts teens/ adults with ASD towards obtaining skills necessary for successful post-secondary outcomes.

### **213.002 (Panel) Virtual Interview Training for Autistic Transition Age Youth: A Randomized Controlled Feasibility and Effectiveness Trial**

**M. J. Smith<sup>1</sup>, K. Sherwood<sup>1,2</sup>, B. Ross<sup>1</sup>, J. D. Smith<sup>3</sup>, L. E. Smith DaWalt<sup>4</sup>, L. Bishop<sup>5</sup>, L. Humm<sup>6</sup>, J. Elkins<sup>6</sup> and C. Steacy<sup>6</sup>,**  
(1)School of Social Work, University of Michigan, Ann Arbor, MI, (2)Department of Psychology, University of Michigan, Ann Arbor, MI, (3)University of Utah, Provo, UT, (4)University of Wisconsin-Madison Waisman Center, Madison, WI, (5)University of Wisconsin - Madison, Madison, WI, (6)SIMMersion, LLC, Columbia, MD

---

**Background:** Autistic transition-age youth struggle with obtaining employment, and interviewing is a critical barrier to getting a job. Currently, the field does not have an evidence-based practice that facilitates training the job interview skills for autistic transition-age youth. We used community-engaged methods to adapt an efficacious virtual reality job interview training intervention to meet the needs of autistic transition-age youth, called Virtual Interview Training for Transition Age Youth (VIT-TAY).

**Objectives:** This study evaluated whether VIT-TAY can be feasibly delivered in high school special education settings and whether VIT-TAY improves job interview skills, job interview self-efficacy, job interview anxiety, and access to employment.

**Methods:** We recruited five special education programs representing rural, suburban, and urban communities. Overall, we recruited n=71 autistic transition-age youth receiving school-based pre-employment transition services (Pre-ETS). We randomized n=48 students to the Pre-ETS + VIT-TAY group and n=23 students to the Pre-ETS only group. We trained and supervised local teachers to implement VIT-TAY. We conducted descriptive statistics to assess the feasibility of VIT-TAY implementation (i.e., process, adherence, and acceptability). We also conducted repeated measures analyses of variance to evaluate group-level difference between pre- and post-test assessments. Additionally, we conducted a Chi-Square analysis and confirmatory Firth logistic regression (covarying for prior employment) to evaluate employment rates by 6-month follow-up. Lastly, we conducted Pearson correlations among the VIT-TAY process data and primary outcomes (i.e., job interview skills, anxiety, self-efficacy, and employment).

**Results:** Students successfully adhered to VIT-TAY training (78.2% completed the minimal requirements) and students found the tool to be highly acceptable (m=20.4, sd=4.2, range=7 to 25). The Pre-ETS + VIT-TAY group, compared to Pre-ETS only, had significant group-by-time interactions reflecting better job interview skills ( $p<0.001$ ), lower job interview anxiety ( $p<0.05$ ), and greater access to competitive employment (25.0% vs. 0.0%,  $\chi^2=6.9$ ,  $p<0.01$ ) and (OR=16.0;  $p<0.05$ ; 95% CI 1.35, 189.17). We did not observe between-group differences in job interview self-efficacy between pre- and post-test ( $p=0.30$ ). We observed that the mean virtual interview performance score (across all trials) was correlated with the post-test job interview skills ( $\rho=0.39$ ,  $p<0.01$ ), which in turn were correlated with competitive employment ( $\rho=0.37$ ,  $p=0.01$ ) by six month follow-up.

**Conclusions:** VIT-TAY appears to be effective at teaching job interview skills and reducing job interview anxiety. Moreover, enhanced job interview skills were associated with accessing competitive jobs. Overall, youth enjoyed and adhered to VIT-TAY and teachers feasibly implemented the tool within special education Pre-ETS. Future research needs to validate these findings and evaluated enhanced job interview skills as a mechanism of employment in a fully-powered trial.

### **213.003 (Panel) Mixed-Methods Implementation Evaluation of School-Based Virtual Interview Training for Transition Age Autistic Youth**

**K. Sherwood<sup>1,2</sup>, M. J. Smith<sup>1</sup>, J. Johnson<sup>1</sup>, M. Harrington<sup>1</sup>, B. Ross<sup>1</sup>, S. Blajeski<sup>1</sup>, L. E. Smith DaWalt<sup>3</sup>, L. Bishop<sup>4</sup> and J. D. Smith<sup>5</sup>,**  
(1)School of Social Work, University of Michigan, Ann Arbor, MI, (2)Department of Psychology, University of Michigan, Ann Arbor, MI, (3)University of Wisconsin-Madison Waisman Center, Madison, WI, (4)University of Wisconsin - Madison, Madison, WI, (5)University of Utah, Provo, UT

---

**Background:** Although recent studies suggest that a large proportion of employed youth with autism are interviewing to get hired (Smith et al., in press), few practices to support this skill are being implemented in pre-employment transition services (Pre-ETS). Although technology-based interview interventions have recently demonstrated efficacy among autistic youth and adults, these interventions need to be more rigorously evaluated with the goal of implementing such tools at scale. As part of a recent randomized controlled trial (RCT) evaluating Virtual Interview Training for Transition Age Youth (VIT-TAY) effectiveness

among autistic youth, we conducted a mixed methods, multi-level evaluation to understand implementation of VIT-TAY across 5 schools.

**Objectives:** This study sought to evaluate implementation feasibility, acceptability, usability, and sustainability of VIT-TAY across five schools using teacher and student reports.

**Methods:** Schools (n=5) were recruited from Michigan and Ohio as part of the RCT. Teachers (n=21) were recruited from these schools as trainers, along with transition-age students with autism (n=71). The intervention was implemented over six to eight weeks to 48 students in the intervention group. Following the implementation of VIT-TAY, we used a mixed methods approach (via self-report surveys and semi-structured interviews) to evaluate the acceptability, usability, feasibility, and sustainability of VIT-TAY. Descriptive statistics characterize the acceptability, usability, and expected implementation feasibility of VIT-TAY. Meanwhile, we conducted a thematic network analysis (Attride-Stirling, 2001) of the qualitative data from the teacher semi-structured interviews and student acceptability and usability surveys, revealing a network of global themes, organizing themes, and basic themes.

**Results:** Teachers reported that VIT-TAY was highly acceptable (M=26.91, SD=2.17) and that VIT-TAY implementation would be sustainable (M=7.36, SD=2.01). Additionally, students reported VIT-TAY to be acceptable (M=23.32, SD=4.69) and usable (M=37.67, SD=6.51). Teachers mentioned introductory materials and in-depth training for teachers and students as important facilitators of implementation. Meanwhile, teachers identified scheduling VIT-TAY within their curriculum, space to implement VIT-TAY, and staff training as potential barriers to future implementation. Approximately 84% of teachers were confident they would be able to deliver VIT-TAY training with fidelity. Regarding implementation feasibility and sustainability, 95% of teachers reported that VIT-TAY would be easy for educators to deliver, while 64% of teachers reported their schools were “somewhat” to “very” well equipped to support continued delivery of VIT-TAY.

**Conclusions:** Student and teacher-reported acceptability and usability and teacher-reported feasibility collected in 5 schools revealed agreement that VIT-TAY was user-friendly, provided useful feedback, and allowed students an opportunity to practice their job interview skills independently. Implementation of evidence-based interventions in schools is a critical component of measuring their ecological validity. Previously identified challenges of implementation in schools include school organizational factors, scheduling constraints, level of implementation support, and training of school professionals, among other factors. The results of this evaluation align with this prior research. Despite these limitations, schools are a vital setting for interventions for transition-age youth with autism. Particularly during this time of a global pandemic, technology-based interventions such as VIT-TAY could play a crucial role in helping youth practice job interview skills somewhat independently.

**213.004 (Panel) Longitudinal Employment Outcomes for Young Adults with Autism: Follow up to a High School-Based RCT**  
*K. Hume<sup>1</sup>, B. Tomaszewski<sup>1</sup>, S. L. Odom<sup>2</sup>, J. R. Steinbrenner<sup>1</sup>, L. J. Hall<sup>3</sup>, L. E. Smith DaWalt<sup>4</sup> and B. Kraemer<sup>3</sup>, (1)Frank Porter Graham Child Development Institute, University of North Carolina at Chapel Hill, Chapel Hill, NC, (2)Frank Porter Graham Child Development Institute, University of North Carolina at Chapel Hill, San Diego, CA, (3)Special Education, San Diego State University, San Diego, CA, (4)University of Wisconsin-Madison Waisman Center, Madison, WI*

---

**Background:** Adolescents and young adults with autism spectrum disorders (ASD) have among the poorest post-school employment outcomes of any disability group. The Center on Secondary Education for Student with Autism (CSESA), was designed to address the needs of adolescents enrolled in public high school programs. CSESA investigators developed a comprehensive intervention model that focused on academics, independence and behavior, peer social interaction, and transition/families and implemented this program within an RCT in 60 high schools across 3 states (N=547 adolescents with ASD). The CSESA model had a significantly positive impact on the quality of high school instructional programs for students with ASD and on individual progress towards IEP goals, when compared to the Services as Usual control group. Given that a goal of high school is to prepare students for post-secondary life, including employment, the ultimate test of a model like CSESA will be the post-school employment outcomes,

**Objectives:** The purpose of this session is to provide follow up data on the employment outcomes for students involved in the CSESA study 1-4 years after exiting high school.

**Methods:** We will present employment findings using a mixed methods approach. Data are being collected at one time point for each parent and young adult through parent report, self-report, and includes both the Vocational Index and a follow up interview that addresses employment outcomes. Descriptive data from the described measures, demographic data, and qualitative data from individual interviews with parents and young adults will be presented, along with comparisons between young adults who received the CSESA intervention and those who were in the SAU group.

**Results:** Data collection is ongoing. We currently have data from 181 young adults and/or their parents and we anticipate having data from 250+ young adults at the time of INSAR 2021 when data collection concludes. Early descriptive analyses from the Vocational Index and parent and young adult interviews indicate that 86% have been engaged in any work or vocational experiences since leaving high school, and 60% of the sample have worked for pay without employment support. Almost 70% of the sample had completed job applications and 65% had interviewed for positions. Only 7% of the sample were engaged in work in a sheltered work environment, and 11% were employed with an adult day program. Detailed data about satisfaction with each employment activity, will be provided, along with links between high school experiences that were deemed helpful in post-high school employment preparedness.

**Conclusions:** This is a follow-up to the largest, most diverse randomized treatment study of adolescents with ASD to be conducted to date. The sample and their high school experiences are well characterized, which allows for one of the first examinations of the longer-term impact (employment status) of a high-school based intervention. Early data indicate higher rate of competitive employment than previous studies for this population (e.g. NLTS-2) and higher rates of job satisfaction and job match (e.g. working in an area of interest). Links to these outcomes and the CSESA intervention/sample characteristics will be discussed.

## ORAL SESSION — INTERVENTIONS - NON-PHARMACOLOGIC - SCHOOL-AGE, ADOLESCENT, ADULT

### Oral 317 - Behavioral Treatments for ASD

**317.001 (Oral)** Effects of Short-Term Low-Intensity Early Start Denver Model on Young Children with Autism Spectrum Disorder in Different Cognitive Ability Levels

**T. L. Lin<sup>1</sup>, C. H. Chiang<sup>2</sup>, S. Y. Ho<sup>3</sup>, H. C. Wu<sup>4</sup> and C. C. Wong<sup>3</sup>,** (1)Research Center for Education and Mind Sciences, National Tsing Hua University, Hsinchu City, Taiwan, (2)Department of Psychology, National Chengchi University, Taipei City, Taiwan, (3)Child Developmental Assessment & Intervention Center, Zhongxing Branch of Taipei City Hospital, Taipei City, Taiwan, (4)Department of Rehabilitation, Taipei Tzu Chi Hospital, Buddhist Tzu Chi Medical Foundation, New Taipei City, Taiwan

**Background:** Several early intervention studies for children with Autism Spectrum Disorder (ASD) have indicated that better pre-intervention cognitive function can predict more positive post-intervention outcomes. However, a limited number of studies have directly compared the intervention outcomes among children with ASD who are with different cognitive ability levels, and the results from these few studies are inconsistent.

**Objectives:** The Early Start Denver Model (ESDM) is one kind of naturalistic developmental behavioral intervention, which is the early intervention trend for young children with ASD in the past decade. This study aimed to compare the effects of 24-weeks low-intensity ESDM intervention among young children with ASD and severe to borderline intellectual disabilities.

**Methods:** A case control study was conducted on 42 children with ASD aged 25–46 months. Children receiving one-on-one ESDM intervention for 9 hours per week in the ESDM group,  $n = 21$ , mean age = 33.23 months, mean overall developmental quotients (DQ) = 55.42 (range = 36.65-77.59), were matched with children receiving community intervention in the control group,  $n = 21$ , mean age = 35.14 months, mean overall DQ = 58.43 (range = 37.82-76.95), in chronological age, overall DQ and sex. In each group, two subgroups were further divided based on pre-intervention overall DQ: lower cognitive level ( $DQ < 55$ ) and higher cognitive level ( $55 < DQ < 80$ ). Four outcome indications: cognitive abilities, language abilities, adaptive behaviors, and symptom severity were measured pre- and post-intervention respectively by the Mullen Scales of Early Learning (MSEL), Mandarin-Chinese Communicative Development Inventory (MCDI), Adaptive Behavior Assessment System (2nd Edition, ABAS-II), and Autism Diagnostic Observation Scales (ADOS).

**Results:** On the base of no difference in intervention hours per week among four subgroups, there were three main findings after 24-weeks intervention. First, in both ESDM and control groups, higher cognitive level children made significantly more progress in overall cognitive ability and language abilities (vocabulary production and mean length of utterances) than lower cognitive level children did. Second, both lower and higher cognitive level children in ESDM group showed significantly post-intervention improvements in nonverbal cognitive ability, verbal cognitive ability, overall cognitive ability and language abilities. However, in control group, only higher cognitive level children showed significantly improvements in verbal cognitive ability and language abilities, while the symptom severity in lower cognitive level children became even worse significantly. Third, for both lower and higher cognitive level children, the post-intervention gains in ESDM group were significantly greater than control group in nonverbal and overall cognitive abilities. Moreover, lower cognitive level children in ESDM group had significantly greater improvements in verbal cognitive ability, vocabulary production and symptom severity than control group.

**Conclusions:** Our results suggest that young children with ASD who have pre-intervention higher cognitive function can benefit more from early intervention no matter the intervention styles. However, short-term low-intensity ESDM may positively impact the cognitive development for both lower and higher cognitive level young children with ASD; furthermore, lower cognitive level children may benefit more in symptom reduction and language development from ESDM intervention than the community intervention.

**317.002 (Oral)** Caregiver Ndbi Strategy Use and Language Input Supports Structurally-Specific Lexical Diversity in Minimally-Verbal Children with Autism

*E. Clark-Whitney, C. B. Klein, A. Lemelman, J. Winter and S. H. Kim, Psychiatry, Center for Autism and the Developing Brain, White Plains, NY*

---

**Background:** Structurally-specific lexical diversity (i.e., variety of unique subject-verb combinations [SVs]) is a robust measure of language development (Hadley & Walsh, 2014). Caregiver input, specifically use of varied SVs through Toy Talk (e.g., giving toys a name and talking about the toy; “The tower fell!”), supports children’s development of lexical diversity. Intervention can increase caregiver Toy Talk (Hadley et al., 2017), producing growth in child language. Given that caregiver-mediated naturalistic developmental behavioral interventions (NDBI) are a core evidence-based treatment known to improve social communication in children with ASD (Schreibman et al., 2015), the current study investigated whether improving caregivers’ NDBI strategy use enhances the impact of caregiver Toy Talk on children’s lexical diversity.

**Objectives:** To examine the moderating role of changes in caregiver NDBI strategy use over time on the impact of caregiver Toy Talk on lexical diversity in minimally-verbal children with ASD.

**Methods:** Participants were drawn from past studies of various caregiver-mediated NDBIs for minimally-verbal children with ASD (50 dyads). Using Systematic Analysis of Language Transcripts software (SALT; Miller & Iglesias, 2012), reliable coders transcribed caregiver and child speech from two interaction videos recorded an average of 5.88 months apart, and coded child unique SVs and caregiver use of Toy Talk. Caregiver NDBI strategies during the same recorded interactions were rated using the Measure of NDBI Strategy Implementation-Caregiver Change (MONSI-CC; Vibert et al., 2020). All coders were blind to video timepoint. Given that many children were not yet using SV combinations (70%-T1; 48%-T2), a zero-inflated negative binomial mixed model was utilized. Main effects of timepoint, MONSI-CC changes (T2-T1), and baseline toy talk were assessed while controlling for age, gender, non-verbal IQ and autism symptom severity. Baseline Toy Talk was used because Toy Talk was not specifically targeted in the current intervention and therefore was not expected to change over time, whereas NDBI strategies were the main target of the caregiver-mediated NDBI. The moderating role of caregiver NDBI strategy changes on the impact of Toy Talk on child SVs was assessed by examining the interaction effect between MONSI-CC and Toy Talk.

**Results:** Greater baseline Toy Talk significantly predicted children’s use of more diverse SVs over time (Table 1). A significant interaction of baseline Toy Talk and NDBI strategy change was also found. The interaction indicated that the relation between baseline Toy Talk and child lexical diversity was stronger when caregivers had greater improvement in NDBI strategy use (Figure 1). Timepoint, age, non-verbal IQ, and gender were also significant.

**Conclusions:** The current study showed that SV combinations in children with ASD increase over time, and that caregiver language input, specifically Toy Talk, and improvement in caregivers’ NDBI strategy use both play a key role in children’s lexical diversity development. Notably, the impact of Toy Talk on child SVs was stronger for dyads with greater improvement in NDBI strategy use. As such, the current results demonstrate that improving caregivers’ overall NDBI strategy use can provide a strong foundation for more specific intervention models that target language acquisition in children with ASD.

**317.003 (Oral)** National Clearinghouse on Autism Evidence & Practice: Examining the Participation of Individuals with ASD across Racial and Ethnic Groups in High Quality Intervention Studies

*N. S. McIntyre<sup>1</sup>, J. R. Steinbrenner<sup>2</sup>, L. F. Rentschler<sup>3</sup>, K. Hume<sup>2</sup> and S. L. Odom<sup>4</sup>, (1)School of Communication Sciences and Disorders, University of Central Florida, Orlando, FL, (2)Frank Porter Graham Child Development Institute, University of North Carolina at Chapel Hill, Chapel Hill, NC, (3)School of Education, University of North Carolina - Chapel Hill, Chapel Hill, NC, (4)Frank Porter Graham Child Development Institute, University of North Carolina at Chapel Hill, San Diego, CA*

---

Background:

The National Professional Development Center on ASD (NPDC) completed a review of literature published between 1990-2011 and identified 27 evidence-based practices (EBPs) for individuals with ASD from birth through age 22 (Wong et al., 2014). A team of researchers analyzed data reported about race, ethnicity, and nationality (REN) from articles included in the previous

review (West et al., 2016) and found that few articles reported information on REN (17.9%). The National Clearinghouse on Autism Evidence & Practice (NCAEP) recently completed an update to the previous review of literature to include articles published from 2012-2017 (Steinbrenner et al., in review). In addition to determining any new and emerging EBPs, it is also important to assess the reporting and inclusion of individuals with ASD across different REN, and to determine whether there are changes in reporting and inclusion over time.

#### Objectives:

The objectives of this session are to (1) determine the proportion of studies that reported data on REN between 1990-2017, (2) examine the proportions of studies and participants within studies based on REN characteristics, and (3) examine trends in reporting over time.

#### Methods:

The NCAEP team used the same search strategy as the 1990-2011 systematic review, using key search terms related to autism (e.g., ASD, Asperger, autistic) and intervention (e.g., education, treatment, strategies) with participants aged birth through 22 years (Steinbrenner et al., in review; Wong et al., 2014). The research team followed a rigorous systematic review process including initial search, screening, full-text reviews, quality reviews, and data extraction. During data extraction, the research team used the procedures of West et al. (2016) to extract REN data from all high-quality studies (1990-2017). Research assistants were trained to reliability; 29.7% of those articles were coded for reliability ( $r=0.80-1.0$ ).

#### Results:

Of the 1001 articles coded for participant information, 244 of 1001 articles report information on REN (24.3%), with reporting rates of 20% in SCD studies and 42.9% in group studies. The total proportion of participants who were reported as white was 63% (SCD = 52.8%; group = 64.3%). Table 1 has additional information about reporting rates of individual REN categories by study type and inclusion of participants from various REN categories by study type. Over 27 years, REN reporting has risen from a low of 0% of studies in 1991 to a high of 37% of studies in 2014, with variability from year to year but a clear trend of increased reporting of REN. In the current review period (2012-2017), group studies fluctuated between 35-71% reporting while SCD studies remained more stable at 20-32% reporting.

#### Conclusions:

Overall, there has been an increase in the reporting of REN data between the 1990-2017, with group studies accounting for more of the increase since 2012. However, the proportion of articles reporting REN data is still strikingly low. While group studies are more likely to report REN, they are also less likely to include non-white participants. Moving forward, to ensure generalizability of intervention results, it is important to recruit and report on more diverse samples.

#### **317.004 (Oral) Critical Time Points When Accessing Diagnosis and Early Treatment Among Children with ASD: A Comparison between Immigrant Children and Children of US-Born Parents**

**Y. Xu<sup>1</sup>, L. A. Bilaver<sup>2</sup>, K. Acharya<sup>3</sup>, R. L. Dodds<sup>4</sup> and S. Magaña<sup>5</sup>**, (1)Disability and Human Development, University of Illinois at Chicago, Chicago, IL, (2)Pediatrics, Northwestern University, Chicago, IL, (3)University of Illinois at Chicago, Chicago, IL, (4)Special Education & Counseling, California State University Los Angeles, Los Angeles, CA, (5)Steve Hicks School of Social Work, University of Texas at Austin, Austin, TX

**Background:** Numerous researches have shown that early detection, treatment and services are crucial in advancing outcomes and reducing symptoms. Center for Disease Control's report on ASD was based on 11 states, which does not include the State of Illinois (Biao et al., 2018). As one of the top immigrants receiving states, Illinois hosts approximately 1.8 million immigrants (US Census Bureau, 2017). While emerging literature has documented the barriers faced by immigrant families of children with ASD when accessing diagnosis and treatment, little is known about the timeline or critical time points of their experiences as they seek diagnosis and therapy.

**Objectives:** Therefore, this paper sought to compare the timeline of diagnosis and early therapy access between immigrant families and US born families of children with ASD in the state of Illinois.

**Methods:** 213 parents of children with ASD who were under the age of 18 at the time of data collection completed a survey on diagnosis and service access. Among them, 21 were immigrant parents. Using immigrant vs US-born as the grouping variable,

we conducted independent sample t-test comparing children's age (in months) when parents first noticed something different in their child, when parents first talked to a doctor or clinician about their concerns, when child gets their diagnosis, and when child first received any kinds of therapy services. We also examined the subsample of 74 children with ASD who requires substantial support using the same aforementioned grouping variable and test variables.

**Results:** Comparing immigrant children with ASD's timeline for diagnosis and treatment with children with ASD of US born parents, we found no significant differences in all critical time points except marginally significant differences in children's first access to any kinds of therapy ( $t=1.148, p=0.058$ ), children of US born parents' first access to therapy earlier ( $M=37.7, SD=28.1$ ) than children of immigrant parents ( $M=46.1, SD=41.6$ ). When only children who requires substantial support were included ( $N=74$ ), children of immigrant parents ( $N=12$ ) were significantly older for all four critical time points compared to children of US born parents ( $N=52$ ). Specifically, immigrant parents first notice something different when their children were significantly older ( $M=29.3, SD=25.4$ ) compared to the other group ( $M=16.5, SD=10.3, t=1.63, p=0.000$ ). Immigrant parents also brought up their concern to a doctor or clinician when their children were much older ( $M=34.6, SD=33.9$ ) compared to US born counterparts ( $M=18.9, SD=13.2, t=1.58, p=0.001$ ). Children of immigrant families also had later diagnosis ( $M=52.9, SD=42$ ) compared to children of US born parents ( $M=40.1, SD=22, t=0.944, p=0.005$ ). Similarly, children of immigrant families also accessed any kinds of therapy at an older age ( $M=54.2, SD=51.3$ ) compared to children of US born parents ( $M=26.7, SD=15, t=1.84, p=0.000$ ).

**Conclusions:** It is alarming that children of immigrant families who requires substantial support had a significantly delayed timeline at every single critical time points as their parents seek diagnosis and therapy. Our findings underscore the importance of targeting immigrant families of children with ASD with more profound functional limitations to facilitate early detection and access to treatment.

## POSTER SESSION — INTERVENTIONS - NON-PHARMACOLOGIC - SCHOOL-AGE, ADOLESCENT, ADULT

### Poster 427 - Interventions - Non-pharmacologic - School-Age, Adolescent, Adult Posters

**427.001** (Poster) A 12-Week Cognitive Behavioral Therapy (CBT) Protocol Specifically Modified for ASD  
**K. Birtwell<sup>1</sup>, C. Ravichandran<sup>2</sup>, H. Saro<sup>3</sup>, J. E. Mullett<sup>1</sup>, C. J. McDougle<sup>1</sup> and L. Nowinski<sup>1</sup>,** (1)Lurie Center for Autism, Massachusetts General Hospital, Lexington, MA, (2)McLean Hospital, Belmont, MA, (3)Massachusetts General Hospital - Lurie Center, Lexington, MA, Lexington, MA

Background: Restricted, repetitive behaviors or interests make up one of the two core symptom areas of autism spectrum disorder (ASD). While up to 95% of children with ASD have restricted interests, our ability to target these interests and their related behaviors in treatment has been limited (Boyd, McDonough, & Bodfish, 2012; Poustka et al., 2014; Turner-Brown, Lam, Holzclaw, Dichter & Bodfish, 2011). In practice, it is not uncommon for clinicians to use the child's restricted interests to bolster motivation, rapport, and to ultimately enhance treatment outcomes (e.g., Kryzak & Jones, 2015).

Clinical trials to date have revealed promising results using cognitive behavioral therapy (CBT) based treatment approaches to decrease symptoms of anxiety in children with high-functioning ASD (for reviews see Sukhodolsky, Bloch, Panza, & Reichow, 2013; Ung, Selles, Small, & Storch, 2015). However, few studies to date have attempted to target the underlying emotion regulation processes in autism which, in turn, may be used to treat a wider array of co-occurring symptoms (Scarpa & Reyes, 2011).

Objectives: The purpose of the present pilot study is to begin to explore the feasibility, satisfaction and efficacy of a 12-week cognitive behavioral therapy (CBT) protocol specifically modified for ASD in that it targets both social communication and emotion regulation skills using restricted interests as a primarily vehicle for therapy.

Methods: Participants included 34 children (6-11 years old) with ASD recruited from a multidisciplinary autism clinic randomized to either the treatment group ( $n=18$ ; CBT) or a waitlist control group ( $n=16$ ; WLC). Participants in the CBT group received 12 weeks of therapy. Pre- and post-assessment measures for both groups included the Social Skills Improvement System (SSiS; Gresham & Elliot, 2008) and a parent-completed home data collection measure of the Frequency and Duration of Emotion Dysregulation Episodes. Feasibility measures included homework compliance and attrition data. Finally, a satisfaction questionnaire was completed by parents in the CBT group at the conclusion of the 12-week therapy.

Results: Data collection was just recently completed. Entry and analysis are in process at this time. Results will include sample descriptive data and primary outcomes (SSiS and Frequency and Duration of Emotion Dysregulation Episodes) will be compared

between groups using univariate and multivariate linear and Poisson regression models as appropriate. We will also compute standardized effect sizes and unstandardized effect sizes with 95% confidence intervals to examine the magnitude of these differences. Qualitative data and quantitative descriptive statistics, including confidence intervals, will be utilized to indicate the extent to which the treatment was found to be feasible and satisfactory by families.

**Conclusions:** These findings will significantly contribute to our limited knowledge of restricted interests and will directly inform subsequent intervention design and implementation. Results will contribute to a small but emerging body of evidence that a new approach to addressing restricted interests in therapeutic interventions for individuals with ASD may be warranted. We will also explore the extent to which a CBT-based individual treatment approach may be used to target emotion regulation and social skills in children with ASD.

---

**Background:** Anxiety is common in autistic adults and significantly limits opportunities and quality of life. Evidence-based psychological therapies currently offered by mental health services often fail to meet the needs of autistic adults. This is reflected in sub-optimal treatment efficacy and widely reported dissatisfaction among autistic people. The development of appropriate treatments for anxiety is a key priority of the autism community. Current clinical guidance recommends that psychological therapies should be personalised to best meet autistic people's needs.

**Objectives:** To investigate the feasibility and acceptability of delivering a novel individualised, modular psychological treatment for anxiety experienced by autistic adults (Personalised Anxiety Treatment for adults, PAT-A<sup>a</sup>).

**Methods:** PAT-A<sup>a</sup> is a pilot randomised controlled trial. Thirty-four autistic adults (aged 18-62, 65% male) with clinically diagnosed anxiety were recruited via UK clinical services and randomised to either PAT-A<sup>a</sup> or current clinical services). All participants received a personalised assessment and formulation of anxiety using the newly developed Personalised Anxiety Interview Supplement – Autism (PAIS-A<sup>a</sup>) prior to randomisation. Both groups initially received two sessions of emotional literacy. PAT-A<sup>a</sup> group participants then received a 12-session intervention including a bespoke, modular, needs-based treatment approach utilising one or more of the following modules: Mindfulness, Coping with Uncertainty in Everyday Situations (CUES), social anxiety, and graded exposure. Control group participants received usual NHS care through their local clinical team. Data regarding anxiety experiences, mental health and related constructs were collected at baseline and at 3 and 12 months following intervention. The main outcomes were recruitment, retention, treatment adherence, completion of outcome measures and acceptability (assessed with a semi-structured interview at 3-months).

**Results:** 31 participants have completed three-month follow-up (87.1% participated in interviews; 82.4% of control group, 92.9% of PAT-A<sup>a</sup> group). The remaining 3 participants will complete follow-ups in January 2021. All participants reported the duration of baseline and follow-up assessments was acceptable. Several commented that the personalised assessment made them feel listened to and understood more than during previous healthcare appointments. 88.2% (n=15) of participants in the PAT-A<sup>a</sup> group, completed all treatment sessions, and reported positive experiences, including that the treatment met their needs more than previous experiences of psychological interventions. Some participants reported they would have preferred more sessions. 82.4% (n= 14) in the control arm attended the psychoeducational sessions; some control arm participants expressed disappointment regarding the outcome of randomisation. However, many commented they were pleased to have a role in the development of a novel anxiety treatment that may have future utility. Preliminary evidence indicates that the PAT-A<sup>a</sup> intervention was associated with improved anxiety outcomes for many participants.

**Conclusions:** The PAT-A intervention is acceptable and feasible to deliver. Autistic adults were willing to be recruited, randomised, and provide follow-up outcome data. Participants reported satisfaction with both the research methods and intervention. Participants valued this personalised approach to mental healthcare. The PAT-A trial methods and materials are suitable for use in an RCT to investigate clinical and cost effectiveness.

**427.003 (Poster)** A Systematic Review and Meta-Analysis of Group Interventions Targeting the Social Competence of Autistic Adolescents

*B. Afsharnejad<sup>1</sup>, M. H. Black<sup>2</sup>, M. Falkmer<sup>3</sup>, S. Bolte<sup>4</sup> and S. J. Girdler<sup>2</sup>, (1)Autism Research Team, Telethon Kids Institute, Perth, Australia, (2)School of Occupational Therapy, Social Work and Speech Pathology, Curtin University, Perth, WA, Australia, (3)Curtin University, Bentley, Australia, (4)Center of Neurodevelopmental Disorders (KIND), Centre for Psychiatry Research;*

**Background:** Social skills group training (SSGT) interventions are amongst the most frequently employed interventions aiming to increase the social competencies of autistic youth.

**Objectives:** Given the variability of available SSGT and the measurement frameworks employed in their evaluation, a systematic review and meta-analysis was undertaken to explore efficacy of SSGT delivered to autistic adolescents via Randomised Controlled Trials (RCT), identifying their intervention targets and providing a summary of the measurement frameworks employed and their outcomes.

**Methods:** The methodological quality and theoretical fidelity of studies was assessed, with a random effect meta-analysis conducted to summarise the efficacy of SSGT in improving autistic symptomology, behavioural/emotional challenges, adaptive functioning, and social outcomes.

**Results:** Database searches identified seventeen studies meeting the study's inclusion criteria. Despite good methodological quality, most studies had a medium to small intervention fidelity, limited by standardised and replicable approaches to training and opportunities to practice taught social skills in everyday contexts. There was a medium overall positive aggregated effect of SSGT on adolescent outcomes ( $g=0.76$ ,  $p<0.001$ ), with significant effects observed only for improving adolescent social outcomes ( $g=1.69$ ,  $p=0.004$ ).

**Conclusions:** While findings suggest that SSGT successfully improve the social competence of autistic youth, the variability in outcome measures and limitations relating to study design and intervention fidelity, limit understanding of the generalisability of these improvements to everyday contexts.

**427.004 (Poster) ADHD Symptoms Moderate the Effect of an Executive Function Skills Training in Children with ASD**  
**S. R. Edmunds<sup>1,2</sup>, G. MacNaughton<sup>3</sup> and S. Faja<sup>1,2</sup>,** (1)Boston Children's Hospital, Boston, MA, (2)Psychiatry, Harvard School of Medicine, Boston, MA, (3)Boston Children's Hospital: Labs of Cognitive Neuroscience, Boston, MA

---

**Background:** Executive functioning (EF) is impaired in children with ASD. Compared to traditional behavioral therapy, preliminary work suggests that computer game-based EF training may be more engaging, individualized, and more easily implemented for children with autism spectrum disorder (ASD). Yet, children with ASD present with heterogeneity both within core ASD symptoms and with respect to psychiatric comorbidity. Co-occurring attention deficit/hyperactivity disorder (ADHD) and anxiety symptoms may affect children's ability to benefit from intervention.

**Objectives:** We explored whether co-occurring ADHD or anxiety symptoms moderate the efficacy of an EF training for children with ASD. We asked, "for whom is training effective?"

**Methods:** We conducted a secondary data analysis of a randomized control trial (RCT) of EF training with 70 7- to 11-year-old children with ASD. All children had FSIQ $\geq$ 80, which did not differ by group ( $M=105$ ). Children in the training group received 1 1-hour training session per week for up to 10 weeks. They played 4 computer games designed to improve working memory, set shifting, and inhibition, and received metacognition and emotion regulation coaching from a supervised trainer. Both the training and the waitlist control group received baseline ADOS, ADI-R, and cognitive testing (WASI-II). All parents filled out the CBCL, BRIEF, and SRS at baseline, measuring mental health, EF, and social communication challenges, respectively. CBCL Anxiety Problems and ADHD Problems scale T-scores were moderators of interest. All participants completed an EF battery pre- and post-training. Stop Signal Reaction Time (SSRT) during the Change Task, a lab-based measure of inhibition and set-shifting, was the outcome of interest. All analyses controlled for baseline SSRT.

**Results:** ADHD and anxiety symptoms were both prevalent in our sample (20 and 30% fell above clinical cutoff, respectively), and did not differ by group,  $t(67)=-1.60$ ,  $p=.12$ , and  $t(67)=-0.42$ ,  $p=.67$ . We found significant moderation by ADHD symptoms such that EF training improved reaction time to a stop signal (SSRT) to execute a nondominant response, compared to waitlist, only for children with clinically significant ADHD symptoms,  $\beta= -.33$ ,  $p= .047$ , Johnson Neyman region of significance = T-score of 70.69 or higher (Figure 1, Table 1). Children with elevated ADHD symptoms who received EF training had post-training reaction time latencies that were 98ms faster, on average, than children with elevated ADHD symptoms in the waitlist group. These children also differed from the overall sample in that they had greater challenges with at-home EF (BRIEF GEC,  $t(67)=-3.91$ ,  $p<.001$ ) and ASD symptoms (SRS-2 Total,  $t(66)=-2.69$ ,  $p<.01$ ). Anxiety symptoms did not moderate the effectiveness of training for children with ASD.

Conclusions: EF training may only improve behavioral outcomes for children with ASD and comorbid ADHD symptoms. Exploratory analyses suggest additional potential characteristics of children for whom this training may be effective, including higher nonverbal cognitive ability. Future trials with larger samples should continue to explore moderators of treatment efficacy. Also, future work should examine whether brain-based outcomes function as measures of target engagement for generalized, behavioral EF training outcomes.

**427.005 (Poster)** Acceptability of an Online Executive Function Coaching Program for Parents in a Community Sample  
**E. Wilkinson, A. Milgramm, M. Rinaldi and K. V. Christodulu, Center for Autism and Related Disabilities, Albany, NY**

---

Background: Executive function (EF) deficits are common among children with ASD and impact functioning across multiple domains (Pellicano, 2012). *e-Unstuck and On Target* is an online course for parents that uses evidence-based strategies to improve flexibility, planning, and organization in children (Kenworthy et al., 2014, 2018). The current study seeks to apply a hybrid delivery model to the *e-Unstuck and On Target* course by combining the online training with professional coaching. This approach has shown success with other intervention programs but has not been studied in this context (Taylor et al., 2008).

Objectives: (1) To pilot an EF online training and coaching program and compare outcomes to training only and control groups in a community sample. (2) To examine the acceptability of the coaching program in a larger sample.

Methods:

**STUDY 1:** Thirty-six parents of school-age children with ASD were randomly assigned to a training, training + coaching, or waitlist control group. Parents in both the training and training + coaching groups completed *e-Unstuck and On Target* (Kenworthy et al., 2014, 2018) over nine weeks. Parents in the training + coaching group also attended weekly 30-minute clinician-led telehealth coaching sessions in small groups. The *Parenting Stress Index, Fourth Edition Short Form (PSI-4-SF)*; Abidin, 2012), *Behavior Rating Inventory of Executive Function – Second Edition (BRIEF-2)*; Gioia et al., 2015), and an EF knowledge test were completed pre- and post-intervention. Parents also reported on their completion of course modules, worksheets, and use of strategies.

**STUDY 2:** Sixty-one parents completed *e-Unstuck and On Target* and weekly coaching sessions. Parents completed the same measures described in Study 1.

Results:

**STUDY 1:** A repeated-measures ANOVA was conducted with time (pre, post) as the within-group variable and group (training, training + coaching, wait-list) as the between-group variable. Results revealed no significant main effects or interactions ( $p$ 's  $>.05$ ). Analysis of only the intervention groups (training, training + coaching) revealed a main effect of time for Knowledge ( $F(1,14)=8.95, p=.02$ ) but no main effect of group or group x time interaction. A chi-square test of independence revealed that the coaching group was more likely to have completed all or most modules, worksheets, and strategies ( $\chi^2(2, N=17)=7.97, p=.03$ ).

**STUDY 2:** Paired samples t-tests revealed significant changes in *PSI-4-SF* Total Stress ( $p=.04$ ) *BRIEF-2* Global Executive Composite ( $p=.01$ ) and knowledge ( $p<.001$ ) (see table 1). Over 95% of parents reported overall program satisfaction. Parents reported feeling more competent using accommodations (70%), feelings identification strategies (67%), “can’t not won’t” thinking (83%), and flexibility words (80%). Average attendance was 7.15 sessions.

Conclusions: Results indicate that coaching sessions may increase engagement with the *e-Unstuck and On Target* course. While there were no outcome differences between groups, the study was limited in power. In a larger sample, we found improvements in parent stress, child EF, and knowledge. High satisfaction ratings combined with high levels of retention and attendance, indicate that the program was acceptable and feasible for families. Overall, these findings support the utility of *e-Unstuck and On Target* and associated coaching sessions in a community sample.

**427.006 (Poster)** Adaptation and Preliminary Evaluation of an Intervention Targeting Intolerance of Uncertainty in Autistic Children with Co-Occurring Intellectual Disability (CUES:ID)  
**J. Maxwell<sup>1</sup>, V. Grahame<sup>2</sup> and J. Rodgers<sup>3</sup>, (1)Newcastle University, Newcastle upon Tyne, United Kingdom, (2)Cumbria, Northumberland, Tyne and Wear NHS Foundation Trust, Newcastle upon Tyne, United Kingdom, (3)Population Health Sciences Institute, Newcastle University, Newcastle upon Tyne, United Kingdom**

---

**Background:** Anxiety is common in autistic children with co-occurring Intellectual Disability (ID) and can cause distress for the child and family. There is a well-supported association between anxiety and the transdiagnostic construct of Intolerance of Uncertainty (IU) in autistic individuals without ID, and interventions targeting IU as a means of managing anxiety have been developed in this group. However, a high proportion of autistic children also have an intellectual disability, and interventions targeting IU have not yet been explored in this population.

**Objectives:** To adapt and undertake preliminary evaluation of the acceptability and feasibility of “Coping with Uncertainty in Everyday Situations” (CUES), a parent mediated group intervention for IU, for delivery to parents of autistic children with co-occurring ID.

**Methods:** Adaptations were made to the CUES intervention materials, informed by consultations with parents and professionals. The adapted intervention was subsequently implemented with parents of five boys with confirmed diagnoses of ASD and an intellectual disability, aged 8 years – 11 years, 9 months. Parents attended eight, two-hour, weekly group sessions. Measures of child IU, child anxiety, child Restricted and Repetitive Behaviours (RRBs), parent IU and parent well-being were taken at baseline, 3 months, 6 months and 12 months following the intervention. Semi-structured satisfaction feedback interviews were carried out 1-2 weeks following intervention.

**Results:** Feedback from parents suggested that they found the intervention to be helpful and appropriate, feasible and acceptable for their children, and that they had learned new strategies and gained confidence. Preliminary analyses of individual change using the Reliable Change Index (RCI) indicated reliable improvement at 6- and 12- month follow up for all participants on the primary measure of parent reported child IU, and all but one on the secondary IU measure. At 6- and 12- months post-intervention, two participants reliably improved on parent reported child anxiety. No reliable improvement was detected for child RRBs or either of the parent measures.

**Conclusions:** Findings from this preliminary study, which was of an adapted version of CUES made suitable for delivery to parents of autistic children with intellectual disability, indicate that the adapted programme is acceptable and feasible to deliver. Initial evidence of effectiveness based on reliable change indices indicates that this programme is promising in relation to a reduction in child IU and anxiety up to twelve months post intervention. Further work to determine the effectiveness of the programme in a fully powered trial is now needed.

**427.007 (Poster) Co-Designing a Primary Care Health Check for Autistic Adults**

**H. Taylor<sup>a</sup>, D. Mason<sup>b</sup>, B. Ingham<sup>c</sup>, T. Finch<sup>d</sup>, C. Wilson<sup>e</sup>, C. Scarlett<sup>f</sup>, S. Moss<sup>g</sup>, C. Buckley<sup>h</sup>, C. Seiboth<sup>i</sup>, R. F. Lees<sup>j</sup> and J. R. Parr<sup>k</sup>,** (1)Population Health Sciences Institute, Newcastle University, Newcastle upon Tyne, United Kingdom, (2)Social, Genetic and Developmental Psychiatry Centre, Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, United Kingdom, (3)Northumberland Tyne and Wear NHS Foundation Trust, Newcastle upon Tyne, United Kingdom, (4)Nursing, Midwifery and Health, Faculty of Health and Life Sciences, Northumbria University, Newcastle upon Tyne, United Kingdom, (5)North Tyneside CCG, Newcastle-upon-Tyne, United Kingdom, (6)Northumberland CCG, Newcastle upon Tyne, United Kingdom, (7)The Royal College of General Practitioners UK, London, United Kingdom of Great Britain and Northern Ireland, (8)Newcastle University, Newcastle upon Tyne, United Kingdom

---

**Background:** Autistic people experience elevated rates of physical and mental health conditions, causing premature morbidity and mortality. They also experience greater barriers to accessing healthcare than the general population (Mason et al., 2019). These barriers likely contribute to problems identifying and treating the health conditions of autistic people. One possible way to improve health outcomes is through primary care health checks for autistic adults.

**Objectives:** 1. To gauge autistic people’s views about a primary care health check for autistic adults. 2. To co-design a primary care health check for autistic adults that addresses their expressed needs and preferences.

**Methods:** We undertook: 1. A survey of 461 autistic adults (N=444), and relatives of autistic people who lacked capacity to consent for themselves (N=17), to capture quantitative and free text views about adjustments needed to health care (Brice et al., 2021 in press), and a NHS primary care health check for autistic adults; people were contacted through the Adult Autism Spectrum Cohort-UK, a UK cohort study of autistic adults. 2. Primary care health check co-design was undertaken through seven consultation groups with autistic people (N=25), two of whom had a learning disability, non-autistic adults with a learning disability (N=10), relatives and carers (N=7), and five interviews with NHS primary care staff (N=5). The consultation groups and interviews focused on participant’s previous experiences of health checks and healthcare appointments, the reasonable adjustments needed, the health check itself, the use and content of a pre-health check questionnaire and the potential future implementation of the health check in the NHS.

Results: Most autistic people (83.4%) thought a primary care health check was needed for all adults on the autism spectrum. There was less agreement about the details of how and what a health check might offer (e.g. the frequency of the health check and how long it should last). Most people rated the need for staff training about autism (89.9%) and delivering health checks (79.8%) very important and this view was reflected in the consultation groups and interviews. There was agreement in the consultation groups and interviews between all stakeholders on a number of key issues including: that the health check should be biopsychosocial covering physical and mental health, and emotional and social wellbeing; that collecting information by online or paper questionnaire beforehand was beneficial; that offering reasonable adjustments was key to increasing healthcare access and that these should be tailored to an individual's needs; and that changes were needed in the communication methods of GP practices with greater use of text, email and online methods.

Conclusions: Our findings clearly demonstrate autistic people are positive about a primary care health check and provide insight into what might enhance, or reduce, autistic people's views on acceptability. Through our co-design process, we have developed a primary care health check for autistic people in collaboration with key stakeholders. The effectiveness of the health check at identifying and meeting new health needs and conditions, and its cost effectiveness will now be investigated in a randomised controlled trial.

**427.008 (Poster)** Cognitive-Behavioral Family Therapy As Psychoeducation for Adolescents with Highfunctioning Autism Spectrum Disorders: Aware and Care for My Autistic Traits (ACAT) Program for a Pragmatic Multisite Randomized Controlled Trial

**F. Oshima<sup>1</sup>, N. Takahashi<sup>2</sup>, H. Kuwabara<sup>3</sup>, W. Mandy<sup>4</sup>, A. Tsuchiyagaito<sup>5</sup>, E. Shimizu<sup>1</sup>, M. Hongo<sup>6</sup>, A. Nakagawa<sup>1</sup>, Y. Hirano<sup>1</sup>, C. Suto<sup>1</sup>, M. Seto<sup>1</sup>, N. Sato<sup>2</sup>, S. Nakamura<sup>2</sup>, J. Masuya<sup>7</sup> and S. Guan<sup>8</sup>, (1)Research Center for Child Mental Development Chiba University, Chiba, Japan, (2)Fukushima University, Fukushima, Japan, (3)University of Tokyo Hospital, Tokyo, Japan, (4)University College London, London, United Kingdom of Great Britain and Northern Ireland, (5)Laureate Instituto for Brain Research, Tulsa, OK, USA, Tarusa, OK, (6)Chiba University, Chiba, Japan, (7)Department of Psychiatry, Tokyo Medical University Ibaraki Medical Center, Ibaraki, Japan, Ibaraki, Japan, (8)Waseda University, Tokyo, Japan**

Background: An autism spectrum disorder (ASD) diagnosis aims to obtain exceptional support for the disorder, though this does not guarantee practical support. We developed a psychoeducational program using cognitive behavioral therapy (CBT), "Aware and Care for My Autistic Traits" (ACAT) for Japanese adolescents with high functioning ASD and their parents.

Objectives: This study aimed to examine the efficacy of the newly developed psychoeducation program for parents and individuals with HF-ASD, or ACAT, by comparing with the treatment-as-usual (TAU) group. Multisite, randomized, controlled trials have conducted to investigate and assess the relative efficacy of COMB compared to TAU. The primary outcome was the increased awareness of ASD measured by the child/youth version of the Autism Knowledge Quiz (AKQ).

Methods: This multisite study was a randomized controlled trial. In total, twenty participants were assigned to the ACAT group and twenty-three to the treatment-as-usual (TAU) group. The ACAT group received a weekly 100-min session for six weeks and one follow-up session. They answered behavioral and clinical measures at pre-, post-intervention, and follow up. The primary outcome was the Autism Knowledge Questionnaire for young people (AKQ-C). Secondary outcome measures included the Strengths and Difficulties Questionnaire (SDQ), the Vineland Adaptive Behavior Scales second edition (Vineland-2), and the Depression Self-Rating Scale for Children assessments (DSRS-C) for children, and the Parenting Resilience Elements Questionnaire (PREQ), the General Health Questionnaire 12 (GHQ-12), Autism Knowledge Questionnaire for parents (AKQ-P) for parents/guardians. The longitudinal change of each outcome was tested by linear mixed effect model analysis (LME). The LME model included fixed effects of time, i.e., pre, post, and follow up, group (COMB and TAU), time by group interaction, age, sex, and the random effect of the subject on intercept.

Results: In this study, the ACAT group had a significantly higher score of self-understanding of ASD (AKQ-C) ( $F(1,41)=15.50, p<.01$ ) and had a lower score of maladaptation (SDQ) ( $F(1,41)=12.23, p<.001$ ) than the TAU group. Additionally, the ACAT group showed an increase in the adaptive behavior (Vineland-2) ( $F(1,41)=6.01, p<.05$ ) compared to the TAU group. For parents/guardians, parent's resiliency significantly increased (PREQ) ( $F(1,41)=4.90, p<.05$ ), and their general health significantly increased (GHQ) ( $F(1,41)=7.38, p=.01$ ) compared to the TAU group. There were no significant differences between two groups for the DSRS-C ( $F(1,41)=7.15, p=n.s.$ ) and AKQ-P ( $F(1,41)=13.32, p=n.s.$ ).

Conclusions: The results showed that the ACAT is an effective treatment for adolescent with HF-ASD by increasing the awareness of ASD. Although a randomized placebo-controlled trial will be needed in future studies, this study may help establish a new evidence-based psychoeducational treatment strategy for child/adolescent patients with HF-ASD and their parents/guardians. The ACAT may afford more treatment options as an after-diagnosis service and improve the dissemination of psychoeducation and CBT for HF-ASD.

Trial registration: UMIN Register 000029851.

**427.009 (Poster)** Combined Data from the Application of the Computerized Progressive Attentional Training (CPAT) across Brazil and the UK Shows Generalized Improvements in Academic Performance and Fluid Intelligence

**M. Muller Spaniol<sup>1</sup>**, C. Mevorach<sup>2</sup>, L. Shalev<sup>3</sup>, M. C. Teixeira<sup>4</sup>, R. Lowenthal<sup>5</sup>, J. Magalhães<sup>6</sup> and C. S. Paula<sup>1</sup>, (1)Developmental Disorders Program, Mackenzie Presbyterian University, Sao Paulo, Brazil, (2)School of Psychology, University of Birmingham, Birmingham, United Kingdom, (3)School of Education and the Sagol School of Neuroscience, Tel-Aviv University, Tel-Aviv, Israel, (4)Developmental Disorder Program, Universidade Presbiteriana Mackenzie, São Paulo, Brazil, (5)Santa Casa Hospital, Sao Paulo, Brazil, (6)Mackenzie Presbyterian University, São Paulo, Brazil

---

**Background:** Although not a core symptom in Autism Spectrum Disorder (ASD), attention atypicalities are found in ASD since early infancy. Attention processes are important for successful interaction with the environment and are also linked to academic performance. Two separate recent pilot studies (Spaniol et al., 2018; under review) tested the efficacy of an attention training program: the Computerized Progressive Attentional Training (CPAT), in small groups of children with ASD compared to active control groups. While both studies reported significant academic and cognitive improvements in the experimental group, there are substantial differences in the settings and populations tested, one study conducted in Brazil and the other in the UK.

**Objectives:** Results from both previous pilot applications of the CPAT, which followed a similar protocol and methodologies, were combined to test: 1. Whether the potential efficacy of CPAT depended on the site it was delivered; and 2. If the efficacy obtained in each study separately also holds when the two cohorts are combined. Thus, we ask whether attention training in the context of the Brazilian public health system yields similar outcomes compared to attention training in the context of the school system in the UK.

**Methods:** The studies were conducted at the Autism Unit CAISM linked to the public mental health system from São Paulo - Brazil, and in special and mainstream primary schools in Birmingham – UK. Combined, 41 participants from 6 - 14 years old took part in the study (26 from Brazil and 15 from the UK). Participants were randomly assigned to either the CPAT (n=22) or active control group (n=19). They were assessed before and immediately after the intervention/active control period (2 sessions per week over 8 weeks). Cognitive and academic performance were assessed using the tests: Raven's Coloured Progressive Matrices for fluid intelligence, and academic tests in math, reading and writing - School performance test in Brazil, and tests from primary schools database in the UK. Assessment was done blindly with the participants unaware of the group affiliation.

**Results:** Performance in the cognitive test and writing differed between the sites. However, regardless of site differences the CPAT intervention yielded similar significant improvements across the three academic assessments and the cognitive measure, compared to the active control group. Thus, while no group differences were recorded before the intervention, the CPAT group showed superior performance in math, reading and writing tests, as well as in the cognitive/intelligence measure following the intervention compared to the active control group and this effect was not mediated by site.

**Conclusions:** Our results show that attention training with CPAT is an effective approach to aid school performance and cognition in ASD and provide support to the pilot studies reported in Spaniol et al. (2018, under review). Furthermore, it points to the generality of the approach, which leads to similar outcomes across different cultural or social contexts. Future large scale studies are necessary to further support the efficacy of cognitive training like the CPAT in promoting academic performance among children with ASD.

**427.010 (Poster)** Coping with Uncertainty in Everyday Situations: Adolescent (CUES-Ad)

**R. Herrema<sup>1,2</sup>**, S. Brice<sup>3</sup>, M. Freeston<sup>4</sup> and J. Rodgers<sup>3</sup>, (1)Newcastle University, Newcastle, United Kingdom, (2)Cumbria, Northumberland, Tyne and Wear NHS Foundation Trust, Newcastle, United Kingdom, (3)Population Health Sciences Institute, Newcastle University, Newcastle upon Tyne, United Kingdom, (4)School of Psychology, Newcastle University, Newcastle upon Tyne, United Kingdom

---

### **Background:**

Anxiety disorders are very common in autistic individuals (Kerns et al., 2016; Wise et al., 2018) and the presentation of anxiety symptoms may be more complex for autistic people (Kerns et al., 2016; White et al., 2009). Intolerance of uncertainty (IU) is a transdiagnostic factor underlying many anxiety disorders and research suggests that autistic people experience high levels of IU (Boulter et al., 2014; Wigham et al., 2015).

Trembath et al. (2012) report young autistic adults describe their experiences of anxiety in ways which indicate that 'unexpected or sudden change' and 'uncertainty/making decisions' are potential triggers for increasing anxiety. In addition, Ozsvadjian et al. (2012) found change or disruption in routine were specific triggers for autistic individuals' anxiety.

Coping with Uncertainty in Everyday Situations (CUES) is a specific CBT based intervention targeting intolerance of uncertainty which has been developed for autistic children (Rodgers et al., 2017) and autistic adults (Rodgers et al., 2018). CUES has shown promise. A single case experimental design study of CUES Adult (CUES-A, Rodgers et al., 2018) reported significant increases in participants' confidence in uncertain situations, reduction in anxiety and a significant reduction in restricted, repetitive behaviours (RRB).

### **Objectives:**

This study aimed to adapt CUES-A and provide preliminary evaluation of the feasibility and acceptability of an intervention designed to address IU in autistic adolescents (CUES-Ad).

### **Methods:**

A single case experimental design (SCED) was used to test the Coping with Uncertainty in Everyday Situations – Adolescent (CUES-Ad) intervention. Four autistic adolescents seeking treatment for anxiety (14-18 years) were recruited from Child and Adolescent Mental Health Services and attended an initial session, eight sessions of Cognitive Behavioural Therapy (CBT) targeting IU and a follow-up session.

Participants completed daily diaries throughout the intervention, which were used to measure the degree and process of therapeutic change in relation to participant selected target uncertain situations. Secondary standardised outcome measures assessed self-reported and parent reported IU, anxiety, worry and RRB at three time points; initial meeting, first therapy session and four weeks' follow-up and reliable and clinically significant change was assessed.

### **Results:**

Results showed some significant improvements. Aggregated change scores from participant selected target uncertain situations (TAU-U) indicated significant reductions in worry, and significant increases in confidence during uncertain situations and management of uncertainty. Anxiety in anticipation of uncertainty did not significantly decrease. Feedback from follow-up interviews was positive and 100% of participants stated they would recommend CUES-Ad to other autistic adolescents.

### **Conclusions:**

CUES-Ad demonstrates promise as a feasible and acceptable intervention to reduce IU in autistic adolescents, in line with our main objective. The SCED findings indicate some individual variability, with evidence of improvements related to confidence in and management of uncertain situations and reduction in worry.

Future evaluation on CUES-Ad should include delivery via a range of therapists, among adolescents with a wider age range, co-morbidities, or intellectual disability and ensure further support for identifying and targeting the most personally salient target situation.

**427.011** (Poster) Discrete Electroocortical Predictors of Anxiety during Follow-up Period after Social Skills Intervention for Youth with Autism Spectrum Disorder

**R. G. McDonald<sup>1</sup>**, N. Yacoub<sup>1</sup>, S. Khawar<sup>1</sup>, M. D. Lerner<sup>2</sup> and E. Kang<sup>1</sup>, (1)Department of Psychology, Montclair State University, Montclair, NJ, (2)Department of Psychology, Stony Brook University, Stony Brook, NY

---

Background: Approximately 40% of youth with autism spectrum disorder (ASD) experience an anxiety disorder in their lifetime (Van Steensel et al., 2014; 2017). Recent innovations in outcome assessment for evidence-based interventions have focused on using neural and other obligatory constructs, which provide unique insight into physiological states of anxiety (De Los Reyes & Aldao, 2015; Kang et al., 2019). Two electroencephalogram (EEG) metrics, error-related negativity (ERN) and right-dominant frontal brain activity (rRFA), have been linked to anxiety symptoms (Meyer, et al., 2016; Reznik et al., 2018). Social Skills Interventions (SSI) have shown some indirect improvements in anxiety symptoms for some individuals with ASD (White et al., 2010; Wood et al., 2015). Previous research demonstrated predictive utility of these metrics in anxiety-related treatment response, wherein larger baseline ERN predicted improvements in anxiety and larger rRFA predicted worsening of self-reported anxiety

over the course of SSI (Kang et al., 2019). However, it is unclear if the effects are maintained after the SSI, when youth no longer receive clinical support and *in vivo* reinforcement. The use of neural metrics can allow for identification of those who would benefit from close monitoring and additional support after SSIs in order to prevent negative outcomes.

**Objectives:** We sought to test the utility of ERN and rRFA in predicting changes in anxiety symptomatology during the follow-up period of SSI.

**Methods:** Fifty-four youth with ASD (72% male,  $M_{age}=12.3$  [at baseline],  $SD_{age}=2.9$ ;  $IQ\geq 70$ ) participated in a 1.5 hr/week SSI for 10 weeks and was followed up after 10 weeks post-SSI. Youth and their parents completed a measure of anxiety (MASC-2; March, 2013). ERN was measured during the flanker task and rRFA was measured during resting state. ANCOVA-of-change models controlling for immediate endpoint anxiety scores and intervention condition were conducted to examine if baseline rRFA and ERN amplitudes independently predicted changes in anxiety from endpoint to follow-up.

**Results:** Larger ERN amplitude predicted increased self-reported total anxiety, performance anxiety, social anxiety, and obsessive-compulsive symptoms (all  $Bs < -.19$ ,  $ps < .04$ ) at follow up (Table 1). Larger rRFA (indicating more relative right than left frontal brain activity) predicted increased self-reported tense/restlessness symptoms ( $B = .3$ ,  $p = .002$ ), and increased parent-reported humiliation/rejection, physical, and tense/restlessness symptoms (all  $Bs > .2$ ,  $ps < .04$ ) at follow-up.

**Conclusions:** Results indicate that ERN and rRFA can predict participants whose anxiety symptoms may improve or worsen post-SSI and provide important clinical implications for using ERN and rRFA as a predictive measure of changes in anxiety not only over the course of SSI but also after the SSI is completed. Surprisingly, whereas larger ERN predicted improvements in anxiety over the course of SSI (Kang et al., 2019), it predicted worsening of symptoms during the follow-up period. Larger rRFA consistently predicted a worsening of anxiety symptoms during and after follow-up. These results highlight the importance of identifying individuals (e.g., those with larger ERN or rRFA) who would benefit from being further monitored and tailoring support during and after the SSI, and provides avenue for future research on the utility of neural indices of anxiety in ASD.

**427.012 (Poster)** Does a Novel Group Parenting Intervention Reduce Emotional and Behavioural Problems in Young Autistic Children? Results from the Autism Spectrum Treatment and Resilience (ASTAR) Pilot Randomised Controlled Trial (RCT) **M. Palmer<sup>1</sup>, T. Charman<sup>2</sup>, D. Stringer<sup>3</sup>, V. Boadu<sup>7</sup>, B. Beresford<sup>7</sup>, M. Knapp<sup>6</sup>, V. Slonims<sup>7</sup>, A. Pickles<sup>4</sup>, S. Scott<sup>1</sup> and E. Simonoff<sup>1</sup>**, (1)King's College London, Institute of Psychiatry, Psychology and Neuroscience, London, United Kingdom, (2)Department of Psychology, Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, United Kingdom, (3)South London and Maudsley NHS Foundation Trust, London, United Kingdom, (4)Aston University, Birmingham, United Kingdom, (5)University of York, York, United Kingdom, (6)PSSRU, LSE, London, United Kingdom, (7)Guy's & St Thomas' NHS Foundation Trust (Evelina Children's Hospital), London, United Kingdom

**Background:** Most young children with autism display co-occurring emotional and behaviour problems (EBPs) that tend to persist over time and impact the lives of the child and their families. There is some evidence that behavioural parenting interventions are effective for reducing parent-reported EBPs in autistic children (Postorino et al., 2017; Tarver et al., 2019). Most RCTs have evaluated individual parenting interventions, even though groups are more scalable and provide a support network. Previous trials also vary in the intervention focus on externalising behaviours versus anxiety. Furthermore, conclusions about the effectiveness of these approaches cannot be drawn as many RCTs do not employ an active control condition or use blinded outcome measures. Cost-effectiveness is also unknown.

**Objectives:** The ASTAR pilot RCT tested the feasibility and pilot efficacy and cost-effectiveness of the ASTAR group parenting intervention against an active control.

**Methods:** As part of the Improving Autism Mental Health (IAMHealth) research programme ([www.iamhealthkcl.net](http://www.iamhealthkcl.net)), 62 parents/carers (91.9% mothers) and their 4–8 year old autistic children participated in the ASTAR pilot RCT (ISRCTN91411078). Participants were randomised 1:1 to the ASTAR group behavioural parenting intervention (Predictive Parenting) or an attention control consisting of psychoeducation parent groups (Psychoeducation). Predictive Parenting provided strategies to manage both externalising behaviours and anxiety and ways to promote parental self-care and reduce stress, whereas Psychoeducation focused on providing knowledge about autism and social support. Both involved 12 weekly groups with 6 to 8 parents/carers. Content was adapted based on child verbal ability (minimally verbal versus verbal). The primary outcome was a blinded observational measure of the rate of child behaviours that challenge displayed during a structured parent- and researcher-child interaction, called the Observation Schedule for Children with Autism – Anxiety, Behaviour and Parenting. Secondary outcomes included observed child compliance, facilitative parenting and non-facilitative parenting behaviours, parent- and teacher-reported child EBPs and parental self-report of parenting practices, stress, self-efficacy and wellbeing (see Table 1 for

baseline sample characteristics). Adverse events, costs and service utilisation were recorded. Feasibility was assessed through recruitment, retention, fidelity and satisfaction. Bivariate linear mixed models were used to obtain estimates of pilot efficacy on the intent-to-treat sample. Pilot cost-effectiveness compared costs and outcomes from three perspectives.

**Results:** Feasibility was demonstrated, with retention, completion of measures, fidelity of implementation and parental satisfaction high for both interventions. There was no group difference in primary outcome but differences in relative observed rates of child compliance, facilitative parenting and parent-defined target symptom change favouring Predictive Parenting were found (see Figure 1 for forest plot of effect sizes). Groups did not differ on other measures but there was a general pattern of favouring toward Predictive Parenting. Predictive Parenting was more expensive than Psychoeducation and had low probability of being more cost-effective.

**Conclusions:** This pilot RCT will add to the growing literature on the effects of behavioural parenting interventions for co-occurring EBPs in autism. It highlights the need for blinded objective measures along with the use of active control intervention conditions to be included in future trials.

**427.013 (Poster)** Double-Blind Placebo-Controlled Trial for the Effects of Propranolol on Anxiety in Autism Spectrum Disorder

---

#### Background:

Autism spectrum disorder (ASD) is often characterized by co-occurring anxiety. Propranolol is widely utilized for the treatment of performance anxiety and public speaking anxiety. We conducted a double-blinded placebo-controlled trial of the beta-adrenergic antagonist propranolol in ASD.

#### Objectives:

Due to its effects on anxiety in a variety of settings, we wished to determine the effects of propranolol on anxiety in ASD.

#### Methods:

ASD patients (age 7-24, mean =14, standard deviation =5 years) were enrolled, and randomized to a 12 week course of propranolol, titrated to 100mg daily in divided doses over 12-weeks (body weight adjusted in children), or placebo. Clinicians and staff were blinded as to treatment group assignment. Anxiety assessments were performed at baseline, at 6-weeks and at 12-weeks. Seventy two participants (53 males, 20 females) completed the 12-week visit. A primary outcome was the Clinician Global Clinical Impression-Improvement (CGI-I) ratings at six and twelve weeks. In this initial analysis, CGI-I scales are reported for anxiety. Ordinal logistic regression was used to analyze CGI-I ratings with respect to anxiety, as well as other outcomes. Separate analyses were performed for self/family ratings and clinician ratings with the relevant baseline CGI severity score used as a covariate. Results are presented as odds ratios (OR), with the control group as the reference category. The odds ratios reflect the change in odds of improvement in the propranolol group relative to the placebo group.

#### Results:

The clinician rating of improvement on anxiety was statistically significant at the 12 week time point ( $p = 0.045$ ) with an OR = 2.58 (95% CI = 1.02, 6.52). The patient or family rating of improvement on anxiety was consistent with physician's, OR = 2.47 (95% CI = .91, 6.71),  $p = 0.077$ . While not statistically significant at the  $p=0.05$  level, self/family and clinician ratings of overall ASD severity were positive at all time points, suggesting a beneficial effect of propranolol. Further analyses will attempt to identify sub-groups of responders and to examine other outcome measures in this trial.

## Conclusions:

Initial analysis examining CGI-I supports a significant beneficial effect of propranolol on anxiety. To our knowledge, this is the first such finding targeting anxiety in ASD. It will be critical to identify best responders, which might occur in individuals with the greatest degree of arousal as measured by psychophysiological markers of stress, and to examine subsequent outcome measures in this manner, as well as examining brain imaging markers that might predict best response. These findings can then guide a larger multicenter trial for the effects of propranolol while also incorporating these markers to confirm predictors of best response.

**427.014 (Poster)** Emotion Dysregulation in ASD: An Examination of an RCT of CBT for Anxiety in Public Schools  
**A. T. Meyer<sup>1</sup>, N. Reyes<sup>2</sup>, K. Pickard<sup>3</sup>, R. E. Boles<sup>4</sup>, E. T. Engstrom<sup>5</sup>, L. Hayutin<sup>6</sup>, C. Middleton<sup>1</sup>, T. Tanda<sup>6</sup>, A. Blakeley-Smith<sup>2</sup> and J. Reaven<sup>2</sup>, (1)JFK Partners, University of Colorado School of Medicine, Aurora, CO, (2)JFK Partners, University of Colorado Anschutz Medical Campus, Aurora, CO, (3)Emory University School of Medicine, Atlanta, GA, (4)University of Colorado Anschutz Medical Campus, Aurora, CO, (5)UC Davis MIND Institute, Sacramento, CA, (6)Developmental Pediatrics, Children's Hospital Colorado, Aurora, CO**

---

**Background:** Youth with ASD often experience difficulties with emotion dysregulation which may underlie and/or exacerbate anxiety (Mazefsky et al., 2013). Although limited, previous research indicates that emotion dysregulation is associated with emotional and behavior difficulties (Rieffer et al, 2011), and is correlated with social competence (Reyes et al., 2020). Recent findings suggest improvements in emotion regulation after youth with ASD participated in CBT (Weiss et al., 2018; Scarpa et al., 2011). These studies were conducted in clinic settings, and there is little examination of whether emotion dysregulation improves after participating in CBT for anxiety in schools.

**Objectives:** The purpose of this study is to (1) examine the relationship between emotion dysregulation and social competence (i.e., peer problems, prosocial behavior) prior to participation in school-based CBT for anxiety and (2) evaluate the impact of the intervention on symptoms of emotion dysregulation and externalizing behaviors (i.e., hyperactivity, conduct) based on parent and child self-report.

**Methods:** This study included 81 youth (M age=10.71 years, SD=1.76 years) with ASD (i.e., SRS-2 T-Scores  $\geq 60$ ; Constantino & Gruber, 2012) and clinically significant symptoms of anxiety who participated in a randomized control trial of a school-based CBT program for anxiety (Facing Your Fears-School Based Program, FYF-SB). Thirty-nine youth were randomized to FYF-SB and 42 youth were randomized to Usual Care (UC). Parents completed The Emotion Dysregulation Inventory (EDI, Mazefsky et al. 2018) and the Strengths and Difficulties Questionnaire (SDQ; Goodman et al. 2000) at pre/post FYF-SB and UC. Youth also completed the SDQ Self-Report at both time points.

**Results:** A significant correlation was found between EDI and SDQ social competence and hyperactivity subscales at baseline. Specifically, increased scores on the SDQ peer problems subscale were associated with higher scores on the EDI reactivity subscale ( $r=.30, p=.005$ ) and EDI dysphoria ( $r=.46, p<.001$ ). Also, decreased scores on the SDQ prosocial behavior subscale were inversely associated with increased scores on the EDI reactivity subscale ( $r=-.20, p=.048$ ) and EDI dysphoria ( $r=-.22, p=.03$ ). To evaluate treatment effects, repeated measures ANOVA were conducted with the treatment and waitlist control groups. A significant time by group interaction was found on parent report for the EDI reactivity subscale,  $F(1,64)=4.32, p=.04$  and a marginally significant interaction effect for the SDQ Hyperactivity subscale,  $F(1,65)=2.92, p=.09$ . These significant interaction effects suggest that youth that received FYF-SB exhibited significant improvements in emotion regulation and hyperactivity compared with the UC group. There was a significant group by time interaction for the SDQ emotional problems subscale on both parent ( $F(1,65)=4.07, p=.05$ ) and child report ( $F(1,67)=8.03, p=.006$ ). There was no significant group by time interaction for the EDI dysphoria subscale, or on the SDQ Conduct subscale (all  $p>.1$ ).

**Conclusions:** A strong association was found between emotion dysregulation and social competence, although causality between constructs is unclear. Nonetheless, results also indicated that CBT for anxiety has the potential to impact a broader constellation of symptoms than anxiety alone (i.e., emotion dysregulation and hyperactivity). Limitations and future directions will be discussed.

**427.015 (Poster)** Examining Gender Differences in Improvement in Loneliness and Social Responsiveness Following PEERS® for Young Adults

**L. C. Savage<sup>1</sup>, C. Moody<sup>2</sup>, E. Denluck<sup>1</sup> and E. A. Laugeson<sup>2</sup>,** (1)UCLA Department of Psychiatry, PEERS lab: UCLA PEERS Clinic, Los Angeles, CA, (2)UCLA Semel Institute for Neuroscience and Human Behavior, Los Angeles, CA

---

**Background:** Previous research has shown that young adults with autism spectrum disorder (ASD) experience elevated difficulty with socialization as compared to typically developing young adults (Ee et al., 2019). Among individuals with ASD, females demonstrate increased functional social behavior as compared to males (Halladay et al., 2015). Given these observed differences in social performance, it is essential to better understand baseline gender differences and to confirm that social skill interventions produce similar gains for males and females. Previous research has shown that the UCLA Program for the Education and Enrichment of Relational Skills (PEERS®; Laugeson, 2017), a caregiver-assisted social skills intervention, is equally efficacious in improving social skills knowledge, social engagement, and social responsiveness in males and females with ASD (McVey et al., 2017); however, the extent to which loneliness and specific aspects of social responsiveness differ across genders following treatment has yet to be extensively explored.

**Objectives:** This study examines gender differences in loneliness and various facets of social responsiveness in young adults with ASD as a result of the PEERS® for Young Adults intervention. We hypothesized that male and female young adults with ASD would show equivalent baseline levels of reported loneliness and social responsiveness, as well as equivalent improvements across these domains following treatment.

**Methods:** Participants included 170 young adults (76.5% male,  $M_{age}=22.25$  years,  $SD=3.78$ ) who completed the UCLA PEERS® for Young Adults program (Laugeson et al. 2015). Participants presented with a previous diagnosis of ASD or heightened ASD symptomatology as demonstrated by a Total Score  $\geq 60$  on the Social Responsiveness Scale, Second Edition (SRS-2; Constantino & Gruber, 2012). Self-reported loneliness was assessed using the Social and Emotional Loneliness Scale for Adults (SELSA; DiTommaso & Spinner, 1993). Distinct elements of social responsiveness were examined using the five subscales of the SRS-2 (i.e. Social Communication, Social Cognition, Social Motivation, Social Awareness, and Restricted Interests and Repetitive Behavior). ANOVAs and MANOVAs were conducted to compare baseline and change scores following treatment by gender on the SELSA and SRS-2.

**Results:** An ANOVA revealed no significant gender differences in baseline loneliness on the SELSA total score,  $F(1,154)=0.003$ ,  $p>.05$ . Similarly, a MANOVA examining SRS-2 subscale scores showed no significant differences in baseline social responsiveness by gender,  $F(5,152)=1.71$ ,  $p>.05$ . Although loneliness significantly improved following the PEERS® intervention,  $t(107)=5.18$ ,  $p<.001$ , there were no significant differences in improvements in loneliness by gender,  $F(1,106)=0.003$ ,  $p>.05$ . Likewise, overall social responsiveness on the SRS-2 improved following treatment,  $t(110)=9.30$ ,  $p<.001$ , however no significant gender differences were observed across the five subscales,  $F(5,105)=1.25$ ,  $p>.05$ .

**Conclusions:** Results suggest that there are no significant gender differences in loneliness or social responsiveness at baseline or following treatment, confirming our hypotheses. These findings demonstrate that both males and females with ASD benefit similarly from an evidence-based social skills intervention. Future research might investigate differences in maintenance of treatment gains between genders. Additionally, exploration of the efficacy of PEERS® for gender nonconforming and/or transgender individuals would be an important extension of the current research.

**427.016 (Poster)** Examining the Association between Self-Concept and Treatment Outcomes in Social Skills and Social Engagement for Adolescents with Autism Spectrum Disorder Following the UCLA PEERS Intervention

**J. Rodstein, C. Moody, Y. S. Lograsso, K. Sung, H. R. Goodman and E. A. Laugeson,** UCLA Semel Institute for Neuroscience and Human Behavior, Los Angeles, CA

---

**Background:** Youth with autism spectrum disorder (ASD) are known to often struggle with poor self-concept, beliefs held about oneself, as well as impaired social functioning (McCauley et al. 2019). While research suggests that self-concept among adolescents with ASD may predict outcomes in academic performance (McCauley et al. 2018), little is known about the impact of self-concept on social skills training. The UCLA Program for the Education and Enrichment of Relational Skills (PEERS®) is a 16-week evidence-based, caregiver-assisted social skills intervention for adolescents with ASD and other developmental disabilities (Laugeson 2012). Previous research has demonstrated the efficacy of the PEERS intervention in improving social skills and self-concept following treatment (Laugeson 2012). Although research may suggest enhanced self-concept as a result of social skills training, self-concept has yet to be evaluated as a predictor of social skills intervention gains.

**Objectives:** The objective of this study was to evaluate the relationship between baseline self-concept and social skills improvement for adolescents with ASD following the UCLA PEERS intervention. The researchers hypothesized that adolescents

with ASD who endorse more favorable self-concept prior to intervention will exhibit greater improvement in social skills following treatment.

**Methods:** Participants included 99 adolescents between the ages of 10 to 18 ( $M=13.94$ ,  $SD=1.94$ ) presenting for social skills treatment through the UCLA PEERS Clinic. All participants had clinically elevated ASD symptoms at baseline as evidenced by a total score  $\geq 60$  on the Social Responsiveness Scale-Second Edition (SRS-2; Constantino & Gruber 2012). To measure self-concept prior to intervention, adolescents completed the Piers-Harris Children's Self Concept Scale-Second Edition (PH-2; Piers et al. 2002). In order to assess improvement in social engagement and social skills following intervention, adolescents and caregivers completed the Quality of Socialization Questionnaire (QSQ; Frankel and Mintz 2008) and caregivers completed the Social Skills Improvement System (SSIS; Elliott & Gresham 2008) pre- and post-intervention.

**Results:** Pearson correlation coefficients were calculated to assess the relationship between baseline adolescent self-reported PH-2 total scores and change in scores from pre- to post-treatment on the adolescent self-reported QSQ, caregiver-reported QSQ, and caregiver-reported SSIS-Social Skills subscale. Results did not reveal a statistically significant correlation between baseline self-concept and social skills improvement in any case ( $r=.014$ ,  $p=.888$ ;  $r=.076$ ,  $p=.457$ ; and  $r=.128$ ,  $p=.207$  respectively).

**Conclusions:** Findings did not support the original hypothesis that there would be a positive correlation between baseline self-concept and social skills gains following the PEERS intervention for adolescents with ASD. The lack of a statistically significant correlation between these factors suggests that the PEERS intervention may be successful in improving social skills among adolescents with ASD regardless of baseline self-concept. Future studies might investigate the potential relationship between social skills improvements in PEERS and other areas of self-concept such as those measured on the PH-2 subscales (Physical Appearance and Attributes, Freedom from Anxiety, Intellectual and School Status, Behavioral Adjustment, Happiness and Satisfaction, and Popularity) in order to identify whether specific aspects of baseline self-concept may play a role in social skills improvement for adolescents on the autism spectrum.

**427.017 (Poster)** Experiences of Young Adults with Autism Spectrum Disorder with Employment Readiness Skills Training: A Qualitative Analysis  
**C. Okyere**, *Department of Counseling, Educational Psychology and Special Education, Michigan State University, East Lansing, MI*

---

**Background:** Although employment is fundamental to the well-being of individuals with autism spectrum disorder (ASD), less than 20% of young adults with ASD are employed resulting in their limited employment-readiness. While employment-related intervention studies exist that focus on soft and hard skills development across employment preparation, obtainment and retention, there is no intervention that focuses on both soft and hard skill development specifically applicable to employment preparation, obtainment and retention for individuals with ASD. Employment Preparation and Application Skills Support (EPASS) is an employment readiness training program designed to improve the employment-readiness of young adults with ASD. Specifically, EPASS focuses on teaching skills important for obtaining and maintaining employment, including: searching for a job, conducting informational interviews, personal branding, applying for a job, developing a resume and cover letter, pre-employment screenings, developing job interview skills, practicing mock interviews, learning disability law and accommodations, and maintaining a job. The 12-session EPASS intervention was delivered during spring semesters at a community center conference room to three cohorts of eligible participants over the course of three years.

**Objectives:** The purpose of this study was to understand the experiences of transition-aged youth with employment readiness pre and post participation in the three-year pilot EPASS intervention. We explored participants experiences to assess the impact of the pilot EPASS intervention on their employment readiness

**Methods:** Following approval from the university's Institutional Review Board, convenience sampling was used to recruit transition-aged youth with ASD (17-25 years of age) from a university disability resource center and a local school district. A qualitative descriptive design (Sandelowski 2010) was employed with 25 transition-aged youth with ASD and data were collected using semi-structured interviews. The data were analyzed to identify themes as they emerged

**Results:** Using Braun and Clark's (2006) thematic analysis, five major themes were identified: (a) Self-Efficacy Pre EPASS-Intervention; (b) Self Efficacy Post the EPASS Intervention; (c) Expectation Outcomes; (d) Personal Goals Post the EPASS Intervention; and (e) Recommendations for the EPASS Intervention. Overall, transition-aged youth with ASD reported significant improvement in both soft and hard skills for employment readiness post-intervention. Participants also provided recommendations that might further advance the impact of the EPASS intervention.

Conclusions: Employment-related interventions such as EPASS is significant to the employment achievements of transition-aged youth with ASD. Future intervention studies could focus on applying experiential learning strategies and video-based instruction to address additional work related and training gaps for transition-aged youth with ASD (e.g., managing personal expenses; conflict management in the workplace; securing volunteer, internships and actual job opportunities). In addition, developing instruments that measure work-related social function, job readiness and performance-based skills could assist professionals in making placement decisions relating to participation in EPASS or other employment related interventions. Finally, encouraging families and caregivers to support the employment and training needs and programs for transition-aged youth is significant to their optimal quality of life.

**427.018** (Poster) Exploring Outcomes of the PEERS Intervention for Adolescents with Autism Spectrum Disorder  
**K. A. Willar<sup>1</sup>, S. Bruce<sup>2</sup> and G. W. Gengoux<sup>1</sup>,** (1)Psychiatry and Behavioral Sciences, Stanford University School of Medicine, Stanford, CA, (2)PGSP-Stanford Psy.D. Consortium, Palo Alto, CA

---

Background: Many individuals with autism present with problematic emotional regulation as well as elevated negative emotions (Samson, Hardan, Podell, Phillips & Gross, 2015). The ability to control one's emotions in social situations is vital, as this behavior can greatly alter the course of a friendship. Therefore, emotion regulation skills that promote positive mental health functioning are equally crucial, in addition to social skills, for optimal social functioning. While it has been well established that PEERS is an effective treatment protocol to address the social skill challenges (Laugeson et al., 2009), other novel aspects of participants' mental health functioning and emotion regulation warrant further exploration and understanding.

Objectives: This study aims to investigate collateral improvements in mental health and emotion regulation relating to the PEERS intervention for adolescents with autism. Additionally, this study aims to analyze participants' satisfaction within the current treatment protocol.

Methods: Adolescents with high functioning autism and their parents were randomized to either the PEERS group (PEERS) or the waitlist control group (WL). For more information on the PEERS intervention, please see previous published studies. Participants completed outcome measures relating to mental health, emotion regulation and treatment satisfaction. Data were collected at both pre- and post-treatment. Repeated measures ANOVAs for analyzing group differences were conducted. Please note that the current study is ongoing and these are preliminary results ( $N = 17$ ; 10 PEERS & 7 WL). The average age of participants was 14.5 years old.

Results: Significant improvements in social anxiety (SAS-A) ( $F = 4.5, p = .05$ ) were observed in the PEERS group over time. Significant improvements in general anxiety (SCARED) ( $F = 4.5, p = .05$ ) were observed in both the PEERS and WL groups over time. No other significant group differences emerged in any of the measures (ERICA, Kidcope, CNCEQ & The Flexibility Scale). Satisfaction forms were collected after the PEERS program. When asked about things that need improvement relating to the program, multiple parents commented inquired about further support relating to anxiety management (e.g. "My child was hard to motivate within PEERS due to her anxiety" and "Tips on how to help my child's individual, emotional struggles were needed").

Conclusions: The results suggest that while adolescents' perceptions of their anxiety levels decreased over time, other mental health and emotion regulation measures remained unaffected by time and/or engagement in the treatment program. Additionally, parental requests to bolster anxiety management training in order to augment social skill development were prominent. While many treatments for autism remain siloed, leading to excessive financial and time expenditures for families, the possibility of providing a treatment that targets two, highly interdependent areas of deficit rather than one may allow for greater efficiency and clinical utility. This study is the first to investigate collateral mental health and emotion regulation improvements associated with PEERS, thereby laying the foundation for future modifications and enhanced clinical effectiveness of the PEERS intervention.

**427.020** (Poster) Feasibility and Attendance in an 8-Week Physical Exercise Program in Underserved Children with ASD  
**J. G. Gehricke<sup>1</sup>, L. Lowery<sup>2</sup>, S. D. D. Alejo<sup>3</sup>, M. N. Dawson<sup>4</sup>, J. Chan<sup>5</sup>, R. A. Parker<sup>6</sup>, A. R. Archibald<sup>6</sup>, H. Benavidez<sup>6</sup>, T. Saini<sup>6</sup>, K. Kuhlthau<sup>7</sup>, Y. Trujillo<sup>6</sup>, O. Grigaux<sup>8</sup>, M. Nguyen<sup>6</sup>, S. A. Cadondon<sup>6</sup>, M. G. Baconawa<sup>6</sup>, S. L. Ferretti<sup>6</sup>, K. R. Bellesheim<sup>7</sup> and M. Sweeney<sup>8</sup>,** (1)The Center for Autism & Neurodevelopmental Disorders, University of California, Irvine, Santa Ana, CA, (2)Thompson Center for Autism and Neurodevelopmental Disorders, University of Missouri, Columbia, MO, (3)Pediatrics, University of California - Irvine, Santa Ana, CA, (4)Massachusetts General Hospital, Boston, MA, (5)Biostatistics, Massachusetts General Hospital and Harvard Medical School, Boston, MA, (6)UC Irvine, Irvine, CA, (7)University of Michigan, Ann Arbor, MI, (8)Thompson Center for Autism and Neurodevelopmental Disorders, University of Missouri, Missouri, MO

---

**Background:** Physical exercise is well-established for its health promoting as well as stress reducing effects and may be an effective intervention for children with Autism Spectrum Disorder (ASD). Physical exercise rates are lower in children with autism compared to peers from the general population. However, little is known about the feasibility of physical exercise in

children with ASD and practical implications for low-income families who experience greater difficulty with access to intervention.

**Objectives:** The objective of this study was to explore the feasibility of a structured 8-week physical exercise intervention for low income families as part of a larger Randomized Clinical Trial (RCT) on fitness and anxiety improvements.

**Methods:** One hundred forty-eight children with ASD, ages 6 – 12 years old from low-income families with a primary focus on Latino and rural populations were recruited at two sites and assigned to an exercise intervention group (N = 76) or a sedentary LEGO/Minecraft control group (N = 72). The physical exercise program was offered 3 times per week and incorporated key guidelines from the Centers for Disease Control (CDC) including aerobic, muscle strengthening, and bone strengthening activities.

**Results:** The average age of participants was 9 years  $\pm$  2 years. The majority of participants were male (84% in the physical exercise and 83% in the control group) and Latino (58% in the physical exercise and 69% in the control group). The average BMI was  $22.0 \pm 6.1$  in the physical exercise group and  $22.7 \pm 6.9$ . The average attendance rate (proportion of sessions attended of the 24 scheduled) was similar between the physical exercise and control group (i.e.,  $50\% \pm 25\%$ -pts versus  $55\% \pm 21\%$ -pts). However, the completion rate was 70% (53/76) in the physical exercise group compared to 89% (64/72) in the control group ( $p = .005$ ). No differences were found in the participant characteristics between the physical exercise and control group.

**Conclusions:** Although the completion rate was higher in the control group, the attendance rate and program completion rate in the physical exercise group were on average higher compared to previous physical activity after school programs in children from the general population. This is the first study that revealed the feasibility of successfully conducting a physical exercise program in children with ASD from low-income families.

**427.021 (Poster)** Implementation of a Robot-Based Intervention for Students with Autism in Public Elementary Schools  
*S. Hurwitz<sup>1</sup>, N. Rodriguez<sup>2</sup>, O. Heck<sup>3</sup>, K. Carlock<sup>3</sup>, A. Thielmeyer<sup>2</sup> and B. Garman-McClaine<sup>2</sup>, (1)Special Education, Indiana University, Bloomington, IN, (2)Indiana University, Bloomington, IN, (3)Indiana University, BLOOMINGTON, IN*

---

**Background:** The use of technology-aided interventions is on the rise including for students with autism (Odom et al., 2015). Research supports using technology as a tool to support learning in multiple domains, including social skills, receptive language, and academics (Grynszpan et al., 2014). One new intervention approach includes a robot-based curriculum developed to teach students with autism social and communication skills. The humanoid robot, called Milo, models human facial expressions, speaks, and moves and delivers a social-communication curriculum to students with autism. This study examines the implementation of this new robot-based intervention in Midwestern public schools.

**Objectives:** The purpose of this study was to determine the perspectives of educational professionals on the introduction of Milo for students with autism in elementary schools in a Midwestern state.

**Methods:** The research questions for this study are: 1) What are teachers' concerns about implementing a robot-based intervention? Are teachers who are more comfortable using technology, more likely to accept and integrate a robot-based intervention into their classroom? 2) Does exposure to the training provided by RoboKind provide teachers with support and does it influence teacher perceptions, attitudes and comfort levels? 3) What are the strengths and pitfalls of using a robot to teach students with autism? Thirteen schools enrolled in the current study. Each school was provided a half-day, in-service training for Milo implementation. Pre- and post-training surveys were sent to teachers, paraprofessionals, and other school specialists who attended the training. Survey questions explored participants' perceptions and attitudes about implementing the intervention within a school-based setting, including issues of administrative support, time constraints and scheduling concerns, and level of enthusiasm.

**Results:** Fifty-eight school-based professionals participated in the study. Survey results were that facilitators overwhelmingly agreed that technology can be a useful tool to enhance the social skills of students with autism. Nearly all facilitators indicated enthusiasm when asked if they believe the robot-based curriculum would help their students with autism learn and agreed that their schools had appropriate resources to implement the curriculum. One teacher wrote in: "I believe Milo will be instrumental in teaching our younger students' social skills in a manner that is more appropriate for them." However, they were less sure about mastering the potential pitfalls of adapting new technology to the classroom environment. Facilitators raised concerns regarding the time commitment required to use Milo and thought it might be challenging to schedule enough time in the school day. Although some facilitators felt prepared to implement the Milo curriculum after the training, several expressed concerns about not having enough experience and some had apprehension about using a humanoid robot.

**Conclusions:** This study sought to examine the perceptions and attitudes of teachers and school personnel regarding adopting a new robot-based intervention for students with autism. Results indicate that although there are concerns regarding the amount of time required by the intervention, participants were excited to integrate and implement this new technology. Next steps are to re-survey these professionals in a few months to evaluate the efficacy of this robot-based intervention.

**427.022 (Poster)** Implementing Social Skills Group during Covid-19 Pandemic in an Ethnically Diverse Population  
*M. Valicenti-McDermott, R. Battino, T. Fried, T. Jimenez, M. O'Neil, S. Siminerio and L. Shulman, Rose F. Kennedy Center, Children's Evaluation and Rehabilitation Center; Montefiore Medical Center, Bronx, NY*

---

**Background:** Social Skills Groups, involving Social Thinking methodology (developed by Michelle Garcia Winner), are often recommended to improve social deficits in individuals with autism. In late March 2020 due to the COVID-19 pandemic and lockdown, in-person visits stopped at our Center, and all therapeutic services were switched to telehealth. Although there is empirical data supporting the use of Social Skills Groups in children with autism, the feasibility and effectiveness of this therapy via telehealth is unknown. Moreover, the Covid-19 pandemic represents a major life stressor for families, and the impact of parental stress in response to interventions is also worthy of examination.

**Objectives:** 1) to assess feasibility of Social Skills Groups via telehealth in children with autism in an ethnically diverse population during the COVID 19 pandemic and lockdown; 2) to assess preliminary effectiveness of social skills groups delivered via telehealth on social competence

**Methods:** Pilot trial assessing feasibility and preliminary efficacy of Social Skills Methodology via telehealth on social competence in all children with autism participating in a program of social skills groups in a university affiliated multidisciplinary developmental center. Intervention included Social skills using the Social Thinking methodology 1/week for 6 months. To measure changes in social competence, the Social Responsiveness Scale-2 (SRS-2) was used at baseline and after 6 months of intervention. Other data collected and analyzed included: demographics, attendance at the program, level of parental stress using the Parent Stress Index short form (PSI). Statistics included paired and t independent test, chi square.

**Results:** Of 31 patients participating in the program, outcome measures (pre and post) were available in 18 patients, 15 boys (83%) and 3 girls (17%) age  $11 \pm 4$  y.o, 2 White (11%), 8 Hispanic (44%), 6 African American (33%), 12 (66%) bilingual households, Childhood Autism Rating Scale:  $31 \pm 4$ ; 2 children with borderline IQ, rest average. Of the 18, 13 started in person and moved to telehealth, while 5 children started via telehealth; 15 families (83%) attended at least 75% of sessions or more. Overall, 9 children showed improvement in SRS-2 social competence subscale (50%) and 7 (39%) showed improved total SRS-2 Scores. 13 parents (72%) reported significant levels of parental stress on the PSI ( $>75$ ) at the end of the program. Children whose parents reported significant stress were less likely to improve in their SRS-2 social competence subscale (4/13 31% vs. 5/5 100%  $p=0.009$ ) and in the total SRS-2 score (3/13 23% vs. 4/5 80%  $p=0.02$ ) than children whose parents did not experience significant stress. In the group of children whose parents did not experience significant stress ( $N=5$ ) there was a significant improvement of the parental ratings of SRS-2 social competence subscale (baseline:  $37 \pm 9$ ; after 6 months:  $32 \pm 6$   $p=0.05$ ). There were no other differences in demographics or autistic severity between these 2 groups.

**Conclusions:** In this pilot study, social skills via telehealth was feasible and well attended by families. Preliminary efficacy was reported in roughly half the children and appeared to be, influenced by parental stress during COVID 19.

**427.023 (Poster)** Improving Social Media Competence and Confidence: The Acceptability, Feasibility, and Preliminary Efficacy of the Selfi Program

*A. Osuna<sup>1</sup>, D. M. Tagavi<sup>2</sup>, K. Sabini<sup>3</sup>, G. Goldschmid<sup>3</sup> and T. W. Vernon<sup>1</sup>, (1)University of California Santa Barbara, Santa Barbara, CA, (2)University of California, Santa Barbara, Santa Barbara, CA, (3)University of California, Santa Barbara (UCSB), Santa Barbara, CA*

---

**Background:** COVID-19 have expedited the move to a primarily digital society, making online social skills critical. While there are many benefits to social media, there are also many consequences if one does not handle themselves appropriately online. Individuals with autism spectrum disorder (ASD) struggle with in-person interactions, however little is known about their social experience online. While targeted social skills interventions have been demonstrated to improve social competency in those on the spectrum, no intervention has been developed that specifically targets the skills necessary for successful online interactions. To address this emerging area of social skill need, the 8-week Socialization and Education Learning for the Internet (SELFIE) program was developed to evaluate and improve the social media experience of those with ASD in an increasingly digital world.

**Objectives:** The present study explores existing vulnerabilities in those with ASD compared to typically developing peers and the acceptability, feasibility, and preliminary efficacy of a novel social media skills program. The objectives were to 1) explore the

feasibility of this type of intervention 2) assess the participant's experience in the SELFI program and 3) understand if one's social media experience was impacted after participation in the program.

**Methods:** The study's sample consisted of 6 males with ASD (mean age= 23.67 years;  $SD = 4.93$ ) and 17 typically developing males (mean age = 21.44,  $SD = 1.042$ ). A cross-sectional design was utilized to understand the social media behavior of those with and without ASD. A pretest-posttest design was utilized to evaluate the SELFI program. Facebook data from participants in both groups were collected at pre-intervention to gain an understanding of baseline vulnerabilities in those with ASD. Data was collected at post-intervention to assess changes in social media activity after participation in the SELFI program. Facebook data were evaluated for post type and frequency. Analysis of treatment acceptability and feasibility were assessed using participant feedback and review of the program's implementation.

**Results:** Before intervention, those with ASD (6.67 mean actions/week) engaged in fewer social media posts than their TD peers (16.12 mean actions/week). After participation in the SELFI program, those with ASD engaged in almost twice as much Facebook behavior than before intervention (13.17 actions), a rate approaching the TD group. Regarding the program's acceptability, participants reported a high level of satisfaction and increased social confidence online. All participants completed the program and sessions were delivered with high fidelity (85.15%), indicating program feasibility.

**Conclusions:** The SELFI program is the first of its kind to explore a social skills program for individuals with ASD on social media. Preliminary results indicate that those with ASD experience vulnerabilities online and that the SELFI program may help those on the spectrum increase their social media use. Information gathered from participant feedback and treatment delivery indicate promise as it relates to acceptability and feasibility. Future directions include an ongoing randomized controlled trial to systematically assess the SELFI program when implemented virtually in a social skills group setting.

**427.024 (Poster)** Influence of ASD Symptom Severity on Treatment Outcome in Young Adults with ASD: The UCLA PEERS® Intervention

**J. E. Lerner, Y. S. Lograsso, L. D. Solouki, K. Sung, H. R. Goodman and E. A. Laugeson, UCLA Semel Institute for Neuroscience and Human Behavior, Los Angeles, CA**

**Background:** Social skill deficits, a hallmark feature among individuals with autism spectrum disorder (ASD), often result in social isolation and problematic relationships (Gantman, Kapp, Orenski, & Laugeson, 2011). Consequently, there is a need for effective social skills training programs for adults with ASD. Severity of social impairment varies widely among this population (Constantino, 2011); therefore, it is important to understand how severity of ASD symptoms may differentially impact treatment outcome.

**Objectives:** This study examines the treatment gains of young adults with mild, moderate, and severe ASD symptoms following the UCLA Program for the Education and Enrichment of Relational Skills (PEERS®; Laugeson, 2017), an evidence-based social skills intervention.

**Methods:** Participants included 91 young adults (males=70, females=21) ranging from 17-35 years of age ( $M=22.77$ ,  $SD=3.66$ ) and their caregivers, presenting for treatment at the UCLA PEERS® program. Young adult participants exhibited clinically elevated ASD symptoms, as determined by a total score  $\geq 60$  on the Social Responsiveness Scale–Second Edition (SRS-2; Constantino & Gruber, 2012). Participants were grouped based on ASD symptom severity according to baseline caregiver-reported total scores on the SRS-2. Participants with T-scores between 60-65 were in the mild ASD group ( $N=28$ ), 66-75 in the moderate group ( $N=38$ ), and 76 or higher in the severe group ( $N=25$ ). Treatment outcome was assessed using pre and post caregiver-reported total scores on the Social Skills and Problem Behavior Subscales of the Social Skills Improvement System (SSiS; Gresham & Elliott, 2008). A paired samples t-test determined outcome measure significance. Group differences were assessed using a one-way ANOVA and Tukey post hoc tests.

**Results:** Results reveal significant improvements in SSiS social skills for participants in the moderate [ $M=5.79$ ,  $SD=9.27$ ],  $t(37)=3.85$ ,  $p=.001$ ] and severe [ $M=16.56$ ,  $SD=10.89$ ],  $t(24)=7.60$ ,  $p<.001$ ] groups, and significant decreases in problem behaviors for participants in the mild [ $M=-5.14$ ,  $SD=9.83$ ],  $t(27)=-2.77$ ,  $p<.001$ ], moderate [ $M=-4.74$ ,  $SD=10.94$ ],  $t(37)=-2.67$ ,  $p<.001$ ], and severe [ $M=-12.12$ ,  $SD=12.69$ ],  $t(24)=-4.77$ ,  $p<.001$ ] groups. Significant between-group differences were observed in treatment outcome for social skills [ $F(2,88)=11.90$ ,  $p<.001$ ] and problem behaviors [ $F(2,88)= 3.82$ ,  $p=.026$ ], such that participants with severe ASD symptoms exhibited greater improvements on both scales compared to those in the mild and moderate groups ( $p<.05$ ). No other statistically significant differences were found.

**Conclusions:** Results suggest that young adults with varying levels of ASD symptomatology are able to improve their social skills and associated behaviors when presenting for social skills treatment. Specifically, findings reveal significant decreases in problem behaviors for young adults across the three ASD symptom severity groups, and increases in social skills in the moderate

and severe symptom groups. Interestingly, there were higher overall treatment gains for participants with severe ASD symptoms, suggesting that young adults with poorer social responsiveness benefit the most from the PEERS® social skills intervention. This may be due to the fact that individuals with milder ASD symptoms might already possess fundamental social skills, and thus need more assistance with other social skills domains. Future studies might examine other factors that influence differential treatment outcome within this population in order to create more effective targeted interventions for adults with ASD.

**Background:**

Among autistic adults, some of the most relevant challenges that prompt interventions arise from core symptoms and poor adaptive functioning that may impede independent living, attendance at university/college and employment. Although intervention services guidelines for autistic adults have been developed (e.g., National Institute for Health and Clinical Excellence (NICE, 2012), Autism Europe (2013), National Audit Office (2009)), it is unknown to what degree the guidelines are applied within local communities. The Autism Spectrum Disorders in the European Union (ASDEU) project administered a survey in 2017 on services availability and experiences related to autistic adult interventions in 11 European countries and targeting 3 groups: autistic adults, carers of autistic adults and professionals in adult services.

**Objectives:**

The present project aimed to investigate the degree of alignment between user experiences and published autistic adult intervention guidelines based on the ASDEU survey.

**Methods:**

The ASDEU survey was translated into 11 languages and distributed by ASDEU partners via electronic media hosted by ASD organizations and in-country adult services facilities. This study examined the following survey items: recommended factors to consider when deciding on an intervention and intervention implementation, recommended factors to consider when deciding on an intervention for challenging behavior such as self-harm or injury to others, use of psychosocial and pharmacological interventions, and family interventions for members of adult's family. Distributions of responses from the three respondent groups were analyzed separately.

**Results:**

697 persons responded to the survey: 263 autistic adults (68% female; 34% 26-35 years old), 302 carers of autistic adults (carers were 85% females; autistic adults were 28% female; 54% 18-25 years old), 132 professionals in adult services (78% female; 81% worked in non-medical services). At least 59% of respondents across all groups experienced eight of thirteen recommendations prior to deciding on an intervention and during the intervention plan and implementation. Psychosocial interventions were the most commonly experienced interventions (autistic adults: 66%, n=161; carers: 65%, n=189, Figure 1), while pharmacological interventions NOT recommended for core autistic symptoms were also reported by fairly large proportions (autistic adults: 15%, n=36; carers: 21%, n=60). Family interventions were experienced by less than 23% of carers or less than 10% adults versus over half of professionals. Adult responders reported experiencing self-harm behaviors (38%; n=181) or harm to other behaviors (12%; n=58), but of these only 22% (n=39) for self-harm behaviors and 26% (n=15) for harm to other behaviors reported receiving interventions.

Conclusions: Results highlight elements of intervention services that are more likely to adhere to published guidelines and those areas that warrant improvement. The results also underscore the need to consider the autistic adults', carers' and providers' experience and perceptions in order to gain a complete view of the services' needs of a community. In Europe, as elsewhere, further development of adult intervention services is a current priority for many stakeholders ranging from autistic adults themselves, their parents and carers, professionals, professional advocacy organizations, and European countries governments and the health and social care sector.

**427.026 (Poster)** Investigating Vocal Variables for Assessing Progress for Children with ASD and Minimal Verbal Skills  
*J. McDaniel<sup>1</sup>, P. Lor<sup>2</sup>, C. Burchfield<sup>2</sup> and N. Brady<sup>2</sup>, (1)Life Span Institute, University of Kansas, Lawrence, KS, (2)University of Kansas, Lawrence, KS*

---

Background: Effective measures of incremental progress of spoken language development are needed for children with autism spectrum disorder (ASD) that are minimally verbal to make decisions about whether to change intervention strategies. Distal measures (e.g., standardized vocabulary assessments) are insufficient for measuring short-term progress. Prior work provides evidence of convergent and divergent validity as well as sensitivity to change of multiple vocal variables for young children with ASD with relatively diverse language skills.

Objectives: Building upon this work, we test the usefulness of vocal variables collected during a structured communication sample (Scripted Communication Complexity Scale [CCS]), for assessing progress of children with ASD, including those with minimal verbal skills, who participated in an intervention designed to improve production of spoken words. We tested whether the vocal variables correlate with one another (RQ1; concurrent validity) and the accuracy of elicited speech attempts of target words predictively and concurrently (RQ2). We also assessed the vocal variables' sensitivity to change across the intervention (RQ3).

Methods: Of the 52 participants in the larger study, preliminary data analyses include 11 participants at pre- and post-intervention and nine others at one time point. Additional coding is on-going. The preliminary participants had a mean age of 79 months ( $SD=18$ , range: 62–129), understood a mean of 190 words ( $SD=111$ , range: 19–395), and used a mean of 50 words ( $SD=79$ , range: 0–276). Many had minimal verbal skills at entry. The participants completed 4-16 weeks of intervention that included speech sound practice, joint book reading, and augmentative and alternative communication practice for target words.

For the current study, we coded the following variables from the CCS:

- Number of total vocalizations
- Number of communicative vocalizations
- Proportion of communicative vocalizations
- Consonant inventory
- Diversity of key consonants used in communication acts
- Number of different words

The participants also completed elicited speech probes for words taught during the intervention. Probes were scored for accuracy of place, manner, and voicing for each phoneme.

Results: For RQ1, all vocal variables correlated with one another ( $r \geq .4$ ) pre- and post-intervention (Table 1), except for the proportion of communication variables, which showed mixed results. For RQ2, all vocal variables correlated with the accuracy of elicited productions ( $r_s = .44-.57$ ) post-intervention and none were significant pre-intervention. Although pre- and post-

intervention differences were non-significant differences for all variables, mean values post-intervention were higher for all variables except for consonant inventory (Table 2).

Conclusions: As expected, vocal variables generally correlated strongly with one another. Correlations with the elicited speech production task were more variable with stronger correlations observed post-intervention than pre-intervention. Results suggest that these vocal variables are evaluating skills related to, but distinct from, the elicited production task. Thus, the vocal variables have the potential to contribute meaningful results for identifying and/or predicting children who benefit from the intervention, including those who are exhibiting little or no progress on elicited probes. The sample size will be increased prior to presenting as coding is ongoing. Additional data will be especially beneficial for examining sensitivity to change.

**427.027 (Poster)** Life-Skills Coaching for Adults with Autism.

**A. Hillier<sup>1</sup>, D. Schena<sup>2</sup>, N. Poto<sup>3</sup>, A. Buckingham<sup>4</sup> and J. Dorey<sup>1</sup>,** (1)University of Massachusetts Lowell, Lowell, MA, (2)University of Massachusetts, Lowell, Lowell, MA, (3)Asperger/Autism Network, Watertown, MA, (4)Psychology, University of Massachusetts Lowell, Lowell, MA

---

Background: The lack of services for adults on the autism spectrum is of growing concern. Given the huge variation in how autism impacts people, individualized approaches might be particularly effective. This study evaluated a community-based life-skills coaching program for adults with autism “LifeMAP.” LifeMAP is structured around individualized meetings between a client and their coach where they identify, prioritize, and make progress towards self-selected goals. LifeMAP was established in 2008 and has since served around 1,500 clients.

Objectives: We aimed to examine the LifeMAP program model, the types of goals adults with autism prioritized, whether clients felt less anxiety and greater confidence towards reaching their goals over time, and progress towards reaching goals.

Methods: Participants were 265 LifeMAP clients with an average age of 26.5 years old with the majority identifying as white (n=186) and male (n=172). Goal Reports were used to collect data describing the goals clients were working on, their self-reported anxiety and confidence towards these goals, and progress made towards these goals. Client’s anxiety concerning their current goal was measured on a 6-point scale (from “not at all anxious” to “extremely anxious”), and confidence from “extremely confident” to “not at all confident”. Level of progress was identified in stages: “Awareness”, “Developing Strategies”, “Applying Strategies with Help”, and “Applying Strategies Independently”. Coaches and clients completed the Goal Reports every 3-6 months. Data was collected over a four and a half year period from January 2016 to June 2020.

Results: Participants had set a wide variety of goals with those categorized to “Employment” being the most common (27.8% of identified goals). Combined with the categories of “Independent Living” (19.7%) and “Education” (15%), over half of goals were categorized within these groups. The categories of “Life Skills” (13.8%) and “Social” (13.1%) were also commonly reported. The remaining categories of “Regulation”, “Communication”, and “Self-Awareness” collectively accounted for around 10% of all goals set. Participants demonstrated a significant reduction in anxiety across goal categories when comparing the first to final Goal Reports ( $t(375)=-4.76, p=0.0001$ ), and a significant increase in confidence ( $t(375)=-6.02, p=0.0001$ ). Comparing stages of progress at time of first report to final report came close to reaching significance ( $t(326)=-1.953, p=0.052$ ).

Conclusions: The LifeMAP program is unique in its focus on the adult age range, the highly individualized approach at the center of the model, and the relatively large number of clients served. Findings indicated that LifeMAP was effective in supporting progress towards goals, increasing confidence towards goals and reducing anxiety. Given the scope of the LifeMAP program these findings are unique in providing pertinent information to others looking for effective strategies to support adults with autism. This study provides a realistic perspective on how programs are applied in community-based settings, outside a structured, formal lab setting. Individualized intervention approaches might be key to successful outcomes for adults with autism and provide an authentic approach where the ideas, perspectives, and priorities of adults with autism themselves are at the center of the model.

**427.028 (Poster)** National Clearinghouse on Autism Evidence & Practice (NCAEP): Updating a Systematic Review to Identify New Evidence-Based Practices for Children and Youth with Autism

**J. R. Steinbrenner<sup>1</sup>, K. Hume<sup>1</sup>, S. L. Odom<sup>2</sup>, K. L. Morin<sup>3</sup>, S. W. Nowell<sup>4</sup>, B. Tomaszewski<sup>1</sup>, S. Szendrey<sup>5</sup>, N. S. McIntyre<sup>6</sup>, S. Yucesoy-Ozkan<sup>7</sup> and M. N. Savage<sup>8</sup>,** (1)Frank Porter Graham Child Development Institute, University of North Carolina at Chapel Hill, Chapel Hill, NC, (2)Frank Porter Graham Child Development Institute, University of North Carolina at Chapel Hill, San Diego, CA, (3)University of North Carolina, Chapel Hill, Chapel Hill, NC, (4)University of North Carolina - Chapel Hill, Chapel Hill, NC, (5)Allied Health, University of North Carolina at Chapel Hill, Chapel Hill, NC, (6)University of California at Davis, Davis, CA, (7)Anadolu University, Eskisehir, Turkey, (8)Educational Psychology, University of North Texas, Denton, TX

---

**Background:** The National Professional Development Center on ASD (NPDC) completed a review of literature published between 1990-2011 and identified 27 evidence-based practices (EBPs) for individuals with ASD from birth through age 21 (Wong et al., 2015). These findings have had a broad impact on the field since their publication in 2015 (e.g. most cited manuscript in JADD in 2017; identified by IACC as one of the top 20 scientific advances in ASD research). These findings are dated, however, and the National Clearinghouse on Autism Evidence and Practice (NCAEP) conducted an updated review of the literature to include six additional years of research.

**Objectives:** The objectives of this session are to (1) identify new practices that have met the criteria for identification as an evidence-based practice, and (2) identify study, participant, and intervention characteristics to identify gaps in the literature base.

**Methods:** The NCAEP team used the same search strategy as the 1990-2011 systematic review, for peer-reviewed articles using variations of the terms (1) autism (e.g., ASD, Asperger) and (2) intervention (e.g., treatment, program, education). The inclusion criteria are high quality single-case design and group design studies that examine a behavioral, educational, or developmental (i.e., non-medical) intervention for individuals with ASD from birth through 22 years old. The following steps were completed for the systematic review: (1) search of 9 databases, (2) title/abstract review, (3) full-text review for inclusion, (4) quality review, determination of effects, and preliminary data extraction, (6) consensus decision for quality and presence of effects as needed, and (7) final data extraction on study participants, outcomes, and interventions.

**Results:** The 2012-2017 review started with over 31,000 articles in the initial search. A total of 545 articles met quality criteria and demonstrate at least some positive effects, resulting in 972 total articles (1990-2017). There is an increasing trend of high-quality peer-reviewed research (see Figure 1). The review identified five new EBPs (augmentative and alternative communication, behavioral momentum, direct instruction, music-mediated interventions, and Sensory Integration®), and identified 10 manualized interventions meeting criteria that are within broader EBP categories (e.g., PEERS in social skills treatment). Several other EBP categories were expanded or reconceptualized.

The participant data indicates that more studies include 6-11.9 year-olds (59%) and 3-5.9 year-olds (45%) participants, with fewer studies including 12-14.9 year-olds (27%), 15-18 year-olds (18%), and the fewest studies including children under 3 years old (9%) and 19-22 year-olds (5%). The data also shows differences in frequencies of the types of intervention targets or outcomes (see Table 1). Additional data on study characteristics and implementation characteristics will also be reported.

**Conclusions:** The updated systematic review of behavioral, developmental, and educational interventions is an important step as research and practice continue to move forward to facilitate the best outcomes for children and youth with ASD, especially given the increasing trends in published research. Despite growth from the previous review period, there remain gaps in research related to age (less research in adolescents/young adults) and outcomes (e.g., mental health, self-determination) which can inform future research efforts.

**427.029 (Poster) Parent Perceptions of Adolescents with ASD in the PEERS Program**

**T. Choy<sup>a</sup>, E. Baker<sup>c</sup>, E. Veytsman<sup>b</sup>, A. M. Martin<sup>b</sup>, J. Blacher<sup>d</sup> and K. K. Stavropoulos<sup>b</sup>, (1)University of California, Riverside, Riverside, CA, (2)University of California Riverside, Riverside, CA, (3)Graduate School of Education, University of California Riverside, Riverside, CA, (4)Graduate School of Education, University of California, Riverside, Riverside, CA**

---

**Background:** As youth with ASD struggle with an array of problem behaviors, parents experience associated stress and family problems (Lecavalier et al., 2006; Blacher & McIntyre, 2006; Sander & Morgan, 1997). Researchers have examined aspects of child impact that affect parent perceived benefits from intervention as well as parent's overall stress and well-being (Blacher & Baker, 2017; Karst et al., 2015; Solish & Perry, 2008). In the current study, parent perceptions of their adolescent and family impact are examined following the PEERS® Program.

**Objectives:** Although PEERS® has been shown to improve social behaviors in adolescents with ASD (e.g., Laugeson et al., 2012), this paper focuses on factors that predict parent perception and family impact following a social skills intervention. We hypothesized that parent report of adolescent problem behaviors before intervention would predict parents' positive and/or negative perception of the youth at post-intervention as well as at four-month follow up, over and above improvement in social skills.

**Methods:** Thirteen adolescents with ASD and their parents ( $M=14.17$ ,  $SD=2.09$ ) participated in the PEERS® intervention. Behavior problem measures were taken at pre- and post- intervention and at a four-month follow up. Standard scores of parent-reported problem behaviors were used from the Social Skills Improvement System (SSIS; Gresham and Elliott, 2008). Subscales of positive parent perceptions and negative family impact (a composite score of negative parent perception and negative impact

of the adolescent on family social life) were assessed through parent completion of the Family Impact Questionnaire (FIQ; Donenberg and Baker, 1993).

Results: A repeated-measures ANOVA revealed a significant change in social skills across time,  $F(1,9)=14.80, p<.01$  such that social skills improved from pre- to post- intervention. A second repeated-measures ANOVA revealed no significant changes across time in either positive or negative impact on the family's life ( $p's >.05$ ). Five separate linear regressions were conducted to test if pre-intervention SSIS problem behaviors predicted impact (positive or negative) at post-intervention and at a four-month follow up. In all five regressions, a significant portion of the variance (ranging from 32.1% to 68.3%) was accounted for by SSIS problem behaviors, such that the higher the problem behaviors pre-intervention, the greater the negative impact and the lower the perception of positive impact. These findings were consistent at both post-intervention and at the four-month follow-up, despite gains in overall adolescent social skills.

Conclusions: This is the first study to measure parent perceptions of adolescents' negative and positive impact on family life following the PEERS® intervention. Findings suggest that parent-reported SSIS problem behaviors at pre-intervention predicted both positive and negative parent perceptions of their adolescents at two later timepoints. These results highlight that broader family life, as determined by parents' perceptions of the impact of their adolescent (both in positive as well as negative ways) does not improve or change following a social skills intervention. Furthermore, the adolescents' challenging behavior problems appear to be the driving factor, suggesting that combining behavioral intervention with social skills training may lead to greater benefit.

**427.030 (Poster) Parenting Teens with Strong Emotions: A Pilot Study of a Group Intervention for Caregivers of Teens with Autism Spectrum Disorder and Depressive Symptoms**

**A. B. Lupas<sup>1</sup>, S. Pickering<sup>1</sup>, M. Cevalco<sup>1</sup>, T. M. Rutter<sup>2</sup>, K. Gurtovenko<sup>1</sup>, J. M. Myers<sup>2</sup> and J. Williamson<sup>3</sup>, (1)Seattle Children's Hospital, Seattle, WA, (2)Seattle Pacific University, Seattle, WA, (3)University of Washington, Seattle, WA**

---

Background: Individuals with autism spectrum disorder (ASD) are four times more likely than their peers to experience depression in their lifetime (Hudson et al., 2019). Additionally, suicide rates in adolescents with ASD are increasing, and youth with ASD currently have double the risk of suicide compared to their peers (Kirby, et al, 2019). Despite this concerning trend, few treatments have been developed specifically for adolescents and families struggling with these issues. Recently a group curriculum targeting caregivers of typically developing adolescents with depression and suicidality (Parenting Teens with Strong Emotions) has shown promising results (Gurtovenko et al, 2020). This curriculum combines techniques from parent management training (PMT) (e.g. Barkley & Robin, 2014) and Dialectical Behavior Therapy (DBT) (Linehan, 1993) to give caregivers effective strategies to support their depressed teenager and improve their relationship without reinforcing problematic symptoms or suicidality.

Objectives: The aim of this study was to pilot an adaptation of the Parenting Teens with Strong Emotions curriculum for caregivers of teens with ASD and co-occurring depression and suicidality, and to examine the group's effectiveness and caregiver satisfaction.

Methods: Caregivers attended weekly Parenting Teens with Strong Emotions groups for 10 weeks at an outpatient clinic or via telemedicine due to the COVID-19 pandemic. Caregivers were taught techniques from DBT (e.g. mindfulness, validation, dialectics) and PMT (e.g. positive time, labeled praise, behavior analysis) to support their adolescent. Caregivers of 24 patients participated in groups; of these, 7 caregivers completed both pre- and post-group measures. Caregiver-report of adolescent total symptom severity (Strengths and Difficulties Questionnaire [SDQ], 2005), caregiver-teen conflict (The Conflict Behavior Questionnaire [CBQ], 1979), and caregiver mindfulness (The Five Facet Mindfulness Questionnaire [FFMQ], 2006) were collected before and after 10 weeks of group. Paired sample t-tests were used to analyze differences in outcomes pre and post group. Caregivers also completed a post-group satisfaction questionnaire.

Results: Caregiver report of total difficulties for their teen on the Strengths and Difficulties Questionnaire significantly reduced after 10 weeks,  $t(6)=3.343, p=.016$ . Caregivers also reported a significant reduction in parent-teen conflict on the Conflict Behavior Questionnaire,  $t(5)=2.779, p=.039$ . A similar but non statistically significant pattern was also observed for caregiver mindfulness,  $t(5)=-2.371, p=.064$ . See Table 1 for descriptive statistics on all measures. The post-group satisfaction questionnaire (using a 5-point Likert scale) indicated caregivers were generally satisfied with group (4.6/5), learned strategies that were helpful in responding to their teen's emotions and behaviors (4.6/5), felt more confident in their parenting (4.3/5), and would continue to use strategies from group (4.7/5).

Conclusions: Results of our pilot study on Parenting Teens with Strong Emotions group for caregivers of teens with ASD and depression and suicidality demonstrated preliminary effectiveness for use of this treatment with the ASD population. Though the teenagers did not directly receive treatment, their caregivers reported reduced teen difficulties, reduced caregiver/teen conflict,

and overall satisfaction with the group. Despite a small sample size, this pilot demonstrated significant, positive change in the lives of depressed teens with ASD and their caregivers.

**427.031 (Poster)** Perspectives of Primary Caregivers and Neurotypical Siblings on a Prospective Sibling-Guided Motor Intervention for Children with Autism Spectrum Disorder

*Y. Lu<sup>1</sup>, K. Erickson<sup>1</sup>, T. Sun<sup>2</sup>, S. Douglas<sup>2</sup> and J. L. Hauck<sup>1</sup>, (1)Department of Kinesiology, College of Education, Michigan State University, East Lansing, MI, (2)Human Development and Family Studies, Michigan State University, East Lansing, MI*

---

**Background:** The long-lasting relationship and the large amount of time siblings spend together may present unique advantages when siblings act as intervention agents. However, the involvement of neurotypical (NT) siblings is limited in the existing literature of Autism Spectrum Disorder (ASD) interventions and existing interventions mostly focus on social and communicative skills. Many individuals with ASD also experience motor delays and abnormalities that are not therapeutically addressed. Therefore, motor interventions with NT siblings acting as intervention agents in the natural setting of their home may be a viable option. But without adequate knowledge and strategies, NT siblings of children with ASD may experience some difficulties in providing instructions and interacting appropriately with their siblings with ASD. Thus, to better assist NT siblings and promote skills of children with ASD, there is a need to first understand the difficulties, needs, and expectations from the perspective of both NT siblings and caregivers.

**Objectives:** This study aimed to gain an in-depth understanding of the perspectives of NT siblings and primary caregivers related to sibling relationships, NT siblings' knowledge about ASD, NT siblings' teaching experiences, and preferences in a prospective sibling-guided motor intervention.

**Methods:** A phenomenological qualitative design guided this study. Ten neurotypical siblings of children with ASD ( $9.00 \pm 2.98$  years) and their primary caregivers ( $36.00 \pm 4.71$  years) were recruited and interviewed. The semi-structured interviews were conducted online with each family to elicit the perceptions and experiences of primary caregivers and NT siblings. Data were analyzed using thematic content analysis.

**Results:** Firstly, most families reported NT siblings and children with ASD share a positive relationship, although NT siblings may experience some barriers in interactions with their siblings with ASD related to the core characteristics of ASD. Secondly, all of the families in our sample stated that they discussed ASD at home. However, NT siblings still lacked comprehensive knowledge of ASD, and their recourse to access information about ASD was limited. Thirdly, we found a majority of NT children indicated they are willing to help their siblings with ASD, but only about half of the NT siblings currently had experience and confidence in teaching or showing things to their siblings with ASD. Lastly, we gained knowledge about the preferences of caregivers and NT siblings on the characteristics of prospective sibling-guided motor interventions.

**Conclusions:** The results of this study will guide the design of a feasible and effective sibling intervention for children with ASD with NT siblings acting as intervention agents, and inform development of targeted NT siblings training sessions (e.g. comprehensive knowledge of ASD, behavioral strategies) prior to the implementation of the intervention. Specific implications for both research and practice will be discussed in the presentation.

**427.032 (Poster)** Randomized Controlled Pilot Study of a Parent-Based Crisis Prevention Institute (CPI) Physical Management Training Program (P-CPI): Safety and Parental Satisfaction

*L. Nowinski<sup>1,2</sup>, N. Simon<sup>1</sup>, K. Birtwell<sup>1,2</sup>, A. Giauque<sup>1</sup>, C. Stamm<sup>1</sup>, A. Tassone<sup>1</sup>, C. J. McDougle<sup>1,2</sup> and C. Ravichandran<sup>1,3</sup>, (1)Lurie Center for Autism, Massachusetts General Hospital, Lexington, MA, (2)Harvard Medical School, Boston, MA, (3)McLean Hospital, Belmont, MA*

---

**Background:**

Aggression, self-injury, and property destruction are among the most impairing and severe behaviors in ASD (Doehring, Reichow, Palka, Phillips and Hagopian, 2014) and often require acute intervention (Akram, Batool, Rafi, and Akram, 2017; Mandell, 2008; Matson and Nebel-Schwalm, 2007). Despite the need for parent training (e.g., Bultas, Johnson, Burkett, and Reinhold, 2016; Doehring, 2014), a paucity of research addresses management of these challenging behaviors at home. Given the significant impact on families and systems of care, the lack of evidence-based and widely available physical management training for parents is a significant omission. Concern about the safety of parental application of such strategies is one significant barrier.

**Objectives:**

The purpose of this pilot study was to investigate the safety, feasibility, acceptability, and efficacy of a novel Crisis Prevention Institute parent training program (P-CPI) to better equip caregivers to manage severe behavior problems. This study reports results on parental satisfaction immediately following training and safety outcomes two weeks post intervention.

#### Methods:

Parents of children 5-12 years old with ASD and irritability recruited from a multidisciplinary autism clinic were randomized in a 1:1 allocation to either P-CPI training or waitlist control (WLC). Participants and staff were unblinded following randomization. P-CPI training consisted of one full-day in-person program, broken into two 3-hour sessions, and facilitated by a CPI-certified Board Certified Behavior Analyst (BCBA). Participants recorded all instances of aggression, self-injurious behavior, and property destruction in the two weeks before and after training. A P-CPI Course Evaluation Assessment (self-reported satisfaction) was also completed at the conclusion of training.

#### Results:

Forty-one parents were randomized to P-CPI and 39 to WLC, of whom 33 and 27 respectively remained in the study two weeks following training.

All 34 participants completing the workshop (100%; 95% CI: 90%, 100%) rated the course as very good or excellent overall, with 30 participants (88%; 95% CI: 73%, 95%) assigning ratings of excellent. All agreed or strongly agreed that the workshop met their expectations and that they would recommend it to others (100%; 95% CI: 90%, 100%), and 32 agreed or strongly agreed they intended to use the techniques (94%; 95% CI: 81%, 98%). See figure for additional results.

Nineteen of 31 participants randomized to P-CPI who completed safety event logs post-training (61%; 95% CI: 44%, 76%) reported using CPI techniques. Estimated aggression, self-injurious behavior, and property destruction rates before and after training are compared between children of parents randomized to P-CPI and WLC in the table. For P-CPI, self-injurious behavior and property destruction rates decreased, and aggression rates were similar, before and after training. For WLC, rates for each of the three behavior categories were similar before and after training. There were no significant differences in changes between P-CPI and WLC, and no events resulted in a 911 call.

#### Conclusions:

Preliminary results of this study suggest the P-CPI workshop is both safe and well-received by parents of children with ASD. Limitations and future directions will be discussed.

This study is registered on ClinicalTrials.gov (identifier NCT03537261) and was funded by CPI.

#### **427.033** (Poster) Self and Parent Reported Treatment Gains Following PEERS: A Replication Study with Latinx Adolescents with ASD

*E. Veytsman<sup>1</sup>, E. Baker<sup>2</sup>, A. M. Martin<sup>1</sup>, T. Choy<sup>3</sup>, J. Blacher<sup>4</sup> and K. K. Stavropoulos<sup>1</sup>, (1)Graduate School of Education, University of California Riverside, Riverside, CA, (2)University of California Riverside, Riverside, CA, (3)University of California, Riverside, Riverside, CA, (4)Graduate School of Education, University of California, Riverside, Riverside, CA*

---

Background: Adolescents with ASD struggle with developing and maintaining friendships (Reichow & Volkmar, 2010). Group social skills interventions (e.g., PEERS) have demonstrated effectiveness based on adolescent- and parent- report (e.g., Gates et al., 2017, Laugeson et al., 2009, 2012). However, social skills research has been limited by methodological weaknesses and lack of skill generalization (Wolstencroft et al., 2018). Additionally, though several cross-cultural validation studies have been conducted on PEERS in Asia and Europe (e.g., Yoo et al., 2014), Latinx families have been consistently underrepresented in ASD intervention research (Bernal & Domenech Rodríguez, 2009; Ratto et al., 2017), and social skills research in particular.

Objectives: This study aims to: 1) Replicate previous PEERS studies by examining self- and parent- reported treatment gains at pre- and post-intervention and at a 4-month follow-up; and 2) Extend these studies by a) including a diverse sample of predominantly Latinx families and an age- and gender-matched control group of typically developing (TD) adolescents not participating in intervention, and b) examining family impact following treatment.

**Methods:** Participants included 13 adolescents with ASD (ten males; 69% Latinx), ages 11-17 ( $M=14.17$ ,  $SD=2.09$ ), with average cognitive abilities (WASI-2;  $M=99.54$ ,  $SD=15.6$ ). Adolescents and parents attended weekly 90-minute PEERS sessions over 16 weeks. Adolescent groups were held in English; parent groups were conducted in English and Spanish simultaneously. Adolescents and parents completed measures of social skills, social anxiety, and family impact at pre- and post-intervention and at a four-month follow-up. 11 control TD participants completed the same measures at three timepoints, each four months apart, to assess the stability of scores over time. Repeated measures ANOVAs were conducted to assess the effect of time on each measure for ASD and TD participants separately, and Bonferroni posthoc tests were conducted to examine differences between timepoints.

**Results:** For the ASD group, three-way repeated-measures ANOVAs demonstrated significant main effects of time for adolescent PEERS-specific social skills knowledge (TASSK), perceived loneliness and social satisfaction (L&SD), parent-reported social skills (SSIS), and social responsiveness (SRS-2). Bonferroni posthoc tests showed significant improvements on the TASSK and SSIS from pre- to post-treatment ( $p's < .01$ ), which remained stable at follow up ( $p's > .05$ ). Though posthoc tests revealed no significant differences between timepoints on the L&SD and SRS-2, two-way repeated-measures ANOVAs showed significant improvements from pre- to post-treatment on the SRS-2 ( $M$  change = -6.0,  $SD = 8.49$ ,  $p < .05$ ), and from pre-treatment to follow-up on the L&SD ( $M$  change = 3.83,  $SD = 5.72$ ,  $p < .05$ ). TD adolescents had stable scores across time. No significant differences were found in social anxiety, family impact, or parenting stress across time (all  $p's > .05$ ).

**Conclusions:** Consistent with previous PEERS studies, adolescents with ASD showed improved social skills and social knowledge after treatment, which were maintained four months later. This is the first study to replicate these findings with a sample of predominantly Latinx teens. Interestingly, adolescents did not perceive greater social satisfaction until four months after treatment, suggesting that some treatment benefits may be delayed. The lack of improvement in adolescent anxiety, family impact, and parenting stress may inform the development of more comprehensive, family-centered interventions.

**427.034 (Poster) Service Dog's Impact Is Mediated By the Severity of Autism Spectrum Disorder Related Symptoms**  
**C. Moses Bélanger<sup>1,2</sup>**, C. L. Normand<sup>3</sup>, S. M. Fecteau<sup>4</sup>, N. Champagne<sup>5</sup> and M. Trudel<sup>6</sup>, (1)Psychologie and psychoéducation, Université du Québec en Outaouais, St-Jérôme, QC, Canada, (2)Fondation Mira, Sainte-Madeleine, QC, Canada, (3)Psychoéducation et psychologie, Université du Québec en Outaouais, Gatineau, QC, Canada, (4)Psychoéducation et psychologie, Université du Québec en Outaouais, St-Jérôme, QC, Canada, (5)Mira Foundation, Sainte-Madeleine, QC, Canada, (6)Psychoéducation, University of Sherbrooke, Sherbrooke, QC, Canada

---

**Background:** The training and allocation of service dogs for children with autism spectrum disorder (ASD) is gaining in popularity. The documented benefits relate to both physiological and behavioral aspects: stress and anxiety reduction, increased social interactions, and language development among others. However, other variables, such as the severity of symptoms, may have an impact on these benefits and have yet to be tested.

**Objectives:** This exploratory study investigates 1- the effect of introducing a service dog in families of autistic children between the ages of five and nine and 2- how this effect is mediated depending on the severity of the autistic symptoms.

**Methods:** Ninety-one parents of children who received a service dog completed a questionnaire on the challenging behaviors of the child one month before and three months after their dog was awarded. The questionnaire contains 13 domains of potential challenging behaviors: (1) sleep ; (2) undesirable behaviors ; (3) family climate ; (4) social interactions ; (5) sensory perceptions ; (6) outings ; (7) daily activities ; (8) going out to various professionals appointments ; (9) temper tantrums ; (10) bolting ; (11) somatic discomfort ; (12) language comprehension and (13) anxiety. The results were analyzed based on the severity of child's symptoms according to two groups (Low and Moderate-Severe), established using the *Childhood Autism Rating Scale* (CARS) (Schopler et al., 1980).

**Results:** Using the Wilcoxon's Signed Ranks Test to compare the median scores in the 13 domains, it was found that children with moderate to severe symptoms of autism appear to benefit more significantly in 11/13 domains (except for family climate and temper tantrums) from the presence of the service dog than children with milder symptoms.

**Conclusions:** Our study adds to the body of evidence supporting the beneficial effect related to the use of a service dog. The dog represents an attachment figure in the child's various environments (e.g. home, community, etc.) and seems to lower the stress that generates various challenging behaviors. It also acts as a social catalyst in the reduction of numerous difficulties observed by parents. Taking the severity of autistic symptoms into consideration could improve the optimal pairing of child and service dog.

**427.035 (Poster) Service Provider Knowledge, Confidence and Treatment Adaptations in the Delivery of Psychotherapy to Autistic Youth and Youth with ADHD**

**Background:** Despite evidence for the efficacy of various psychotherapeutic approaches to address mental health problems in autistic youth (e.g., cognitive behaviour therapy; Weston et al., 2016), they often struggle to receive these interventions (Brookman-Frazee et al., 2012). Evidence suggests therapists' decisions to provide care are impacted by their experience and self-perceived skills (Maddox et al., 2019). However, more studies are needed to explore therapists' knowledge and confidence in treating autistic youth, compared to clients with other neurodevelopmental disabilities (e.g., ADHD), who may also require adaptations to psychotherapeutic practice.

**Objectives:** To examine mental health service providers' knowledge, confidence and treatment adaptations towards working with youth with mental health problems who were autistic or with ADHD.

**Methods:** Data were collected from 163 service providers across 11 agencies in Ontario, Canada, who provided psychotherapy to youth. Participants were 20 to 63 years of age ( $M = 38.24$ ,  $SD = 10.14$ ; 80% female). Most participants were employed full time (91%) and received post-secondary education (84%). Professions included social workers (38%), child/youth workers (27%), registered psychotherapists (15%), or other designations (20%). The following measures were used and asked separately about autistic clients or those with ADHD and were counterbalanced across participants. The 14-item Therapist Confidence Scale – Autism Spectrum Disorder Adapted (Cooper et al., 2018) assessed confidence in delivering therapeutic activities common across psychosocial interventions using a 5-point Likert scale (1 = not confident; 5 = highly confident). Participants self-rated their knowledge about six topics related to mental health problems, using a 5-point Likert scale (1 = not at all knowledgeable; 5 = extremely knowledgeable) (Maddox et al., 2019). Participants identified adaptations they have implemented from a list of treatment modifications (Angus et al., 2014; Burke et al., 2017; Cooper et al., 2018).

**Results:** Paired sample t-tests revealed significantly lower confidence in delivering different psychotherapy components for autistic clients than clients with ADHD,  $t(161) = -10.41$ ,  $p < .001$ . For example, 33% of participants reported feeling *not confident* or *slightly confident* in their abilities to identify therapeutic approaches that would be effective for autistic clients compared to only 6% for clients with ADHD. Knowledge was also significantly lower when referencing autistic clients than clients with ADHD,  $t(161) = -10.81$ ,  $p < .001$ . For instance, 38% of participants felt *not at all* or *slightly knowledgeable* in providing psychotherapy for autistic clients compared to 9% for clients with ADHD. Participants indicated using similar modifications in their psychotherapy work for autistic clients and those with ADHD, including implementing structure and predictability, incorporating youth interests into therapy, using simplified language and making abstract concepts more concrete.

**Conclusions:** Results indicate potential barriers or challenges to treatment delivery for autistic youth with mental health problems. Compared to clients with ADHD, service providers felt less confident and knowledgeable. Simultaneously, the majority of participants endorsed delivering evidence-based approaches and adapting their practices to their service provision. This research suggests that targeted training around autism and mental health care may be a useful initiative for agency staff.

**427.036 (Poster)** Sex Differences of Early School-Aged Children in Clinical Presentation and Treatment Response to Pivotal Response Treatment

K. Drapalik<sup>1</sup> and P. E. Ventola<sup>2</sup>, (1)Yale Child Study Center, New Haven, CT, (2)Yale Child Study Center, Yale University School of Medicine, New Haven, CT

---

**Background:**

Compared to females, males are 4.3 times more likely to be diagnosed with autism spectrum disorders (ASD) (Maenner et al., 2020). Moreover, there is a paucity of research investigating differences in treatment responses of females diagnosed with ASD in comparison to their male counterparts.

**Objectives:**

The present study examines sex differences in clinical presentations and treatment response to Pivotal Response Treatment (PRT) in young children with ASD.

**Methods:**

The study was comprised of sixteen children, including six girls ( $M = 74.67$  months;  $SD = 15.63$ ) and ten boys ( $M = 61.1$  months;  $SD = 7.01$ ). All children had an ASD diagnosis as confirmed by the Autism Diagnostic Observation Schedule (ADOS).

Participants received 6 hours of PRT for 16 weeks. Clinical outcome measures were administered before and after treatment including the SRS-II, Vineland-III, and ADOS. Additionally, participants received the DAS-II prior to study participation. Paired-samples t-tests were used to examine sex differences of clinical presentations and change in measures of ASD symptom severity.

#### Results:

At baseline, boys had significantly higher General Conceptual Ability (GCA) scores on the DAS-II compared to girls (boys M = 92.7, SD = 14.92; girls M = 81.17, SD = 5.12;  $p < 0.05$ ). Boys also had stronger adaptive behavior skills, as assessed by the Adaptive Behavior Composite (ABC) of the Vineland-III (boys M = 83.3, girls M = 75.5), SRS-II (boys Total t-score M = 71.5, girls Total t-score M = 77), and lower ASD symptomology as measured by the Calibrated Severity Scale (CSS) of the ADOS (boys M = 7.67, girls M = 8.17). Following PRT, there were no significant differences between girls and boys in adaptive functioning (boys M = 81.2, girls M = 77.83) or ASD symptom severity, SRS-II (boys Total t-score M = 69.1, girls Total t-score M = 71.17) and ADOS CSS (boys M = 7.3, girls M = 8.0). However, both male and female groups individually improved across all outcome measures post-treatment. The magnitude of change within each group varied, as girls exhibited larger gains in their adaptive functioning abilities and social abilities evident in the Vineland-III ABC (boys DM = -2.1, girls DM = 2.33) and SRS-II (boys Total t-score DM = 2.4, girls Total t-score DM = 5.83), and boys exhibited an increased change in their CSS of the ADOS (boys DM = 0.37, girls DM = 0.17).

#### Conclusions:

These results indicate both boys and girls show improvement in social communication and adaptive functioning following PRT, supporting the efficacy of PRT as an effective treatment for children with ASD. The exact nature of these improvements differed wherein boys maintained improvements in core social communication skills and girls improved in the real-world application of these skills. This study demonstrates that although boys and girls maintain varying clinical presentations that diverge significantly as they age into later school-age, PRT remains a valid treatment for both young boys and girls with ASD.

**427.037 (Poster)** Skolkontakt - Social Validity of Social Skills Training in School Settings

*E. Leifler<sup>a</sup>, A. Borg<sup>a</sup>, C. Coco<sup>a</sup>, A. Fridell<sup>a</sup> and S. Bolte<sup>b</sup>; (1)Department of Women's and Children's Health, KIND Karolinska Institutet Center of Neurodevelopmental Disorders, Stockholm, Sweden, (2)Center of Neurodevelopmental Disorders (KIND), Centre for Psychiatry Research; Department of Women's and Children's Health, Karolinska Institutet, & Stockholm Health Care Services, Region Stockholm, Stockholm, Sweden*

**Background:** Social impairments are associated with Autism spectrum disorders (ASD). Individuals with ASD are at increased risk for mental disorders and are overrepresented among school absenteeism. Little is known about social skills group training for adolescents in naturalistic treatment settings. Furthermore, there is a lack of qualitative elements in experimental research designs.

**Objectives:** This exploratory study examines the feasibility and social validity of SKOLKONTAKT, a social skills training program for educational settings derived from the scientifically well-ensured clinical training KONTAKT. The current study builds on our previous experience, seeking to systematically enlarge it in terms of further feasibility assurance, students' satisfaction and controlled training efficacy.

**Methods:** Participants are recruited from an on-going RCT of social skills group training. The study is a multi-responders study where participants are the students, the facilitating teachers and the school management. This triangulation will increase the validity through the convergence of information from different participants. Data collection are semi structured interviews. Social validity is measured by interviews with the students (both in control and active group), the facilitating teachers and the school management. At present the sample size is  $n = 17$  (i. e. students  $n = 11$ , teachers  $n = 4$  and school management  $n = 2$ ). Larger sample sizes are preferable and this study will continue with data collection after the third RCT session. Data is handled with the NVivo 12 (QSR and Ltd.), and thematically analyzed.

**Results:** The preliminary results based on the completed interviews ( $n = 17$ ) show high levels of satisfaction. According to the responses, the school setting is beneficial for several reasons: the closeness, typically developed peers to interact with and

develop friendship, the environment is less vulnerable though teachers and students have a reciprocal relationship. Teachers expressed better quality of life for adolescents as well as enlarged possibilities for academic achievement due to increased attendance at school. Students (n = 11) expressed enhanced social skills, where students in the training group expressed broader and more detail improvements. Furthermore, students expressed developed social skills valuable for future employment and overall more happiness and engagement. The school management saw overall improvements in students' social skills. However, according to facilitating teachers (n = 4), the training is time demanding, especially at initial phase.

### **Conclusions:**

These findings show advantages in implementing social skills group training in naturalistic settings for generalization and reflection of reality. Methods originally designed to support individuals on the autism in clinical settings are feasible and effective in school settings. Interventions targeting social skills can successfully be implemented in real-world settings like school and improves inclusion. As more student on the autism are attending inclusive environments, there is a need for interventions to increase social interactions and possibilities for enhanced participation.

This study contributes to stakeholders and educators as well as to the society as a whole. Students's well-being and safety in the school environment reduces school absenteeism and enhances academic achievement.

---

**Background:** Research shows that relationships with caring, non-parental adult mentors are critical to healthy development and can positively influence a range of outcomes, such as peer and parent-child relationships, identity development, academic achievement, self-confidence, the prevention of problem behaviors, and reducing mental health problems (DuBois et al., 2011; Haft et al., 2019; Raposa et al., 2019; Taussig et al., 2019; Wyman et al., 2010). While youth and adolescents with autism spectrum disorder (ASD) often experience challenges related to communication, social relationships, and co-occurring emotional and behavioral concerns (Vasa et al., 2019), there are limited targeted mental health interventions or mentoring opportunities available for youth with ASD.

**Objectives:** The aim of this study was to examine the social and emotional outcomes for AMP participants.

**Methods:** AMP involves one-to-one mentorship of youth with ASD by adults with ASD. Mentoring sessions consisted of 22 weekly 60-minute meetings within the teens' high school. Fall sessions were in person and spring sessions were virtual due to COVID-19. Pairs participated in semi-structured activities centered around common interests. Participants included 14 mentees (ages 14-17), 14 mentors (ages 19-34), and 17 parents of the mentees. Mentees were recruited from a local high school, and mentors were recruited from a local community transition program for young adults with ASD. All participants had a diagnosis of ASD without co-occurring intellectual disability or language impairments. The majority of participants had co-occurring diagnoses of anxiety, depression, or ADHD. Multi-informant data was collected throughout the study. Participants completed a variety of standardized questionnaires including the Social Skills Improvement System (SSIS), the Achenbach Rating Scales (YSR, ASR, CBCL), the Rosenberg Self-Esteem Scale, and a study developed survey evaluating self-concept, quality of life, and daily activities. Descriptive and associational statistics were used to meet objectives.

**Results:** Participants reported improvements in social and emotional functioning during AMP. Mentees experienced emotional and behavioral outcomes including an increase in pride in their autistic identity ( $g=.80$ ), improved self-esteem ( $g=.62$ ), decreased internalizing ( $g=-.24$ ) and externalizing behaviors ( $g=-.16$ ), and increased satisfaction with life ( $g=.60$ ). Mentors reported by mentors included improved quality of life ( $g=.58$ ) and reduced problem behaviors ( $g=-.27$ ). Mentees and mentors also experienced a slight increase in internalizing behaviors in the spring, which many reported as related to COVID-19. Mentees experienced increased initiation of social interactions with friends ( $g=.88$ ), increased social interactions in person ( $g=.50$ ) and online ( $g=.62$ ), and increased communication ( $g=.59$ ). Mentors reported increased electronic communication with peers ( $g=.50$ ) and increased satisfaction with peer relationships ( $g=.19$ ). Mentees and mentors described the quality of their mentoring relationship as an average 4.12 on a scale from 1-5 with 5 being the strongest.

**Conclusions:** AMP can positively impact the social and emotional functioning of mentors and mentees. AMP has promise as a social-emotional intervention for students and young adults with ASD. This program can be implemented within a community setting, making it accessible to a range of participants. A virtual pilot of AMP is taking place to explore additional outcomes. The program aims to expand to additional school districts in the future.

**427.039** (Poster) Step It up: Increasing Physical Activity for Adults with Autism Spectrum Disorder and Intellectual Disability Using Supported Self-Management and Fitbit Technology  
*M. N. Savage, B. Tomaszewski and K. Hume, (1)Educational Psychology, University of North Texas, Denton, TX, (2)Frank Porter Graham Child Development Institute, University of North Carolina at Chapel Hill, Chapel Hill, NC*

---

Background:

Individuals with ASD often do not engage in recommended levels of physical activity and levels continue to drop as individuals with ASD move into adulthood. The promising results of using strategies such as goal setting, self-monitoring, and reinforcement to increase engagement in physical activity for individuals with ASD and ID and the report of family members being a facilitator to engagement in physical activity led to the current study.

Objectives:

To determine if a supported self-managed exercise program, implemented by a caregiver, was an effective and feasible program to increase engagement in physical activity for adults with ASD and ID.

Methods:

The study used a randomized control trial to evaluate the effectiveness of a self-management intervention package with coaching component on daily step counts, health measures, and perceived quality of life for adults with ASD and ID. Coaches included a family or community member who had, at a minimum, weekly contact with the participant. Forty adults with ASD and ID were randomly assigned to a control group (n=20) or an intervention group (n=20). Both groups received Fitbits, Fitbit training, and participated in pre- and post-assessments. The intervention group participated in the self-management exercise program, which included weekly goal setting meetings. Weekly goal setting meetings were video-taped and coaches collected data on the level of participant independence throughout the goal setting meeting and integrated self-management components (self-monitoring, self-evaluation, and self-reinforcement).

Members of the research team watched videos to evaluate fidelity. Members of the research team verified goal attainment through access to the Fitbit database and evaluation of the weekly step count goal setting template filled out by the participant each week. Coaches filled out a feasibility and usage rating profile at the end of intervention. Members of the research team also conducted an interview with each coach.

Results:

Participants in the intervention group took, on average, greater weekly steps across the intervention period controlling for their baseline weekly step count (adjusted Post-Test  $M=61,548$   $SE=5,471$ ) compared to the control group (adjusted Post-Test  $M=46,377$ ,  $SE=46,377$ ). Participants in the intervention group, on average, lost more weight from baseline to posttest ( $M$  weight loss=3.25 pounds), whereas the control group made a slight gain in weight. The BMI model did not have a statistically significant main effect of Time, Group, or Time X Group intervention nor were their statistically significant main effects of Time, Group, or Time X Group Interaction for the overall quality of life model.

Participants reported high feasibility and acceptability for the Fitbit. Coaches reported high feasibility for the training and overall project as well as high ratings on the usage rating profile.

Conclusions:

These results provide some support for parents and community members implementing self-management strategies with adults with ASD and ID to increase engagement in physical activity. The intervention improved health outcomes above and beyond just having access to the Fitbit alone (control). Limitations and challenges that surfaced throughout the study will also be discussed.

**427.040** (Poster) The Development and Acceptability Testing of 'Empower-ASD': A Psycho-Educational and Psycho-Therapeutic Group-Based Programme for Parents of Children Recently Diagnosed with Autism  
**K. Leadbitter<sup>1</sup>, C. Ellis<sup>1</sup>, S. Langhorne<sup>2</sup>, L. Harrison<sup>1</sup>, A. Pearson<sup>1</sup>, R. Smallman<sup>1</sup>, J. Green<sup>2</sup> and T. Reach-ASD Team<sup>1</sup>,**  
(1)University of Manchester, Manchester, United Kingdom, (2)Division of Neuroscience & Experimental Psychology, University of Manchester, Manchester, United Kingdom, (3)University of Manchester, Manchester, United Kingdom of Great Britain and Northern Ireland, (4)Manchester University NHS Foundation Trust, Manchester, United Kingdom

---

#### Background:

Parents of autistic children face many practical, emotional and social challenges. Parental responses to the diagnosis are diverse and complex. 20-50% of parents show clinically-elevated mental health needs in the post-diagnostic period (Davis & Carter, 2008; Casey et al., 2012). Parental wellbeing is of public health importance in and of itself. It is also important for effective uptake of parent-mediated interventions known to bring long-term benefits. Best practice guidelines recommend provision of timely post-diagnostic support. However, current UK provision is patchy, a source of increasing dissatisfaction and, crucially, lacks an evidence-base for effectiveness. There is a pressing need for an evidence-based programme of post-diagnostic support for parents, focussed on both psycho-education and mental health.

#### Objectives:

- Through co-design and co-production, to develop a high-quality autism psycho-education programme that draws upon Acceptance & Commitment Therapy (ACT) to boost parental wellbeing and adjustment
- To evaluate the acceptability of the programme to parents

#### Methods:

**Development:** Two pre-existing approaches formed the foundation of the intervention development: the Central Manchester Post-diagnostic Workshop (Mockett et al., 2011) and a Brief ACT programme devised by Whittingham, Sofranoff and colleagues (Whittingham et al., 2016). Multiple stages of co-design and co-production were undertaken with various stakeholder groups to: integrate and further develop the foundational approaches and understand likely feasibility and acceptability of different aspects of the programme. Session materials and practitioner guidelines were produced in draft and then subject to acceptability testing.

**Acceptability testing:** We recruited a diverse sample of 29 parents/caregivers of children (aged 2-15 years) recently diagnosed with autism from a UK NHS autism clinic. Participants were invited to attend one of three intervention programmes (two in-person; one online). Acceptability was assessed through attendance and satisfaction ratings. Qualitative feedback was obtained through: (a) post-session feedback forms; (b) interviews with 17 parents sampled purposively on attendance.

#### Results:

The resulting programme consisted of 5 3-hour sessions of group-based delivery blending (1) autism psycho-education (etiology, prevalence, characterisation, lived experience, communication, interaction, sensory experiences, emotion regulation, cognition, behaviour); (2) ACT content linked to their parenting experience (e.g. mindfulness, acceptance, values, committed action); (3) ACT-informed reflection and discussion; (4) peer support.

**Attendance:** 22/29 participants attended  $\geq 3$  sessions (3 sessions=satisfactory dosage). 3 participants attended  $< 3$  sessions and 4 participants attended none. Non-attendance was due to external circumstances (illness, caring responsibilities, employment).

**Satisfaction:** 72% of sessions were rated 'very satisfied' and 28% of sessions 'satisfied'. No sessions were rated unsatisfied/very unsatisfied. Ratings looked similar across sessions and delivery modes.

Feedback and interview data were analysed with thematic analysis. Five main themes were identified: (1) a positive experience for all; (2) the richness of the therapeutic approach; (3) the value and impact of peer support; (4) resources and technology; (5) room for improvement.

#### Conclusions:

EMPOWER-ASD is feasible and acceptable to deliver in-person or online within a UK clinical context. Attendance was satisfactory; satisfaction was excellent. Parents described beneficial processes and outcomes. Constructive criticism served to

further modify the programme. The EMPOWER-ASD programme is now being tested within a large randomised-controlled effectiveness trial.

**427.042 (Poster)** The Floreo Police Safety Module: Results of a Randomized Control Trial

**A. S. Russell<sup>1</sup>, A. Zitter<sup>1</sup>, L. E. Cordero<sup>1</sup>, K. G. Tena<sup>1</sup>, M. L. Cola<sup>1</sup>, M. Udhmani<sup>1</sup>, R. Solorzano<sup>2</sup>, S. Turnacioglu<sup>2</sup>, J. S. Miller<sup>1</sup>, V. Ravindran<sup>3</sup>, J. McCleery<sup>3</sup> and J. Parish-Morris<sup>1</sup>,** (1)Center for Autism Research, Children's Hospital of Philadelphia, Philadelphia, PA, (2)Floreo, Inc., Washington DC, DC, (3)Psychology, Saint Joseph's University, Philadelphia, PA

---

**Background:** Approximately one fifth of adolescents with ASD will be stopped and questioned by a police officer before their early twenties (Rava, Shattuck, Rast, & Roux, 2016). Individuals on the spectrum often have difficulty with sensory stimulation, novel problem solving, and rapidly processing social situations in real time, which can make police interactions particularly challenging (Channon et al., 2001; Salerno-Ferraro & Schuller, 2020; Vanmarcke et al., 2016). Police interactions are unique, unscheduled, and unplanned social situations that can introduce a high level of stress and are experienced by individuals across a wide range of functioning. Therefore, it is important to prepare individuals for this type of encounter. Virtual reality (VR) can be a useful tool as it provides individuals with the opportunity to practice interacting with police officers in a safe, simulated environment. Therefore, VR-based intervention is a promising complement to help individuals with ASD prepare for police interactions. In the current study, we compare the efficacy of an immersive VR-based intervention (Floreo PSM) versus a video-modeling intervention (BeSAFE) for increasing key police interaction skills in adolescents and adults with ASD.

**Objectives:** Compare the efficacy of two different intervention formats by assessing masked behavioral ratings of a filmed live interaction with a police officer.

**Methods:** Forty-seven verbally fluent adolescents and adults with ASD were randomly assigned to three sessions of either an immersive VR-Based intervention (Floreo PSM) or a video modeling-based intervention (BeSAFE) designed to increase knowledge and skills necessary for interacting with police officers. To measure behavior change, participants engaged in a 3- to 5-minute live interaction assessment before and after intervention. Pre-intervention, participants interacted with a novel study staff member who presented as a police officer. Post-intervention, participants interacted with an actual police officer or a uniformed security officer. Interactions were recorded and scored in 15-second segments. Each segment was coded for: appropriateness of verbal response, orienting behavior, fidgeting behavior, and overall behavior. Scores were averaged across each behavioral category and compared pre- and post-intervention. 20% of videos were double-coded (kappas in the moderate-to-good range).

**Results:** Linear mixed effects regression revealed significant conditional main effects of time (pre-/post-intervention) on ratings of overall behavior (estimate: 0.29,  $t=3.04$ ,  $p=.004$ ), appropriate verbal response (estimate: 0.21,  $t=3.14$ ,  $p=.003$ ), and fidgeting (estimate: 0.44,  $t=3.86$ ,  $p<.001$ ), after controlling for IQ, age, and sex. There was no significant effect of time on orienting ( $p=n.s.$ ). A significant condition-by-time interaction emerged for fidgeting (estimate: -0.47,  $t=0.16$ ,  $p=.005$ ). Pre-planned pairwise comparisons of Tukey-corrected estimated marginal means revealed significant improvements from pre- to post-intervention in the Floreo PSM condition as compared to the BeSAFE condition on three out of four variables (Figure a-d).

**Conclusions:** VR has great potential to serve as a comfortable and motivating platform for individuals with autism to safely practice interacting with police officers. In this study, participants' behaviors when interacting with a live police officer were rated as more appropriate after completing VR-based or video modeling-based interventions, with some evidence that VR-based practice was particularly effective at reducing anxiety-related (fidgeting) behavior.

**427.043 (Poster)** The Impact of COVID-19 on Anxiety Symptoms Among Children with ASD Entering Group CBT Treatment

**S. Pickering<sup>1</sup>, T. M. Rutter<sup>2</sup>, A. B. Lupas<sup>3</sup>, J. L. Peterson<sup>4</sup> and R. K. Earl<sup>5</sup>,** (1)Seattle Children's Hospital, Seattle, WA, (2)Seattle Pacific University, Seattle, WA, (3)Seattle Children's Autism Center, Seattle, WA, (4)Department of Psychiatry and Behavioral Sciences, University of Washington, Seattle, WA, (5)Psychiatry and Behavioral Sciences, University of Washington, Seattle, WA

---

**Background:** Nearly 40% of individuals with autism spectrum disorder (ASD) are diagnosed with at least one comorbid anxiety disorder (van Steensel, Bögels, & Perrin, 2011). The onset of the COVID-19 pandemic and subsequent containment procedures resulted in high levels of anxiety for many people worldwide (e.g., Shaw et al., 2020). Additionally, individuals with pre-existing anxiety disorders may have experienced an increase in anxiety symptoms (Taylor & Asmundson, 2020). Little is known, however, about how the pandemic impacted anxiety levels in children with ASD. Our study sought to clarify whether children with ASD presenting for group cognitive behavioral therapy (CBT) demonstrated higher levels of anxiety after the onset of the global pandemic.

**Objectives:** To determine anxiety symptom severity among children with ASD presenting for Facing Your Fears (FYF) group CBT intervention in an outpatient clinic, and examine group differences in baseline child anxiety symptoms between pre and post-pandemic groups. We hypothesized that children presenting for FYF after the onset of the COVID-19 pandemic would demonstrate significantly greater overall anxiety symptoms compared to children presenting for FYF prior to COVID-19.

**Methods:** A total of 56 children and their parents presented for FYF group anxiety treatment. These were divided into those who presented for in-person group ( $n = 42$ ) before the onset of the pandemic versus telehealth ( $n = 14$ ) after the onset of the pandemic. All children had a confirmed diagnosis of ASD, cognitive functioning broadly within the average range, and at least one anxiety diagnosis. Twenty-five patients ( $M_{Age} = 10.24$ ,  $SD_{Age} = 1.66$ ) were included in this analysis; individuals who did not complete measures were excluded ( $n = 31$ ). Pre-treatment (baseline) anxiety symptoms were measured via parent-rated Multidimensional Anxiety Scale for Children, Second Edition (MASC-2; March, 2012); total anxiety  $T$ -scores were examined.

**Results:** Children entering FYF presented, on average, with anxiety symptoms in the *Very Elevated* range on the MASC-2 ( $M = 72.92$ ,  $SD = 10.49$ ). Independent samples  $t$ -tests were conducted to compare parent-reported MASC-2 total scores across pre- and post-COVID groups. Results indicated there were no significant differences in baseline MASC-2 total scores pre-COVID ( $n = 16$ ;  $M = 71.87$ ,  $SD = 11.68$ ) and post-COVID ( $n = 9$ ,  $M = 74.77$ ,  $SD = 8.27$ ),  $t(23) = -0.65$ ,  $p = .51$ .

**Conclusions:** In our sample, parent-reported anxiety severity among children with ASD did not significantly change after the onset of the COVID-19 pandemic. While some research suggests parent-reported anxiety about the pandemic and containment procedures is higher among children with ASD than typically-developing peers (Amorim et al., 2020), this may not be a significant departure from already-high baseline anxiety symptoms common among this population. In fact, others suggest that children with ASD and average cognitive skills may demonstrate improvements in overall mental health without the social and sensory demands of pre-COVID-19 learning environments (Reicher, 2020). Though our findings did not demonstrate an exacerbation of baseline anxiety symptoms in children with ASD relative to pre-COVID-19 cohorts, it does indicate a continued need to prioritize anxiety treatment for this population, as anxiety remains clinically significant.

**427.044 (Poster)** Virtual Emotion Regulation Treatment for Children Ages 8-12 with ASD: An Intensive, Video Based, Parent-Assisted Program Pilot

**R. Shaffer<sup>a</sup>**, **M. Coffman<sup>a</sup>**, **L. M. Schmitt<sup>b</sup>**, **D. L. Reisinger<sup>c</sup>** and **S. Randall<sup>b</sup>**, (1)Division of Developmental and Behavioral Pediatrics, Cincinnati Children's Hospital Medical Center, Cincinnati, OH, (2)Virginia Tech, Blacksburg, VA, (3)Cincinnati Children's Hospital Medical Center, Cincinnati, OH

**Background:** Regulating Together is an evidence-based intervention for youth with ASD and co-occurring emotion dysregulation (ASD+ED; (Shaffer et al., 2018). Youth with ASD+ED have higher rates of psychiatric hospitalizations, school disciplinary action, failed transitions, and use of psychotropic medications compared to their typical peers (Mazefsky et al., 2013). Due to the severity of these concerns, school- and outpatient-based programs are often not equipped to deal with this population, and specialized services often have extensive waitlists. There is a pressing need for interventions that can be widely and easily accessed for individuals with ASD given the relative lack of resources in many rural and underprivileged areas, a need that was further exacerbated by the COVID-19 pandemic.

**Objectives:** To assess satisfaction, feasibility, and efficacy of a virtual treatment for ASD+ED.

**Methods:** A virtual group program was offered to 8-12-year-old children with ASD+ED, with synchronous caregiver groups via Zoom and caregiver facilitated child videos with children ( $n=12$ ; 72.2% males). We completed a within-subjects trial with a screening visit, 5-week baseline period, 5-week intervention period, post treatment, and 5- and 10-week follow up. Adaptations were made to the curriculum and delivery based on family feedback and expert consultation. All participants received caregiver and child workbooks before the start of the group. Child videos taught the material with guided pauses for caregivers to discuss the material covered and complete activities. Caregivers completed satisfaction surveys post-treatment. Feasibility was assessed with enrollment and attendance rates. Initial efficacy was assessed with the Aberrant Behavior Checklist-Community (ABC), Emotion Dysregulation Inventory (EDI), Flexibility Scale (FS) and clinician rated CGI-I.

**Results:** At submission, two groups completed treatment, with 10-week follow-up visits completed for one group and post-treatment visits completed for the second group. Both groups will have completed 10-week follow-ups at the time of the conference. Caregiver education included: 25% high school graduate, 41.6% college graduate, and 33.3% advanced graduate degree. Annual household income included: 8.3% \$20,000-40,000, 33.3% \$40,001-60,000, 25% \$60,001-90,000, and 33.3% over \$90,000. At the completion of treatment, 41.7% were Much Improved and 58.3% were Minimally Improved on CGI-I. No significant changes from screen were demonstrated during the baseline period for any measures. However, comparisons between baseline and post treatment showed improvement (EDI-Reactivity:  $t(11)=2.09$ ,  $p=0.04$ , Cohen's  $d=0.86$ , trending; EDI-Dysphoria:  $t(11)=1.87$ ,  $p=0.07$ ,  $d=0.76$ ; Flexibility Scale Total:  $t(11)=2.32$ ,  $p=0.03$ ,  $d=0.95$ ; ABC-Irritability= $t(11)=1.72$ ,  $p=0.10$ ,

$d=0.70$ ). There was a 100% retention rate of youth who started the program, 93.3% attendance rate, and 82.5% completion of video material with children. Additionally, 100% of parents reported being very satisfied with the program.

**Conclusions:** We created a virtual version of an established intervention for ASD+ED. Satisfaction by caregivers was high and the retention rate was 15% improved for virtual versus in-person. Participants demonstrated improvement in ED, similar to our in-person treatment results. Despite very promising preliminary findings, our initial sample only included 12 children with ASD, which limits our ability to determine efficacy of our virtual program. In addition, because data was collected during the COVID-19 pandemic, participants' stress response, and emotion dysregulation in general, were likely impacted.

## Interventions - Pharmacologic

### PANEL DISCUSSION — INTERVENTIONS - PHARMACOLOGIC

#### Panel 217 - Mechanistic Biomarkers of E:I Dynamics and Nextgen Clinical Trials with Arbaclofen

**Panel Chair: Paul Wang**, *Simons Foundation / CRA, New York, NY*

Arbaclofen is a GABA-B receptor agonist and is hypothesized to have beneficial effects in ASD by moderating excitatory:inhibitory dynamics. It shows rescue effects in multiple animal models of ASD, from the cellular to the behavioral level, but a first generation of clinical trials failed on their primary endpoints. These trials were limited by their failure to include biomarker measures of drug action, and by their broad inclusion criteria. In fact, post-hoc analyses of the trial data suggested that the drug might be beneficial in a subset of individuals. In this symposium, we will present the results of new, clinical biomarker studies that explore the effects of arbaclofen on sensory phenomena that are known to be mediated by the dynamic interplay of excitatory and inhibitory neurotransmission. These investigations use psychophysical, electrophysiologic, and neuroimaging experimental approaches. In addition, we will describe two new clinical trials of arbaclofen that incorporate refinements in trial design, to better address placebo effects and to account for the restricted range of sensitivity of standard outcome measures. Together, these mechanistic biomarkers and refinements in "NextGen" clinical trial design have potential to identify a subset of individuals with ASD for whom arbaclofen may be beneficial.

**217.001** (*Panel Discussion*) GABA-B Gating of Perceptual Awareness during Binocular Rivalry  
**C. Robertson<sup>1</sup>**, *J. Mentch<sup>2</sup>, A. Spiegel<sup>3</sup> and C. Ricciardi<sup>4</sup>*, (1)*Psychological and Brain Sciences, Dartmouth College, Hanover, NH*, (2)*Massachusetts Institute of Technology, Cambridge, MA*, (3)*Johns Hopkins University, Baltimore, MD*, (4)*MIT, Cambridge, MA*

**Background:** During binocular rivalry, two dichoptically-presented images are suppressed from perceptual awareness in alternation. Computational models of rivalry (Laing and Chow, 2002; Seely et al., 2011; Said and Heeger, 2013) and magnetic resonance spectroscopy research (Robertson et al., 2016) suggest that the depth of perceptual suppression is governed, in part, by the strength of interocular inhibition in visual cortex. Further, rivalry dynamics are altered in the brains of adult individuals with autism (Robertson et al., 2013; Spiegel et al., 2019; Robertson et al., 2016). As a result, rivalry has been suggested as a noninvasive perceptual marker of inhibitory signaling in visual cortex, and its putative alteration in autism.

**Objectives:** Here, we present causal, pharmacological tests of the impact of GABAergic inhibition on rivalry dynamics, and the contribution of specific GABA receptors to these dynamics.

**Methods:** Neurotypical adults participated in three separate studies investigating the effects of GABA modulators on binocular rivalry dynamics: Study 1 GABA A modulator clobazam, N = 21; Study 2 GABA B modulator arbaclofen, N = 22; Study 3 (arbaclofen replication study), N = 22. Each study took part over 3 days: practice session / health assessment (day 1) and two experimental days (day 2-3). On each of the experimental days, a participant was given either a drug or a placebo (within-subjects, crossover design), and participated in a short binocular rivalry experiment after the drug had come into effect.

**Results:** We found that drugs that modulate the two dominant GABA receptor types in the brain, GABAA (clobazam) and GABAB (arbaclofen), increase perceptual suppression during rivalry relative to a placebo. Crucially, these results could not be explained by changes in reaction times or response criteria, as determined through rivalry simulation trials, suggesting a direct and specific influence of GABA on perceptual suppression. A full replication study of the GABAB modulator reinforces these findings.

**Conclusions:** All in all, these results provide direct evidence for a causal link between GABAergic inhibition and binocular rivalry and implicate specific GABA receptors (GABA A and GABA B) in perceptual suppression. More broadly, these results identify binocular rivalry as a simple yet powerful perceptual tool to index GABAergic drug response in the brain, which may further research on psychiatric conditions in which neural inhibition is thought to be affected.

**217.002** (*Panel Discussion*) Brain Response to Gabab Receptor Modulation with Arbaclofen in Adults with and without ASD

---

**Background:** Differences in pathways controlling neural excitation (E) and inhibition (I), especially GABAergic circuits, in ASD are thought to contribute to differences in sensory sensitivities, repetitive behaviours and social communication difficulties in ASD. However, the evidence has been largely indirect, coming from preclinical models, genetics and correlational studies carried out at a single (cross-sectional) timepoints.

**Objectives:** Here we directly tested the hypothesis that GABAergic neural pathways are *functionally* distinct in individuals with ASD.

**Methods:** We examined the brain response to GABA<sub>B</sub> modulation with the agonist arbaclofen in 48 adults with (n = 24) and without ASD (n = 24) at 3 levels: i) 'Local' sensory processing in visual cortex was examined using a visual contrast EEG task; ii) Regional tissue levels of GABA metabolites were quantified using Magnetic Resonance Spectroscopy (MRS); iii) Network level functional connectivity was assessed using BOLD fMRI. Data were collected following a single oral dose of either placebo, low (15mg) dose arbaclofen or high (30mg) dose arbaclofen. The order of administration was randomized and double blind.

**Results:** In neurotypical controls, in the visual task, the response to foreground stimuli increased with increasing foreground contrast and decreasing background interference. In ASD all stimuli had equal salience regardless of contrast or background interference. In addition, the neurotypical relationship between MRS measured occipital GABA and SSVEP elicited by maximum foreground contrast during maximum background interference was absent in autistics. This implied that GABA modulates visual perception differently in people with and without ASD. We confirmed this by showing that visual processing differences in ASD were abolished by (high dose) arbaclofen. In contrast, arbaclofen disrupted the control response profile. A differential group response to arbaclofen was also evident at the brain network level. Arbaclofen significantly lowered intrinsic functional connectivity in a subnetwork comprising regions within dorsal attention and salience networks, including the medial prefrontal cortex, in individuals with ASD but not in neurotypical controls.

**Conclusions:** Thus, the autistic brain is differentially responsive to GABAergic pharmacological challenge. This has implications for development of pharmacological interventions in ASD. We show for the first time that a visual processing mechanism which is GABA dependent in neurotypicals, is altered in ASD. We also show that targeting the GABA<sub>B</sub> receptor removes these differences in visual processing between adults with and without ASD and alters the activity of brain networks in ASD. We will discuss the utility of these approaches to improve our understanding of brain biology in ASD and capture individual pharmacological responses to candidate interventions. How our results have application to clinical trials will be considered.

**217.003 (Panel Discussion) Tactile Perception As a Potential Target for Gabaergic Intervention in Neurodevelopmental Disorders**

*N. A. Puts<sup>1</sup>, J. L. He<sup>1</sup>, G. Oeltzschner<sup>2</sup>, E. Wodka<sup>3</sup>, R. A. Edden<sup>2</sup> and S. H. Mostofsky<sup>3</sup>, (1)Institute of Psychiatry, Psychology and Neuroscience, London, United Kingdom, (2)Russell H. ---

**Background:** Sensory difficulties are common in autism and are being increasingly recognized. 70-90% of those with ASD report having sensory difficulties with tactile difficulties being most common. Sensory difficulties are described as severely debilitating and present across the lifespan. Touch plays an important role in perception of the world, as well as in early social development. It is well-established that encoding of tactile information relies on homeostatic balance between excitation and inhibition (E-I balance). The excitation-inhibition (E-I) balance theory of ASD suggests that an increase in excitatory and/or decrease in inhibitory signaling in key brain-regions in ASD results in a hyper-excitable system which may be less efficient at processing sensory signals. Given the well-known role of E-I in driving the neuronal response to touch, early emergence, and potential impact on social difficulties, the tactile domain is a promising domain for establishing stratification and intervention.

**Objectives:** Interestingly, alterations of tactile processing have also long been identified in other neurodevelopmental disorders, including attention-deficit/hyperactivity disorder (ADHD). However, the extent to which these alterations are disorder-specific,

rather than disorder-general, and how they relate to the core symptoms of each disorder, remains unclear. Furthermore, it remains unclear how differences in E-I balance lead to differences in perception, and subsequently, to altered reactivity and social difficulties. In this talk I will provide an overview linking difficulties in tactile processing in ASD (and ADHD) to differences in E-I balance and to the core symptoms of ASD, motivating the tactile domain as a promising target for targeted intervention.

**Methods:** First, I will describe psychophysical work measuring tactile detection, discrimination, and order judgment thresholds between a large sample of children with ASD, ADHD, ASD + ADHD combined and typically developing controls. Then, I will present work by our lab and others, linking differences in tactile processing to brain measures of E-I balance as obtained using Magnetic Resonance Spectroscopy (MRS). Edited MRS can be used to provide measures of the relative concentration of GABA and Glx (Glutamate + glutamine) in specific brain regions as proxy markers of excitation and inhibition respectively.

**Results:** We show that difficulties at the perceptual level are disorder-specific and are specifically related to higher-level clinical symptoms of each disorder, with clear links to different inhibitory mechanisms (such as lateral inhibition, and feed-forward inhibition). Imaging data shows that region-specific alterations in MRS-markers of excitation and inhibition are associated with both difficulties in tactile perception (as measured through psychophysics) and tactile hyper- and hyporeactivity.

**Conclusions:** These data provide strong empirical support for increased excitation and reduced inhibition in ASD and provide a clear link between measures of E-I and the sensory symptoms of ASD at the behavioural and perceptual levels. Together, these data motivate GABAergic mechanisms as a mechanistically-informed target for intervention with clearly delineated perceptual and clinical outcomes.

#### 217.004 (Panel Discussion) Clinical Trial Design for Evaluating Arbaclofen in Children and Adolescents with ASD

**Background:** Current pharmacological treatments for ASD are focused on comorbid conditions such irritability, ADHD, and others. However, treatment for the core symptoms of ASD remains a challenge. To date, approximately only 20 RCTs have looked into bio-treatments for the core symptoms in ASD, with just a handful of those correlating positively with changes at the biochemical/imaging level (Parellada et al., in prep). An excitatory-inhibitory imbalance at the neural level has been pointed out as a plausible cause for the condition. Therefore, restoring this equilibrium could potentially improve core deficits in ASD.

**Objectives:** To study the efficacy and safety of arbaclofen, a GABA<sub>B</sub> agonist (which inhibits presynaptic release of glutamate, and postsynaptic transmission), for the treatment of social function in ASD within a network of academic centers.

**Methods:** In the format of a randomized, double-blind, placebo-controlled study, we will test arbaclofen in a sample of 210 high functioning individuals (130 + 90 from our Canadian counterpart, the POND consortium) from 5-17 years of age. We will a) use measures of EEG to explore potential predictive biomarkers of change, or surrogate outcome measure, b) explore genetic markers of response to treatment, and c) explore the use of digital technologies to monitor treatment changes.

*Results:* Three European countries have successfully been approved by their respective ethics and medical agencies to conduct the trial. At the moment, recruitment is ongoing, with almost a third of the sample already recruited. The protocol works well, showing good compliance from the families. No serious adverse events have been reported.

*Conclusions:* The successful setup and running of this RCT is a world-wide class success from an academic perspective. Results will inform future treatments for core ASD symptoms in high functioning individuals, which ultimately may lead in to an improved quality of life.

## ORAL SESSION — INTERVENTIONS - PHARMACOLOGIC

### Oral 303 - Pharmacological Treatment Studies

#### **303.001** (Oral) Oxytocin Increases Amygdala Response to Emotional Faces Among Autistic Women

**T. L. Procyshyn<sup>1</sup>, M. V. Lombardo<sup>2</sup>, B. Auyeung<sup>3</sup>, M. C. Lai<sup>1</sup>, S. Crockford<sup>4</sup>, J. B. Deakin<sup>5</sup>, S. Soubramanian<sup>1</sup>, A. Sule<sup>6</sup>, S. Baron-Cohen<sup>1</sup> and R. A. Bethlehem<sup>1</sup>,** (1)Autism Research Centre, Department of Psychiatry, University of Cambridge, Cambridge, United Kingdom, (2)Center for Neuroscience and Cognitive Systems, Laboratory for Autism and Neurodevelopmental Disorders, Istituto Italiano di Tecnologia, Rovereto, Italy, (3)University of Edinburgh, Edinburgh, United Kingdom, (4)Autism Research Centre, Department of Psychiatry, University of Cambridge, Cambridge, ON, United Kingdom, (5)University of Cambridge, Cambridge, United Kingdom, (6)Cambridgeshire and Peterborough NHS Foundation Trust, Cambridge, United Kingdom, (7)Liaison Psychiatry, South West London St. George's Mental Health NHS Trust, Carshalton, United Kingdom, (8)Department of Psychiatry, University of Cambridge, Cambridge, United Kingdom

**Background:** Oxytocin administration has attracted interest for its potential to alleviate the social challenges experienced by autistic people, including its ability to enhance eye contact and emotion recognition as well as to reduce social anxiety. The influence of oxytocin on the amygdala—a region considered a hub of the social brain—may underlie such behavioural effects. The effects of oxytocin on the amygdala are well-documented in neurotypical individuals, individuals with anxiety and trauma-related disorders, and animal models. By contrast, few studies have examined the effects of oxytocin on amygdala activation in autistic individuals, and those that have involved only male participants.

**Objectives:** To examine the effect of oxytocin on amygdala activation among autistic and non-autistic women during a socially-relevant fMRI task known to induce a robust amygdala response (i.e. Hariri task). Furthermore, we explored how effects of oxytocin on amygdala response varied with autism diagnosis and trait social anxiety.

**Methods:** Thirty-seven women (aged 18-50 years; 16 with an autism diagnosis) completed a modified version of the Hariri task once after receiving placebo and once after receiving 24IU intranasal oxytocin. The task required participants to match emotions or shapes (6 blocks of shape-matching, 5 blocks of face-matching, each block comprised 6 trials). Participants were scanned on a 3T Siemens MRI scanner using a multi-echo sequence (TR = 2400 ms, TE = 12, 29, 46 ms, interleaved, 140 volumes, slice thickness 3.8 mm). Pre-processing was carried out using the ME-ICA pipeline to optimally combine echoes and denoise data. Subsequent task analysis was performed using FEAT (FMRIB Software Library v6.0, cluster-corrected  $p = 0.05$ ,  $z > 2.3$ ). Left and right amygdala were defined from the Harvard-Oxford subcortical atlas, and voxel-based analyses were carried out to compare activation was compared between groups and drug conditions. The relationship was also explored between change in amygdala activation between drug conditions and Liebowitz Social Anxiety Scale (LSAS) questionnaire score.

**Results:** Relative to matching shapes, matching emotional faces induced strong bilateral amygdala activation in both autistic and non-autistic women. A significant Group  $\times$  Drug interaction was observed (left amygdala: 102 voxels,  $Z$ -max = 3.8, cluster-corrected  $p = 0.008$ , MNI coordinates of peak activation: -32 -4 -24; right amygdala: 87 voxels,  $Z$ -max = 4.1, cluster-corrected  $p = 0.012$ , MNI coordinates of peak activation: 18 -4 -16), such that autistic women showed increased left amygdala activation (Figure 1a) whereas non-autistic women showed decreased right amygdala activation (Figure 1b). Among all participants LSAS score was positively correlated with change in left amygdala activation, meaning that activation increased in the oxytocin relative to placebo condition among women with higher social anxiety ( $r=0.32$ ,  $p=0.06$ ). As autistic women had higher average LSAS scores than non-autistic women, this correlation was confirmed among non-autistic women only ( $r=0.44$ ,  $p=0.05$ ).

**Conclusions:** Oxytocin differentially affected amygdala reactivity to emotional faces in autistic compared to non-autistic women, which is consistent with findings from studies involving autistic men. Interestingly, our results suggest that oxytocin also differentially influences amygdala response to emotional facial stimuli in women with high versus low social anxiety.

**303.002** (Oral) Social and Non-Social Effects of Oxytocin: Enhancement of Approach Motivation Towards All Emotionally-Evocative Stimuli

**J. Prinsen**<sup>1,2</sup>, **A. Taillieu**<sup>1</sup>, **N. Daniels**<sup>1,3</sup>, **J. R. Soriano**<sup>1</sup> and **K. Alaerts**<sup>1,3</sup>, (1)Rehabilitation Sciences, KU Leuven, Leuven, Belgium, (2)Leuven Autism Research Consortium (LAuRes), KU Leuven, Leuven, Belgium, (3)Leuven Autism Research Consortium (LAuRes), Leuven, Belgium

---

**Background:** The neuropeptide oxytocin is suggested to exert a pivotal role in a variety of complex social behaviors, for example by modulating approach-avoidance motivational tendencies during perception of social events. Recently however, its social specificity has been challenged by the General Approach-Avoidance hypothesis of Oxytocin (GAAO) in order to account for several observations of non-social effects of oxytocin.

**Objectives:** To investigate the effect of a single dose of intranasal oxytocin (24IU) on behavioral (adjustment of viewing time) and neural (EEG-based frontal alpha asymmetry) indices of approach-avoidance motivation during perception of social and non-social affective stimuli, in order to test predictions based on the GAAO account.

**Methods:** 52 healthy adult men (18-35 years) participated in this placebo-controlled study with parallel design. Before and after nasal spray administration, participants were presented with a series of pictures (selected from the Nencki Affective Picture System database), while frontal alpha asymmetry (indexing neural approach-avoidance) was obtained from EEG recordings. Additionally, participants were able to prolong (approach) or shorten (avoid) the viewing time of each picture, allowing to obtain a measure of behavioral approach-avoidance. The presented pictures were individually rated in terms of valence (positive or negative) and sociality (social or non-social) on a visual analog scale. Ratings of sociality of the stimuli were subjected to a median split, yielding for each participant a self-rated social and non-social category. Ratings of valence were subjected to a quartile split, yielding for each participant a set of negative and positive stimuli with high versus low emotional evocativeness (i.e. valency intensity).

**Results:** Irrespective of the stimulus' social nature (or valence intensity), intranasal oxytocin maintained behavioral approach towards negatively valenced pictures (compared to decreased viewing time of negative stimuli in the placebo group). At the neural level, oxytocin specifically amplified approach-related motivational saliency of stimuli that were self-rated to have high personal relevance, but irrespective of their social nature or direction of rated valence (positive or negative).

**Conclusions:** These findings further challenge the social specificity of oxytocin and provide further evidence for a general role of oxytocin in modulating approach-avoidance motivational tendencies. In particular, our data indicate that oxytocin may specifically promote approach-related motivational tendencies towards sensory input that is of high personal relevance, irrespective of the stimulus' valence or social/non-social nature. This mechanism may provide an entry point for reconciling prior observations of oxytocin's social, non-social or even anti-social effects.

**303.003** (Oral) Functional Connectivity Differences in Autism Spectrum Disorder Associated with SSRI Medication

**J. Bartolotti**<sup>1,2</sup> and **M. W. Mosconi**<sup>1,3</sup>, (1)Kansas Center for Autism Research and Training (K-CART), University of Kansas, Lawrence, KS, (2)Life Span Institute, University of Kansas, Lawrence, KS, (3)Clinical Child Psychology Program, Schiefelbusch Institute for Life Span Studies, University of Kansas, Lawrence, KS

---

**Background:** Over half of children with autism spectrum disorder (ASD) are prescribed psychotropic medication; Selective Serotonin Reuptake Inhibitors (SSRIs) are one of the most commonly prescribed, at 25%. SSRIs are primarily used in ASD to treat commonly comorbid anxiety or depression with variable effectiveness, but they may also be effective in managing some core symptoms of ASD, including RRBs. Despite evidence that SSRIs have different impacts on brain function across psychiatric disorders and evidence for changes to brain connectivity in individuals with ASD associated with psychotropic medication use, the impact of SSRIs on brain function in ASD is not known.

**Objectives:** Our goal was to identify associations between SSRI medication use and functional connectivity of select brain networks involved in emotion processing and regulation in individuals with ASD.

**Methods:** Three samples matched on age, sex, and IQ were identified from the Autism Brain Imaging and Data Exchange. 1) ASD+SSRI (N=28) individuals were taking an SSRI and no other psychoactive medications, and had no comorbid disorders; 2) ASD-Unmedicated (N=27) individuals reported no medications or comorbidities and were matched with the ASD+SSRI individuals on ASD severity; 3) typically developing (N=28) individuals had no psychiatric or developmental issues. Network analysis using GIMME (Group Iterative Multiple Model Estimation) was used to identify differences in directed, weighted functional connectivity between groups at rest in bilateral prefrontal cortex, including dorsomedial (dmPFC), ventromedial (vmPFC), dorsolateral (dlPFC), and ventrolateral (vlPFC) areas, anterior cingulate dorsal (dACC) and rostral (rACC) divisions,

and two subcortical ROIs in dorsal striatum (DS) and ventral striatum (VS). We report pathways that showed significant functional connectivity in  $\geq 50\%$  of at least one subject group, and for pathways common to all groups, we compare the strengths of individuals' connections between groups.

**Results:** All three groups showed directed functional connectivity in dACC-rACC, vmPFC-rACC, dlPFC-vlPFC, and VS-DS pathways. The TD and ASD+SSRI groups each showed dmPFC-dACC functional connectivity, but the ASD-unmedicated individuals did not show connectivity of this pathway. In contrast, the ASD-unmedicated group showed dmPFC-rACC connectivity whereas neither the TD or ASD+SSRI individuals showed connectivity of this pathway (Figure 1). The strength of the vmPFC-rACC connection was lower for the two ASD groups compared to TD, with no difference between ASD+SSRI and ASD-Unmedicated.

**Conclusions:** These results indicate that SSRI use in ASD is associated with differences in PFC-ACC functional connectivity. Findings that dmPFC-dACC functional connectivity is reduced in unmedicated but not medicated individuals with ASD suggests that this pathway, which is involved in cognitive control, may be normalized by SSRIs. In contrast, findings that vmPFC-rACC connectivity is reduced in both ASD groups relative to TD individuals suggests that this pathway is unaffected by SSRIs in ASD, which is dissimilar to findings from non-ASD individuals using SSRIs. These results highlight the need to assess the unique impacts of medication use on brain function in individuals with ASD.

### 303.004 (Oral) Clinical and Biological Characterization of a New, Biologically-Defined, Subgroup of Patients with ASD: ASD Phenotype 1 (ASD-Phen1)

**S. Baudouin<sup>1</sup>, M. Bosio<sup>2</sup>, L. Boccuto<sup>3</sup>, J. M. Hyvelin<sup>1</sup>, L. Perez-Cano<sup>2</sup>, E. Guney<sup>2</sup>, A. Tierney<sup>4</sup>, R. Pauly<sup>4</sup>, S. A. Skinner<sup>3</sup>, J. Cachat<sup>1</sup>, A. Souza<sup>1</sup>, D. Charvin<sup>3</sup> and L. Durham<sup>3</sup>,** (1)Drug Development Unit (DDU), STALICLA SA, Geneva, Switzerland, (2)Discovery and Data Science (DDS) unit, STALICLA SL, Barcelona, Spain, (3)Greenwood Genetic Center, Greenwood, SC, (4)Greenwood Genetic Center, Greenwood, SC, (5)STALICLA SA, Geneva, Switzerland

---

#### Background:

Autism Spectrum Disorder (ASD) is the umbrella term for diseases and disorders with considerable clinical and pathophysiological variability. Such heterogeneity is a major hindrance to the development of diagnostic tests and pharmacological treatments. The identification of novel clinical and biological criteria for the stratification of patients with ASD represents a way to address this issue and thereby increase the likelihood of success in the development of therapeutics. Using systems biology analyses and integration of network analysis, machine learning and in-silico modeling techniques, we identified a new subgroup of patients with ASD, referred to as ASD Phenotype 1 (ASD-Phen1).

#### Objectives:

The goal of our study was to validate the capacity of STALICLA's computational system biology platform to accurately identify association of pathological or physiological features predictive of clinically and biologically distinct subgroup of patients with Autism when compared with non-phenotypically enriched populations with idiopathic ASD and typically developing (TD) individuals.

#### Methods:

The clinical set of signs and symptoms identified by STALICLA to define ASD-Phen1 has been used and applied in an observational clinical study conducted at the Greenwood Genetic Center (GGC) in an original cohort of 313 patients with idiopathic ASD out of which 90 patients were further selected based on full availability of early life health records. Blood samples were also collected during this study and lymphoblastoid cell lines (LCLs) were derived from patients with ASD-Phen1, patients with ASD not meeting clinical criteria for ASD-Phen1 (ASD-nonPhen1) and TD individuals. The Phenotype MicroArray technology was used to determine the energy metabolism profile of the different LCLs. RNA-Seq experiments were also performed to compare gene expression profiles in the three groups (ASD-Phen1, ASD-nonPhen1, TD). Such a hypothesis-free approach was designed to allow the unbiased validation of STALICLA's models.

#### Results:

The observational clinical study confirmed the existence of a specific subpopulation matching the clinical enrichment criteria defined by STALICLA's computational biology modeling, counting for approximately 25% of the enrolled participants. Metabolic analyses revealed that LCLs derived from patients with ASD-Phen1 have a distinct bioenergetic profile when

compared to LCLs from patients with ASD-nonPhen1 or TD individuals. The differential gene expression analyses also confirmed that patients with ASD-Phen1 are more homogeneous phenotypically than the wide ASD population, and that ASD-Phen1 has a specific biological signature.

#### Conclusions:

These clinical and experimental data validate the existence of a convergent pathophysiology for the ASD-Phen1 subgroup of patients, significantly different from other idiopathic ASD patients as well as from control individuals. Three independent experiments and data types confirmed this biological validation: metabolic, metabolomic and RNA-seq data analyses. These results supported the development of a precision medicine treatment specifically for patients with ASD-Phen1.

## POSTER SESSION — INTERVENTIONS - PHARMACOLOGIC

### Poster 428 - Interventions - Pharmacologic Posters

**428.001** (Poster) Antipsychotics, Dysphagia, Aspiration Pneumonia, Bowel Obstruction and Related Surgeries in Adults with Severe Developmental Disabilities

**J. A. Hellings<sup>1</sup>, S. C. Singh<sup>2</sup> and S. Singh<sup>3</sup>,** (1)Psychiatry, University of Missouri Kansas City and Truman Behavioral Health, Kansas City, MO, (2)University of Missouri-Kansas City, Kansas City, MO, (3)Harbor-UCLA Medical Center, Torrance, CA

**Background:** Dysphagia, aspiration pneumonia and bowel obstruction are serious side effects of antipsychotic medications. The FDA recently increased warnings for clozapine producing constipation and bowel obstruction, however both typical and atypical antipsychotics can produce such problems, especially in high doses. Individuals with severe developmental disabilities including cerebral palsy or minimally verbal status appear more prone to such side effects, but published information is sparse.

**Objectives:** To examine pharmacologic treatments and dosing, including but not limited to antipsychotics and selective serotonin reuptake inhibitors that inhibit antipsychotic metabolism via CYP2D6, predisposing to such problems in individuals with severe DD. Also to examine outcomes of any drug taper attempts as they impacted dysphagia and food intake.

**Methods:** We extracted cases from our IRB-approved Neuropsychiatry Clinical Database with a history of dysphagia, aspiration pneumonia and/or bowel obstruction. Data extracted includes age, race, gender, intellectual disability (ID) level, minimally verbal status, history of dysphagia/aspiration pneumonia/ bowel obstruction/surgeries for these including ostomy placement and feeding details. Antipsychotic medications and dosing were extracted from time of presentation and following any dosing reductions, and outcomes of such problems and feeding improvements.

**Results:** Thirteen adults met symptom inclusion criteria: 7 males, 6 females. Median age was 59 years, range 29-69 years, all but 2 were < 65 years. Two were African American and 11 Caucasian. One had borderline intellectual functioning and spastic quadriplegia; ID was moderate in 1, severe in 7, and profound in 4. All but 4 were minimally verbal. Nine of 13 (69.2%) had dysphagia, of which 8 had a history of aspiration pneumonia (61.5%). Five of 13 (38.5%) had a bowel obstruction history. Of the 13 cases, 7 (53.8%) had prior surgery for bowel resections/ ostomy placement. All 13 received moderate or high dose antipsychotics: olanzapine in 4: 40mg, 40 mg, 30mg and 25mg daily; clozapine in 3: 750mg (plus paroxetine 20mg), 400mg and 375mg daily; quetiapine in 3: 800mg (plus paroxetine 30mg), 600mg, 400mg daily; and risperidone in 1: 8 mg daily. Two received olanzapine plus a selective serotonin reuptake inhibitor (SSRI) inhibiting CYP2D6, increasing antipsychotic dose: olanzapine 10mg and fluoxetine 80mg daily; olanzapine 20mg and sertraline 150mg daily. Some cases in whom the antipsychotic and/or SSRI was tapered down gradually had improved swallowing on repeat video swallow and restoration of normal feeding or less thickened liquids (n=2) or G-tube removal (n=1). In other cases, guardians were not willing for medications to be tapered. In one case the subject described fear of eating again.

**Conclusions:** Individuals with severe developmental disabilities including those with cerebral palsy or who are minimally verbal receiving high dose antipsychotics are prone to dysphagia, aspiration pneumonia, bowel obstruction and surgeries including at a young age. Subsequent parenteral feeding removes pleasure of eating and drinking normally. Gradual taper of such medications, including of any CYP2D6-inhibiting SSRIs may improve normal feeding outcomes. High doses of antipsychotics should be avoided in such individuals.

# Medical and Psychiatric Comorbidity

## PANEL DISCUSSION — MEDICAL AND PSYCHIATRIC COMORBIDITY

### Panel 232 - Novel Findings to Inform Suicide Prevention for Autistic Individuals

**Panel Chair:** Brenna Maddox, *University of North Carolina-Chapel Hill, Chapel Hill, NC*

**Discussant:** Lisa Morgan, *American Association of Suicidology, Washington, DC*

The last decade has brought substantial progress in understanding the heightened risk of suicide in autistic people. Most research to date has focused on prevalence, risk factors, assessment, and screening. While this work has addressed many important questions, there is a dearth of research on what happens after an autistic person is determined to be at risk for suicide – how do we intervene appropriately and prevent suicide? The current panel focuses on this nascent area of suicide and autism research. Sarah Cassidy will present data from the first psychological autopsy study to identify how many people who died by suicide had an autism diagnosis or high autistic traits. Mirabel Pelton will discuss how the Interpersonal Theory of Suicide can inform suicide prevention efforts for autistic individuals. Anne Huntjens will present on an ongoing trial of dialectical-behavioral therapy for reducing suicidal thoughts and behaviors in autistic adults. Brenna Maddox will share key stakeholder insights about tailoring the Safety Planning Intervention for autistic adolescents and adults. Finally, Lisa Morgan, an autistic adult and suicide loss survivor, will lead a discussion about the practical implications of these novel findings and future directions for reducing suicide risk in autistic people of all ages.

**232.001 (Panel Discussion) Autism and Autistic Traits in Those Who Died By Suicide in the UK**

**S. A. Cassidy<sup>1</sup>, S. Au-Yeung<sup>1,2</sup>, A. Robertson<sup>3</sup>, H. Cogger-Ward<sup>1</sup>, G. Richards<sup>4</sup>, C. Allison<sup>5</sup>, L. Bradley<sup>6,7</sup>, R. Kenny<sup>8</sup>, R. O'Connor<sup>3</sup>, D. Mosse<sup>9</sup>, J. Rodgers<sup>10</sup> and S. Baron-Cohen<sup>1</sup>.** (1)School of Psychology, University of Nottingham, Nottingham, United Kingdom, (2)University of Oxford, Oxford, United Kingdom, (3)University of Glasgow, Glasgow, United Kingdom, (4)Newcastle University, Newcastle, United Kingdom, (5)Autism Research Centre, Department of Psychiatry, University of Cambridge, Cambridge, United Kingdom, (6)Coventry University, Coventry, United Kingdom, (7)University of Bedfordshire, Luton, United Kingdom, (8)University of Cambridge, Cambridge, United Kingdom, (9)Department of Anthropology and Sociology, SOAS University of London, London, United Kingdom, (10)Population Health Sciences Institute, Newcastle University, Newcastle upon Tyne, United Kingdom

#### Background

Autism and autistic traits are risk factors for suicide attempts, but no studies have yet explored the rate of autism (diagnosed and possible undiagnosed) in those who die by suicide or explored potentially unique risk factors for suicide in this group.

#### Objectives

First, to identify how many people who died by suicide in two regions of the UK between 2014-2017 had evidence of diagnosed autism or possible undiagnosed autism (high autistic traits). Second, to explore whether the circumstances and characteristics of those who died with evidence of autism (diagnosed or possible undiagnosed) were different to those with no evidence of autism. Third, to make recommendations for future suicide prevention efforts.

#### Methods

We conducted the first Psychological Autopsy (PA) study to consider evidence of autism and autistic traits, in two stages. *Stage 1:* 372 coroners' inquest records covering the period 2014-2017 from two regions of the UK, independently judged as likely suicide, were analysed for evidence that the person who died had diagnosed autism or undiagnosed possible autism (high autistic traits). Content analysis of the records identified risk markers. *Stage 2:* 40 interviews were conducted with: a) 29 next of kin of those who died from the coroners' cohort; and b) 11 next of kin recruited from public adverts where the person who died was likely to be autistic (diagnosed or undiagnosed). Interviews assessed the circumstances and characteristics of the person who died, in order to identify possible risk factors, and further evidence of autism and autistic traits was obtained using validated autism screening and diagnostic tools (SRS-2 and ADI-R).

#### Results

*Stage 1:* The total evidence of autism (possible/strong/definite; 10.75%) was significantly higher in those who died by self-harm or suicide than the 1.1% prevalence rate expected in the UK general alive population (including previously unknown [i.e. undiagnosed] cases) ( $\chi^2=31.31, p<0.001$ ; OR 11.08, 95% CI 3.92 – 31.31). This is 11 times higher than the rate of autism in the UK. *Stage 2:* 5 (17.24%) of the follow-up sample had possible/strong evidence of autism identified from the coroners' records in Stage 1. The PA interview/SRS identified evidence of *possible autism* in an additional 7 (24.14%), giving an overall rate of 12 (41.4%). However, *strong evidence* of autism was not confirmed, as none of the 12 met the cutoff for autism diagnosis on the ADI-R. The rate of possible autism in the coroners' cohort (n=12, 41.4%) was significantly higher than expected in the general alive population (1.1%) ( $\chi^2=12, p<0.001$ ; OR 19.76, 95% CI 2.36 – 165.84). Those with evidence of autism diagnosis or high autistic traits were significantly more likely to have experienced social isolation, to have been diagnosed with anxiety, and to have experienced increased recent disengagement from services before they died, compared to those without evidence of autism.

## Conclusion

Elevated autistic traits, in the range of clinical concern for possible autism, are significantly over-represented in those who die by suicide. Suicide prevention strategies must consider increased vulnerability of those with high autistic traits to established risk markers for suicide.

### 232.002 (Panel Discussion) Suicide Prevention in Autistic Adults: What Can We Learn from the Interpersonal Theory of Suicide?

*M. K. Pelton<sup>1</sup>, S. A. Cassidy<sup>2</sup>, A. Robertson<sup>3</sup>, H. Crawford<sup>4</sup>, S. Baron-Cohen<sup>5</sup> and J. Rodgers<sup>6</sup>, (1)Coventry University, Coventry, United Kingdom, (2)School of Psychology, University of Nottingham, Nottingham, United Kingdom, (3)University of Glasgow, Glasgow, United Kingdom, (4)Faculty of Health and Life Sciences, Coventry University, Coventry, United Kingdom, (5)Autism Research Centre, Department of Psychiatry, University of Cambridge, Cambridge, United Kingdom, (6)Population Health Sciences Institute, Newcastle University, Newcastle upon Tyne, United Kingdom*

## Background

Autistic people are more likely to experience suicidal thoughts and behaviours than non-autistic people but, to date, there is a weak evidence base for intervention. The Interpersonal Theory of Suicide (ITS) posits that suicidal thoughts result from experiencing both 'thwarted belongingness' (social isolation) and 'perceived burdensomeness' (social worthlessness). Existing research associates these concepts with mental health difficulties, social exclusion and poor quality of life in autistic adults, suggesting the ITS may be useful to understand suicide in this group.

## Objectives

This study had three objectives: 1) to explore whether the ITS describes similar pathways to suicidal thoughts and behaviours in autistic and non-autistic adults, 2) to examine whether questionnaire measurement properties were equivalent in autistic and non-autistic people and 3) to explore how symptoms of depression and ITS constructs interact with suicidal thoughts in autistic and non-autistic people.

## Methods

Data from 696 autistic and non-autistic people matched on age and gender (mean age 41.7, 58% female) were extracted from an online cross-sectional survey dataset of self-report questionnaires measuring thwarted belonging and burdensomeness (Interpersonal Needs Questionnaire-10), lifetime suicidality (Suicidal Behaviours Questionnaire revised, item 1), depression (Patient Health Questionnaire-9) and autistic traits (Autism Spectrum Quotient – Short Form). Moderated path analyses explored pathways from autistic traits to suicidal thoughts and behaviours; measurement invariance analysis explored equivalence of measurement properties and network analysis explored pathways through depression to suicidal thoughts in autistic and non-autistic people.

## Results

In both autistic and non-autistic people there was an indirect effect of autistic traits on suicidality through thwarted belonging and perceived burden, however, the association of each of these with suicidality was significantly attenuated by autism diagnosis. Table 1 shows that all items of the burdensomeness subscale and two items of the belonging subscale were non-invariant between autistic and non-autistic people. Network analysis (Figure 1) showed that, in both groups, thwarted belonging was indirectly connected to suicidal thoughts through depression whilst perceived burden was closely, directly connected to suicidal thoughts.

In the autistic group, depression symptoms were more closely, strongly inter-connected and symptoms of restlessness/ moving slowly were more closely, strongly connected to suicidal thoughts than in the non-autistic group.

## Conclusions

Results suggest, firstly, that addressing feelings of thwarted belonging and burdensomeness could help prevent suicide in autistic adults, such as promoting autism acceptance and meeting autistic peoples' support needs. Secondly, autistic people interpreted the questionnaire items asking about burdensomeness and thwarted belonging differently to non-autistic people. Conceptualizing how autistic people experience these feelings will be important for suicide prevention. Thirdly, in autistic and non-autistic people, thwarted belonging is a distal risk factor whilst perceived burden is a proximal risk marker for suicidal ideation. Promoting social belonging may protect against depression with suicidal ideation. In autistic people, depression symptoms interact more strongly than in non-autistic people suggesting suicidal thoughts may develop more quickly. The close connection of symptoms of restlessness/ moving slowly with suicidal thoughts in autistic people could inform autism-specific risk markers.

### **232.003** *(Panel Discussion)* The Effect of Dialectical Behavior Therapy in Autism Spectrum Patients with Suicidality and/or Self-Destructive Behavior: A Randomized Multi-Center Controlled Trial

*A. Huntjens<sup>1</sup>, W. van den Bosch<sup>2</sup>, B. Sizoo<sup>3</sup>, A. Kerkhof<sup>4</sup>, M. Huibers<sup>5</sup> and M. van der Gaag<sup>6</sup>, (1)VU University, Amsterdam, Netherlands, (2)Scelta, Apeldoorn, Netherlands, (3)Dimence, Deventer, Netherlands, (4)CLINICAL PSYCHOLOGY, Amsterdam Public Mental Health Research Institute, Amsterdam, Netherlands, (5)Amsterdam Public Mental Health Research Institute, Amsterdam, Netherlands, (6)Parnassia Psychiatric Institute, The Hague, Netherlands*

---

**Background:** Many patients with autism spectrum disorder (ASD) are treated in long-term specialized care. In this population, suicidal behavior troubles patients, families, and specialists in the field because it is difficult to treat. At present, there is no documented effective therapy for suicidal behavior in ASD. Dialectical Behavior Therapy (DBT) is an efficacious treatment program for chronically suicidal and/or self-harm behavior in patients with Borderline Personality Disorder. This study will evaluate the efficacy of DBT in patients with ASD and suicidal/ self- destructive behavior in a randomized controlled multisite clinical trial.

**Objectives:** The primary outcome is the level of suicidal ideation and behavior. The secondary outcomes are anxiety and social performance, depression, core symptoms of ASD, quality of life, and cost-utility. Emotion regulation and therapeutic alliance will be investigated for mediation effects.

**Method:** 128 patients with autism and suicidal and/or self-harming behavior will be recruited from specialized mental healthcare services and randomized into two conditions: 1) the DBT condition in which the participants have weekly individual cognitive behavioral therapy sessions and a 2.5 hour skills training group session twice per week, and 2) the treatment as usual condition which consists of weekly individual therapy sessions of 30-45 minutes with a psychotherapist or social worker. Assessments will take place at baseline, at post-treatment (6 months), and after a follow-up period of 12 months. The mediators will also be assessed at three months.

**Results:** DIASS is an ongoing study and there are no results yet. Based on the positive clinical observations, we have seen that patients and therapist benefits from DBT therapy. Patients build a life worth living and suicidal behavior decreases; therapist experience competence and less fear to treat people with suicidality. DIASS has already led to implementation of new care in the mental health care in the Netherlands.

**Conclusion:** The results from this study will provide an evaluation of the effectiveness of DBT treatment in patients with ASD on suicidal and/or self-harming behavior. The study is conducted in routine mental health services which enhances the generalisability of the study results to clinical practices.

### **232.004** *(Panel Discussion)* Tailoring an Evidence-Based Suicide Prevention Intervention for Use with Autistic Adolescents and Adults

*B. B. Maddox<sup>1</sup>, S. R. Crabbe<sup>2</sup>, K. Myhre<sup>2</sup>, D. S. Mandell<sup>3</sup> and S. Jager-Hyman<sup>2</sup>, (1)University of North Carolina-Chapel Hill, Chapel Hill, NC, (2)University of Pennsylvania, Philadelphia, PA, (3)Penn Center for Mental Health, University of Pennsylvania, Philadelphia, PA*

---

**Background:** Suicide is a leading cause of premature death in autistic people. Autistic individuals are significantly more likely to think about and attempt suicide than the general population. Yet no published research has examined the effectiveness of suicide interventions for autistic individuals. The Safety Planning Intervention (SPI), an evidence-based suicide prevention intervention,

may be an ideal intervention, with some modifications, for autistic individuals who experience suicidal thoughts or behaviors. SPI is a brief, individually-tailored, and easy-to-use approach designed to lower the short-term risk of suicide. Little is known about the utility of SPI for autistic individuals, nor has research examined adaptations necessary to best fit this population.

**Objectives:** The objective of this community-partnered study is to learn from autistic adolescents and adults, their family members, and community clinicians about their perceptions of using SPI with autistic clients and their recommendations for tailoring the SPI for this population.

**Methods:** One hundred and twenty-one clinicians (82.6% female, mean age = 37 years) completed an online survey about their clinical experience managing suicide risk in autistic clients. We also completed semi-structured interviews with 17 adolescents and adults on the spectrum (59% male, mean age = 28 years), 12 family members (83% female, mean age = 56 years), and 31 community clinicians (81% female, mean age = 43 years) with a range of experience working with autistic clients. All interviews were audio-recorded and professionally transcribed for analyses.

**Results:** Of the survey participants, only 24% reported feeling very confident in their abilities to intervene when an autistic client is at risk for suicide, and only 17.4% reported using SPI with autistic clients. Clinicians rated SPI as a more acceptable suicide prevention strategy for clients without autism than for autistic clients ( $p < .001$ ). During the interviews, stakeholders discussed advantages of using the SPI with autistic clients (e.g., helpful structure with logical progression of steps, individually tailored). As one young woman on the spectrum said, “I found it helpful having it already written down, not having to think it up on my own.” Autistic individuals and their family members were particularly enthusiastic about a suicide prevention strategy that can be initiated in an outpatient therapy setting, given their negative experiences with inpatient hospitalization for suicidal thoughts and behaviors. Participants also shared their concerns about using the SPI with autistic clients (e.g., difficulties with generalizing the plan outside session, steps that involve introspection may be challenging). Suggested modifications to SPI included making the text more direct and concise, decreasing the emphasis on social supports and settings, increasing education and practice about internal coping strategies, increasing the involvement of family members, incorporating visual supports (e.g., photos for each step), and leveraging technology.

**Conclusions:** Although some aspects of SPI are a good fit for the learning style of many autistic people, other aspects pose challenges given the core traits of autism and other common co-occurring difficulties. Our three stakeholder groups expressed support for modifying SPI for autistic individuals and provided valuable recommendations to guide this process.

## PANEL SESSION — MEDICAL AND PSYCHIATRIC COMORBIDITY

### Panel 218 - The Interpretation and Impacts of Traumatic Life Events for ASD Adults

**Panel Chair:** Freya Rumball, *Adult ASD Assessment Service and Transforming Care Team, Oxleas NHS foundation trust, Kent, United Kingdom*

**Discussant:** Francesca Happé, *Social, Genetic and Developmental Psychiatry Centre, Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, United Kingdom*

Individuals with ASD are known to be at increased risk of experiencing adverse life events, such as peer victimisation. It has been posited that core features of ASD may confer a heightened risk of exposure to traumatic life events and the development mental health difficulties post-trauma. However, such definitions of ‘trauma’ are limited to the neurotypical experience of life-threatening events. An emerging body of research suggests that a range of life events may be interpreted as traumatic, and increase risk of mental health difficulties such as posttraumatic stress disorder (PTSD), depression and anxiety disorders. The aim of this session is to explore the nature of trauma and its impact on adults with ASD and those with high ASD traits, elucidating individual interpretations of what constitutes a traumatic life event, risk and resilience mechanisms associated with post-trauma mental health outcomes, and the types of coping strategies and interventions that may help or hinder recovery for trauma-exposed ASD adults. Talks will focus on a range of stressful and traumatic experiences, from traditional to atypical traumas, as well as elucidating the impact of the COVID-19 pandemic on adults with ASD.

**218.001 (Panel)** Risk Mechanisms for Posttraumatic Stress Disorder in Autism Spectrum Disorder Adults: Exploring the Ehlers and Clark Model of PTSD

**F. Rumball<sup>1</sup>, N. Grey<sup>2</sup> and F. Happé<sup>3</sup>,** (1)*Adult ASD Assessment Service and Transforming Care Team, Oxleas NHS foundation trust, Kent, United Kingdom,* (2)*Sussex Partnership NHS Trust, Sussex, United Kingdom,* (3)*Social, Genetic and Developmental Psychiatry Centre, Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, United Kingdom*

**Background:** Empirically supported general population cognitive models of posttraumatic stress disorder (PTSD), such as the Ehlers and Clark model, implicate pre-, peri- and post-trauma individual difference in the development and maintenance of PTSD. Individuals with autism spectrum disorder (ASD) are known to be at increased risk of developing anxiety and mood disorders, and a growing body of research has illustrated high rates of PTSD. It is posited that ASD characteristics may increase vulnerability to both trauma exposure and subsequent PTSD development.

**Objectives:** The present study aimed to investigate whether similar mechanisms of PTSD development and maintenance, present in the general population, are associated with PTSD symptomatology in trauma-exposed adults with a diagnosis of ASD

**Methods:** The study recruited ASD adults who had experienced an event(s), at some point in their lifetime, which they interpreted as having been extremely stressful or traumatic. Using a cross-sectional design, participants completed a series of self-report questionnaires either online or in person, depending on their preference. Fifty-nine trauma-exposed adults with ASD took part in the study, 33 reported a traditional traumatic event which the DSM-5 criterion A definition of 'trauma' and 35 reported a trauma not meeting DSM-5 criterion A.

**Results:** Adults with ASD were found to be at increased risk of PTSD development, compared to previous general population statistics, following both trauma types. A comparable profile of cognitive, emotional and behavioral risk and resilience mechanisms from the Ehlers and Clark model of PTSD were found to be associated with PTSD symptomatology in ASD adults. Trait suppression and post-traumatic cognitions and appraisals were found to explain the largest amount of variance in PTSD symptomatology following Criterion A traumas, whilst post-trauma responses to intrusive memories, safety behaviours and cognitions and appraisals of the trauma and/or its sequelae explained the largest amount of variance in PTSD symptomatology following non-Criterion A traumas. The amount of variance in PTSD symptomatology explained by factors from the Ehlers and Clark model of PTSD tended to be smaller for non-Criterion A traumas than Criterion A traumas.

**Conclusions:** These findings highlight the importance of routine screening for trauma and PTSD symptomatology in ASD adults presenting to clinical services and provide preliminary evidence that existing evidence-based treatments such as trauma-focused Cognitive Behavioral Therapy, with appropriate ASD adaptations, may be appropriate treatments for the alleviation of PTSD symptoms in ASD adults. Further research is needed to replicate these findings in ASD adults with clinically confirmed PTSD diagnoses, in addition to examining potential novel PTSD risk and resilience mechanisms for ASD individuals. Treatment studies are needed to investigate the feasibility, acceptability and effectiveness of existing PTSD treatments for ASD individuals with PTSD and any necessary adaptations to treatment protocols to support ASD-needs.

**218.002 (Panel)** Traumatic Life Experiences and Post-Traumatic Stress Symptoms in Older Adults with High Autistic Traits  
**G. R. Stewart<sup>1</sup>, R. A. Charlton<sup>2</sup> and F. Happé<sup>1</sup>,** (1)Social, Genetic and Developmental Psychiatry Centre, Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, United Kingdom, (2)Psychology, Goldsmiths University of London, London, United Kingdom

---

**Background:** Research with young adults has begun to explore possible associations between autism/autistic traits and vulnerability to Post Traumatic Stress Disorder (PTSD). Large scale studies have not been conducted, however, nor have associations been explored in older adults.

**Objectives:** This study will explore differences in the frequency and types of traumatic experience and symptoms of post-traumatic stress among older adults with/without elevated autistic traits.

**Methods:** Using baseline cross-sectional data from the ongoing online PROTECT study, a total of 20,220 adults age 50 years+ reported whether they experience behavioural qualities commonly observed in the autistic spectrum. Approximately 1%, 251 individuals, were identified as endorsing elevated autistic traits in childhood and currently, referred to henceforth as the Autism Spectrum Trait (AST) group. Differences between the AST and an age mean/range and sex ratio matched Control Older Adults (COA; n = 9,179) group were explored in self-reported traumatic experience throughout their lives and current symptoms of post-traumatic stress.

**Results:** The experience of childhood and adulthood trauma and symptoms of post-traumatic stress were found to be negatively associated with age in the COA group, but not in AST. Individuals in the AST group demonstrated significantly higher rates of self-reported traumatic events both childhood and adulthood, including emotional, physical and sexual abuse. Furthermore, elevated current symptoms of post-traumatic stress were reported by AST when compared to COA. An interaction was also observed between autistic traits and severity of traumatic experience, with those in the AST group reporting elevated rates of current post-traumatic stress symptoms increasing with severity of traumatic experience when compared to COA. This interaction remains significant when controlling for current depression and anxiety symptoms.

**Conclusions:** The findings from the current study suggest that elevated autistic traits may increase the likelihood of experiencing trauma throughout childhood and adulthood. Furthermore, older adults with elevated autistic traits may be at a greater risk for experiencing post-traumatic stress symptoms in later life when compared to those with few autistic traits. Further work is needed to see whether these results extend to individuals meeting diagnostic criteria for autism.

**218.003 (Panel) Impact of the COVID-19 Pandemic on Mental Health in Autistic and Non-Autistic Adults**

**J. Maljaars<sup>1,2,3</sup>, D. Spain<sup>4</sup>, K. Evers<sup>1,2,3</sup>, F. Rumball<sup>5</sup>, F. Happé<sup>6</sup> and I. Noens<sup>1,2</sup>,** (1)Leuven Autism Research (LAuRes), KU Leuven, Leuven, Belgium, (2)Parenting and Special Education Research Unit, KU Leuven, Leuven, Belgium, (3)Child Psychiatry, UPC Z.org KU Leuven, Leuven, Belgium, (4)King's College London, Institute of Psychiatry, London, UNITED KINGDOM, (5)Adult ASD Assessment Service and Transforming Care Team, Oxleas NHS foundation trust, Kent, United Kingdom, (6)Social, Genetic and Developmental Psychiatry Centre, Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, United Kingdom

---

**Background:** The COVID-19 pandemic is associated with high levels of stress and symptoms of anxiety, depression and post-traumatic stress disorder in the general population (Xiong et al., 2020) and is expected to have a negative impact on mental health in autistic adults as well (Ameis et al., 2020), especially in those with pre-pandemic mental health conditions (Yao, Chen, & Xu, 2020).

**Objectives:** In our questionnaire study, we set out to compare autistic and non-autistic adults experiences of the COVID-19 pandemic and examine perceived stress and mental health problems. In addition, we wanted to explore personal and contextual risk factors for mental health problems.

**Methods:** This online survey study used a longitudinal design with four time points. At T1 (summer 2020), we collected data from 315 participants (43% with autism; 70% female) in Belgium and the Netherlands and from 120 participants (46% autism; 74% female) in the UK. Data collection for T2 is currently ongoing. The Perceived Stress Scale (PSS), Generalized Anxiety Disorder (GAD-7) and Patient Health Questionnaire (PHQ) were used to measure perceived stress, anxiety and depressive symptoms, respectively. The Intolerance of Uncertainty Scale (IUS-12) was also included. The reported results are based on the Belgian and Dutch data only, but the analysis will be run on the complete data at a later stage.

**Results:** The survey enquired about the impact of the pandemic on several areas of life during lockdown. Autistic individuals mainly experienced a negative impact on their contact with health services (65%), while for individuals without autism the negative impact on social life was the most profound (79%). The largest positive impact was found in the area of 'home/family life' (autism = 52%; without autism = 45%). In general, participants experienced other people not following COVID-19 restrictions and the unpredictability of the situation as most stressful. Autistic adults also reported stress in relation to grocery shopping, taking public transport and reduction of restrictions, whereas for individuals without autism other aspects, such as not being able to meet family/friends, home schooling their child(ren), and fear of contamination were experienced as stressful. In both groups, negative experiences during and after lockdown were associated with significantly higher levels of stress, anxiety and depressive symptoms. Based on regression analyses, higher levels of stress, anxiety, and depression were predicted by being younger, having an existing psychiatric condition, higher intolerance of uncertainty, problems in keeping a healthy work-life balance and experiencing less emotional support. In autistic individuals, those with poorer physical health also suffered from more severe mental health symptoms.

**Conclusions:** Although both positive and negative experiences were reported by the participants, autistic and non-autistic adults experienced relatively high rates of mental health problems during the lockdown of summer 2020. Alleviating the negative effects of COVID-19 on mental health has to be a focus of attention in public health policy.

**218.004 (Panel) A Qualitative Exploration of Traumatic Life Experiences Leading to PTSD Symptoms in ASD Adults**

**A. Kumar<sup>1</sup>, F. Rumball<sup>2</sup> and F. Happé<sup>3</sup>,** (1)South London and Maudsley NHS foundation trust; King's College London, London, United Kingdom, (2)Adult ASD Assessment Service and Transforming Care Team, Oxleas NHS foundation trust, Kent, United Kingdom, (3)Social, Genetic and Developmental Psychiatry Centre, Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, United Kingdom

---

**Background:** Individuals with Autism Spectrum Disorder (ASD) have an increased risk of exposure to traumatic life events, and particular features associated with ASD may serve as risk factors in the development of Post-traumatic Stress Disorder (PTSD). It has been posited that autistic individuals may be at increased risk of developing PTSD due to: 1) increased exposure to traumatic events, 2) potentially experiencing a wider range of life events as traumatic, 3) having a unique perception and experience of trauma and 4) a tendency to use more avoidant coping strategies. However, research into ASD and PTSD remains very limited, particularly concerning individuals' subjective experience of trauma.

**Objectives:** The aim of this study was to qualitatively explore how autistic adults experience and cope with traumatic life events and PTSD related symptomology.

**Methods:** The study used a qualitative design and recruited 12 individuals with a diagnosis of ASD, who had experienced PTSD symptomology in their lifetime following exposure to a traumatic life event. Current and lifetime PTSD symptomology was measured using an adapted version of the PTSD Checklist for DSM-5 (PCL-5). Semi-structured interviews were used to collect data and an inductive thematic analysis was conducted.

**Results:** Eleven themes emerged from the analysis: ‘intertwined ASD and trauma’, ‘memory’, ‘sensory features’, ‘heightened and flattened emotions’, ‘escapism’, ‘self-blame and loss of confidence’, ‘feeling silenced’, ‘social isolation and social connection’, ‘quality of life and practical functioning’, ‘the healing process’ and ‘clinical support’. Participants described experiencing intrusive memories which were highly sensory in nature. Participants commonly reported experiencing multiple traumatic events in their lifetime and felt that the impact of these events often intertwined. It was found that following traumatic exposure, participants often used more avoidant coping strategies such as avoidance and suppression. However, additional areas that were helpful in recovery were identified, for example, music, nature and physical exercise. When seeking support, participants frequently reported not being offered talking therapies in mainstream services and were often prescribed medication as a first line treatment.

**Conclusions:** This is the first study to qualitatively explore how autistic adults experience and cope with traumatic life events and PTSD related symptomology. The findings highlight that autistic individuals may tend to experience multiple traumatic events, often resulting in a severe clinical presentation more akin to complex PTSD (CPTSD). The findings highlight the importance of routine screening for trauma exposure and PTSD symptoms in autistic adults and the use of evidence-based psychological therapies for PTSD, in line with National Institute for Health and Care Excellence (NICE) recommended first line interventions, with appropriate adaptations for ASD. Future research is required to explore the prevalence and presentation of CPTSD in autistic individuals.

## ORAL SESSION — MEDICAL AND PSYCHIATRIC COMORBIDITY

### Oral 318 - Exploring the Origins of Poor Mental Health in Autism

**318.001** (Oral) Behavioral and Neural Mechanisms of Trauma Symptomatology in Youth with Autism Spectrum Disorder  
*E. T. Wood, J. Melbourne, S. A. Green, S. Y. Bookheimer and M. Dapretto, Dept of Psychiatry and Biobehavioral Sciences, University of California, Los Angeles, Los Angeles, CA*

**Background:** Previous research has demonstrated that youth with autism spectrum disorders (ASD) are more likely to experience adverse childhood experiences (ACEs) or trauma and may be at greater risk for developing post-traumatic stress disorder (PTSD) following such events. However, the rates and causes of PTSD in individuals with ASD are poorly understood.

**Objectives:** Our research aims to utilize the longitudinal Adolescent Brain Cognitive Development (ABCD) study to assess the prevalence and underlying mechanisms of increased risk of ACEs, trauma, and PTSD in ASD youth. We hypothesized that functional connectivity (fc) MRI in networks implicated in fear learning, sensory processing, and emotion regulation will mediate the relationships between group status, ACEs, and PTSD symptoms.

**Methods:** Sixty-six ASD participants were identified based on parent reports of a clinical diagnosis in the first release of the ABCD Year 1 follow-up. After excluding for missing data and siblings, a typically-developing (TD) control group of 5:1 TD:ASD peers was established using nearest neighbor greedy matching on gender, MRI scanner, composite IQ, and socioeconomic status. Using data from the Youth and Parent Family Environment Scales, K-SADS, Family History, Short Social Responsiveness Scale (SSRS), Youth Life Events Scale (YLES), and Longitudinal Parent Demographics Survey, we compared the relationship between ACEs and PTSD symptoms between groups. fMRI measures provided by the ABCD consortium seeded in the salience network (SN) were linearly regressed with ACEs and PTSD symptoms and compared between groups.

**Results:** Contrary to prior reports, in this group of 55 ASD participants and 275 TD peers, there were no between-group differences in number of ACEs experienced and rates of PTSD symptoms were also similar. For both groups, number of ACEs was positively correlated with both greater PTSD symptoms ( $R^2 = 0.09, p < 0.001$ ) and impairments in social responsiveness (SSRS;  $R^2 = 0.52, p = 0.03$ , figure 1). Interestingly, however, SN functional connectivity was positively correlated with PTSD symptoms and SSRS scores in ASD ( $R^2 = 0.09, p = 0.04$ ) but negatively correlated in TD ( $R^2 = 0.03, p < 0.01$ ), slope difference  $p < 0.01$ , figure 2).

**Conclusions:** These suggest that this well-matched group of relatively high-functioning (average IQ, able to consent to study) youth with ASD in the ABCD dataset are similar to TD peers in both the rates of ACEs and PTSD as well as in the likelihood of developing post-trauma symptoms following early life adversity. Furthermore, greater social impairments were related to more ACEs and PTSD symptoms for both groups. However, social impairments and PTSD symptoms were differentially related to SN connectivity in ASD youth compared to TD peers such that SN connectivity was positively correlated with social deficits and PTSD for the ASD group only. Atypicalities in SN connectivity have been previously reported in ASD youth in multiple studies and associated with ASD-related social impairments. These data suggest that, whereas greater within SN connectivity in TD youth relates to fewer PTSD symptoms, in ASD youth atypical SN connectivity may amplify the potential negative outcomes of aversive experiences.

**318.002 (Oral)** Clinical Characteristics of Autistic Youth in the SPARK Cohort with a Co-Occurring Schizophrenia Diagnosis  
**A. Jutla<sup>1</sup>** and **J. Veenstra-VanderWeele<sup>2</sup>**, (1)1051 Riverside Drive, New York State Psychiatric Institute / Columbia University, New York, NY, (2)Psychiatry, New York State Psychiatric Institute / Columbia University, New York, NY

---

**Background:** Three to five percent of autistic individuals have a co-occurring schizophrenia diagnosis. Little is known about the clinical characteristics of this group, particularly during childhood and adolescence. To investigate this question, we leveraged the size of the Simons Powering Autism Research for Knowledge (SPARK) study, which to date has recruited 77,017 children and adolescents with an autism spectrum disorder (ASD) diagnosis from across the United States.

**Objectives:** We hypothesized that 1) characteristics associated with schizophrenia in the general population (a history of birth complications, obsessive-compulsive disorder (OCD) and tics) and 2) characteristics associated with severity of impairment in the autistic population (younger age of diagnosis, lower intellectual ability, and neurological problems) would both statistically predict a schizophrenia diagnosis among autistic children and adolescents.

**Methods:** We fit a logistic regression model with history of premature birth, history of serious infection during pregnancy, OCD, tic disorder, age at autism diagnosis, age at study enrollment, intellectual disability, and seizures as predictors of schizophrenia diagnosis. Sex and language level were covariates. We excluded 3,582 participants with missing data for any of the variables described above, leaving a sample of 73,435 ASD youth.

**Results:** The sample was 79% male, with a mean age of 4.47 years (SD 3.10 years) at autism diagnosis, and a mean age of 9.83 years (SD 6.06 years) at study enrollment. 333 participants (0.45%) had a schizophrenia diagnosis. OCD diagnosis was the strongest positive predictor of schizophrenia diagnosis, (odds ratio 6.68, 95% confidence interval 5.06 – 8.75,  $p = 5.1 \times 10^{-42}$ ), followed by tic disorder diagnosis (odds ratio 4.23, 95% confidence interval 2.94 – 5.98,  $p = 1.7 \times 10^{-15}$ ), cognitive impairment (odds ratio 1.75, 95% confidence interval 1.36 – 2.24,  $p = 1.2 \times 10^{-5}$ ) and age at autism diagnosis (odds ratio 1.34 for a two-standard deviation increase in age, 95% confidence interval 1.11 – 1.61,  $p = 0.0021$ ). The strongest negative predictors were male sex (odds ratio 0.50, 95% confidence interval 0.40 – 0.63,  $p = 2.7 \times 10^{-9}$ ) and nonverbal language level (odds ratio 0.41, 95% confidence interval 0.23 – 0.68,  $p = 9.1 \times 10^{-4}$ ). No other predictors were statistically significant.

**Conclusions:** The finding that OCD and tic disorder diagnosis strongly predicted schizophrenia diagnosis in the SPARK sample may highlight the clinical challenge of separating intense rituals or special interests from psychotic symptoms such as delusions. The overlap is also consistent with increasing evidence of genetic overlap among OCD, schizophrenia and ASD. That older, rather than younger, age at ASD diagnosis, and female sex predicted schizophrenia diagnosis were unexpected findings that warrant further study. The small number of participants in our sample with a schizophrenia diagnosis is somewhat surprising given reported rates in ASD, but this likely reflects the young age of our sample at time of enrollment in SPARK. Future longitudinal work with the SPARK cohort may be able to confirm whether, as in the general population, emergence of schizophrenia is highest in ASD during late adolescence and early adulthood.

**318.003 (Oral)** The Development of the Personalised Anxiety Interview Schedule - Autism (PAIS-A) and What the Tool Can Tell Us about the Anxiety Profiles of Autistic Adults  
**S. Brice<sup>1</sup>**, **P. Welsh<sup>2</sup>**, **M. Freeston<sup>3</sup>**, **J. R. Parr<sup>1,2</sup>**, **B. Ingham<sup>1,2</sup>**, **A. LeCouteur<sup>4</sup>** and **J. Rodgers<sup>1</sup>**, (1)Population Health Sciences Institute, Newcastle University, Newcastle upon Tyne, United Kingdom, (2)Cumbria, Northumberland, Tyne and Wear NHS Foundation Trust, Newcastle upon Tyne, United Kingdom, (3)School of Psychology, Newcastle University, Newcastle upon Tyne, United Kingdom

---

**Background:** Autistic people are more likely to experience anxiety than neurotypical people. Anxiety significantly impacts on daily life and predicts poorer quality of life. Evidence suggests that anxiety may have a differential presentation in autistic people compared with neurotypical people (requiring differential conceptualisation and diagnostic criteria). This is likely driven by a number of factors, including the way in which autism characteristics (such as sensory differences) interact with anxiety and the

role of transdiagnostic factors such as Intolerance of Uncertainty (IU). These differences challenge but do not necessarily invalidate existing diagnostic criteria and assessment tools when used with autistic people. One key question is the extent to which evidence-based psychological interventions for anxiety can be targeted and personalised for autistic people. To accurately inform intervention, assessments should be adapted so they accurately capture the anxiety profiles of autistic adults and inform personalised intervention. Anxiety screening questionnaires designed specifically for use with autistic adults have recently been published (e.g. the Anxiety Scale Autism – Adults; ASA-A). However, there is not currently a bespoke anxiety diagnostic interview for use with autistic adults.

### Objectives:

To investigate:

- A set of supplementary questions (PAIS-A<sup>a</sup>) to be used alongside existing clinical interviews to identify anxiety experienced by autistic people and its mechanisms
- The anxiety profiles of autistic adults participating in the Personalised Anxiety Treatment – Autism (PAT-A<sup>a</sup>) clinical trial

**Methods:** The PAIS-A<sup>a</sup> is an addendum that can be used alongside any existing informal or formal diagnostic interview for anxiety. The PAIS-A<sup>a</sup> was developed as part of a feasibility and acceptability trial of a personalised, modular psychological treatment for anxiety in autistic adults (PAT-A<sup>a</sup>). The PAIS-A<sup>a</sup> was administered in conjunction with the Anxiety and Related Disorders Interview Schedule (ADIS-5) with 34 clinically anxious autistic adults (aged 18-62, 65% male). A proportion (25%) of interviews were rated independently by a second clinician to estimate diagnostic inter-rater reliability.

**Results:** The PAIS-A<sup>a</sup> demonstrated good inter-rater reliability (ICC = .82). The PAIS-A<sup>a</sup> allowed anxiety subtypes to be identified as well as the relative contribution of ASD specific features to anxiety in any given situation. 75% of participants were experiencing 3 or more concurrent anxiety conditions. The most common anxiety types were social anxiety (97%) and generalised anxiety (78%). Some participants experienced anxiety that did not map onto existing DSM-5 diagnoses. For example, 12% of those with anxiety in social situations did not meet DSM-5 criteria for ‘social anxiety disorder’ because their anxiety was not primarily driven by a fear of negative evaluation. Additional non-standard patterns were seen across other common anxiety conditions.

**Conclusions:** The PAIS-A<sup>a</sup> has enabled us to assess specific ‘autism-related’ presentations of anxiety and provides an indication of potential underlying mechanisms. These results are consistent with previous research suggesting that anxiety often has a different presentation in autistic people. This information has been used to inform personalised intervention in the PAT-A<sup>a</sup> trial. Further work is needed to replicate and extend these findings. The PAIS-A<sup>a</sup> and related training will be available upon completion of the PAT-A<sup>a</sup> trial in 2021.

## POSTER SESSION — MEDICAL AND PSYCHIATRIC COMORBIDITY

### Poster 429 - Medical and Psychiatric Comorbidity Posters

**429.001 (Poster)** A Longitudinal Look: How Sleep Impacts Suicidal Thoughts and Behaviors in Autism and Social Anxiety  
**L. J. Regehr<sup>1</sup>, T. P. Gabrielsen<sup>2</sup>, J. A. Nielsen<sup>3</sup> and M. South<sup>4</sup>,** (1)Brigham Young University, Provo, UT, (2)Counseling & Special Education, Brigham Young University, Provo, UT, (3)Harvard University, Cambridge, UT, (4)Psychology & Neuroscience, Brigham Young University, Provo, UT

**Background:** Suicide research often looks at single risk factors through cross-sectional and longitudinal studies. These studies give snapshots of individual’s experiences, but may not accurately reflect day-to-day experiences. State factors, such as sleep, change over time and are not accurately portrayed in trait-like cross-sectional analysis. Individuals with poor sleep quality, difficulty falling asleep, irregular sleep patterns, and perpetual lack of sleep have between 1.39 and 2.24 increased risk of STBs (Bernert et al., 2014; Bernert et al., 2017). Research also identifies high-risk groups more likely to experience STBs. Individuals with autism and social anxiety have significantly higher rates of suicide deaths than the general population. They are also more likely to experience sleep problems.

**Objectives:** We evaluated sleep quality and sleep duration (state factors) in combination with the trait factor of membership in a high risk-group, specifically individuals with autism or social anxiety, and how these factors impact suicidal thoughts and behaviors. This is an exploratory study that will show trends in longitudinal data collected over a period of six months.

**Methods:** We recruited a sample size of 50+ human participants across three groups (social anxiety, autism, and control) including males and females ages 18-31 (mean=22.5). Recruitment is ongoing with a goal of 25-30 in each group. Group membership was determined by Mini-International Neuropsychiatric Interview (M.I.N.I.), Autism Diagnostic Observation Schedule (ADOS-2), and Columbia-Suicide Severity Rating Scale (C-SSRS). Longitudinal variables include daily self-reported sleep duration and quality; daily self-report of suicide thoughts in prior 12 hours, level of desire for suicide, level of intention, and ability to resist; as well as periodic Insomnia Severity Index, PROMIS adult sleep disturbance short form, Pittsburgh Sleep Quality Index, and C-SSRS questionnaires given every 6 weeks. The study design also includes daily actigraphy and other monitoring with a wrist device over 6 months.

**Results:** Statistical analysis was performed with preliminary data from the first 12 weeks.

We have 3769 observations from 51 subjects who were classified as Controls (18), Social Anxiety(21), or ASD (12). Tracking suicidal thoughts over time, we see that the Social Anxiety group tends to show proportionally more reports of suicidal thoughts than we would expect (standardized residual = 16.1). The autism group did not show a disproportionate pattern of observations of suicidal thoughts. The observations are not independent, and this is a glimpse of the pattern to date. Other analysis show trends in sleep quality increasing with the increase of duration. Responses of “yes” to STBs in the past 12 hours are associated with lower quality and duration of sleep; Significant difference in quality of sleep between participants who reported “yes” or “no” to STBs in prior 12 hours, with some differences by group; Greater sleep duration associated with lower STB intensity. Reports of early bed times had less variable overall with bedtimes.

**Conclusions:** These preliminary data suggest a relationship regarding state and trait factors of sleep and STBs. We are committed to helping individuals with STBs and hope to uncover more treatable factors to aid in their recovery.

**429.002 (Poster)** A Pilot Chart Review of Suicidal Thoughts and Behaviours Among Autistic Adults

*P. Jachyra<sup>1</sup>, M. C. Lai<sup>2,3</sup>, M. Dale<sup>4</sup>, A. Sawyer<sup>5</sup>, N. Fernandes<sup>6</sup>, J. Zaheer<sup>6</sup> and Y. Lunsky<sup>1</sup>, (1)Azrieli Adult Neurodevelopmental Centre, Centre for Addiction and Mental Health, Toronto, ON, Canada, (2)Autism Research Centre, Department of Psychiatry, University of Cambridge, Cambridge, ON, United Kingdom, (3)The Margaret and Wallace McCain Centre for Child, Youth and Family Mental Health, Centre for Addiction and Mental Health, Toronto, ON, Canada, (4)University of Toronto, Toronto, ON, Canada, (5)Centre for Addiction and Mental Health, Toronto, ON, Canada, (6)Centre for Addiction and Mental Health, Toronto, ON, Canada*

Background: Autistic people think about, and attempt death by suicide at worrying high rates. Two systematic reviews highlight that between 7 and 66% of autistic individuals (Hedley & Uljaveric 2018; Segers & Rawana, 2014) experienced suicidal thoughts and behaviours (STB), and the prevalence of suicide attempts varied between 7-47% (Zahid & Upthegrove, 2017). A high incidence of STB has also been reported at the population level, where Taiwanese autistic adolescents and young adults had higher incidences of suicide attempt, compared to non-autistic people (Chen et al., 2017). Latest registry-based studies in Sweden (Hirvikoski et al., 2020; Hirvikoski et al., 2016) and the United States (Kirby et al., 2019) accentuate that autistic people are at increased risks to die by suicide than non-autistic people.

To date, research examining STB has predominantly used administrative and retrospective self-report approaches. In this vein, there is little research that has examined emergency department (ED) charts regarding STB in autistic adults. There is a need for this work as the depth and nuance of data gleaned from ED charts has the potential to inform our understanding of key factors associated with suicide among autistic people, identify research gaps, as well as inform potential prevention and intervention possibilities.

Objectives: This study describes the characteristics and presentations of STB, associated features, along with the ED care and dispositions received among a group of autistic adults receiving emergency mental health services.

Methods: A retrospective chart review was conducted for visits to a tertiary psychiatric ED in Toronto, Canada. Autistic adults attended the ED for reasons associated with STB during a 10-week period between October 2016 and January 2017. Charts were analyzed qualitatively to identify recurring patterns, deviations, and contraindications.

Results: Sixteen individuals (10 males, 6 females) who ranged in age from 17 to 31 years, had their charts reviewed. The majority (14) described suicidal thoughts, with vague descriptions of plans and intent. Some individuals reported using alcohol and substances such as marijuana, methamphetamine, crack/cocaine, mushrooms and heroin; for three individuals, healthcare providers noted that it was difficult to discriminate whether STB were substance induced. Reported STB were not always the presenting issue, sometimes only being identified following a comprehensive mental health exam. Six autistic adults ruminated about STB, and ruminating about STB was described as emotionally unsettling, fatiguing, and further exacerbated emotional

distress. Individuals with collateral involvement had more detail about broader medical history included in their ED chart, with more detailed discharge and follow-up plans included in their chart records.

**Conclusions:** In this study, STB was not always the initial presenting issue when autistic individuals attended the psychiatric ED. With multiple forms of presentation, efforts are needed to ensure STB among autistic people is not missed. With some individuals ruminating about STB, it may be important to screen for STB as soon as there is any form of visible distress, especially in a standard ED. Visits to an ED can be a pivotal opportunity for prevention and intervention to reduce STB risks in autistic individuals.

**429.003 (Poster)** Adapted Cognitive Behavioral Therapy for School-Aged Children with Autism Spectrum Disorders and Interfering Anxiety: Impact on Caregiver-Defined Goals

*V. Sklar, A. R. Johnson and J. J. Wood, Human Development & Psychology, University of California, Los Angeles, Los Angeles, CA*

---

**Background:** It is well documented that for children with autism spectrum disorder (ASD), central challenges can include difficulties with social communication, challenges of emotional dysregulation, as well as pervasive effects of rigid and repetitive behaviors (Matson & Nebel-Schwalm, 2007; Samson et al., 2014). However, with nearly 40% of children with ASD estimated to present with clinically elevated levels of anxiety (Van Steensel et al., 2011), there is a need for interventions that better understand and address this heterogeneity while also targeting improvement of these competencies for productive change over time. Therefore, the purpose of this study was to compare two variants of cognitive behavioral therapy (CBT), specifically, adapted CBT (BIACA; Wood et al., 2009) and standard-of-practice CBT (Coping Cat (CC); Kendall & Hedtke, 2006) in order to explore the most efficacious treatment for addressing specific caregiver-defined goals.

**Objectives:** To categorize the range of caregiver-defined goals for therapy from a sample of caregivers of children with both ASD and concurrent anxiety and explore if the modular/personalized format of adapted CBT is the most efficacious treatment for addressing specific caregiver-defined challenges in these children.

**Methods:** This secondary data analysis used a previous multisite randomized clinical trial (RCT; Wood et al., 2019) conducted at a large metropolitan research institution with a subsample of, children with ASD and clinical levels of anxiety (N=148; aged 7-13 years,  $Mage=9.90$ ,  $SD=1.78$ ). Through descriptive analysis and linear mixed modelling (LLM), this study investigated varying treatment effects of BIACA and CC on caregiver-defined goals via the idiographic Youth Top Problems (YTP) scale (Weisz et al., 2011; 2012). Treatment effects were represented by change in caregiver-defined goals and symptom severity ratings over treatment. In the LMMs, 16 session time points were nested within children, and random intercepts included in all models.

**Results:** Primary outcome analysis revealed BIACA ( $EMM=4.60$ ,  $SE=.20$ ) significantly outperformed CC ( $EMM=5.21$ ,  $SE=.21$ ) in reduction of child's mean YTP symptom severity ratings at the end of treatment ( $p=.005$ ). Investigating differential treatment effects of BIACA and CC on symptom reduction of rigid/repetitive behaviors, Site 3 showed particularly pronounced symptom reduction of rigid/repetitive behavior YTPs in BIACA ( $EMM=3.37$ ,  $SE=.95$ ) compared to CC ( $EMM=5.94$ ,  $SE=.61$ ). Site 2 also showed pronounced symptom reduction of internalizing/anxiety YTPs in BIACA ( $EMM=3.58$ ,  $SE=.40$ ) as compared to CC ( $EMM=4.95$ ,  $SE=.42$ ). Finally, in exploring differential treatment effects of BIACA and CC on the symptom reduction of externalizing symptom YTPs, differences across sites were slight. However, Site 1 showed noticeable decreases in symptom severity of externalizing symptom YTPs in BIACA ( $EMM=4.60$ ,  $SE=.38$ ) as compared to CC ( $EMM=5.21$ ,  $SE=.39$ ).

**Conclusions:** The present study categorized various caregiver-defined goals that parents have for their child's treatment. Results provide additional evidence suggesting CBT is an efficacious treatment for school-aged children with ASD and maladaptive and interfering anxiety, with an adapted CBT approach exhibiting additional advantages on both nomothetic, standardized and idiographic, personalized outcome measures. Meaning, when practitioners match evidence-based therapeutic techniques directly to a child's clinical needs, the modular/personalized approach of adapted CBT may better address caregiver's treatment goals.

**429.004 (Poster)** An Examination of the Buffering Hypothesis of Suicide Risk in Young Autistic Adults: Does Mental Wellbeing Buffer the Effect of Depression on Suicidal Ideation?

*D. Hedley<sup>1</sup>, J. den Houting<sup>2</sup>, S. M. Hayward<sup>3</sup>, M. Uljarevic<sup>4</sup>, S. M. Bury<sup>1</sup>, L. P. Lawson<sup>5,6</sup>, A. Clapperton<sup>7</sup>, A. Haschek<sup>8,6</sup>, C. Dissanayake<sup>1</sup>, J. Robinson<sup>1,8</sup>, J. N. Trollor<sup>6,9</sup> and M. A. Stokes<sup>10</sup>, (1)Olga Tennison Autism Research Centre, School of Psychology and Public Health, La Trobe University, Melbourne, VIC, Australia, (2)Macquarie University, Sydney, Australia, (3)School of Health and Social Development, Deakin University, Burwood, VIC, Australia, (4)School of Psychological Sciences, University of Melbourne, Melbourne, VIC, Australia, (5)Olga Tennison Autism Research Centre, La Trobe University, Melbourne, VIC, Australia, (6)Cooperative Research Centre for Living with Autism (Autism CRC), Brisbane, QLD, Australia, (7)School of Population and Global Health, University of Melbourne, Melbourne, VIC, Australia, (8)Centre for Youth Mental Health, Orygen,*

**Background:** Autistic people are at significantly increased risk of suicide, yet few studies have examined resilience factors in this population. Studies in general population samples have shown that mental wellbeing can moderate the effects of depression on suicidal ideation, thereby mitigating the impact of this risk factor. Additionally, while some studies have demonstrated a relationship between autistic traits and suicide risk, results are mixed and no studies to date have examined the relationship over time.

**Objectives:** 1) Test the hypothesis that mental wellbeing moderates the impact of depression on suicidal ideation in a two-year follow-up study of young autistic adults; 2) Examine autistic traits as a predictor of suicidal ideation at 2-year follow-up.

**Methods:** The study was approved by the relevant university ethics committees (HEC14095, HEC20235, HC15001). Participants were 83 (60% male) autistic young adults aged 15 to 25 years ( $M=18.68$ ,  $SD=2.33$ ) at baseline, who were participants in the longitudinal Study of Australian School Leavers with Autism. In addition to age and gender, predictor variables included autistic traits (Autism Spectrum Quotient, 28-item), depression (Hospital Anxiety and Depression Scale), mental wellbeing (Warwick Edinburgh Mental Wellbeing Scale), and suicidal ideation (PHQ-9). Correlational and hierarchical regression analyses were used to examine relationships between predictor variables at baseline (T1) and suicidal ideation at 2-year follow-up (T2). The moderating effect of mental wellbeing on the relationship between depression and suicidal ideation was examined by including the Depression $\times$ Wellbeing interaction term in the regression analysis. This study was pre-registered with Open Science Foundation, <https://osf.io/dhnw8/>

**Results:** Approximately one quarter of the sample reported recent suicidal ideation (T1=26%, T2=28%). Although autistic traits were negatively correlated with mental wellbeing at baseline ( $r=-.35$ ,  $p=.003$ ), neither T1 autistic traits nor age were significantly associated with T2 suicide ideation ( $p>.05$ ) and were thus excluded from the regression model. T1 gender ( $r=.26$ ,  $p=.02$ ), depression ( $r=.53$ ,  $p<.001$ ), mental wellbeing ( $r=-.32$ ,  $p=.005$ ), and the Depression $\times$ Wellbeing interaction term ( $r=.39$ ,  $p=.001$ ) were all significantly correlated with T2 suicide ideation and were entered as predictors into the regression model. Overall, the model explained 30% of the variance in T2 suicidal ideation ( $R^2=.303$ ). However, only T1 depression significantly predicted T2 suicide ideation ( $\beta=1.009$ ,  $p=.015$ ); T1 mental wellbeing and the interaction term were not found to significantly predict T2 suicidal ideation when controlling for T1 depression.

**Conclusions:** Contrary to some recent research, we did not identify a significant relationship between autistic traits and suicidal ideation at 2-year follow-up in a sample of young autistic adults. Although we found significant relationships between baseline mental wellbeing and suicidal ideation at follow up, mental wellbeing was not found to significantly predict suicidal ideation when controlling for T1 depression. We did not find support for the hypothesis that mental wellbeing buffers the relationship between depression and suicidal ideation in young autistic adults. In developing suicide risk models in the autistic population it is imperative that the identification of risk factors is balanced with the identification of protective factors that might mitigate suicide risk, thereby informing suicide prevention strategies and intervention.

**429.005 (Poster) Analyzing the Relationship between IQ, Language Skills, and Anxiety in Autism Spectrum Disorder**  
**E. Rinaldo<sup>1</sup>, E. Kelley<sup>2</sup>, E. Anagnostou<sup>3</sup>, S. Georgiades<sup>4</sup>, R. Nicolson<sup>5</sup> and M. Ayub<sup>6</sup>,** (1)York University, Toronto, ON, Canada, (2)Queen's University, Kingston, ON, Canada, (3)Autism Research Center, Bloorview Research Institute, Holland Bloorview Kids Rehabilitation Hospital, Toronto, ON, Canada, (4)McMaster Autism Research Team, McMaster University, Hamilton, ON, Canada, (5)University of Western Ontario, London, ON, Canada, (6)Psychiatry, Queen's University, Kingston, ON, Canada

---

Background:

Anxiety is a common condition noted to cause significant impairment in some children with autism spectrum disorder (ASD) (White et al., 2009). Lower intelligence and language impairment have been associated with anxiety in typically developing (TD) children; however, children with ASD tend to show higher levels of anxiety with higher intelligence scores and higher language abilities (Davis et al., 2011; Hodges & Plow, 1990; Sukhodolsky et al., 2008).

Objectives:

Considering the strong correlation between language skills and intelligence scores we decided to investigate whether the shared influence of these constructs on anxiety could be occurring in a mediational relationship. It was hypothesized that a mediational relationship would be seen in children with ASD in which intelligence exerts its influence over anxiety through language skills,

given that only children with higher verbal skills are able to truly express their anxiety. For TD children it was hypothesized that the opposite effect would occur.

#### Methods:

Participants included children between the ages of 7 and 19, 371 with a clinical diagnosis of ASD (n=287 males) and 63 that were TD (n=34 males). Our measures included the Revised Children's Anxiety and Depression Scale (RCADS; Chorpita et al., 2000), the Oral and Written Language Scale (OWLS; Carrow-Woolfolk, 1995; OWLS-II; Carrow-Woolfolk, 2011), the Wechsler Abbreviated Scale of Intelligence (WASI; Wechsler, 1999; WASI-II; Wechsler, 2011), and the Wechsler Intelligence Scale for Children (WISC-IV; Wechsler, 2003; WISC-V; Wechsler, 2014). The analysis was conducted in SPSS using model 4 from the Process v3 (Hayes, 2013).

#### Results:

The results of this study supported our hypothesized mediation with a small effect in the ASD group ( $b = 0.20$ , 95% BCa CI [0.12, 0.29], Figure 1). In the TD group a mediation effect was not supported ( $b = -0.03$ ,  $p = 0.667$ , 95% BCa CI [-0.19, 0.12]). Our study also supports previously reported findings showing that children with ASD exhibit higher levels of anxiety than their TD peers.

#### Conclusions:

The mediational model investigated in this study should inform further research in ASD that the influence of intelligence and language over anxiety should not be viewed as independent factors but as a set of constructs that exert a shared influence. While our study provides evidence supporting a relationship between intelligence, language, and anxiety, it cannot determine whether higher intellectual and linguistic abilities lead to higher anxiety or if this relationship occurs due to the increased ability to communicate feelings of anxiety. Future research should focus on assessing different presentations and predictors of anxiety in children with ASD that have intellectual disabilities and more severe ASD symptoms.

#### **429.006 (Poster)** Autism Spectrum Disorder (ASD) and Other Neurodevelopmental Disorders As a Risk Factor for Delayed Diagnosis of Catatonia.

**K. J. Zappia**<sup>1,2</sup>, **A. Shillington**<sup>1</sup>, **M. Lamy**<sup>1</sup> and **K. Dominick**<sup>3</sup>, (1)Pediatrics; Child and Adolescent Psychiatry, Cincinnati Children's Hospital Medical Center, Cincinnati, OH, (2)Psychiatry, University of Cincinnati, Cincinnati, OH, (3)Cincinnati Children's Hospital Medical Center, Cincinnati, OH, (4)Division of Child and Adolescent Psychiatry, Cincinnati Children's Hospital Medical Center, Cincinnati, OH

**Background:** Catatonia is a distinct and severe medical syndrome comprised of motor, somatic and psychiatric symptoms seen in range of conditions. Catatonia is reported in upwards of seventeen percent of young patients with autism spectrum disorder (ASD) (reviewed in Ghaziuddin, Andersen, & Ghaziuddin, 2020), and clinical experience indicates catatonia is often under-recognized in this clinical population.

**Objectives:** Here we characterize the clinical presentation of catatonia in patients with and without neurodevelopmental disorders (NDD) including ASD, examining the time from symptom onset to diagnosis, clinical features, and the process to diagnosis.

**Methods:** Pediatric and young adult patients with a charted history of catatonia were identified through retrospective review of electronic medical records (EMR), as any patient with a catatonia listed on their problem list. Patients were 10 to 35 years old at time of diagnosis. Of this initial cohort of 53 patients, 30 patients have intellectual disability or NDD (17 of whom specifically carry an ASD diagnosis), three have no formal diagnosis of ASD but it has been questioned, and 20 patients are neurotypical. We will continue to expand this cohort through EMR review for individuals with an encounter diagnosis of catatonia, ultimately reviewing encounters from the past 10 years, with an additional 5 patients with sufficient clinical data identified to date.

**Results:** We observed a clear and substantial delay in identification and diagnosis of catatonia in the NDD population: delays of months to years (some instances over a decade) for most patients with NDD versus only days to weeks for most neurotypical patients, whose catatonia was typically comorbid with a psychotic disorder and developed more rapidly. Additionally, in NDD patients, catatonia symptoms appeared to persist longer following treatment initiation.

**Conclusions:** Intellectual disability and ASD are risk factors for significantly delayed diagnosis of catatonia, which can lead to notable morbidity. It is unknown if delayed diagnosis contributes to the difficulty in treating catatonia in this patient population,

or if the treatment difficulties relate instead to differential and ongoing biological mechanisms and underlying encephalopathy. Overall, these findings highlight the importance of increased recognition of catatonia symptoms in patients with NDD and ASD.

**429.007 (Poster) Autistic Adults and Psychiatry; Experiences and Barriers to Access**

**M. Doherty<sup>1</sup>, J. D. O'Sullivan<sup>2</sup>, S. D. Neilson<sup>3</sup>, J. K. Doyle<sup>4</sup>, D. Burke<sup>5</sup>, M. Botha<sup>6</sup>, S. Sultan<sup>7</sup> and L. Gallagher<sup>8</sup>,** (1)Anaesthesia, Our Lady's Hospital, Navan, Ireland, (2)Anaesthesia, Mater Private Hospital, Dublin, Ireland, (3)Independent Researcher, Cork, Ireland, (4)School of Psychology, University of Dublin, Trinity College, Dublin, Dublin 2, Ireland, (5)Galway Autism Partnership, Galway, Ireland, (6)Psychology, University of Stirling, Stirling, United Kingdom, (7)Singer and Sultan: Consultants Plus+, Montreal, QC, Canada, (8)Trinity College Dublin, Dublin, Ireland

---

**Background:** Autistic adults report high rates of co-occurring mental illness. Suicide rates for autistic adults without an intellectual disability are 9 times the general population rate. Awareness of the prevalence of autism in general adult psychiatry and the needs of autistic adults accessing mental health services is increasing. Mental health is a key research priority for the autistic community.

**Objectives:** This study provides a perspective on barriers faced by autistic adults in accessing and successfully interacting with psychiatric services. A mixed methods analysis identifies issues in the mental health experiences of autistic adults. The qualitative aspect of the study is ongoing.

**Methods:** Participants at Autscope 2019, a conference organised by and for autistic people, were invited to complete a questionnaire about their experiences accessing out-patient and in-patient mental health services, as well as their history of co-occurring psychiatric conditions, self-harm, suicidal ideation & previous suicide attempts. The questions included demographic, quantitative and qualitative elements.

**Results:** Of 101 respondents, 42% were female, 33% male and 25% identified as non-binary. 78% were from the UK, 20% from Europe and 2% from Australia.

99% of respondents identified as autistic, with 92% reporting a formal diagnosis, specifically Asperger Syndrome (48%), Autism Spectrum Disorder (29%), High Functioning Autism (10%) and Autism Spectrum Condition (5%). Median age at diagnosis was 32, range (6 - 66 years).

94% were registered with a GP, whereas 6% were not. 19% of respondents were currently attending a psychiatrist, 64% had attended in the past and 44% expressed difficulty in attending. A good relationship with their current psychiatrist was reported by 21%, and 42% reported current use of psychotropic medication, most commonly for anxiety and depression.

Respondents reported moderate use of alcohol (28%) and illicit substances (12%) to manage mental health issues, with 18% reporting difficulties due to substance use. High levels of self-harm were reported (69%) with 21% requiring medical care. Experience of suicidal ideation (86%) and attempted suicide (46%) were higher than previously reported in autistic cohorts.

67% reported that they would seek support for mental health concerns from their GP, 53% from friends, 42% from the online autistic community and 37% from family. Only 15% reported they would seek support from a psychiatrist and 11% from community mental health services. 55% reported that they would not attend a hospital emergency department for mental health and 39% would not attend a psychiatrist.

27% had used psychiatric in-patient services. 11% had been involuntarily detained (sectioned) and 10% had experienced physical restraint in hospital. Of those aware of their autism diagnosis at the time of inpatient treatment (n=12), 50% reported that their psychiatric team was aware of the diagnosis and 33% reported that it was taken into account in their management plan.

**Conclusions:** Autistic adults self-report a high level of mental ill-health, and significant barriers in accessing psychiatric services. Those who accessed care typically did so late, with negative experiences of seclusion and restraint. Our data suggest a need for improved community mental health support that needs to be investigated further.

**429.009 (Poster) Birth-Assigned Sex, Gender, and Sexual Orientation Are Associated with Depression and Anxiety Scores in Autistic Adults**

**M. B. Mason<sup>1</sup>, J. Gamutan<sup>1</sup>, J. Richards<sup>1</sup> and K. O. Gotham<sup>2</sup>,** (1)Rowan University, Glassboro, NJ, (2)Psychiatry and Behavioral Sciences, Vanderbilt University Medical Center, Nashville, TN

---

Background: Prior research suggests that autistic women experience notably higher rates of depression and anxiety compared to autistic men (Uljarević et al., 2019). Additionally, recent findings suggest that identifying with a minority group, such as gender and sexual minorities and/or the autism population, is associated with poorer emotional health outcomes (George & Stokes, 2018). More research is needed to understand how birth-assigned sex and gender/sexual orientation identity affect emotional health outcomes within the autistic adult population.

Objectives: We aimed to examine how birth-assigned sex, gender, and sexual orientation relate to depression and anxiety outcomes in a large sample of autistic adults. We hypothesized that participants who were birth-assigned female, non-binary gendered, or who identified as non-heterosexual would endorse higher levels of depression and anxiety.

Methods: Data were collected from  $N=727$  adults with self-reported autism diagnoses recruited through the SPARK registry (63.4% birth-assigned female; 55.2% identified as women; 56.9% heterosexual). The Beck Depression Inventory (BDI-II; Beck, 1996) and Generalized Anxiety Disorder-7 (GAD-7; Spitzer et al., 2006) indexed depression and anxiety symptoms, respectively. Univariate analyses of variance with Tukey post-hoc tests were conducted to examine specific patterns of association between sex/identity and emotional health scores.

Results:

Birth-assigned females experienced significantly higher depression ( $F(1,725)=20.83, p<.001$ ) and anxiety ( $F(1,725)=22.59, p<.001$ ) scores compared to birth-assigned males. Findings also indicated a significant difference in depression ( $F(2,723)=16.50, p<.001$ ) and anxiety ( $F(2,723)=13.31, p<.001$ ) scores across gender groups: Depression scores were significantly higher in non-binary participants ( $M=24.88, SD=13.33$ ) compared to women ( $M=20.33, SD=13.80$ ) and men ( $M=15.68, SD=12.48$ ), and higher for women compared to men. Anxiety scores were significantly higher for non-binary participants ( $M=10.47, SD=5.64$ ) and women ( $M=8.89, SD=5.74$ ) compared to men ( $M=7.04, SD=5.60$ ). Finally, significantly higher depression ( $F(3,723)=8.63, p<.001$ ) and anxiety scores ( $F(3,723)=8.71, p<.001$ ) were endorsed by some sexual orientation minorities compared to those attracted to the opposite gender. Post-hoc test indicated higher depression scores for those sexually oriented towards 2+ genders ( $M=22.64, SD=13.10$ ) and those oriented toward other/neither gender ( $M=21.95, SD=15.20$ ) compared to those attracted to the opposite gender ( $M=17.02, SD=13.00$ ). The same pattern was noted for anxiety scores, with those sexually oriented towards 2+ genders ( $M=10.05, SD=5.76$ ) or other/neither gender ( $M=9.58, SD=6.36$ ) endorsing higher anxiety scores compared to those attracted to the opposite gender ( $M=7.53, SD=5.61$ ). We observed no significant differences in depression or anxiety scores for those attracted within their own gender compared to those traditionally considered heterosexual or to those attracted to 2+ genders or other/neither gender.

Conclusions: Sex, gender, and sexual orientation appear to have a significant influence on emotional health in autistic adults, with birth-assigned females, women and non-binary gendered individuals, and those attracted to multiple or “other/neither” genders endorsing higher depression and anxiety scores in compared to birth-assigned males, men, or conventionally heterosexual or homosexual individuals within this large sample. This replicates findings from the general population (Halladay et al., 2015), and may have specific import to the autistic population, which tends to report proportionally higher rates of non-conforming gender and sexual identities (Halladay et al., 2015; Strang et al., 2014).

**429.010** (Poster) Burnout in Women with ASD: An Underexposed Problem.

*E. M. Blijd-Hoogewys<sup>1</sup>, M. L. Bezemer<sup>1</sup> and A. MoP, (1)INTER-PSY, Groningen, Netherlands, (2)dr. Leo Kannerhuis, Amsterdam, Netherlands*

Background:

In clinical practice, a substantial number of women with ASD is experiencing burnout. Often, this concerns an ‘autistic burnout’, which is the result of chronic life stress and a lifelong mismatch of expectations and abilities without adequate support (Raymaker et al., 2020). As a result, these women experience physical and mental fatigue, heightened stress, and diminished capacity to manage life skills, sensory input, and/or social interactions. Social camouflaging may play a big role.

When turning to their General Practitioner (GP) with burnout complaints, ASD often is not immediately considered as an underlying factor. This risk is even more likely when the GP has insufficient knowledge about ASD in general and ASD in women in particular. It is important that ASD is recognized in order to really help these women. Therefore, it is important to first gain insight into how burnout manifests itself in women with ASD. Little research has been done into this yet.

Objectives:

Looking at possible differences in burnout complaints between women with and without ASD.

#### Methods:

The research group ( $N = 497$ ) consisted of a convenience sample of women who recently experienced burnout. Two subgroups were formed: a subgroup with and without ASD ( $n = 350$  and  $n = 147$ , respectively). All filled in an AQ-10, a screening tool for ASD symptoms. They also filled in questions concerning the duration of their most recent burnout episode, the experienced burnout symptoms (18 physical symptoms, 17 mental symptoms, 14 emotional symptoms, 19 behavioral symptoms; 5-point Likert scale) and common risk factors leading to burnout (obligations, conflicts, life events, experiences of loss, growing demands, lack of possibilities, lack of social support). Data were collected via social media channels.

#### Results:

There were no significant differences in reported burnout symptoms between both groups (see Table 1). As expected, women with ASD scored significantly higher on the AQ-10 (ASD:  $M = 7.01$ ,  $SD = 1.94$ ; non-ASD:  $M = 3.86$ ,  $SD = 2.39$ ;  $t(230.55) = 14.10$ ,  $p < .001$ ,  $d = 1.51$ ). Correlations between AQ-10 and experienced burnout symptoms (physical symptoms .128,  $p < .01$ ; mental symptoms .283,  $p < .01$ ; emotional symptoms, .156,  $p < .01$ ; behavioral symptoms, .084, ns) were low.

There was a significant difference between both groups in duration of the most recent burnout episode, where the ASD group had the longest duration (see Table 2;  $\chi^2(3) = 22.57$ ,  $p < .001$ ). There was also a significant difference between these groups concerning experienced 'growing demands' prior to the most recent burnout (ASD 50% vs. non-ASD 34%;  $\chi^2(1) = 10.31$ ,  $p = .001$ ).

#### Conclusions:

In this convenience sample of women with and without ASD, we found no difference in experienced burnout symptoms. However, in women with ASD the most recent burnout episode lasted longer and a higher percentage perceived growing demands prior to their burnout. Given these results, it is important that the GP learns to better recognize ASD in women, in order to engage in conversation about the negative effect of experienced growing demands, constant adaptation and social camouflaging.

#### 429.012 (Poster) Core Autism Symptoms Are Connected to Schizophrenia Symptoms: Examination of Autism and Schizophrenia Symptom Overlap Using Network Analysis

**G. T. Han<sup>1</sup>**, D. A. Trevisan<sup>1</sup>, J. H. Foss-Feig<sup>2</sup>, V. Srihari<sup>3</sup>, A. Anticevic<sup>4</sup> and J. McPartland<sup>1</sup>, (1)Child Study Center, Yale University School of Medicine, New Haven, CT, (2)Seaver Autism Center for Research and Treatment, Department of Psychiatry, Icahn School of Medicine at Mount Sinai Hospital, New York, NY, (3)Program for Specialized Treatment Early in Psychosis (STEP), Department of Psychiatry, Yale University School of Medicine, New Haven, CT, (4)Division of Neurocognition, Neurocomputation, and Neurogenetics (N3), Yale University School of Medicine, New Haven, CT

**Background:** Autism Spectrum Disorder (ASD) and schizophrenia (SCZ) are neurodevelopmental conditions with clinically significant rates of co-occurrence and overlapping symptomatology. Both disorders share differences in social functioning, sensory processing, theory of mind, and cognition compared to typically developing controls. Despite this degree of symptom overlap, relations among respective ASD and SCZ symptom domains remain unclear. Network analysis offers a promising tool to examine patterns of symptom organization both within and across diagnostic categories.

**Objectives:** The current study examined relationships among ASD and SCZ symptoms using a novel network analysis approach to inform the nature of symptom overlap and provide insights relevant to differential diagnosis.

**Methods:** Participants included  $N=92$  adults aged 18 to 48 years [ $M(SD)=25.30$  (6.10)] across ASD ( $n=53$ ) and SCZ ( $n=39$ ) diagnostic groups. Diagnoses were confirmed according to gold standard research instruments administered by clinicians skilled in differential diagnosis, and participants were excluded if they met criteria for any other disorder. ASD and SCZ symptoms were assessed via self-report on the Social Responsiveness Scale, 2<sup>nd</sup> Edition (SRS-2) and Schizotypal Personality Questionnaire (SPQ), respectively. Relations among clinical symptoms were modeled using network analysis. Specifically, subscales of the SRS-2 and SPQ served as network 'nodes' connected by 'edges' that corresponded to partial correlations among symptom subscales after conditioning over all other nodes. Separate networks were modeled for each clinical group to examine symptom organization within diagnostic category. Centrality analyses identified the most central and influential variables in each network.

**Results:** Within the ASD group, autism symptoms formed a central symptom cluster (Fig. 1a; ASD Network), with restricted and repetitive behaviors (RRBs) demonstrating the greatest degree of connections with other nodes (node strength=2.25). SCZ symptoms were less influential (Fig. 1c) and situated on the network periphery. RRBs bridged the ASD symptom cluster to cognitive-perceptual (e.g., suspiciousness,  $r=0.17$ ; unusual perceptions,  $r=0.19$ ) and disorganized (e.g., eccentric behavior,  $r=0.31$ ) SCZ symptoms, while ASD-related deficits in social motivation were linked to interpersonal (e.g., no close friends,  $r=0.32$ ; social anxiety,  $r=0.43$ ) SCZ symptoms. The SCZ Network (Fig. 1b) revealed a SCZ-specific symptom cluster of cognitive-perceptual symptoms centered around ideas of reference (node strength=1.27). Notably, ASD symptoms demonstrated high levels of influence in the SCZ network (Fig. 1d). Specifically, social communication was particularly influential (node strength=1.48) and connected to both interpersonal (e.g., constricted affect,  $r=0.32$ ) and disorganized SCZ symptoms (e.g., odd speech,  $r=0.26$ ).

**Conclusions:** Results indicate qualitatively different transdiagnostic symptom networks for individuals with ASD compared to SCZ. Whereas symptom clusters were more distinct for individuals with a confirmed ASD diagnosis, the SCZ network yielded an intermixed network with notable overlap between ASD-related social impairments and SCZ symptoms. The networks were primarily differentiated by the central role of cognitive-perceptual symptoms in the SCZ group, and both RRBs and social communication in the ASD group. Network structures suggest that ASD-related social impairments offer poor specificity in differential diagnosis and are linked to SCZ symptoms in individuals with SCZ and without ASD. Detailed assessment of ASD-related RRBs and SCZ-related cognitive-perceptual symptoms may be instrumental for achieving diagnostic clarity.

**429.013 (Poster)** COVID-19 Pandemic Effects in People with Autism Spectrum Disorder and Their Caregivers: Evaluation of Social Distancing and Lockdown Impact on Mental Health and General Status.

**J. Lugo Marín<sup>1</sup>, L. Gisbert<sup>1</sup>, I. Setien<sup>1</sup>, G. Español Martín<sup>1</sup>, P. Ibáñez Jiménez<sup>1</sup>, M. Forner Puntonet<sup>1</sup>, E. Diez Villoria<sup>2</sup>, R. Canal-Bedia<sup>2</sup> and J. A. Ramos-Quiroga<sup>1</sup>, (1)Psychiatry, Hospital Universitari Vall d'Hebron, Barcelona, Spain, (2)University of Salamanca, Salamanca, Spain**

**Background:** Among the difficulties associated with ASD are those related to adaptation to changes and new situations, as well as anxious-depressive symptoms frequently related to exceeding environmental requirements.

**Objectives:** The main objective of this research is to study the psychological impact of lockdown caused by the social emergency situation (COVID-19) in children/adolescents and adults diagnosed with ASD.

**Methods:** Participants were 37 caregivers of children/adolescents with ASD, also 35 ASD adults and 32 informants. Evaluation was conducted through a web survey system and included clinical standardized questionnaires (CBCL and SCL-90-R), which were compared with results prior to lockdown start, and a brief self-developed survey addressing subjective perception of changes on daily functioning areas.

**Results:** The results found a reduction of psychopathological symptoms in both age groups, but only reaching statistical significance in the adult group, except for Somatization, Anxiety and Obsessive-Compulsive domains. ASD severity level 2 showed greater improvement after lockdown onset in the children/adolescents group when compared to ASD level 1 participants. Younger adults (18-25 yoa) reported greater improvement when compared to older adults ( $\geq 25$  yoa). Survey results point to an improvement of feeding quality and a reduction in number of social initiations during lockdown period. Adult ASD participants self-perceived a decreasing in stress levels after lockdown onset, while caregivers reported higher stress levels at the same point in both age groups.

**Conclusions:** Limitations included a small number of participants and a heterogeneous evaluation window between measures. Psychopathological status after two months of social distancing and lockdown seems to improve in ASD young adult population.

**429.015 (Poster)** Exploring the Associations between Polygenic Risk for Autism, Autistic Traits and Psychotic Experiences until Young Adulthood: Evidence from the Alspac Birth Cohort

**C. Dardani<sup>1</sup>, R. Schalbroeck<sup>2</sup>, H. J. Jones<sup>1</sup>, G. Hammerton<sup>3</sup>, J. Croft<sup>4</sup>, P. Madley-Dowd<sup>5</sup>, S. Sullivan<sup>1</sup>, S. Zammit<sup>1</sup>, J. P. Selten<sup>5</sup> and D. Rai<sup>5</sup>, (1)Population Health Sciences, Bristol Medical School, Centre for Academic Mental Health, Bristol, United Kingdom, (2)Rivierduinen Institute for Mental Healthcare, Leiden, Netherlands, (3)University of Bristol, Bristol, United Kingdom, (4)Division of Psychological Medicine and Clinical Neurosciences, Cardiff University, Cardiff, United Kingdom, (5)Psychosis Research Group, Rivierduinen Institute for Mental Healthcare, Leiden, Netherlands**

**Background:** There is increasing evidence suggesting associations between liability to autism (autism polygenic risk/autistic traits) and psychotic experiences in adolescence. However, the mechanisms for such associations are currently unknown. For

example, it is unclear whether these associations persist into adulthood, are confounded by schizophrenia polygenic risk, and/or mediated by childhood traumatic experiences.

**Objectives:** To investigate:

- i. the associations between autism polygenic risk as well as autistic traits with psychotic experiences until young adulthood,
- ii. the role of genetic confounding by schizophrenia polygenic risk,
- iii. the possible mediating role of traumatic experiences in childhood.

**Methods:** We conducted a longitudinal study in the population-based ALSPAC birth cohort based in the South West of England. Leveraging participant genetic information, we constructed polygenic risk scores for autism across 13 p-value thresholds, using the latest publicly available autism GWAS (Grove et al., 2019), as the discovery sample. We used four dichotomised (upper 10% of the distribution) measures of autistic traits (social communication, assessed at 7 years; coherence, assessed at 9 years; repetitive behaviour, assessed at 5 years; and sociability, assessed at 3 years). Psychotic experiences were assessed at ages 18 and 24 using the semi-structured Psychosis-Like Symptoms interview (PLIKSi) and categorised as distressing or frequent which represents a phenotype more strongly indexing schizophrenia liability). Traumatic experiences (between ages 5 to 11) were assessed by parental questionnaires and interviews about domestic violence, physical abuse, emotional abuse, emotional neglect, sexual abuse, and bullying victimization.

**Results:** The maximum sample with complete data was 4,015 for the autism polygenic risk-psychotic experiences analyses, 3,410 for the autistic traits-psychotic experiences analyses and 3,327 for the mediation analyses. Childhood social communication difficulties were associated with distressing or frequent psychotic experiences measured until age 24 (adjusted OR 1.61, 95% CI 1.01–2.56,  $p = 0.05$ ). This association did not seem to be confounded by schizophrenia polygenic risk. In mediation analysis, traumatic experiences in childhood explained a substantial proportion of the association between social communication and later psychotic experiences (approximately 33%). There was limited evidence to suggest an association between autism polygenic risk and psychotic experiences (OR 1.11, 95% CI 0.97–1.26,  $p = 0.12$ ).

**Conclusions:** We found that the childhood autistic trait of social communication was associated with psychotic experiences by age 24. This association was substantially mediated by childhood traumatic experiences and not confounded by polygenic risk for schizophrenia. Experience of trauma may be an important, potentially modifiable pathway between autistic features and later onset of psychotic psychopathology where interventions could be targeted.

**429.016 (Poster)** Exploring the Links between Perception, Cognition and Anxiety in Autistic Adults through the Lens of Hierarchical Predictive Coding.

**J. K. Doyle<sup>1</sup>** and **C. E. Wilson<sup>2</sup>**, (1)School of Psychology, University of Dublin, Trinity College, Dublin, Dublin 2, Ireland, (2)Psychology, University of Dublin, Trinity College, Dublin, Ireland

---

**Background:** Research has discovered a high prevalence of psychological issues in autistic individuals with 79% experiencing at least one psychiatric disorder (Lever & Geurts, 2016). The purpose of this study is to extend the existing work by other researchers which examines the relationship between perception, cognition and anxiety in autistic children to include autistic adults. We investigated the relationship between these variables under a model of autism that proposes all features result from a fundamental perceptual difference: High, Inflexible Precision of Prediction Errors (HIPPEA); excessive prediction errors at low levels lead to sensory sensitivity (SS), resulting in intolerance of uncertainty (IU), increases in anxiety and the employment of coping strategies (Van de Cruys et al., 2014).

**Objectives:** This study had two aims:

Investigate the factor structure of the Sussex Cognitive Style Questionnaire (SCSQ) in an adult autistic population.

Utilise the SCSQ to investigate the relationship between SS, IU, anxiety and cognitive style by testing the hypotheses that:

- 1) SS predicts local processing bias.
- 2) SS predicts IU.
- 3) IU predicts anxiety.
- 4) IU predicts systemising tendency.

**Methods:** This study used an online questionnaire with a sample of four hundred and eighty-six autistic adults (70% with a formal autism diagnosis), 315 females, 89 males and 82 nonbinary genders (18 to 74 years  $M = 39.09$ ,  $SD = 11.77$ ) from 6 continents. The scales used were the Sussex Cognitive Style Questionnaire (SCSQ), (Mealor et al., 2016), Sensory Perception

Quotient (SPQ), (Tavassoli et al., 2014). Intolerance of Uncertainty 12-item Scale (IUS-12), (Carleton et al., 2007) and Generalised Anxiety Disorder 7-item scale (GAD-7), (Spitzer et al., 2006). Two qualitative questions (on more information on responses to scales and formats of Autistic thinking) were also included and are being analysed with completion expected early Spring 2021.

**Results:** Exploratory factor analysis revealed a 6-factor structure with four original and two new (“Local Bias”, “Concrete/statistical Preference”) factors, explaining 41.3% of the variance; F1 “Imagery Ability” explained 15.61%, ( $\alpha = .94$ ), F2 “Technical/Spatial” (8.73%  $\alpha = .87$ ), F3 “Local Bias” 5.10%, ( $\alpha = .73$ ), F4 “Language and Words Forms” (4.29%,  $\alpha = .73$ ), F5 “Concrete/Statistical preference” (3.88%,  $\alpha = .77$ ) and F6 “Systemising Tendency” (3.66%,  $\alpha = .72$ ).

Regression analysis found a medium relationship between SS and local bias ( $r(423) = -.46$ ,  $p < .001$ . 95% CI [-.53, -.38]), a small relationship between SS and IU ( $r(484) = -.20$ ,  $p < .001$ . 95% CI [-.28, -.11]) and a large relationship between IU and anxiety ( $r(484) = .52$ ,  $p < .001$ . 95% CI [.45, .58]). There was no significant association between IU and Systemising tendency ( $r(423) = .04$ ,  $p = .43$ . 95% CI [-.06, .13]).

**Conclusions:** This study offers insight into the relationships between perception, cognition and anxiety in autistic adults. Interpretation of these findings can illuminate the mechanisms underpinning autism. Though results align with the assumptions of HIPPEA, research that can directly test the perceptual mechanisms proposed by the model are needed. Additionally, we highlight a need for research that considers the diversity of the autistic spectrum.

**429.017 (Poster)** Exploring the Relationship between Sensory Processing Atypicalities, Restricted and Repetitive Behaviours and Depression in Autistic Adults

**S. Brice<sup>1</sup>, J. Bamford<sup>2</sup>, M. Freeston<sup>3</sup>, B. Ingham<sup>4</sup>, A. LeCouteur<sup>1</sup>, J. R. Parr<sup>1</sup> and J. Rodgers<sup>1</sup>,** (1)Population Health Sciences Institute, Newcastle University, Newcastle upon Tyne, United Kingdom, (2)Newcastle University, Newcastle, United Kingdom, (3)School of Psychology, Newcastle University, Newcastle upon Tyne, United Kingdom, (4)Northumberland Tyne and Wear NHS Foundation Trust, Newcastle upon Tyne, United Kingdom

## **Background:**

Autistic adults are 3-4 times more likely to experience depression compared to neurotypical people. Depression is associated with increased suicidality and lower quality of life. Research investigating anxiety indicates that autism-related constructs (e.g. reactions to the sensory environment, restricted and repetitive behaviours (RRB) and intolerance of uncertainty (IU)) may be important in our conceptualisation of mental health difficulties for autistic people and lead to differential presentations. Our conceptual understanding of depression in autistic adults is currently limited. However, emergent evidence suggests that autism characteristics may interact with depression symptoms in important ways. Developing our understanding of depression in autistic people is vital for the development of effective assessments and interventions.

## **Objectives:**

To explore the relationship between sensory processing atypicalities, RRB, anxiety, IU and depression.

## **Methods:**

Archival data from 420 autistic adults without intellectual disability recruited from the Adult Autism Spectrum Cohort UK (ASC-UK) (age range 18 – 77 years; mean age = 42.8 years; 44.5% male, 52.9% female, 2.6% another gender) were analysed. Participants completed the Social Responsiveness Scale - 2 to determine ‘severity’ of autistic traits (mean = 111.7; 96% scored above clinical threshold for autism). Participants completed measures of depression (Hospital Anxiety and Depression Scale; HADS), anxiety (Anxiety Scale for Autism - Adults), RRB (Repetitive Behaviour Questionnaire-2), IU (Intolerance of Uncertainty Scale-12) and sensory processing atypicalities (Sensory Preferences Questionnaire). The factor structure of the HADS was assessed using confirmatory factor analysis, to provide an indication of construct validity. Correlational analyses were conducted to explore the relationship between the constructs. Additionally, conceptual mediation models were tested. One simple mediation model explored the potential interplay between sensory processing atypicalities and depression via RRB. Three further serial mediation models explored the interplay between sensory processing atypicalities and depression via proposed mediators IU, anxiety and RRB.

## **Results:**

63% of participants scored above the clinical threshold for depression as rated by the HADS. Confirmatory factor analysis indicated satisfactory construct validity for the HADS. Internal consistency for all measures was good to excellent (Cronbach's  $\alpha=.82-.90$ ). Significant positive correlations were identified between depression and all constructs of interest, ranging from  $r=.49$  (anxiety) to  $r=.32$  (sensory processing atypicalities). The simple mediation model (sensory processing atypicalities  $\rightarrow$  RRB  $\rightarrow$  depression) identified that there was a significant direct and indirect effect between sensory processing atypicalities and depression (partial mediation). However, the serial mediation models identified that there was no direct effect between sensory processing atypicalities and depression and that the models were fully mediated via anxiety and via IU and anxiety but not via RRB.

## Conclusions:

Our findings suggest that IU and anxiety play a key role in understanding the relationship between sensory processing atypicalities and depression for autistic adults. Interventions that aim to address IU and anxiety may also have a beneficial impact on depression associated with sensory processing atypicalities. Further research is needed to replicate and extend these findings and use them to develop specific and personalised assessments and intervention for depression in autistic adults.

## 429.018 (Poster) Frontal EEG Asymmetry, Maternal Depression, and Child Internalizing and Externalizing Symptoms in Autism

*E. Neuhaus<sup>1,2</sup>, S. J. Lowry<sup>1</sup>, M. Santhosh<sup>3</sup>, A. Kresse<sup>4</sup>, E. J. Libsack<sup>5</sup>, V. Y. Kang<sup>6</sup>, R. A. Bernier<sup>6</sup>, K. A. Pelphrey<sup>7</sup>, S. J. Webb<sup>6</sup> and G. A. Consortium<sup>1</sup>, (1)Seattle Children's Research Institute, Seattle, WA, (2)Psychiatry & Behavioral Sciences, University of Washington, Seattle, WA, (3)Center for Child Health, Behavior and Development, Seattle Children's Research Institute, Seattle, WA, (4)Stony Brook University, Stony Brook, NY, (5)Special Education, University of Illinois at Chicago, Chicago, IL, (6)Psychiatry and Behavioral Sciences, University of Washington, Seattle, WA, (7)University of Virginia, Charlottesville, VA*

**Background:** Frontal asymmetry (FA) in EEG alpha band activity corresponds to affective style and vulnerability to psychopathology, such that relatively stronger right activity portends risk for childhood internalizing and externalizing. Similarly, maternal depression is a powerful familial risk factor for a range of emotional difficulties from very early in life. However, we know little regarding the interaction of FA and maternal depression among youth with autism spectrum disorder (ASD) despite elevated rates of psychopathology in this population.

**Objectives:** We aim to (1) Characterize EEG FA among children and adolescents with ASD relative to those without ASD, and (2) Consider main and interactive effects of FA and maternal depression history on internalizing and externalizing symptoms for youth with ASD.

**Methods:** Data were obtained within a large study spanning four US sites. Current analyses include 280 youth (mean age=12.8 years,  $SD=2.9$ , range=8.0-18.0) with ( $n=142$ ; 43% female) and without ASD ( $n=138$ ; 49% female), without intellectual disability. ASD diagnoses were well-established and confirmed via ADOS-2, ADI-R, and DSM-IV criteria. Parents reported child symptoms with the Child Behavior Checklist (Internalizing and Externalizing broadband scores), and maternal mental health history through clinician interview. High-density EEG was collected during resting state, and alpha band FA was extracted. General linear models were conducted to consider age, sex, and diagnostic effects on FA, as well as main and interactive effects of FA and maternal depression history on child symptoms.

**Results:** Frontal asymmetry did not differ by age, sex, or diagnosis ( $F(4, 275)=.18, p=.95$ ), nor was there an interaction between sex and diagnosis (Figure 1). Within our ASD group, models containing FA, maternal depression history, and their interaction were associated with both internalizing ( $F(4,103)=5.5, p<.001$ ) and externalizing symptoms ( $F(4,103)=4.64, p=.002$ ), with elevated symptoms associated with a positive history of maternal depression. However, subsequent models indicated sex differences in these effects. Whereas these factors accounted for 19% of variance in internalizing symptoms among females ( $F(4,42)=3.74, p=.01$ ), a comparable model among males was nonsignificant. The reverse was true for externalizing, with null effects for girls but approximately one third (32.6%) of externalizing variance accounted for among boys ( $F(4,56)=8.24, p<.001$ ). In particular, the interaction of FA and maternal depression ( $F(1, 56)=8.83, p=.004$ ), as well as their main effects ( $ps<.05$ ), were significant for males. FA was not associated with externalizing in the context of maternal depression, but higher externalizing scores corresponded to stronger right asymmetry (relatively less left frontal activity) for those males whose mothers did not have a history of depression (Figure 2).

**Conclusions:** Maternal depression was a robust risk factor for child psychopathology symptoms across symptom domains and sex in youth with ASD, whereas FA emerged specifically with regard to externalizing among males without maternal depression history. Broadly, findings suggest that risk factors may operate differently for females and males with ASD, despite the absence of sex differences in frontal asymmetry itself. Continued consideration of individual differences across levels of analysis (e.g.,

EEG, family factors) will be essential to parsing out models of risk and resilience among youth with ASD.

**429.019 (Poster)** Gender Nonconformity and the Broader Autism Phenotype in College Students: Links with Mental Health  
**H. K. Schiltz<sup>1</sup>, A. J. McVey<sup>2</sup>, I. Seager van Dyk<sup>3</sup> and A. V. Van Hecke<sup>1</sup>,** (1)Psychology, Marquette University, Milwaukee, WI, (2)University of British Columbia, Vancouver, BC, Canada, (3)Yale School of Public Health, New Haven, CT

---

**Background:** Studies have identified higher levels of autism traits and a greater incidence of autism among youth and adults with gender variance (Heylens et al., 2018; van der Miesen et al., 2018). Likewise, gender variance is more common among autistic children and adults and is linked with autism characteristics (George & Stokes, 2018; Nabbijohn et al., 2019). Mental health concerns are common among autistic adults (Hollocks et al., 2019) and gender minorities (Warren et al., 2016). Thus, adults with high levels of autistic traits and nonconformity to social gender norms (i.e., gender nonconformity; GNC) may be at additional risk for mental health concerns. Little research to date, however, has examined broad features of these presentations (i.e., the Broader Autism Phenotype [BAP] and GNC) in a general population sample.

**Objectives:** To explore 1) associations between the BAP and GNC, 2) links between internalizing symptoms (i.e., depression, anxiety) with each BAP and GNC, and 3) the relative contribution of BAP, GNC, and their interaction in predicting internalizing symptoms in a sample of college students.

**Methods:** College students ( $N=181$ ) aged 18–25 ( $M=18.74$ ) (69% female) completed questionnaires for course credit. The BAP was assessed using the Broad Autism Phenotype Questionnaire (BAPQ; Hurley, et al., 2007) including the Aloofness, Pragmatic Language Difficulties, and Rigidity subscales. Internalizing symptoms were measured with the Center for Epidemiologic Studies Depression Scale (CES-D; Radloff, 1977) and State-Trait Anxiety Inventory (STAI, Trait subscale; Spielberger et al., 1983). GNC was quantified using the Marquette Measure of Gender Conformity (MMGC; Matelski et al., 2016) which includes Behaviors, Physical Presentation, and Attitudes and Values; lower scores indicate less gender conformity (i.e., more GNC).

**Results:** Due to skew of the MMGC subscales, Spearman's rho was used to calculate correlations (Table 1). MMGC Physical Presentation was significantly negatively related to BAPQ Total, Pragmatic Language, and Aloofness. Internalizing symptoms (CES-D, STAI) were significantly positively related to all BAPQ measures as well as negatively significantly related to the MMGC Physical Presentation. Moderation analyses indicated a marginal interaction ( $p=0.10$ ) between the BAPQ and MMGC Total in predicting CES-D; the effect of the BAPQ on CES-D was stronger at lower levels of MMGC (i.e., more GNC). No main or interaction effects were detected when predicting STAI.

**Conclusions:** Our results reveal that those with more BAP features reported less conformity to physical gender presentation conventions (clothing, hairstyle, makeup, etc.) in a college student sample. Additionally, more internalizing symptoms were related to greater endorsement of the physical facet of GNC, as well as higher levels of all BAP dimensions. Importantly, GNC marginally moderated the effect of BAP on depression; the link between BAP and depression was stronger for those with higher GNC. The effect of the BAP on anxiety, however, was invariant across levels of GNC. This study highlights the need to consider both BAP and GNC, even at sub-threshold levels, in supporting mental well-being. Limitations include the homogeneity of the sample with regard to age, race, ethnicity, and gender identity, as well as the limited psychometric evidence of the MMGC.

**429.020 (Poster)** Genetic Etiologies of Catatonia in Patients with Autism Spectrum and Other Neurodevelopmental Disorders: A Retrospective Review and Case Series

**A. Shillington<sup>1</sup>, R. Hopkin<sup>1</sup>, C. A. Erickson<sup>1</sup>, M. Lamy<sup>2</sup>, E. Pedapati<sup>1</sup>, K. J. Zappia<sup>1</sup> and K. Dominick<sup>1</sup>,** (1)Cincinnati Children's Hospital Medical Center, Cincinnati, OH, (2)Division of Child and Adolescent Psychiatry, Cincinnati Children's Hospital Medical Center, Cincinnati, OH

---

Background:

The association between catatonia and autism spectrum disorder (ASD) is a rare but clinically significant comorbidity. There have been many single case reports of catatonia in patients with ASD identifying an underlying genetic diagnosis; though analysis of larger cohorts of pediatric catatonia is limited.

Objectives:

Here we analyze a cohort of pediatric patients with neurodevelopmental disorders including ASD a diagnosis of catatonia to identify underlying genetic diagnoses in an effort to better understand molecular pathways involved in ASD and catatonia.

## Methods:

Data was collected from medical records at Cincinnati Children's Hospital Medical Center (CCHMC) of patients with catatonia along with well-characterized neurodevelopmental disorder including ASD based on multidisciplinary evaluation. Genetic test results were abstracted from medical records and analyzed to identify the proportion of this cohort that received genetic testing along with the proportion of the cohort that received a specific genetic diagnosis or presumptive diagnosis.

## Results:

Forty-nine patients were identified in the electronic medical records to have a diagnosis of catatonia. Sixty one percent (n=30) had a diagnosis of neurodevelopmental disorder, 18 ASD, 5 idiopathic ID, and 6 with ID in the setting of Down Syndrome. Of these 30 patients, 63% (n=19) received some clinical genetic testing, and of the patients who received genetic testing, 47% (n=9) had a confirmed genetic diagnosis or presumptive genetic diagnosis. Seventy two percent (n= 13) of those patients with ASD received genetic testing, with 22% (n=4) receiving a confirmed or presumptive genetic diagnosis. Two of the 7 patients with ID received testing with 1 receiving a confirmed or presumptive genetic diagnosis.

## Conclusions:

In our retrospective review, patients with catatonia and ASD have a high burden of pathogenic disease variants, consistent with previously reported yields in the literature for NDD cohorts. Variants identified in this retrospective review are detailed in case examples. Molecular pathways of interest identified include genes involved in GABA and glutamate synaptic function, (*NLGN2*, *NRXN1*, *NRXN4*, *NAA15*, *DSCAM*). Opportunities for further investigation include prospective genetic testing of the remaining patients in the cohort in an attempt to identify

### **429.021 (Poster)** Homotypic and Heterotypic Continuity in Mental Health Symptoms in Autistic Youth: Prediction from Childhood to Adolescence

*V. Carter Leno<sup>1</sup>, S. Chandler<sup>1</sup>, I. Yorke<sup>1</sup>, T. Charman<sup>1</sup>, A. Pickles<sup>1</sup> and E. Simonoff<sup>1</sup>, (1)King's College London, Institute of Psychiatry, Psychology and Neuroscience, London, United Kingdom, (2)Department of Psychology, Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, United Kingdom*

---

**Background:** Mental health difficulties are prevalent in autistic adolescents, yet their developmental precursors are not well understood. In neurotypical youth, substantial homotypic (within-disorder) continuity over development is reported, although there is some evidence for specific types of heterotypic (between-disorder) prediction (e.g. behavioural problems in childhood predicting emotional problems in adolescence). In autistic populations, whether a similar pattern of prediction exists, and if these longitudinal pathways are moderated by child and environmental factors, remains unknown.

**Objectives:** To test prediction of mental health symptoms from childhood to adolescence in a population-based sample of autistic youth.

**Methods:** Parents of a stratified sample (T1; N=101; 57/44 male/female; aged 4–8 years) completed a semi-structured psychiatric interview (Preschool Age Psychiatric Assessment), and measures of parental distress (Kessler Psychological Distress Scale). SES was measured using the 2007 English Indices of Multiple Deprivation. Child IQ was measured using standardised instruments. The stratified sample were selected from the larger total sample, consisting of all children who received an autism spectrum disorder diagnosis in a defined geographical area between 2000-2004 (N=477). The stratified sample were followed six (T2; age 11-15 years) and eight (T3; age 13-17 years) years later. At T3, 72 parents completed the Child and Adolescent Psychiatric Assessment.

Structural equation models, weighted for sample stratification and attrition, tested unadjusted univariate and adjusted multivariate (adjusting for co-occurrence between T1 symptoms) prediction from T1 to T3, grouping symptoms into emotional (anxiety and depression), behavioural (conduct and oppositional defiant disorder) and attention-deficit hyperactivity (ADHD) domains. Multi-group models tested for moderation of T1 to T3 prediction by child sex, IQ (<70/≥70), SES (median split) and parental distress (<24/≥24). As symptom data was a count of the number of endorsed symptoms, estimates are given as incidence-rate ratios (IRRs).

**Results:** In unadjusted analyses, there was evidence of homotypic and heterotypic continuity, with T1 emotional, behavioural and ADHD symptoms all predicting T3 emotional and behavioural symptoms (all *ps* < .05; see Table 1 / Figure 1). However, in adjusted analyses, only homotypic continuity was seen; only within-disorder predictions were significant (all *ps* < .01; see Table 1 / Figure 1).

Sex moderated the T1 to T3 ADHD symptoms pathway ( $c^2(1) = 5.10, p = .02$ ); this was significant in females (IRR = 1.28,  $p < .001$ ) but not males (IRR = 1.06,  $p = .262$ ), and parental distress moderated the T1 behavioural symptoms to T3 emotional symptoms pathway ( $c^2(1) = 8.96, p = .003$ ); this was significant in the low parental distress group (IRR = 1.20,  $p = .010$ ), but non-significant in high parental distress group (IRR = .93,  $p = .131$ ). Moderation by SES and child IQ was not significant.

Conclusions: Comparison of the unadjusted and adjusted results suggests that within-disorder continuity in autistic youth may look like cross-disorder prediction if co-occurrence of mental health symptoms in childhood is not taken into account. Results highlight the importance of early focused interventions for mental health difficulties in autistic young people.

**429.022 (Poster)** Impact of COVID-19 on Stress, Anxiety, and Coping in Youth with and without Autism and Their Parents  
**B. A. Corbett<sup>1</sup>, R. A. Muscatello<sup>1</sup>, M. E. Klemencic<sup>2</sup> and J. M. Schwartzman<sup>3</sup>,** (1)Psychiatry and Behavioral Sciences, Vanderbilt University Medical Center, Nashville, TN, (2)Vanderbilt University Medical Center, Nashville, TN, (3)Palo Alto University, Palo Alto, CA

---

Background: In the wake of COVID-19, the world has become a more uncertain, unpredictable environment – a breeding ground for stress and anxiety, especially for individuals with autism spectrum disorder (ASD) who often respond poorly to change and have heightened stress and anxiety. The overarching objective of the study was to examine stress, coping and anxiety in a data-driven, real-time assessment of adolescents with and without ASD and their parents at the height of the COVID-19 shutdown and three months later.

Objectives: The study had four primary aims: Aim 1, Child: examined stress, coping and anxiety during the height of the pandemic in self-reports of children and adolescents with and without ASD. Aim 2, Parent: examined stress, coping and anxiety on parents of children with and without ASD regarding their own self-reported stress and anxiety. Aim 3, Predictive: examined the effect of adults' self-reported stress and coping style on the perception of their child's stress and coping skills. Aim 4, Longitudinal: examined the impact of COVID-19 longitudinally by comparing stress and coping over two time-points.

Methods: The respondents to the stress and anxiety measures participate in a longitudinal study of stress and physiological arousal in pubertal development in ASD. Participants included 122 fully-characterized adolescents (ASD=61, TD=61), and their parents (96.3% mothers). Four standardized measures were administered via REDCap to ascertain stress and coping explicitly related to the COVID-19 pandemic (RSQ COVID-19-Child, Adult, Parent) and anxiety (STAI-C, STAI-A). Multivariate, univariate analysis of variance and hierarchical regression approaches were used.

Results: Significant differences emerged with ASD youth endorsing more trait anxiety ( $p < 0.05$ ) and response to specific stressors (e.g., virus, access to healthcare) ( $F(14,91)=2.82, p=0.002; \Lambda=0.698, \eta^2=.302$ ). Parents of children with ASD showed higher self-reported anxiety ( $p < 0.05$ ), yet scores were elevated for both parent groups. ASD parents reported more stress ( $F(1,106)=22.38, p < 0.001, \eta^2=.174$ ), especially related to the virus, access to supplies and healthcare, work, and concern for the future. TD youth and their parents used more Primary and Secondary Control Coping whereas ASD youth and their parents use more Disengagement Coping. Using hierarchical regression, child self-reported stress ( $\beta = 0.28, p < 0.001$ ) and parents' adult self-reported stress ( $\beta = 0.55, p < 0.001$ ) were significant predictors of the parent-rated perception of their child's stress. Importantly, it was parents' own stress that was the strongest predictor of child stress accounting for 24% of the model variance ( $\Delta F(1,87) = 55.31, p < 0.001$ ). Finally, longitudinal analyses revealed persistent RSQ Total stress with significantly higher levels in the ASD group for children  $F(1,85)=7.524, p=0.007$ , adult  $F(1,83)=8.584, p=0.004$ , and parent-report of child stress  $F(1,89)=6.997, p=0.01$ .

Conclusions: Results reveal striking differences in youth with ASD and their parents regarding anxiety, stress, and coping. Findings highlight the need for essential support, access to services, and strategies to enhance psychological and emotional well-being.

**429.023 (Poster)** Incorporating ASD Symptoms into a Transdiagnostic Model of Internalizing Symptoms Results in an Improved Model for Youth with ASD  
**T. Rosen<sup>1</sup>, C. Rodriguez-seijas<sup>2</sup>, K. D. Gadow<sup>3</sup> and M. D. Lerner<sup>4</sup>,** (1)University of Colorado School of Medicine, JFK Partners, Aurora, CO, (2)Stony Brook University, Stony Brook, NY, (3)Department of Psychiatry, Stony Brook University, Stony Brook, NY, (4)Department of Psychology, Stony Brook University, Stony Brook, NY

---

**Background:** Youth with autism spectrum disorder (ASD) are at increased risk for co-occurring anxiety symptoms (van Steensel, Bögels, & Perrin, 2011). Factor analytic studies of anxiety often find poor model fit (e.g., White, Lerner, et al., 2014; Magiati et al., 2017), which complicates diagnostic conceptualization and subsequent treatment of anxiety in ASD. Additionally,

there is evidence that ASD symptoms are closely related to anxiety symptoms (e.g., Kerns et al., 2020). Moreover, while the high co-occurrence of anxiety and depression is well-established outside of ASD (e.g., Kessler et al., 2005), the relationship of anxiety and depression is not well-understood in ASD (e.g., Kerns et al., 2015).

**Objectives:** The present study sought to identify an improved model of internalizing symptoms in ASD by examining a broader, transdiagnostic model of internalizing symptoms (e.g., anxiety *and* depression symptoms) that also included core ASD symptoms.

**Methods:** Participants were ages 6-18, diagnosed with ASD in an outpatient clinic ( $N=280$ ;  $M_{age}=10.7$ ,  $SD_{age}=3.4$ ). Anxiety, depression, and ASD symptoms were measured using the parent CASI-4R (Gadow & Sprafkin, 2008), a DSM-IV referenced rating scale.

An exploratory factor analysis (EFA) of CASI-4R anxiety, depression, and ASD symptoms was pursued using WSLMV and Geomin rotation (e.g., Browne, 2001). Factor solution was guided by substantive interpretability (Brown, 2015; Norris & Lecavalier, 2010), scree plot analysis (Cattell, 1966), and evaluation of standard fit indices. Fit indices from a confirmatory factor analysis (CFA) of the CASI-4R original structure (e.g., anxiety, depression, and ASD symptoms fixed to load on their respective, distinct factors) were then compared against fit indices from the EFA-derived model.

**Results:** The EFA supported a 3-factor model as follows (see Table 1): Factor 1: Anxiety, Depression, and 3 ASD symptoms from the restricted interests/repetitive behaviors (RRB) domain; Factor 2: Social anxiety and social ASD symptoms, and Factor 3: ASD symptoms (including social and RRB symptoms). CFA indices suggested that the EFA model demonstrated better fit compared to the original CASI-4R model (see Table 2).

**Conclusions:** The first symptom factor suggests that similar to that seen in the general population (Kessler et al., 2005), anxiety and depression symptoms are likely to co-occur in ASD. Social anxiety however formed a second, separate factor, suggesting that it may present more distinctly in youth with ASD. Overall, modeling ASD symptoms along with internalizing symptoms revealed that no internalizing factor (e.g., factors 1 and 2) was free of ASD symptoms; these factors are consistent with theories stating that internalizing symptoms are influenced by ASD symptoms (e.g., Wood & Gadow, 2010). However, this association may not be bidirectional; ASD symptoms formed their own distinct factor, separate from internalizing symptoms, suggesting that internalizing symptoms may be less likely to influence the presentation of core ASD symptoms. Crucially, incorporating ASD symptoms into a broader internalizing model of comorbidity allowed for identification of an improved structure of symptoms compared to that of a DSM-derived model. Together, findings have important implications for treatment, assessment, and nosological classification systems.

#### **429.024 (Poster)** Insights from Parents and Caregivers: A Systematic Pursuit of Treatable Conditions in Agitated Individuals with Neurodevelopmental Disabilities

*M. Weaver<sup>1</sup>, W. Worsham<sup>1</sup>, J. Davis<sup>2</sup>, T. P. Singh<sup>1</sup>, P. Aguayo<sup>3</sup> and D. A. Bilder<sup>4</sup>, (1)University of Utah, Salt Lake City, UT, (2)Educational Psychology, University of Utah, Salt Lake City, UT, (3)Psychiatry, University of Utah, South Salt Lake, UT, (4)Psychiatry, University of Utah, Salt Lake City, UT*

**Background:** Individuals with neurodevelopmental disabilities (NDD) such as autism spectrum disorder (ASD) and intellectual disability (ID) experience deficits in communication that impair their ability to express their needs and wants verbally. Although agitation commonly occurs in individuals with NDD (Lai et al 2014), it cannot be attributed to the disability itself. The effects of many conditions and circumstances converge into the final common pathway of agitation in this population (McGuire K et al., 2016). Providers may rely on parents/caregivers for their insight into affected individuals' emotional and physical state (Selekman et al., 1995). This study used the Sources of Distress ("Sources," an online, branching logic questionnaire for parents/caregivers) to identify potential underlying contributors or causes of distress that commonly occur in the NDD population.

**Objectives:** Describe and report associations among distress manifestations, psychotropic medication use, and psychiatric/medical conditions identified.

**Methods:** Six focus groups consisting of parents (n=6), professional caregivers (n=6), and adults with NDD and expressive language ability (n=5) were conducted on Sources. Following modification based on focus group feedback, male and female versions of Sources (101 and 104 items, respectively) were adopted for clinical use in February 2019. Parents/caregivers of 72 individuals with NDD (53 males, 19 females) with significant behavior and/or mood concerns completed Sources. Symptom thresholds for classifying psychiatric conditions were based upon *Diagnostic Manual - Intellectual Disability 2* and clinical experience. Descriptive statistics, independent samples T-test, and Chi-square tests were conducted in SPSS Version 24.

Results: ASD (77.8%) and ID/cognitive delay (36.1%) were the most common developmental disabilities reported. The most common distress manifestations were agitation (97.2%), aggression (79.2%), increased fixation (79.2%), and moodiness (77.8%). All but one participant had a psychiatric condition classified through Sources. Participants had a mean of 3.6 (SD=1.3, range 0-6) psychiatric conditions; >50% of participants were classified with an anxiety disorder (90.3%), attention deficit hyperactivity disorder (70.8%), or sleep disturbances (66.7%). Endorsed medical concern categories included gastrointestinal (63.9%), general medical (44.4%, including 27.4% with seizures), dental (44.4%), and menstrual-related (42.1% of females). The following distress manifestations were associated with the respective conditions with a significance threshold of  $p \leq 0.01$ : sleep disturbance – bipolar disorder; fixation – unipolar depression; personality changes – psychosis; and eating pattern changes – general medical concern. Among the 66.7% of participants taking antipsychotics, 54.2% had an indication for 1<sup>st</sup> line use of either bipolar disorder and/or psychosis. Of participants classified with bipolar disorder taking antipsychotics, 57.9% were concurrently on an antidepressant, which may reduce antipsychotic mood stabilizing effects.

Conclusions: Individuals with NDD and agitation experience high rates of medical and psychiatric conditions that can contribute to or manifest as distress. Recognizing patients' psychiatric and medical profile allows providers to consider (1) medical conditions that merit non-psychotropic intervention, (2) safer alternatives to antipsychotics in the absence of a 1<sup>st</sup> line indication (e.g., bipolar disorder, psychosis), and (3) iatrogenic interference on antipsychotic efficacy when bipolar disorder is present. If accessed purposefully and systematically, parent/caregiver knowledge can identify underlying conditions that illuminate the path forward for medical decision-making surrounding agitation.

**429.025 (Poster)** Intergenerational Trauma in Autism: An Examination of Adverse Childhood Experiences Among Children with Autism Spectrum Disorder and Their Caregivers  
*T. M. Andrzejewski, O. Semones, E. A. DeLucia and C. G. McDonnell, Department of Psychology, Virginia Polytechnic Institute and State University, Blacksburg, VA*

---

Background: Adverse childhood experiences (ACES) are associated with a multitude of negative short- and long-term outcomes in physical health, behavior, and psychological functioning. Although children with ASD have a higher risk of experiencing ACES, little research has also considered caregiver ACES in the context of autism. Parent ACES predict child ACES as well as child behavioral and psychological outcomes among non-autistic children. Thus, examining the intergenerational association between parent and child ACES in the context of autism is a key research priority.

Objectives: The goals of the current investigation were to (1) identify rates of ACES among children with ASD and their parents, (2) evaluate the intergenerational association between parent and child ACES, and (3) explore main and interactive effects of parent and child ACES on parent psychological and child behavioral outcomes, controlling for demographic factors.

Methods: Participants included 109 caregivers of children with diagnoses of ASD who completed an online survey. Caregivers reported on their own and their child's history of ACES using the 10-item ACES checklist used by the Centers for Disease Control and Prevention, which assesses 5 indicators of child maltreatment (abuse and neglect) and 5 indicators of household dysfunction (parental incarceration, substance use, divorce, etc.). Participants also completed measures of parent stress (Perceived Stress Scale) and internalizing symptoms of depression and anxiety (Inventory for Depressive and Anxiety Symptoms (IDAS-2 Dysphoria subscale)). Lastly, participants reported on child autism traits (Autism-Spectrum Quotient, 10-Item Version) and child co-occurring internalizing and externalizing behaviors (Strengths and Difficulties Questionnaire).

Results: Results showed high rates of ACES among children with ASD and their caregivers (see Table 1). Correlational analyses showed that caregiver and child total ACES scores were significantly and strongly inter-correlated. At the item-level, chi-square analyses supported that the parent-child association was significant for all individual ACES except for physical abuse and substance use in the home. Multiple regression analyses indicated that child ACES were associated with higher levels of parent stress and internalizing symptoms and lower levels of autism symptoms (see Table 2). In contrast, parent ACES were only associated with higher levels of parent stress. The interaction between parent and child ACES was not significant for any outcome.

Conclusions: Overall, our results show high rates of ACES among children with ASD and their caregivers and demonstrate that parent and child ACES are strongly inter-correlated. Moreover, parent and child ACES showed differential associations with parent and child psychological and behavioral outcomes. Child ACES were associated with higher parent stress and mental health symptoms, even when controlling for demographic factors and parent ACES. Child ACES negatively predicted autism symptoms, suggesting that children with ASD with lower autism traits are at higher risk for ACES. Future research should consider intergenerational trauma in the context of autism.

**429.026 (Poster)** Longitudinal Associations between Signs of Attention-Deficit/Hyperactivity Disorder (ADHD) in Infancy and Toddlerhood and Mid-Childhood Functional Neural Connectivity in Infant Siblings of Autistic Children  
**E. Shephard<sup>1</sup>, B. Milosavljevic<sup>2</sup>, L. Mason<sup>3</sup>, R. Haartsen<sup>4</sup>, E. J. Jones<sup>5</sup>, M. Johnson<sup>6</sup> and T. Charman<sup>6</sup>,** (1)Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, United Kingdom of Great Britain and Northern Ireland, (2)Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, UNITED KINGDOM, (3)Centre for Brain and Cognitive Development, Birkbeck, University of London, London, United Kingdom, (4)Centre for Brain and Cognitive Development, Birkbeck University of London, London, United Kingdom, (5)Department of Psychology, University of Cambridge, Cambridge, United Kingdom, (6)Department of Psychology, Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, United Kingdom

---

**Background:** Infant siblings of autistic children are at elevated likelihood for developing autism and other neurodevelopmental conditions, including attention-deficit/hyperactivity disorder (ADHD). Previous work has indicated that infant siblings who later develop ADHD show atypically increased activity levels and poor inhibitory control in the first two years of life. Yet, how these early-life atypicalities influence development beyond the emergence of ADHD symptoms, such as the formation of functional neural networks, has not been investigated.

**Objectives:** To investigate (1) if elevated activity levels and poor inhibitory control in infancy and toddlerhood are associated with functional neural connectivity in mid-childhood and (2) whether atypicalities in functional connectivity associated with early signs of ADHD are in turn associated with parent-reported ADHD symptoms in mid-childhood.

**Methods:** We investigated these objectives in a prospective longitudinal study of infant siblings at elevated and typical familial likelihood for autism (n=104), in which we previously reported increased activity levels and poor inhibitory control measured by parent-report at age 7-24 months to be associated with elevated parent-report ADHD symptoms in mid-childhood (age 6-8 years). The current analyses were conducted on a subset of this sample (n=54) with electrophysiological (EEG) data collected during eyes-open resting-state in mid-childhood. Functional neural connectivity was computed from the mid-childhood EEG data in terms of oscillatory phase synchronisation quantified by the debiased weighted phase lag index (dwPLI) in the theta (4-8Hz) and alpha (8-12Hz) frequency bands. Network based statistic (NBS) and Spearman correlation coefficients were used to test whether activity level measured at 7-24 months and inhibitory control measured at 24 months were associated with over- or under-connected functional neural networks (NBS) and increased or decreased "whole-brain" (dwPLI averaged across all electrodes) functional connectivity (correlations) in mid-childhood. Functional connectivity metrics significantly associated with early signs of ADHD were then correlated with mid-childhood inattentive and hyperactive/impulsive traits using Spearman correlations.

**Results:** Poorer early-life inhibitory control was significantly correlated with lower whole-brain connectivity in the alpha frequency in mid-childhood ( $\rho(53)=0.28, p=0.03$ , Fig. 1a); in turn, lower whole-brain alpha connectivity tended to be associated with greater inattentive symptoms in mid-childhood ( $\rho(53)=-0.26, p=0.06$ , Fig. 1b). Early-life inhibitory control was not associated with mid-childhood theta connectivity in correlations or with alpha or theta neural networks; early-life activity level was not associated with any mid-childhood connectivity measure. Since we have previously found altered alpha connectivity in infancy to be associated with autism symptoms in this sample, we conducted a post-hoc analysis to test whether the associations between toddlerhood inhibitory control and mid-childhood alpha connectivity remained significant when adjusting for infant alpha connectivity. Multiple linear regression with infant alpha connectivity and toddlerhood inhibitory control predicting mid-childhood alpha connectivity revealed that early-life inhibitory control remained a significant predictor of mid-childhood alpha connectivity ( $\beta=0.51, p=0.008$ ).

**Conclusions:** Our findings suggest that early-life difficulties with inhibitory control are related to reduced whole-brain functional neural connectivity in the alpha range later in childhood and together these alterations may contribute to the severity of attention problems. These ADHD-related connectivity atypicalities appear to be distinct from infant connectivity alterations associated with autism.

---

Background: Sleep problems are more common and severe among young children with autism spectrum disorder (ASD) than typically developing peers. Although sleep is considered to be important for socio-emotional and physical development, little is known about the changes in sleep problems over time among children with ASD. Previous research has mainly been cross-sectional, examining associations between sleep problems and various child characteristics.

Objectives: The goals of this study were: 1) to examine changes in sleep problems over a 1-year period in a large inception cohort of preschoolers with ASD; 2) to examine relations between family-related risk factors and children's sleep problems (i.e., intercept and change); and 3) to examine the associations between child sleep problems change over time and children's internalizing symptoms.

Methods: Data were drawn from the Canadian Pathways in ASD study and included 217 children aged three- to-five year ( $M = 44.86$  months;  $SD = 6.7$ ). Data were collected within four months of diagnosis (T1), 6 months later (T2); and an additional 6 months later (T3). Sleep problems were assessed using the six items from the parent-report Child Behavior Checklist (CBCL, Achenbach et al., 2000), comprising the sleep problem scale. The CBCL sleep composite is strongly correlated with the validated Children's Sleep Habits Questionnaire (Owens, Spirito, & McGuinn, 2000) and widely used as a measure of sleep functioning (Gregory & O'Connor, 2002). The CBCL was also used to assess internalizing and externalizing symptoms. Mothers completed the Symptom Checklist-90-R (Derogatis, 1994) to assess maternal anxiety. We used the Autism Diagnostic Observation Schedule to measure ASD symptom severity (i.e., Social Affect, Restricted and Repetitive Behaviors).

Latent growth curve analysis was employed to examine child sleep problems over a 1-year period and its possible predictors and correlates. The model employed maximum likelihood estimation with robust standard errors using Mplus Version 7.4. Next, children's internalizing and externalizing symptoms at T3 were regressed on latent intercept and slope parameters. Models included child age, ASD severity, family income, internalizing and externalizing symptoms, family functioning, and maternal anxiety at T1.

Results: The unconditional growth model fit the data ( $CFI = 1.00$ ,  $RMSEA = .00$ ,  $SRMR = .01$ ). The intercept mean ( $M = .65$ ,  $SE = .04$ ) and the slope mean ( $M = -.04$ ,  $SE = .01$ ) were both significant, indicating a decrease in sleep problems over time. The variance component of the intercept was significant, suggesting between-subject variability in initial levels of sleep problems. Yet, the variance component of the slope was not significant.

The conditional model demonstrated a significant positive association between ASD symptom severity, maternal anxiety and level of sleep problems at T1. However, no associations were found with change in sleep problems over time.

Last, children with more sleep problems at T1, more persistent sleep problems, showed more internalizing symptoms at T3, even after controlling for T1 internalizing symptoms.

Conclusions: Sleep problems in young children with ASD may represent early and modifiable risk markers for persistent child sleep and emotional difficulties, as well as promising targets for early intervention aimed at improving child (and caregiver) well-being.

**429.028** (Poster) Medical, Developmental, and Behavioral Associations with Sleep Problems in Young Children

*A. M. Reynolds<sup>1</sup>, J. Brinton<sup>2</sup>, G. N. Soke<sup>3</sup>, T. Katz<sup>4</sup>, L. Wiggins<sup>5</sup>, L. J. Meltzer<sup>6</sup>, L. Schieve<sup>7</sup>, L. A. Croen<sup>8</sup>, K. R. Sabourin<sup>7</sup> and S. E. Levy<sup>8</sup>, (1)University of Colorado School of Medicine, Aurora, CO, (2)University of Colorado Denver School of Medicine, Aurora, CO, (3)Centers for Disease Control and Prevention, Atlanta, GA, (4)Department of Pediatrics, University of Colorado School of Medicine, Aurora, CO, (5)Pediatric Behavioral Health, National Jewish Health, Denver, CO, (6)Division of Research, Kaiser Permanente, Oakland, CA, (7)University of Colorado Anschutz Medical Campus, Aurora, CO, (8)Division of Developmental and Behavioral Pediatrics, Center for Autism Research, Children's Hospital of Philadelphia; Perelman School of Medicine at the University of Pennsylvania, Philadelphia, PA*

Background: Sleep problems may have a negative impact on behavior, mental health, and physical well-being in young children and their families. About 40% to 80% of children with autism spectrum disorder (ASD) and developmental delay (DD), and about 10% to 50% of children from the general population (POP) have been reported to have sleep problems. The multi-factorial nature of sleep problems makes management challenging. Previous studies evaluating factors associated with sleep problems in children with ASD are limited due to lack of control groups and inability to control for socio-demographic and cognitive abilities.

Objectives: Assess whether selected developmental, behavioral, and medical conditions or symptoms (i.e., those related to sleep problems in existing literature) are associated with sleep problems.

**Methods:** We included 2- to 5-year-old children in the Study to Explore Early Development (SEED), a multi-site community-based study, whose parent completed the Children's Sleep Habits Questionnaire (CSHQ). The CSHQ is a standardized 33-item questionnaire with cut off score greater than 41 representing sleep problems. There were 522 children with ASD, 762 children with DD, and 703 POP children in the analytic sample. Data collection instruments that captured co-occurring conditions were the Child Behavior Checklist (CBCL), Social Responsiveness Scale (SRS), Mullen Scales of Early Learning (MSEL), SEED Gastrointestinal Questionnaire, and height and weight measured during clinic visit in order to calculate body mass index (BMI). The presence of child genetic or neurologic conditions was reported by the mother (i.e., Down syndrome, fragile X syndrome, Rett syndrome, tuberous sclerosis, neurofibromatosis, cerebral palsy, and seizures). Socio-demographic variables were child age and sex, household income, and maternal education and race/ethnicity). A logistic regression model adjusted for socio-demographic variables assessed associations between sleep problems and CBCL clinical risk for anxiety/depression (yes/no), SRS moderate-severe risk for ASD (yes/no), MSEL <70 (yes/no), MSEL below average visual reception, expressive language, or receptive language skills (yes/no), parent reported GI problems (yes/no), BMI z-score (continuous), and parent-reported genetic or neurological diagnosis (yes/no). A second logistic regression model adjusted for study group status (i.e., ASD/DD/POP) to test associations relevant to all children.

**Results:** The first model found the following were associated with sleep problems in our sample of children: CBCL clinical risk for anxiety/depression (aOR=5.08; 95%CI=2.53,10.22); SRS moderate-severe risk for ASD (aOR=1.94; 95%CI=1.39,2.71); MSEL low developmental level (aOR=1.31; 95%CI=0.96,1.80); MSEL below average visual reception (aOR=1.34; 95%CI=0.94,1.92), expressive language (aOR=1.24; 95%CI=0.88,1.75), or receptive language skills (aOR=1.30; 95%CI=0.94,1.81), and parent reported GI problems (aOR=1.65; 95%CI=1.24,2.18). When the model was adjusted for study group status, CBCL clinical risk for anxiety/depression (aOR=4.42; 95%CI=2.08,8.65), parent reported GI problems (aOR=1.61; 95%CI=1.20,2.17), and elevated SRS score (aOR=1.94; 95%CI=1.39, 2.71) remained statistically significant. Post-hoc, we examined the interaction between GI problems and symptoms of anxiety/depression and found no interaction between the variables.

**Conclusions:** Gastrointestinal problems, social problems, and symptoms of anxiety/depression were associated with more sleep problems in all children regardless of study group classification. These results highlight the need to consider gastrointestinal problems and symptoms of anxiety/depression when developing a treatment plan for pre-school aged children with sleep issues.

**429.030 (Poster) Predictors of Adaptive Functioning in Autism Spectrum Disorders from Early Childhood to Adolescence**  
**S. Chandler<sup>a</sup>, I. Yorke<sup>b</sup>, V. Carter Leno<sup>c</sup>, G. Baird<sup>d</sup>, A. Pickles<sup>e</sup>, T. Charman<sup>f</sup> and E. Simonoff<sup>g</sup>, (1)King's College London, Institute of Psychiatry, Psychology and Neuroscience, London, United Kingdom, (2)Guy's and St Thomas' NHS Foundation Trust, London, United Kingdom, (3)Department of Psychology, Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, United Kingdom**

**Background:** Adaptive functioning refers to how well an individual manages the demands of everyday life and is an important factor in determining outcomes such as independent living. Studies consistently show adaptive functioning to be impaired in individuals with autism spectrum disorders (ASD), relative to cognitive ability, particularly in higher-ability individuals. However, the clinical drivers for this are less well understood. Some studies point to core ASD symptoms impeding adaptive functioning, while others (but not all) suggest an independent effect of co-occurring psychiatric symptoms. Most studies have used cross-sectional designs and focused on higher-ability individuals. The current study takes a developmental approach to examine longitudinal and contemporaneous predictors of adaptive functioning in a sample of young people (YP) with ASD from across the entire ability range.

**Objectives:** Using a longitudinal sample, to identify predictors of adaptive functioning in YP with ASD. Specifically, to test associations between adaptive functioning and ASD symptoms (social communication difficulties and restricted and repetitive behaviours (RRBs)) and co-occurring psychiatric symptoms (emotional, conduct and ADHD symptoms), while controlling for IQ.

**Methods:** Participants were part of the QUEST cohort, a community-based sample of children with a diagnosis of autism. Children were recruited at age 4-8 years (t1, total n=277), and followed at a mean age of 13 years (t2, total n=211). ASD symptoms were measured at t1 and t2 using the Social Communication Questionnaire (SCQ). IQ was assessed at t1 and (on a stratified subsample) at t2. Emotional, conduct and hyperactivity symptoms were measured using the Anxiety, Disruptive/Antisocial and Hyperactivity subscales from the parent-report Developmental Behaviour Checklist (DBC) at t1, and the Emotional, Conduct and Hyperactivity-Inattention subscales from the parent-report Strengths and Difficulties Questionnaire (SDQ) at t2. Adaptive functioning was assessed using the Adaptive Behaviour Assessment System (ABAS-II) at t2. This study focuses on the 179 YP (144 male, 35 female) with complete datasets at both timepoints (see Table 1).

Structural equation modelling was used to test the pathways to adaptive functioning from t1 and t2 predictors, whilst also testing for covariances between symptom domains. Moderator paths (for sex, and  $IQ < / \geq 70$ ) were subsequently added to the significant paths of interest.

Results: Adaptive functioning at t2 was associated with higher t1 IQ ( $\beta = .38$ ,  $p < .001$ ), lower t1 hyperactivity scores ( $\beta = -.32$ ,  $p = .001$ ), lower t2 hyperactivity scores ( $\beta = -.22$ ,  $p = .001$ ), and with lower social communication difficulties ( $\beta = -.34$ ,  $p < .001$ ) and RRBs ( $\beta = -.17$ ,  $p < .001$ ) at t2 (see Figure 1). Neither conduct symptoms at t1 or t2, nor emotional symptoms at t1 or t2 were associated with t2 adaptive functioning. Sex and IQ did not moderate the paths from t1 hyperactivity to t2 adaptive functioning or from t2 hyperactivity to t2 adaptive functioning.

Conclusions: In a model that included ASD symptoms and IQ, hyperactivity symptoms, both contemporaneously and in early childhood, were associated with reduced adaptive functioning at age 13. This highlights the importance of considering co-occurring psychiatric symptoms and their treatment at an early age, as these could have a significant impact on later outcomes.

**429.031 (Poster)** Prevalence of Parent-Reported Feeding Concerns in Children with Autism Spectrum Disorder: A Cross-Sectional Study of Patients Evaluated at a Tertiary Care Center

**E. S. Kushner<sup>a</sup>**, S. Sivathanan<sup>a</sup>, E. McQueen<sup>b</sup>, R. Berry<sup>c</sup>, S. P. White<sup>d</sup>, W. Sharp<sup>e</sup> and C. Klaiman<sup>f</sup>, (1)Lurie Family Foundations MEG Imaging Center, Department of Radiology, Children's Hospital of Philadelphia, Philadelphia, PA, (2)Educational & Counselling Psychology, McGill University, Montreal, QC, Canada, (3)Department of Allied Health Sciences, University of North Carolina at Chapel Hill, Chapel Hill, NC, (4)Marcus Autism Center, Atlanta, GA, (5)Marcus Autism Center, Emory University School of Medicine, Atlanta, GA, (6)Marcus Autism Center, Children's Healthcare of Atlanta and Emory University School of Medicine, Atlanta, GA

---

Background: Feeding issues are a commonly reported concern for parents of children who have autism spectrum disorder (ASD). Food selectivity - or eating a narrow range of foods - represents the most frequently documented feeding concern in ASD. To date, variability in study design, however, has limited a clear understanding of prevalence of feeding and related mealtime concerns in ASD, yielding a wide range (46-89%) of estimates across the extant literature. Sample bias contributes to lack of clarity regarding prevalence, with most studies identifying rates of feeding issues in children referred to related subspecialty clinics (e.g., feeding teams). The current study aims to address this gap by describing the prevalence of parent-reported feeding concerns in a large cohort of children evaluated for ASD at a tertiary care center.

Objectives: To identify the rate of parent-reported feeding concerns regarding dietary diversity and weight status in children consecutively referred for diagnosis of autism spectrum disorder.

Methods: The study included 935 consecutive patients evaluated for ASD (September 2019-October 2020) ranging from 14 months to 17 years old (Mean=55.9 mos, SD=34.9 mos; Median=43.9 mos). The assessment clinic incorporated a brief, eight-item parent questionnaire screening for general feeding concerns, weight status, and dietary variety.

Results: Of the 935 patients evaluated, 783 (83.7%) patients (74.6% male) received an ASD diagnosis. Of those with a primary ASD diagnosis, 225 parents (29%) endorsed concerns about their child's feeding, 127 (17.1%) reported concerns about their child being underweight, and 53 (7.2%) reported concerns about overweight. Over half of parents (52.8%) indicated that their child rejects all items from at least one food group from their diet.

Conclusions: Our results suggest that feeding concerns in a general ASD population may be less prevalent than previous reports involving children referred to specialty clinics for feeding or weight concerns. Food selectivity, however, may still represent a commonly observed feature in youth who have ASD, with more than half of parents indicating that their child refuses items from at least one food group. Further research in other ASD diagnostic settings and specialty clinics is warranted to understand true and nuanced prevalence rates of feeding and weight concerns.

**429.032 (Poster)** Racial/Ethnic Disparities in Psychiatric and Medical Diagnoses Among Autistic Adults

**J. L. Ames**, L. A. Croen, M. L. Massolo and Y. Qian, Division of Research, Kaiser Permanente, Oakland, CA

---

Background: Racial and ethnic disparities in access to diagnostic and support services are pervasive for autistic children and youth, which has implications for health and well-being into adulthood. However, few studies have examined racial/ethnic differences in diagnoses and healthcare use among autistic adults, who commonly experience a higher burden of many psychiatric and medical conditions than non-autistic adults.

**Objectives:** To describe racial/ethnic differences in the frequency of health diagnoses in autistic adults.

**Methods:** The study population included adult members ( $\geq 18$  years) of Kaiser Permanente Northern California (KPNC) enrolled in the health plan for at least 9 months of each year from 2008-2012. We ascertained 1,507 adults who had an autism spectrum disorder (ASD) diagnosis documented in their KPNC medical records on at least 2 occasions by December 2012. A control group of adults without any ASD diagnoses ( $N=15,070$ ) was sampled at a 10:1 ratio and frequency-matched to autistic adults on total length of KPNC membership, gender, and age. Our sample was 46% White, 16% Asian, 7% Black, 4% Hispanic, and 26% other race/ethnicity. We examined physician-documented medical and psychiatric diagnoses routinely captured in KPNC's electronic medical records. We first compared the health status of autistic adults with non-autistic controls within strata of race/ethnicity. We next examined racial/ethnic differences in medical and psychiatric conditions among autistic adults only. All analyses were conducted using logistic regression and included adjustment for age, gender, length of KPNC membership, and insurance payer.

**Results:** Among each racial/ethnic group, most conditions, including psychiatric disorders, cardiovascular diseases, diabetes, and epilepsy, were significantly more prevalent among autistic adults compared with non-autistic adults. However, the magnitude of the difference between autistic and non-autistic adults varied widely across racial/ethnic strata for some conditions. For example, the odds ratio of any major psychiatric condition was largest among Asian adults ( $OR=5.5$ , 95%CI: 3.9-7.6) and smallest among Black adults ( $OR=2.0$ , 95%CI: 1.4, 3.0). Among autistic adults, odds of hypertension ( $OR=1.9$ , 95%CI: 1.2, 2.9) and obesity ( $OR=1.7$ , 95%CI: 1.2, 2.5) were elevated among Black adults and odds of non-seizure disorders of the central nervous system ( $OR=2.0$ , 95%CI: 1.1, 3.7) and gastrointestinal disorders ( $OR=1.7$ , 95%CI: 1.0, 3.0) were elevated among Hispanic adults compared with White adults. In contrast, several psychiatric conditions, including anxiety and depression, were significantly less likely to be diagnosed in Asian, Black, and Hispanic autistic adults than in White autistic adults.

**Conclusions:** Our study found that autistic adults generally had higher rates of co-occurring medical and psychiatric conditions compared to their non-autistic counterparts of the same race/ethnicity. However, among autistic adults, Black and Hispanic adults were more likely to be diagnosed with some major medical conditions, including cardiometabolic diseases, and Black, Hispanic, and Asian adults were markedly less likely to be diagnosed with psychiatric conditions than their White counterparts. The observed racial/ethnic differences among autistic adults mirror the racial/ethnic disparities that are widespread in the general population. Future work will examine whether these differences reflect disparities in healthcare utilization, possibly identifying targets for intervention.

**429.033 (Poster) Self-Report of Emotion Regulation Impairment: Initial Analyses of Response Patterns**

*C. M. Conner<sup>1</sup>, S. W. White<sup>2</sup> and C. A. Mazefsky<sup>1</sup>, (1)Department of Psychiatry, University of Pittsburgh School of Medicine, Pittsburgh, PA, (2)Psychology, The University of Alabama, Tuscaloosa, AL*

---

**Background:**

The Emotion Dysregulation Inventory (EDI) is the first measure developed and validated to measure emotion regulation (ER) impairment in youth with ASD<sup>1,2</sup>. The EDI was designed using caregiver-report; however, validating a self-report form of the measure is needed to support multi-method assessment for future research and treatment of ER impairment.

**Objectives:**

We conducted a preliminary investigation of the self-report version of the EDI, including item response frequency, item-total correlations, internal consistency, and convergent validity in an ER treatment-seeking sample.

**Methods:**

Our sample consisted of 53 adolescents and young adults (12-21 years old) with ADOS-confirmed ASD and verbal IQ scores above 80 and their caregivers who participated in a randomized control trial of the EASE program (Emotional Awareness and Skills Enhancement- a mindfulness-based intervention). Parent- and self-report of the EDI and PROMIS depression and anxiety scales were completed at pre-treatment. The EDI provides scores for Reactivity (EDI-R; intense and poorly regulated negative emotional reactivity) and Dysphoria (EDI-D; negative affect)<sup>1</sup>. For the current study, we explored the short form of the EDI-R (7 items) and the EDI-D (6 items).

**Results:**

Overall, internal consistency of self-report EDI-R short form ( $\alpha=.925$ ) and EDI-D ( $\alpha=.882$ ) were high and consistent with prior parent-report studies<sup>2</sup>. Item-total correlations (ITC) for both subscales did not indicate any weak items; all items in EDI-R short

form were correlated  $>.700$  with the total, and all items except for one (item 51 ITC = .402) on the EDI-D were  $>.670$ . Frequency distributions of the response options for each item were examined. Although participants endorsed 'none' at a high rate (generally greater than 50%), the full range of response options were utilized. Convergent validity was strong with both EDI-D and PROMIS anxiety and depression scores ( $r = .787, p < .001$ ;  $r = .853, p < .001$ ) and EDI-R and PROMIS anxiety and depression ( $r = .664, p < .001$ ;  $r = .588, p < .001$ ).

Mean EDI scores were higher for parent-report over self-report on both subscales. Parent- and self-report EDI-R and EDI-D were not significantly correlated at baseline ( $r = .112, p = .44$ ;  $r = .147, p = .31$ , respectively).

Conclusions:

The current results provide preliminary psychometric evidence for using the EDI self-report in adolescents and young adults with ASD, with strong internal consistency, item-total correlations, convergent validity, and a range of item responses. Limitations include a small, ER treatment-seeking sample without co-occurring ID. Next steps including drafting of additional items to enrich the item pool and cognitive interviews with self-reporting adolescents and adults to refine item wording and enhance validity. Further psychometric research will require a large and more diverse ASD sample to better assess the sensitivity of the EDI self-report, as well as how characteristics such as alexithymia affect self-report responses.

**429.034 (Poster)** Sex Differences in the Stability of Psychopathology Symptoms in Young Children with Autism

*Q. Lee<sup>1</sup>, J. K. Lee<sup>2</sup>, M. Solomon<sup>2</sup>, S. J. Rogers<sup>2</sup> and C. W. Nordahl<sup>1</sup>, (1)UC Davis Neuroscience Graduate Group, Davis, CA, (2)Department of Psychiatry and Behavioral Sciences, The Medical Investigation of Neurodevelopmental Disorders (MIND) Institute, UC Davis School of Medicine, University of California Davis, Sacramento, CA*

---

**Background:** Sex differences in symptom presentation and developmental trajectories of co-occurring psychopathology in autism are understudied in young children. Previously, we assessed 300 children with ASD (209 males, 91 females; mean age 37 months) and identified 3 subgroups based on DSM-oriented subscales of the Child Behavior Checklist (CBCL), cognitive development, adaptive functioning, and autism severity, using latent profile analysis: high psychopathology with mild impairment (HPMI), low psychopathology with high impairment (LPHI), and low psychopathology with low impairment (LPLI). Autistic girls were over-represented in the HPMI subgroup (Nordahl, 2020).

**Objectives:** To evaluate the trajectory of psychopathology symptoms across subgroups and sex. We hypothesized that the high psychopathology group would maintain elevated symptoms.

**Methods:** 148 children (102 males, 46 females) returned for longitudinal assessment 2 years after study entry (mean age 67 months). First, we evaluated correlations between baseline and follow-up CBCL internalizing and externalizing t-scores within subgroup and sex. We also examined changes in CBCL DSM-oriented t-scores (anxiety, affective, attention deficit/hyperactivity [ADHD], and oppositional defiant [ODD]) within subgroups and sex using linear mixed effects models.

**Results:** In the HPMI subgroup, baseline internalizing and externalizing scores were highly correlated with follow-up scores in females (internalizing  $r = 0.73, p = 0.003$ , externalizing  $r = 0.762, p = 0.002$ ), but not males (internalizing  $r = 0.167, p = 0.569$ , externalizing  $r = 0.232, p = 0.369$ ) (Figure 1A). Fisher's z-tests reveal that these sex differences in correlations were marginally significant for both internalizing ( $z = 1.78, p = 0.075$ ) and externalizing ( $z = 1.90, p = 0.057$ ) scores. In the LPLI subgroup, correlations between baseline and follow-up internalizing t-scores were significant in both females ( $r = 0.591, p = 0.043$ ) and males ( $r = 0.425, p = 0.009$ ), while correlations between baseline and follow-up externalizing t-scores were only significant in males ( $r = 0.491, p = 0.001$ ). In the LPHI subgroup, correlations between baseline and follow-up externalizing t-scores were significant in both females ( $r = 0.692, p = 0.027$ ) and males ( $r = 0.616, p = 0.004$ ), but internalizing scores were not significant in either sex. Sex differences in correlations were not evident for the low psychopathology subgroups.

The trajectory of DSM anxiety t-scores in the HPMI subgroup differed marginally by sex ( $p = 0.054$ ). In females, all three subgroups demonstrated similarly stable trajectories. The HPMI group maintained elevated DSM anxiety t-scores over time. In contrast, male trajectories differed across subgroups ( $p < .01$ ); anxiety scores decreased over time in the HPMI subgroup but remained stable in the other two subgroups. Trajectories for the other DSM-subscales show scores of the HPMI subgroup decreasing toward scores of the other subgroups over time in both sexes. Lastly, none of the DSM-subscale scores differed between returning and non-returning participants, suggesting that participant attrition was not a factor.

**Conclusions:** In the HPMI subgroup, females, but not males, had internalizing and externalizing scores at baseline that were predictive of follow-up scores, and a trajectory of anxiety scores that remained elevated above the low psychopathology subgroups. Symptoms of psychopathology at age 3 were predictive of higher levels of anxiety at age 5 in females with ASD, but

not males. These results suggest that symptoms of psychopathology may be more stable in females with ASD across early childhood than in males.

**429.035 (Poster)** Sleep Differences Among Autistic Children with and without a History of Suicide

**H. D. Sanguino<sup>1</sup>, S. J. Howe<sup>1</sup> and C. McMorris<sup>1,2,3</sup>,** (1)University of Calgary, Calgary, AB, Canada, (2)Alberta Children's Hospital Research Institute, University of Calgary, Calgary, AB, Canada, (3)Werklund School of Education, University of Calgary, Calgary, AB, Canada

---

**Background:** Emerging literature suggests that sleep disturbances are associated with suicidal thoughts and behaviours (hereafter referred to as suicidality) in the general population. Despite this, few studies have examined the relation between sleep and suicidality in children with autism. Suicide attempts range between 7-47%, and 71% of autistic youth experience suicidal ideation, which is far more than non-autistic youth. In addition to this, individuals with autism also experience greater levels of depression, anxiety, social isolation, low self-esteem and peer victimization, which can exacerbate feelings of suicide. Given the limited existing literature in this population, there is a need for more research to clarify the relation between sleep (i.e., disturbances and parameters) and suicidality in children with autism.

**Objectives:** The current study aimed to determine whether subjective 7-day sleep parameters, using a sleep diary and actigraphy, vary between autistic participants with and without recent suicidality in the past 30 days.

**Methods:** In this cross-sectional online study, participants were 25 caregivers of children with autism. On average, participants were 12 years old (range, 7-21 years,  $SD = 3.6$ ), most children were male (68%), white (84%) and had a co-occurring diagnosis (64%) with the most common being ADHD (20%) and anxiety (20%). Caregivers were mothers (84%) with an average age of 41 (range, 32-55 years,  $SD = 7.5$ ). Sleep disturbances, 7-day sleep parameters and suicidality were reported by caregivers of children with autism using a caregiver-reported sleep-diary, the Children's Sleep Habits Questionnaire (CSHQ) and a modified caregiver-report version of the Columbia-Suicide Severity Rating Scale (C-SSRS). Data collection is still underway and anticipate 50 participants by May 2021.

**Results:** The majority of children were "poor sleepers" (84%) and reported suicidal thoughts and behaviours (60%). Four participants (22%) slept less than the recommended amount for their age, based on the National Sleep Foundation's (NSF) recommendations. Preliminary independent samples *t*-test demonstrated a significant difference in quality of sleep, such that those with a history of suicidality experienced worse sleep quality, ( $t(20) = 2.12, p = .047, d = .91, 95\% CI: 0.01, 0.83$ ). Furthermore, a significant difference was found in daytime sleepiness where those with a history of suicidality experience greater daytime sleepiness,  $t(22) = 4.86, p = .036, d = .43, 95\% CI (-2.61, 4.60)$ . The daytime sleepiness index was derived from the CSHQ.

**Conclusions:** These findings are partially consistent with the existing literature highlighting associations between sleep disturbances and suicidality in the general population. Group differences indicated that children with suicidality had significantly lower sleep quality scores (i.e., more fatigued) and greater daytime sleepiness. However, despite our expectation, no other significant differences were found regarding total sleep time, bedtime and length of night making. Findings highlight the importance of assessing for sleep changes in relation to mental health concerns as these changes may indicate vulnerability and may be important for this already at-risk population. Future work should explore this association longitudinally using objective measures such as actigraphy and polysomnography (PSG) which are needed to confirm our findings.

**429.036 (Poster)** Sleep Disturbances in Autism Spectrum Disorder: Relationship with Autism Severity, Executive Function and Psychiatric Symptoms.

**L. Gisbert<sup>1</sup>, J. Lugo Marín<sup>1</sup>, I. Setien<sup>1</sup>, P. Ibáñez Jiménez<sup>1</sup>, O. Romero Santo-Tomás<sup>2</sup>, M. J. Jurado Luque<sup>2</sup>, P. Ballester-Navarro<sup>3</sup>, E. Díez Villoria<sup>4</sup>, R. Canal-Bedia<sup>4</sup> and J. A. Ramos-Quiroga<sup>1</sup>,** (1)Psychiatry, Hospital Universitari Vall d'Hebron, Barcelona, Spain, (2)Sleep Unit, Hospital Universitari Vall d'Hebron, Barcelona, Spain, (3)Hospital General Universitario de Alicante, Alicante, Spain, (4)University of Salamanca, Salamanca, Spain

---

**Background:** Autism Spectrum Disorder (ASD) is a neurodevelopmental condition accompanied frequently with medical and psychiatric pathology. One of the most commonly found problems associated with ASD are sleep disturbances, which are estimated to affect approximately 80% of people with ASD, not only in childhood but also in adolescent and through adult stages. Nevertheless, the relation of these sleep difficulties with autism severity, as well as other associated impairments, such as executive functioning and psychiatric disorders has not been yet widely studied.

**Objectives:** The main objective of the present study is to explore the relation of sleep disturbances and subjective measures of autism severity, executive function and psychopathology in ASD population.

**Methods:** For this, a group of 89 participants with ASD (44 children/adolescents and 45 adults) were recruited and evaluated with ASD gold-standard evaluation measures and self-reported measures of executive function performance and psychiatric pathology.

**Results:** Results showed all total scores exceeding cut-off points in both ASD groups. Regarding association of sleep disturbances with psychiatric disorder, multivariate analysis showed significant association between both variables in both ASD groups, with greater sleep disturbances predicting more severe psychiatric pathology. Also, autism severity only showed significant association with sleep problems in the Adult ASD group. No significant association was found with executive function in any ASD group.

**Conclusions:** Thus, sleep problems seem to be associated with the severity of psychopathology through lifespan, increasing the chance of developing psychiatric symptoms. Improving sleep quality in ASD children/adolescents and adults may result in a preventing and/or decreasing psychiatric pathology in this population.

**429.038 (Poster)** The Comorbidity between Autism Spectrum Disorder and Post-Traumatic Stress Disorder Is Mediated By Brooding Rumination

**O. Golan<sup>1,2</sup>**, N. Haruvi Lamdan<sup>1</sup>, N. Laor<sup>2,3</sup> and D. Horesh<sup>1,2</sup>, (1)Department of Psychology, Bar-Ilan University, Ramat-Gan, Israel, (2)Association for Children at Risk, Givat-Shmuel, Israel, (3)Sackler School of Medicine, Tel-Aviv University, Tel-Aviv, Israel

---

**Background:** Autism Spectrum Disorder (ASD) is a neurodevelopmental condition, characterized by social communication deficits and restricted, repetitive behaviors. ASD is highly co-morbid with other neuro-psychiatric disorders, such as ADHD, anxiety, and depression. However, research on post-traumatic stress disorder (PTSD) among individuals with ASD is scarce. Furthermore, the understanding of shared mechanisms underlying ASD co-morbidity with other conditions may assist in both diagnostic and intervention efforts with affected individuals.

**Objectives:** To examine the role of brooding and reflective rumination as mediators between ASD and PTSD.

**Methods:** Thirty-four (34) adults with ASD (with no intellectual impairment) and 66 typically developing controls, comparable on age and gender, filled out the PTSD Checklist for DSM-5 and the Rumination Response Scale.

**Results:** Results indicated increased PTSD symptoms, as well as elevated brooding levels, in adults with ASD, compared to typically developing controls. Brooding, but not reflective, rumination mediated the association between ASD and PTSD symptoms (See Figure 1).

**Conclusions:** Rumination and cognitive inflexibility, which are common in ASD, may exacerbate post traumatic symptoms among traumatized individuals who have ASD. Interventions targeting brooding rumination and cognitive flexibility may assist in alleviating post-traumatic symptoms in individuals with ASD.

**429.039 (Poster)** The Etiology of Comorbid Physical Problems in Autism— a Nationwide Population-Based Twin Study

**P. Y. Pan<sup>1</sup>** and S. Bolte<sup>2</sup>, (1)Department of Women's and Children's Health, Karolinska Institutet, Stockholm, Sweden, (2)Center of Neurodevelopmental Disorders (KIND), Centre for Psychiatry Research; Department of Women's and Children's Health, Karolinska Institutet, & Stockholm Health Care Services, Region Stockholm, Stockholm, Sweden

---

**Background:**

Autism is associated with a range of physical comorbidities, including neurological disorders, immune dysregulation, and gastrointestinal (GI) problems. The co-existence of physical health problems is linked to premature mortality and a higher degree of impairment in this population. However, the etiological significance of physical comorbidities in autism is still unclear, and the population-based studies of heritability of overlapping between physical comorbidities and autism have also been sparse.

**Objectives:**

This study aimed to use a Swedish nationwide population-based twin cohort and structural equation modeling to investigate the causes for common physical problems among children and the physical comorbidities in children with autism.

#### Methods:

A total of 10,347 twin pairs from the Child and Adolescent Twin Study in Sweden (CATSS) were included for analysis in this study (mean age  $9.75 \pm 1.23$  yrs). The diagnosis of autism and physical disorders were identified by the International Classification of Diseases (ICD) codes through the Swedish National Patient Register (NPR). Common pediatric physical problems of three physical systems were investigated: neurological disorders (4 disorders included), immune dysregulation (9 disorders), and GI problems (6 disorders). Familial coaggregation between physical comorbidities and autism was examined. Bivariate liability threshold twin modeling was used to estimate the degree of genetic and common and unique environmental influences contributing to the variation in liability to the comorbidities of physical disorders and autism.

#### Results:

Genetic effects accounted for 52% (95% CI=42–60) of the variation in liability for neurological disorders (ADE model, additive and dominance genetic effects), 64% (95% CI=53–74) for immune dysregulation (ACE model), and 57% (95% CI=51–63) for GI problems (ADE model). Monozygotic (MZ) co-twins of children with autism had higher probability of having diagnoses of neurological disorder and GI problems compared with dizygotic (DZ) co-twins (5.9% vs 5.2%, and 15.3% vs 11.4%, respectively), while familial coaggregation was not found between immune dysregulation and autism (MZ vs DZ: 23.7% vs 30.3%). The phenotypic correlation between neurological disorders and autism was 0.23 (95% CI=0.16–0.30), and genetic effects contributed 77% of the correlation (ADE model). For GI problems, the twin-based phenotypic correlation with autism was 0.19 (95% CI=0.13–0.26), and non-shared environmental factors showed protective effects (-5.2%) to the correlation (ADE model).

#### Conclusions:

Our findings suggest that the comorbid neurological disorders and GI problems in children with autism may largely be because of shared genetic influences. Although immune dysregulation was also highly heritable, the etiology of its overlapping with autism did not fit our modeling and thus the contribution of interplay between genetics and environmental factors should be considered. Further studies with larger sample sizes and focusing on specific physical disorders are warranted to validate our results.

**429.040 (Poster)** The Hierarchical Taxonomy of Psychopathology as the Next Frontier for Understanding Comorbidity in Autism: An Empirically Based Approach to Delineating the Structure of Autism, Internalizing, and Externalizing Symptoms **M. R. Altschuler<sup>a</sup>, G. Michelin<sup>b</sup>, J. T. Ellison<sup>c</sup> and S. Wilson<sup>a</sup>**, (1)Institute of Child Development & Department of Psychology, University of Minnesota, Minneapolis, MN, (2)Semel Institute for Neuroscience & Human Behavior, Department of Psychiatry & Biobehavioral Sciences, University of California Los Angeles, Los Angeles, CA, (3)University of Minnesota, Minneapolis, MN

Background: Individuals with autism spectrum disorder (ASD) are at high risk for developing comorbid conditions, with approximately 70% to 96% of children with ASD having at least one other co-occurring psychiatric condition. Some argue that associations between ASD traits and internalizing and externalizing symptoms suggest measures of ASD are confounded by measurement error and may represent non-ASD behavioral problems; others argue the term “comorbidity” is likely inappropriately named if the “comorbidities” contribute to the cause of ASD itself. Recent efforts leverage an empirically based approach to delineate the structure of psychopathology (in contrast to the field’s traditional case-control approach, e.g., Hierarchical Taxonomy of Psychopathology, HiTOP). HiTOP focuses on continuously distributed and transdiagnostic traits, theorized to form the scaffolding for psychopathology based on hierarchical structural equation modeling approaches, thereby providing a framework for directly testing the relative importance of symptom components, syndromes, spectra, and superspectra. Currently, HiTOP framework includes a *p* factor at the apex, with somatoform, internalizing, thought disorder, externalizing disinhibited, externalizing antagonistic, and detachment factors at the spectra level (see Figure 1). Whether an autism dimension, or a neurodevelopmental dimension more broadly, should be incorporated into HiTOP remains an empirical question.

Objectives: 1) Comprehensively review the empirical support for the existence of a neurodevelopmental or autism dimension in the HiTOP classification framework and 2) provide recommendations for future autism work.

Methods: Database and HiTOP consortium article searches were conducted of the literature examining a neurodevelopmental or autism dimension in the HiTOP classification framework.

Results: Only a handful of studies have examined and found evidence of a potential neurodevelopmental dimension in the hierarchical structure of psychopathology (Bloemen et al., 2018; Holmes et al., 2020; Michelini et al., 2019; Riglin et al., 2019; Waldman et al., 2020), and only one study found evidence of an autism specific dimension (Noordhof et al., 2015). Most studies examining a potential neurodevelopmental or autism dimension of psychopathology did not have any measure specifically designed to assess autistic traits. One exception examined the Child Social Behavior Questionnaire as an index of autistic traits, in addition to the Child Behavior Checklist, and found evidence for five factors, including what they labeled an autism dimension ( $p$ , internalizing, externalizing, attention and orientation, and autism) (Noordhof et al., 2015).

Conclusions: The majority of studies that found initial evidence for a neurodevelopmental dimension in the hierarchical structure of psychopathology did not include measures specifically designed to assess autistic traits. As such, a crucial gap in the field is understanding the extent to which autistic traits can or should be incorporated into the existing HiTOP framework or added as a separate structure (or structures) within the framework. Future work should utilize hierarchical structural equation modeling approaches (e.g., bass-ackwards method) to examine the hierarchical structure of autism and co-occurring symptoms. Understanding where autism and autistic traits fit in the hierarchical taxonomy of psychopathology and the latent structure underlying observed co-occurrence of autism, internalizing, and externalizing symptoms will inform an understanding of the etiology of autism and lead to the development of more targeted treatments.

**429.041 (Poster)** The Impact of the Comorbidity of ASD and ADHD on Social Impairment  
*C. M. Harkins and M. O. Mazurek, University of Virginia, Charlottesville, VA*

---

**Background:** Children with autism spectrum disorder (ASD) and children with attention deficit/hyperactivity disorder (ADHD) both experience behavioral and social difficulties. Research has shown that when these disorders co-occur, behavioral symptoms associated with both disorders may be more severe. There is only limited research on the impact of ASD + ADHD comorbidity on social functioning and results have yielded mixed findings.

**Objectives:** To evaluate group differences in social impairment among children with ASD, ADHD, and ASD + ADHD using two assessment tools, clinician- and parent-informed, to examine the impact of the ASD + ADHD comorbidity on social functioning.

**Methods:** Participants included 282 youth age 2-17 diagnosed with ASD ( $n=151$ ), ADHD ( $n=82$ ), or ASD + ADHD ( $n=49$ ) participating in a larger research study. Participants completed a measure of IQ, the Autism Diagnostic Observation Schedule (ADOS-2), and parents completed the Aberrant Behavior Checklist (ABC-C). The ADOS-2 social affect calibrated severity score (SA-CSS) and the ABC-C Lethargy/Social Withdrawal subscale were used to measure social impairment. Multivariate analysis of covariance (MANCOVA) was employed to determine the presence of mean differences across diagnostic groups of measures of social impairment while accounting for covariates, age and IQ.

**Results:** Bivariate correlations were calculated between the ADOS-2 SA-CSS score and covariates, age ( $r=-.396$ ,  $p<.01$ ) and IQ ( $r=-.302$ ,  $p<.01$ ) and between the ABC-C Lethargy/Social Withdrawal subscale and, age ( $r=.011$ ,  $p<.05$ ) and IQ ( $r=-.079$ ,  $p<.05$ ). The hypothesis that children with ASD + ADHD would show greater social impairment than children with ASD or ADHD alone was tested using MANCOVA. The independent variable was diagnostic group status, the dependent variables were the ADOS-2 SA-CSS and the ABC Lethargy/Social Withdrawal score, and covariates included age and IQ. Multivariate results were significant for diagnostic group status,  $F(4,548)=24.59$ ,  $p<.001$ , Wilks'  $\Lambda = .719$ , partial  $\eta^2 = .152$  above the significant effect of age,  $F(2,274)=5.49$ ,  $p<.001$ , Wilks'  $\Lambda = .961$ , partial  $\eta^2 = .039$ . Multivariate results were not significant for IQ,  $F(2,274)=1.49$ ,  $p=.227$ , Wilks'  $\Lambda = .989$ , partial  $\eta^2 = .011$ . Post-hoc multiple pairwise comparisons (Bonferroni adjusted) found significant differences on only one measure of social functioning, the ADOS-2 SA-CSS,  $F(2,275)=50.79$ ,  $p<.001$ , partial  $\eta^2 = .27$ , with the ASD group scoring significantly higher than the ADHD group, and the ASD + ADHD group scoring significantly higher than the ADHD group, both at the .001 level. No significant differences on the ADOS-2 SA-CSS were observed between the ASD and ASD + ADHD groups.

**Conclusions:** Children with ASD versus ASD + ADHD may appear to display similar profiles of social problems when using the ADOS-2 SA-CSS and ABC Lethargy/Social Withdrawal subscale. The ADOS-2 may be helpful in differentiating social challenges in children presenting with ASD and/or ADHD concerns. The lack of significant differences in degree of social impairment observed between the ASD and ASD + ADHD groups may indicate that social challenges associated with both diagnostic groups may benefit from similar social skills interventions.

**429.042 (Poster)** The Relationship between Sensory Reactivity, Intolerance of Uncertainty and Anxiety Subtypes in Preschool-Age Autistic Children

## **Background:**

Sensory reactivity differences are experienced by 60-90% of autistic individuals, such as being hyperreactive (e.g. over-sensitive to sounds), hyporeactive (e.g. under-responsive to touch), or seeking (e.g. fascinated by lights). Sensory hyperreactivity has been linked to anxiety, which is co-occurring in over half of autistic children. It has previously been suggested that this relationship may be mediated by intolerance of uncertainty (IU). However, little is understood about this relationship in preschool-age autistic children, or how sensory reactivity and IU relate to anxiety sub-types, such as generalised anxiety disorder (GAD).

**Objectives:** In this study we aimed to elucidate the relationship between sensory reactivity, IU and anxiety subtypes in preschool-age autistic children.

## **Methods:**

54 autistic children (3-5 years, 41 males, 13 females) were assessed for sensory reactivity, IU and anxiety using observational and parent-report assessments.

Sensory reactivity was measured by the Sensory Processing Scale Inventory (SPSI) and the Sensory Assessment for Neurodevelopmental Differences (SAND). Total anxiety, and anxiety subtypes was measured by the Preschool Anxiety Scale (PAS). IU was measured using the Responses to Uncertainty and Low Environmental Structure (RULES) questionnaire.

## **Results:**

A correlation analysis was conducted to examine the relationship between sensory reactivity differences, IU, and anxiety (Table 1). Correlation analysis revealed significant correlations between sensory hyperreactivity and total anxiety ( $r_s = .56, p < .001$ ), GAD ( $r_s = .50, p < .001$ ), social anxiety ( $r_s = .47, p = .001$ ), OCD ( $r_s = .44, p = .002$ ), physical injury fears ( $r_s = .48, p < .001$ ), separation anxiety ( $r_s = .53, p < .001$ ), and IU ( $r_s = .59, p < .001$ ). IU was also significantly positively correlated with total anxiety ( $r_s = .79, p < .001$ ), GAD ( $r_s = .75, p < .001$ ), social anxiety ( $r_s = .72, p < .001$ ), OCD ( $r_s = .69, p < .001$ ), physical injury fears ( $r_s = .56, p < .001$ ), and separation anxiety ( $r_s = .72, p < .001$ ). Sensory hyporeactivity and seeking were not significantly related to anxiety or IU. The results were independent of the effects of covariates (age, IQ, verbal ability, autism traits).

Mediation analysis (Figure 1) indicated that the relationship between sensory hyperreactivity and anxiety is fully mediated by IU, as the direct coefficient was non-significant and the indirect coefficient was significant, (Direct:  $B = .16, SE = .12, LLCI = -.09, ULCI = .40$ ; Indirect:  $B = .356, SE = .10, LLCI = .27, ULCI = .65$ ), and the relationship between sensory hyperreactivity and IU is partially mediated by anxiety, as the direct coefficient and the indirect coefficient was significant (Direct:  $B = .24, SE = .12, LLCI = .00, ULLL = .47$ ; Indirect:  $B = .42, SE = .12, LLCI = .22, ULCI = .67$ ).

## **Conclusions:**

Our results suggest sensory hyperreactivity is unidirectionally related to anxiety in autistic pre-schoolers and that IU could be an important mediator and outcome in this relationship. These findings have important implications for early clinical interventions that improve outcomes for autistic children.

**429.043 (Poster)** The Role of Fatigue and Social Wellbeing in Depressive Symptomatology in Autistic Older Adolescents and Young Adults

*A. L. Richdale<sup>1,2</sup>, L. P. Lawson<sup>1,2</sup>, A. Haschek<sup>1,2</sup>, S. M. Hayward<sup>1,2</sup>, I. Abdullahi<sup>1,2</sup> and E. Morris<sup>3</sup>, (1)Olga Tennison Autism Research Centre, La Trobe University, Melbourne, VIC, Australia, (2)Cooperative Research Centre for Living with Autism (Autism CRC), Brisbane, QLD, Australia, (3)Psychology & Counselling, La Trobe University, Melbourne, Australia*

---

## **Background:**

Social wellbeing is an individual's experience of a sense of wellbeing associated with their social context (Keyes, 1998). Social wellbeing encompasses feelings of connectedness to community and while not identical, has some similarity to, or overlap with

quality of life, life satisfaction, loneliness and social support, which are linked to depression. Lack of community involvement has been linked to poor mental health in population studies (van Lente et al., 2012), while adverse childhood experiences have been related to poor psychological wellbeing, reduced life satisfaction, and reduced social wellbeing in adulthood (Mosley-Johnson et al., 2019). However, the relationship between social wellbeing and mental health variables seems to be unexplored in autistic populations, with limited exploration in non-autistic populations.

#### Objectives:

To examine the role of social wellbeing in predicting depression in young autistic adults after accounting for sleep and fatigue which are known to be linked to depression.

#### Methods:

Participants were 113 (48 female) autistic individuals aged 15 to 25 years ( $M = 18.9$ ;  $SD = 2.5$ ) participating in the longitudinal Study of Australian School Leavers with Autism (SASLA). Independent variables included in this study were age, gender, autistic traits, sleep quality, daytime fatigue and social wellbeing (Social Integration, Social Contribution). The dependent variable of interest was depression. A 2000 bootstrap, 4-step hierarchical regression with 95% BCa was conducted predicting depressive symptomatology in a cross-sectional data set.

#### Results:

The additions of age and gender at step 1 ( $p = .623$ ) and autistic traits ( $p = .223$ ) at step 2 were not significant. However, the addition of sleep quality and fatigue at step 3 was significant ( $p = .001$ ) as was the addition of social wellbeing at step 4 ( $p = .008$ ). The final model was significant accounting for 39% of variance in depression scores,  $R^2 = .393$ ,  $F(7,55) = 5.082$ ,  $p < .001$ . Daytime fatigue 95% BCa CI [.137, .453] ( $p = .003$ ) and Social contribution 95% BCa CI [-.725, -.095] ( $p = .014$ ) were the only unique significant predictors in the final model.

#### Conclusions:

Our results support that both fatigue and lack of sense of contribution to one's community impact significantly on depressive symptomatology in older adolescents and young autistic adults. To date, research has focussed on individual factors such as poor sleep, loneliness and social supports as contributors to poor mental health in autism but, fatigue is largely unexplored. Poor sleep quality can lead to fatigue, which can be further exacerbated by daily stressors, while loneliness and lack of social supports can lead to a loss of community connectedness. Our results present new avenues for the exploration of prevention and intervention supports for depression in autism. We need to further understand what factors contribute to fatigue in autistic individuals, and what social wellbeing means for members of the autistic community

**429.044 (Poster)** Understanding Autistic People's Experiences of Anxiety: Findings from a National Cohort Study  
**E. Lomax<sup>1</sup>**, S. Brice<sup>2</sup>, C. Wilson<sup>2</sup>, B. Ingham<sup>2,3</sup>, A. LeCouteur<sup>2</sup>, J. Rodgers<sup>2</sup> and J. R. Parr<sup>2,3</sup>, (1)School of Psychology, Newcastle University, Newcastle upon Tyne, United Kingdom, (2)Population Health Sciences Institute, Newcastle University, Newcastle upon Tyne, United Kingdom, (3)Cumbria, Northumberland, Tyne and Wear NHS Foundation Trust, Newcastle upon Tyne, United Kingdom

---

**Background:** Autistic people are more likely to experience anxiety than neurotypical people. There is also evidence to suggest that anxiety significantly impacts on daily life and is associated with lower quality of life. Previous research suggests that mental health conditions, such as anxiety, may present differently for autistic people, though most of this work has been conducted with autistic children and their families. It is therefore important to understand how anxiety is experienced by autistic adults to inform clinical assessments and plan appropriate and personalised anxiety interventions.

#### Objectives:

- To conduct a thematic analysis of free text data from a UK national survey conducted with autistic adults with anxiety, to determine how anxiety is experienced.
- Use the information to plan a personalised anxiety intervention for autistic adults.

**Methods:** 568 autistic adults (53.7% female, 42.8% male, 3.5% other genders) aged 18-77 ( $M=41.7$ ,  $SD=13.7$ ) were recruited from the Adult Autism Spectrum Cohort- UK (ASC-UK; <https://research.ncl.ac.uk/adultautismspectrum/>). In the survey, participants (or a relative/supporter as a proxy reporter) answered:

1. (childhood) Please describe briefly what made you most anxious at that time.
2. What was it about that situation that was difficult?
3. (adulthood) Please describe briefly what made you anxious at the time?
4. What was it about the situation that was difficult?
5. If you feel able to, please briefly describe the impact that anxiety has had on your life, either now or in the past
6. Everyone copes with their anxiety in different ways. Have you found any successful ways of coping with your anxiety that might be helpful for other autistic adults to try?

Free text data were available from 555 participants and subject to thematic analysis.

**Results:** Three overarching themes relevant to both childhood and adulthood were identified: “sensory issues”, “difficulty socialising” and “intolerance of uncertainty”, as important factors in relation to why autistic people experience anxiety. Themes specific to childhood included “attending school” and “negative family events”, whilst adulthood specific themes included “failing to meet own and/or others’ expectations”, “not fitting in” and “lack of control”. In terms of how anxiety impacts on daily life themes related to “poor mental and physical health”, “limited opportunities” and “isolation”. 82% ( $n=407$ ) of responders identified as coping strategies: “hobbies”, “prescribed and non-prescribed interventions (including medication, substance misuse and non-pharmacological interventions, such as mindfulness)” and “increased responsibility and control over life and the environment”.

**Conclusions:** Anxiety experienced by autistic children and adults may be underpinned by difficulties with uncertainty, social situations and the sensory environment. When present, anxiety has a wide-ranging impact on daily life indicating the importance of a detailed and personalised formulation to guide intervention. These findings have informed our current research programme evaluating three individualised approaches to anxiety interventions for autistic adults and children: Coping with Uncertainty in Everyday Situations; Personalised Anxiety Treatments for Autistic Adults and Virtual Reality Environment interventions for situation specific anxiety.

**429.045 (Poster)** Understanding the Role of Sex in Depression Symptoms in Early Adolescents with and without Autism Spectrum Disorder

*J. M. Schwartzman<sup>1</sup>, Z. J. Williams<sup>2</sup> and B. A. Corbett<sup>1</sup>, (1)Psychiatry and Behavioral Sciences, Vanderbilt University Medical Center, Nashville, TN, (2)Medical Scientist Training Program, Vanderbilt University School of Medicine, Nashville, TN*

---

**Background:** Adolescents with Autism Spectrum Disorder (ASD) endorse higher levels of depression than their typically-developing (TD) peers. Enhanced screening for depression is vital given the association between earlier detection, earlier intervention, and improved long-term outcomes. Similarly, adapted interventions informed by empirical study appear more effective than standard delivery in youth with ASD. To date, no studies have examined sex-based differences in prevalence and type of depressive symptoms endorsed by early adolescents with ASD as compared to TD peers, which may inform treatments.

**Objectives:** The primary objective of this study was to examine the role of sex in the prevalence of depression in early adolescents (10:0-13:5 years) with and without ASD based on self-reports on the Children’s Depression Inventory, Second Edition (CDI-2). A secondary aim was to identify specific depressive symptoms endorsed by early adolescents based on diagnosis and sex using item-level analyses of CDI-2 responses.

**Methods:** The sample included 212 early adolescents (144 males, 68 females), of which 125 had ASD (93 males, 32 females, mean age = 11.4 years) and 87 were TD peers (51 males, 36 females, mean age = 11.5 years). Participants rated depressive symptoms on the CDI-2 independently of their parents during the first year of a longitudinal study of pubertal development in ASD (Corbett, 2017). To understand the roles of sex and diagnosis in depression prevalence, a two-way ANCOVA was employed to assess sex- and diagnostic-based differences in CDI-2 Total T-scores with Full Scale IQ and age as covariates. A series of Mann-Whitney U tests were employed to examine the specific depressive symptoms that were differentially endorsed based on sex and diagnosis. The  $p$ -values were adjusted based on a 5% false discovery rate using the Benjamini-Hochberg procedure, and the magnitude of each comparison was measured using probability of superiority effect size ( $PS$ ; Ruscio, 2008).

**Results:** Results from the two-way ANCOVA revealed significant main effects of sex ( $d = 0.365$ , 95% CI [0.089, 0.641],  $p = 0.023$ ) and diagnosis ( $d = 0.587$ , 95% CI [0.308, 0.867],  $p < 0.001$ ). However, the interaction of sex and diagnosis was not significant ( $p = 0.321$ ). Early adolescents with ASD and females reported higher levels of depression symptoms, with the highest symptom severity among females with ASD. Item-level analyses demonstrated diagnostic-based differences on 12 of the 28 CDI-

2 items (PS range = 0.42-0.65), especially in terms of interpersonal problems and negative self-esteem. In terms of sex, there were no significant differences in items endorsed within diagnostic groups. However, males with ASD endorsed 10 items more frequently than their male TD peers (e.g., anhedonia, peer conflict, unlovable), while females with ASD endorsed 2 items more frequently than their female TD peers (e.g., worthlessness, not as good as other kids).

**Conclusions:** Findings indicate that sex and diagnosis may be particularly important in understanding depression prevalence and type of symptoms in early adolescents with ASD. A more nuanced understanding of distinct symptom profiles may uncover salient intervention targets for the treatment of depression in the unique context of ASD.

**429.046 (Poster)** Utility of Complex Trauma Questionnaires for Adults on the Autism Spectrum with Mild Intellectual Disability: A Systematic Review

**I. McKinnon<sup>1</sup>, S. Wigham<sup>1</sup>, K. Reid<sup>2</sup>, D. Milton<sup>3</sup>, R. Lingam<sup>2</sup> and J. Rodgers<sup>1</sup>,** (1)Population Health Sciences Institute, Newcastle University, Newcastle upon Tyne, United Kingdom, (2)Cumbria, Northumberland Tyne and Wear NHS Foundation Trust, Newcastle upon Tyne, United Kingdom, (3)Tizard Centre, University of Kent, Canterbury, United Kingdom

---

**Background:** Identification of trauma in people on the autism spectrum with intellectual disability is difficult as there are few trauma assessment tools available. Trauma questionnaires can support clinical case recognition, information gathering and formulation, and facilitate research evaluations of interventions for trauma-related mental health conditions during clinical trials. However research suggests existing trauma questionnaires may not capture all symptoms of trauma relevant to autistic people with intellectual disabilities. Research suggests some trauma symptoms e.g. avoidance may be difficult to identify in people on the autism spectrum with intellectual disability while emotion dysregulation and interpersonal difficulties may be useful indicators.

**Objectives:** The aims of this two-stage review were to (i) identify questionnaires used in neuro-typical complex trauma intervention evaluations to measure emotion dysregulation and interpersonal difficulties and (ii) evaluate their psychometric properties. Finally, to discuss potential utility of the questionnaires for people on the autism spectrum with mild intellectual disability and co-occurring trauma-related mental health conditions.

**Methods:** In Stage 1 four electronic databases (Medline, Cinahl, Embase, PsychInfo) were searched for neuro-typical complex trauma intervention studies. Second reviewers completed 20% of article sifting. In Stage 2 we used a formal search filter in Embase to identify articles evaluating the psychometric properties of the questionnaires used to measure emotion dysregulation and interpersonal difficulties in the Stage 1 studies. The quality of psychometric evidence for each measure was then assessed using the COSMIN (COnsensus based Standards for the selection of health based Measurement INstruments) risk of bias checklist and this information was synthesized narratively.

**Results:** Twenty-one complex trauma intervention studies were identified in Stage 1 and they utilised four measures of emotion dysregulation and interpersonal difficulties. These measures included the Emotion Regulation Questionnaire, the Difficulties in Emotion Regulation Scale, the Inventory of Interpersonal Problems and the Inventory of Altered Self-Capacities. Thirty-five articles on their psychometric properties were identified during Stage 2 of the review. While unique qualities were identified for all four measures, overall the findings suggested the strongest psychometric evidence was for the Emotion Regulation Questionnaire (ERQ), and the Difficulties in Emotion Regulation Scale (DERS). While evaluations of content validity were scarce, several international versions of the ERQ and the DERS were evaluated and found to have good internal reliability, structural validity and construct validity across a range of clinical and neuro-typical groups.

**Conclusions:** Reviewing the psychometric properties of questionnaires used in neuro-typical complex trauma research is an important preliminary stage in a process of exploring their utility and appropriateness for autistic people with mild intellectual disability. Evaluation of content validity and acceptability of the ERQ and DERS for people on the autism spectrum with mild intellectual disability will be useful next steps to inform future use and/or adaptation in the context of trauma-related mental health conditions.

## Molecular Genetics

### PANEL DISCUSSION — MOLECULAR GENETICS

#### Panel 205 - ASD Genetics: New Data and New Insights

**CoChair: Joseph Buxbaum**, *Department of Psychiatry, Icahn School of Medicine at Mount Sinai, New York, NY*

**Panel Chair: Elise Robinson**, *Program in Medical and Population Genetics, Broad Institute of MIT and Harvard, Cambridge, MA*

ASD genetics data sets have grown substantially over the last year, further clarifying the disorder's genetic architecture. In this session, panelists will describe recent work of the Autism Sequencing Consortium, introducing new ASD-associated genes and comparing ASD's genetic basis to that of schizophrenia and intellectual disability. Panelists will also introduce new work characterizing ASD risk subsequent to structural and noncoding variation. Lastly, the panel will consider the heterogeneity of ASD through the lenses of both phenotypic and genetic data.

**205.001 (Panel Discussion)** Identification and Characterization of Noncoding De Novo Variants in Autism  
**T. N. Turner**, *Department of Genetics, Washington University in St. Louis, St. Louis, MO*

**Background:** Large-scale gene discovery in autism has been facilitated by whole-exome sequencing and has led to the identification of protein-coding *de novo* genetic variants relevant in ~30% of individuals with autism. While these discoveries have been critical, there is still an appreciable gap in our understanding of genetic contributions to autism. Recently, whole-genome sequencing has enabled characterization of other forms of genetic variation not detectable with previous technologies. In this talk, I will focus on *de novo* noncoding variants involved in the regulation of genes.

**Objectives:** We and others have previously discovered a role for *de novo* variants in noncoding regulatory regions of the genome and predict that they explain 2-5% of individuals with autism. The objective of this talk is to describe current topics in the study of noncoding variation in autism. In particular, I will discuss our assessment of whole-genome sequencing data in autism, development of new approaches to analyze noncoding variants, and detailed characterization of one enhancer with enrichment of *de novo* variants.

**Methods:** We called single-nucleotide variants, insertions/deletions, and structural variants from whole-genome sequencing data in 2,671 families with autism. To assess statistical significance of *de novo* variants in specific noncoding regions involved in the regulation of genes (enhancers) we modified a statistical model, previously used to test protein-coding variants, to test for significance in these enhancers. We applied this to a discovery cohort of 516 previously published families and a replication cohort of 2,155 families. As we describe in the results, one enhancer was enriched for variation in both discovery and replication cohorts. We performed extensive bioinformatic, functional, expression, and phenotypic assessment of this enhancer.

**Results:** Statistical assessment of enhancers identified one enhancer with nominal significance in both the discovery ( $p = 0.0172$ ) and replication ( $p = 2.5 \times 10^{-3}$ ) cohorts. There were three *de novo* variants in this enhancer all residing in a transcription factor binding site or conserved region. By luciferase assays, we found that the variants each affect the function of the enhancer. Our further assessment found that the enhancer is sensitive to dosage in the population, is active during early embryonic development in the brain, and by Hi-C analysis targets the *EBF3* gene. Protein-coding variants in this gene are genome-wide significant for enrichment in neurodevelopmental disorders. We found that individuals with variants in the enhancer share some phenotypes with individuals with protein-coding variants in this gene, but individuals with noncoding variants tend to have less severe phenotypes.

**Conclusions:** We are beginning to understand the role of noncoding variants in autism. Comprehensive understanding of the functional impact that these variants and the regulatory networks that are involved are critical for the next phase of understanding the genetics of autism and a more thorough model of its underlying genetic etiology.

**205.002 (Panel Discussion)** Cross-Disorder Dosage Sensitivity Mapping in the Human Genome  
**R. L. Collins**<sup>1</sup>, **H. Brand**<sup>2</sup> and **M. E. Talkowski**<sup>1</sup>, *(1)Division of Medical Sciences, Harvard Medical School, Boston, MA, (2)Program in Medical and Population Genetics, Broad Institute of MIT and Harvard, Cambridge, MA*

**Background:** Rare deletions and duplications of genomic segments, collectively known as rare copy number variants (rCNVs), are important contributors to autism spectrum disorder (ASD) and other neurodevelopmental disorders (NDDs). To date, most studies of rCNVs in NDDs have focused on recognized genomic disorders or on the impact of haploinsufficiency caused by deletions. By comparison, our understanding of duplications in NDDs remains rudimentary as very few individual genes are known to be triplosensitive (*i.e.*, duplication intolerant).

**Objectives:** In this study, we aimed to (1) identify disease-associated rCNV loci, (2) understand the genomic properties of these loci, and (3) develop a statistical model to predict dosage sensitivity for all human genes.

**Methods:** We meta-analyzed rCNVs from 753,994 individuals aggregated from 13 cohorts to create a genome-wide catalog of rCNV association statistics across 30 primarily neurological disease phenotypes. In order to understand the genomic features that drive rCNV-disease associations, we combined all genome-wide significant ( $P=3.72 \times 10^{-6}$ ) regions with a curated list of genomic disorders previously reported in the literature and analyzed this merged dataset for enrichments of known disease genes, mutationally constrained genes, and *de novo* mutations (DNMs) identified in individuals with ASD or NDD in prior exome sequencing studies. Finally, we developed a statistical model to predict dosage sensitivity for all genes.

**Results:** We discovered 114 rCNV-disease associations at 52 distinct loci surpassing genome-wide significance, 42% of which involve duplications. Nearly all loci (87%; 45/52) were associated with at least one neurological phenotype and half (50%; 26/52) were associated with ASD or NDDs. Using Bayesian fine-mapping methods, we further prioritized 38 novel triplosensitive disease genes (*e.g.*, *GMEB2* in brain abnormalities), including three known haploinsufficient genes that we now reveal as bidirectionally dosage sensitive (*e.g.*, *ANKRD11*). We found that disease-associated rCNV segments were enriched for genes constrained against damaging coding variation and identified likely dominant driver genes for about one-third (32%) of rCNV segments based on DNMs from exome sequencing of ASD and NDDs. Finally, we developed a machine learning model to define 3,006 haploinsufficient and 295 triplosensitive genes where the effect sizes of rCNVs in NDDs were comparable to deletions of genes constrained against truncating mutations. These dosage sensitivity scores classified disease genes across molecular mechanisms and prioritized pathogenic *de novo* rCNVs in children with ASD.

**Conclusions:** Our study demonstrates that rCNVs confer substantial disease risk across a range of loci and disease phenotypes, particularly ASD and NDDs. We further show that most rCNVs with strong effects in disease likely act through the direct disruption of one or more protein-coding genes. While the presence of constrained driver genes was a common feature of many pathogenic large rCNVs across disorders, most of the genome-wide significant rCNVs were incompletely penetrant and some appeared not to involve any alterations to protein-coding genes. Collectively, the cross-disorder rCNV maps and metrics derived in this study provide a comprehensive assessment of dosage sensitive loci in disease to date and set the foundation for future studies of dosage sensitivity throughout the human genome.

### 205.003 (Panel Discussion) Genetics and ASD Heterogeneity

**E. B. Robinson<sup>1</sup>**, C. E. Carey<sup>2</sup>, S. S. Kuo<sup>3</sup>, J. Taylor<sup>4</sup>, C. van der Merwe<sup>5</sup> and D. Weiner<sup>5</sup>, (1)Program in Medical and Population Genetics, Broad Institute of MIT and Harvard, Cambridge, MA, (2)Analytic and Translational Genetics Unit, Massachusetts General Hospital, Boston, MA, (3)Stanley Center for Psychiatric Research, Broad Institute of MIT and Harvard, Cambridge, MA, (4)Psychiatry, Brigham and Women's Hospital, Boston, MA, (5)Harvard Medical School, Boston, MA

**Background.** Autism spectrum disorder (ASD) is characterized by social communication impairment and restricted, repetitive behaviors and interests. While impairment in these domains is definitional to ASD, it is far from uniform and ASD is broadly heterogeneous. People with ASD vary enormously in their functional independence, cognitive and language abilities, and medical comorbidities. Many of these differences reflect genetic heterogeneity, as well as broader variation in the causal architecture of ASD.

**Objectives.** This project was designed to clarify heterogeneity within and between ASD research cohorts.

**Methods.** We aggregated phenotype and genotype data from several family-based ASD cohorts (Simons Simplex Collection (SSC); Simons Powering Autism Research (SPARK); the Autism Genetic Resource Exchange (AGP); and the Autism Simplex Collection (TASC)). We compared the data sets in terms of key phenotypic variables (*e.g.* mean case IQ, score on the Vineland Scales of Adaptive Behavior, developmental milestone timing) and genetic architecture (*e.g.* rate of high impact *de novo* variants; over-transmission of polygenic risk for ASD from parents to affected children). Using simulated data, we also estimated the impact of ASD heterogeneity on GWAS and sequencing efforts.

**Results.** The data sets varied in ways that reflected their collection decade and ascertainment approach. Newer data sets (*e.g.* SPARK) most reflect ASD's diagnostic expansion – a larger fraction of probands are functionally independent. Shifts in average

case severity were also induced by study selection criteria. The SSC excluded case individuals with craniofacial dysmorphism or other indicators of syndromic medical conditions. This induced a shift in average genetic architecture, as well as in genotype to phenotype relationships. For example, for probands with a disruptive *de novo* variant in genes associated with ASD and ID, we observed lower rates of gross motor impairment and seizure disorders among SSC cases as compared to TASC cases. Results of the simulated data analysis showed that some genetic influences on ASD risk will be easier to detect in restricted analyses (e.g. GWAS that only include ASD case individuals without co-occurring intellectual disability).

**Conclusions.** As the average ASD phenotype varies between collections, and is changing over time, genetic studies of ASD will need to thoughtfully consider issues of replication. The heterogeneity of ASD produces challenges for genetic research, but is also likely to present opportunities to better identify and understand points of intersection among risk factors. These intersections could highlight genetic results and biological pathways most relevant to large numbers of people with ASD.

**205.004 (Panel Discussion) Large-Scale Gene Discovery in Autism and Comparison to Schizophrenia and Developmental Delay**

*Background:* Rare genetic variants, particularly *de novo* (newly arising) mutations, play an important role in individual risk for autism spectrum disorder (ASD). A decade ago, we formed the Autism Sequencing Consortium to collaborate with clinicians and research groups around the world in an effort to identify the types of rare variants that confer risk for ASD and the genes where they occur. As our datasets have grown, so have our findings – from 33 genes identified as ASD-associated at a false discovery rate (FDR)  $\leq 0.1$  in 2014 (De Rubeis *et al.*, *Nature* 515:209-215) to 65 genes in 2015 (Sanders *et al.*, *Neuron* 87:1215-1233) to 102 genes recently (Satterstrom, Kosmicki, Wang *et al.*, 2020, *Cell* 180:568-584).

*Objectives:* We seek to 1) identify novel ASD-associated genes and 2) learn more about the neurobiology of ASD by analyzing the set of ASD-associated genes, as well as by comparing it to genes associated with other neurodevelopmental disorders. To achieve the first goal, we combine our data with publicly available data from SPARK, the Simons Foundation study of ASD, which doubles our sample size and increases our power for gene discovery. To inform the second, we draw upon studies of schizophrenia and more broadly defined developmental delay.

*Methods:* We present the largest autism-focused sequencing study to date. We analyze the exome sequences from over 20,000 individuals with ASD, including *de novo* variants from 14,578 probands and 5,391 unaffected siblings, as well as rare variants from 5,590 cases (primarily from the iPSYCH study in Denmark) and 8,588 controls. We call copy number variants in addition to single nucleotide variants and short insertion/deletions, and we use an enhanced version of a Bayesian model called TADA (He *et al.*, 2013, *PLoS Genetics* 9:e1003671) to integrate the different classes of variation into a single association framework. After analyzing our data on its own, we also analyze it alongside data from the Schizophrenia Exome Meta-Analysis (SCHEMA) study of schizophrenia (Singh *et al.*, 2020, <https://www.medrxiv.org/content/10.1101/2020.09.18.20192815v1>) and the Deciphering Developmental Disorders (DDD) study of developmental delay (Kaplanis, Samocha, Wiel, Zhang *et al.*, 2020, *Nature* 586:757-762).

*Results:* We find 255 genes associated with ASD at a threshold of FDR  $\leq 0.1$ , of which 71 meet FDR  $\leq 0.001$ , approximately corresponding to Bonferroni correction. Analyzing our data and DDD together, we identify 352 genes at the same threshold (86 more than DDD alone). While many genes are associated with both ASD and developmental delay, we identify a set of genes clearly associated with ASD that have little signal in DDD and, among these, a set that overlaps risk signal in schizophrenia.

*Conclusions:* Our analyses provide a significant advance in ASD gene discovery and support both shared and distinct contributions of the genes underlying different neurodevelopmental phenotypes. Next, we plan to expand our analyses to include *de novo* variation from a new wave of 2,000 ASD probands from SPARK whose data has recently been released, and we will share preliminary results at the meeting.

## PANEL DISCUSSION — MOLECULAR GENETICS

### Panel 233 - Large-scale Gene Discovery in Autism and Converging Pathways of Autism Risk

**Panel Chair: Joseph Buxbaum**, *Department of Psychiatry, Icahn School of Medicine at Mount Sinai, New York, NY*

Large-scale genetic and genomic studies have identified structural variants and gene mutations that confer very high risk for ASD. These studies have implicated tens of recurrent structural variants and hundreds of genes in autism risk. This etiological heterogeneity is daunting, and it has overturned hopes for a single, primary, molecular and/or cellular pathway for autism risk, hence precision medicine approaches will be critical for novel interventions. This panel will summarize the recent focus on whether the genetic and genomic discoveries converge into a smaller number of pathways, which would greatly facilitate precision treatments. Knowing recurrent pathways to autism will also permit intervention in those that do not have a defined genetic mutation. The speakers will share results on the functional follow up of multiple genetic/genomic discoveries using molecular, cellular and animal model approaches.

**233.001** (*Panel Discussion*) Neuroanatomical Convergence in Autism Related Mouse Models

**J. Ellegood<sup>1</sup>**, **Y. Yee<sup>1</sup>** and **J. P. Lerch<sup>1,2</sup>**, (*1*)*Mouse Imaging Centre, Hospital for Sick Children, Toronto, ON, Canada*, (*2*)*Wellcome Centre for Integrative Neuroimaging (WIN), University of Oxford, Oxford, United Kingdom*

**Background** – Over the past 12 years, we have established a magnetic resonance imaging (MRI) database of mouse models related to autism, which allows us to investigate convergence in the neuroanatomy in a large autism population. This further provides us with a metric by which we can cluster these models and examine commonalities and differences between them in the hope of subcategorizing autism.

**Objectives** – The purpose here is two-fold. 1) Characterize and cluster our dataset of 125 different mouse models related to autism, and 2) Examine the convergence of the neuroanatomy and how it relates to specific biological pathways and disease phenotypes.

**Methods** – The data used in this study was collected from 125 different autism related mouse lines and includes over 4000 mice. Imaging was performed *ex-vivo* using a 7T MRI with a T2 weighted, 3D fast spin echo sequence which acquires data at an isotropic resolution of 40  $\mu\text{m}$  (Spencer Noakes et al. 2017).

**Data Analysis** – To visualize and compare any differences, the images are registered together (Lerch et al., 2011). Voxelwise difference in both absolute ( $\text{mm}^3$ ) and relative volume (% total brain vol.) are calculated from each of the 125 different models. This data is then combined using similarity network fusion to create a fused dataset that incorporates both these differences. Spectral clustering was used to cluster the fused dataset and cluster divisions were determined from 2 to 10 total clusters.

**Bioinformatics** – Online databases, including StringDB ([string-db.org](http://string-db.org)), the Reactome Pathway Database ([reactome.org](http://reactome.org)), Human Phenotype Ontology ([hpo.jax.org](http://hpo.jax.org)), and the gene sets provided by the Bader Lab ([baderlab.org](http://baderlab.org)) (Merico et al., 2010) were used to link specific molecular pathways and disease phenotypes to our clusters to provide more information about potential common determinants that underlie the models.

**Results** – Our data suggests that the autistic phenotype both preferentially affects key regions of the brain, but also divides the autism neuroanatomical phenotype based on directionality and localization of the differences throughout the brain. The data shows that the autism phenotype is broad as there was little overlap between the high confidence autism related genes nor the comorbid/syndromic genes. The clusters represent known connections, like 16p11.2(df/+), Taok2, and Cul3; and Chd8 and Arid1b; but they also highlight unknown connections between Pten, Nrnx1a, and Taok2; and 16p11.2(dp/+), 15q11-13, and Dyrk1a(+/-). Additionally, two clusters were linked specifically to “signaling by wnt”, “MAPK family signaling”, and “signaling by hedgehog” and another two clusters to “transmission across the synapse” and “chromatin organization”.

**Conclusions** – The work presented here shows that, as seen through the lens of brain structure, there is more than one autism. These autism subtypes span related disorders and can in part be identified by the shared pathways of the originating mutation. Clustering autism based on brain phenotypes and linked genetic pathways will help to further categorize the autistic population to aid with a more specific diagnosis and hopefully, in the future, better treatment options.

**233.002** (*Panel Discussion*) Using 3D Models of Brain Development to Study Convergence in ASD

**A. Gordon**, UCLA, Los Angeles, CA

---

**Background:** Genetic studies have connected mutations in hundreds of different genes with autism spectrum disorders (ASD). This genetic heterogeneity highlights the importance of identifying convergent biological pathways and molecular mechanisms. In this regard, studies have identified a common pattern of changes in gene expression in post-mortem brain from individuals diagnosed with ASD. However, it still is not known to what extent do the many different genetic risk variants associated with ASD lead to common dysregulated pathways in brain development and function. The advent of human stem cell-based systems allows for the modeling of typical early human brain development, as well as potential disruptions in ASD. Cortical organoids, which are 3D models of cortical development, were recently shown to model human cortical development more faithfully than the more traditional 2D models. These models can serve as a powerful complement to animal models to interrogate the neurobiological impact of disease-associated common and rare genetic risk variants in ASD.

**Objectives:** To investigate how different genetic developmental disorders associated with ASD affect cortical development and to test the hypothesis as to whether there are convergent phenotypes in distinct genetic forms of ASD during cortical development.

**Methods:** We generated 3D brain organoids from stem cells derived from individuals with one of nine different genetic developmental disorders associated with ASD (16p11.2 deletion, 16p11.2 duplication, 15q13.3 deletion, 22q13.3 deletion, 22q11.2 deletion, PCDH19 mutations, CACNA1C mutations (Timothy syndrome), and SHANK3 mutations). We profiled 30 individuals with one of the known mutations, 8 with idiopathic ASD, and 17 controls and collected 464 samples for analysis at four timepoints during organoid differentiation. We used functional genomic analysis to identify common pathways dysregulated across these multiple forms of ASD during early brain development up to 15 weeks in vitro.

**Results:** Transcriptomic changes implicate the early stages of cortical development during cortical neurogenesis, largely affecting progenitor cell types. The transcriptomic patterns allowed us to robustly cluster the different mutations into subgroups, suggesting that different genetic forms of ASD follow the same developmental trajectory and that there are a number of distinct developmental trajectories that may underlie ASD.

**Conclusions:** Cortical organoids are an effective way to study the early stages of brain development and the changes that occur at these stages in ASD. Combining functional genomics with these cortical organoids allows us to identify shared molecular processes across different genetic forms of ASD during early cortical development and to categorize different groupings of different genetic forms of ASD based on these changes. We believe that this type of analysis may help in the discovery of new drug targets and in improving design of drug trials.

**233.003** (*Panel Discussion*) Functional Convergence Across Genes Associated with Neuropsychiatric Disorders

**S. J. Sanders<sup>1</sup>** and **J. Y. Y. An<sup>2</sup>**, (1)Department of Psychiatry, Weill Institute for Neuroscience, UCSF School of Medicine, San Francisco, CA, (2)School of Biosystem & Biomedical Science, Korea University, Seoul, Korea, Republic of (South)

---

**Background:** The past decade has seen tremendous progress in identifying the genes underlying autism spectrum disorder, neurodevelopmental delay, and schizophrenia. These genes provide an entrée into the underlying neurobiology and the opportunity to access functional similarities and differences within and between conditions.

**Objectives:** To perform parallel analyses of genes associated with neuropsychiatric conditions in the context of functional datasets to provide insights into when, where, and how disruption of these genes may lead to the observed phenotypes.

**Methods:** Genes with genome-wide significant evidence of association from exome and genome sequencing were identified from the literature and ongoing analyses from autism spectrum disorder, neurodevelopmental delay, and schizophrenia. These were integrated with data from gene ontologies, literature on gene function, gene expression in the developing human brain, and single cell gene expression data in the developing human brain

**Results:** There is substantial overlap with genes associated with neurodevelopmental delay and autism spectrum disorder and neurodevelopmental delay and schizophrenia, but no genes overlap between autism spectrum disorder and schizophrenia. Across the gene sets, four major functional groups are apparent: gene expression regulation (e.g., transcription factors), neuronal

communication (e.g., synaptic proteins), cytoskeleton, and cell signaling. All four groups are represented in the gene sets from all three disorders. Almost all genes are expressed in the developing human cortex, many of them starting early during prenatal development. Gene function is more predictive of expression trajectory than phenotype. Single cell analyses strongly implicate neurons across all three conditions based on both enrichment analyses and absolute expression.

**Conclusions:** Convergent patterns of gene function and neuron-specific expression are apparent between all three disorders, even though there is substantial heterogeneity in the individual gene lists and expression trajectories across development.

**233.004 (Panel Discussion)** Parallel In Vivo Analysis of Large-Effect Autism Genes Implicates Neurogenesis and Estrogen in Risk and Resilience

**H. R. Willsey<sup>1</sup>, C. R. Exner<sup>1</sup>, Y. Xu<sup>1</sup>, A. Everitt<sup>1</sup>, N. Sun<sup>1</sup>, T. Nowakowski<sup>1</sup>, R. M. Harland<sup>2</sup>, A. J. Willsey<sup>1</sup> and M. W. State<sup>1</sup>,**  
(1)University of California San Francisco, San Francisco, CA, (2)UC Berkeley, Berkeley, CA

**Background:** Over the last decade, dozens of genes carrying *de novo* variants have been identified, each contributing large biological effects to autism spectrum disorders (ASD). The remarkable degree of locus and biological heterogeneity so far identified has raised concerns of an impenetrably complex biology and the necessity for a multitude of individualized treatments. Starting from the earliest successful efforts at systematic ASD gene discovery, systems biological analyses have pointed to a more coherent underlying structure of ASD pathology. However, convergent phenotypes and their corresponding biological pathways have not been systematically explored across multiple risk genes.

**Objectives:** Here we studied multiple ASD risk genes in parallel *in vivo* in order to identify points of functional convergence during brain development as well as small molecule modulators of ASD risk gene disruption.

**Methods:** We used the diploid frog *Xenopus tropicalis* to study, *in vivo*, ten genes with the strongest statistical evidence for association with ASD by CRISPR-Cas9 mutagenesis. We used systematic small molecule screening in *Xenopus* to identify compounds intersecting the biology of these genes. Finally, we used *Xenopus* and human models of brain development to dissect and validate the underlying molecular mechanisms.

**Results:** All ten high-confidence ASD genes are expressed in the *Xenopus* developing telencephalon at timepoints mapping to human mid-prenatal development and loss of function mutations lead to an increase in the ratio of excitatory neural progenitor cells to maturing excitatory neurons in the dorsal forebrain. Systematic small molecule screening identified that estrogen, via Sonic hedgehog signaling, rescued this convergent phenotype in *Xenopus* and human models of brain development.

**Conclusions:** This work supports previous *in silico* systems-biological findings implicating cortical excitatory neurons in ASD vulnerability, and extends them by demonstrating that ten of the most strongly associated ASD genes converge on neurogenesis of these cell types--despite apparent diverse cellular functions. It also suggests estrogen as a resilience factor that may mitigate a broad range of ASD genetic risks, an intriguing finding given the strong male sex bias in ASD diagnosis.

Background: Autism spectrum disorder (ASD) is highly heritable based on data from large population and twin studies. ASD risk is complex and stems from genetic and non-genetic factors. Studies have identified ~100 ASD genes, yet most risk genes are unknown. SPARK (SPARKForAutism.org), a national research cohort, has recruited tens of thousands of recontactable families affected with ASD, allowing longitudinal phenotypic and genomic characterization.

Objectives: Significantly larger sample sizes are needed to identify all genetic risk factors for ASD.

Methods:

10,242 ASD cases from 9,136 SPARK families were genotyped with 654,027 SNPs (Infinium Global Screening Array v 2.0) and exome sequenced. We identified *de novo* variants (DNVs) from 10,097 SPARK trios (including 7,051 affected individuals and 3,046 unaffected siblings) and meta-analyzed with DNVs from 9,847 published autism trios. To identify new autism risk genes, we applied DeNovoWEST to test the enrichment of *de novo* damaging variants in each gene. We also applied a modified version of TADA that integrates gene level constraint and allows a fraction of risk genes to harbor only deleterious missense variants. To analyze the contribution of inherited variants to ASD risk, we applied a transmission disequilibrium test to rare loss of function (LoF) variants in 9621 autism trios and 193 parent-ASD offspring pairs from SPARK and the Simons Simplex Collection (SSC). CNVs were called from SNP chromosome microarrays and normalized exome read depth using multiple pipelines.

Results: Forty-seven genes were identified as exome-wide significant by DeNovoWEST ( $p < 0.05 / (2 * 19000) = 1.3e-6$ ); most of these genes have been implicated in autism or NDDs. To further prioritize candidate genes, we applied a modified TADA and identified 145 genes that fall below the commonly used threshold of  $FDR < 0.1$ . A comparison of significance values (by DeNovoWEST) to posterior probability of association (PPA) shows that the top 100 PPA-ranked genes by modified TADA all have significant p-values from DeNovoWEST ( $p < 1E-3$ ) and therefore can be considered high-confidence autism candidate risk genes. DNVs in these 100 genes and 359 known NDD genes explain two-thirds of the overall enrichment of this class of variants in individuals with ASD versus controls. We also found significant over-transmission of rare, likely gene-disrupting variants (1.13x,  $p = 1.8e-9$ ) in LoF intolerant genes (ExAC  $pLI \geq 0.5$ ). Variants in the high-confidence ASD risk genes and 359 known NDD genes account for less than 15% of the over-transmission of rare, inherited variants, suggesting that many risk genes harboring inherited LoF variants remain to be identified.

We identified the first gene, *UBR1*, that increases ASD risk only through inherited variants ( $p_{Meta} = 1.36E-06$ ). No transmitting parent of a *UBR1* mutation has an ASD diagnosis, consistent with reduced penetrance. Only one of the 22 SPARK or SSC probands harboring deleterious alleles of *UBR1* has intellectual disability and this individual also harbors a damaging variant in *TSC1*.

Conclusions: Our results highlight the value of sequencing ASD exomes at scale, leading to new insights on inherited risk in ASD. Samples from the ongoing recruitment efforts of SPARK will help address the missing heritability in ASD.

**430.002 (Poster)** The Clinical and Molecular Consequences of Variation in the Chromodomain DNA Helicase Binding Protein (CHD) Gene Family

**M. A. Gillentine<sup>1</sup>, E. E. Eichler<sup>2</sup>, T. Wang<sup>3</sup>, K. Hoekzema<sup>4</sup>, J. Rosenfeld<sup>5</sup>, P. Liu<sup>6</sup>, T. Nowakowski<sup>6</sup>, M. Nordenskjold<sup>7</sup>, J. Gecz<sup>8</sup>, R. K. Earl<sup>9</sup>, F. Kooy<sup>10</sup>, X. Kun<sup>3</sup> and M. I. Valenzuela Palafoll<sup>11</sup>.** (1)Genome Sciences, University of Washington, Seattle, WA, (2)Department of Genome Sciences, University of Washington, Seattle, WA, (3)Center for Medical Genetics, School of Life Sciences, Central South University, Changsha, China, (4)Baylor College of Medicine, Houston, TX, (5)Baylor Genetics, Houston, TX, (6)University of California San Francisco, San Francisco, CA, (7)Karolinska Institutet, Stockholm, Sweden, (8)Adelaide Medical School and the Robinson Research Institute, University of Adelaide, Adelaide, Australia, Adelaide, SA, Australia, (9)Psychiatry and Behavioral Sciences, University of Washington, Seattle, WA, (10)Department of Medical Genetics, University of Antwerp, Edegem, Belgium, (11)Hospital Vall d'Hebron, Barcelona, Spain

Background: Genes underlying neurodevelopmental disorders (NDDs) converge on shared functional networks. We hypothesize that variants in related genes, particularly gene families, result in shared clinical phenotypes and, as such, patients may benefit from shared targeted therapies. Here, we focus on the chromodomain DNA helicase binding protein (*CHD*) gene family, consisting of 10 genes involved in chromatin remodeling which have an enrichment of *de novo* variants among NDDs based on analysis of >152,000 exomes. Several *CHD* members have been strongly implicated in NDDs, including CHARGE syndrome (*CHD7*), autism spectrum disorder (ASD, *CHD8*), and epileptic encephalopathy (*CHD2*).

Objectives: We aim to explore the impact of *CHD* variation at the gene family level in NDDs and determine the phenotypic and molecular consequences of such variation.

Methods: We identified probands with variants in the *CHD* genes through targeted sequencing data from our Autism Spectrum/Intellectual Disability network (n = 16,377), exome data from the SPARK consortium (n = 6,499), clinical sequencing data generated by Baylor Genetics Laboratories (n = 9,536), collaborations through GeneMatcher and international collaborations, as well as the literature. We identified >900 probands with variation in all 10 *CHD*-encoding genes (*CHD1-CHD9* and *CHD1L*). We are correlating these findings with transcriptional signatures generated from single-cell RNA-seq (scRNA-seq) of human fetal cortex samples, as well as patient-derived and Cas9 gene-edited induced pluripotent stem cells. We are using differentiated neuronal cells to assess broad cellular changes, as well as *CHD*-specific functionality.

Results: Using two statistical models, four *CHDs* meet genome-wide significance ( $p < 5 \times 10^{-7}$ ) for loss-of-function and/or missense variants. We expanded the clinical phenotype associated with variation in *CHDs*, including rare *CHD*-related disorders and those without identified syndromes, such as *CHD5* (n = 57) and *CHD9* (n = 74). We found there is a shared phenotypic spectrum of developmental delay/intellectual disability, ASD, and seizures, with varying frequency among different *CHD* genes. Based on the types of variation discovered, we conclude that *de novo* missense variation contributes to the majority of probands in our cohort, suggesting a dominant negative impact for chromatin remodeling complexes. The exceptions are *CHD2*, *CHD7*, and *CHD8*, which are more consistent with haploinsufficiency.

Protein homology analyses distinguish three unique homology groups: 1) *CHD1/CHD2*, 2) *CHD3-5*, and 3) *CHD6-9*. scRNA-seq of fetal cortex samples shows high levels of expression of the *CHD* genes among dividing radial glia, outer and truncated radial glia, and intermediate progenitor cells, with decreased expression generally among inhibitory and MGE newborn neurons, although *CHD3* and *CHD5* share their own unique expression pattern with highly enriched expression in excitatory neurons. Fibroblasts from probands with *CHD1*, *CHD2* and *CHD8* variants reprogrammed successfully and are being utilized for functional work, while other cell lines are being generated using Cas9 gene editing.

Conclusions: We show that *CHDs* broadly have clinical relevance for NDDs, including those not described as syndromic, and share phenotypic similarities, but that the class of mutations differ with respect to groups. Finally, we have begun to determine some of the molecular characteristics and pathomechanisms of variation in this gene family.

#### **430.003 (Poster)** The Genetic Characterization of Probands with Autism Spectrum Disorder and Their Extended Family Members

**J. Zhang<sup>1</sup>**, A. Ghorai<sup>2</sup>, S. C. Taylor<sup>3</sup>, H. C. Dow<sup>2,4</sup>, B. N. Gehringer<sup>2,4</sup>, A. Langer<sup>2,4</sup>, E. Rawof<sup>2,4</sup>, L. S. Perez<sup>2,4</sup>, M. H. Goodman<sup>2,4</sup>, A. A. Pallathra<sup>5</sup>, S. D. Elkhatib Smidt<sup>2,6</sup>, D. J. Rader<sup>2</sup>, L. Almasy<sup>2,7</sup>, E. S. Brodtkin<sup>4</sup> and M. Bucan<sup>2</sup>, (1)Graduate Group in Epidemiology and Biostatistics, University of Pennsylvania, Philadelphia, PA, (2)Department of Genetics, University of Pennsylvania, Philadelphia, PA, (3)Graduate Group in Neuroscience, University of Pennsylvania, Philadelphia, PA, (4)Department of Psychiatry, University of Pennsylvania, Philadelphia, PA, (5)Department of Psychiatry, Catholic University of America, Washington, DC, (6)Division of Neurology and Sleep Center, Children's Hospital of Philadelphia, Philadelphia, PA, (7)Department of Biomedical and Health Informatics, Children's Hospital of Philadelphia, Philadelphia, PA

Background: Autism Spectrum Disorder (ASD) is a group of heterogeneous disorders with heritability estimated at 60% to 90%, suggesting a strong genetic etiology. However, the genetic causes of more than 90% of the ASD cases remain unknown. The genetic etiology of "idiopathic" ASD is complex and polygenic, involving multiple susceptibility genes and genetic variation of varying frequency and inheritance patterns. The Autism Spectrum Program of Excellence (ASPE) at the University of Pennsylvania is focusing on the genetic etiology of ASD by recruiting individuals with ASD without intellectual disability (ID) and their extended family members. ASPE also recruits families with variants in *NRXN1*, a known ASD-risk gene encoding a transsynaptic protein neurexin 1. Through quantitative phenotyping and whole genome sequencing (WGS), ASPE focuses on the genetic etiology of the entire autism spectrum.

Objectives: To characterize the full spectrum (rare, common, inherited and *de novo*) of genetic risk alleles in ASPE families without ID.

Methods: Standard quality control procedures were performed on ASPE WGS data. Genetic variants were annotated using ANNOVAR. Deleterious single nucleotide variants (SNVs) and insertions and deletions (indels) were selected if they were rare (gnomAD allele frequency < 0.1%) protein-truncating variants (nonsense, frameshift, splicing), or rare missense variants with CADD score > 20 or REVEL score > 0.5. Structural variants (SVs) and copy number variation (CNV) were called by Manta and Canvas. ExpansionHunter was used to detect 19 well-known repeat expansions in ASPE families. Inheritance pattern of these variants were inferred from the pedigree. A list of 155 ASD risk genes was created by combining published ASD risk gene lists based on the Transmission And *De novo* Association test (TADA).

Results: ASPE is an ongoing study. Currently, 315 individuals (117 probands) in 118 families have been sequenced. The average age of probands is 33 years old and 78 (66.7%) of them are male. Ten families (8.5%) had known *NRXN1* deletion/mutation prior

to recruitment (*NRXN1* family). In 7 *NRXN1* probands/families (70.0%), we identified 19 inherited deleterious SNVs/indels in 19 TADA ASD risk genes. For the rest of the families without known ASD-related genetic variants prior to recruitment (phenotype-first probands/families, n = 108), we identified 57 inherited deleterious SNVs/indels in 39 TADA ASD risk genes in 29 probands/families (26.9%). Among them, 14 probands/families (48.3%) carry inherited deleterious SNVs/indels in multiple TADA ASD risk genes. We are in the process of analyzing the SV, CNV and repeat expansion data.

**Conclusions:** We have identified genetic variants that are likely to contribute to the risk of ASD for 29 out of 108 phenotype-first families (26.9%). Moreover, 70.0% of the *NRXN1* families and 13.0% of the phenotype-first families carry more than one deletion/mutation in different ASD risk genes. These data support the hypothesis that ASD phenotypes are due to multiple genes and their interactions. The integrative analysis of variants of varying frequency, inheritance patterns and type (SNV, indel, SV, CNV, and repeat expansion), and ASD polygenic risk score will help us better understand the genetic basis of ASD.

**430.004 (Poster)** Whole Exome Sequencing Reveals Complex Genetic Architecture of Autism Spectrum Disorder in an Israeli Population

---

**Background:** Autism Spectrum Disorder (ASD) is a multifactorial neurodevelopmental condition with a significant genetic susceptibility component. Recent whole-exome sequencing (WES) studies have found hundreds of rare ASD susceptibility variants distributed in hundreds of genes suggesting a complex genetic architecture of ASD etiology. The Israeli population is comprised of heterogeneous ethnic groups some of which are characterized with high consanguinity (e.g. Jewish orthodox, Bedouin Arabs), which leads to high prevalence of genetic diseases in these population. Yet, until now no attempt was made to identify ASD susceptible genetic variants in Israel.

**Objectives:** To identify genetic variants associated with ASD in an Israeli population.

**Methods:** DNA samples were collected from children with ASD enrolled at the National Autism Research Center (NARC) of Israel and their parents. WES was performed at the Broad Institute on Illumina HiSeq sequencers using the Illumina Nextera exome capture kit as part of the autism sequencing consortium (ASC). GATK's best practice guidelines were used for variant discovery from the WES data. We defined gene-disrupting variants (GDVs) associated with ASD according to the following criteria: (1) high-quality and rare (allele frequency <5%) SNVs; (2) SNVs with deleterious functional consequences according to Ensembl's VEP criteria (e.g. frameshifts indels, nonsense variations, splice acceptor/donor variants and deleterious missense substitutions according to SIFT and PolyPhen-2 algorithms); (3) SNVs were identified in exons of 224 genes with established association with ASD according to SFARI and ASC databases; and (4) genotype was unique in the child with ASD compared to his/her parents.

**Results:** The exome of 171 children from 159 families were evaluated in this study. Of these, 26 children (15.2%) had one or more GDVs distributed in 25 ASD genes. The majority of these GDVs were missense de-novo variants. To the best of our knowledge, none of the identified GDVs were associated with ASD before. Interestingly, our sample included two affected siblings that carried the same recessively inherited GDV, thus increasing the likelihood for this GDV to cause ASD in this family. Further support in our findings was by the hypergeometric analysis indicating statistically significant concordance between observed and expected phenotypes associated with these GDVs ( $p < 10^{-20}$ ).

**Conclusions:** Our results suggest a unique genetic architecture underlying ASD in the Israeli population.

## POSTER SESSION — MOLECULAR NEUROSCIENCE

### Poster 431 - Molecular Neuroscience Posters

**431.002** (Poster) Circulating Noncoding RNAs As a Signature of Autism Spectrum Disorder Symptomatology  
**S. Salloum-Asfar<sup>1</sup>**, **K. Errafii<sup>1,2</sup>**, **S. F. Elhag<sup>1</sup>**, **N. J. Satheesh<sup>1</sup>** and **S. A. Abdulla<sup>1</sup>**, (1)Qatar Biomedical Research Institute (QBRI), HBKU, Qatar Foundation, Doha, Qatar, (2)College of Health and Life Sciences, Hamad Bin Khalifa University, Qatar Foundation, Education City, Doha, Qatar., Doha, Qatar

**Background:** Autism Spectrum Disorder (ASD) is a multi-faced neurodevelopmental disorder that uncovers itself during the early years of child development. The complexity of ASD makes clinically diagnosing the condition, not an easy feat. Consequently, by identifying biomarkers that associate itself with ASD severity and combining it with clinical diagnosis, one may better factionalize within the spectrum and therefore devise more targeted therapeutic strategies.

**Objectives:** Currently, there are no reliable biomarkers that can be used for precise ASD diagnosis, our objective is to define circulating noncoding RNA profile in plasma of ASD with mild and severe symptomatology.

**Methods:** We have subdivided our cohort (N=45) into two groups, the first of which entails children who express severe ASD symptoms and the second mild ASD symptoms. Using next-generation sequencing, we were able to identify several circulating noncoding RNAs in plasma. Differential expression analysis was performed using the CLC Genomics Workbench version 20.0.4 on miRNAs, piRNAs, snoRNAs, and Y-RNAs between the two groups.

**Results:** This study is the first to show that miRNAs, piRNAs, snoRNAs, and Y-RNAs are stably expressed in plasma in our ASD cohort. We utilized comprehensive evidence-based data sources to introduce, for the first time, several potential circulating ncRNAs biomarkers, isolated from plasma, with the prospect of recognizing cases that manifest severe ASD characteristics from mild ones and hence may be implemented as early diagnostic biomarkers (Figure 1).

**Conclusions:** Our data identifies circulating ncRNAs specific to either our severe or mild group and hence stands as an objective diagnostic biomarker and potential therapeutic target.

**431.003** (Poster) Transcriptome-(Phospho)Proteome Characterization of the Brain of a Constitutional Model of Cytoplasmic-Predominant Pten Expression with Autism-like Phenotypes  
**S. T. Thacker<sup>1</sup>** and **C. Eng<sup>2</sup>**, (1)Genomic Medicine Institute, Lerner Research Institute of Cleveland Clinic, Cleveland, OH, (2)Genomic Medicine, Cleveland Clinic, Cleveland, OH

**Background:** *PTEN*, a well-studied tumor suppressor, has one of the strongest Mendelian associations with autism spectrum disorder (ASD), representing a special case in autism's complex genetic architecture. Animal modeling for constitutional *Pten* mutation creates an opportunity to study how disruption of Pten affects neurobiology, providing insights that may be generalizable or at least inform our understanding of ASD. Although the neural transcriptome has been well characterized in *Pten* models, little has been done concerning the proteome and phosphoproteome. This is a critical gap in knowledge given that these – omic landscapes are more proximal to the actively observed biology than the transcriptome.

**Objectives:** We sought to comprehensively characterize the neural proteome and phosphoproteome of the *Pten<sup>m3m4/m3m4</sup>* mouse, which exhibits cytoplasmic-predominant Pten expression and has known behavioral and neurodevelopmental phenotypes.

**Methods:** Proteomic and phosphoproteomic scans of *Pten<sup>m3m4/m3m4</sup>* (N = 3) and wildtype (N = 3) mouse brain at two-weeks- (P14) and six-weeks-of-age (P40) were performed using liquid chromatography with tandem mass spectrometry technology with prior phosphopeptide enrichment when appropriate. Following quantification of differentially expressed/phosphorylated proteins, we performed various bioinformatics analyses, including gene overlap, gene enrichment, pathway, and network analyses, to identify the similarity across the various datasets, understand the affected biological landscape, and identify important regulatory molecules.

**Results:** We identified numerous differentially expressed/phosphorylated proteins, finding that dysregulation was greater at P40, consistent with the prior neural transcriptome data. We found the affected biological pathways were largely related to PTEN function, neurological processes, or neuroinflammation. Although we found minimal overlap among differentially expressed transcriptome-proteome-phosphoproteome molecules between P14 and P40 brains (never more than 35%), there was congruence amongst the affected pathways. Importantly, network analysis identified Pten and Psd-95 (encoded by *Dlg4*) as predominant regulatory nodes in the proteome and phosphoproteome, respectively. Moreover, we found overlap between our differentially expressed/phosphorylated proteins and known ASD risk genes.

**Conclusions:** Differential expression/phosphorylation revealed by transcriptome-proteome/phosphoproteome analyses of a germline *Pten* mutation model point to ASD risk genes like *Pten* and *Dlg4* as major hubs in the protein networks, highlighting their important regulatory influence. Our observations here suggest Pten and Psd-95, known interactors in biological networks in the brain, are critical to either initiation or maintenance of cellular and perhaps organismal phenotypes related to ASD. Future research should explore rescuing Pten and Psd-95 function in attempts to ameliorate neurological pathologies and behavioral abnormalities.

## POSTER SESSION — NEUROCHEMISTRY

### Poster 433 - Neurochemistry Posters

**433.001** (Poster) Neuronal Damage Associated NAA-Naag Metabolism Imbalance and Socio-Communicative Impairments Correlation in ASD.

*C. D. Jimenez-Espinoza, Physiology, University of La Laguna, Santa Cruz de Tenerife, Spain*

**Background:** Autism Spectrum Disorder (ASD) is a neurodevelopment disorder characterized by socio-communicative impairments as one of the core symptoms. Autistic symptoms may be seen in the first year of life, they vary in severity from mild to severe, and in a few instances, they may improve over time, even without treatment. The neuropeptide N-acetyl-aspartyl-glutamate (NAAG) modulates glutamate release which has been proposed as a key mechanism underlying symptoms of ASD. NAAG provides one of the components of the proton magnetic resonance spectrum ( $^1\text{H-MRS}$ ) in humans. The signal of NAAG, however, largely overlaps with its precursor and degrading product N-acetyl aspartate (NAA) that by itself does not act in glutamatergic neurotransmission. Previously, we described the altered N-Acetyl-aspartyl-glutamate levels found in cingulated cortices by  $^1\text{H-MRS}$  in individuals with ASD that suggested neuronal damage. Taken together, the findings of this study support our hypothesis and a role for NAA-NAAG imbalance and impairments in the Social-communication skills in autism, which lead the next step in our investigation to correlate imbalances neurochemistry linked to cingulated cortices in social and communicational skills in the autism spectrum disorders.

**Objectives:** To study imbalance of NAA-NAAG metabolism in the cingulated cortices correlated with the AQ domains social skills and communication associated with ASD severity using  $^1\text{H-MRS}$ .

**Methods:** We quantified NAAG and NAA separately from the  $^1\text{H-MRS}$  signal in 22 patients with ASD and 44 healthy comparison subjects, matched for age, gender on a 3.0 Tesla MR scanner. Autism quotients (AQ) scores were assessed. Statistic one-way ANOVA and Bonferroni correction was applied. Furthermore, the Pearson correlation hallmarks the goal.

**Results:** The results of the Pearson correlation were represented graphically, where it was observed that there is no correlation between the Socio-communicative skills and the NAA/NAAG ratio in the ACC ( $r = -0.43$ ,  $P = .005$ ) in ASD group (Fig.1). However, when was stratified ASD plus TD groups as AQ1, AQ2, AQ3, and AQ4, there was within groups differences (AQ1, AQ2, AQ3, and AQ4) of NAA/NAAG, was increased significantly ( $P = .05$ ) in AQ3 (Fig. 2). There was no ASD group difference of NAAG, NAA, or NAA/NAAG in the PCC, but a positive linear correlation with communication ( $r = .55$ ,  $P = .049$ ). In addition, in both ACC and PCC, the AQ2, AQ3, and AQ4 groups maintain a different correlations pattern than the AQ1 group, both in social skills and communication. These results make us suggest the relation of the deficit socio-communicational with the enlarged relative grey matter volumes (rGMV) of auditory network in ASD adults; in accordance with that described by (Watanabe & Rees, 2016); who demonstrated the relation of the deficits associated with the severity of autistic socio-communicational core symptom.

**Conclusions:** We conclude that the concentrations of NAAG and NAA act differently in ASD. The opportunity to measure NAAG in patients creates a new and promising approach for intensified research on the glutamatergic systems and on the effects of novel drug candidates.

## PANEL SESSION — NEUROIMAGING

### Panel 219 - Etiologies of Atypical Prenatal Development in Autism Spectrum Disorder and Implications for Early Treatment

**Panel Chair: Yehezkel Ben-Ari, Neurochlore, Marseille, France**

Autism Spectrum Disorders (ASD) are “born” in utero by environmental and genetic pathogenic events. The link between initial pathogenic insults and the clinical manifestations years later is complex as it takes place in a particularly dynamic process with all ionic currents and molecular processes engaged in profound modifications. Indeed, initial pathogenic insults impacts brain development and growth, alters developmental sequences leading to misplaced/misconnected neuronal circuits and miswired connectivity that both perturb the operation of behaviorally relevant oscillations and prevent the interactions needed to develop social interactions in the first postnatal years. These changes are therefore the direct cause of the disorder and a possible target of treatments using agents that selectively block these alterations. A multidisciplinary approach devoted to determine these changes during pregnancy, birth and early post-natal life is therefore mandatory. Physiological, molecular, genetic and immunological features have to be determined as initial insults impact all of these parameters. Therefore, to understand and treat ASD and other neurodevelopmental disorders, a dynamic and distinctive look on development is needed. This panel will bring a fresh and novel developmental view on the origin, impact and treatment of ASD.

**219.001 (Panel) ASD Living Biology: The “When, What and How” of ASD Prenatal Beginnings**  
**E. Courchesne, University of California San Diego, San Diego, CA**

Background: ASD genetic studies identify hundreds of ASD risk (rASD) genes contributing to its high heritability. The conundrum is that the majority of rASD genes are involved in different biological processes, expressed in many non-brain tissues, and some have unclear relevance and connection to neurodevelopment. Because ASD begins in the womb, the “when, what and how” of ASD beginnings remains unclear.

Objectives: Identify the when, what and how of ASD prenatal beginnings; test the hypothesis that ASD is a multistage, progressive disorder of prenatal development; and address a key question of how hundreds of diverse rASD genes dysregulate common gene networks leading to ASD.

Methods: Re-analyses of multiple studies of idiopathic ASD and rASD genes; novel analyses of co-expression in large samples of idiopathic ASD; and novel analyses of 193 SFARI ASD risk genes in the context of regulatory and brain-specific gene networks using multiple datasets.

Results:

First, using GTEx data, we found 193 SFARI rASD genes fall into two major groups: broadly-expressed regulatory genes and brain-specific ones. Analyses find both major groups occur in early Epoch-1 and later Epoch-2 prenatal periods. Thus, broadly-expressed and brain-specific rASD genes operate in combination in each Epoch, a finding at odds with three previous studies. Re-analyzing those studies, we demonstrate broadly-expressed and brain-specific rASD genes do indeed express during both Epoch-1 and Epoch-2. In Epoch-1, one set of regulatory broadly-expressed and brain-specific rASD genes disrupts corticogenesis. In Epoch-2, a different set disrupts late fetal and postnatal synaptogenesis and wiring of cortex.

Second, we show broadly-expressed genes in living ASD toddlers are associated with hypoactive brain responses to language; poor language outcomes; published ASD and language relevant and prenatal genes; and patterns of cortical surface area and cortical thickness. These cortex function- and structure-relevant genes are enriched in prenatal cell types including neural-progenitor cells, immature excitatory cells and microglia.

Third, we developed a novel systems-level approach linking ASD genetics with perturbed gene expression in living ASD toddlers, and demonstrated rASD genes are upstream regulators of PI3K/AKT, RAS/ERK, and WNT/B-catenin signaling pathways in ASD toddlers and converge on these pathways through chromatin remodelers, transcriptional factors, and ubiquitination and protease complexes. These disrupted networks in living ASD toddlers enrich Epoch-1 prenatal-stage, and the degree of dysregulation correlates with ASD social symptom severity.

Lastly, we linked these two rASD gene groups with neurodevelopmental processes by leveraging multiple transcriptomic datasets. Systems-level analyses show ASD genetic architecture is hierarchical with broadly-expressed rASD genes converging upon brain-specific genes and multiple neurodevelopmental processes through regulatory networks and signaling pathways, disrupting multiple prenatal stages from proliferation through synaptogenesis.

Conclusions: Broadly-expressed and brain-specific rASD genes form separate networks, but are connected through intermediate genes and signaling pathways including RAS/ERK, PI3K/AKT, and WNT/B-catenin. We call this unified hierarchical architecture the ASD “SPHeRe” model (Sequential, Prenatal, Hierarchical, and Regulatory). Upstream broadly-expressed genes send disrupting signals through regulatory networks and signaling pathways that in turn disrupt downstream brain-specific genes and core neurodevelopmental processes, which cause ASD. Broadly-expressed rASD genes impact multiple organ development including brain.

**219.002 (Panel)** Harnessing the Power of Advanced Fetal MRI to Understanding the Prenatal Origins of ASD  
**C. Limperopoulos, Radiology, Neurology, Pediatrics, Children’s National Health System, Washington, DC**

---

Background: There is a growing body of evidence showing that neuropsychiatric disorders including ASD are increasingly finding their footprints in the womb. Novel quantitative fetal MRI tools are advancing our understanding of the prenatal origins of these prevalent and pervasive disorders.

Objectives: Characterize normal in-vivo human fetal brain growth, cortical folding and biochemistry using quantitative prenatal MRI; Examine the role of prenatal maternal stress and premature birth on disrupted fetal brain development; Investigate the relationship between altered prenatal brain development and early features of ASD.

Methods: We prospectively enrolled healthy and high-risk pregnant women into a longitudinal observational study of fetal brain development using quantitative fetal and postnatal MRI brain studies and standardized neurodevelopmental assessments. Fetal brain MRI: performed at 2 time points between 24-40 weeks' gestation. We also enrolled a cohort of ex-utero very preterm infants (<32 weeks gestational; <1500 grams): MRI between 24-40 weeks postconceptional age. Brain/structures volume: calculated from 3-dimensional reconstructed T2-weighted MRI scans. Cortical folding measurements: local gyrification index, sulcal depth, curvedness. Prenatal maternal stress, anxiety, and depression: Perceived Stress Scale, Spielberger State-Trait Anxiety Inventory, Edinburgh Postnatal Depression Scale. The Bayley of Infant and Toddler Development III, the Infant-Toddler Social and Emotional Assessment and the Modified Checklist for Autism in Toddlers: administered at 18 months. Premature cohort also completed: Communication and Symbolic Behavior Scales (CSBS).

Results:

In-utero cohort: We enrolled 325 pregnant women, for which 147 mother/baby dyads (70 male and 77 female fetuses) with 238 fetal MRI visits have undergone infant neurodevelopment testing to date (mean age of 19.67±4.50 months). Elevated prenatal maternal stress, anxiety, and depression scores were negatively associated with infant cognitive, motor, and social-emotional performance and early autistic features. Fetal cortical grey matter volume was negatively associated with infant internalizing and dysregulation domains; fetal brainstem volume was negatively associated with infant language skills. Regional fetal cortical LGI and sulcal depth were negatively associated with infant social-emotional performance; externalizing, dysregulation, and competence domains, and cortical curvedness in frontal lobe was positively associated with infant internalizing domain.

Ex-utero (preterm) cohort: We enrolled 142 infants (81 males, 51 females): early preterm MRI (mean gestational age of 29.1 weeks), term-equivalent MRI (mean of 39.3 weeks), no evidence of parenchymal brain injury. 95 infants have completed 18-month neurodevelopmental evaluations. 39% of preterm infants tested positive on the CSBS. Lower cerebellar volumes at preterm and term were associated with increased risk for elevated scores on the CSBS, infant social emotional problems, cognitive delays. Cortical gray matter volumes at term were negatively associated with cognitive and language performance, as well as externalizing and domains.

Conclusions: Our data suggest that elevated prenatal maternal psychological distress is associated with impaired regional fetal brain growth and long-term risk for socio-affective behavioral deficits. Similarly, early extrauterine exposure following preterm birth is associated with altered third trimester brain growth and an elevated risk for cognitive impairments and autistic features. Elucidating the exact timing and underlying mechanisms of ASD will require novel, non-invasive approaches to study the emerging structural and functional brain development of the fetus.

**219.003 (Panel)** Maternal Autoantibodies As a Pathway to ASD  
**J. Van de Water, MIND Institute, University of California, Davis, Davis, CA**

---

**Background:** The incidence of autism spectrum disorder (ASD) has been rising, however ASD-risk biomarkers remain lacking. We previously identified the presence of maternal autoantibodies to fetal brain proteins specific to ASD, now termed maternal autoantibody-related (MAR) ASD.

**Objectives:** The current study aimed to create and validate a serological assay to identify ASD-specific maternal autoantibody patterns of reactivity against 8 previously identified proteins (CRMP1, CRMP2, GDA, NSE, LDHA, LDHB, STIP1 and YBOX) that are highly expressed in the developing brain and determine the relationship of these reactivity patterns with ASD outcome severity.

**Methods:** We used plasma from mothers of children diagnosed with ASD (n=450) and from typically developing children (TD, n=342) to develop an ELISA test for each of the protein antigens.

**Results:** We determined patterns of reactivity a highly significant association with ASD and discovered several patterns that were ASD-specific (18% in the training set and 10% in the validation set vs 0% TD). The three main patterns associated with MAR ASD are CRMP1 + GDA (ASD%= 4.2 vs TD%=0, OR 31.04,  $p < 0.0001$ ), CRMP1+ CRMP2 (ASD%= 3.6 vs TD%=0, OR 26.08,  $p = 0.0005$ ) and NSE + STIP1 (ASD%= 3.1 vs TD%=0, OR 22.82,  $p = 0.0001$ ). Additionally, we found that maternal autoantibody reactivity to CRMP1 significantly increases the odds of a child having a higher ADOS severity score (OR 2.3; 95% CI: 1.358- 3.987,  $p = 0.0021$ ).

**Conclusions:** We used machine learning sub-group discovery to identify with 100% accuracy MAR ASD-specific patterns as potential biomarkers of risk for a subset of nearly 20% of ASD cases. Further, maternal autoantibodies to the CRMP1 biomarker increases ASD severity suggesting potential differential mechanisms of pathogenicity based on the pattern of autoantibodies present.

**219.004 (Panel) Early Prognosis of ASD through Machine Learning Analysis of Pregnancy and Birth Data**  
*Y. Ben-Ari, Neurochlore, Marseille, France*

---

**Background:** Clinical and experimental observations suggest that ASD is generated in the womb. The incidence of ASD is also increased by C-Section delivery, obstetric complications and preterm birth.

**Objectives:** To identify newborns at risk of developing ASD and identify impacting parameters in order to facilitate early behavioral treatment, known to ameliorate ASD deficits and attenuate long-term outcomes.

**Methods:** We compared retrospectively without a priori maternity parameters in babies diagnosed 4-5 years later with ASD (63) and age-matched neurotypical (NT) babies born in the same maternity and similar conditions (189). For each mother and baby at birth, 116 parameters were recorded: 77 numerical (ultrasound measurements, etc.) and 39 categorical (sex, familial medical history, etc.). A supervised machine learning algorithm was trained to classify babies in two groups, ASD and NT, using a model based on the gradient boosting decision tree algorithm. A cross-validation technique was used to ensure the generalizability of the classifier's results on an unseen independent cohort. Parameters with the highest impact on the classifier were extracted. The difference in the distribution of the 116 parameters between NT and ASD groups were investigated by statistical tests. Covariance analysis was used to model fetal brain developmental trajectories and head circumference (HC) obtained from ultrasound acquisitions during the 2nd (T2) and 3rd (T3) trimesters and before birth.

**Results:** Classifier. We trained a classifier on our dataset aiming to minimize false ASD detections while keeping true ASD detection rate as high as possible. The proportion of NT babies correctly classified as NT was of 0.96 (95% CI = [0.95, 0.97]). The proportion of babies with ASD correctly classified in the ASD group was of 0.41 (95% CI = [0.37, 0.45]) but with a positive predictive value of 0.77 (95%CI = [0.72, 0.81]), meaning that 77% of babies classified as ASD were indeed diagnosed later with ASD.

Impactful Parameters: Timing of fetal rotation on head, femur length in T3, sex, mother's white blood cell count in T3, and the type of feeding of newborns have the highest impact on the classifier's decisions.

Significant Parameters. Sex ( $p < 0.001$ ), newborn's temperature difference between birth and day 1 ( $p < 0.001$ ), results of CMV test ( $p < 0.001$ ), fetal heart rate during labor ( $p = 0.001$ ) and IgG level ( $p < 0.001$ ) are significantly different between ASD and NT groups.

**Head circumference (HC) growth.** The HC growth rate is significantly different between NT and ASD during the 2nd trimester ( $p=0.046$ ). A subpopulation of ASD fetuses (38%) had significantly larger HC in T2 ( $p=0.02$ ), T3 ( $p<0.001$ ) and before birth ( $p<0.001$ ) in comparison to NT and other ASD ones.

**Conclusions:** Our results suggest that it might be possible to establish a prognosis at birth of a subpopulation of babies who will develop ASD. Further replications are needed to optimize the analysis and better specify impacting parameters. Results suggest an in utero origin of the reported bigger brains of children and adolescents with ASD (Caly et al. Sci.Rep. in press).

## POSTER SESSION — NEUROIMAGING

### Poster 434 - Neuroimaging Posters

**434.001 (Poster)** A Connectome-Wide Mega-Analysis of Functional Dysconnectivity in Autism Spectrum Disorder  
**I. Ilioska<sup>1,2</sup>, M. Oldehinkel<sup>1</sup>, A. Llera<sup>3</sup>, M. Mennes<sup>1</sup>, C. Beckmann<sup>3,4</sup>, A. Fornito<sup>2</sup> and J. K. Buitelaar<sup>3,5</sup>,** (1)Department of Cognitive Neuroscience, Donders Institute for Brain, Cognition and Behaviour, Nijmegen, Netherlands, (2)Turner Institute for Brain and Mental Health, School of Psychological Sciences, and Monash Biomedical Imaging, Monash University, Melbourne, VIC, Australia, (3)Department of Cognitive Neuroscience, Donders Institute for Brain, Cognition and Behaviour, Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands, (4)Centre for Functional MRI of the Brain (FMRIB), University of Oxford, Oxford, United Kingdom, (5)Karakter Child and Adolescent Psychiatry University Center, Nijmegen, Netherlands

**Background:** Autism spectrum disorder (ASD) has been conceptualized as a disorder of brain connectivity. However, neuroimaging research studies have been hampered by small sample sizes and inconsistent findings with regard to whether connectivity is increased or decreased in patients, whether these alterations affect focal systems or reflect a brain-wide dysfunction, and whether these disturbances are age- and/or sex-dependent.

**Objectives:** To use a connectome-wide mega-analytic approach aggregating data from three large autism cohorts to map functional dysconnectivity across the entire brain in ASD patients and to relate these connectivity disturbances to distinct dimensions of clinical symptomatology.

**Methods:** Following preprocessing, denoising, and application of stringent quality control criteria, our final sample consisted of 1824 (1427 male) participants, including 796 individuals diagnosed with ASD and 1028 neurotypical controls aged 5-64 years old with  $IQ>70$ . Functional images were parcellated into 390 brain regions, assigned to 7 canonical brain functional networks and subcortical structures. Functional connectivity (FC) between each pair of nodes (i.e., brain regions) was measured using the Pearson correlation coefficient between regional time courses. Fisher z-transformation and mixture modeling were applied to normalize these values. We used ComBat to harmonize the data for the effect of scanning site. Group differences between ASD and TD were evaluated on a connectome-wide basis using the network-based statistic. Differences in both directions (ASD>TD and vice versa) as well as interactions of diagnosis with age and sex were evaluated at  $p = \{.05, .01 \text{ and } .001\}$  component-forming thresholds. Head motion was controlled for in a multiple linear regression model.

**Results:** Autism patients showed complex, widely distributed alterations of FC that encompassed the entire brain and which reflected both increased and decreased inter-regional coupling. Functional hypoconnectivity predominantly affected sensory and higher-order attentional networks and was strongly associated with both social impairments and restrictive and repetitive behaviors in autism. Functional hyperconnectivity was observed primarily in cortico-subcortical systems and between the default mode network (DMN) and the rest of the brain, and this pattern was strongly associated with social impairments. All subscales of the short sensory profile were strongly associated with both hyperconnectivity and hypoconnectivity. Interactions between diagnosis and age or sex were not significant.

**Conclusions:** Autism is associated with a complex pattern of both hypo and hyperconnectivity that encompasses the entire brain. These widespread connectivity alterations correlate with clinical dimensions related to sensory processing, social impairment and restricted, repetitive behaviors, and do not appear to vary significantly as a function of age and sex.

**434.002 (Poster)** Altered Cerebellar White Matter in Sensory Processing Dysfunction Is Associated with Impaired Multisensory Integration and Attention

**M. A. Rowe<sup>1,2</sup>, A. Narayan<sup>1,3</sup>, E. M. Palacios<sup>1</sup>, J. Wren-Jarvis<sup>1</sup>, I. Bourla<sup>1</sup>, S. Desai<sup>1</sup>, E. J. Marco<sup>2</sup> and P. Mukherjee<sup>1,2</sup>,** (1)Department of Radiology and Biomedical Imaging, University of California, San Francisco, San Francisco, CA, (2)Neurodevelopmental Medicine, Cortica Healthcare, San Rafael, CA, (3)Department of Medicine, Tulane University School of

**Background:** Sensory processing dysfunction (SPD) consists of behaviorally-observed differences in response to incoming sensory information. SPD is estimated to affect up to 16% of all children and 40-80% of children with other neurodevelopmental disorders, such as autism spectrum disorder (ASD) or attention deficit hyperactivity disorder (ADHD). While SPD is not recognized as a standalone disorder, the DSM-V includes sensory hyper- and hypo-responsivity as core symptoms of ASD.

**Objectives:** We compare cerebellar white matter (WM) microstructure between children with SPD and typically developing controls (TDC). Furthermore, we examine the relationship between cerebellar WM microstructure and behavioral measures of sensory processing.

**Methods:** Forty-two children (8-12 years) with SPD (29 male) and 39 TDC (31 male) were enrolled through the University of California, San Francisco. SPD designation required a "Definite Difference" label for at least one of the following subtotals of the Sensory Profile (SP): Auditory Processing, Visual Processing, Vestibular Processing, Tactile Processing, Multisensory Processing, Oral Sensory Processing, or Short Sensory Profile total. Participants also completed the Differential Screening Test for Processing (DSTP), a direct measure of auditory discrimination. Whole-brain DTI scans were obtained using a 3-Tesla MRI scanner. Five WM tracts were examined: the left and right cerebral peduncles (CP-L and -R), middle cerebellar peduncle (MCP), and left and right superior cerebellar peduncles (SCP-L and -R). For each tract, the following values were generated using the FMRIB Software Library: fractional anisotropy (FA), mean diffusivity (MD), radial diffusivity (RD), and axial diffusivity (AD). Two-tailed *t*-tests ( $\alpha = 0.05$ ) were run to investigate group differences in DTI metrics, and Pearson correlations were used to examine relationships between DTI metrics and behavioral measures.

**Results:** Compared to TDC, the SPD group showed impaired microstructure: low FA, high MD, and high RD in the SCP-R ( $p = 0.0499, 0.004, 0.004$ ), high MD and RD in the MCP ( $p = 0.03, 0.03$ ), and low FA and high RD in the CP-R ( $p = 0.03, 0.03$ ; *Figure 1*). Significant, moderate correlations were found between WM microstructure and DSTP Acoustic, Acoustic-Linguistic, and Total scores in the CP-L and -R (*Table 1*). SP Auditory Processing subtotal significantly correlated with microstructure in all tracts examined. SP Tactile Processing subtotal significantly correlated with microstructure in the CP-L. SP Multisensory Processing subtotal significantly correlated with microstructure in the SCP-L and -R. SP Inattention subtotal significantly correlated with microstructure in the SCP-L, -R and MCP. Overall, correlations were significant for the SPD group but not TDC.

**Conclusions:** Results suggest children with SPD have altered cerebellar WM microstructure relative to TDC. Correlations suggest a dissociation between WM microstructure in the cerebrum versus the cerebellum, where cerebellar tracts are associated with measures of higher-order functions (e.g. attention and multisensory processing) more than with unimodal or direct sensory measures (e.g. SP Tactile or DSTP). The SP Auditory subtotal correlates with microstructure in all tracts, which can potentially be explained by the SP Auditory subtotal including aspects of both auditory processing and attention. These findings may help elucidate the role of the cerebellum in normal and altered sensory processing.

**434.003 (Poster)** Altered Patterns of Brain Dynamics Linked with Body Mass Index in Youth with Autism  
*L. Kupis<sup>1</sup>, Z. T. Goodman<sup>2</sup>, L. Kircher<sup>2</sup>, C. Romero<sup>1</sup>, B. Dirks<sup>1</sup>, C. Chang<sup>3</sup>, J. S. Nomi<sup>1</sup> and L. ---

Background:

Children with autism spectrum disorder (ASD) are more likely to be overweight and obese (OWOB) compared with typically developing (TD) children (Kahathuduwa, West, Blume, et al., 2019). Functional brain differences have also been shown in both ASD (Hull et al., 2018) and OWOB children (Moreno-Lopez et al., 2016). However, only one study has examined brain differences in children with ASD and OWOB concurrently (Kahathuduwa, West, & Mastergeorge, 2019) so little is known regarding the neural mechanisms associated with OWOB in ASD and its associated behavioral impacts.

Objectives:

To identify dynamic brain activation patterns underlying OWOB in children with ASD compared with TD children and characterize their relationships with assessments of behavior.

Methods:

Using a large resting-state fMRI dataset from the Autism Brain Imaging Data Exchange (ABIDE), we investigated co-activation patterns (CAPs) of brain nodes identified by independent component analysis in 129 children and adolescents between 6 and 18 years of age ( $n = 68$  ASD; Mean age = 10.69; Mean BMI = 19.51 kg/m<sup>2</sup>). Inclusion criteria were clinician's DSM-IV-TR or DSM-5 diagnosis of ASD for ASD participants, mean framewise displacement (FD) < 0.5 mm, and body mass index (BMI) for age and sex above the 5th percentile (healthy weight, overweight, and obese). Group independent component analysis (ICA) was used to parcellate the brain (**Figure 1**). Following ICA,  $k$ -means clustering was used to identify the recurring CAPs or brain states (**Figure 1**). Dynamic brain state metrics were calculated, including dwell time (DT), frequency of occurrence, and transitions. Data were analyzed using hierarchical multiple regression models. The first model used BMI and diagnosis to predict each dynamic brain metric for the 5 CAPs. The second model included the interaction term between BMI and diagnosis as a predictor. Covariates included age, sex, mean FD, and Full IQ. Scores from the Behavior Rating Inventory of Executive Function (BRIEF) and Social Communication Questionnaire (SCQ) were used as dimensional predictors to examine how behavior moderates the relationship between BMI and CAP metrics.

#### Results:

A BMI x diagnosis interaction showed that children with ASD had a positive relationship with the frequency of CAP 4 (characterized by co-activation of lateral frontoparietal, temporal, and frontal networks), while TD children had a negative relationship with the frequency of CAP 4 on the basis of BMI. Dimensionally, this pattern was negatively associated with inhibition skills. Children with ASD had shorter CAP 1 (characterized by co-activation of the subcortical, temporal, sensorimotor, and frontal networks) and CAP 4 DTs compared with TD children. CAP 1 DT was negatively associated with cognitive flexibility, inhibition, social functioning, and BMI. Cognitive flexibility additionally moderated the relationship between BMI and brain dynamics in CAP 2 (visual network) (**Figure 2**).

#### Conclusions:

Our findings provide novel evidence of neural mechanisms associated with OWOB in children with ASD, and suggests children with ASD may have different neural mechanisms associated with OWOB compared with TD children. Further, children with ASD may be more vulnerable to the moderating effects of cognitive inflexibility on the relationship between brain flexibility and co-occurring OWOB.

#### 434.004 (Poster) Amygdala Connectivity As a Marker for Social Functioning in Autism Spectrum Disorder

**Background:** Autism Spectrum Disorder (ASD) is a highly heritable disorder with a complex polygenic architecture<sup>1</sup>. Polygenic scores for ASD (PS-ASD) measure the cumulative effect of common genetic variants nominally associated to ASD, providing the opportunity to investigate neuroimaging markers influenced by genetic predisposition to ASD. Previous neuroimaging studies have linked social symptoms of ASD to structural and functional alterations of the amygdala, a composite subcortical structure with different connectivity pathways subserving different aspects of social functioning<sup>2,3</sup>. However, our understanding of which amygdala pathways may be altered in ASD is still very limited<sup>4</sup>.

**Objectives:** This study aims to investigate alterations in amygdala functional connections as a potential intermediate phenotype for ASD, and more specifically, a biomarker for social functioning.

**Methods:** PS- ASD were computed on 343 ASD cases and 241 typically developed (TD) controls from the EU-AIMS Longitudinal European Autism Project (LEAP<sup>5</sup>). We used resting-state functional magnetic resonance imaging data on a subsample of 380 individuals between 7 and 30 years of age (211 ASD cases) to define parcels of amygdala based on its functional connectivity within three large-scale networks subserving distinct aspects of social functioning<sup>3</sup>. Thus, we obtained three parcels defined by maximal connectivity with lateral orbitofrontal cortex (IOFC: AOF), with ventromedial prefrontal cortex

(vmPFC: APF), or with caudal anterior cingulate cortex (cACC: AAC). We used regression models to test the associations between PS-ASD and parcel volumes, and between parcel volumes and Vineland scores of adaptive functioning in the socialisation domain. We included as covariates: age, sex, intelligence quotient (IQ), diagnostic group, total brain volume, site of data acquisition, levels of comorbid ADHD traits and the first four principal components of genetic ancestry.

**Results:** We found a significant association between volumes of APF ( $b=-0.13$ ,  $t(363)=-4.44$ ,  $p<0.001$ ; Figure 1.A) and AAC ( $b=0.07$ ,  $t(363)=2.50$ ,  $p=0.013$ ; Figure 1.B) and levels of adaptive social functioning. There was no main effect of PS-ASD on parcel volumes, but we found a significant interaction effect between PS-ASD and ADHD traits ( $t(363)=2.32$ ,  $p=0.02$ ) on AAC volume. Higher PS-ASD was linked to larger AAC volume in individuals with high levels of ADHD traits ( $b=0.21$ ,  $p=0.01$ ; Figure 2). Finally, PS-ASD was significantly associated to measures of adaptive social functioning ( $b=-0.02$ ,  $p<0.001$ ), and significance of both PS-ASD and AAC volumes on social scores was retained in the full model.

**Conclusions:** We found that reduced amygdala connectivity with the prefrontal cortex, and increased connectivity with the anterior cingulate cortex were associated with better adaptive social functioning. Furthermore, we found preliminary evidence for a possible role of dorsal amygdala connectivity as mediator between cumulative effects of common genetic variants associated with ASD and adaptive social functioning, at least in individuals with high levels of ADHD traits. Our results support previous findings on alterations of frontal-amygdala connectivity in ASD and the role in generating appropriate adaptive social behaviour<sup>4,6</sup>, and extend these findings to amygdala connections with the anterior cingulate cortex. Further work is needed to investigate how ADHD comorbidity interplays with the cumulative genetic load for ASD to modulate its association with amygdala connectivity.

**434.005 (Poster)** Amygdala-Rostral Anterior Cingulate Cortex Connectivity Changes in Children and Young People with ASD Receiving AB-2004

**G. M. Preston<sup>1</sup>**, C. S. Meyer<sup>1</sup>, A. C. Janes<sup>2</sup>, B. Federick<sup>2</sup>, M. P. Daly<sup>2</sup>, C. Larkin<sup>2</sup>, H. Heussler<sup>2</sup>, R. Griffith<sup>4</sup>, A. J. Guastella<sup>5</sup> and S. Campbell<sup>1</sup>, (1)Axial Therapeutics, Inc., Waltham, MA, (2)Department of Psychiatry, Harvard Medical School & McLean Hospital, Belmont, MA, (3)Centre for Clinical Trials in Rare Neurodevelopmental Disorders, Queensland Children's Hospital, Brisbane, QLD, Australia, (4)Optimal Clinical Trials, Auckland, New Zealand, (5)Brain and Mind Centre, Children's Hospital Westmead Clinical School, Faculty of Medicine and Health, University of Sydney, Sydney, NSW, Australia

Background: Functional magnetic resonance imaging (fMRI) studies have provided biological evidence that individuals with autism spectrum disorder (ASD) have altered connectivity, linking aberrant brain region connectivity patterns to behaviors. AB-2004 is an investigational compound in development that binds a certain class of microbial metabolites in the lumen of the gastrointestinal tract, and is expected to result in reduced levels of these and related metabolites in the blood and the brain. Preclinical studies suggest these metabolites of microbial origin may impact oligodendrocyte maturation and myelination capacity, leading to the possibility that AB-2004 treatment may result in improvements in functional connectivity in the brain coinciding with improvements in ASD-related behaviors.

Objectives: Measure changes in resting connectivity by fMRI at baseline and after 8 weeks of treatment with AB-2004 in ASD participants with gastrointestinal dysfunction enrolled in the AXL-1224-2004-001 clinical trial.

Methods: MRI sessions were designed to collect data for anatomical registration (T1), resting fMRI, myelin maps (T1/T2), and structural connectivity (DTI). Resting state fMRI scans (two 5 -minute sessions with alternating phase encode directions) were performed without any external stimuli to detect functional connectivity between brain regions. Of the ten participants enrolled in this sub-study, reliable baseline and end-of-treatment data were obtained from eight participants. Areas of interest included the amygdala, which is essential for emotions and fear responses, and the rostral anterior cingulate cortex (rACC), involved in emotion assessment, including empathy, impulse control, emotion, and decision making, all of which are affected to varying degrees in people with ASD.

Results: Significant reductions were detected in coupling strength between the bilateral amygdala and the rACC when comparing baseline (mean  $r$ -value = 0.45) and end of treatment values (mean  $r$ -value = 0.37; Pearson corrected paired  $t$ -test  $p$  = 0.048). Six of the eight participants (75%) showed post-treatment decreases in connectivity. There was no apparent impact of age on amygdala-rACC connectivity. Potential relationships between these observed changes in functional connectivity and anxiety were identified. There was a trend toward significance between reduced post-treatment anxiety (assessed by the Pediatric Anxiety Rating Scale (PARS) at baseline relative to end of treatment) and reductions in coupling ( $n=6$ , Pearson  $r$  = 0.75,  $p$  = 0.087; 2 subjects without end-of-treatment PARS were excluded).

Conclusions: These data provide preliminary evidence that AB-2004 treatment may lead to changes in functional connectivity in brain regions associated with emotional processing in ASD subjects, and serve as an hypothesis-generating dataset to support

further evaluation of MRI as a potential biomarker linking drug activity with changes in behavior. A larger placebo-controlled clinical study is being planned.

---

**Background:** Anxiety is commonly experienced by autistic individuals, but is challenging to quantify and disentangle from core autistic symptoms. For example, a recent study estimated 17% of children with autism have clinically significant anxiety related to distinct aspects of autism that would not be captured by traditional anxiety assessments. Within the brain, the amygdala has been associated with both autism and anxiety. However, the relationship between early development of amygdala structure and later observed anxiety within autistic individuals, particularly possible differences between traditional and autism distinct anxieties, is unclear.

**Objectives:** Explore associations in autism between amygdala volume and development across early childhood with measures of comorbid anxiety, including anxiety domains distinct to autism spectrum disorder.

**Methods:** Structural MRI scans were acquired across four timepoints (mean study ages 3.18, 4.28, 5.35, 11.37 years) within a longitudinal sample consisting of 283 ASD (89 females) and 133 TD (60 females) participants, for a total of 953 timepoints. Left and right amygdala volumes were extracted for all participants. At study time 4, anxiety was assessed in 70 ASD (14 females) participants using the Anxiety Disorders Interview Schedule-IV-Parent Interview (ADIS) with the Autism Spectrum Addendum (ADIS-ASA). The ADIS assesses traditional DSM anxiety domains (OCD, separation, social, specific phobia, generalized anxiety disorders) while the ADIS-ASA measures additional forms of anxiety distinctly related to autism (idiosyncratic fears, fear relating to social confusion, special interest fears, fears of change, atypical OCD). Individual measures of traditional and distinct anxiety were computed by taking the highest score among the subdomains comprising the ADIS and ADIS-ASA. Linear mixed effects models were first used to estimate annualized percent change (annual growth) in amygdala volumes from study time 1 to 3. Subsequent linear effects models tested for associations with both traditional DSM and distinct autism related anxieties assessed in mid/late childhood (study time 4) with baseline (study time 1) amygdala volume, concurrent amygdala volume (study time 4), and amygdala annualized percent change (study time 1-3).

**Results:** Statistically significant (FDR corrected  $p < 0.05$ ) associations of left and right amygdala volumes at both study time 1, and study time 4 were found with ADIS-ASA measures of distinct autism related anxieties. Smaller amygdala volumes at both timepoints were associated with increased ADIS-ASA anxiety scores. No such associations were observed with traditional ADIS measures of anxiety. However, right amygdala annualized percent change scores were found to be significantly associated with this measure. Faster amygdala growth was associated with increased traditional ADIS anxiety scores. A trend relationship between right amygdala annualized percent change and ADIS-ASA anxiety scores did not reach statistical significance.

**Conclusions:** Significant associations between anxiety and amygdala volume in autism indicate that early life brain measures may be predictive of anxiety levels in later childhood. Furthermore, associations with autism distinct anxieties but not traditional anxiety measures highlight possible unique neurophenotypes underlying different types of anxiety in autism. Further research is needed to identify how specific anxiety subdomains are reflected in the brain in autism.

**434.007 (Poster)** Atypical Cerebellar Activity during Sensory Stimulation in ASD Youth  
**M. E. Cakar<sup>1</sup>, K. K. Cummings<sup>2</sup>, N. J. Okada<sup>3</sup>, S. Y. Bookheimer<sup>2</sup>, M. Dapretto<sup>1</sup> and S. A. Green<sup>1</sup>,** (1)Interdepartmental Neuroscience Program, University of California, Los Angeles, Los Angeles, CA, (2)Semel Institute of Neuroscience and Human Behavior, University of California, Los Angeles, Los Angeles, CA, (3)Dept of Psychiatry and Biobehavioral Sciences, University of California, Los Angeles, Los Angeles, CA

---

### **Background:**

Sensory overresponsivity (SOR) is a debilitating sensory modulation impairment commonly experienced by individuals with autism spectrum disorder (ASD), characterized by an extreme negative response to sensory stimulation such as loud noises and scratchy fabric (Kientz and Dunn, 1997; Baranek et al., 2006; Klintwall et al., 2011). While SOR is often associated with poor social and adaptive behavior (Ben-Sasson et al., 2009; Schaaf et al., 2010), it has only recently begun receiving attention from ASD researchers and its neural mechanisms continue to be investigated (Green et al., 2015, 2016, 2019).

The cerebellum plays a key role in sensory-motor function, and prior research has shown structural, cellular and functional atypicalities in the ASD cerebellum (Rogers et al., 2013; Khan et al., 2015). Recent studies have found increased cerebellar resting-state functional connectivity with sensory-motor regions and linked atypical cerebellar connectivity to sensory symptoms in ASD (Khan et al., 2015; Oldehinkel et al., 2019). Despite the important role of the cerebellum in sensory-motor processing and cerebellar pathology in ASD, there is currently almost no research on the role of the cerebellum in SOR in ASD.

### Objectives:

To investigate differences in cerebellar activity in ASD compared to typically developing (TD) youth during aversive sensory (auditory and/or tactile) stimulation, and to determine whether these differences are associated with SOR severity.

### Methods:

We collected functional magnetic resonance imaging (fMRI) data to examine cerebellar activation in response to mildly aversive auditory, tactile and joint (auditory + tactile) stimuli in 19 high-functioning ASD (16M) and 19 TD (16M) participants. Participants were age- and IQ-matched (age range 9-17, mean age = 13.66). SOR severity was measured using a composite of parent-reported tactile/auditory subscales from the Short Sensory Profile and Sensory Over-Responsivity Inventory (Dunn, 1999; Schoen et al., 2008). Results were cluster corrected for multiple comparisons at  $p < 0.05$  and thresholded at  $z > 2.3$ .

### Results:

No significant cerebellar activation clusters were identified in the tactile condition in either group. In the auditory condition, the ASD group showed left cerebellar activation including the Left Crus I, Left Crus II, Left VIIb and Left VIIa regions (Figure 1A), but there was no significant within-group TD activation, or diagnostic group differences. In the joint condition (Figure 1B), only the ASD group showed bilateral activation of the cerebellum including bilateral Crus I, Crus II, lobule VIIb and lobule VIIa. Similar to our previous findings in the cerebral cortex (Green et al., 2015), these cerebellar regions showed significantly greater activation in the ASD compared to TD group in the joint condition. Further analyses will examine whether this greater cerebellar activation relates to SOR symptom severity within the ASD group.

### Conclusions:

While the cerebellum was active in the ASD group during auditory stimulation alone, it was hyper-activated in ASD compared to TD only during joint auditory and tactile stimulation. These results implicate abnormal cerebellar function in sensory processing atypicalities in ASD, especially when the brain is tasked with processing stimuli across multiple sensory modalities, as is the case in real-world situations.

**434.008 (Poster)** Atypical Development of Emotional Face Processing Networks in Autism Spectrum Disorder from Childhood through to Adulthood

*K. Safar<sup>1</sup>, M. M. Vandewouw<sup>2</sup> and M. J. Taylor<sup>3</sup>, (1)Diagnostic Imaging, Hospital for Sick Children, Toronto, ON, Canada, (2)Program in Neuroscience & Mental Health, The Hospital for Sick Children, Toronto, ON, Canada, (3)The Hospital for Sick Children, Toronto, ON, Canada*

Background: Impairments in social functioning are hallmarks of autism spectrum disorder (ASD), and atypical functional connectivity may underlie these difficulties. Patterns of both hyper- and hypo-connectivity have been reported in those with ASD compared to typically developing individuals, and it is hypothesized that these conflicting findings may be reconciled by accounting for developmental changes.

Objectives: Magnetoencephalography (MEG) was used to investigate age-related changes in whole-brain functional connectivity of eight emotion processing regions of interest (ROIs) during happy and angry face processing in children, adolescents and adults (6-39 years) with ASD (N=83) and age- and sex-matched controls (N=107).

Methods: Happy or angry faces and a scrambled pattern (target) were presented simultaneously while MEG was recorded. Participants indicated the location of the target (left or right) as rapidly as possible by a button press. Time-series for each emotion were derived from 90 cortical and subcortical sources of the AAL atlas using the LCMV beamformer. The phase difference derivative was used to assess phase synchronization of ongoing neural oscillations among sources. Main effects of age, group, emotion and their interactions on the connectivity between the 8 ROIs and the rest of the brain were assessed using Network Based Statistics.

Results: In ASD and controls, increased functional connectivity across age was found predominately in networks in the theta band to happy and angry faces (ASD Happy:  $p_{\text{corr}}=0.004$ ; ASD Angry:  $p_{\text{corr}}<0.002$ ; Controls Happy:  $p_{\text{corr}}<0.002$ ; Controls Angry:  $p_{\text{corr}}<0.002$ ).

We also observed, age-related group differences in functional connectivity in a gamma band network across emotions ( $p_{\text{corr}}=0.016$ ), indicating a disordinal age-related trajectory of functional connectivity to emotional faces. In ASD, age was negatively correlated with the network's connectivity strength ( $r=-0.395$ ,  $p=0.0002$ ), but positively correlated in controls ( $r=0.557$ ,  $p<0.0001$ ). The network contained connections involving the bilateral fusiform gyri (FG), amygdalae, right insula and left anterior cingulate (ACC), with several connections between inferior brain regions and orbital frontal cortices.

Lastly, we found emotion-specific age-related differences in connectivity between groups in the beta frequency band ( $p_{\text{corr}}=0.025$ ). In ASD, age was positively correlated with the network's connectivity strength to happy faces ( $r=0.276$ ,  $p=0.012$ ), while to angry faces, age was negatively correlated ( $r=-0.24$ ,  $p=0.029$ ). In contrast, in the control group age was negatively correlated with the network's connectivity strength to happy faces, ( $r=-0.312$ ,  $p=0.001$ ), while no significant correlation was found for angry faces ( $r=0.109$ ,  $p=0.265$ ). The network included connections involving the bilateral ACC, amygdalae, left FG and right insula, with the highest number of connections in the left ACC.

Conclusions: We observed age-related changes in MEG connectivity underpinning emotion processing in ASD and in typical controls, as well as age-related between-group differences across emotions. These findings establish altered frequency-specific developmental trajectories of functional connectivity in ASD, across distributed networks and a broad age range, which may finally explain the heterogeneity in the literature. Emotion-specific differences in functional connectivity with age between groups, suggest that even happy faces remain difficult to process in those with ASD.

#### **434.010** (Poster) Autism Diagnosis Prediction from Inter-Subject Similarity of Video-Evoked fMRI Timeseries

**L. Byrge<sup>1</sup>**, D. Kliemann<sup>2</sup>, U. Keles<sup>3</sup>, H. Saarimäki<sup>4</sup>, R. Adolphs<sup>5</sup> and D. P. Kennedy<sup>6</sup>, (1)University of North Florida, Jacksonville, FL, (2)University of Iowa, Iowa City, IA, (3)California Institute of Technology, Pasadena, CA, (4)Tampere University, Tampere, Finland, (5)Caltech, Pasadena, CA, (6)Psychological and Brain Sciences, Indiana University, Bloomington, IN

Background: Naturalistic viewing paradigms, in which participants undergo functional magnetic resonance imaging (fMRI) scanning while watching videos depicting semi-naturalistic stimuli, have emerged as an important methodological advance toward improving ecological validity in human neuroscience. Coupling these paradigms with machine learning approaches may particularly benefit clinical neuroscience, by providing the power to both inform neurobiological differences between clinical and control groups in more naturalistic contexts (Eickhoff et al., 2020), and to pinpoint the specific stimulus properties that evoke the most robust group differences.

Objectives: Here, we present novel analytic approaches for predicting ASD diagnosis using inter-subject similarity of brain responses across epochs of video clip viewing. Eventually, this technique may yield insights into stimulus properties that are linked with the greatest differences in brain functioning between individuals with Autism Spectrum Disorder (ASD) and controls.

Methods: We used an extensively and densely sampled fMRI dataset from 29 adults with ASD and 22 age-, IQ-, and sex-matched controls with 4 ~15 min video-watching scans (813 TR) and resting-state scans; preprocessing is described in Byrge & Kennedy (2018; 2020). Video scan stimuli were movie trailers from various genres. Results presented here include 36-40 participants per scan (13-15 ASD) following data quality -related exclusions and employ censored timeseries for highest quality from 110 regions of interest (ROIs) from a common anatomical parcellation (Harvard-Oxford). We combined various feature selection and modeling approaches into a cross-validated inter-subject-similarity-based predictive modeling framework (c.f. Shen et al., 2017), using mean pairwise inter-subject correlations between a held-out subject and healthy controls as similarity measures (ISCs) and both permuted group assignments and resting state data as null models.

Results: Using brain-wide ISCs across the entire video, we achieved above-chance diagnosis prediction accuracy of 73.7%-80.6% for the 4 video scans. Preliminary analyses using feature selection to model only subsets of timepoints from each scan obtain even higher accuracy. In previous work using this same dataset, (Byrge & Kennedy, 2020) we were unable to predict diagnosis above chance levels using functional connectivity matrices derived from these same scans.

Conclusions: We can predict ASD diagnosis from video- evoked brain responses but not from video- evoked functional connectomes in this dataset. Ongoing work aims to understand whether this dissociation arises due to statistical properties or neurocognitive differences informative about ASD. Next steps will examine whether the most informative video segments and brain regions replicate in an independent dataset, and will characterize stimulus features of those segments, providing important insights into the low-level stimulus properties and/or socio-cognitive processes driving brain response differences in ASD.

**434.011 (Poster)** Brain Structural Correlates of Autistic Traits across the Diagnostic Divide: A Surface Based Morphometry Study

**V. Arunachalam Chandran<sup>1</sup>**, C. Pliatsikas<sup>2</sup>, J. Neufeld<sup>3</sup>, G. O'Connell<sup>4</sup>, A. Haffey<sup>5</sup> and B. Chakrabarti<sup>1</sup>, (1)Centre for Autism, School of Psychology & Clinical Language Sciences, University of Reading, Reading, United Kingdom, (2)School of Psychology & Clinical Language Sciences, University of Reading, Reading, United Kingdom, (3)Center of Neurodevelopmental Disorders (KIND), Centre for Psychiatry Research; Department of Women's and Children's Health, Karolinska Institutet, & Stockholm Health Care Services, Region Stockholm, Srockholm, Sweden, (4)School of Mind and Brain, Humboldt University, Berlin, Germany, (5)School of Psychology and Clinical Language Sciences, University of Reading, Reading, United Kingdom

---

Background: Autistic traits (AT) lie in a continuum in the general population, and the higher end of this trait distribution is often linked with a clinical diagnosis of ASD (Robinson et al., 2011; Whitehouse et al., 2011). Majority of previous studies examining the brain structure have used voxel based morphometry to assess the regional grey matter volume (GMV) differences in ASD, using a case-control design. However, these regional GMV differences may also be driven by other surface based metrics such as cortical thickness (CT), surface area (SA) and gyrification (Ecker et al., 2013; Libero et al., 2014). Taking this into account, we aimed to investigate the relationship between CT, SA, volume and gyrification and autistic traits across a sample including individuals with and without ASD, using a dimensional approach.

Objectives: To this end, we collected high resolution T1-weighted structural brain images and Autism Spectrum Quotient (AQ). Surface Based Morphometry (SBM) was used to examine the regional differences in the brain structure in relation to AT.

Methods: Ninety-one adults (66 neurotypicals, 25 ASD: 52 males, 39 females, age 18-60 years) were recruited for this study. This study was approved by the school research ethics committee, University of Reading. High resolution whole brain MPRAGE images were acquired using Siemens 3T MRI scanner installed at the Centre for Neurosciences and Neurodynamics. Freesurfer neuroimaging analysis suite was used to perform the SBM. All the structural brain images were preprocessed using the following steps: 1) correction for head motion, 2) bias field correction, 3) skull-stripping, 4) segmentation, 5) registration, 6) spatial normalisation and 7) smoothing (Fischl, 2012). For the statistical analysis, a Different Offset Same Slope (DOSS) model was used to test the relationship between CT, SA, volume, local gyrification index (LGI) and AT, including age and gender as nuisance variables. Precomputed Monte-Carlo Simulation was used to run the multiple comparisons test with a vertex-wise cluster-forming threshold (0.05) and the threshold for statistical significance ( $p=0.05$ , two-tailed).

Results: We found significant positive association between all four metrics including CT, SA, volume, LGI and AT. The significantly associated cluster in CT were observed in the left lingual gyrus, right lateral occipital cortex and right pars triangularis, whereas the significantly associated cluster in SA were observed only in the right lateral occipital cortex. The significant associations with cortical volume were observed in the left lingual gyrus, right lateral occipital cortex and right pars triangularis. A significant cluster for LGI was observed in the right lingual gyrus.

Conclusions: Our study findings were consistent with previous reports (Ecker et al., 2013; Yang et al., 2016) of brain structural differences in individuals with ASD. These findings suggest widespread cortical volume differences (in the pars triangularis, lateral occipital cortex and lingual gyrus) may be significantly driven by CT and SA, including the social brain regions. Such brain structural differences may underlie aberrant cortical cytoarchitecture properties underpinning atypical socio-communication and visual processing behaviour respectively associated with higher AT.

**434.013 (Poster)** Corpus Callosum Structure and Inter-Hemispheric Functional Connectivity in Autism Spectrum Disorder

**M. E. Beckerson<sup>1,2</sup>**, N. Loomba<sup>3</sup>, C. Ammons<sup>4</sup> and R. K. Kana<sup>1,2</sup>, (1)Department of Psychology, University of Alabama, Tuscaloosa, AL, (2)Center for Innovative Research in Autism, Tuscaloosa, AL, (3)Vanderbilt University, Nashville, TN, (4)Emory University School of Medicine, Children's Healthcare of Atlanta, Atlanta, GA

---

Background:

Autism Spectrum Disorder (ASD) is a complex neurodevelopmental disorder characterized by impairments in social communication and repetitive, restricted patterns of behaviors and interests (American Psychological Association, 2013). Using neuroimaging to discover reliable markers of ASD is an avenue of ongoing research that may lead to earlier diagnosis and identify targets for intervention. Smaller corpus callosum (cc) volume (Anderson et al., 2011) and disruptions in functional connectivity (Kana, Libero, Moore, 2011) are some of the consistently reported neural impairments in ASD. However, few studies have examined the relationship between cortical morphology and functional connectivity in ASD.

Objectives:

The objectives of the current study were to characterize volumetric differences in specific segments of the cc in ASD, measure inter-hemispheric (homotopic) functional connectivity, and elucidate the structure-function correspondence by examining the relationship between these two variables.

#### Methods:

Structural MRI and resting state fMRI data from 39 males with ASD ( $16.5 \pm 7.0$  years) and 55 typically-developing (TD) controls ( $16.7 \pm 6.2$  years) matched on age ( $t(92) = .097, p = .92$ ) were obtained from the Autism Brain Imaging Data Exchange (ABIDE I) database. The corpus callosum (cc) was divided into five subdivisions (anterior, mid-anterior, central, mid-posterior, and posterior) using the *FreeSurfer* 6.0 software (Fischl, 2012). Volumes were calculated for each sub-region and were summed together to yield a total cc volume for each subject. Homotopic functional connectivity was calculated between a voxel in one hemisphere and its mirror voxel in the opposite hemisphere using the Resting-State fMRI Data Analysis Toolkit (REST) in MATLAB. Total cc volumes were also correlated with z-scores of interhemispheric correlation values to establish a structure-function relationship.

#### Results:

The ASD group had significantly smaller volumes in the central section ( $M = 486.23\text{cm}^3, SD = 84.50, F(93) = 7.69, p = .007$ ) of the cc. However, a one-tailed t-test revealed no differences in total cc volume between ASD and TD ( $t(93) = .802, p = .373$ ). Further, the ASD group showed stronger interhemispheric connectivity in the superior frontal gyrus (SFG) than the TD group ( $t = 1.988, p = .05$ ). There was no significant correlation between these structural and functional variables in the ASD group ( $r = -.137, p = .413$ ), nor the TD group ( $r = -.027, p = .844$ ).

#### Conclusions:

These findings suggest that individuals with ASD have morphological differences in the cc that may be specific to certain sub-regions. The total cc volume and resting-state interhemispheric functional connectivity may not be directly related, aligning with previous findings (Anderson et al., 2011). Targeted comparisons between specific sub-regions and corresponding homotopic region connectivity may reveal subtle differences in structure-function relationship. Additional research is necessary to determine the effects of these structural differences on ASD symptomatology and behavior.

#### **434.014 (Poster)** Cortical Gyrfication Morphology in ASD and ADHD: Implication for Further Similarities or Disorder-Specific Features?

Background: Shared etiological pathways are suggested in autism spectrum disorder (ASD) and attention-deficit/hyperactivity disorder (ADHD) given high rates of comorbidity, phenotypic overlap and shared genetic susceptibility. Investigation of both neurodevelopmental disorders (NDDs) in the same study using common methodology will enhance our understanding of further shared and possible disorder-specific underlying neurobiological mechanisms that may drive these conditions. Cortical gyrfication morphology, measured through magnetic resonance imaging (MRI), is an understudied brain construct in ASD and ADHD literature. However, considering that the peak of gyrfication expansion occurs in the early developmental years and the timing of onset of ASD and ADHD symptomatology is also in early childhood, investigating this brain construct in these two NDDs may provide insight into important contributing etiopathological factors. Contradictory findings have been found in the few studies that have examined gyrfication morphology in ASD and ADHD, possibly due to small sample sizes among other limitations. To our knowledge, no study has yet investigated gyrfication in ASD and ADHD versus typically developing (TD) children in the same study and there is limited evidence of the relation of this measure to clinical symptoms.

Objectives: 1. To investigate gyrification morphology in a large sample of children and adolescents with ASD and ADHD compared to TDs. 2. To examine potential functional implications of gyrification differences by investigating the relation between this brain construct and ASD and ADHD symptomatology, across diagnostic groups.

Methods: Neuroimaging (T<sub>1</sub>-weighted), cognitive and behavioural data were obtained from Province of Ontario Neurodevelopmental Disorders (POND) network, a multi-site Canadian study. We undertook a whole-brain, vertex-wise approach using FreeSurfer software to measure local Gyrification Index (*I*GI), a surface-based measure of the degree of local gyrification. General linear models (GLMs) were conducted on the command-line stream of FreeSurfer to examine *I*GI differences between groups and investigate the effect of IQ. The QDEC application on FreeSurfer was used to examine brain-behaviour relations. We controlled for the effects of age, sex and surface area in all analyses.

Results: Analyses were performed on 539 (197 ASD; 96 ADHD; 246 TD) children and adolescents 6-17 years of age. We found no significant group differences in *I*GI, but significant age and sex effects across diagnostic groups. Specifically we report a decrease of *I*GI with age and greater *I*GI in girls compared to boys. There were also no diagnosis-by-age interaction effects, suggesting similar developmental trajectories of *I*GI across ASD, ADHD and TDs in the age range of our cohort. Including IQ in the model yielded similar results except for the absence of main effects of sex. Brain-behaviour relations generally showed increased *I*GI in the right medial temporal lobe was associated with higher social communication, hyperactive/impulsive and inattentive problems but lower adaptive functioning.

Conclusions: This investigation of gyrification morphology in ASD and ADHD in the same cohort with common methodology contributes to our understanding of shared and disorder-specific brain mechanisms in these two NDDs, and informs potential contributing etiopathological factors of these two NDDs. Our results support the emerging literature suggesting overlap of neuropathology in ASD and ADHD.

---

Background: Disruptions to brain maturation in the first years of life in ASD are well documented, including early brain overgrowth, primarily driven by surface area overexpansion, and accelerated white matter development (i.e., increased fractional anisotropy). However, knowledge of the specific neurodevelopmental processes contributing to atypical brain maturation is extremely limited. Among such neural maturational processes is intracortical myelination, which is thought to contribute to fine-tuning of brain network connectivity. To our knowledge, this is the first in-vivo study reporting on intracortical myelin content in toddlers and preschoolers with ASD.

Objectives: To examine intracortical myelin content (MC) in young children with ASD as compared to typically developing (TD) peers.

Methods: Participants were young children with ASD (mean age: 44±12 months; range: 23-62 months) and TD children (mean age: 42±15 months; range: 20-65 months) enrolled in a longitudinal study of early brain markers of autism. ASD diagnoses (or clinical best estimates for the youngest participants) were established based on the DSM-5 criteria, supported by the ADOS-2 and ADI-R. Data from 36 participants (20 ASD, 16 TD) for whom both T<sub>1</sub>-weighted (T<sub>1w</sub>) and T<sub>2</sub>-weighted (T<sub>2w</sub>) anatomical MRI scans were successfully acquired during natural sleep were included. Data quality, inspected by two independent raters, was equivalent in both groups. MC was estimated through the ratio of T<sub>1w</sub>/T<sub>2w</sub> signal intensity, using the Human Connectome Project pipelines. The average T<sub>1w</sub>/T<sub>2w</sub> ratio was extracted from 34 regions of interest (ROIs) per hemisphere from the Desikan-Killiany atlas. Analyses were performed on the 12 ROIs with the highest T<sub>1w</sub>/T<sub>2w</sub> ratio (averaged between hemispheres), representing the most myelinated cortices (i.e., visual, sensorimotor, auditory, posterior aspects of cingulate, and limbic cortices). Group differences in MC were examined with two-sample t-tests. General linear models (GLM) were employed, with the T<sub>1w</sub>/T<sub>2w</sub> ratios as outcome variables, and diagnostic group, age, and group-by-age interaction terms as predictors for each ROI. Grey/white contrast to noise ratio (CNR) and sex were included as covariates in all analyses. Corrections for multiple comparisons were conducted using Benjamini-Hochberg False Discovery Rate (FDR; corrected  $p_{FDR} < 0.1$ ).

Results: Direct group comparisons revealed no group differences (ASD vs. TD) in the T<sub>1w</sub>/T<sub>2w</sub> ratio for the 12 ROIs. The GLM analyses revealed significant group-by-age interaction effects in 6 out of the 12 ROIs (i.e., cuneus, lateral occipital, pericalcarine, posterior cingulate, parahippocampal, and precuneus cortices), with T<sub>1w</sub>/T<sub>2w</sub> ratio consistently increasing with age in TD children but not in the ASD group, while controlling for sex and grey/white CNR (Figure 1).

Conclusions: Although no group differences were observed in MC in the selected heavily myelinated areas, a consistent pattern of differential relationships between age and MC was evident in children with ASD vs. their TD peers across multiple ROIs. Specifically, TD children showed age-related increase in MC in visual, posterior cingulate, precuneus and parahippocampal cortices, consistent with prior studies on typical myelin development in this age range. However, there was a general lack of relationship between MC and age in the ASD group, suggesting a disrupted developmental trajectory of intracortical myelination in ASD.

**434.016 (Poster)** Developmental Predictors of the Fusiform Gyrus Cortical Morphology

L. E. Duvall<sup>1</sup> and R. K. Kana<sup>2</sup>, (1)Psychology, University of Alabama, Tuscaloosa, AL, (2)Department of Psychology, University of Alabama, Tuscaloosa, AL

---

Background:

The fusiform gyrus (FG), located in the ventral occipitotemporal cortex has been found to play differential roles in the left and right hemispheres, with visual word learning and word formation being left lateralized and face processing being right lateralized (Davies-Thompson et al., 2016). Previous research has demonstrated that these skills improve with age (Herba & Phillips, 2004; Nelson, 1981). People with autism spectrum disorder (ASD) have shown altered activation and connectivity of the FG reportedly due to delays and deviations during development (Schultz, 2005). However, few studies have investigated the morphometric features (cortical thickness, CT; grey matter volume, GMV) of the FG as they relate to age. CT reflects the size, density and arrangement of cells and has been shown to develop differently in individuals with ASD (Zielinski et al, 2014); GMV also has been shown to have developmental differences in ASD (Foster et al., 2015). In the present study, we focused on how development, as measured by age, and autism symptoms predicted morphometric features of the FG.

Objectives:

The goal of the present study was to examine morphometric features of the FG (CT and GMV) as they relate to age and autism symptomatology.

Methods:

A total of 106 individuals (age range: 8-40 years) participated in this structural MRI study. High resolution T1 weighted images were acquired using a 160 slice 3D MPRAGE volume scan (TR = 200 ms, TE = 3.34 ms, flip angle = 12, FOV = 25.6, 256 × 256 matrix size, 1 mm slice thickness) on a 3T Siemens Allegra scanner. Established *Freesurfer* morphometric data analysis procedures were used to extract the mean GMV and CT from these participants. All participants also completed the Autism Spectrum Quotient (AQ), a measure of autism symptoms. Separate linear regression analyses compared each morphometric measure of the left and right FG with age and AQ scores.

Results:

The linear regression model revealed that age statistically significantly predicted GMV in the left,  $F(1,107) = 8.197$ ,  $p = 0.005$ , adj.  $R^2 = 0.62$ , and right FG,  $F(1,107) = 4.145$ ,  $p = 0.044$ , adj.  $R^2 = 0.28$ . CT significantly predicted only the right FG,  $F(1,105) = 16.511$ ,  $p < 0.005$ , adj.  $R^2 = 0.128$ . AQ score was not a statistically significant predictor of GMV in the left,  $F(1,75) = 0.677$ ,  $p = 0.413$ , adj.  $R^2 = -0.4\%$ , or right FG,  $F(1,75) = 1.233$ ,  $p = 0.270$ , adj.  $R^2 = 0.3\%$  or CT in the left,  $F(1,73) = 0.636$ ,  $p = 0.428$ , adj.  $R^2 = -0.5\%$ , or right FG,  $F(1,74) = 1.183$ ,  $p = 0.280$ , adj.  $R^2 = 0.2\%$ .

Conclusions:

The findings of the current study suggest that morphological features of the FG change as a function of development. This may also provide neurobiological insights into the role of cortical morphology of FG in functions, such as face processing and visual word learning.

---

**Background:** Autism Spectrum Disorder (ASD) is a neurodevelopmental condition accompanied by differences in brain morphometry. Neuroanatomical abnormalities in ASD include differences in the development of grey matter volume, which has extensively been studied in the past (Courchesne et al., 2001; Hazlett et al., 2011; Ecker et al., 2017). However, traditional analyses do not assess how grey matter volume is distributed across cortical layers. This is of importance as ASD-related genes have been shown not to be equally expressed across all cortical layers, but may affect either the superficial (Parikshak et al., 2013) or the inner (Willsey et al., 2013) layers differentially, which in turn may impact on cortical lamination and folding.

**Objectives:** We aimed to characterize a novel feature assessing the surface-based distortion of grey matter volume across cortical surfaces based on typically developing (TD) controls, and to utilize this feature to characterize differences in brain morphometry between individuals with ASD relative to TD.

**Methods:** We included 92 adults with ASD and 92 TD, aged 18-52 years. Cortical surface models were extracted from T1-weighted volumetric images using FreeSurfer (<http://surfer.nmr.mgh.harvard.edu/>). Vertex-wise estimates of 'Frustum Surface Ratio' (FSR) were calculated as the ratio of the volume expected based on the pial surface ( $V_E$ ), and the actual (i.e. analytical) volume ( $V_A$ ) (Winkler et al., 2018). We examined the relationship between FSR and other cortical measures to explore its biological plausibility in the subsample of TD. Subsequently, we examined differences between ASD and TD by regression of a GLM at each vertex with (1) group, gender, and site as categorical fixed-effects factors, (2) an age-by-group interaction term, and (3) age and FSIQ as continuous covariates.

**Results:** The spatial distribution of FSR appeared to approximate the normal distribution, capturing information on cortical volume and brain geometry, and followed the outline of primary and secondary gyri and sulci (Figure 1A). Measures of FSR were highly correlated with vertex-wise estimates of mean curvature, sulcal depth, and pial surface area, although none of these features explained more than 76% variability in FSR on their own (Figure 1B). Following correction for multiple comparisons (RFT-based cluster-corrected,  $p=0.05$ ), we observed that the degree of FSR was significantly increased in ASD relative to TD in many cortical clusters, including inferior parietal, superior temporal, and cingulate regions (Figure 2A). We also observed significant age-by-group interactions, indicating that between-group differences in FSR are age-dependent, with differences being most prominent at age 40 and above (Figure 2B).

**Conclusions:** Our findings suggest a more outward-weighted gradient of CV in ASD, which may indicate a larger contribution of supragranular layers to regional differences in CV. Therulesult of a steeper age-related decline of FSR are in line with similar developmental trajectories been reported for cortical volume (Lange et al., 2015), cortical thickness (Zielinski et al., 2014), and gyrification (Kohli et al., 2019) in ASD. The degree of FSR might therefore serve as a novel proxy measure assessing volumetric gradients along the depth of the cortical mantle, and may guide future studies into the genetic underpinnings of ASD.

#### 434.018 (Poster) Extra-Axial Cerebrospinal Fluid Volume Normalizes with Age in Autistic Individuals

M. Peterson<sup>1</sup>, M. D. Prigge<sup>2</sup>, E. Bigler<sup>3</sup>, B. A. Zielinski<sup>3</sup>, J. B. King<sup>4</sup>, N. Lange<sup>5</sup>, A. L. Alexander<sup>6</sup>, J. E. Lainhart<sup>7</sup> and J. A. Nielsen<sup>8</sup>, (1)Brigham Young University, Provo, UT, (2)Developmental Network Neurobiology Laboratory, University of Utah, Salt Lake City, UT, (3)Pediatrics and Neurology, University of Utah, Salt Lake City, UT, (4)University of Utah, Salt Lake City, UT, (5)McLean Hospital, Cambridge, MA, (6)Medical Physics & Psychiatry, University of Wisconsin - Madison, Madison, WI, (7)Psychiatry, University of Wisconsin - Madison, Madison, WI, (8)Harvard University, Cambridge, UT

---

**Background:** Autism spectrum disorder has long been associated with a variety of organizational and developmental abnormalities within the brain. In a series of recent studies, an increase in extra-axial CSF volume has been reported in autistic individuals between the ages of 6 months and 4 years (Shen et al., 2013; Shen et al., 2017; Shen et al., 2018). In each of these studies, the increased extra-axial CSF volume was predictive of the diagnosis and severity of the autism symptoms, irrespective of whether or not the individual came from a simplex or multiplex family.

**Objectives:** In the present study, we explored the trajectory of extra-axial CSF volume throughout the lifespan in both autistic and typically developing (TD) participants. We hypothesized that an elevated extra-axial CSF volume would be found in autistic individuals compared with TD controls, with that difference persisting throughout the lifespan.

**Methods:** We tested the hypothesis with a dataset that implemented an accelerated longitudinal design and included 201 individuals. Each individual had between 1-5 timepoints of data with each timepoint separated by 2-3 years. A total of 456 T1-weighted MRI scans were analyzed. The segmentation of extra-axial CSF from these scans was accomplished via a previously established pipeline (Mostapha et al., 2018; Shen et al., 2018). Using a separate dataset from the Human Connectome Project, the pipeline was found to be highly reliable (ICC = 0.96). A linear mixed-effects model fit was used to determine longitudinal, age-related changes in extra-axial CSF volume as a function of diagnostic group, diagnostic group by age<sup>2</sup>, age, age<sup>2</sup>, and sex in R 4.0.2 using the package nlme.

**Results:** Starting at age three, we estimated an average extra-axial CSF volume of approximately 45 cm<sup>3</sup> for both the autistic and TD groups. Between 3 and 20 years, the volume of extra-axial CSF approximately doubled. After age 20, the extra-axial CSF volumes leveled off through age 42. The trajectories of extra-axial CSF volume between 3 and 42 years were similar for the autistic and TD groups (group x age interaction,  $t(251) = -0.72, p = 0.47$ ). Also, no significant differences between the autistic and control groups were observed after recentering age at 10 ( $t(198) = -0.93, p = 0.36$ ), 20 ( $t(198) = -1.71, p = 0.09$ ), and 30 ( $t(198) = -1.52, p = 0.13$ ) years.

**Conclusions:** In contrast to our hypothesis and previous reports of increased extra-axial CSF volume in autistic individuals between six months and four years, we found no group differences in extra-axial CSF volume between 3 to 42 years. When considered in combination with previous reports, our results suggest that the increased extra-axial CSF volume in young autistic children normalizes later in childhood.

**434.019 (Poster)** Functional Lateralization of Language Processing in Individuals with a History of ASD, Current ASD, and Typical Development

**H. R. Thomas<sup>1</sup>, M. J. Stabile<sup>1</sup>, D. A. Fein<sup>1</sup>, M. C. Stevens<sup>2</sup> and I. M. Eigsti<sup>1</sup>,** (1)Psychological Sciences, University of Connecticut, Storrs, CT, (2)Olin Neuropsychiatry Research Center, Hartford Hospital, Hartford, CT

**Background:** Left-hemisphere (LH) language dominance characterizes 76-96% of the population; degree of asymmetry predicts handedness (Berl, et al., 2014), and relates to individual differences in language. Individuals with autism spectrum disorder (ASD) and language impairment show more atypical hand-dominance (Markou et al., 2017) and lateralization; greater symmetry predicts greater language impairment (Lindell & Hudry, 2013; Herbert et al., 2004). While atypical asymmetry of brain *structure* is prominent in ASD (Postema, et al., 2019), less is known about asymmetries of brain *function*. Studies of individuals with a clear history of ASD, who lose the ASD diagnosis (LAD) and have no symptoms or language impairment in adolescence (Fein et al., 2013), may reveal whether *functional* neural asymmetry becomes more typical after language impairments resolve.

**Objectives:** We assessed ASD-specific differences in functional hemispheric asymmetry using an fMRI-based lateralization index (LI), quantifying how LH versus right-hemisphere (RH) brain regions were differently engaged during a language task. LI scores for Broca's area, which is highly LH-lateralized during language processing, were predicted to differ in ASD. Because few studies have examined functional brain LI in ASD, supplemental analyses explored group differences in 180 cortical regions of interest (ROIs).

**Methods:** We re-examined fMRI data from a sentence comprehension task (Eigsti et al. 2016) for three groups: (1) ASD, with average cognitive abilities [ $n=23$ ; M(SD) age=13.9(3.3) years]; (2) LAD [ $n=16$ ; 13.7(3.6)]; and (3) typically-developing (TD) participants [ $n=19$ ; 13.3(2.8)]. Groups did not differ on age, handedness, gender, or nonverbal IQ. MRI data, collected on a 3T Siemens Allegra, were prepared using fMRIPrep v20.0.6, converted into CIFTI format, and co-registered to the Human Connectome Project (HCP) cortical atlas (Glasser et al. 2016) using Ciftify (Dickie et al. 2019). Task-activated brain regions were identified using GLM; LI was calculated for HCP parcels: (Ract-Lact)/ [abs(Ract)+abs(Lact)]. One-way ANOVAs with planned comparisons were conducted to assess diagnostic differences in LI for Broca's area and for exploratory analyses of 180 HCP cortical ROIs, uncorrected for multiple comparisons.

**Results:** No main effect of diagnosis for Broca's area LI emerged. Planned  $t$ -tests revealed significantly reduced LH lateralization in Broca's area in ASD compared to TD, with medium effect size ( $t=-1.89^*$ , Cohen's  $d=0.57$ ); LAD/ASD and LAD/TD groups did not differ. Exploratory analyses found significant group differences with medium-to-large effect sizes in 17 cortical ROIs; all demonstrated reduced leftward asymmetry of language-related activations for ASD and LAD compared to TD (Table 1, Figure 1).

**Conclusions:** We probed hemispheric asymmetry in ASD using an fMRI language task. Participants with current ASD showed atypically reduced functional asymmetry in Broca's area, and exploratory analyses suggested atypical activity-related asymmetry in both ASD and LAD for numerous cortical regions. Broadly, these results suggest that there is reduced LH specialization during language processing in individuals with ASD by history, even in the absence of *current* language impairment. Future work will examine correlations between functional asymmetries and behavioral characteristics, and interpret functional differences in the light of structural brain asymmetry.

**434.021 (Poster) Longitudinal Analysis of Amygdala Connected Cortical and Limbic Regions**

**J. K. Lee<sup>1</sup>, D. S. Andrews<sup>1</sup>, M. Solomon<sup>1</sup>, S. J. Rogers<sup>1</sup>, S. Ozonoff<sup>2</sup>, D. G. Amaral<sup>1</sup> and C. W. Nordahl<sup>1</sup>,** (1)Department of Psychiatry and Behavioral Sciences, The Medical Investigation of Neurodevelopmental Disorders (MIND) Institute, UC Davis School of Medicine, University of California Davis, Sacramento, CA, (2)Psychiatry and Behavioral Sciences, University of California at Davis, MIND Institute, Sacramento, CA

**Background:** The amygdala is widely implicated in the neurobiology of autism spectrum disorder (ASD) and social functioning. Altered trajectories of amygdala growth in childhood are observed in ASD, however little is known about how this occurs within the context of the network of brain regions sharing direct anatomical connection with the amygdala, and what those implications are for ASD.

**Objectives:** To conduct a study of the structural development of the amygdala and of limbic and cortical brain regions with known direct anatomical connections to the amygdala in boys and girls with ASD and with typical development (TD).

**Methods:** Nine-hundred and fifty longitudinal structural MRI were acquired from 282 children with ASD (93 female) and 128 children with TD (61 female) on up to four timepoints (Mean ages: 3.2, 4.3, 5.3, 11.4 years). Images were segmented using MRICloud (Mori et al., 2016), producing volumes for subcortical and cortical regions of interest which were normalized as proportion of total cerebral volume. Thirty-two regions of interest with known anatomical connection to the amygdala (Freese & Amaral 2009; Hennessey et al., 2018) were submitted to mixed effects multivariate distance matrix regression (mMDMR) analysis which assessed global phenotypical differences associated with ASD diagnosis, sex, and age, and the two- and three-way interactions thereof. mMDMR is a multivariate, person-centered statistical method that allowed us to test longitudinal associations between predictor variables (i.e. age, diagnosis, sex) and a distance matrix, where the distance matrix contains pair-wise dissimilarities between each individual's amygdala anatomical profile at a point in time. Inspection of effect sizes identified the region(s) that drove the multivariate effects, which were then descriptively plotted using univariate mixed level models. Social Responsiveness Scale and Vineland Adaptive Behavior Scales were acquired.

**Results:** The anatomical profiles of amygdala-connected regions exhibited persistent diagnostic differences (Diagnosis:  $X = 2.1, p = .015$ ) that grew larger over time (Age x Diagnosis:  $X = 1.9, p = .035$ ) (Figure 1A). Overall, robust developmental changes were observed for both ASD and TD ( $X_s \geq 169, p_s < .001$ ). Sex differences between anatomical profiles were observed (Sex:  $X = 2.9, p = .002$ ), which did not differ by diagnosis or change in magnitude over development ( $X_s \leq 1.3, p_s \geq .21$ ). Although the magnitude of diagnostic differences was similar in males and females with ASD, an examination of effect sizes revealed that in boys diagnostic differences were disproportionately due to differences at the middle temporal pole and subgenual anterior cingulate cortex, while in girls, diagnostic differences were primarily due to differences in the fusiform gyrus, entorhinal cortex, and superior temporal gyrus (Figure 1B). Descriptive analyses of these regions revealed unique longitudinal trajectories in males and females with ASD and TD. Analysis then revealed significant associations between amygdala-connected anatomy and the Social Responsiveness Scale and Vineland Adaptive Behavior Scales.

**Conclusions:** The anatomical profile of amygdala connected regions differ in autism, and those differences increase over development in childhood. While the magnitude of differences associated with ASD were similar in males and females across this anatomical profile, different regions were affected by autism in boys and girls.

**434.022 (Poster) Lower Sex Prediction Accuracy in Females with Autism Supports the Extreme Male Brain Theory**

---

**Background:** Autism spectrum disorder (ASD) is characterized by a male preponderance with four to five times more males diagnosed than females. Even studies accounting for potential ascertainment bias still report a ratio of around two times more males than females. This makes it very likely that factors related to typical sexual differentiation are involved in the neurobiology of ASD. The extreme male brain theory (EMB) states that one mechanism contributing to such skewed sex ratio is elevated exposure to prenatal testosterone in utero (Lai et al., 2015). Increasingly, studies provide indirect and direct evidence for this, but neuroimaging studies into this question are still scarce. Here we leverage two large-scale datasets with sufficient numbers of females to address whether sex classification accuracy in females with ASD can be informative about the EMB.

**Objectives:** To test the predictions of the EMB theory using machine learning.

**Methods:** We used the Simple Fully Convolutional Network (SFCN) architecture (Peng et al., 2019) to predict biological sex based on linearly registered 3D T1 images, as shown in Fig 1. This model was trained and validated with 14,503 neurotypical (NT) male and female subjects from the UK Biobank (UKB) dataset. Next, we transferred the UKB-trained model to the LEAP dataset by finetuning it with just NT subjects and then testing it in both NT and autistic (ASD) subjects, including males (M) and females (F). The Longitudinal European Autism Project (LEAP) dataset comprised 98 ASD-F, 94 NT-F, 276 ASD-M and 173 NT-M. Two-fold cross validation was used to generate prediction results for all subjects. For the first (second) fold, the model was finetuned with 133 (134) NT subjects, and tested with 134 (133) NT and 187 (187) ASD subjects. To test reproducibility of results, the UKB-trained model was also transferred to the Autism Brain Imaging Data Exchange (ABIDE I+II) datasets by finetuning it with 276 NT-M and 276 NT-F. The model was then tested in NT and ASD subjects (138 NT-F, 138 NT-M, 138 ASD-F, 138 ASD-M).

**Results:** Sex classification accuracy was lower for female ASD subjects than for female NT subjects (ASD-F: 77.55%; NT-F: 86.17%, rank-sum test p-value:  $1.7e-2$ ). This observation supports the extreme male brain hypothesis, which states that females with ASD resemble NT males. The same pattern was also true for both ABIDE datasets (sex classification accuracy for ASD-F: 68.12%; NT-F: 84.78%, rank-sum test p-value:  $1.8e-7$ ), where ASD females were also more likely to be misclassified as males. For males, the sex classification accuracy for ASD and NT subjects was comparable. In the LEAP dataset, sex classification accuracy for: ASD-M, 93.84%; NT-M, 90.17%, whereas in ABIDE dataset, the sex classification accuracy for: ASD-M, 78.99%; NT-M, 83.33%.

**Conclusions:** We found replicable patterns of females with ASD being more likely to be misclassified as males based on their structural brain image. Considering such sex differences in ASD neurobiology can give us a better understanding of sex-related mechanisms contributing to ASD risk.

#### **434.023 (Poster)** Microstructural Neural Correlates of Maximal Grip Strength in Children and Adolescents on the Autism Spectrum

**O. J. Sargent<sup>1</sup>, D. C. Dean<sup>2</sup>, A. L. Alexander<sup>3</sup> and B. G. Travers<sup>1</sup>,** (1)University of Wisconsin - Madison, Madison, WI, (2)Pediatrics & Medical Physics, University of Wisconsin - Madison, Madison, WI, (3)Medical Physics & Psychiatry, University of Wisconsin - Madison, Madison, WI

---

**Background:** Children with ASD exhibit weaker grip strength compared to typically developing (TD) peers, and this group difference becomes exacerbated in adolescence and adulthood (Abu-Dahab et al., 2013; Travers et al., 2017). This is concerning because grip strength has been associated with concurrent and future daily living skills (Travers et al., 2017). While some have investigated the neural basis of grip in ASD (Unruh et al., 2019; Wang et al., 2019; Travers et al., 2015), it remains unclear how grip strength may map onto neural structures in ASD compared to TD, and whether these grip-brain relationships are similar or different in childhood compared adolescence.

**Objectives:** Examine diagnostic similarities and differences in the microstructural correlates of grip strength in ASD and TD during childhood and adolescence.

Methods: Data were acquired from two cohorts: the first, children (ages 6-10), 56 with ASD and 73 with TD; the second, adolescents (ages 11-17), 31 with ASD and 28 with TD. Maximal grip strength was collected using a hand dynamometer according to Halstead-Reitan Battery guidelines (Heaton et al., 1991). Multi-shell DWI was performed on a 3T scanner with isotropic 1.8mm<sup>3</sup> voxels and 2mm<sup>3</sup> voxels for the childhood and adolescent cohorts, respectively. Neurite orientation and dispersion index (NODDI) values of intracellular volume fraction (ICVF) and orientation dispersion index (ODI) were calculated (Zhang et al., 2012). Using T-SPOON corrected maps (Lee et al., 2009), voxel-based analyses were performed within each cohort predicting NODDI metrics from grip strength, diagnostic status, and their interaction controlling for age, sex, and head motion. False discovery rate ( $p < .05$ ) was used for multiple comparisons with a cluster threshold of  $k > 10$  contiguous voxels.

Results: Figures 1 and 2 depict significant clusters associated with grip strength. In the childhood cohort, one ICVF and 20 ODI (average: 60 voxels) clusters were similarly associated with grip across groups. These clusters included the frontal white matter, superior corona radiata, and cerebral peduncles. 19 ICVF and 6 ODI clusters (average: 126 voxels) demonstrated grip-by-group interactions in areas including the precentral gyrus, thalamic radiation, and cerebellar peduncles. In the adolescent cohort, one ICVF and four ODI clusters (average: 23 voxels) were similarly associated with grip across groups. Clusters included the postcentral gyrus and inferior corticospinal tract. The adolescent cohort showed 14 ICVF and 6 ODI grip-by-group interactions (average: 20 voxels) in areas including the precentral gyrus and internal capsule.

Conclusions: Across childhood and adolescence, there are more diagnosis-specific microstructural correlates of grip than diagnostic-independent correlates. This may suggest altered neural recruitment for motor tasks in ASD, even during childhood when grip is similar to TD. A diagnosis-specific relationship between grip and microstructure in cortical areas, such as the precentral gyrus, an area critical for directing motor actions, is consistent across cohorts. The adolescent cohort appears to show diagnosis-specific relationships between grip and microstructure in subcortical areas such as the brainstem, where the childhood cohort does not. These results may reflect differential motor circuit maturation in the ASD group during adolescence, when grip behavior begins to diverge from TD.

#### 434.024 (Poster) Motion Sensitivity and Visual Gamma Oscillations in Children with ASD

V. O. Manyukhina<sup>1,2</sup>, E. V. Orekhova<sup>1,3</sup>, A. O. Prokofyev<sup>1</sup> and T. A. Stroganova<sup>1</sup>, (1)MEG-Center, Moscow University of Psychology and Education (MSUPE), Moscow, Russian Federation, (2)National Research University Higher School of Economics, Moscow, Russian Federation, (3)MedTech West and the Institute of Neuroscience and Physiology, Sahlgrenska Academy, the University of Gothenburg, Gothenburg, Sweden

Background: People with ASD have atypical visual motion sensitivity, e.g. a significant reduction in spatial suppression (SS) compared to neurotypical (NT) controls that may result from disturbed excitatory-inhibitory interactions in the visual cortex. SS is a perceptual phenomenon of impaired motion direction sensitivity to large high-contrast moving stimuli as compared to small ones (~1 degree of visual angle). The SS is thought to reflect enhanced surround inhibition in the primary visual cortex (V1) caused by an excitatory feedback from extrastriate visual areas that is engaged by the large stimuli. We have previously suggested that in NT individuals the top-down potentiation of surround inhibition by intensity of visual input may also explain attenuation of the magnetoencephalographic (MEG) high-frequency gamma response (GR) with increasing motion velocity of large high-contrast gratings. This was supported by the fact that the strength of velocity-related GR attenuation reliably predicted inter-individual differences in the SS both in typical adults and in children.

Objectives: We tested the prediction that an atypically reduced SS in children with ASD is associated with a weak velocity-related GR attenuation and/or with abnormal correlation between these behavioral and neural indexes of surround inhibition in the visual cortex.

Methods: GRs to large high-contrast gratings moving with three velocities (1.2, 3.6 and 6.0 deg/sec) were measured in the visual cortex in 35 NT boys and 36 boys with ASD aged 7-15 years using MEG and individual MRI-derived brain models. Both psychophysical direction duration thresholds for large and small gratings ( $\text{Threshold}_{\text{LARGE}}$  and  $\text{Threshold}_{\text{SMALL}}$ ) and MEG data were available for 33 NT and 23 ASD children. SS was estimated as  $\log_{10}(\text{Threshold}_{\text{LARGE}}) - \log_{10}(\text{Threshold}_{\text{SMALL}})$ .

Results: At the group level, children with ASD did not differ from NT children in regard to GR amplitude or frequency. Both groups demonstrated similar developmental decreases in GR frequency and increases in GR power. Velocity-related suppression of GR was observed in both groups and did not differ between NT and ASD children. In NT children the stronger GR attenuation in V1 correlated with stronger SS ( $R = -0.38$ ,  $p = 0.03$ ) and *higher*  $\text{Threshold}_{\text{LARGE}}$ , as it has been previously described in this sample using sensor-level analysis (Orekhova et al, Neuroimage 2020). In children with ASD the stronger GR attenuation in V1 also correlated with stronger SS ( $R = -0.51$ ,  $p = 0.01$ ), but, unlike that in NT children, this correlation was driven by the correlation with *lower*  $\text{Threshold}_{\text{SMALL}}$ .

Conclusions: Typical GR parameters and velocity-related GR attenuation in children with ASD indicate that excitatory-inhibitory interaction in the visual cortex is not commonly disturbed in this population. Qualitatively different correlations between GR attenuation and motion direction detection thresholds in NT and ASD groups suggest that reduced spatial suppression in children with ASD may depend, at least in part, on a weaker surround inhibition within the V1. This feature mainly worsens their perception of small moving stimuli and may not be attributable to atypical top-down modulation of V1 circuitry.

**434.025 (Poster)** Multivariate Analysis of Atypical Patterns of fMRI Connectivity Modulation in ASD

*T. Looden<sup>1</sup>, D. Floris<sup>1</sup>, A. Llera<sup>2</sup>, J. K. Buitelaar<sup>2</sup> and C. Beckmann<sup>2</sup>, (1)Donders Centre for Cognitive Neuroimaging, Nijmegen, Netherlands, (2)Department of Cognitive Neuroscience, Donders Institute for Brain, Cognition and Behaviour, Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands*

---

Background:

Autism spectrum disorder is a complex neurodevelopmental condition. There appears to exist pronounced behavioural, cognitive, and neural heterogeneities across individuals diagnosed with autism. These heterogeneities can complicate traditional case-control studies – for instance in situations where an autism behavioural phenotype is related to an atypical, but strongly individualized brain phenotype. The heterogeneity in autism has made understanding underlying mechanisms and the complex interrelation between neurobiology and cognitive profiles in autism challenging. A more fine-grained characterization of the neural processes specifically in action under cognitive loads might however advance our understanding of this disorder. Therefore, in this study, we explore the added value of novel, innovative tools with the aim to improve the interpretability of task-based functional magnetic resonance imaging (fMRI) and parse heterogeneity in autism.

Objectives:

To identify patterns of neural (a)typicality in the way individuals with autism engage with cognitive demands at the individual level.

Methods:

All analyses were based on different subsamples from the EU-AIMS/AIMS2TRIALS multisite Longitudinal European Autism Project (LEAP) with participants between 6 and 30 years of age. This study includes data drawn from five different fMRI task paradigms. We employ a novel task-potency approach which combines the unique aspects of both resting-state fMRI and task-fMRI. This allows us to disentangle the relative contribution of task-induced functional connectivity from that of the individuals' baseline connectivity architecture in a multiple task setting. Second, we use a method called normative modeling which maps atypicality of features on an individual basis with respect to the distribution of those features in a group of typically developing controls. It is well suited to parse sample heterogeneity at the individual level. Third, we apply robust out-of-sample canonical correlation analysis to relate high dimensional brain data to behavioural data in a way without making prior assumptions on the most relevant features.

Results:

We found greater levels of global functional connectivity atypicality for autism in each fMRI task paradigm (all  $p < 0.001$ ). The 10% brain regions that on average are most atypical for each separate task are shown in the attached figure. The particular spatial patterns of this atypicality furthermore show similarity across tasks - more so in autism than controls ( $p = 0.002$ ). We found significant and robust brain-behavior modes of covariation between functional connectivity atypicality spatial patterns and autism-related behavioral features for each of the tasks.

Conclusions:

we have applied innovative techniques to aid understanding of autism brain connectivity heterogeneity in a multi-task setting. We found that these techniques reveal a globally atypical strategy in which individuals with autism engage with tasks, and that this carries a level of similarity across tasks that could benefit from further exploration. We furthermore validated the behavioural relevance of these techniques through showing significant relationships between brain and behavioural data. This suggests that normative modelling and task potency can be useful tools in the challenge of understanding the neural foundations of autism.

**434.026 (Poster)** Robust and Interpretable Brain Signatures of Autism and Predictors of Clinical Symptom Severity

**Background:**

Autism spectrum disorder (ASD) is among the most common and pervasive neurodevelopmental disorders, affecting 1 in 54 children. Despite decades of research, the neurobiology of ASD is still poorly understood, as inconsistent findings preclude the identification of robust and interpretable neurobiological markers and predictors of clinical symptoms.

**Objectives:**

Identify robust and interpretable dynamic brain markers that distinguish children with ASD from typically-developing (TD) children and predict clinical symptom severity.

**Methods:**

We leverage multiple brain imaging cohorts (ABIDE: 403 ASD children with mean age 13.9 years, 399 TD children with mean age 14.9 years; Stanford 101 ASD children with mean age 11.7 years, 101 TD children with mean age 10.9 years) and exciting recent advances in explainable artificial intelligence (xAI), to develop a novel multivariate time series deep neural network (tsDNN) that extracts informative brain dynamics features that accurately distinguish between ASD and TD controls, and predict clinical symptom severity.

**Results:**

Our model achieved consistently high classification accuracies in cross-validation analysis of data from the multisite ABIDE cohort. Crucially, our tsDNN model also accurately classified data from an independent Stanford cohort without additional training. xAI analyses revealed that brain features associated with posterior cingulate cortex and medial prefrontal cortex, which anchor the default mode network, and the superior temporal sulcus and fusiform gyrus, which anchor the human voice and face processing and communication systems, most clearly distinguished ASD from neurotypical controls in both cohorts. Furthermore, feature identification procedures yielded a unique predictive fingerprint in each individual and features associated with the posterior cingulate cortex emerged as robust predictors of the severity of social and communication deficits in ASD in both cohorts.

**Conclusions:**

Our findings, replicated across two independent cohorts, advance our understanding of brain mechanisms underlying behavioral impairments in childhood autism, and contribute significantly towards the development of more effective and precise diagnostic and treatment strategies for autism.

---

**Background:**

There is increasing interest in using human genetic models to better understand the mechanistic underpinnings of autism spectrum disorder (ASD). A crucial step in this process, however, is to demonstrate that the biological underpinnings of ASD in genetic high-risk conditions are similar to those in idiopathic illness. 22q11.2 deletion syndrome (22q11.2DS) is a genetic condition with complex clinical phenotypes that include ASD. Evidence from *in vivo* neuroimaging studies (Antshel et al., 2007; Jalbrzikowski et al., 2017; Gudbrandsen et al., 2019) suggests that 22q11.2DS individuals with ASD symptomatology are neuroanatomically distinct from those without, and may represent a distinct neurobiological subgroup. None of these previous studies, however, included individuals with idiopathic ASD. It therefore remains unknown how closely the neurobiological phenotype of ASD in 22q11.2DS resembles the ASD phenotype in those without the microdeletion.

Objectives:

To establish whether ASD symptomatology in 22q11.2 deletion carriers is underpinned by the same – or distinct – neural systems that mediate these symptoms in non-carriers.

Methods:

We examined vertex-wise estimates of cortical volume, surface area, and cortical thickness across 131 individuals (6-25 years). We included (1) 50 22q11.2 deletion carriers (n=25 ASD, n=25 without ASD), and (2) 81 non-carriers (n=40 ASD, n=41 healthy controls). In accordance with previously published studies (Jalbrzikowski et al., 2017; Gudbrandsen et al., 2019), all individuals with ASD met diagnostic cut-offs in the reciprocal social interaction and communication domain of the ADI-R (Lord et al., 1994), but were allowed to fall below threshold in the repetitive behaviors domain. We employed a multivariate dimensional approach using canonical correlation analysis (CCA). This allowed us to; 1) treat ASD as a continuous clinical construct spanned by multiple symptom domains assessed via the five subscales of the Social Responsiveness Scale (SRS; Bölte & Poustka, 2008; Constantino & Gruber, 2012), and 2) to examine the multivariate association between inter-individual clinical profiles and neuroanatomical variability in 22q11.2 deletion carriers and non-carriers.

Results:

Initially, CCA was performed across all individuals within our sample (see **Fig.1**), where clinical variability across the five subdomains of the SRS could be reduced to two latent trait variables that were (1) highly predictive of group membership (i.e. ASD vs. nonASD), and (2) significantly associated with neuroanatomical variability across multiple morphometric features. However, when comparing the multivariate association between inter-individual clinical profiles and neuroanatomical variability between groups, i.e. 22q11.2 deletion carriers and non-carriers (see **Fig.2**), we identified a high degree of factor similarity in the clinical canonical variate structure, but a low neuroanatomical factor similarity.

Conclusions:

ASD symptomatology is mediated by distinct neuroanatomical substrates in individuals with and without the 22q11.2 microdeletion, even when taking inter-individual variability in SRS subdomains of ASD into account. Brain mechanisms underlying ASD associated with specific genetic etiology may thus diverge from those in idiopathic illness.

**434.028 (Poster)** Social and Repetitive Behaviours in Youth with Autism Spectrum Disorder and the Association with Amygdala Subnuclei Maturation

**D. Seguin<sup>1</sup>, S. Pac<sup>1</sup>, J. Chen<sup>1</sup>, R. Nicolson<sup>2</sup>, J. Martinez-Trujillo<sup>1</sup> and E. Duerden<sup>1</sup>, (1)Western University, London, ON, Canada, (2)University of Western Ontario, London, ON, Canada**

Background: The amygdala plays a key role in regulating emotional processes, including emotional recognition and some aspects of fear and anxiety responses. Dysregulated amygdala development has been reported in young children with ASD, while less is known about amygdala maturation in later childhood and adolescence, a sensitive window for social skill development.

Objectives: To determine if amygdala subnuclei follow different developmental growth trajectories in youth with ASD compared to TD youth, and whether specific amygdala subnuclei growth associate with ASD symptoms.

Methods: In this longitudinal magnetic resonance imaging (MRI) study, we assessed macrostructural development of the amygdala subnuclei in older children and adolescents with (n=23) and without ASD (n=15) at 2 timepoints 3 years apart. At the first session, participants were scanned with MRI at a median age of 12 years, with a second scan at a median age of 15 years.

The volumes of seven subnuclei (basolateral, central, medial, cortical, paralaminar, corticoamygdaloid area and anterior amygdaloid area) were extracted using an automatic segmentation algorithm for the two timepoints, to examine growth.

Results: In adolescents with ASD only, amygdala subnuclear volumetric changes were assessed in relation to ASD symptomatology. Participants with ASD were diagnosed using the Autism Diagnostic Observation Schedule, General (ADOS-G) and the Autism Diagnostic Interview, revised (ADI-R). Amygdala subnuclei growth was compared between the participant groups and revealed larger BLA nuclei volumes in adolescents with ASD compared to neurotypical participants ( $B=46.8$ ,  $p=0.04$ ). When examining ASD symptomatology in relation to the growth of the amygdala subnuclei, reciprocal social interaction scores on the ADI-R were positively associated with increased growth of the BLA nuclei ( $B=8.3$ ,  $p=0.001$ ). Growth in the medial nucleus predicted the communication ( $B=-46.9$ ,  $p=0.02$ ) and social ( $B=-47.7$ ,  $p<0.001$ ) domains on the ADOS-G. Growth in the right cortical nucleus ( $B=26.14$ ,  $p=0.02$ ) predicted ADOS-G social scores. Central nucleus maturation ( $B=29.9$ ,  $p=0.02$ ) was associated with the repetitive behaviors domain on the ADOS-G. Larger BLA volumes may be due to increased neuronal density, consistent with postmortem studies.

Conclusions: These findings reveal an association between amygdala subnuclei volumes and ASD symptoms, which may reflect activity-dependent plasticity. Improved understanding of amygdala subnuclei growth trajectories in youth may aid in identifying key windows for targeted interventions, particularly for social communication in adolescents with ASD who display social impairments.

Background:

The presence of sensory symptoms has recently been recognized as a core feature of autism spectrum (AS), consistent with estimates suggesting that over 90% of individuals with autism show atypical responses to sensory stimuli that affect every-day functioning. It is during the early years of life that sensory symptoms emerge (<age 3) and may exacerbate the core social communicative and behavioral difficulties observed in autistic individuals. While increasing evidence suggests that altered inhibitory function results in atypical responses to sensory stimuli, little is known about the neural mechanisms underlying sensory differences in early childhood autism (<age 8).

Objectives:

Here, we use electroencephalography (EEG) to investigate tactile cortical processing in young children aged 3-6 years with autism compared to typically developing (TD) children, and to determine if properties of somatosensory-evoked potentials (SEPs) are associated with "real-world" parent-reported tactile symptoms.

Methods:

Scalp EEG was recorded from 28 children with a diagnosis of autism and 41 age- and sex-matched TD children aged 3-6 years during passive tactile fingertip stimulation. Children received tactile fingertip stimulation at different rates (1050ms and 150ms interstimulus interval (ISI) in blocked presentations) while watching a movie. Latency and amplitude measures for various SEP responses elicited with the 1050ms ISI were derived and the difference between SEP amplitudes elicited by 1050ms and 150ms ISIs was used as a measure of adaptation.

The Wechsler Non-Verbal Scale of Ability (non-verbal IQ) was utilized to assess intellectual functioning, and parents completed a standardized questionnaire to assess sensory symptoms in everyday life (Child Sensory Profile 2, CSP-2).

Properties of SEPs and adaptation were compared between autistic and TD children using ANCOVA models controlling for age and sex. Partial correlations, controlling for age and sex, were used to determine associations with parent-reported tactile symptoms.

#### Results:

As expected, autistic children had a lower non-verbal IQ compared to the TD children ( $p=0.006$ ) and showed significantly more parent-reported tactile symptoms, including both greater hyper- and hypo-sensitivity (all  $p<0.001$ ). There were no differences in the latency and amplitude of early and mid-latency SEP responses (P50, N80, P100), nor adaptation between autistic and TD children. However, the latency of a later SEP response (N140) differed between autistic and TD children, suggesting faster processing speed in children with autism ( $p_{corr}=0.035$ ). Further, correlational analyses showed an association between early SEP responses and behavioral tactile symptoms specific to the autism group (Figure, P50:  $r=0.38$ ,  $p=0.057$ ; N80:  $r=0.53$ ,  $p=0.005$ ; P100:  $r=0.52$ ,  $p=0.007$ ). This observation prompted an exploratory analysis using tactile phenotype as grouping variable rather than autism diagnosis. With this sensory-based regrouping, we observed differences in the late SEP response (N140), but also earlier responses (N80, P100) between the tactile sensitive and tactile typical groups; however, these fell short of corrected significance.

#### Conclusions:

Our findings suggest that altered early somatosensory cortex processing may index tactile symptoms in early childhood autism. Together, these findings advance our understanding of the neurophysiological mechanisms underlying tactile symptoms in early childhood autism and, in the clinical context, may have implications for improving therapies and creating autism-friendly environments.

#### **434.030 (Poster)** Structural Growth Trajectories and Rates of Change of Infant Brain Development in the First Six Months of Life

*L. Li<sup>1</sup>, P. Y. Wong<sup>1</sup>, W. Jones<sup>2</sup>, A. Klin<sup>2</sup> and S. Shultz<sup>2</sup>, (1)Marcus Autism Center, Children's Healthcare of Atlanta, Emory University, Atlanta, GA, (2)Marcus Autism Center, Children's Healthcare of Atlanta and Emory University School of Medicine, Atlanta, GA*

---

#### Background:

The most rapid changes in postnatal brain development occur in an infant's very first months, as brain volume doubles and synaptic density quadruples. Multiple lines of evidence also show that changes during this critical developmental period are highly dynamic. Notably, the first months' of life are also an important period of behavioral development, when many early milestones are met and signs of neurodevelopmental disorders, such as autism, first become identifiable.

#### Objectives:

To assess dynamic growth trajectories of early structural brain development in typically developing infants' first six months of life.

#### Methods:

A Siemens 3T Prisma scanner was used to collect T1 and T2 weighted images from 68 typically developing infants (37 males, gestational age: 38.5+/-2.1 weeks). Each infant was scanned at up to three times between birth and 6 months of age, with age at first scan and time between MRI scans pseudo-randomly distributed, resulting in 110 scans total. A 3D T2-weighted SPACE sequence and T1-weighted 3D MPRAGE sequence were employed T2- and T1-weighted anatomical images. A deep learning-based method was applied on combined T1w and T2w images to segment brain images into three tissue types: corticospinal fluid (CSF), gray matter (GM) and white matter (WM)(Wang et al., 2014). Quality of segmented brain images was ensured by carefully performing quality control using qualitative and quantitative measures. Total intracranial volume (ICV, CSF+GM+WM) and total brain volume (TB, GM+WM) were summed based on segmented images. Changes of ICV and TB over time were analyzed by generalized additive mixed effect model (GAMM). Both chronological age and corrected chronological age using infant's gestational age were used in the GAMM analyses. Effects of gestational age and sex effects were also examined.

#### Results:

The deep learning based method reliably identified different tissue types, even in images acquired around the 6<sup>th</sup> month of life which are known to have low image contrast between GM and WM. Consistent with the literature on infants between birth and three months of age (Holland et al., 2014), significant effects of corrected age and sex were observed for both ICV (age:  $p < 2.12 \times 10^{-18}$ , sex:  $p < 2.29 \times 10^{-6}$ ) and TB (age:  $p < 9.22 \times 10^{-29}$ , sex:  $p < 1.05 \times 10^{-6}$ ). Infants' ICV and TB increase rapidly over time and males have overall larger ICV and TB than females. In contrast to Holland et al., the main effect of gestational age and interactions between gestational age and age were not observed for either ICV or TB ( $p > 0.05$ ). Developmental trajectories of the structural brain in the first six months of life is dynamic (i.e., time-varying change rates instead of constant change rates): change rates of ICV and TB at birth were over 3 times higher than at month 6 (0.7%/day vs. 0.18%/day, respectively).

#### Conclusions:

Using a non-uniform longitudinal sampling strategy and a relatively large cohort of typically developing infants, we demonstrated dynamic structural growth trajectories of typically developing infants between birth and 6 months of age. Establishing normative trajectories during this critical period of development may facilitate the detection of deviated growth trajectories associated with neurodevelopmental disorders.

## POSTER SESSION — NEUROPHYSIOLOGY/ELECTROPHYSIOLOGY

### Poster 435 - Neurophysiology/electrophysiology Posters

**435.001** (Poster) Anticipation of Social and Non-Social Rewards in Youth with and without ASD  
*C. M. Keifer<sup>1</sup>, T. C. Day<sup>2</sup>, B. D. Nelson<sup>1</sup>, J. M. Jarcho<sup>3</sup>, T. Clarkson<sup>3</sup> and M. D. Lerner<sup>4</sup>, (1)Stony Brook University, Stony Brook, NY, (2)Psychology, Stony Brook University, Stony Brook, NY, (3)Psychology, Temple University, Philadelphia, PA, (4)Department of Psychology, Stony Brook University, Stony Brook, NY*

**Background:** While there has been sustained interest in the role of reward processing in autism spectrum disorder (ASD), researchers are just beginning to focus on the anticipation, as opposed to receipt, phase of reward processing in this population (Keifer et al., 2019). However, most social reward paradigms are not naturalistic and thus may not be as salient as their non-social monetary reward counterparts (Matyjek et al., 2020). Thus, we developed a naturalistic novel social interaction paradigm that models the anticipation of social rewards (Jarcho et al., 2013) and adapted it for event-related potential (ERP). Examining ERPs during reward anticipation may be particularly useful in parsing apart different stages of reward processing given its high temporal resolution. This task has never been applied in individuals with ASD and it is essential to utilize naturalistic tasks to model social reward processing in this population to better understand associated anticipatory reward processing deficits.

**Objectives:** This study examined ERP response during the anticipation of social rewards using a novel, naturalistic paradigm and a non-social control task in youth with and without ASD.

**Methods:** Thirteen youth with ADOS-2 confirmed diagnoses of ASD (10 male;  $M_{age}=13.53$ ,  $SD_{age}=1.83$ ) and 10 IQ-matched youth without ASD (5 male;  $M_{age}=13.38$ ,  $SD_{age}=1.56$ ), while undergoing EEG, completed the Virtual School Paradigm (VSP; Figure 1) and a non-social comparison task, the Doors Task. Both task modeled anticipation of social/monetary rewards in three conditions; 100% chance of nice/winning, 100% chance of mean/losing, or 50% chance of nice/mean or winning/losing social feedback/money (Hajcak et al., 2005). In both tasks, the SPN, an ERP that is generated by reward-related brain regions and sensitive to the anticipation of motivationally relevant feedback (Brunia et al., 2011), was extracted while participants waited to receive feedback. Each participant's parent completed the SRS-2 measure of autism symptom severity.

**Results:** The overall deception rate (i.e., belief they were interacting with real peers) did not differ between ASD and Non-ASD groups ( $t(20)=.313$ ,  $p=.76$ ). SRS-2 was associated with SPN response to anticipation of unpredictable peer feedback ( $r=.432$ ,  $p<.05$ ) such that participants with more ASD symptoms demonstrated attenuated (more positive) SPN amplitudes across groups (Figure 2). SPN to the anticipation of feedback from unpredictable peers was correlated with the social- awareness, communication, and motivation (all  $r>.42$ ,  $ps<.05$ ), but not social cognition or restricted/repetitive behavior subscales of the SRS-2. Correlations between the SRS-2 and SPN did not emerge during trials with predictably nice or mean peers nor on unpredictable, predictable win, or predictable loss trials on the Doors Task (all  $p$ 's $>.05$ ).

**Conclusions:** More ASD symptoms were related to attenuated SPN amplitudes in anticipation of feedback from unpredictable peers, but not predictable peers nor monetary rewards. These findings diverge from prior work and suggest that during anticipatory reward processing, youth with ASD demonstrate deficits specific to the social domain (Clements et al., 2018). Additionally, given that unpredictable peers tend to be the most motivationally salient, decreased anticipation or 'wanting' of feedback in youth with more ASD symptoms may reflect attenuated engagement with salient social partners.

**435.002** (Poster) EEG Study of Local and Global Perception in Children with Autism and Children with an Increased Likelihood of Synaesthesia

*T. M. van Leeuwen<sup>1</sup>, M. Druyvesteyn<sup>1</sup>, C. K. Donaldson<sup>1</sup>, E. van Petersen<sup>1</sup>, M. Van Dongen - Boomsma<sup>2</sup>, J. K. Buitelaar<sup>2,3</sup>, S. Hunnius<sup>1,4</sup> and R. van Lier<sup>1</sup>, (1)Donders Institute for Brain, Cognition and Behaviour, Radboud University, Nijmegen, Netherlands, (2)Karakter Child and Adolescent Psychiatry University Center, Nijmegen, Netherlands, (3)Department of Cognitive Neuroscience, Donders Institute for Brain, Cognition and Behaviour, Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands, (4)Baby and Child Research Center, Radboud University, Nijmegen, Netherlands*

**Background:** Synaesthesia, a mixing of the senses, is more common in autism. Behavioural findings suggest synaesthesia and autism share perceptual alterations, e.g. favouring local (details) over global visual processing. Here we compared electrophysiological responses to local/global visual input in children with autism, children with an increased likelihood of

synaesthesia, and control children (ages 4–6 years, pre-literate). We hypothesized that even prior to developing synaesthesia, children with an increased likelihood of developing synaesthesia would resemble children with autism in the pattern of Visual Evoked Potentials for local vs global visual input. Grapheme-colour synaesthesia, one of the most common forms, usually develops during/after acquiring literacy.

**Objectives:** To demonstrate that children with autism and potential synaesthetes share characteristics of electrophysiological responses to visual input. To explore the behavioural characteristics of children with an increased likelihood to develop synaesthesia.

**Methods:** We measured EEG during passive viewing of high/low spatial frequency (6.0/0.75 c/deg) gratings at high/low luminance contrast (100%/10%). We hypothesized larger Visual Evoked Potentials in the autism and synaesthesia groups for the high versus low spatial frequency stimuli, especially at high contrast, reflecting higher sensitivity to details and enhanced responses in the parvocellular visual system. We additionally assessed letter reading skills and synaesthesia consistency, and collected questionnaire data (Sensory Profile, Social Responsiveness Scale).

**Results: EEG data:** We found a main effect of contrast on P1 amplitudes ( $p < .001$ ), and main effects of spatial frequency, contrast, and their interaction for N2 amplitudes (all  $p < .001$ ) for control children ( $N = 20$ , 9F/11M, age  $67.2 \pm 3.2$  months). Preliminary data from the synaesthesia ( $N = 9$ , 3F/6M, age  $65.2 \pm 5.9$  months) and autism ( $N = 9$ , 1F/8M, age  $69.6 \pm 3.8$  months) groups revealed numerically larger P1 amplitudes for high versus low spatial frequency stimuli; this effect was reversed for controls, in line with our hypothesis. There were no group differences for the N2 component. **Behavioural data:** Sensory Profile and Social Responsiveness Scale scores were significantly different for children with autism ( $t(30) = 5.8$ ,  $p < .001$ ), with the synaesthesia and control groups scoring similarly ( $t(22) = .61$ ,  $p = .55$ ). There were no group differences in pre-literate letter recognition ( $F(2,36) = .62$ ,  $p = .54$ ). Regarding synaesthesia consistency at follow-up after learning to read, in the synaesthesia group 66% of 6 re-tested individuals scored within the synaesthetic range, versus 13% for controls ( $z = 2.4$ ,  $p = 0.015$ ), and 25% for the autism group (only 4 children re-tested).

**Conclusions:** Preliminary EEG results suggest favouring of detailed stimuli in early visual cortex in autism and synaesthesia groups. Behaviourally, potential synaesthetes do not show autistic traits or altered letter recognition, while as expected, synaesthesia was more prevalent in this group at follow-up after acquiring reading skills.

**435.003 (Poster)** Effects of Age and Cognitive Ability on Maturation of Resting-State Peak Alpha Frequency in Children with Autism

*C. E. Finn, G. T. Han, C. Carlos, J. M. Wolf, A. Naples and J. McPartland, Child Study Center, Yale University School of Medicine, New Haven, CT*

---

**Background:** Electroencephalographic (EEG) peak alpha frequency (PAF) represents a marker of neural maturation (Miskovic et al., 2015) that typically increases with age throughout childhood (Chiang et al., 2011). Abnormal maturation of PAF is observed in children with autism spectrum disorder (ASD). PAF does not increase with age in young children (aged 2 to 12 years) with ASD and, in contrast to typical development (TD), is positively associated with cognitive ability in this cohort (Dickinson et al., 2017). These differences appear to depend upon age (Edgar et al., 2019), underscoring the importance of considering both age and cognitive ability from childhood throughout adolescence to further understanding of PAF maturation in ASD.

**Objectives:** The current study aimed to clarify and extend previous findings by assessing the effects of age, cognitive ability, and diagnostic status on PAF in a sample of children and adolescents with and without ASD.

**Methods:** Resting EEG data (with eyes closed) and behavioral measures were collected from 54 children with ASD and 48 TD controls aged 9 to 18 years. At least 30 seconds of artifact free EEG data were available for each participant. PAF was extracted from occipital electrodes. Statistical analyses included t-tests to examine between-group differences in PAF, Pearson correlations to examine bivariate relations, and multiple regression to assess the incremental and joint effects of age, NVIQ, and diagnosis (TD vs. ASD) on PAF.

**Results:** Age was positively associated with PAF in both TD ( $r(46) = .391$ ,  $p = .006$ ) and ASD ( $r(52) = .323$ ,  $p = .017$ ) groups, with no between-group difference in strength of the association. NVIQ was positively associated with PAF ( $r(52) = .204$ ,  $p = .140$ ) in ASD but not TD ( $r(46) = -.008$ ,  $p = .959$ ). A multiple regression model with age, NVIQ, and diagnosis as predictors significantly predicted PAF ( $F(7, 94) = 3.01$ ,  $p < .007$ ,  $R^2 = .183$ ). Examination of the three-way age x NVIQ x diagnosis interaction and lower order effects indicated a marginally-significant three-way interaction effect ( $p = .085$ ). Simple slopes plots (Figure 1) derived from this model illustrate that the relationship between NVIQ and PAF shifts from negative to positive as a function of age in TD children but remains stable and slightly positive in ASD irrespective of age.

**Conclusions:** Findings add to a body of evidence indicating relationships among resting-state neural rhythms and developmental differences in ASD. Whereas previous studies utilizing younger ASD samples indicated the absence of association between age and PAF (Dickinson et al., 2017), current results indicated that age was positively associated with PAF in both ASD and TD groups. Notably, the relationship between NVIQ and PAF shifted from negative to positive in the TD group during middle adolescence (14 years old). By contrast, the ASD group maintained a stable relationship between NVIQ and PAF throughout adolescence, indicating a different trajectory of neural maturation. These findings support previous reports that PAF abnormalities in ASD depend on age (Edgar et al., 2019) and further underscore the importance of examining resting-state neural rhythms in relation to age and cognitive function to interpret neural maturation in ASD.

**435.004 (Poster)** Greater P1 Mean Amplitude in Children with ASD Versus ASD+ADHD during Pattern-Reversal VEP Task  
*A. M. Cremonese-Caira<sup>1</sup>, Y. Braverman<sup>2</sup>, G. MacNaughton<sup>3</sup>, J. I. Nikolaeva<sup>4</sup> and S. Faja<sup>2</sup>, (1)Assumption University, Worcester, MA, (2)Boston Children's Hospital, Boston, MA, (3)Boston Children's Hospital: Labs of Cognitive Neuroscience, Boston, MA, (4)Communication Sciences and Disorders, Northwestern University, Evanston, IL*

---

**Background:** The visual evoked potential (VEP) is a reliable brain signal obtained in response to controlled flash stimuli. The P1 VEP component characterizes the integrity of early visual attention systems. Alterations in VEP waveforms have been detected among children with genetic variants of ASD (e.g., LeBlanc & Nelson, 2016) and other developmental disorders such as attention-deficit/hyperactivity disorder (ADHD; e.g., Anjana et al., 2010). Thirty to 80% of children with ASD experience clinical symptoms of ADHD (Rommelese et al., 2010). Whether or not VEP waveforms differentiate children with a dual diagnosis of ASD and ADHD (ASD+ADHD) from children with ASD alone is unknown and may offer insight into the biological basis of comorbidity among these developmental disorders.

**Objectives:** The objective of these analyses was to determine whether P1 amplitude differed among school-aged children with ASD and ASD+ADHD.

**Methods:** As part of a larger study, ERP data was derived from 38 children with ASD (35 males,  $M_{age} = 9.13 \pm 1.33$  years), 21 children with ASD+ADHD (17 males,  $M_{age} = 9.28 \pm 1.33$  years), and 26 children without clinical concerns (19 males,  $M_{age} = 8.86 \pm 1.44$  years) during a pattern-reversal VEP task. The VEP stimulus was a white and black checkerboard presented in the center of the screen with each checker subtending a  $0.86 \times 0.86$  degree visual angle. The stimulus pattern was reversed every 500 ms for 100 trials. P1 mean amplitude was extracted from the midline occipital electrode Oz (70 ms after event for 100 ms) and compared between groups using univariate ANOVA. Bivariate correlations between P1 mean amplitude and caregiver-reported behavioral outcomes on the Behavior Rating Inventory of Executive Function (BRIEF) were also explored within each group.

**Results:** There was a significant effect of group for P1 mean amplitude,  $F(2,82) = 3.29, p = 0.042, \eta^2 = 0.074$ . Post-hoc comparisons indicate that this effect was driven by differences in the ASD groups, such that P1 mean amplitude was greater among children with ASD ( $M = 6.12, SD = 0.53$ ) relative to children with ASD+ADHD ( $M = 3.94, SD = 0.71, p = 0.046$ ). P1 mean amplitude was negatively correlated with the BRIEF planning/organization ( $r = -0.50, p = 0.020$ ), monitoring ( $r = -0.57, p = 0.007$ ), and metacognition ( $r = -0.52, p = 0.015$ ) scales in the ASD+ADHD group but not in the ASD or control groups, suggesting that children with lower P1 mean amplitude had more difficulty in these domains.

**Conclusions:** Taken together, the results of the current study suggest that VEP waveforms may differentiate children with ASD alone from those with a comorbid presentation of ASD and ADHD. These results add to a growing body of literature that reinforces the utility of studying neural generators of VEPs as a stratification biomarker of ASD. Moreover, our data suggest that the VEP may also provide meaningful information about neurocognitive factors contributing to the comorbidity ASD and ADHD clinical profile.

**435.005 (Poster)** Lower Autonomic Tonus at Rest in Children with Autism Spectrum Disorder  
*M. R. Bufo<sup>1</sup>, M. Guidotti<sup>1,2,3</sup>, J. Malvy<sup>2,3</sup>, Y. Mofid<sup>1</sup>, F. Bonnet-Brilhault<sup>1,3</sup>, C. Wardak<sup>1</sup> and N. Hernandez<sup>1</sup>, (1)UMR 1253, iBrain, Université de Tours, Inserm, Tours, France, (2)CHRU Tours, Tours, France, (3)EXcellence Center in Autism and neurodevelopmental disorders, Tours, France*

---

**Background:**

Autism spectrum disorder (ASD) is a neurodevelopmental disorder more and more associated with autonomic nervous system (ANS) dysregulation. Surprisingly, few studies have looked at the state of the ANS at rest, on which the activation state depends. Children with ASD seem to suffer from cardiovascular dysregulation, predominantly involving parasympathetic control, as well as reduced sympathetic electrodermal tonus at rest (Bujkonava et al., 2016). The evaluation of the complex mobilization of the

sympathetic and parasympathetic branches of the ANS needs to be characterized through a set of effectors. However, no studies have yet examined the physiological ANS tonus at rest with multiple simultaneous physiological parameters recordings in ASD children.

#### Objectives:

The aim of this study is to examine parasympathetic (PNS) and sympathetic nervous system (SNS) activity at rest via measures of pupillary oscillations (hippus), electrodermal activity (EDA), cardiac inter beat interval (RR interval) and heart rate variability (HRV) in children with ASD.

#### Methods:

ASD children (n=15, 15 males; age in months: 104±23) were compared to age-matched typically developing (TD) controls (n=15, 6 males; age in months: 106±24). Pupillary hippus, EDA, RR and HRV have been continuously recorded during five minutes in a seated position. We evaluated the following parameters: pupillary hippus frequency (Hz), median pupillary value (mm), positive and negative pupillary amplitude (mm), EDA number of spontaneous peaks, EDA amplitude (μS), EDA area under the curve (AUC), EDA tonus (μS), RR interval (ms), peak frequency (Hz) and absolute power density (ms<sup>2</sup>) in low (LF-HRV: 0.04-0.15 Hz) and high frequency (HF-HRV: 0.15-0.4 Hz) bands of HRV spectral analysis. Participants have been asked to look at a screen during the whole length of the experiment and stay still on the armchair. Conditions of luminosity (10 Lux), hygrometry (27% rh) and temperature (23°C/ 76.4°F) were constant.

#### Results:

As many ASD participants presented difficulties in looking at the screen for a long period, we did not obtain sufficient pupillary data to analyze. We excluded two participants from EDA analysis due to excessive movements. The analysis of EDA parameters did not show any significant difference between ASD and TD children, but we observed a trend of both increased spontaneous EDA activity and reduced EDA tonus in ASD compared to TD children. We found significantly shortened RR intervals (631±82 ms vs. 694±92 ms, p=0.05), reduced absolute power density in HF-HRV (2.68±0.44 ms<sup>2</sup> vs. 3.00±0.39 ms<sup>2</sup>, p=0.04) and reduced peak frequency in LF-HRV (0.08±0.03 ms<sup>2</sup> vs. 0.11±0.02 ms<sup>2</sup>, p=0.009) in ASD compared to TD children. Interestingly, HRV analysis showed a more important inner variability among ASD children suggesting lower vagal control.

#### Conclusions:

We observed that ASD is associated with abnormal parasympathetic and sympathetic mechanisms involved in ANS regulation at rest in childhood. Lower cardiac vagal regulation and faster heartbeat as assessed in our ASD group may indicate a low level of arousal at rest (a low ANS tonus) and an impaired vagal control that could be associated with deficits in behavioral and psychological features of the social engagement system.

**435.006 (Poster)** Measurement of Sympathetically Driven Autonomic Arousal during Eye Contact in Children with and without an Autism Diagnosis

*N. Daniels<sup>1,2</sup>, M. Moerkerke<sup>2,3</sup>, J. Prinsen<sup>1,2</sup>, B. Boets<sup>3,4</sup>, J. Steyaert<sup>2,3</sup> and K. Alaerts<sup>1,2</sup>, (1)Rehabilitation Sciences, KU Leuven, Leuven, Belgium, (2)Leuven Autism Research Consortium (LAuRes), Leuven, Belgium, (3)Center for Developmental Psychiatry, KU Leuven, Leuven, Belgium, (4)Leuven Autism Research Consortium (LAuRes), KU Leuven, Leuven, Belgium*

---

#### Background:

Autism spectrum disorder (ASD) is a prevalent neurodevelopmental condition, characterized by difficulties in the social domain and repetitive and restricted behaviors. In recent years, there has been an increased interest in identifying the role of aberrant stress regulation and anxiety in ASD and emerging reports have shown a link between aberrant functioning of the autonomic nervous system (ANS), a central component of the physiological stress system, and ASD. Previous studies have demonstrated for example, aberrant sympathetically driven autonomic arousal responses upon the presentation of eye contact with a live interacting model.

#### Objectives:

The current study aimed to further investigate the impact of live dyadic eye contact on autonomic arousal responses in children with ASD.

## Methods:

Recordings of skin conductance responses (SCR) were performed while the children were presented with a live model facing them either with a direct eye gaze or with closed eyes. An assessment was made of both the absolute SCR amplitude, which is the maximum change in skin conductance relative to baseline after the onset of the (eye contact) event, as well as the half-recovery time (50%) of recorded skin conductance responses, defined as the time elapsed between the SCR peak amplitude and the decline back to 50% of the amplitude.

## Results:

Within a preliminary sample of 21 children with ASD (8-12 years) and 8 control children (without a diagnosis of ASD), no group-related differences were revealed in overall amplitude of the SCR arousal response (SCR amplitude) ( $p > 0.05$ ). In terms of SCR half-recovery time, it was shown that only in the control group, not in the ASD group, a condition effect of eye contact was present, indicating faster recovery upon the eyes closed, compared to the direct eye contact condition. No such modulation was evident in the ASD group (condition  $\times$  group:  $F(1,22) = 5.13, p = .03, \eta^2 = .19$ ).

## Conclusions:

Together, these findings indicate that typical condition-related modulations of autonomic arousal upon live eye contact are absent in children with ASD, further highlighting a role of aberrant autonomic nervous system functioning in ASD. Future directions include an investigation of the impact of intranasal administration of oxytocin on these processes, considering the implicated role of oxytocin in balancing ANS function.

### **435.007** (Poster) Measures of Tonic and Phasic Activity of the Locus Coeruleus – Norepinephrine System in Children with Autism Spectrum Disorder

**Y. Kim<sup>1</sup>**, **G. Kadlaskar<sup>2</sup>**, **S. Bergmann<sup>1</sup>** and **B. Keehn<sup>1</sup>**, (1)Speech, Language, and Hearing Sciences, Purdue University, West Lafayette, IN, (2)Department of Psychiatry & Behavioral Sciences, University of California, Davis, MIND Institute, Sacramento, CA

---

**Background:** The locus coeruleus-norepinephrine (LC-NE) system plays a critical role in arousal regulation and selective attention. A growing body of research suggests that this system may function differently in individuals with autism spectrum disorder (ASD). For example, indirect psychophysiological measurements of the LC-NE system, including pupil diameter and the event-related potential (ERP) P3 component may be atypical in ASD. Thus, understanding the dynamics of both tonic (resting pupil size) and phasic (pupil dilation and P3) indices may provide meaningful insights about how the LC-NE system may function differently in ASD.

**Objectives:** To examine tonic and phasic LC-NE activities, and to determine the association between these measures in children with ASD.

**Methods:** Participants included 24 children with ASD and 27 age- and nonverbal-IQ matched typically developing (TD) children. The study included two experiments: 1) a baseline eye-tracking task to measure resting, tonic pupil diameter, and 2) a three-stimulus oddball paradigm to measure P3 amplitude and phasic changes in pupil size. For the baseline task, participants were asked to relax, remain still, and look at a black central crosshair, which was displayed on a grey background. For the oddball paradigm, isoluminant stimuli (small circle = standard [76% of trials]; large circle = target [12%]; square = novel [12%]) were presented on a gray background. Participants were instructed to respond via a button press when a large circle was presented. Pupil diameter was monitored using an EyeLink 1000 Plus remote eye-tracking system and EEG was recorded using a 128-channel high-density Geodesic electrode array.

**Results:** For the baseline eye-tracking paradigm, children with ASD showed significantly increased pupil diameter compared to their TD peers ( $p < .05$ ). For the oddball task, phasic changes in pupil dilation to standard stimuli was significantly increased in children with ASD ( $p < .01$ ), whereas pupil dilation to oddball stimuli was decreased ( $p < .05$ ) compared to their TD peers. The mean amplitude of the P3 component (400-600ms) peaked at the posterior region of interest (ROI) but did not differ between ASD and TD groups ( $p = 0.054$ ). However, the re-orienting negativity (RON) found in the frontal ROI (400-600ms) was significantly decreased in children with ASD ( $p < .05$ ). For both groups, the relationship between tonic and phasic indices showed that reduced pupil dilation to oddball stimuli was correlated with increased baseline pupil size ( $r = -.35, p < .05$ ). Analysis among phasic indices found that greater RON amplitude was associated with larger pupil dilation to oddball stimuli ( $r = -.39, p < .01$ ) and smaller pupil dilation to standard stimuli ( $r = .42, p < .01$ ) across the group.

Conclusions: Consistent with prior reports, our results show that children with ASD exhibit increased tonic (pupil) and reduced phasic (P3 and pupil dilation) activation of the LC-NE system. Across both groups, atypically elevated tonic activation of the LC-NE system was associated with reduced phasic responsiveness. These findings expand our understanding of neurophysiological differences present in ASD, and suggest that aberrant LC-NE activation may be associated with atypical arousal and decreased responsivity to behaviorally-relevant information in ASD.

**435.008** (Poster) Obtaining Valid ERP Data: Implementing a Single Session Behavioral Protocol for Valid EEG Data Collection  
**C. J. Black<sup>1</sup>, M. Guy<sup>2</sup>, A. L. Hogan<sup>1</sup>, R. E. Coyle<sup>1</sup>, J. E. Richards<sup>4</sup> and J. Roberts<sup>1</sup>,** (1)Department of Psychology, University of South Carolina, Columbia, SC, (2)Loyola University Chicago, Chicago, IL, (3)Psychology, USC Neurodevelopmental Disorders Lab, Columbia, SC, (4)University of South Carolina, Columbia, SC

---

#### Background:

Event-related potentials (ERPs) measure the timing and nature of neural responses and can be used with a range of participants including individuals with autism spectrum disorder (ASD). However, due to the perceived difficulty of acquiring ERP data, research has often excluded preschool-aged children with ASD with lower cognitive functioning and significant comorbid disorders. Previous researchers addressed this issue through multiple desensitization sessions completed before data acquisition, which are not always feasible. We have developed an intensive behavioral support protocol to increase feasibility of successful data collection within a single ERP session. Before the child arrives at the laboratory, a research assistant conducts a semi-structured interview to assess the child's readiness for data collection. After interview completion, we send a bathing cap to practice applying in the bathtub. This may prepare the child for the EEG net, which is soaked in an electrolyte solution before application. When the child enters the lab, a visual schedule and social story is presented to the child by a trained research assistant. Predesignated reinforcers are provided throughout the experiment to promote engagement (e.g., breaks, chocolate). This protocol has led to successful ERP data collection across children with ASD and other neurodevelopmental disorders (NDDs), including fragile X syndrome and Down syndrome.

#### Objectives:

The objective of the current study was to examine clinical characteristics that may have contributed to the success of ERP experiment completion. This work aims to promote representation of lower-functioning children with NDDs in neuroscience research and emphasize the need for continued development of ERP methods that support inclusion of diverse, representative samples.

#### Methods:

Participants with NDDs and typical development were recruited for an ERP experiment on face processing, as part of a larger longitudinal study on the development of ASD. The collection of ERP data was attempted in 125 participants ranging from 35 to 108 months of age ( $M=62.58$  months,  $SD=17.00$ ). Independent samples t-test were calculated to examine clinical measures that may influence data collection, including: 1) T-scores from The Child Behavior Checklist as a measure of anxiety and attention deficit hyperactivity disorder (ADHD); 2) the Clinical Severity Score (CSS) from the Autism Diagnostic Observation Schedule-Second Edition as a measure of ASD impairment; 3) the Sensory Experiences Questionnaire total score as a measure of sensory sensitivity; 4) the Early Learning Composite from the Mullen as a measure of cognitive ability.

#### Results:

ERP data was successfully collected from 69% of the sample demonstrating validity in comparison to other studies utilizing a longer behavioral protocol. As seen in Table 1, participants successfully completing the experiment scored lower on measures of ASD impairment, ADHD symptoms, and sensory sensitivity. Anxiety symptoms and cognitive ability were not associated with successful experiment completion.

#### Conclusions:

The results of the current study demonstrate that clinical characteristics were significantly associated with successful ERP data acquisition. Specifically, greater ADHD symptoms, autism severity, and sensory sensitivity may have inhibited valid data acquisition. Alteration to the current protocol should be considered and implemented in future work to promote broader success in ERP experiment completion.

**435.009** (Poster) Phase-Amplitude Coupling in Autism Spectrum Disorder: Results from the Autism Biomarkers Consortium for Clinical Trials (ABC-CT)

---

**Background:** Electrical activity recorded from neuron populations in the brain oscillates at distinct frequencies and can be recorded from the scalp using electroencephalography (EEG). Phase-amplitude coupling (PAC) describes how these neural populations interact by measuring the modulation of high frequency activity amplitude by low frequency activity phase. The topography and phase bias (i.e., phase of the low frequency oscillation at which high frequency activity has the highest amplitude) of PAC can give insight into the feedforward and feedback information flow in resting-state network dynamics. Given the hypotheses that imbalances in excitatory/inhibitory and/or feedforward/feedback activity occur in autism spectrum disorder (ASD), we speculate that coupling characteristics (in terms of PAC strength, phase bias, and spatial location) between high and low frequencies may be a useful brain-based biomarker of ASD.

**Objectives:** We evaluate differences in PAC metrics of resting-state brain dynamics between children with and without ASD.

**Methods:** We draw from data collected by the multi-site Autism Biomarkers Consortium – Clinical Trials (ABC-CT), including high-quality data from 211 ASD and 104 typically-developing (TD) children aged 6-11 years old. We measure PAC from six 10-second EEG segments from each participant. PAC clustering was evaluated within diagnostic groups over all high and low frequency pairs in each of 18 electrodes spanning the surface of the scalp. We identify where significant PAC occurs in terms of frequency pairing and channel location, and we evaluate the low frequency phase in which the high frequency amplitude is most biased. We statistically compare groups in terms of PAC strength, phase bias, and topography.

**Results:** We found increased PAC in ASD, most notably in alpha-gamma coupling in frontal electrodes and beta-gamma coupling in temporal electrodes (Figure 1). Additionally, we found a decrease of phase bias (i.e. maximum gamma amplitude shifted towards the trough of the alpha wave) in frontal channels for participants with ASD. Alpha-gamma PAC strength in the in FP1 and FP2 electrodes was significantly and positively correlated with multiple domains of ASD behaviors as measured by the Social Responsiveness Scale Restricted and Repetitive Behaviors section and the Autism Diagnostic Observation Schedule (ADOS) Social Affect and Total scaled scores (all  $p < 0.05$ ).

**Conclusions:** The findings of increased PAC activity and atypical phase bias in ASD are shown here using a large, well-controlled sample with a thorough comparison of all potential frequency pairs and electrodes where PAC can occur, using clustering techniques to limit spurious findings. Prior studies suggest a mechanistic link between phase bias and circuit-level mechanisms that are likely to be altered in ASD (e.g. balance between bottom-up (feedforward) and top-down (feedback) activity in the cortex); our findings therefore offer opportunities for back-translation into animal models. Overall, these findings hold strong potential to inform brain-based biomarker development.

**435.010** (Poster) Relating ASD Traits and Sensory Overresponsivity to Early Electrophysiological Indices of Auditory Processing in Children with and without ASD.

---

**Background:**

DSM-V criteria of autism spectrum disorder (ASD) includes for the first time a focus on sensory differences (e.g., sensory hypersensitivity). While research suggests that sensory hypersensitivity is common in ASD, there is also mounting evidence that perception, the interpretation of sensory stimuli, is often better among those with ASD. We sought to disentangle the complex relationship between sensation and sensory differences in ASD by studying brain signatures that remain as close as possible, temporally, to the sensory input being processed. Here we measure auditory habituation and discrimination in the first 125ms of processing in addition to the more traditional mismatch negativity (MMN), and map these onto sensory features and autistic traits in both autistic and typical populations.

## Objectives:

We sought to identify differences between ASD and TD children in habituation and early and late discrimination and determine how these neurophysiological indices correlate with ASD traits and sensory overresponsivity. We then investigated how early and later neural indices of discrimination are correlated across and between groups.

## Methods:

Thirteen children with ADOS-2 and ADI-R confirmed ASD and 13 TD children matched on chronological age (TD  $M = 12.53$ ; ASD  $M = 12.81$ ) and nonverbal IQ (TD  $M = 109.46$ ; ASD  $M = 110.00$ ) participated in this study. The P1 and MMN were evoked by pure tones of 1000Hz and 1200Hz at 60 dB during a passive oddball task. ERPs were measured as the mean amplitude 50ms around the component's peak latency (P1: 71-121ms; MMN: 126-226ms). Habituation was measured by the difference of the response to standard auditory stimuli over consecutive repetitions, and discrimination by the difference between standard and deviant waveforms. ASD traits were measured by the Autism Quotient and sensory overresponsivity was measured from items on the Sensory Profile.

## Results:

At the early P1, children with ASD had marginally better discrimination ( $T = 1.76, p = 0.09$ ) and less habituation ( $T = 2.76, p = 0.01$ ). Higher ASD traits correlated with marginally better P1 discrimination ( $r = -0.38, p = 0.06$ ), better MMN discrimination ( $r = -0.49, p = 0.01$ ), and less P1 habituation ( $r = -0.38, p = 0.05$ ). Only late MMN discrimination (not early P1 perceptual indices) correlated with more sensory overresponsivity ( $r = -0.49, p = 0.01$ ). This correlation was driven by ASD participants ( $r = -0.67, p = 0.02$ ) and was nonsignificant for TD participants. Early P1 and late MMN discrimination were positively correlated ( $r = 0.64, p < 0.001$ ) especially for TD participants ( $r = 0.82, p = 0.001$ ), and only marginally for ASD participants ( $r = 0.49, p = 0.09$ ).

## Conclusions:

Results suggest that children who have better auditory discrimination at the MMN have more ASD traits and more sensory overresponsivity. Children with ASD also have marginally better early discrimination, with less habituation. While early and late discrimination are highly linked in TD children, they are only marginally correlated in ASD. These data support findings low-level perception operates more independently in autistic cognition than in typical development.

### **435.011** (Poster) Respiratory Sinus Arrhythmia and Sleep Problems Among Children on the Autism Spectrum

**H. K. Schiltz<sup>1</sup>, R. M. Fenning<sup>2</sup>, S. A. Erath<sup>3</sup> and J. K. Baker<sup>4</sup>,** (1)Psychology, Marquette University, Milwaukee, WI, (2)Center for Autism, Child and Adolescent Studies, California State University, Fullerton, Fullerton, CA, (3)Human Development and Family Studies, Auburn University, Auburn, AL, (4)Center for Autism; Dept. of Child & Adolescent Studies, California State University, Fullerton, Fullerton, CA

**Background:** A biopsychosocial framework of sleep problems in autism highlights complex interrelations between sleep and bioregulatory systems (Schreck & Richdale, 2020). Little empirical work, however, has explored physiological indices related to sleep among children on the autism spectrum, a group at considerable risk for sleep problems (Díaz-Román et al., 2018). Respiratory sinus arrhythmia (RSA), an index of parasympathetic nervous system activity, has been linked with sleep quality, but not duration, among neurotypical children. Whereas higher baseline RSA (RSAB) is a robust physiological marker of emotion regulation that should support sleep, the effect of RSAB may depend on RSA reactivity (RSAR) to stress (i.e., withdrawal of parasympathetic activity, or RSA withdrawal; El-Sheikh et al., 2013). No studies have explored RSAR nor the interaction between RSAB and RSAR as related to sleep in children on the autism spectrum.

**Objectives:** Among a sample of children on the autism spectrum, the current study explored RSAB, RSAR, and the interaction between RSAB and RSAR in relation to sleep problems and duration.

**Methods:** The sample included sixty-one children (Age  $M=7.95, SD=1.47$ ; 26% female) with community diagnoses of autism spectrum disorder (ASD) confirmed by clinical best estimate procedures involving the ADOS-2. Estimated IQ ranged from 47 to 121 ( $M=80.35; SD=20.36$ ; 39%  $\leq 75$ ). RSA data was collected via a 3-minute baseline and a 3-minute challenge task. Sleep problems and duration were measured using the Children's Sleep Habits Questionnaire, Abbreviated (NICHD SECCYD-Wisconsin, 2017). A neurotypical sample ( $N=23$ ; Age  $M=5.73, SD=1.63$ ; 35% female) was used to contextualize the degree of sleep problems in the children with ASD.

Results: No significant correlations emerged between RSA indices and sleep. Age was significantly negatively related to sleep problems,  $r(60)=-0.32, p<0.05$ , and was controlled in subsequent analyses. RSAB and RSAR interacted in the prediction of sleep problems (Table 1). For children with high RSAR, there was a significant inverse effect of RSAB on sleep problems,  $B=-5.00, p=0.04$ ; for children with low RSAR, the association between RSAB and sleep problems was nonsignificant,  $B=2.67, p=0.15$  (Figure 1). No main effects or interactions of RSA predicted sleep duration. The sample with ASD ( $M=26.98, SD=11.89$ ) had significantly more sleep problems than neurotypical sample ( $M=18.13, SD=8.07$ ),  $t(66)=3.20, p<0.01$ .

Conclusions: This study extended evidence from neurotypical development (El-Sheik et al., 2013) to show that RSAB and RSAR interacted to predict sleep problems (but not duration) in children with ASD. At lower levels of RSA withdrawal in response to stress, baseline RSA may be less consequential for sleep due to the limited range of arousal in response to stress. In contrast, at higher levels of RSA withdrawal in response to stress, moderate arousal that is compatible with sleep may be preserved when RSA is generally higher, whereas hyperarousal that disrupts sleep may ensue when RSA is generally lower. Contrasts with the comparison sample suggest potential resilience against sleep problems for children with ASD who exhibit high RSAB and high RSAR. Future longitudinal research may help to clarify the directionality of these effects across time.

**435.012 (Poster)** rTMS to the Superior Temporal Sulcus Modulates EEG Theta Power in Occipital Cortex in Autism Spectrum Disorder

**C. J. Stevens, A. Naples, D. A. Trevisan, M. Zhou, C. Carlos, E. Cummings, J. M. Wolf and J. McPartland, Child Study Center, Yale University School of Medicine, New Haven, CT**

---

Background: Atypicalities in visual processing, specifically in facial processing, are well-documented in individuals with autism spectrum disorder (ASD). Prior work has revealed associations between impairments in facial recognition and evoked power in several electroencephalographic (EEG) spectral bands (Martinez et al., 2019; Rojas & Wilson, 2015). Transcranial magnetic stimulation (TMS) to the dorsolateral prefrontal cortex modulated gamma activity in individuals with ASD in a visual perception paradigm (Casanova, Sokhadze, Casanova, & Li, 2020); Given the relevance of the right posterior superior temporal sulcus (rpSTS) in atypical face and social perception in ASD, the effects of TMS to this region on EEG signatures and visual attention warrant investigation.

Objectives: To evaluate modulatory effects of TMS to the rpSTS on EEG power spectra while viewing social and nonsocial stimuli in adults with and without ASD.

Methods: The preliminary sample included five individuals with ASD (1 female, mean age = 27.96) and nine controls (8 females, mean age = 29.22); data collection is ongoing. Intermittent theta burst stimulation (iTBS) was conducted using the Magstim Super Rapid system with four booster modules (Magstim Ltd, Whitland, Wales). Right pSTS was targeted based on its primary role in social cognition in ASD (Ozonoff & Miller, 1996; Zilbovicius et al., 2006); stimulation site was determined by anatomical estimates based on the 10-20 EEG coordinate system. EEG was recorded using a MicroCel 128-channel sensor net while participants passively viewed faces and houses. Spectral power was averaged across all epochs for each stimulus type. Theta (4-8 Hz), alpha (8-12Hz), beta (12-30Hz), low gamma (30-50Hz), and high gamma (70-90Hz) power were examined across stimulus types in EEG recordings before and after iTBS administration. Power data were logarithmically transformed, examined via repeated measures ANOVA, and corrected for multiple comparisons. Regions of interest included right parietooccipital cortex (P8, site of stimulation) and occipital cortex (O2, OZ, O1).

Results: Main effects emerged in occipital cortex. At OZ, a stimulation by diagnosis interaction in theta power was observed, such that theta power in participants with ASD increased from pre-TMS EEG to post-TMS EEG while remaining stable in controls,  $F(1,12)=14.14, p<.01$ . A similar interaction effect was found at O2, such that theta power increased after TMS administration in individuals with ASD but decreased marginally in controls,  $F(1,12)=6.38, p<.05$ . There were no significant changes in power for any of the spectral bands in the right parietooccipital cortex near TMS stimulation site in either group.

Conclusions: Results suggest that iTBS impacts theta power differently in ASD vs. TD. Continued research is needed to determine if results replicate in a larger sample, and, if so, why TMS impacts theta power differently in these respective groups. Although little is known about the functional significance of theta power in occipital regions, Dawson and colleagues (2012) found that in individuals with ASD receiving early intervention, greater theta power to faces was associated with better social communication. It is therefore possible that increases in theta power due to rTMS may index potential improvements in social communication in individuals with ASD.

**435.013 (Poster)** Sensory Correlates of Electrophysiological Responses to Repeated Auditory Stimuli in Activity-Dependent Neuroprotective Protein Syndrome

---

**Background:** ADNP syndrome is an autosomal dominant neurodevelopmental disorder caused by pathogenic variants in the activity dependent neuroprotective protein (ADNP) gene, involved in chromatin remodeling and synaptic function. ADNP syndrome is characterized by mild-to-severe intellectual disability, autism spectrum disorder (ASD), speech and motor delays, and medical comorbidities. Abnormal sensory processing is also prominent. ADNP syndrome is among the most common single gene causes of ASD, and ASD presents in 50-70% of cases.

**Objectives:** This study aimed to characterize neurobiological markers of ADNP by examining electrophysiological responses to repeated auditory stimuli. Additionally, we explored whether neural responsiveness and habituation related to clinical sensory symptoms.

**Methods:** EEG was recorded from children ages 3-17 with ADNP syndrome (n=16) and typically developing (TD) controls (n=16). Participants heard a series of four consecutive 50ms, 1000hz tones. Inter-tone interval was 616ms; inter-trial interval was 4000ms. Amplitudes and latencies of N1, P2, and N2 event-related potentials were extracted and compared between groups. Habituation was defined as the amplitude difference between tone one and two. Sensory symptoms (hyperreactivity, hyporeactivity, seeking behaviors) were assessed using the Sensory Assessment for Neurodevelopmental Disorders (SAND).

**Results:** In response to tone one, the ADNP group showed significantly longer latency than TD controls for P2 ( $M_{ADNP}=306\text{ms}$ ,  $SD_{ADNP}=42.5$ ;  $M_{TD}=265\text{ms}$ ,  $SD_{TD}=21.4$ ;  $p=.002$ ) and N2 ( $M_{ADNP}=440\text{ms}$ ,  $SD_{ADNP}=35.4$ ;  $M_{TD}=387\text{ms}$ ,  $SD_{TD}=39.1$ ;  $p<.001$ ) components, with large effect sizes ( $d=1.21$ ;  $d=1.42$ ; respectively). Compared to the TD group's average tone one P2 amplitude ( $M=4.40\text{mV}$ ,  $SD=2.47$ ) and P2 habituation ( $M=2.37\text{mV}$ ,  $SD=1.78$ ), the ADNP group showed a subset of participants with significantly higher P2 amplitudes (n=5;  $M_{High}=10.50\text{mV}$ ,  $SD_{High}=4.28$ ;  $p=.03$ ) and P2 habituation ( $M_{High}=8.19\text{mV}$ ,  $SD_{High}=4.77$ ;  $p=.05$ ), and a subset of participants with significantly lower P2 amplitudes (n=11;  $M_{Low}=2.25\text{mV}$ ,  $SD_{Low}=1.33$ ;  $p=.007$ ), with a trend toward lower P2 habituation ( $M_{Low}=1.39\text{mV}$ ,  $SD_{Low}=2.31$ ). When comparing SAND scores, ADNP most prominently differed from TD in seeking behaviors ( $p<.001$ ). Within the ADNP group, the attenuated P2 response subset trended toward more seeking behaviors than the enhanced P2 response subset ( $M_{Low}=20.54$ ,  $SD_{Low}=4.37$ ;  $M_{High}=14.60$ ,  $SD_{High}=6.50$ ), with a large effect size ( $d=1.07$ ). Seeking behaviors was also negatively correlated with tone one P2 amplitude ( $r=-.70$ ,  $p=.002$ ) and habituation ( $r=-.63$ ,  $p=.009$ ) across the full ADNP group.

**Conclusions:** Results suggest that electrophysiological responses in ADNP syndrome differ from controls. The ADNP group showed delayed auditory processing, specifically for later neural components, P2 and N2. The ADNP group also showed impaired sensory perception modulation, with subsets of participants showing either attenuated or enhanced P2 amplitudes and habituation compared to TD controls. Further research is necessary in order to determine factors underlying these differences in stimulus response profiles within ADNP syndrome. While the sensory profile of ADNP syndrome is still being explored, seeking behaviors are most notable, and their increased use among those with lower P2 response and habituation indicates that altered auditory processing may relate to sensory seeking behaviors. In fact, these results suggest that sensory seeking may be a compensatory function used by children with low response to external sensory stimuli to make sense of their environments.

---

**Background:** Multiple candidate electroencephalogram (EEG) and eye tracking (ET) biomarkers have been put forward for use in understanding the development and trajectory of symptoms in individuals with autism spectrum disorder (ASD)(e.g., Ewen et al.,

2019; McPartland et al., 2020). These markers may be useful in clinical trials as stratification markers that identify more homogeneous subgroups (McPartland et al., 2020). We focus on two variables derived from EEG and ET assays used in the Autism Biomarkers Consortium for Clinical Trials (ABC-CT): N170 latency to upright faces (N170L) and the Oculomotor index of gaze to human faces (OMI). Evidence suggests that children with ASD show longer latencies for the N170L compared to typically developing (TD) children, indicating slower processing of faces (Kang et al., 2018). The OMI was developed by the ABC-CT (McPartland et al., 2020) to quantify visual attention to faces across three ET assays. Lower OMI scores reflect diminished attention to human faces.

**Objectives:** The aim of this project is to evaluate the potential of N170L and the OMI as stratification biomarkers.

**Methods:** The ABC-CT is a NIH funded study that evaluated candidate biomarkers in children with ASD (n=280) and TD (n=119) at three timepoints (McPartland et al., 2020; Webb et al., 2019). For OMI and for N170L, thresholds were compared when constructed based on the outlying 10% of the TD control group at baseline and on the outlying 25% of the ASD group at baseline. Because of a clear age-based effect in N170L, we considered thresholds for the variables adjusted for age. ASD and TD participants who fell outside of the threshold at baseline were assessed for clinical correlates and for consistency of stratification variables across timepoints.

**Results:** (1) OMI: Although age is also significantly associated with OMI ( $p < .001$ ), it appears to be less crucial to consider an age-adjustment with OMI. Without an age-adjustment, a cut-off of the lower 10% of the OMI in the TD group, corresponding to participants spending 22% or less time looking at faces, includes approximately 40% of the OMI scores in the ASD group (Figure 1). (2) N170L: Age was significantly associated with N170L ( $p < .001$ ). In contrast to the OMI, a cut-off of the upper 10% of age-adjusted N170L in the TD group includes a much smaller number of ASD participants (22.1% of the age-adjusted N170L in the ASD group). A single value cutoff is less informative for the N170L, as the cutoff will be age-adjusted. Results on within-subjects variability across timepoints and results on clinical correlates of the subgroups defined by the cut-offs will be described in the presentation.

**Conclusions:** OMI shows promise as a stratification biomarker for autism research. Further study is required to evaluate the utility of the N170L as a stratification biomarker. Initial results from this dataset indicate that age-based adjustments will be necessary. Discussion of the impact of age adjustment on creation of biomarkers for use in clinical trials will be included in the presentation.

**435.015 (Poster)** The Relationship between Resting EEG Frontal Theta Power, Eye-Blink-Rates, and Restrictive and Repetitive Behaviors in Children with Autism Spectrum Disorder: Results from the ABC-CT

**L. Pisani<sup>1</sup>, A. Naples<sup>1</sup>, K. Chawarska<sup>1</sup>, G. Dawson<sup>2</sup>, R. A. Bernier<sup>3</sup>, N. M. Kleinhans<sup>4</sup>, S. Jeste<sup>5</sup>, C. A. Nelson<sup>6</sup>, J. Dziura<sup>7</sup>, S. J. Webb<sup>3</sup>, C. Sugar<sup>8</sup>, F. Shic<sup>8</sup>, H. Seow<sup>7</sup> and J. McPartland<sup>1</sup>,** (1)Child Study Center, Yale University School of Medicine, New Haven, CT, (2)Department of Psychiatry and Behavioral Sciences, Duke Center for Autism and Brain Development, Durham, NC, (3)Psychiatry and Behavioral Sciences, University of Washington, Seattle, WA, (4)University of Washington, Seattle, WA, (5)University of California, Los Angeles, Los Angeles, CA, (6)Developmental Medicine, Boston Children's Hospital, Boston, MA, (7)Yale University, New Haven, CT, (8)Center for Child Health, Behavior and Development, Seattle Children's Research Institute, Seattle, WA

**Background:** Poor performance on dopamine-mediated cognitive tasks (e.g., inhibitory control) is associated with lower frontal theta activity, measured by electroencephalography (EEG), and decreased dopamine levels are indexed by reduced eye-blink-rates (EBRs). Hornung et al. (2019) found reduced resting theta power and EBRs in males with ASD, which were further associated with greater ASD symptomology, suggesting the potential influence of atypical dopamine levels on the clinical phenotype. The relationship between dopamine levels, as indexed by theta power and EBR, and restricted and repetitive behaviors (RRBs) in ASD is poorly understood, despite the recognized influence of dopamine-related inhibitory control deficits on RRB severity.

**Objectives:** Compare (1) absolute resting frontal theta power and (2) EBRs in children with ASD and healthy-controls to evaluate (3) whether EEG or EBR-based indices of dopaminergic function explain variance in RRBs.

**Methods:** This study used data from the Autism Biomarkers Consortium for Clinical Trials (ABC-CT). Participants included 280 children with ASD (215 males; age  $M=8.55 \pm 1.65$ ; FSIQ  $M=96.58 \pm 18.11$ ) and 119 typically developing (TD) controls (83 males; age  $M=8.51 \pm 1.61$ ; FSIQ  $M=115.12 \pm 12.55$ ). Participants were administered the ADOS-2, ADI-R, and DAS-2. The SRS-2 was used to examine ASD symptomology, specifically RRBs. EEG recorded absolute resting theta power was extracted from the midline frontal electrode (Fz). EBR was obtained from eye-tracking collected during viewing of paradigms assessing attention and social information: activity monitoring (AM), biological motion (BM), interactive social task (SI), static scenes (SS), and

visual search (VS). Independent samples t-tests were used to compare group means of EBRs, theta power, and SRS-2 scores, and linear regression analyses were performed to examine the relationships between these variables.

**Results:** There were no significant differences in theta power between diagnostic groups. Children with ASD had significantly higher EBRs only during the SI paradigm compared to TD ( $t(197)=4.93, p<.001$ ). No significant relationships were found between theta power or EBRs and RRBs in ASD. There was a significant group-by-sex interaction for predicting theta power ( $F(1,323)=4.69, p=.031$ ), such that males had significantly lower theta power compared to females in ASD; this was not observed in TD children. Furthermore, males with ASD had significantly lower theta power compared to TD males ( $t(174)=-2.53, p=.012$ ); this relationship was not significant in females. There was also a significant EBR-by-sex interaction for predicting RRBs during the SI paradigm in ASD ( $F(1,253)=7.18, p=.008$ ), where lower EBRs were associated with higher RRBs in females with ASD, but not males.

**Conclusions:** Consistent with previous findings, males with ASD had reduced absolute resting frontal theta power. However, this difference was not observed in females, suggesting there are sex-specific differences in frontal theta within ASD. EBRs were elevated in ASD during viewing of a social interaction, which may be indicative of increased dopamine activity during this specific stimulus. However, further research should also examine levels of attention which may impact dopamine. While theta power was not associated with RRBs, EBRs were only predictive of RRB scores in females with ASD, again suggesting the need for further exploration of sex differences in both neural activity and behavior within ASD.

## POSTER SESSION — NEUROPSYCHOLOGY

### Poster 436 - Neuropsychology Posters

**436.002** (Poster) Executive Functioning Skills in Early Childhood: Comparing Children with ASD, ID, and Co-Occurring ASD and ID

*M. E. Golson<sup>1</sup>, M. McClain Verdoes<sup>1</sup> and L. E. Murphy<sup>2</sup>, (1)Psychology, Utah State University, Logan, UT, (2)Psychiatry, Boling Center for Disabilities, Memphis, TN*

#### Background:

Executive functioning (EF) is broadly defined as higher-order cognitive abilities to facilitate independent and goal-directed behaviors (Lezak et al., 2012). Specific EF skills frequently include working memory, inhibition, cognitive flexibility, planning and organization, and attention. EF skills are important to academic, adaptive, and social success (e.g., Moriguchi, 2014). These skills develop rapidly in early childhood (Blair, 2016) and are linked to early school readiness (Vitiello & Greenfield, 2017).

Approximately 30% of children with autism spectrum disorder (ASD) have an intellectual disability (ID; American Psychiatric Association, 2013). Many children with ASD, ID, and co-occurring ASD/ID experience EF deficits. However, there is minimal research on EF skills in early childhood for these populations. The majority of the existing research is over a decade old and generally indicate early childhood children with ASD exhibit poorer EF skills than children with other developmental delays (Griffith et al., 1999). Research regarding EF skills in children with ID and ASD/ID is limited to individuals who are school-aged and older. Given the importance of EF skills to daily functioning, additional research is needed to understand their development and presentation in early childhood for children with ASD, ID, and ASD/ID.

#### Objectives:

This research evaluated parent-reported EF skills among children in early childhood with ASD, ID, and ASD/ID.

#### Methods:

Participants included 87 children between the ages of 24 and 71 months diagnosed with ASD ( $n=24$ ), ID ( $n=23$ ), or co-occurring ASD/ID ( $n=40$ ) that had completed a comprehensive psychological evaluation at a university developmental clinic. Diagnoses were made by a psychology team that included a licensed psychologist following diagnostic caregiver interview, rating scale administration, performance-based assessments, and behavioral observations. Parent ratings of child EF skills on the Behavior Rating Inventory of Executive Function – Preschool Version (BRIEF-P) were evaluated using mixed analysis of variance (ANOVA) comparing diagnostic groups.

#### Results:

Participants overall exhibited clinically significant deficits in EF. Further, results suggest that early childhood children with ASD, ID, and ASD/ID may have somewhat unique EF skill profiles. Children with ID exhibited the most significant EF impairments and children with ASD displayed the least. Working memory deficits were the most impaired EF skill across all diagnostic groups.

#### Conclusions:

Early childhood children with ASD, ID, and ASD/ID demonstrate EF deficits. Our results tentatively suggest that EF skills in children with ASD, ID, and ASD/ID may present differently in early childhood as compared to school-age. Clinicians should consider assessing EF skills at initial evaluations and re-evaluations as children develop to ensure interventions and educational placements are appropriately designed. Further research is needed to evaluate longitudinal differences between early childhood and school-aged EF skills.

**436.003** (Poster) Neuropsychological Profiles of a Spanish Preterm and Very Low Birth Weight Children Cohort  
*M. Magan Maganto<sup>1</sup>, R. Canal-Bedia<sup>1</sup>, Á. Bejarano<sup>1</sup>, M. V. Martín Cilleros<sup>1</sup>, A. Hernández Fabián<sup>2</sup>, A. Calvarro-Castañeda<sup>1</sup>, J. A. Yon Hernández<sup>1</sup>, E. Díez Villoria<sup>1</sup>, H. Roeyers<sup>3</sup> and M. Posada<sup>4</sup>, (1)University of Salamanca, Salamanca, Spain, (2)Hospital Clínico Universitario de Salamanca, Salamanca, Spain, (3)Department of Experimental-Clinical and Health Psychology, Ghent University, Ghent, Belgium, (4)Institute of Rare Diseases Research, Instituto de Salud Carlos III, Madrid, Spain*

---

**Background:**

Children born preterm have a higher risk to develop neurodevelopmental disorders (Twilhaar et al., 2018), such as Autism Spectrum Disorder (ASD), with a prevalence of 7% (Agrawal et al., 2018) compared to <2% in the general population (CDC, 2020).

The study of neurodevelopmental trajectories and neuropsychological profiles of preterm children is essential to understand potential future difficulties they may face. A recent prospective study by Chen et al. (2020) describes early cognitive functioning trajectories in premature children and associates them with the later diagnosis of ASD. Although this contributes to ASD early detection in preterm children, neuropsychological trajectories and the difficulties encountered at different developmental ages are still lacking.

**Objectives:**

The objective was to explore the neuropsychological profiles of Spanish preterm children with very low birth weight (VLBW, <1500gr) in function of gestational age (GA) and growth percentiles (GP). This study focused on ASD symptomatology, cognitive development, executive functions and adaptive behavior.

**Methods:**

A total of 62 children born preterm with LBW participated in this research. Assessment evaluation, at 7-10 years old, consisted of the application of the following standardized tests: ADOS-2 module 3 (Lord et al., 2012) for ASD symptomatology; WISC-V (Wechsler, 2014) for cognitive development; ENFEN (Portellano et al., 2009) and BRIEF-2 (Gioia et al., 2015) for executive functions; and Vineland-3, parent version (Sparrow et al., 2016) for adaptive behavior.

Standardized index scores were compared to the general population with  $p < 0.01$ . The general indexes and sub-indexes of each instrument were also compared to GA and GP to evaluate associations using Kendall's tau-b ( $\tau_b$ ) with  $p < 0.01$ . Visual representations of the profiles were made for each instrument to better conceptualize the domains that were affected. This was done by converting the scores into standardized mean differences and grouping by GA and GP.

**Results:**

Scores in ADOS-2 showed a moderate association between GA and the Restricted and Repetitive Behaviour (RRB) domain ( $\tau_b = 0.34$ ), particularly "Unusual sensory interest in play material/person" ( $\tau_b = -0.31$ ) and "Excessive interest in unusual or highly specific topics/objects" ( $\tau_b = 0.28$ ).

The most affected scores in the WISC-V were Working Memory (median=94) and the Picture Span subtest (mean=8.66). A higher GP was also moderately associated with better Verbal Comprehension scores ( $\tau_b = 0.27$ ).

In the ENFEN, scores on the Phonological Fluency, Colour Making Trail and Planning subtests were lower than in the general population (median=5).

The raw scores of the BRIEF-2 were significantly associated with GP for Global Executive Composite (weak association;  $\tau_b = 0.22$ ), Emotion Regulation Index (moderate;  $\tau_b = -0.28$ ), Emotional Control (moderate;  $\tau_b = -0.28$ ) and Plan/Organize (weak;  $\tau_b = 0.23$ ).

In the Vineland-3, scores of Daily Living Skills (mean=89.18), Socialization (mean=92.94) and Motor Skills (median=92) domains were significantly lower than the general population.

## Conclusions:

The results of this study contribute to the description of neuropsychological profiles that could help to develop and design personalized preventive interventions that focus on the specific difficulties which are found in the preterm population. Particularly, it seems that preterm children are more affected in the RRB domain, which suggests further research on specific trajectories could differentiate between ASD and non-ASD preterm children.

**436.004 (Poster)** Proprioceptive Channel Bias during Postural Control in Young Adults with Autism Spectrum Disorder (ASD).  
**R. J. Knox and M. Dumas, School of Psychology, Queen's University Belfast, Belfast, United Kingdom**

---

## Background:

Postural control deficits in Autism Spectrum Disorder (ASD) are well established, yet their aetiology remains unclear. Postural control involves the integration of proprioceptive, visual and vestibular information. In neurotypical (NT) participants, proprioception contributes the most, followed by vestibular sense and vision least. However, when one sense is perturbed, for example when eyes are closed, resulting in vision loss, vision is down-weighted and the remaining senses up-weighted to maintain postural control. Evidence suggests adults with autism might weight these senses differently, relying less on vision and more on proprioception during balance tasks than NT. For instance, impaired postural control in adults with autism has been observed in response to proprioceptive, but not visual, perturbations and they may be less destabilised by visual perturbations than NT (Dumas et al., 2016; Greffou et al., 2012). However, due to a lack of research in this area, it is unclear how NT and ASD adults may differ in their ability to re-weight these senses during the minutes immediately following perturbation.

## Objectives:

The aim of this study was to investigate a bias for using proprioceptive over visual information for postural control in adults with autism. Accordingly, it compared how NT and ASD adults adapt to visual and proprioceptive perturbations.

## Methods:

16 young adults with ASD (age range: 16-40) with IQ>80 and 20 NT age, gender and IQ matched controls participated. Non-postural measures included an IQ test, sensory profile and ADOS-2 (for ASD group only). Postural assessments involved measurement of sway in response to three sensory conditions: visual perturbation (surround sway-referencing), proprioceptive perturbation (platform sway-referencing) and combined visual and proprioceptive perturbation. Participants stood unshod on a balance platform and sway was measured using motion capture. Each trial comprised a practice of the condition, 2 minutes of baseline gathering, 3 minutes of perturbation and a further 2 minutes without perturbation.

## Results:

Postural sway between groups did not differ at baseline. In response to the visual-only perturbation, NT, but not ASD adults, showed an increase in sway from baseline. Conversely, in response to the proprioceptive-only perturbation, ASD, but not NT adults increased their sway from baseline. Both groups showed the greatest increase in sway in response to the combined visual and proprioceptive perturbation, although there was no group difference in response magnitude. During the 3-minute adaptation period following perturbation, the ASD group showed consistently higher sway levels compared to the NT group, regardless of sensory condition.

## Conclusions:

Our results indicate increased reliance on proprioceptive and decreased reliance on visual information for postural control in ASD, as ASD participants were more affected by proprioceptive and less affected by visual perturbation than NT participants. The lack of group difference in sway from baseline to perturbation-onset in the combined condition suggests that these sensory-channel-specific group differences may be offset by one another. Finally, increased postural sway in the ASD group across the adaptation period of all sensory conditions suggested that adults with ASD found it more difficult than NT adults to adapt.

**436.005 (Poster)** Reduced Flexibility in Autism on an Unpredicted Emotional Flexibility Task

*A. Lacroix<sup>1</sup>, M. Gomoš<sup>2</sup>, A. Logemann<sup>3</sup>, C. Peyrin<sup>1</sup>, F. Dutheil<sup>1</sup>, B. Biro<sup>5,6</sup>, R. Cserjesi<sup>3</sup> and M. Mermillod<sup>1</sup>, (1)LPNC, Univ. Grenoble Alpes, Univ. Savoie Mont Blanc, CNRS, Grenoble, France, (2)UMR 1253, iBrain, Université de Tours, Inserm, Tours, France, (3)Institute of Psychology, ELTE Eötvös Loránd University, Budapest, Hungary, (4)Université Clermont Auvergne, CNRS, LaPSCo, CHU Clermont-Ferrand, WittyFit, Clermont-Ferrand, France, (5)Doctoral School of Psychology, Eotvos Lorand University, Budapest, Hungary, (6)Institute of Psychology, Eotvos Lorand University, Budapest, Hungary*

---

**Background:** Flexibility is the ability to switch from one task or from one perspective to another and is an adaptive skill usually required in unexpected situations. Autistic individuals encounter flexibility difficulties in the daily life, but laboratory tasks often fail to demonstrate them. A weak ecological validity of laboratory tasks, partly due to their predictability, could be responsible of this apparent contradiction.

**Objectives:** The aim of the study was to investigate whether autism is associated with difficulties in flexibility using an ecological valid shifting paradigm inducing unpredictable emotional shifts.

**Methods:** Our online study was completed by 101 autistic adults without intellectual deficiency (47 females) and 145 typically developed controls (85 females). Participants (18 - 45 years old) performed the Emotional Shifting Task, involving unpredictable switches of valence of sequentially presented socioemotional stimuli. They also performed the Task Switching Task (TST), involving predictable switches and letter/number stimuli.

**Results:** Autistic participants had a larger switch cost than control participants (i.e, lower correct response rate and longer response time in the shift but not in the non-shift condition) in the Emotional Shifting Task only ( $p < .001$ ). On the Task Switching Task autistic participants did not differ from control participants in their correct response rate but had longer response time in the shift and in the non-shift condition ( $p < .001$ ).

**Conclusions:** Our findings might suggest a critical role of unpredictability in flexibility difficulties in autism. However, there might be also a critical role of socio-emotional stimuli. Thus, we also discuss our results in the context of socio-emotional avoidance hypothesis and of the locally oriented perception hypothesis.

## Novel Therapeutic Approaches (gene, protein or RNA targeted therapies)

### PANEL DISCUSSION — NOVEL THERAPEUTIC APPROACHES (GENE, PROTEIN OR RNA TARGETED THERAPIES)

#### Panel 206 - Gene-Based Therapies in Development for Rett Syndrome

**Panel Chair:** Randall Carpenter, *Rett Syndrome Research Trust, Trumble, CT*

**Discussant:** Dominique Pichard, *International Rett Syndrome Foundation, Cincinnati, OH*

Rett Syndrome (RTT) is a developmental disorder characterized by loss of spoken language and hand use, and distinctive stereotypic hand movements. Typical RTT is almost exclusively caused by de novo loss of function mutations in the X-linked gene, *MECP2*. Mouse models deficient in *Mecp2* protein have a range of phenotypes that mimic the human syndrome. Mice with induced Rett Syndrome do not have evidence of neuronal death, suggesting that Rett syndrome is a neurodevelopmental condition as opposed to a neurodegenerative condition. Furthermore, genetic reactivation of silenced *Mecp2* in conditional knockout mice produces a robust and enduring reversal of phenotypes. The inherent reversibility of the mouse phenotypes makes restoration of *MECP2* protein an obvious therapeutic strategy for treatment of RTT. This session will provide an update on the molecular pathophysiology of RTT and significant progress with four genetically based therapeutic approaches – gene replacement, DNA editing, RNA editing and RNA transsplicing. The therapeutic presentations will review the scientific foundation for each approach, current status of development as well as advantages and disadvantages compared to the alternative therapeutic approaches.

**206.001** (*Panel Discussion*) Scientific Rationale for Restoring *MECP2* Protein As a Treatment for Rett Syndrome  
*M. J. Lyst, University of Edinburgh, Edinburgh, United Kingdom*

Rett syndrome (RTT) is a severe neurological disorder that is associated with intellectual disability and features of autism. RTT predominantly affects females, and arises due to loss-of-function mutations in the X-linked *MECP2* (methyl-CpG binding protein) gene. After decades of research, *MECP2* is now understood to be an abundant nuclear protein which functions predominantly in neurons. There, *MECP2* binds broadly across the genome by associating with DNA sequences containing methylated cytosine. *MECP2* then recruits the NCoR co-repressor complex and brings about subtle transcriptional down-regulation of thousands of genes. Aberrant regulation of gene expression is therefore thought to be an important component of the pathology of RTT. Despite this progress in our understanding of the molecular function of *MECP2*, the knowledge gained has not yet suggested a straightforward path towards the development of a therapy for RTT. Efforts to devise treatments for RTT have therefore focussed on strategies – such as gene therapy - which aim to directly restore expression of the *MECP2* protein, and that do not rely on understanding the molecular mechanism of action of *MECP2*. This work has accelerated greatly over the last decade, motivated by the observation that restoration of *MECP2* expression in adult mice – using conditional alleles of the gene - results in a dramatic reversal of the neurological symptoms associated with *MECP2* deficiency. However, obstacles still remain for the RTT gene therapy field. For example, the toxicity that would result if *MECP2* is expressed at too highly levels – as illustrated by the severity of the symptoms of *MECP2* duplication syndrome – must be avoided, whilst, at the same time, robust expression of *MECP2* in a high proportion of neurons must be achieved. There are many approaches aimed at solving such problems, and success would make RTT the first autism spectrum disorder to be treated by a therapy that is targeted at the underlying pathology.

**206.002** (*Panel Discussion*) An Innovative Regulated Gene Replacement Therapy Approach for Rett Syndrome  
*S. Prasad, Taysha Gene Therapies, San Francisco, CA*

#### **Background:**

Rett syndrome (RTT) is an X-linked neurodevelopmental disorder that can be caused by loss-of-function mutations in the dose-sensitive gene *MECP2*. RTT is characterized by a period of typical development followed by the onset of psychomotor regression, development of repetitive hand stereotypies, loss of verbal abilities, social withdrawal, and gait impairment. As a monogenic disease, development of gene replacement therapy has long been considered for RTT. However, due to random X inactivation, *MECP2* expression varies on a cell-by-cell basis. Thus, a gene replacement therapy approach is needed with flexible therapeutic gene expression within each cell, that addresses the deficiency of *MECP2*, but also, importantly, avoids harmful overexpression of *MECP2*. Our academic collaborators at UTSouthwestern have designed a proprietary method that enables

titration of therapeutic gene expression on a cell-by-cell basis. A regulatory element added to the untranslated region of the therapeutic gene harnesses endogenous microRNAs to titrate expression based on cellular *MECP2* protein levels. This technology is termed miRARE (microRNA-responsive autoregulatory element) (Sinnott 2017, 2020; Gadalla 2017). Taysha's approach leverages the clinically and commercially proven AAV9 vector platform, which has been widely characterized in preclinical and clinical studies, and now also in the commercial setting. Taysha utilizes a scaled manufacturing process in the HEK293 mammalian system across all our programs and the lumbar intrathecal route of administration. Taysha is currently developing a gene replacement therapy (TSHA-102) for RTT, which includes the miRARE technology that enables flexible and regulated gene expression.

#### **Objectives:**

The aim of this presentation is to introduce Taysha's approach to gene therapy development for rare neurological genetic diseases. The specific approach for gene replacement therapy development for RTT (TSHA-102) will also be presented.

#### **Methods:**

Broadly, the AAV9 vector platform has clinical precedent and a well-delineated biodistribution, safety, tolerability, and efficacy profile in the gene therapy field. Also, intrathecal delivery of AAV9-based gene therapies delivered through lumbar intrathecal injection has been shown to result in significant transduction across multiple cells within the CNS in preclinical studies and clinical experience with this route of administration is increasing. TSHA-102 has been tested in both wild-type and RTT knockout mice in order to assess safety and efficacy.

#### **Results:**

TSHA-102 demonstrated a favorable tolerability profile in wild-type mice, specifically exploring overexpression of *MECP2*, and increased survival in knockout mice. We plan to initiate the first-in-human phase 1/2 study for RTT, delivering TSHA-102 intrathecally at escalating doses. Safety and tolerability will be assessed and efficacy assessments spanning RTT symptomatology will be included.

#### **Conclusions:**

Due to the complexity of ensuring that *MECP2* expression occurs within strict physiological parameters, gene replacement therapy development for RTT has yet to enter clinical studies. Preclinical studies with TSHA-102 — a gene replacement therapy utilizing the miRARE regulatory element that allows for flexible expression of the therapeutic gene — demonstrated the potential for benefit of TSHA-102 as a treatment for RTT. Taysha plans for an IND or CTA submission for a first-in-human phase 1/2 study in the second half of 2021 and study initiation by the end of the year.

**206.003** (*Panel Discussion*) Development of RNA Editing As a Therapeutic Approach for Rett Syndrome  
**J. Sinnamoni, M. Jacobson and G. Mandel, Oregon Health & Science University, Portland, OR**

---

**Background:** RNA editing is a form of post-transcriptional regulation where specific RNA nucleotides are modified to produce a different sequence than what is encoded in the genome. In mammalian cells, the prominent form of RNA editing is the deamination of adenosine to form inosine by a family of enzymes known as adenosine deaminases acting on RNA (ADARs). Inosine is interpreted by the cellular machinery as guanosine, allowing RNA editing to have a wide range of important regulatory effects including changes in RNA splicing, miRNA biogenesis, and protein function. The potential for using the activity of ADARs to edit specific adenosines in a transcript to correct genetic mutations was first proposed 25 years ago, but only recently have specific approaches been developed for this purpose. We are testing RNA editing as a potential therapy in the context of Rett Syndrome, which is caused by loss-of-function mutations in the gene encoding the X-linked transcription factor, Methyl-CpG binding protein 2 (*MECP2*). Approximately 36% of Rett Syndrome mutations are potentially amenable to correction by RNA editing, and restoration of *MeCP2* expression has been shown by multiple groups to improve or even reverse the progression of Rett-like symptoms in mice.

**Objectives:** Our objective is to harness the RNA editing activity of ADAR enzymes to correct Rett Syndrome G>A mutations using two distinct but complementary approaches. 1) Using specially designed guide RNAs to recruit the endogenous enzymes, which are highly expressed in the nervous system. 2) Delivering engineered guide-directed enzymes containing the ADAR catalytic domain.

**Methods:** We have developed and characterized several mouse models and human neuronal cell lines containing Rett Syndrome patient mutations to test the different editing approaches. Endogenous ADARs can be recruited to edit specific mutations using guide RNAs that can be delivered either as modified anti-sense oligonucleotides or expressed from adeno-associated viruses (AAV). The engineered enzymes are expressed along with the appropriate guide RNAs using AAV and can be delivered either directly into specific brain regions or systemically.

**Results:** Using both *in vitro* and, most recently, *in vivo* models, we have shown that Rett Syndrome patient mutations can be edited efficiently in the brain and that repaired MeCP2 protein localizes to heterochromatin as wild-type. Editing rates as high as 50% can be achieved in multiple neuronal cell-types *in vivo* and the restoration of protein function correlates with the level of RNA repair.

**Conclusions:** RNA editing represents a promising therapeutic avenue for Rett Syndrome and offers distinct advantages over other approaches that rely on delivering MeCP2 at the correct physiological level. Ongoing studies will determine if sufficient levels of RNA editing can be achieved throughout the brain to prevent or reverse Rett-like symptoms in mice.

**206.004 (Panel Discussion) RNA Transsplicing Therapeutic Development for Rett Syndrome**  
**S. R. Cobb**, Centre for Discovery Brain Sciences, University of Edinburgh, Edinburgh, United Kingdom

Rett syndrome (RTT) is a severe neurological disorder resulting from loss-of-function mutations in the X-linked *MECP2* gene. A related but equally severe neurological disorder is *MECP2* duplication syndrome in which affected individuals express one or more extra copies of *MECP2*. The gene product encoded by *MECP2* is a nuclear localized protein that is especially abundant in neurons. Deletion of *MeCP2* in mice, either globally or exclusively in the nervous system, recapitulates the cardinal features of the disorder seen in patients. Conversely, genetic rescue experiments in mice have shown that profound neurological defects caused by lack of MeCP2 can be corrected if MeCP2 is subsequently made available. Spurred on by this work, several groups have gone on to develop gene therapy vectors to show an effect in ameliorating certain RTT-like dysfunction in mice. Whilst encouraging, these studies have also shown that excessive or ectopic expression of vector-derived MeCP2 can be detrimental both in peripheral tissues and in the nervous system. There is thus a barrier to clinical translation in the form of the ability to achieve widespread delivery of vector-derived *MECP2* throughout the brain whilst ensuring MeCP2 is expressed at appropriate levels in the appropriate cells. This is especially challenging given that most patients with RTT are females displaying X-linked mosaicism whereby only a proportion of the cells express the mutant *MECP2* allele and thus require gene restoration.

Trans-splicing therapy represents an attractive strategy to overcome many of these hurdles. The approach works by targeting between the *MECP2* gene and the MeCP2 protein at the level of RNA. Specifically, by hijacking a cell's natural RNA splicing machinery to join a therapeutic RNA trans-splicing molecule to 'healthy' parts of the endogenous gene, entire regions harbouring disease-causing mutations can effectively be 'bypassed'. By enabling the correction of entire chunks of *MECP2* sequence, any given therapeutic trans-splicing molecule would be effective across a significant proportion of the Rett patient population (>95%). This is distinct from other editing approaches which would necessitate developing interventions on a more patient specific basis. Since the RTM can only join the endogenous target that is already expressed at physiological levels, this approach would also restore MeCP2 levels towards normal without the possibility of elevating MeCP2 towards toxic thresholds.

## PANEL DISCUSSION — NOVEL THERAPEUTIC APPROACHES (GENE, PROTEIN OR RNA TARGETED THERAPIES)

### Panel 234 - Advances in Gene-Based Therapies in Neurodevelopmental Disorders

**Panel Chair: Mustafa Sahin**, Boston Children's Hospital/Harvard Medical School, Boston, MA

Due to advances in genetics and genomics, we now realize that autism spectrum disorder (ASD) has a strong genetic basis. There is a list of over 100 validated genes, variants in which are highly associated with autism. Meanwhile, gene based therapies have found their way into the central nervous system. Case in point is spinal muscular atrophy, for which three gene based treatments are now FDA-approved. The combination of these advances have brought us to the doorstep of an era where gene-based therapies for various causes associated with ASD are being developed and tested. This panel is aimed to inform the INSAR community about the opportunities and challenges in developing gene-based therapies for autism-related disorders. We will highlight four talks focusing on introducing genetic expression constructs into the brain and manipulating gene expression using anti-sense oligonucleotides.

**234.001 (Panel Discussion) Gene Therapy for Tuberous Sclerosis in Mouse Models**  
**X. Breakefield**, Massachusetts General Hospital, Boston, MA

We have created stochastic models of TSC1 and TSC2 in mice by injecting a vector encoding Cre recombinase into the brain ventricles of newborn pups which are homozygous for floxed loci of the equivalent mouse genes. This results in loss of function of the encoded proteins, hamartin and tuberlin, respectively in a subset of neural cell types in the brain. Such mice show neuropathologic abnormalities seen in TSC patients, develop hydrocephalus and epilepsy, and typically die at 1-2 months of age. Intravenous injection of adeno-associated virus (AAV) vectors encoding hamartin or a condensed form of tuberlin at three weeks of age extends the lifespan of these mice for over 300 days and normalizes some of the neuropathology. These AAV vectors deliver the gene to cells throughout the body and are able to cross the blood-brain barrier. They have been used clinically with benefit in other hereditary neurologic, metabolic and eye diseases. Studies are underway to evaluate biodistribution and potential toxicity of these “gene replacement” AAV vectors prior to consideration of clinical trials for TSC.

**234.002 (Panel Discussion) CRISPR Activation to Rescue SCN2A Haploinsufficiency in Autism Spectrum Disorder**

S. Tamura<sup>1</sup>, P. W. Spratt<sup>2</sup>, A. Nelson<sup>3</sup>, S. J. Sanders<sup>3</sup>, K. J. Bender<sup>4</sup> and N. Ahituv<sup>5</sup>, (1)Bioengineering and Therapeutic Sciences, UCSF, San Francisco, CA, (2)UCSF, San Francisco, CA, (3)Department of Psychiatry, Weill Institute for Neuroscience, UCSF School of Medicine, San Francisco, CA, (4)Department of Neurology, UCSF, San Francisco, CA, (5)UCSF, San Francisco, CA

---

**Background,** Loss-of-function (LoF) mutations that cause haploinsufficiency (having only one of two functional gene copies) in *SCN2A* are one of the most frequent causes of autism spectrum disorder (ASD). Individuals with *SCN2A* haploinsufficiency are often comorbid with intellectual disability and developmental delay.

**Objectives,** Here, we set out to use CRISPR activation (CRISPRa) to target the promoter of *SCN2A* and upregulate its expression to overcome *SCN2A* haploinsufficiency in mice and human ESC-differentiated excitatory neurons.

**Methods,** We optimized adeno-associated virus (AAV) CRISPRa conditions to upregulate *SCN2A* both in mice and human cell lines. We then optimized these conditions in mice and carried out electrophysiological phenotyping to analyze the degree of rescue following upregulation.

**Results,** We injected AAV CRISPRa into the medial prefrontal cortex of *Scn2a*<sup>+/−</sup> mice and observed a rescue of the associated heterozygous cellular deficits, including action potential firing speed and synaptic maturation. In human ESC-differentiated excitatory neurons, we are currently growing these cells to maturation and plan to treat with CRISPRa to functionally assess whether we can rescue their electrophysiological properties.

**Conclusions,** In summary, our project provides a potential therapeutic for one of the most significant causes of ASD and can also be adapted to treat other commonly observed haploinsufficient neurodevelopmental disorders.

**234.003 (Panel Discussion) Targeted Augmentation of Nuclear Gene Output (TANGO) Technology for Protein Upregulation**

I. Aznarez, Stoke Therapeutics, Bedford, MA

---

**Background:** TANGO is a novel technology which exploits antisense oligonucleotide (ASO)-mediated modulation of pre-mRNA splicing to increase protein expression. TANGO ASOs prevent naturally occurring non-productive events that lead to either transcript degradation by nonsense-mediated mRNA decay (NMD) or nuclear retention. This results in increased productive mRNA and full-length, fully functional protein. Using bioinformatic analyses of RNA sequencing datasets, we identified non-productive events in more than 50% of protein-coding genes, of which approximately 1,246 are disease-associated.

**Objectives:** To provide support for the TANGO concept and the broad applicability of the technology to address genetic diseases amenable to protein upregulation.

**Methods:** We selected targets representing various types of NMD-inducing, non-productive alternatively spliced (AS) events (cassette exons, alternative splice sites, and alternative introns), as well as gene functions and gene sizes. ASOs were designed to target the various events and screened using a combination of *in vitro*, *in vivo*, and efficacy studies in human cells, mice, and non-human primates (NHP).

**Results:** TANGO ASOs designed to target the three types of non-productive AS events led to dose-dependent reductions in non-productive mRNA and dose-dependent increases in both productive mRNA and protein levels *in vitro*. The *in vivo* effectiveness of upregulating protein through TANGO was demonstrated in Dravet Syndrome (DS), a developmental and epileptic encephalopathy caused by haploinsufficiency in which 25% of patients present with autism spectrum disorder (ASD). We employed the *Scn1a*<sup>tm1Kca</sup>, F1:129S-*Scn1a*<sup>+/-</sup> x C57BL/6J mouse model (DS mouse), which has been shown to recapitulate features of DS including seizures and sudden unexpected death. DS mice were administered a single dose of STK-001, an ASO that targets the *SCN1A* gene, via intracerebroventricular (ICV) injection. We show that STK-001 increases productive *Scn1a*

mRNA and restores Nav1.1 protein from 50% to near normal levels in the brain for up to 14 weeks. The restoration of Nav1.1 resulted in 76% of STK-001-treated mice being seizure-free versus 48% of placebo-treated mice with 80% reduction in the average number of spontaneous seizures in the STK-001 group measured by electroencephalography (EEG). Two dose levels of STK-001 were also evaluated in NHP via a single intrathecal lumbar bolus injection. Twenty-eight days post-injection, Nav1.1 was increased up to 3-fold in the high-dose group in regions of the cerebral cortex which are thought to be involved in disease pathology.

*Conclusions:* STK-001 has potential to provide a gene-specific, disease-modifying treatment to restore Nav1.1 to physiological levels and provide a therapeutic benefit. STK-001 is currently being evaluated in a Phase 1/2a clinical trial in patients with DS. Collectively, these data suggest that TANGO can be employed to upregulate a wide range of gene types, functions, and sizes to treat genetic diseases. As most monogenic causes of ASD are haploinsufficiencies, the TANGO technology is especially suited as a potential therapeutic approach.

**234.004** (*Panel Discussion*) From Impossible to Possible: A Personal Journey from Diagnosis through Drug Development for Angelman Syndrome.

*A. Berent, GeneTx Biotherapeutics, New York, NY; Foundation for Angelman Syndrome Therapeutics, New York, NY*

---

**Title:** From Impossible to Possible: A personal journey from diagnosis through drug development for Angelman syndrome.

**Speaker:**

Allyson Berent, DVM, DACVIM

New York, NY

Chief Operating Officer: GeneTx Biotherapeutics

Chief Science Officer: Foundation for Angelman Syndrome Therapeutics

Director: Angelman syndrome Biomarker and Outcome Measure Consortium (ABOM)

Director: International Angelman Syndrome Research Council (INSYNC)

Mother of Quincy: 6 year old beautiful little girl that needs more UBE3A

Veterinarian: Director of Interventional Endoscopy

In 2014 everything changed. The life of a successful veterinary specialist designing medical devices and enthralled in clinical research for animals came to a screeching halt. My little girl Quincy, 5.5 months old, was diagnosed with a random, rare, neurogenetic disorder called Angelman syndrome (AS). Through pure passion, scientific understanding, and medical education, I knew a treatment for this disorder was possible, with the understanding there was absolutely no approved therapeutics. After countless conference calls, scientific stalking, and a dream, I started my journey from becoming a fierce advocate, the Chief Science Officer of the largest non-governmental research funding foundation in AS in the world (FAST), to the co-founder and Chief Operating Officer of GeneTx Biotherapeutics, focused on developing an antisense oligonucleotide for the treatment of Angelman syndrome. The foundation funded an academic lab to develop this ASO and deeply understand the unique phenomenon associated with AS (imprinting). This funding resulted in the discovery of a unique genetic region that could be exploited, essentially turning on the gene missing in neurons of those with AS. It was at that time that the foundation decided to advance the development of this potential disease modifying therapeutic, recruit some of the most experienced experts in ASO drug development in the world, and drive the program for a first in human clinical trial. Through determination, supportive expertise, and amazing consultants, GeneTx completed IND enabling studies and launched a clinical trial for FIH in 2020. The vision and dedication of parents and loved ones drove this program, allowing the team to remain singularly focused on a population approximating 1:15,000.

## Other - Multiple Topic Areas

### PANEL DISCUSSION — OTHER - MULTIPLE TOPIC AREAS

#### Panel 220 - Mechanism in Autism Intervention – Identifying Active Ingredients and Developing Innovative Practice

**Panel Chair:** Jonathan Green, *University of Manchester, Manchester, United Kingdom of Great Britain and Northern Ireland*

**Discussant:** Connie Kasari, *University of California, Los Angeles, Los Angeles, CA*

The autism intervention field is characterised by many studies of bespoke interventions with often seemingly overlapping procedures, tested individually on often quite small samples. How can we bring together the positive elements from all this work to progress rigorously validated common interventions that can be used flexibly in different contexts? There are many putative candidates for ‘active ingredients’ of therapy in autism, but demonstrating their validity and specificity requires a mechanistic approach. There have been unfortunately few robust mechanism studies to date in autism intervention science. This symposium will aim to inspire more use of mechanism designs by showing how they can contribute to refining intervention process, contribute to progress by identifying common active elements across apparently different intervention models, and eventually developing effective modular elements for flexible use in different settings. Leaders in clinical science and trial methodology will discuss approaches to intervention for core autism symptoms and co-occurring mental health conditions across the age range; the potential but also challenges for identifying active ingredients and the pros and cons of implementing modular intervention.

**220.001 (Panel Discussion)** Challenges and Solutions for Assessing Treatment-Effect Mechanisms for Modular Interventions  
**R. Emsley**, *Department of Biostatistics & Health Informatics, Kings College, London, United Kingdom*

Background:

Modelling treatment effect mechanisms allows investigators to understand the pathways through which the intervention affects the outcome. Often there is a range of plausible mechanisms to be tested in order to determine which are the true mechanistic components of a modular intervention. Several assumptions are necessary for obtaining valid causal inferences from mediation analysis.

Objectives:

1. To review statistical methods for assessing mechanisms in observational studies and clinical trials
2. To describe the limitations of these methods and show how they can produce biased results if the underlying assumptions do not hold
3. To introduce novel clinical trial designs that allow investigators to test treatment effect mechanisms as an integral part of the study design

Methods:

Mediation analysis uses statistical models to estimate three parameters: the effect of treatment on the mediator; the effect of the mediator on outcome; the effect of the treatment on the outcome in the presence of the mediator. All three of these parameters can be susceptible to bias unless there is no unmeasured confounding of any of the pathways, and no measurement error in the mediator.

Results:

While random allocation of treatment satisfies some of the assumptions (such as no confounding of the randomisation to mediator or outcome pathways, respectively), conclusions drawn are still susceptible to: i) bias in the presence of mediator-outcome confounding; ii) measurement error in the mediator.

Improving clinical trial designs can provide more powerful tests of whether candidate core components represent truly causal mechanisms. Traditional parallel group designs with between-group comparisons are not optimal for disentangling putative and

possible competing treatment-effect mechanisms. Methodological advances such as *dismantling designs* (removing one aspect of the intervention), *randomising multiple components* of an intervention, *multiphase optimization strategy* (MOST) focussing on their promise to test the underlying aetiological mechanisms of an intervention.

Conclusions:

Mediation analysis is a powerful statistical tool to unpick how treatments work and which are the active ingredients. Like all statistical methods, if the necessary assumptions do not hold then the resulting estimates can be biased. Improving the design of studies, especially the use of randomisation to all or parts of a modular intervention, can improve the validity of the assumptions.

**220.002** (*Panel Discussion*) A Mechanistic Approach to Early Social Communication Intervention in Autism – Findings and Possibilities

**J. Green**, *University of Manchester, Manchester, United Kingdom of Great Britain and Northern Ireland*

---

**Background** - Paediatric Autism Communication Therapy (PACT) is an approach to early autism intervention derived from ideas in neurotypical developmental science. This theory (eg Tomasello 2003) locates the origin of infant and young child social communication in the quality and extent of their experience of responsive interaction and communication with key adults. Studies have suggested that similar processes may apply also within early autism development (Siller and Sigman 2008, Wan et al 2013), thus providing a natural target for intervention. PACT works with caregivers using video-feedback therapy to achieve a proximal increase in adult synchronous response to child communication. Following developmental theory, it postulates then a chain of effect from this caregiver responsiveness to increased child dyadic social initiation, and then generalisation of these child acquired skills across person and context into adaptive function. This theoretical formulation of intervention process thus lends itself to mechanistic evaluation.

**Objectives** – To test the logic model of the PACT intervention using mechanistic analysis.

**Method** – Mechanism analysis within a parallel group RCT of PACT vs Usual Care (Pickles et al 2016), incorporating novel use of repeated measures to mitigate measurement error in behavioural observations.

**Results** – The analysis supported the intervention logic model by demonstrating that proximal change through intervention on sensitising caregiver synchronous response strongly mediated a significant improvement in dyadic child social communication: and that this change in child communication generalised across context, person and skill strongly to mediate the significant reduction found in researcher-rated autism symptom severity on ADOS. The results replicated a simpler mediation analysis (Aldred et al 2012) from a previous PACT trial. They supported causal inferences from related observational developmental studies.

**Conclusions** – Substantial mechanism analyses require large enough and good enough quality trial design but can be invaluable in identifying active ingredients of therapy and allowing strong causal inferences within developmental theory itself (inferences difficult to make in a non-experimental context). The mechanistic analyses here support the PACT logic model and define what we consider therefore effective components of the intervention, which we have made use of in different contexts:

1. *Across age* - a similar parent-mediated social communication intervention with babies at familial risk from nine months, demonstrated effects on elements of the mediation pathway, but was underpowered to test actual mediation. (This illustrates one of the key issues in mechanism testing – the need for samples large enough to be powered for the test).
2. *Across culture* – the active components of intervention were adapted into a culturally appropriate task-shifted non-specialist health worker intervention in South Asia, and two trials have showed that the first part of the mediation pathway at least shows effectiveness.

*Future opportunities* include the combination of such active components with other validated elements, perhaps derived from different studies, so as to further pursue common treatment progression and refinement in an evidenced fashion for the core autism condition. We can also explore different delivery and dosage options for this active module, so as to maximise treatment efficiency.

**220.003** (*Panel Discussion*) Developing a Modular Intervention for School-Aged Children Addressing Autism-Related Challenges and Mental Health Needs

**J. J. Wood**, *Human Development & Psychology, University of California, Los Angeles, Los Angeles, CA*

---

**Background:** School-aged children with autism often exhibit substantial heterogeneity in comorbid conditions and clinical needs, posing a challenge to the design of successful intervention protocols. This clinical heterogeneity entails varied expressions of the core syndrome of autism as well as frequent manifestations of mental health challenges experienced by children with typical development, such as anxiety and aggression, and thus may be a good match to modular cognitive behavior therapy (CBT) protocols that can flexibly address individualized clinical needs for each child (cf. Weisz et al., 2012). We have proposed that CBT protocols with a modular format might usefully incorporate evidence-based intervention components capable of addressing the most pressing clinical needs of individual children with autism within the domains of social-communication skills, peer relationships, flexibility, emotion regulation, and self-care skills. Further, the inherent complexity of module selection is a critical feature of this type of intervention package that requires special attention and pilot testing by end users (e.g., community practitioners).

**Objectives:** The primary objective of our research program has been to develop an efficacious modular intervention with the capacity to address the heterogeneous clinical needs of individual school-aged children with autism in a weekly outpatient psychotherapy context.

**Methods:** Through iterative research, we have developed a free, open-access online modular intervention compendium for school-aged children with autism using four strategies/lenses for module selection and integration: (1) a transdiagnostic approach to selecting module content for specific clinical needs, such as aggression, based upon distillation procedures and empirically-supported intervention criteria, which begins with the assumption that focal interventions that work for children with typical development might also help children with autism; (2) modifications to standard evidence-based practices for specific clinical needs that have proven to be more efficacious than the standard-of-practice in head-to-head comparisons of multicomponent intervention packages; (3) studies of the correlates of desired outcomes (e.g., the duration of gradual exposure associated with the greatest reduction of obsessions and compulsions within CBT clinical trials); and (4) conceptual models of the mechanisms of action of CBT with direct implications for module design (e.g., Brewin, 2006). Ultimately, modules addressing some of the core aspects of autism (e.g., friendship; conversation) as well as concurrent mental health needs were developed in a traditional manual format. These modules were then redesigned for implementation by community practitioners through the development of a free online platform with video training elements and an automatized module selection algorithm that relies on session-by-session formative assessment.

**Results:** Several randomized controlled trials of these modular CBT interventions have been conducted (e.g., Wood et al., 2020, 2021), with promising treatment effects on autism-related clinical needs as well as concurrent mental health challenges. The redesigned online version of the intervention has been tested in a recent implementation study, with positive practitioner outcomes found in preliminary analyses.

**Conclusions:** An internet-based modular intervention package that can be updated in response to new empirical findings may be a practical method for both disseminating and continuously updating interventions that are flexible in addressing heterogeneous clinical needs in autism.

---

**PANEL DISCUSSION — OTHER - MULTIPLE TOPIC AREAS**

**Panel 226 - New Approaches to Parsing Heterogeneity in Autism and Understanding Cross-Disorder Similarities**

**Panel Chair:** *Eva Loth, Department of Forensic and Neurodevelopmental Sciences, Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, United Kingdom*

**Discussant:** *Evdokia Anagnostou, Autism Research Center, Bloorview Research Institute, Holland Bloorview Kids Rehabilitation Hospital, Toronto, ON, Canada*

The past decade has shown that no single clinical, neurobiological or genetic feature is universal or specific to autism. Instead, considerable heterogeneity within the autism spectrum paired with frequent overlaps between neurodevelopmental conditions have crystallised as key barriers to our ability to map genotype-phenotype links and to develop targeted support and treatments

for particular individuals. Hence, new designs and methodologies beyond traditional case-control comparisons are required to identify markers and mechanisms of subgroups with shared characteristics within and/ or across established diagnostic boundaries. This symposium brings together clinical and preclinical scientists from several international autism consortia to discuss new cohort designs, translatable tests and analytical approaches. Eva Loth will present the design and methods of the AIMS-2-TRIALS/ CANDY Preschool Imaging Study that compares children with autism, ADHD, ID and epilepsy across six dimensions. Minshi Peng will show similarities and differences in gene expression patterns between autism and ID. Adriana di Martino will present work aimed to identify common and distinct functional patterns between autism and ADHD in a deeply phenotyped neuroimaging sample. Azadeh Kushki will present a data-driven, diagnosis-agnostic approach to discover subgroups across autism, ADHD and OCD. Evdokia Anagnostou will synthesise approaches and discuss their strengths and challenges.

**226.001 (Panel Discussion) Designs and Methods to Identifying Neurocognitive Subgroups across Six Dimensions from Preschoolers to Adults**

---

## Background

Clinical and genetic findings converge in highlighting both considerable heterogeneity within autism and substantial overlaps between autism and other neurodevelopmental conditions. These factors hinder our ability to predict individual developmental outcomes and develop targeted therapies. To identify markers that parse heterogeneity within autism, several large-scale research initiatives have been established. However, despite recent transdiagnostic approaches to psychiatry, such as the NIMH Research Domain Criteria, most clinical studies compare a single condition (e.g., autism) to a 'neurotypical' control group. New study designs, reliable transdiagnostic tests suitable for broad age and ability ranges, and analysis methods that capture individual profiles of relative strengths/ difficulties are required to identify subgroups within or across neurodevelopmental conditions.

## Objectives

To create a multi-disciplinary research platform comparing individuals with autism, Intellectual Disability, ADHD, and/ or high rates of environmental risks factors impacting social, emotional and cognitive development; 2) to develop valid and reliable tests that assess six bio-behavioural dimensions and that are comparable across broad age and ability ranges; 3) to develop robust methods to assess individual profiles across multiple measures and identify subgroups within and/ or across established diagnostic categories.

## Methods

First, by partnering AIMS-2-TRIALS with CANDY we set up a series of linked studies from preschoolers to adults with common or comparable 'deep-phenotyping' protocols, including clinical characterisation, functional outcome, neurocognitive development, brain structure, function, and genetic and environmental risk factors. The Preschool Imaging Project compares 500 children with autism, ADHD, ID and epilepsy and typical development longitudinally between the ages of 3 to 6 years; the Multiplex Family Study comprehensively assesses 100 families, and the South African PASS study longitudinally follows 4,500 children with high environmental risk factors for social, emotional or cognitive development. Second, we developed scalable

smartphone/ tablet apps that assess social, emotional, cognitive, reward, sensory and unpredictability processing. We created three versions for preschoolers, school-age children and adolescents/ adults and use Bayesian Optimisation to vary task parameters/ complexity. Third, to establish individual cross-domain profiles and identify data-driven subgroups, we created an analysis pipeline including imputation, normative modelling and the intersection of 2-12 different clustering techniques (e.g., centroid, connectivity based).

## Results

We demonstrate feasibility of this approach (including pediatric MRI sleep-scanning) in 50 preschool children in Europe and 100 children in South Africa. (2) We developed the first touch screen battery comprising established and new tests (social reinforcement learning, social habituation, auditory and tactile discrimination) that span broad age and ability ranges. (3) Our analysis pipeline allows us to create for each individual within and cross-domain profiles, relative to, for example age, sex, and/ or mental age expectations. We show that the ‘clustering intersection method’ not only enables us to determine the optimal number of clusters (subgroups) but determines which participants may be reliably allocated to the same subgroup by different methods, which is essential for subgrouping in a clinical context.

## Conclusion

By combining cross-disorder designs, new scalable tests assessing relevant bio-behavioural dimensions, and robust multi-variate analysis methods we provide tools to better understand both within-disorder heterogeneity and cross-disorder commonalities.

**226.002 (Panel Discussion)** Heterogeneity within Autism Viewed through Its Mutational and Gene Expression Patterns and Those of Developmental Disability

*M. Peng<sup>1</sup>, B. Wamsley<sup>2</sup> and K. Roeder<sup>3</sup>, (1)Carnegie Mellon University, Pittsburgh, PA, (2)University of California, Los Angeles, Los Angeles, CA, (3)Department of Statistics and Data Science, Carnegie Mellon University, Pittsburgh, PA*

---

## Background

The genetic architecture of autism spectrum disorder (ASD) is increasing coming into focus through studies of both rare and common variation. Clearly both types of variation affect risk, with common variation apparently playing the prominent role at the level of populations. For developmental disabilities (DD) more broadly, rare *de novo* variation plays the larger role. Still, the nature of the overlap in genetic architecture between ASD and more broadly defined DDs, and its implications for both shared and distinct neurodevelopmental deficits remains poorly characterized.

## Objectives

To understand similarities and differences between cohorts ascertained for ASD and DD more broadly (which includes ASD) through the study of their mutational patterns as well as the expression patterns of the genes implicated for either or both.

## Methods

We study cohorts of subjects ascertained for ASD whose DNA was assessed by whole-exome sequencing (WES) to discover protein coding mutations. Likewise, we obtained data from a large cohort of subjects who were ascertained for DD and whose DNA was also characterized by WES, specifically the Deciphering Developmental Disorders (DDD) study. For each cohort, we evaluate the distribution of protein-truncating and severe missense *de novo* variants in each gene using the Transmitted And De novo Association framework. Comparing the expectation of mutations to the observed count, TADA integrates the information into a summary statistic of association for each gene implicating genes in ASD or DD or both. We also evaluate the expression patterns of these genes in fetal brain cells utilizing two single-cell RNA sequencing datasets, which were jointly analyzed through integration and hierarchical clustering of cells.

## Results

Using the pattern of *de novo* mutations in subjects ascertained for ASD, we implicated 120 genes in risk at an FDR < 0.05 threshold. Likewise, from the DDD cohort, we implicated 428 genes in risk. The intersection of these lists produced 84 genes, consistent with the known comorbidities. Nonetheless, the mutational patterns also showed high heterogeneity between ASD and DDD cohorts, suggesting somewhat distinct etiologies. From single cell enrichment analysis, we found that ASD genes were associated with a subcluster of upper layer excitatory neurons. By contrast, DDD genes were enriched in a subcluster of maturing

excitatory neurons. In addition, the upper layer neurons enriched in ASD best resemble layers 3/4 neurons whereas for DDD they best resemble layers 2/3 neurons.

## Conclusions

Sources of risk for ASD and other DD overlap and this is reflected in shared risk genes identified from the ASD and DDD cohorts. The observation of some distinct mutational patterns, however, argues for important, yet nuanced differences among genes in their impact on core features of ASD. Moreover, the gene expression patterns in cell types suggest DD gene expression is enriched in cells engaged in active transcription, protein translation/modifications, migration and extension of axons, whereas ASD gene expression is enriched in cells engaged in cytoskeleton organization, synaptic signaling and activity dependent programs. Thus, despite both being enriched in superficial cortex, they likely have different effects on cortical development.

### 226.003 (Panel Discussion) A Data-Driven, Diagnosis-Agnostic Approach to Discover Subgroups across Autism, ADHD and OCD

*M. M. Vandewouw<sup>1</sup>, E. Anagnostou<sup>2</sup>, J. P. Lerch<sup>3</sup>, M. J. Taylor<sup>4</sup>, J. Crosbie<sup>5</sup> and A. Kushki<sup>6</sup>, (1)Program in Neuroscience & Mental Health, The Hospital for Sick Children, Toronto, ON, Canada, (2)Autism Research Center, Bloorview Research Institute, Holland Bloorview Kids Rehabilitation Hospital, Toronto, ON, Canada, (3)Wellcome Centre for Integrative Neuroimaging (WIN), University of Oxford, Oxford, ON, United Kingdom, (4)The Hospital for Sick Children, Toronto, ON, Canada, (5)Psychology, The Hospital for Sick Children, Toronto, ON, Canada, (6)Bloorview Research Institute, Toronto, ON, Canada*

---

**Background:** Autism spectrum disorder (ASD), attention-deficit/hyperactivity disorder (ADHD), and obsessive-compulsive disorder (OCD), are neurodevelopmental conditions with overlapping etiology, neurobiology, and phenotype, and large within condition heterogeneity. Existing studies examining shared neurobiological characteristics among these conditions often use diagnostic labels to derive group-level statistics for comparisons, an approach that often fails to capture the large within-diagnosis variability and between-group overlap. To address this limitation, data-driven and diagnosis-agnostic approaches have been proposed to characterize the nature of variability across neurodevelopmental conditions. These techniques have been used to discover homogeneous subgroups that transcend diagnostic boundaries, demonstrating that homogeneity in neurobiology does not align closely with existing diagnostic labels. These studies, however, have focused on measures of brain structure, and a gap still remains in diagnostic-agnostic characterization of brain function across ASD, ADHD, and OCD. This is a critical gap given the well-established patterns of hyper- and hypo-connectivity in neurodevelopmental conditions.

**Objectives:** We employed a data-driven clustering approach to identify homogeneous subgroups of typically developing (TD) children and those with labels of ASD, ADHD, or OCD based on measures of resting-state functional magnetic resonance imaging (fMRI) connectivity.

**Methods:** Five minutes of resting-state fMRI data were obtained on 442 ASD (N=195; age=11.7±4.1years), ADHD (N=126; age=11.6±2.8years), OCD (N=42; age=12.5±2.6years), and TD (N=79; age=11.0±4.2years) children from the Province of Ontario Neurodevelopmental Disorders (POND) network. Data were preprocessed using fMRIPrep, and time-series were extracted for 200 bilateral cortical regions belonging to seven canonical resting-state sub-networks and 32 bilateral subcortical regions. Brain connectivity networks for each participant were constructed from pairwise correlations thresholded using orthogonal minimal spanning trees. Graph theory measures were calculated at three levels: individual brain regions (nodal strength, clustering coefficient, and centrality), resting-state networks (density and subnetwork segregation), and the global network (global efficiency and modularity). Graph measures were regressed against age, sex, motion, and resting-state acquisition type, and the z-scored residuals were used in the analysis. Affinity matrices were computed for each measure using a scaled exponential similarity kernel and fused using Similarity Network Fusion. Subgroups of participants were identified from the fused matrix using hierarchical clustering.

**Results:** Preliminary analyses revealed three subgroups (Predominantly-ASD: 14 ADHD, 56 ASD, 8 OCD, 13 TD; Mixed: 29 ADHD, 38 ASD, 14 OCD, 13 TD; Predominantly ADHD/TD: 79 ADHD, 96 ASD, 20 OCD, 52 TD). The predominantly-ASD group had a higher proportion of ASD compared to ADHD participants (pcorr=0.001), while the predominantly ADHD/TD group had higher proportion of ADHD (pcorr=0.047) and TD (pcorr=0.047) compared to ASD participants. The groups were significantly different in Child Behaviour Checklist (CBCL) attentional problems scores (p=0.0099), but not in general adaptive functioning (ABAS), social communication (total SCQ score), or full-scale IQ. Several methodological challenges may have contributed to the clustering results as the groups differed on age (p<0.001), scan type (movie or Inscapes; p=3.0402e-44), and motion (p=2.1713e-12). Global efficiency and strength of subcortical regions contributed most to the clustering results.

**Conclusions:** Preliminary results suggest that homogeneity in resting state connectivity may not align with diagnostic labels, although several methodological challenges remain to be explored.

---

**Background.**

Clinical and biological heterogeneity remain major challenges for biomarker identification in psychiatry, including autism. An illustration of such challenge is the frequent cooccurrence of symptoms qualitatively similar to those observed in autism spectrum disorder (ASD) in children with attention deficit hyperactivity disorder (ADHD). The extent to which autism traits share common neural correlates across these diagnoses remains largely unclear. Mixed results of common and/or shared atypicality emerged from initial studies, that however have been largely focusing on parent ratings and on diffusion or structural MRI.

**Objective.**

To identify shared and distinct effects of autistic traits on intrinsic functional connectivity (iFC) in a well characterized sample of children of either ASD or ADHD

**Methods.**

We analyzed data from children aged 9+2 yrs with a primary DSM-5 diagnosis of either ADHD (n=98) or ASD (n=64) based on multisource assessment of two independent evaluators following a diagnostic consensus. Autistic traits were indexed by calibrated severity scores (CSS) of the Autism Diagnostic Observation Schedule-2 (ADOS-2) administered/scored “blindly” to prior history/diagnostic concerns. Using resting state fMRI low motion images an unbiased voxel-wise brain connectome multi-distance-based matrix regression (MDMR) examined regions whose iFC was associated with ADOS-2 CSS and follow up seed-based correlation analysis (SCA) explored their iFC-ADOS-2 CSS patterns. To examine both diagnostic shared and specific iFC patterns analyses were conducted across and between diagnostic groups (i.e., Dx by CSS interaction). Median FD, ADHD symptoms, and age were covariates and Gaussian random field corrected for multiple tests ( $Z > 3.1$ ,  $p < 0.05$ ). Replication of results was assessed in an independent sample including group age-matched children with ASD, ADHD, TDC (n=64, 98, 53, respectively).

**Results.**

MDMR across diagnoses revealed two clusters significantly related to inter-individual differences in autistic traits: 1) PCC and precuneus portions of the default network (PCC-DN), 2) middle frontal gyrus aspects of the fronto-parietal network (MFG-FP). SCA revealed a pattern consistent with higher internetwork iFC for children with autistic traits across diagnosis. MDMR

diagnosis by ADOS-2 CSS interactions revealed an ASD-specific negative association between ADOS-CSS S and interhemispheric iFC of MFG-FP. A similar iFC pattern was confirmed in the independent transdiagnostic sample.

**Conclusions.**

Results showed both transdiagnostic and diagnostic-specific brain-behavior relations with autistic traits. Specifically, a stronger FP-DN internetwork iFC characterized individuals with elevated ADOS-2 CSS transdiagnostically and differentiated them from ADHD<sup>AS</sup> and TDC. This suggests that atypical network segregation may be a risk factor for autistic traits in neurodevelopmental conditions. At the same time, findings that a negative interhemispheric iFC-AS relation only characterized children with ASD, underscores that additional diagnostic specific pathways specific to ASD exist. Overall, these results suggest that emerging hybrid, dimensional and categorical models of psychopathology also apply to autism and autistic symptoms.

## ORAL SESSION — OTHER - MULTIPLE TOPIC AREAS

### Oral 304 - Behavioral Treatment Trials

**304.001** (Oral) Facing Your Fears in Schools: Implementing CBT for Anxiety in Students with ASD in Urban Schools – Results from a Randomized Trial.

**J. Reaven<sup>1</sup>**, K. Pickard<sup>2</sup>, R. E. Boles<sup>3</sup>, A. Meyer<sup>4</sup>, C. Middleton<sup>3</sup>, L. Hayutin<sup>3</sup>, N. Reyes<sup>1</sup>, E. T. Engstrom<sup>4</sup>, T. Tanda<sup>5</sup>, A. C. Stahmer<sup>6</sup> and A. Blakeley-Smith<sup>1</sup>, (1)JFK Partners, University of Colorado Anschutz Medical Campus, Aurora, CO, (2)Emory University School of Medicine, Atlanta, GA, (3)University of Colorado Anschutz Medical Campus, Aurora, CO, (4)UC Davis MIND Institute, Sacramento, CA, (5)Developmental Pediatrics, Children's Hospital Colorado, Aurora, CO, (6)UC Davis MIND Institute, University of California, Davis, Sacramento, CA

Background: Youth with ASD are at high risk for developing clinically interfering anxiety that negatively affects friendships, home life, school participation and performance (Adams et al. 2018). Unfortunately, substantial disparities in access to mental health services exist, especially for traditionally underserved students (Zuckerman et al. 2014). The implementation of evidence-based mental health programs to students with ASD in schools is emerging, and the need for a sustainable delivery model is essential. The purpose of the current study is to train interdisciplinary school providers (ISPs) to deliver a school-based CBT program (Facing Your Fears- School Based (FYF-SB; Reaven et al. 2019) to traditionally underserved students with ASD or other social/communication difficulties and anxiety, and examine implementation and treatment outcomes.

Objectives: To examine the effectiveness of a Train-the-Trainer approach to implement FYF-SB in urban schools to students with ASD and anxiety, via a randomized trial, and examine preliminary outcomes.

Methods: Seventy-seven ISPs, from 25 schools (27 school teams) across 3 public school districts were trained to deliver FYF-SB. Thirteen school teams were randomized to FYF-SB, and 14 teams to Usual Care (UC). Trainings were co-led by teams of previously trained ISPs and research personnel (clinical psychologists). CBT Knowledge was measured pre/post training. Eighty-one students (82% male; 31% Latino, 30% non-white; M age=10.71; 7-14 years) participated. Inclusion criteria: Exceeding clinical threshold on the Screen for Childhood Anxiety and Related Disorders (SCARED; Birmaher et al. 1999), T-scores above 60 on the Social Responsiveness Scale-2<sup>nd</sup> Edition (SRS-2; Constantino & Gruber, 2012), and estimated IQ above 70. Fidelity was coded for 60% of sessions. SCARED and acceptability measures were administered post-intervention.

Results: ISPs demonstrated significantly increased CBT Knowledge following training:  $t(60)=-6.29, p<.001$ . An average of 10/12 sessions were completed. Very good treatment fidelity (absence/presence of core components) was obtained across teams;  $M=86%$  (range: 76%-98%). Upon completion of FYF-SB, providers reported that FYF-SB was easy to understand and put into practice (90% agree/strongly agree) and indicated that FYF-SB enhanced their ability to manage their students' anxiety (88% agree/strongly agree). Overall, students reported that they enjoyed FYF-SB (71% the most/very much). Students who received FYF-SB displayed significantly greater reductions in anxiety compared to students who received UC according to SCARED-Parent report for Total Anxiety ( $p=.011$ ) and the following subscales: Panic ( $p=.014$ ), Separation ( $p=.003$ ), and Social Anxiety ( $p=.005$ ). Students who received FYF-SB also reported significantly greater reductions in anxiety compared to students who received UC according to Separation ( $p=.014$ ) and Social anxiety subscales ( $p=.002$ ) on the SCARED.

Conclusions: Results indicated that ISPs demonstrated significant improvements in CBT knowledge following training and can deliver FYF-SB as intended. FYF-SB was seen as acceptable by school providers and students. Significantly greater reductions in anxiety occurred according to parent and student report, for students randomized to FYF-SB. Implementing evidence-based mental health interventions in public schools, via a Train-the-Trainer approach has the potential to increase access to care for traditionally underserved students with ASD and broaden provider capacity via a sustainable delivery model. Future research directions and limitations will be discussed.

**304.002** (Oral) Social Rhythmic Entrainment to Child-Directed Singing in ASD and TD Toddlers

**S. Chawla<sup>1</sup>**, L. A. Edwards<sup>1</sup>, T. Liu<sup>2</sup>, Y. Wang<sup>2</sup>, W. Jones<sup>1</sup> and M. D. Lense<sup>2</sup>, (1)Marcus Autism Center, Children's Healthcare of Atlanta and Emory University School of Medicine, Atlanta, GA, (2)Vanderbilt University Medical Center, Nashville, TN

Background: Caregiver-infant rhythmic social interactions are crucial to social development (Beebe et al., 2016). Typically developing (TD) individuals are sensitive to the timing of social engagement from infancy. In our recent work using child-directed singing, a naturally-occurring, rhythmic, social interactive behavior, both the caregiver and typically developing (TD) infants time-locked their own social-affective cues to key rhythmic moments; infants as young as two months old increased attention to caregivers' eyes at the song beats, and such rhythmically entrained eye-looking further increased in six-month infants. Here we examine whether and how rhythm continues to serve as a mechanism for the scaffolding of social attention into

toddlerhood. Given the critical importance of looking at the eyes of others for understanding social information, we examined whether attention to the eyes of a caregiver is modulated by rhythmic structure in TD toddlers, and in toddlers with autism spectrum disorder (ASD) who have impairments in social timing and coordination (Ozonoff et al., 2010).

**Objectives:** Examine modulations in eye-looking arising from rhythmic entrainment in TD and ASD toddlers.

**Methods:** Seventy-two chronologically age- and sex-matched TD (n=33) and ASD (n=39) toddlers (18-26 months) watched videos of an actress engaging them with child-directed singing while eye-tracking data was collected. Eye-looking was quantified as the amount and timing of toddlers' fixations on actresses' eyes. Rhythmic structure (song beats) were determined using vowel onsets and offsets of the beat-aligned syllables. We measured whether changes in looking to the eyes of actresses were time-locked to the beats using permutation testing of crosscorrelograms compared with chance rates of eye-looking in both ASD and TD samples. Distributions of individual toddlers' eye-looking timing at the beat were analyzed using circular  $\nu$ -tests.

**Results:** Time-locked to the rhythm of the singing, toddlers increased their eye-looking at levels greater than expected by chance ( $p < 0.05$ ; Figure 1a,b). At the beat, TD toddlers exhibited a 13.1% increase in eye-looking above mean levels while ASD toddlers' eye-looking increased 8.3% above mean levels. Phase analyses indicated rhythmically entrained eye-looking across individual toddlers in both TD and ASD groups ( $p < 0.01$ ; Figure 1c,d). There were no significant differences in the overall proportion of time TD ( $\bar{x}=0.26$ ,  $s=0.20$ ) and ASD ( $\bar{x}=0.23$ ,  $s=0.21$ ) toddlers fixated on the actresses' eyes during naturalistic child-directed singing ( $p > 0.05$ ).

**Conclusions:** These findings extend prior demonstrations of rhythmically-entrained eye-looking in TD infants to TD toddlers suggesting that rhythm continues to be an important structuring mechanism for supporting social behavior throughout early childhood. Initial analyses with toddlers with ASD suggest that eye-looking in ASD is also modulated by rhythmic structure during child-directed singing perhaps due to the robust, stereotyped, predictable, and repetitive cueing provided in the song context. Future analyses will examine whether rhythmically-entrained eye-looking is attenuated in toddlers with ASD and potential (differential) drivers of entrained eye-looking in both TD and ASD toddlers.

**304.003 (Oral) Supporting Caregivers Post Participation in Caregiver-Mediated Jasper Intervention: Needs and Assistance during Follow up**

**S. L. Arbuckle<sup>1</sup>, S. Y. Shire<sup>2</sup> and L. Baker Worthman<sup>3</sup>, (1)Special Education, University of Oregon, Eugene, OR, (2)University of Oregon, Eugene, OR, (3)Department of Health and Community Services, St. John's, Newfoundland and Labrador, Canada**

---

**Background:** Caregiver-mediated social communication intervention can lead to gains in children's engagement and communication as well as caregivers' use of intervention strategies (e.g., Shire et al., 2015). Although gains over baseline continue, child and caregiver outcomes often dip during follow up. Little is known about if and when caregivers may want support to maintain their treatment gains as their children's needs change in the period after intervention has ended.

**Objectives:** Explore caregivers' experiences following parent-mediated intervention through (a) quantitative data from a novel mobile health questionnaire (MHQ) given weekly for three months following intervention to examine if, when, and how often caregivers endorsed a need for support and (b) qualitative data from focus groups.

**Methods:** Fifteen children with autism age 2.0-8.7 years ( $M=55.8$  months) and their caregivers received 12 weeks of a caregiver-mediated developmental social communication intervention- Joint Attention, Symbolic Play, Engagement, and Regulation (JASPER: Kasari et al., 2006) from community interventionists employed by a provincial public health system in Canada. The five interventionists were trained to intervention fidelity by the study team with fidelity checks scoring at or above the required criterion of 80%.

**Measures:** First, the MHQ included 3 questions rated from 1 (typical/no support needs) to 7 (getting worse, high support needs), modeled after Clinical Global Impressions (Guy, 1976). Weekly, caregivers rated the child's social communication, engagement, and their perceived support needs. Second, three focus groups (3-4 families/group) were led by their health region leadership. Open-ended questions addressed families' experience in the follow-up period.

**Results:**

**Children's engagement and communication in follow up:** MHQ scores ranged from 1 to 4 for question 1 and question 2 ( $M=2.16$ ,  $SD=.875$ ;  $M=2.10$ ,  $SD=.854$ ).

Need for support during follow up. Scores ranged from 1 to 5 for question 3 ( $M=2.29$ ,  $SD=.74$ ). Caregivers reported a need for support (MHQ score of 3-7) on average 4 times over 12 weeks. Most families indicated a mild need for support (score of 3), however, 4 families indicated moderate (4) or marked (5) needs for support. More intense support needs emerged mid-way through follow up period. Interventionists responded within 24 hours by email to check-in and provide suggestions to resolve challenges.

Constant comparative analysis of coded focus group data led to five themes including feeling sufficiently supported by weekly check-ins that encouraged accountability and personal reflection on strengths and challenges. However, the families also reported challenges maintaining children's engagement and regulation, replicating the intervention structure, and integrating strategies into more 'naturalistic' daily routines.

Conclusions: Two-thirds of families desired support during follow up. On average, caregivers indicated a need for support 4 times during the follow up period. Caregivers were contacted through email and phone calls by their interventionist which families reported were sufficient to resolve challenges such that no family requested a video conference or home visit. Caregivers suggested readily-accessible electronic resources may support continued learning. Future research to understand child and family predictors of differential support needs may help plan to allocate limited resources.

#### **304.004 (Oral) Parents' Application of Mediated Learning Principles As Predictors of Toddler Preverbal Social Communication Outcomes**

*H. Schertz' and X. Liu', (1)Indiana University, Bloomington, IN, (2)Indiana University - Bloomington, Bloomington, IN*

---

Background: Prior research on parent-mediated intervention (PMI) for toddlers with autism used "naturalistic developmental behavioral intervention" (NDBI) strategies for parent learning. Relationships between child outcomes and parent factors were addressed by three NDBI research teams to explain intervention effects (Brian et al, 2016, 2017; Gulsrud et al., 2016 and Shire, et al., 2016; and Rogers et al., 2019). As yet unexplored is whether promoting active social engagement using a mediated learning approach predicts unprompted social initiations for toddlers with autism.

Objectives:

Two research questions (RQs) were explored.

1. How did parents who received the Joint Attention Mediated Learning (JAML) intervention compare with control group participants in their post-intervention application of three mediated learning principles in unstructured parent-toddler interaction?
2. To what extent were parents' application of these principles associated with toddlers' preverbal social communication outcomes.

Methods: Parent-toddler dyads ( $n = 120$ ; child age  $M = 24.7$ ; 69% Caucasian; 84% male) were randomized to JAML ( $n = 58$ ) and control ( $n = 62$ ) conditions. A partial-interval recording system was applied in observer-blinded independent coding of parent-child interaction videos. The Mediation of Social and Transactional Engagement Measure (MOSTE) measured parents' application of mediated learning principles focusing (FO), giving meaning (GM), and encouraging (EN). The Preverbal Joint Attention Measure (PJAM) assessed toddler's focusing on faces (FF), turn taking (TT), responding to joint attention (RJA), and initiating joint attention (IJA). RQ 1 was investigated through MANOVA to detect mean differences between intervention and control conditions at post assessment. RQ2 was examined through linear multiple regression with post-intervention child outcomes as dependent variables and parents' application of mediated learning principles as predictors.

Results: RQ1: Post-intervention analysis found significant group differences for parent application of mediated learning principles in favor of the intervention group: FO,  $F(1,118) = 21.14$ ,  $p < 0.001$ ; GM,  $F(1,118) = 24.73$ ,  $p < 0.001$ ; and EN,  $F(1,118) = 7.38$ ,  $p = 0.01$ . RQ2: Significant linear relationships were found between outcome and predictor variables. Analyzed together, group differences in parents' use of mediated learning principles explained variances in child outcomes (24% for FF, 12% for TT, 16% for RJA, and 41% for IJA). While holding other variables constant, EN ( $t = 1.95$ ,  $p < 0.05$ ) predicted RJA and GM ( $t = 3.2$ ,  $p < 0.01$ ) and EN ( $t = 1.21$ ,  $p < 0.05$ ) predicted IJA.

Conclusions: JAML was effective for supporting parents of toddlers with autism to apply mediated learning principles in parent-toddler interaction with successful application of principles predicting increases in toddler outcomes. Specific advantages were found for use of "encouraging" and "giving meaning" to facilitate toddlers' joint attention, defined in the PJAM as (a) occurring on the child's own volition for the purpose of social sharing (e.g., showing or responding to non-directive showing) without prompting, modeling, or reinforcement of predetermined behaviors and (b) excluding instrumental communication (i.e.,

requesting/directing or following directions). Because of its integration into everyday parent-child interaction, parent-mediated learning may have potential to extend social competency beyond immediate intervention contexts.

## ORAL SESSION — OTHER - MULTIPLE TOPIC AREAS

### Oral 305 - 'Getting it Right' for Autistic Children, Youth and Adults: Diagnostic, Transition & Mental Health Support Challenges

**305.001** (Oral) When Are Clinicians Sure? Identifying Socio-Demographic Predictors of Diagnostic Certainty to Inform Diagnosis Among Underserved Populations

*C. G. McDonnell, E. A. DeLucia, T. M. Andrzejewski, O. Semones and M. Fok, Department of Psychology, Virginia Polytechnic Institute and State University, Blacksburg, VA*

#### Background:

Despite the importance of evidence-based diagnostic assessment of autism spectrum disorder (ASD), the diagnosis of ASD has many challenges and inequities. There are socio-demographic disparities in ASD diagnostic practices, including misdiagnosis and delayed identification that disproportionately affect children and families who have historically been excluded from autism research and clinical services. Clinician decision-making is one factor that may contribute to issues with equitable and timely diagnosis. Diagnostic certainty refers to the extent to which a clinician is certain in their diagnosis, or how sure they are that the individual actually meets ASD diagnostic criteria. Better understanding how diagnostic certainty relates to socio-demographic characteristics is an important research priority with the potential to advance understanding of how clinicians perceive and make decisions about autism diagnoses.

#### Objectives:

Our specific aims were to (1) identify how demographic factors, including child sex, race, age, and family income, predict diagnostic certainty, controlling for core diagnostic measures such as autistic traits and cognitive abilities, and (2) determine whether demographic factors moderate the agreement between core diagnostic measures with diagnostic certainty.

#### Methods:

Participants included youth with ASD from the Simons Simplex Collection (N = 1,869) who completed gold-standard diagnostic assessments at university-affiliated autism research centers. Diagnostic certainty was assessed by asking clinicians how certain they were that the child met criteria for an autism diagnosis (ranged from not at all certain (score of 6) to completely certain (score of 15)). Core diagnostic assessment measures included clinician-observed autism traits (comparison score from Autism Diagnostic Observation Schedule (ADOS-2)), parent-reported autism traits (Social Communication Questionnaire), and an overall estimate of cognitive ability (full scale IQ score). Moderated regression analysis was used to examine (1) main effects of demographic factors and the core diagnostic assessment measures, and (2) interactive effects of demographic factors and the core assessment measures on diagnostic certainty.

#### Results:

Demographic factors were significantly associated with diagnostic certainty, even controlling for core assessment measures (ADOS-2 score, SCQ score, full-scale IQ; see Table 1). Lower income and older child age were associated with less clinician certainty. Children identified as White also had lower levels of clinician certainty. Moreover, family income moderated the association between ADOS-2 scores and diagnostic certainty (see Figure 1). The agreement between ADOS-2 scores and diagnostic certainty was significantly weaker for lower income families.

#### Conclusions:

The present results show that diagnostic certainty (the extent to which a clinician feels sure about the autism diagnosis) relates to child race, child age, and family income, even when controlling for core clinical assessment measures (ADOS-2, SCQ, and IQ scores). Moreover, the agreement between ADOS-2 comparison scores and diagnostic certainty was moderated by family income, such that this association, which ideally should be highly concordant (high ADOS-2 scores associated closely with high diagnostic certainty), is weaker for lower income families. These findings show that diagnostic certainty is not synonymous with the level of autism symptoms, and suggests that demographic factors may influence how clinicians perceive autism diagnoses.

Research on diagnostic practices is urgently needed among diverse and historically excluded communities.

**305.002 (Oral) Building Better Bridges: Outcomes of a Community-Partnered School Transition Intervention for Students with Autism**

**H. J. Nuske<sup>1</sup>, T. Smith<sup>2</sup>, L. Levato<sup>2</sup>, B. Bronstein<sup>1</sup>, A. R. Fitzgerald<sup>3</sup>, C. Garcia<sup>4</sup>, S. F. Vejnaska<sup>3</sup>, S. Hochheimer<sup>2</sup>, F. A. Castellon<sup>4</sup>, J. Chiappe<sup>5</sup>, N. Sparapani<sup>3</sup>, J. Li<sup>3</sup>, A. D. Nunnally<sup>3</sup>, W. I. Shih<sup>4</sup>, A. C. Stahmer<sup>3</sup>, S. Iadarola<sup>2</sup>, D. S. Mandell<sup>1</sup>, E. McGhee Hassrick<sup>6</sup>, S. Kataoka<sup>4</sup> and C. Kasari<sup>1</sup>, (1)Penn Center for Mental Health, University of Pennsylvania, Philadelphia, PA, (2)University of Rochester Medical Center, Rochester, NY, (3)UC Davis MIND Institute, University of California, Davis, Sacramento, CA, (4)University of California, Los Angeles, Los Angeles, CA, (5)California State University, Dominguez Hills, Carson, CA, (6)A..J. Drexel Autism Institute, Drexel University, Philadelphia, PA**

---

**Background:** For any student, new school transitions can pose challenges. For children with autism, who often poorly tolerate uncertainty and have difficulty navigating complex social environments, these challenges are exacerbated. To date, there are no evidence-based interventions to support children with autism, or their parents and teachers, which are designed to facilitate successful school transitions during this sensitive period.

**Objectives:** We tested the recently developed *Building Better Bridges*, an intervention to improve transitions from kindergarten to primary school and from primary to secondary school. The *Building Better Bridges* intervention includes six parent coaching sessions and a resource binder through which parents learn about special education, the transition process, and how to advocate for their child. Goals include: gathering key information from current teachers about their child to pass on to new school teachers; effectively communicating with school teams; knowing educational policy rights relating to school transition, and; engaging their child in activities over the summer in preparation for the transition.

**Methods:** We tested the *Building Better Bridges* intervention in a four-site (Los Angeles, Davis, Philadelphia and Rochester) randomized controlled trial (*Building Better Bridges* vs. resource binder only control group) to examine its effect on school transition-related outcomes for students with autism as well as their parents and teachers. Inclusion criteria were that families were under-resourced, children attended a preschool or public school, were transitioning to a new school in the upcoming academic year, and had an educational classification or medical diagnosis of autism, confirmed by their score on the Social Communication Questionnaire. We recruited 168 children with autism (treatment n=84, control n=87), and their parents and teachers. See Table 1 for participant characteristics. The primary outcome measure was the Transition Evaluation Questionnaire, which measures parents' and teachers' perceived transition success. Secondary outcomes included children's engagement in learning, parents' self-efficacy and worry regarding managing the transition to school, parents' perceptions of, and children's behavior problems. Measures were collected at three time points: study enrollment, second half of the school year (T1), last 6 weeks of pre-transition school year (T2), and first 6 weeks after the new school year (T3). We used 2-way repeated measures ANCOVAs, controlling for site, to examine the interaction effect of treatment status (treatment, control) and time (T1, T2, T3) on the aforementioned outcomes, and examined pairwise comparisons between treatment groups at each timepoint.

**Results:** Compared with the control group, parents and teachers in *Building Better Bridges* rated the transition as more successful. Teachers, but not parents, rated children as more emotionally engaged in class post-transition. Parents rated themselves as having more self-efficacy in managing the school transition. The *Building Better Bridges* intervention did not improve parents' perceptions of school involvement or reduce children's behavior problems post-transition relative to control. Parental worry decreased from T1-T3 for both groups.

**Conclusions:** Results suggest the *Building Better Bridges* intervention improves some of the key transition outcomes, supporting potential dissemination to school systems. Findings warrant replication.

**305.003 (Oral) Why Are Autistic People More Likely to Experience Suicidal Thoughts? Applying the Integrated Motivational-Volitional Model in Autistic Adults.**

**J. Graham<sup>1</sup>, J. Rodgers<sup>2</sup> and S. A. Cassidy<sup>3</sup>, (1)Newcastle University, Newcastle, United Kingdom, (2)Population Health Sciences Institute, Newcastle University, Newcastle upon Tyne, United Kingdom, (3)School of Psychology, University of Nottingham, Nottingham, United Kingdom**

---

**Background:**

Autistic people are more at risk of suicidal and behaviours and dying by suicide than the general population and other clinical groups. The Integrated Motivational-Volitional Model of Suicidal Behaviour predicts risk factors, in the presence of stressors,

can increase feelings of defeat and entrapment with suicide perceived as the only available escape route. Characteristics associated with ASD, such as camouflaging and intolerance of uncertainty (IU), not currently in the IMV model, could interact with known risk markers to further increase risk of suicidal intent in this group.

#### Objectives:

1. Do defeat and entrapment apply to suicidal ideation for autistic people?
2. Do camouflaging and IU mediate the relationship between defeat, entrapment and suicidal ideation?

#### Methods:

Data were collected online on: depression (PHQ9-ASC), camouflaging (CATQ), intolerance of uncertainty (IUS12), feelings of defeat and entrapment and suicidality (SBQR-ASC).

#### Results:

Preliminary findings are presented based on a sample of 150 autistic participants: (mean age= 31.6; SD= 10.9).

Suicidality was significantly correlated with entrapment ( $r(61) = .728, p < .001$ ) and defeat ( $r(58) = .606, p < .001$ ). Current experiences of depression significantly correlated with suicidality ( $r(94) = .668, p < .001$ ). Analysis of the subscales for the adapted measure of depression indicated that both the original psychosomatic PHQ-9 items and the adapted autism specific items correlated with suicidality ( $r(58) = .623, p < .001$  and  $r(56) = .535, p < .001$  respectively).

Higher IU correlated with higher levels of defeat ( $r(101) = .532, p < .001$ ) and entrapment ( $r(104) = .504, p < .001$ ). Intolerance of uncertainty also correlated with suicidality ( $r(61) = .348, p = .005$ ) and current depression ( $r(95) = .460, p < .001$ ).

Camouflaging was positively correlated with feelings of defeat ( $r(101) = .264, p = .007$ ) and entrapment ( $r(104) = .336, p < .001$ ). Similarly, camouflaging correlated with higher ratings of current depression ( $r(95) = .408, p < .001$ ), particularly the autism trait subscale ( $r(98) = .448, p < .001$ ).

Initial regression analysis indicates, that when controlling for age, current depression scores accounted for 44.1% of the variance in suicidality ( $p < .001$ ). When age and depression are controlled for, entrapment accounts for 15.9% of total variance ( $p < .001$ ); whilst defeat only accounts for 4.5% of total variance ( $p = .037$ ) in suicidality.

#### Conclusions:

This is the first study to explore the IMV model with a sample with autistic adults. Furthermore it is the first study to explore the additional contribution of constructs known to be important to the understanding of experiences of mental health in autistic people. Suicidality, current depression symptoms, camouflaging and IU were all significantly correlated with defeat, entrapment and all other variables, with the exception of camouflaging where no significant correlation with suicidality was found. Our findings provide preliminary support for the importance of the IMV model predictors of suicidality (defeat and entrapment) when applied to autistic people. In addition, we found that the autism related constructs of intolerance of uncertainty and camouflaging are strongly associated with experiences of defeat, entrapment and depression. Intolerance of uncertainty, in particular, is significantly associated with suicidality. Camouflaging, however, is not (contradicting previous studies).

**305.004 (Oral)** “Listen, I’ve Been Thriving” Vs. “This Is the Worst I’ve Ever Felt!”: An Exploratory Study of Autistic Experiences with In-Person and Online Social Interaction during the COVID-19 Pandemic

**R. E. Stanley**, Marquette University, Milwaukee, WI

---

Background: Social distancing during the COVID-19 pandemic has significantly affected the social behavior of people across the world. Social relationships play a key role in health (Umberson & Montez, 2011), and social isolation is associated with increased mortality and poorer mental health (Leigh-Hunt et al., 2017). However, it is unclear whether in-person and online interaction produce equivalent effects on mental health, with research showing both positive and negative outcomes associated with increased social media use (Pantic, 2014; Frost & Rickwood, 2017). Even less understood is how this relationship may be affected by autism spectrum disorder (ASD), which is characterized by atypical social behavior. There is a dearth of qualitative

research assessing autistic perspectives on social interaction and mental health. Given the potential health risks to increased isolation during the COVID-19 pandemic, autistic adults' insight on the topic is more salient than ever.

**Objectives:** To qualitatively explore the in-person and online social interaction experiences of autistic young adults during the COVID-19 pandemic, and their perspectives on the subsequent relationship to mental health.

**Methods:** 83 autistic adults from the United States (23 female, 10 male, 49 nonbinary/other, 2 prefer not to respond, M = 25.7) answered a multiple-choice question about reducing in-person contact during the pandemic, and 10 open-ended questions about their in-person and online social interactions and mental health both before and during the pandemic. Survey responses were coded using thematic analysis. Responses were also coded for mental health symptoms as well as change in mental health symptoms over the course of the pandemic.

**Results:** The majority (83%) of participants reported "significantly" reducing their in-person contact during the pandemic, with the remaining (17%) reporting "somewhat" reducing their in-person contact. The majority (55%) of participants described worsening mental health symptoms during the pandemic, including depression, anxiety, and increased symptoms of ASD, as well as loneliness and generalized stress. However, a portion of participants (13%) described their mental health improving in some ways while worsening in others, while another group (15%) described unmitigated improvement (8% no change, 9% did not answer). Themes and sub-themes generated by the thematic analysis are included in Figure 1.

**Conclusions:** In-person social interaction was described as important for mental health and reducing loneliness, but also overwhelming and exhausting. Online interaction was also described as important for mental health and social connection, a lifeline during the pandemic. Perspectives on the shift to online varied greatly, with some preferring this "new normal," describing it as easier and better for their mental health. However, others reported that online interaction was harder, and that it was not a replacement for in-person interaction. Some participants also reported that they were already socializing primarily online prior to the pandemic, either due to preference or isolation. These results highlight the complexity of social interaction across multiple modalities, opening new avenues for understanding autistic social experiences and mental health. Findings will inform future research on social and mental health interventions, and provide insight on how autistic adults can meet their social needs.

## ORAL SESSION — OTHER - MULTIPLE TOPIC AREAS

### Oral 306 - fMRI and EEG Task-Induced Responses in Autism

**306.001** (Oral) Changes in Amygdala Activity across the PEERS® Intervention: The Role of Fear of Negative Evaluation  
**A. J. McVey<sup>1</sup>, J. D. Herrington<sup>2</sup>, A. Barrington<sup>3</sup>, A. Porcelli<sup>4</sup>, H. K. Schiltz<sup>5</sup>, A. D. Haendel<sup>6</sup>, B. Dolan<sup>7</sup>, A. Arias<sup>8</sup>, M. Carlson<sup>9</sup>, W. Krueger<sup>10</sup>, B. Yund<sup>11</sup> and A. V. Van Hecke<sup>3</sup>,** (1)University of British Columbia, Vancouver, BC, Canada, (2)Perelman School of Medicine, University of Pennsylvania, Philadelphia, PA, (3)Biomedical Engineering, Marquette University, Milwaukee, WI, (4)Unknown Affiliation, Milwaukee, WI, (5)Psychology, Marquette University, Milwaukee, WI, (6)Speech-Language Pathology, Concordia University Wisconsin, Mequon, WI, (7)Medical College of Wisconsin, Milwaukee, WI, (8)University of California,, Milwaukee, WI, (9)Education, Marquette University, Milwaukee, WI, (10)Speech Pathology and Audiology, Marquette University, Milwaukee, WI, (11)Psychology, University of Wisconsin Milwaukee, Milwaukee, WI

**Background:** Social skills and anxiety are highly overlapping among autistic youth (Wood & Gadow, 2010), and improvements in both have been identified across a well-validated social skills intervention (Hill et al., 2017; Lordo et al., 2017; McVey et al., 2016; Schohl et al., 2014), the *Program for the Education and Enrichment in Relational Skills (PEERS®)*; Laugeson & Frankel, 2010). Biomarkers may prove critical in establishing the precise mechanisms of action in treatments like *PEERS®* (Stavropoulos, 2017). Evidence points to electrophysiological underpinnings of response to *PEERS®* (Van Hecke et al., 2013), but further study is needed to examine specific brain regions implicated in social functioning via MRI and explore the role of social anxiety.

**Objectives:** To test baseline anxiety as a predictor of change in amygdala activity following *PEERS®*.

**Methods:** 38 autistic youth (19 in each the experimental [EXP] and waitlist control [WL] groups) drawn from a larger randomized clinical trial of *PEERS®*. Data were collected at two timepoints: before and after the intervention for the youth in the EXP group, or after approximately 14 weeks for the WL group. Parent- and self-report questionnaires measuring social skills and anxiety and functional MRI data were collected. A face processing task was chosen based on existing literature (e.g., Herrington et al., 2016). Functional images were acquired across two runs of a 1-back task which included gray-scale visual stimuli of angry

faces, happy faces, neutral faces, houses, and scrambled images. A face-versus-house contrast based on the literature (e.g., Aoki et al., 2015) was used to elicit amygdala activity.

Results: A 2-way Mixed Effects, Group (EXP vs. WL) x Time (pretest vs. posttest) ANOVA was conducted to examine changes in amygdala activity using FSL's FEAT (Woolrich et al., 2001). There were no significant within- or between-group effects or interaction effects. Multiple regression was used to examine anxiety symptoms as predictors of change in amygdala activity from pretest to posttest in the EXP group. Higher social anxiety symptoms (*Social Anxiety Scale for Adolescents, Fear of Negative Evaluation*) predicted greater decrease in amygdala activity across the intervention ( $\beta = 0.49, p = 0.040, R^2 = 0.24$ ).

Conclusions: Social anxiety, specifically fear of negative evaluation, predicted change in amygdala activity from pretest to posttest; that is, higher social anxiety at pretest was associated with a larger decline in amygdala activity across intervention. This finding aligns with work demonstrating a link between greater fear of negative evaluation and longer gaze duration to emotional faces in autistic adolescents (White et al., 2015), and points to the potential importance of fear of negative evaluation when testing the neural underpinnings of response to social skills intervention among autistic youth. Clinical implications highlight the importance of identifying social anxiety symptoms among autistic youth participating in social skills intervention, as these youth may be the ripest for the greatest benefits from such an intervention.

**306.002 (Oral)** Neural Mechanisms of Emotion Regulation in Children with ASD As Treatment Targets for Anxiety  
**D. G. Sukhodolsky<sup>1</sup>, C. Kalvin<sup>2</sup>, R. Jordan<sup>3</sup>, S. Rowley<sup>4</sup>, K. Ibrahim<sup>1</sup> and W. L. Tseng<sup>1</sup>,** (1)Yale Child Study Center, Yale University School of Medicine, New Haven, CT, (2)Child Study Center, Yale University, New Haven, CT, (3)Yale Child Study Center, New Haven, CT, (4)Child Study Center, Yale School of Medicine, New Haven, CT

---

Background: Anxiety is a common and impairing problem in children with autism spectrum disorder (ASD) but the neural mechanisms of anxiety in ASD are not well understood. This study examined associations of anxiety with the BOLD signal change during performance of a neurocognitive task of emotion regulation in a sample of children with ASD and co-occurring anxiety disorder who were seeking treatment with cognitive behavior therapy (CBT).

Objectives: To examine neural mechanisms of emotion regulation in children with autism and co-occurring anxiety disorders.

Methods: The sample included 45 children with ASD [mean age (SD) = 12.2 (1.7), 70 percent male] and 27 typically developing controls unaffected by psychiatric disorders [mean age (SD) = 12.0 (1.7), 60 percent male]. Subjects were characterized with ADOS, ADI-R, and DAS-II and co-occurring disorders were assessed by the Anxiety Disorders Interview Schedule conducted by an expert clinician. Parents complete the Multidimensional Anxiety Scale for Children (MASC). Children completed fMRI task of emotion regulation that required to either passively viewing negative affective images or down-regulate their emotional response to the images.

Results: Whole-brain fMRI analysis of group (ASD vs TD) by task (view vs regulate) interactions revealed reduced activation in children with ASD, relative to TD, during the down-regulation condition of the task in four regions: left superior temporal gyrus, right inferior parietal lobule, right precentral gyrus, left superior parietal lobule. Next, whole-brain fMRI analysis in children with ASD (n=45) was used to test the interaction effect of the total MASC score with the BOLD signal change during decrease vs look-negative conditions of the emotion regulation task. There were significant negative correlations of anxiety with the change of the BOLD signal in three regions: left medial frontal gyrus (k=195, x,y,z=-14,-19,54); right superior frontal gyrus (k=124, x,y,z=11,11,31) and right inferior parietal lobule (k=42, x,y,z=31,-41,36).

Conclusions: Patterns of neural activation during emotion regulation differed between the two groups in: 1) temporal and parietal regions, including the superior temporal gyrus (STG), inferior parietal lobule (IPL) which have been implicated in self-referential processes such as perspective-taking and 2) the ventrolateral prefrontal cortex (vlPFC), implicated in the cognitive control of emotions, with abnormal vlPFC patterns during cognitive reappraisal associated with anxiety. Clinical implications of understanding neural mechanisms to enhance the effectiveness of CBT for anxiety symptoms in ASD are discussed.

**306.003 (Oral)** Early Quantitative and Later Qualitative Neural Differences during Face Processing in Autistic Individuals from Childhood to Adulthood  
**R. Haartsen<sup>1</sup>, L. Mason<sup>2</sup>, P. Garces<sup>3</sup>, A. Gui<sup>4</sup>, T. Charman<sup>1</sup>, M. H. Johnson<sup>2</sup>, J. Tillmann<sup>2</sup>, J. K. Buitelaar<sup>5</sup>, E. Loth<sup>1</sup>, D. Murphy<sup>1</sup>, E. J. Jones<sup>2</sup> and L. G. EEU-AIMS<sup>5</sup>,** (1)Centre for Brain and Cognitive Development, Birkbeck University of London, London, United Kingdom, (2)Centre for Brain and Cognitive Development, Birkbeck, University of London, London, United Kingdom, (3)Neuroscience, Ophthalmology, and Rare Diseases (NORD) Roche Pharma Research and Early Development, Roche Innovation Center Basel, Hoffmann-La Roche, Basel, Switzerland, (4)Department of Psychology, Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, United Kingdom, (5)Institute of Psychiatry, Psychology and

#### Background:

Social communication difficulties in autism are related to adaptive functioning during daily life (Tillman et al., 2019). Rapid and efficient face processing provides crucial information during communication and may be an endophenotype for autism. The underlying neural mechanisms however remain unclear. One theory suggests that differences between autistic and neurotypical individuals arise from quantitative differences in the activation of similar neural pathways, whereas another theory suggests there are qualitative differences in the involvement of different neural pathways. These patterns of neural differences may further vary with development. Temporally sensitive electroencephalography (EEG) research focuses on limited time windows and channels and is unable to disentangle quantitative and qualitative differences, whereas spatially sensitive fMRI evidence is mixed. Multi-channel data-driven approaches that are more temporally and spatially sensitive may provide further answers.

#### Objectives:

In this study, we investigated whether differences in face processing between autistic and neurotypical individuals are better explained by quantitative or qualitative neural processing using a multi-channel analysis approach to event-related EEG responses in 6 to 31-year-olds.

#### Methods:

Participants with and without autism were recruited into child (6-11 years), adolescent (12-17 years), and adult (18-31 years) groups in the EU-AIMS Longitudinal European Autism Project (Loth et al., 2017). Participants passively viewed upright and inverted faces while their 59-channel EEG was measured. 182 (64 females) neurotypical and 222 (55 females) autistic participants with clean EEG data were included in multi-channel EEG analyses.

We used topographic analyses of variance (TANOVA) to test for qualitative differences in topography and analysis of the global field power (GFP) to test for quantitative differences in strength of particular profiles across the whole trial between orientations (upright, inverted faces) and diagnostic groups (autism, neurotypical). Next, we extracted distinct spatiotemporal microstates across orientations and diagnostic groups. Microstates are stable spatial configurations of brain activations that change rapidly to new configurations during the trial.

#### Results:

Upright and inverted faces produced characteristic profiles of topography and strength in the neurotypical groups. These profiles showed subtle differences between the diagnostic groups in adolescents, but not in children or adults (Figure 1).

Analyses of distinct spatiotemporal microstates revealed that compared to the neurotypical group the autistic group showed 1) quantitative differences during early perceptual processing in childhood (orientation\*group interaction for GFP in microstate 4,  $p = .033$ ), 2) early face processing in adolescence (interaction for GFP in microstate 2,  $p = .0009$ ) and adulthood (interaction for GFP in microstate 2,  $p = .001$ ), and 3) qualitative differences during late stage processing across all age groups (microstate 2 and 5 in children, microstate 3 and 4 in adolescents, and microstate 4 and 5 in adults, see Figure 2).

#### Conclusions:

We observed both quantitative and qualitative neural processing differences during face processing between autistic and neurotypical children, adolescents, and adults. These findings may reflect early sensory difficulties and later compensatory processes in autism triggered during adolescence and demonstrate the importance of integrated spatiotemporal analytic approaches in comparing brain processes in neurodevelopmental disorders.

### **306.004 (Oral) Action Monitoring Deficits in Toddlers and Preschoolers with Autism Spectrum Disorder**

#### Background:

Behavioral studies have shown that individuals with autism spectrum disorder (ASD) have problems coordinating their own motor actions (meta-analysis: Fournier et al., 2010). There is also evidence that delays and atypical patterns of development emerge early in the onset of ASD (Iverson et al., 2019). Although we know from previous studies that most individuals with ASD experience motor deficits, the mechanisms underlying these deficits are still unclear. The present study explored two EEG markers during the execution of motor actions to shed light on the neural processes involved in performing actions in toddlers and preschoolers with and without ASD.

#### Objectives:

1. To investigate whether young children with ASD compared to typically-developed (TD) children show altered EEG activation during action execution.
2. To explore if the neural activation is related to a child's fine motor and motor imitation abilities.

#### Methods:

##### *Participants*

The sample that was included in the analysis consisted of two groups of toddlers and preschoolers (ages 21 – 59 months; mean age = 41.1): 30 children that met criteria for ASD on the Autism Diagnostic Observation Schedule (ADOS-2) and 29 TD children.

##### *Behavioral measures*

- Mullen Scales of Early Learning (MSEL; Mullen, 1995) to assess fine motor abilities.
- Elicited imitation battery (based on Rogers et al., 2003) to estimate imitation abilities.

##### *EEG measures*

During the EEG task, children grasped a small toy (e.g., fish) and placed it in a container (e.g., fishbowl). They performed a minimum of 15 trials. EEG data were recorded during this action execution task to measure frontal theta activity, as an index for action monitoring, and central alpha (a.k.a. mu) activity, as an index for motor activity.

#### Results:

The frontal theta activation in the group with ASD ( $M=-.82$ ,  $SD=1.30$ ) was significantly reduced compared to the control group ( $M=.05$ ,  $SD=.82$ ),  $F(1,55)=4.47$ ,  $p=.04$ ,  $\eta p^2=.08$ , even if we control for age and number of clean trials. There was no significant group difference in central alpha/mu activation, C3:  $F(1,55)=.03$ ,  $p=.86$ ,  $\eta p^2=.001$ ; C4:  $F(1,55)=.55$ ,  $p=.46$ ,  $\eta p^2=.01$ . Both groups showed a centrally localized power reduction (see Figure 1). Interestingly, we found significant positive correlations between the frontal theta activation and performance on fine motor,  $r(54)=.34$ ,  $p=.01$ , and imitation tasks,  $r(58)=.41$ ,  $p=.001$ . These correlations appear to be the strongest in the ASD group (see Figure 2). There were no significant correlations between central alpha/mu activation and the behavioral measures: fine motor:  $r(54)=.02$ ,  $p=.92$ ; imitation:  $r(58)=.11$ ,  $p=.42$ .

#### Conclusions:

The group with ASD showed reduced frontal theta activation, which could be an indication of motor control and monitoring deficits. However, the two groups did not differ in mu suppression, so there was equivalent activation of the motor system. There was a positive relation between frontal theta activation and measures of fine motor and imitation abilities. This link might suggest that deficits in action monitoring are involved in compromised motor abilities, such as problems in fine motor movements and imitation. The present study contributes to a better understanding of the neural underpinning of the motor deficits seen in

individuals with ASD.

## ORAL SESSION — OTHER - MULTIPLE TOPIC AREAS

### Oral 307 - Functional and Anatomical Neuroimaging Markers of Autism I

**307.001** (Oral) An Integrated Analysis of Autism Associated Inter-Individual Variations of Gray and White Matter Morphology

Background: Autism Spectrum Disorder (henceforth autism) is a complex condition associated with alterations in the gray matter (GM) and white matter (WM) morphometry. Although lots of studies have explored the atypical characterizations particularly in GM volume or WM microstructure of autism, the commonality of most of these studies is their reliance on unimodal analyses. These neglect the possibility that different modalities may reflect common pathological pathways. Studies that highlight the underlying shared variance between modalities in autism remain scarce.

Objectives: To better learn a comprehensive integrated pattern of GM and WM morphometry covariation in autism, we applied a multimodal integrative approach to fuse GM volume and WM diffusion measures in a large deeply phenotyped autism dataset – the EU-AIMS LEAP. Subsequently, we aimed to unravel the associations in autism between multi-modal brain substrates and clinical phenotypes in a general univariate and a multivariate way.

Methods: We studied 183 individuals with autism and 157 typically developing individuals, aged between 6 and 30 years in the LEAP dataset. Linked Independent Component Analysis (LICA) was utilized to simultaneously factorize all subjects' voxel-based morphometry (VBM), fractional anisotropy (FA), mean diffusivity (MD), anisotropy mode (MO), axial diffusivity (L1) and radial diffusivity (RA) into 80 independent components (ICs) of spatial variations. A Generalized Linear Model (GLM) was used to examine case-control differences and univariate brain-behavior associations while regressing out the effects of age, gender, IQ and scan site. Next, Canonical Correlation Analysis (CCA) was performed to respectively explore the aggregated effects between all multi-modal ICs of GM-WM covariations and subscales of ADI and ADOS, and Social Responsiveness Scale (SRS), Repetitive Behavior Scale-Revised (RBS) and Short Sensory Profile (SSP) in autism. The statistical significance of each pair of canonical variates was determined by permutation testing (10,000 times).

Results: We found one IC with a significant group effect in the GLM analyses ( $b=0.189$ ,  $p=5.030 \times 10^{-4}$ ; FDR corrected,  $p=0.040$ ). This component was primarily associated with decreased density of bilateral insula, frontal area, postcentral, angular, cingulate and inferior temporal gyrus, and increased density of caudate and supra-/intra-calcarine cortex in autism; and co-occurred with altered WM diffusion features in superior longitudinal fasciculus, superior, posterior corona radiator (Figure 1). The CCA results showed one significant correlation ( $r=0.618$ , permutation  $p=0.006$ ) between components that involved variation of thalamus, superior and inferior longitudinal fasciculus that mostly located in temporal lobe, and the symptoms of communication and social interaction in autism group (Figure 2). Note that the IC with significant group effect was one of the three ICs that contributed most to the correlation.

Conclusions: Our findings replicate our previous GM density covariations results (Mei et al., 2020), and extend the former results by demonstrating that frontal, parietal, inferior temporal area, basal ganglia, limbic system, and thalamus cooperating with their related WM fasciculi are implicated in autism. Therefore, the convergence of our findings suggests that co-occurring modality patterns of GM and WM morphometry in our study are found collaborating and connecting in the brain underlying mechanisms of autism.

---

**Background:** Autism spectrum disorder (ASD) is a neurodevelopmental disorder diagnosed on the basis of social impairment and restricted, repetitive behaviors (RRBs). Converging results from animal and adult human neuroimaging studies have generated great interest in the cerebellum's role in the pathophysiology of ASD. Specifically, recent theoretical commentaries have posited that cerebellar-mediated error signaling impairments may account for the emergence of ASD-associated behaviors during the second year of life. Together, this work identifies infant cerebellar connectivity as a promising presymptomatic neural biomarker of ASD. However, supportive evidence from pre-specified, longitudinal tests of cerebellar function in human infants is lacking.

**Objectives:** This project aimed to interrogate infant cerebellar functional connectivity (fcMRI) as a presymptomatic neural biomarker of ASD, in a rigorous manner using univariate, multivariate, and enrichment approaches.

**Methods:** We analyzed data from the Infant Brain Imaging Study (IBIS), a prospective study of infants at high and low familial risk for ASD. Imaging processing methods are similar to Eggebrecht et al. (2017). To be included in analyses, we stipulated that participants ( $n = 94$ , 68 male) provide at least 6.25 minutes of motion-scrubbed fcMRI data. Brain-behavior associations were analyzed for 6-month cerebellar functional connections in relation to 12 and 24-month ASD-associated behavior (measures of joint attention, RRBs, and motor coordination; assessed via parent-report and clinical observation) and 24-month ASD diagnostic outcome (positive/negative; assessed via clinical best estimate). Univariate (generalized linear modeling) hypothesis testing, multivariate (support vector machine with nested, leave-one-out cross-validation) predictive classification, and enrichment-based brain-wide screening were used to evaluate potential cerebellar contributions to ASD. Our hypothesis-driven tests focused on cerebellar-frontoparietal (FPN: implicated in error signaling) and cerebellar-default mode (DMN: implicated in prior studies of ASD) connections.

**Results:** Univariate tests of cerebellar-FPN and cerebellar-DMN connections failed to implicate the cerebellum in ASD-associated behaviors in a convincing manner (only .02% of tested cerebellar-cortical connections survived multiple comparisons correction), despite > 80% power to detect medium-sized effects. Multivariate predictive tests with cerebellar-FPN and cerebellar-DMN connections similarly failed to achieve above-chance classification accuracy for 24-month ASD outcomes, despite utilizing procedures that achieved > 80% positive predictive value in prior brain-wide work (Emerson et al., 2017). Whole-brain enrichment approaches identified three 6-month network pairs that were strongly associated with RRBs at 12 or 24 months (**Figure 1**). However, cerebellar regions of interest were implicated at chance within these networks (**Figure 2**).

**Conclusions:** The present study interrogated infant cerebellar connectivity as a presymptomatic neural biomarker of ASD using multiple analytic approaches. Contrary to hypotheses, we failed to observe strong associations between 6-month cerebellar fcMRI and 12-24-month ASD-associated behaviors and outcomes, casting doubt on cerebellar theories of ASD etiology and arguing that cerebellar effects, if present, are likely small. Instead, we identified brain-behavior associations between multiple 6-month network pairs and later RRBs, indicating network-level correlates for emerging ASD behaviors that warrant future testing in independent samples. The frequency of cerebellar contributions within these networks was at chance, suggesting that the cerebellum may support the development of RRBs in the broad context of other (non-cerebellar) functional connections.

### **307.003 (Oral) Dopaminergic Functioning in Autism Spectrum Disorder: An [18F]-Fdopa PET/CT Study**

**R. Schallbroeck<sup>1,2</sup>, F. H. P. van Velden<sup>3</sup>, L. F. de Geus-Oei<sup>3,4</sup>, M. Yaqub<sup>5</sup>, A. Schranter<sup>6</sup>, T. van Amelsvoort<sup>1</sup>, J. Booij<sup>6</sup> and J. P. Sellen<sup>1,2</sup>,** (1)School for Mental Health and Neuroscience, Maastricht University, Maastricht, Netherlands, (2)Psychosis Research Group, Rivierduinen Institute for Mental Healthcare, Leiden, Netherlands, (3)Section of Nuclear Medicine, Department of Radiology, Leiden University Medical Center, Leiden, Netherlands, (4)Biomedical Imaging Group, University of Twente, Enschede, Netherlands, (5)Department of Radiology and Nuclear Medicine, Amsterdam University Medical Centers, location VU

**Background:** Dopaminergic signaling has long been hypothesized to contribute to autism spectrum disorder (ASD) traits, such as difficulties in social interaction and communication and stereotyped behaviors. However, few studies examined dopamine functioning *in vivo* in ASD.

**Objectives:** To examine whether (1) individuals with ASD show an increase in striatal presynaptic dopamine synthesis capacity relative to controls, and whether (2) striatal presynaptic dopamine synthesis capacity is associated with self-reported autistic traits.

**Methods:** We recruited unmedicated, non-psychotic adults with ASD ( $n = 44$ ) and matched controls ( $n = 22$ ), aged 18 to 30 years old and with an average-to-high intelligence. All adults with ASD had previously received this diagnosis from a registered mental health clinician, and the first author confirmed this diagnosis using the Autism Diagnostic Observation Schedule-2 (ADOS-2) module 4. After a CT-scan, which was acquired for attenuation-correction purposes, participants underwent a 90-minute dynamic [ $^{18}\text{F}$ ]-FDOPA PET-scan. The influx constant  $k_{in}^{cor}$ , indicative of presynaptic dopamine synthesis capacity, was calculated using reference Patlak graphical analysis. A co-registered, structural T1-weighted MRI-scan, acquired prior to the PET/CT-scan, was used to identify the cerebellar reference region and striatal regions of interest. Both a region-of-interest analysis and a voxel-based analysis was conducted. The Autism Spectrum Quotient (AQ) was used to assess autistic traits.

**Results:** We found no statistically significant differences in striatal dopamine synthesis capacity between ASD and controls ( $F_{1,60} = 0.026$ ,  $p = 0.87$ ). This was confirmed with voxel-based analysis, which showed similar whole-brain distribution of [ $^{18}\text{F}$ ]-FDOPA uptake in ASD and controls. Participants with ASD had significantly higher AQ total scores ( $t_{64} = 8.74$ ,  $p < 0.001$ ), as well as social interaction ( $t_{64} = 8.34$ ,  $p < 0.001$ ) and attention to detail ( $t_{64} = 5.55$ ,  $p < 0.001$ ) subscale scores. However, in both samples, striatal dopamine synthesis capacity was neither significantly related to AQ total scores, nor to AQ social interaction or attention to detail subscale scores (all family-wise error corrected  $p$ -values n.s.). Results were similar before and after adjusting for age, sex, smoking-status, and PET/CT-scanner-type.

**Conclusions:** In contrast to previous hypotheses about the role of dopamine in ASD, the results of this large-sample PET/CT-study show that striatal dopamine synthesis capacity is not increased in ASD and not associated with self-reported autistic traits. Further research is necessary to examine whether the findings generalize to a broader ASD population and to examine other aspects of dopamine signalling in ASD.

### 307.004 (Oral) Increased Glutamate + Glutamine Correlates with Autism Severity and Tactile Sensitivity in Children with Autism Spectrum Disorders

**J. L. He<sup>1</sup>**, G. Oeltzschner<sup>2</sup>, M. Mikkelsen<sup>3</sup>, A. Deronda<sup>4</sup>, D. Crocetti<sup>5</sup>, S. H. Mostofsky<sup>6</sup>, R. A. Edden<sup>2</sup> and N. A. ---

**Background:** While autism spectrum disorders (ASD) are characterized by difficulties with social and communicative function, sensory abnormalities are common and are increasingly recognized. One of the prevailing theories of sensory abnormalities in ASD is that of altered excitation-inhibition (E-I) balance. This theory suggests that an increase in excitation and/or a decrease in inhibition results in a hyper-excitability and hence 'noisier' system, which in turn results in less efficient encoding and discrimination of sensory information. Despite early suggestions of altered E-I balance in ASD, the literature has produced mixed findings, perhaps owing to the heterogeneity of methods used to quantify and operationalize E-I. Whether and how E-I is associated with sensory processing and autism-related symptom severity also remains unclear.

**Objectives:** In the current study, edited magnetic resonance spectroscopy (MRS) was used to determine and compare levels of glutamate + glutamine (Glx) and  $\gamma$ -aminobutyric acid (GABA) as indirect markers of E-I in a large sample of children with ASD. We also assessed the relationship between these markers of E-I with tactile sensitivity and autism symptom severity.

**Methods:** Ninety-three children with ASD (5 females;  $M_{Age} = 10.19$ ,  $SD_{Age} = 1.57$ ) and ninety-eight typically-developing controls (TDC) (23 females;  $M_{Age} = 9.73$ ,  $SD_{Age} = 1.17$ ) participated in this study. Structural imaging and MRS (i.e., Glx and GABA levels) data were acquired on a Philips 3T Achieva MRI scanner using spectral-edited MRS (TE = 80 ms; 320 averages) from the

primary sensorimotor cortex (SM1) and thalamus (Figure 1a) (~27 ml voxels). Tactile perceptual thresholds (e.g., detection, discrimination and order judgement thresholds) were determined with psychophysics and symptom severity was assessed with the Autism-Diagnostic Observation (ADOS) and ADOS-2.

Results: While we did not observe reduced SM1 GABA levels in children with ASD ( $z = 0.089, p = 0.929$ ) as previously reported, after controlling for age and sex, we found significantly increased levels of Glx ( $z = 2.95, p < 0.003$ ) in children with ASD (see Figure 1b and 1c). Interestingly, higher Glx levels in SM1 predicted lower (i.e., better) sequential frequency discrimination (SQFD) thresholds ( $r = -0.39, p = 0.003$ ) and lower symptom severity scores on all total scales of the ADOS (Communication:  $r = -0.27, p = 0.015$ ; Social Interaction:  $r = -0.23, p = 0.039$ ; Restricted and Repetitive Behaviors:  $r = -0.31, p = 0.004$ ) in children with ASD (see Figure 2).

Conclusions: The finding of higher SM1 Glx levels and its association with lower SQFD thresholds in ASD provides some support for the altered E-I balance theory of sensory abnormalities in ASD. Interestingly, while Glx was increased in ASD relative to TDCs, higher levels of Glx was associated with lower ASD-associated symptom severity. It is important to note that although Glx might reflect glutamatergic function (and 'excitation'), the Glx MRS signal captures both glutamate and glutamine, and cannot distinguish between synaptic, vesicular, or other pools. Thus, how Glx functionally contributes to altered sensory processing and reduced symptom severity in ASD requires further investigation.

#### Background:

Observational behavior analysis of children, which is critical for the evaluation, monitoring, and discovery of biomarkers related to Autism Spectrum Disorder (ASD), is performed in-person by trained clinicians. With the rapid development of computer vision and machine learning technology, scalable and objective methods make automatic analysis of human behavior possible.

#### Objectives:

Develop and deploy in pediatric clinics scalable computational behavioral phenotyping tools for screening ASD using a combination of strategically-designed stimuli and computer vision and machine learning tools.

#### Methods:

We developed and deployed in pediatric clinics a scalable tool for computational behavioral phenotyping. The child's face is recorded using the front-facing camera of a mobile device while short movies are presented, these are designed to elicit specific social, emotional, and motor responses (Figure 1). Computer vision algorithms are used to detect and track the child's face position, facial landmarks, gaze, and attention. In addition, interactive games are used to analyze the child's sensory-motor skills.

#### Results:

17-37 months old toddlers were recruited at four Primary Care clinics by study staff or the family's primary physician (ASD: N=40, Typical Developing (TD): N=936). The percentages of usable data was high, 95% and 87% for the iPhone and 95% and 93% for the iPad, for the TD and ASD groups, respectively. Figure 2 summarizes a subset of the main results. First, (a-c), we show that children in the ASD group tend to orient less when their name is called, and if they do orient, they tend to present a higher latency. We show these two features can be combined to improve the assessment precision and specificity. Figure 2 (b-d)

shows the recognition results when gaze data is used, and more interestingly, combined across multiple stimuli. First we illustrate the ROC curves for data collected from individual stimuli and their combination. The bottom illustration (d) shows the space of gaze features, and how tree classifiers partition it, red is associated with a higher risk of ASD and blue with a lower risk.

Conclusions:

We developed and deployed in pediatric clinics a mobile application that displays visual and interactive stimuli designed to elicit behaviors relevant to ASD. Using computer vision techniques, we can automatically track a child's head, facial expressions, and gaze, which are used and combined to infer critical behavioral patterns.

**312.002 (Oral)** Initial Psychometrics of an Early Childhood Social Motivation Questionnaire and Differentiation of Children with ASD

*S. Davis<sup>1</sup>, D. Abrams<sup>2</sup>, P. Mei<sup>2</sup>, G. Dent<sup>2</sup>, A. Rocca<sup>2</sup> and N. Marrus<sup>1</sup>, (1)Washington University School of Medicine, St. Louis, MO, (2)Washington University in St. Louis, St. Louis, MO*

---

Background: Early disruptions in social motivation, the predisposition for preferential social orienting; seeking, wanting, and liking social contact; and maintaining social engagement (Chevallier et al., TICS, 2012), are hypothesized to constrain social learning and to contribute to atypical development preceding ASD. Studying social motivation's role in the ontogeny of ASD has been hindered by the lack of measurement tools; here we evaluate a novel social motivation questionnaire for early childhood.

Objectives: To evaluate psychometrics of a parent-report Social Motivation Questionnaire (SMQ) designed for infants through preschoolers and test whether it differentiates children with and without ASD.

Methods: SMQ items provided balanced representation of elements of social motivation described above. Items were informed by the developmental literature, consultation with child development experts, and parent feedback. SMQ versions for specific age groups contained a common set of 51 items adapted for developmental stage, specifically infant (6-17 months), toddler (18 months-3 years), and preschooler (4-6 years). The SMQ was deployed online in two samples: 1) a Qualtrics-recruited sample of typically-developing children ages 6 months-5 years (n=509) and 2) a community-based sample of children ages 18 months-6 years with and without ASD (n=107, n=28 with ASD). Internal consistency was calculated using Cronbach's alpha. Pearson's correlations tested for temporal stability in participants with repeat SMQ ratings after 4 months (n=273), as well as convergent validity with available age-appropriate versions of the Social Responsiveness Scale (SRS), a quantitative ASD trait measure. Exploratory factor analysis (EFA) using principal axis factoring and an oblimin rotation was applied in the larger Qualtrics sample. T-tests compared scores in children with and without ASD.

Results: SMQ scores collected via Qualtrics demonstrated continuous, unimodal distributions (Figure 1A-C), excellent internal consistency for each age group ( $\alpha > 0.93$ ), and evidence of temporal stability,  $r = 0.68$  ( $p < .001$ ). SMQ scores inversely correlated with ASD traits indexed by the SRS,  $r = -0.60$  ( $p < .001$ ), indicating 36% shared variance ( $r^2$ ). Two factors were identified: an overarching social motivation factor (F1) accounting for 28% variance that encompassed all aspects of social motivation and a social withdrawal factor (F2) accounting for 8% variance. These factors showed strong internal consistency ( $\alpha_{F1} = 0.95$ ;  $\alpha_{F2} = 0.87$ ), item loadings between 0.73-0.32, and modest intra-correlation ( $r = 0.23$ ,  $p < .001$ ). In the community sample, children with versus without ASD had lower SMQ scores (Figure 1D;  $t(39) = 9.50$ ,  $p < .001$ ), with a large effect size (Cohen's  $d = 2.4$ ); similar differences were also observed for SMQ factors (F1: Cohen's  $d = 1.9$ ; F2: Cohen's  $d = 2.0$ ).

Conclusions: Strong initial psychometrics were observed for the early childhood SMQ. Measurable cross-age stability during early development suggests trait-like properties of social motivation, while EFA was consistent with a unified social motivation construct in which opposing withdrawal-related behaviors comprised a separable dimension rather than the distal end of a single continuum. The SMQ differentiates young children with and without ASD and correlates with ASD traits but also demonstrates unique variance, consistent with a behavioral dimension having potential transdiagnostic relevance. Future directions include testing this scale prospectively in at-risk populations to assess whether the SMQ can enhance early identification or clinical subtyping to guide intervention.

**312.003 (Oral)** Development and Standardization of the Brief Observation of Symptoms of Autism (BOSA) in Response to COVID-19

*D. Dow<sup>1</sup>, A. Holbrook<sup>2</sup>, C. K. Toolan<sup>2</sup>, S. H. Kim<sup>2</sup> and C. Lord<sup>2</sup>, (1)UCLA Semel Institute for Neuroscience & Human Behavior, Los Angeles, CA, (2)University of California, Los Angeles, Los Angeles, CA, (3)Psychiatry, Center for Autism and the Developing Brain, White Plains, NY*

---

**Background:** The COVID-19 pandemic has presented new challenges to accessing care for individuals with autism, prompting researchers and practitioners to seek innovative approaches that are feasible through telehealth or in-person visits with necessary safety protocols. The Brief Observation of Symptoms of Autism (BOSA) was adapted from the Brief Observation of Social Communication Change (BOSCC) to provide a social context with standardized toys and activities. These can be presented in-person without PPE by a parent, caregiver, or therapist within a 12-14-minute observation. Clinicians familiar with the ADOS-2 can observe the BOSA live, through telehealth, or on recorded video and complete many ADOS-2 codes, which can then be mapped onto DSM-5 criteria to aid in making a diagnosis.

**Objectives:** To examine psychometric properties and determine optimal use as supported by empirical evidence and data-driven scoring procedures for each BOSA version: for minimally verbal children (MV), those with phrase speech and younger fluent (PSYF), fluent 6-10 year old's (F1), and fluent children 11 through adults (F2). Differences between scoring modules (ADOS Toddler, 1-4), examiners (caregiver, therapist) and settings (clinic, home) will also be explored.

**Methods:** ADOS-2 scores were first dichotomized based on existing data to create a "recode rule" for each item. Preliminary analyses were conducted on a sample of 152 participants (84 ASD, 68 non-ASD) who completed BOSCCs as part of previous studies at UCLA and Weill Cornell and included item level distributions and interrater and test-retest reliability. Final analyses will also include factor analysis, correspondence with the ADOS-2, age and IQ effects, recommended cutoff scores, and reliability using interclass correlation coefficients (ICCs).

**Results:** Dichotomized codes were determined by balancing sensitivity and specificity, with specificity  $\geq .65$  as the cut-point for a code of 1 to represent symptom presence. Preliminary results suggest strong interrater reliability and test-retest reliability (percent agreement=85.2% and 94.1%, respectively). Most ADOS-2 items could be reliably scored in this context, though items related to deficits in relationships (e.g., insight into emotions and social situations, responsibility) were coded an "8" in over 50% of the cases. Opportunity to observe the use of joint attention (>80% "8" for MV), gestures (>20% "8" for F1), and presence of restricted and repetitive behaviors (RRBs) was also limited.

**Conclusions:** While the BOSA provides a standardized context to observe behaviors consistent with autism, symptom presence in certain subdomains (e.g., deficits in relationships, RRBs) is not as readily observable in this context and needs to be gathered through supplemental parent report and developmental history. When used in combination with other measures (e.g., the ADI-R), the BOSA provides a social context that allows a clinician to gain clinical information to reliably code many ADOS-2 items that can be mapped onto diagnostic criteria. Widespread interest in and use of the BOSA has already begun due to the urgent need to provide critical services through the pandemic. Even after COVID-19, there is likely to be continued interest in flexible approaches to screening and diagnosis that could potentially improve timely access to appropriate care for families in need of services.

**312.004 (Oral)** Structural Validation of the Autism-Spectrum Quotient Short Form (AQ-Short) in Children with an Autism Spectrum Disorder: A Comparison between China and the Netherlands

**F. Liu<sup>1</sup>, A. M. Scheeren<sup>2</sup>, R. A. Hoekstra<sup>3</sup>, R. Grove<sup>4</sup>, C. Wang<sup>5</sup> and S. Begeer<sup>2</sup>, (1)Horstenberg, Vrije University Amsterdam, Amsterdam, Netherlands, (2)Vrije Universiteit, Amsterdam, Netherlands, (3)Department of Psychology, King's College London, London, United Kingdom, (4)University of Technology Sydney, Sydney, NSW, Australia, (5)NanKai University, TianJin, China**

**Background:** While Autism spectrum disorders (ASD) are recognized and diagnosed globally, there may be subtle differences in autistic traits across cultures. With a population of almost 1.4 billion, and an increasing prevalence of ASD, China represents the largest growing population of autistic individuals in Eastern countries. So far there have been no systematic comparisons of children's autistic traits from Chinese and Western samples using standardized tools and procedures. Autism Spectrum Quotient-Short (AQ-S) has been proven to be a reliable brief questionnaire in successfully capturing the core dimensions of autistic traits in adults but has not been studied on child version. Before any meaningful cross-country comparisons in severity of autistic traits can be made, it is important to investigate whether the tool used is conceptually equivalent across cultures.

**Objectives:** To examine the factor structure of the Chinese and Dutch version of the AQ-S in children with ASD and compare autistic traits in children with ASD in China and the Netherlands.

**Methods:** We analysed parent-reported AQ-S in children with ASD from China (327 children with autism diagnosis, 277 boys and 50 girls) and the Netherlands (694 children with autism diagnosis, 539 boys and 155 girls). The mean age of Chinese children was 8.57 years (SD= 2.97, range=3.5-16.92 years) and the mean age of Dutch children was 11.81 years (SD= 2.54, range= 6-16.12 years). Confirmatory and exploratory factor analyses were performed for the whole sample, as well as for Chinese and Dutch children separately.

Results: Initial confirmatory factor analysis testing the two-factor hierarchical model previously identified in the AQ-S in adult samples did not fit our data of parent ratings of the AQ-S well. Subsequent exploratory factor analyses indicated most support for a three-factor model in the Chinese sample, with factors reflecting “numbers and patterns”, “social skills”, and “mind-reading”; and a five-factor model for the Dutch sample, with factors reflecting “imagination”, “numbers and patterns”, “attention switching”, “social skills”, and “mind-reading”. Differences were observed in the items loading on the factors common to both countries. For example, item 15 “S/he finds it hard to make new friends” loaded on factor mind-reading in China, but on factor Social skills in the Netherlands. The numbers and patterns factor showed a negative association with the social skills factor in Chinese ASD children; this inverse correlation was not observed in the Dutch data.

Conclusions: Our results indicate differences in the underlying factor structure of parent-reported autistic traits in Eastern and Western populations of autistic children. This lack of conceptual equivalence may be due to subtle differences in the expression, recognition, interpretation and reporting of autistic traits across cultures.

Szatmari<sup>15</sup> and M. Elsabbagh<sup>16</sup>, (1)King's College London, Institute of Psychiatry, Psychology and Neuroscience, London, United Kingdom, (2)Biostatistics & Health Informatics, Kings College London, London, United Kingdom, (3)Kings College London, London, United Kingdom, (4)Azrieli Center for Autism Research, Montreal Neurological Institute-Hospital, Montreal, QC, Canada, (5)Offord Centre for Child Studies, McMaster University, Hamilton, ON, Canada, (6)University of British Columbia, Vancouver, BC, Canada, (7)Offord Centre for Child Studies, McMaster University, Hamilton, ON, CANADA, (8)McMaster Autism Research Team, McMaster University, Hamilton, ON, Canada, (9)Dalhousie University / IWK Health Centre, Halifax, NS, CANADA, (10)The Hospital for Sick Children Research Institute, Toronto, ON, Canada, (11)University of Ottawa, Ottawa, ON, Canada, (12)Simon Fraser University, Vancouver, BC, Canada, (13)Tel-Aviv University, Tel-Aviv, Israel, (14)University of Alberta, Edmonton, AB, Canada, (15)The Hospital for Sick Children, Toronto, ON, Canada, (16)Neurology and Neurosurgery, McGill University, Montreal, QC, Canada

**Background:** Regression, broadly defined as the loss of acquired skills in early childhood, is a key clinical feature of autism. Despite its importance clinically, we know little about factors underlying regression in autism or about the prognosis of children who exhibit regression compared to those who do not. These knowledge gaps are in part due to a lack of consensus on how regression is operationally defined (relative to other domains), the retrospective nature of caregiver report of regression (often years after onset), and the lack of prospective longitudinal data on related developmental outcomes.

**Objectives:** To identify rates and potential predictors of regression and its impact on subsequent development in a prospective longitudinal sample of children with ASD from diagnosis until age 10 years.

**Methods:** We analyzed data from *Pathways in ASD*, a prospective longitudinal study of 421 Canadian children enrolled around the time of an autism diagnosis between ages 2 and 5 years. Rates of regression were identified based on parent report on the ADI-R. Profiles of those with and without regression were compared around the time of diagnosis. Potential differences in various domains of development were evaluated using the VABS-II, including expressive and receptive communication. Trajectories from the time of diagnosis to 10 years of age were compared for those with and without regression.

**Results:** ADI-R data was available for 408 children, of whom 90 (22%) were classified as having regression in the communication domain. Demographic and other health factors did not differ in the two groups, including caregiver education ( $p=.377$ ), family income ( $p=.824$ ), child sex ( $p=.180$ ), reported seizures ( $p=.459$ ), and age of enrollment ( $p=.991$ ). Children with regression walked somewhat earlier (hazard ratio (HR) 1.50,  $p=.001$ ) and attained first words sooner (HR=2.38,  $p<.001$ ) than those without regression. However, both groups attained phrase speech at comparable ages ( $n=318$ ; HR=1.02,  $p=.863$ ). Around the time of diagnosis Those with regression exhibited comparatively greater delays in expressive and receptive communication (ES = -0.36;  $p=.002$ ; ES=-.38,  $p=.002$ ), but not in fine or gross motor skills (ES=-.05,  $p=.676$ ; ES=.13,  $p=.268$ ). Overall, those with regression continued to exhibit expressive communication impairment (95% CI 2.37 to 7.15,  $p<.001$ ) but not receptive communication delay compared to the remainder of the sample. Trajectories of development in communication skills were highly heterogeneous to age 10 years; children with or without regression were equally likely to achieve functional language by this age.

**Conclusions:** Findings from the *Pathways in ASD* cohort analysis replicated those reported in Pickles et al. (2009) showing that parent reporting of regression is more likely if children have already exhibited some clear language milestones such as single words, whereas regression is not associated with the eventual age of attaining phrase speech. While subsequent communication trajectories of those with regression were more impaired than those without, this pattern only persists for expressive not receptive communication development.

**313.002 (Oral)** Comparison of Trajectories of Emotional and Behavioural Problems from Age 2-10 Years in an Autistic and a Typically Developing Cohort

**N. J. Wright<sup>1</sup>, V. Courchesne<sup>2,3</sup>, R. Bedford<sup>4</sup>, A. Pickles<sup>5</sup>, T. Bennett<sup>6</sup>, E. Duku<sup>7</sup>, S. Georgiades<sup>8</sup>, C. M. ---

**Background:** Autistic youth experience elevated rates of mental health problems. Cross-sectional studies using clinical cut offs report prevalence rates ranging from 30% in autistic pre-schoolers (Hartley et al., 2008) to 70-75% in older autistic children (Chandler et al., 2016; Simonoff et al., 2008). Few studies have compared rates of mental health problems in autism with neurotypical age-matched children, nor examined the longitudinal course of mental health problems over childhood.

**Objectives:** To compare the evolution of three common mental health domains (aggressive behaviors, Anxiety/Depression and Attention Problems) from aged 2-10 years in a sample of autistic children and a sample of neurotypical children, from two independent cohorts: Pathways to Better Outcomes and the Wirral Child Health and Development Study (WCHADS).

**Methods:** The Pathways study enrolled children with ASD (n=421) who were assessed eight times from around the time of diagnosis (age 2-4 years) to age 10.5 years. The neurotypical sample in the WCHADS(n=1233) were assessed five times from age 2.5 to 9.5 years. Mental health problems were assessed using the parent report Child Behaviour Checklist (Achenbach & Rescorla, 2001) preschool (age 2-5 years) and school-age (age 6+ years) aggression, attention problems and anxiety-depression syndrome scales. Growth curve models were fitted with a scaling factor to accommodate the change from the preschool to school age questionnaires. Models assume attrition based on observed scores (i.e. missing at random; MAR).

**Results:** The autistic children had significantly higher scores on the three mental health domains at every time point, and there were significant cohort differences at the intercepts (all  $p < .001$ ). Inspection of Figure 1 suggests the pathway of development in neurotypical and autistic cohorts are not as strikingly different as the intercept. Model fitting nonetheless shows significant differences in log, linear and quadratic growth (all  $p < .05$ ). Differences in slope are due to steeper decline across all domains in autistic children in early childhood, with the model-based estimates suggesting that in late childhood the autistic children continue to show decline in mental health symptoms whereas the neurotypical children began to level out. The WCHADS data on neurotypical children was used to generate percentiles to compare the two cohorts, and the autistic children began around or above the 80<sup>th</sup> percentile on WCHADS scores for aggression and anxiety-depression, and 85<sup>th</sup> percentile for attention problems.

**Conclusions:** Autistic children showed substantially elevated rates of all three mental health domains compared to the neurotypical children at every age, but particularly in early childhood. Both autistic and neurotypical children showed a decrease in all three domains over childhood, with the model-based estimates accounting for attrition suggesting that children with autism showed a steeper decline in early childhood and a continuing decline in late childhood when scores in neurotypical children were levelling out.

**313.003 (Oral)** Distinct IQ Trajectories in Youth with ASD: A Latent Class Growth Analysis

**A. C. Cho<sup>1</sup>, A. M. Iosif<sup>1</sup>, N. Dalloul<sup>1</sup>, D. G. Amaral<sup>1</sup>, C. W. Nordahl<sup>1</sup>, E. Ferrer<sup>2</sup> and M. Solomon<sup>1</sup>,** (1)Human Development & Psychology, University of California, Los Angeles, Los Angeles, CA, (2)Public Health Sciences, University of California Davis, Davis, CA, (3)Psychiatry and Behavioral Sciences, UC Davis MIND Institute, Sacramento, CA, (4)Department of Psychiatry and Behavioral Sciences, The Medical Investigation of Neurodevelopmental Disorders (MIND) Institute, UC Davis School of Medicine, University of California Davis, Sacramento, CA, (5)UC Davis, Davis, CA

---

**Background:** Researchers have highlighted heterogeneity in autism spectrum disorder (ASD) as a serious barrier to scientific progress (e.g., Georgiades, Szatmari, & Boyle, 2013). Variation in intellectual ability is particularly important, as it represents a primary aspect of heterogeneity within the ASD phenotype and is a strong predictor of outcomes in ASD individuals (Gillespie-Lynch et al., 2012; Munson et al., 2008). While intelligence quotient (IQ) typically improves through early childhood in ASD (Flanagan et al., 2015), our previous research using the Autism Phenome Project (APP) cohort identified four distinct IQ trajectories in a longitudinal sample of ASD youth from early (ages 2-3.5 years) to middle (ages 5-8) childhood (Solomon et al., 2018). Subgroup membership predicted unique starting points and changes in adaptive communication, externalizing symptoms, and ASD symptom severity. These findings provide initial evidence of different developmentally homogeneous ASD phenotypes; however, we do not know whether these subgroups persist into adolescence and if they are significant predictors of more distal outcomes.

**Objectives:** The present study follows up on the APP cohort to determine whether these IQ trajectories extend into early adolescence (ages 9-13).

**Methods:** IQ scores were computed using the Mullen Scales of Early Learning (Mullen, 1995) and the Differential Ability Scales-II (Elliot, 2007). Latent class growth analysis was used to identify distinct IQ trajectories in a sample of ASD youth with at least one timepoint of data (Timepoint 1:  $n=373$ ; ages 1.7-5.0; Timepoint 2:  $n=154$ ; ages 4.3-9.4; Timepoint 3:  $n=116$ ; ages 9.0-13.6), with neurotypical peers serving as a reference group (Timepoint 1:  $n=162$ ; ages 2.0-4.5; Timepoint 2:  $n=86$ ; ages 4.2-9.9; Timepoint 3:  $n=72$ ; ages 9.9-13.7). Linear and quadratic age-based models were tested for the ASD group.

**Results:** A quadratic model with three classes best fit the data. The reference TD group model presented a normative mean IQ with mild increases that gradually tapered off into early adolescence. In contrast, ASD subgroup 1 ( $n=146$  [39%]; labeled “Changers”) began with notably low IQ followed by large increases that more sharply diminished as individuals entered early adolescence. The trajectory for subgroup 2 ( $n=168$  [45%]; “High Challenges”) also began with a low IQ but presented a decline over time. Subgroup 3 ( $n=59$  [16%]; “Lesser Challenges”) presented a trajectory that was comparable to the reference group (i.e., relatively normative IQ with gradual increase during childhood).

**Conclusions:** Largely replicating our original study, there were three distinct IQ trajectories in the current sample’s ASD group which extended into preadolescence. Unlike the reference group, which exhibited an IQ developmental trajectory consistent with the literature, ASD subgroups 1 and 2 showed distinct trajectories of rapid IQ increase that leveled off and low and declining IQ over time, respectively. Subgroup 3 resembled the normative group and may represent an “optimal outcome” phenotype that has been consistently replicated in the extant literature (Fein et al., 2013). Future analyses will investigate this content by examining whether subgroup membership predicts adaptive communication (Vineland Adaptive Behavior Scales; Sparrow et al., 2005) and internalizing and externalizing behavior (Child Behavior Checklist; Achenbach & Rescorla, 2000, 2001).

**313.004 (Oral)** Influence of Siblings on Adaptive Behavior Trajectories in Autism Spectrum Disorder  
*N. E. Rosen<sup>1</sup>, J. B. McCauley<sup>2</sup> and C. Lord<sup>1</sup>, (1)University of California, Los Angeles, Los Angeles, CA, (2)Saint Mary's College of California, Moraga, CA*

**Background:** It is widely believed that siblings play an important role in shaping the developmental trajectories of individuals with autism spectrum disorder (ASD). The presence of siblings has been associated with better social communication skills, less severe non-verbal communication deficits, and improved theory of mind abilities among individuals with ASD. However, little is known about the impact of siblings on the growth of overall adaptive skills over time, even though adaptive behavior competencies are among the strongest predictors of positive outcomes in individuals with ASD.

**Objectives:** The current study aims to examine the influence of sibling constellation factors, including the presence of a sibling, position in the birth order, gender of the closest-age sibling, and gender match of the sibling dyad, on the adaptive behavior trajectories of individuals with ASD and those with a history of non-spectrum developmental disorders from 9 to 26 years of age.

**Methods:** Participants included 208 individuals with ASD or non-spectrum developmental disorders selected from an ongoing longitudinal study following participants from childhood through adulthood. The Vineland Adaptive Behavior Scales (VABS) was administered to participants at six timepoints between ages 9-26, and change in VABS age equivalents was examined using multilevel models while controlling for demographic and individual descriptive factors.

**Results:** Participants with siblings presented with higher VABS age equivalents from ages 9-26 and experienced significantly steeper growth trajectories ( $B=.49$ ) compared to participants with no siblings ( $B=.39$ ;  $p=.005$ ). Among participants with one or more siblings, multilevel models revealed significantly steeper adaptive skill growth trajectories among participants with a male ( $B=.54$ ) compared to a female ( $B=.44$ ) closest-age sibling ( $p=.001$ ), and among participants with a gender-matched ( $B=.52$ ) compared to a non-gender-matched ( $B=.46$ ) closest-age sibling ( $p=.023$ ). No significant differences were noted based on birth

order position between youngest ( $B=.51$ ), middle ( $B=.44$ ), and oldest children ( $B=.47$ ;  $p=.078$ ). Within these sibling constellation factors, models also revealed a significant interaction with race; while patterns were similar across Black and White participants, the effects were magnified among Black participants.

**Conclusions:** Findings support the importance of siblings on adaptive skill development among individuals with ASD. While the existing limited literature consisting primarily of cross-sectional and/or small sample studies has revealed that siblings have been positively associated with stronger skill profiles across each of the three domains (socialization, communication, and daily living skills) that comprise adaptive behavior, this study is the first to underscore the significant influence of siblings and specific sibling constellation factors on adaptive functioning broadly as well as change in adaptive functioning over time in ASD. Future studies are needed to replicate the present findings, explore the specific qualities of siblings that may be driving the improvement, and assess the importance of the sibling relationship closeness on adaptive skill growth over time.

## ORAL SESSION — OTHER - MULTIPLE TOPIC AREAS

### Oral 319 - Functional and Anatomical Neuroimaging Markers of Autism II

**319.001 (Oral)** Cortico-Cerebellar Functional Connectivity in 9-Month-Old Infants at High and Low Familial Risk for Autism Predicts Later Socio-Communicative Developmental Trajectories

*N. J. Okada<sup>1</sup>, J. Liu<sup>2</sup>, T. Tsang<sup>2</sup>, K. K. Cummings<sup>3</sup>, J. Jung<sup>1</sup>, G. Patterson<sup>4</sup>, S. A. Green<sup>1</sup>, S. Y. Bookheimer<sup>1</sup>, S. Jeste<sup>2</sup> and M. Dapretto<sup>1</sup>, (1)Dept of Psychiatry and Biobehavioral Sciences, University of California, Los Angeles, Los Angeles, CA, (2)University of California, Los Angeles, Los Angeles, CA, (3)Semel Institute of Neuroscience and Human Behavior, University of California, Los Angeles, Los Angeles, CA, (4)University of Denver, Denver, CO*

**Background:** While the cerebellum is traditionally known for its role in sensorimotor control, specific subregions including the right Crus I (RCrusI) also support language and social cognition (Van Overwalle et al., 2020). Indeed, emerging research has also revealed an association between cerebellar atypicalities and impaired social communication in autism (D’Mello and Stoodley, 2015; Jack et al., 2017). However, it remains virtually unknown how early cerebellar development in infancy relates to later socio-communicative trajectories.

**Objectives:** To characterize functional connectivity within cortico-cerebellar networks implicated in social/language functions in early infancy and examine its relationship to later impairments in socio-communicative development.

**Methods:** An initial sample of infants at high ( $n=82$ ) and low ( $n=37$ ) familial risk for ASD was stratified into distinct cohorts by employing K-means longitudinal clustering on receptive language T-scores from the Mullen Scales of Early Learning (at 6, 9, 12, 18 & 36 months). This yielded a three-cluster solution: a Declining, Inclining, High-Inclining cohort exhibiting divergent socio-communicative trajectories (Figure 1a). To validate our clustering method, we compared these cohorts on other measures of language development (MCDI), joint attention skills (ESCS), and autism symptomatology (AOSI, ADOS-T, ADOS). A subset of 66 infants provided usable 8-min resting-state fMRI scans at 9 months (Declining:  $n=18$ ; Inclining:  $n=25$ ; High-Inclining:  $n=23$ ). Seed-based connectivity analyses using RCrusI were run within each cohort. Parameter estimates of connectivity were extracted from clusters showing significant RCrusI connectivity within four anatomically-based regions of interest (ROIs). ROIs were selected based on prior findings showing coactivation of these regions with RCrusI during social and language tasks (D’Mello et al., 2017; Lesage et al. 2017; Van Overwalle et al., 2015). These connectivity indices were then used in between-group comparisons.

**Results:** Validation analyses revealed that the three cohorts clustered by receptive language scores exhibited significantly divergent trajectories in the number of words comprehended and produced (from 9 to 18 months; Figure 1b-c), as well as significant differences on responses to joint attention (at 12 and 18 months; Figure 1d-e), and autism symptomatology (at 12, 18, and 36 months; Figure 1f-g-h). Importantly, at 9 months of age, infants in these three cohorts showed striking differences in cortico-cerebellar circuits implicated in social/language functions. Specifically, for all ROIs examined -frontal cortex, supplementary motor area, basal ganglia, and thalamus- the Declining cohort exhibited significantly weaker RCrusI connectivity compared to both the Inclining and High-Inclining cohorts (Figure 2). No significant differences between the Inclining and High-Inclining cohorts were observed.

**Conclusions:** To our knowledge, this is the first study in infants to examine functional connectivity of cortico-cerebellar networks implicated in language and social cognition and to relate early cortico-cerebellar connectivity to later social communication development. Our findings demonstrate that early cortico-cerebellar connectivity within these circuits is already atypical in 9-month-old infants who exhibit declining socio-communicative trajectories in the second and third year of life. Given the

cerebellum's role in prediction, these findings suggest that the establishment of early connectivity within "social" cortico-cerebellar circuits may help scaffold infants' ability to learn from social feedback which tends to be highly probabilistic in nature.

**319.002 (Oral)** Resting Frontostriatal and Frontoparietal Functional Connectivity and Inhibitory Control Ability in Autism Spectrum Disorder

**S. E. Kelly<sup>1</sup>**, **J. Bartolotti<sup>2</sup>**, **K. E. Unruh<sup>2</sup>** and **M. W. Mosconi<sup>3</sup>**, (1)Clinical Child Psychology Program, Schiefelbusch Institute for Life Span Studies, Kansas Center for Autism Research and Training (KCART), University of Kansas, Lawrence, KS, (2)Kansas Center for Autism Research and Training (K-CART), University of Kansas, Lawrence, KS, (3)Clinical Child Psychology Program, Schiefelbusch Institute for Life Span Studies, University of Kansas, Lawrence, KS

---

Background: Individuals with autism spectrum disorder (ASD) show impairments in inhibitory control, or the ability to inhibit dominant behavioral responses, that are related to increased severity of core clinical symptoms. In typical development, inhibitory control is supported by prefrontal cortical (PFC) and striatal network suppression of PFC-parietal motor networks. Atypical activation of PFC and striatum have been observed in individuals with ASD during inhibitory control, but the degree to which brain functional network connectivity is disrupted and associated with behavioral outcomes in ASD is not well understood. Resting-state functional magnetic resonance imaging (fMRI) offers a highly scalable method of quantifying communication within and across networks. The examination of functional connectivity within frontostriatal and frontoparietal networks in relation to inhibitory control behaviors may provide insight into functional differences in neural circuitry involved in inhibitory control impairments in ASD.

Objectives: To characterize relationships between inhibitory control behavior and resting state functional brain connectivity in ASD.

Methods: Twenty-five individuals with ASD (aged 10-33 years) and 19 age-, sex-, and nonverbal IQ-matched typically developing (TD) controls completed an antisaccade task of inhibitory control prior to a resting-state fMRI scan. During the antisaccade task, peripheral stimuli (i.e., white circles) appeared pseudorandomly at  $\pm 12$  or  $\pm 24$  degrees from center, and participants were tasked with inhibiting saccades toward the stimuli and making volitional saccades in the opposite direction. Antisaccade accuracy (i.e., whether the first saccade was correctly directed away from the stimulus), latencies of incorrect saccades toward stimuli (i.e., prosaccades), and latencies of correct antisaccades were examined. Normalized correlation coefficients of fMRI activity at rest between selected regions were derived to examine functional connectivity within frontostriatal (dorsolateral PFC [dlPFC], ventrolateral PFC [vlPFC], caudate, and putamen), and frontoparietal (dlPFC, angular gyrus, and supramarginal gyrus) networks. Relationships between functional connectivity outcomes and antisaccade performance were analyzed separately for each group.

Results: Individuals with ASD showed reduced antisaccade accuracy but no differences in pro- or anti-saccade latencies relative to controls. Connection strength did not differ between groups for any frontostriatal or frontoparietal network examined. Several brain-behavior associations were observed in control participants: increased accuracy during the antisaccade task was related to decreased functional connectivity between dlPFC and angular gyrus, faster prosaccade latencies were associated with increased connectivity between right vlPFC and putamen, and increased prosaccade and antisaccade latencies each were correlated with increased connectivity between dlPFC and posterior supramarginal gyrus. However, neither frontostriatal nor frontoparietal connectivity were associated with antisaccade performance in the ASD group.

Conclusions: Results indicate that frontoparietal networks that control behavioral responses and frontostriatal connections utilized for top-down inhibition of behaviors in TD individuals are not related to inhibitory control behavioral outcomes in individuals with ASD. These findings are consistent with previously identified connectivity disruptions in ASD and suggest that differences in the organization of network functioning is associated with inhibitory control impairments in this population. Our results have broad implications for understanding the neurophysiology of executive dysfunction and core clinical symptomatology in ASD.

**319.003 (Oral)** Do Shapes Have Feelings? Examining Social Attribution in Children with Autism Spectrum Disorder and Attention Deficit Hyperactivity Disorder Using fMRI

---

**Background:** Theory of Mind (ToM) is the ability to think about mental states and understand that others can have a different mental state from one's own, and strongly influences the quality of one's social interactions. ToM deficits are more common in children with neurodevelopmental disorders (NDDs), such as autism spectrum disorder (ASD) and attention-deficit/hyperactivity disorder (ADHD) compared to typically developing (TD) children, which contributes to their life-long social and cognitive difficulties. The social attribution task (SAT), consisting of videos of geometrical shapes designed to move in patterns that depict positive social (e.g., helping) or negative social interactions (e.g., fighting), prompts the recruitment of a network of brain regions, compared to random movement, that are reliably active during ToM processing.

**Objectives:** This study is the first to examine the neural correlates of ToM using the SAT during fMRI in a large cohort of ASD, ADHD and TD children and adolescents.

**Methods:** fMRI data were acquired during the SAT (3 runs of 8 pseudorandomized blocks of positive and negative social interactions and random movement) in 76 ASD, 74 ADHD, and 50 TD children (4-19yrs). After scanning, participants were asked to describe what happened in each video; descriptions were scored on the type of social attributions and attribution errors made in each scenario. fMRI data were preprocessed, and within-run time-series analysis was performed using task conditions (social help, social threat, random) as explanatory variables to examine pairwise contrasts (social versus random, social help versus threat). Contrasts were averaged over runs within each subject, and pairwise t-tests were used to investigate group differences, covarying for age and sex ( $Z > 2.3$ ;  $p < 0.05$ , cluster-corrected).

**Results:** TD children made fewer errors when describing the videos compared to the children with NDDs, and were also able to make more social attributions to the social videos compared to the ASD participants; the ASD and ADHD children did not differ in either ToM performance measure. Contrasting the social and random conditions, fMRI data showed differences in neural activation between TD children and children with NDDs in social brain areas, including the right middle temporal gyrus and bilateral anterior cingulate gyri; no differences between the NDDs were observed. Compared to children with NDDs, TD children demonstrated greater recruitment of the right supramarginal, superior temporal gyri and supplementary motor area, in the social help than social threat condition. Additionally, we found that TD children activated bilateral orbitofrontal regions more to social threat than social help animations, while children with ADHD showed no activation difference between these conditions. The only observed between-NDD difference was enhanced activity in the right fusiform gyrus in the ASD children to social help versus threat animations. Distinct brain-behaviour correlations were also seen.

**Conclusions:** Both the NDD and TD participants recruited classic ToM regions during the SAT, supporting the usefulness of this complex task to examine social cognition. However, atypical and distinct activation of social brain areas was found in the children with ASD and ADHD, which could index the neural underpinnings of their ToM behavioural deficits.

### **319.004 (Oral) Genetic and Environmental Influences on Brain Structure in Twins with Autism**

---

**Background:** Brain development is altered in children with autism spectrum disorder (ASD); however, the type and degree of these alterations are heterogeneous across individuals. This extreme neurobiological heterogeneity may be due to the variable effects of genetic and environmental influences on brain development.

**Objectives:** The primary objective of this investigation is to synthesize our findings across multimodal neuroimaging approaches to provide a comprehensive analysis of differences in genetic and environmental influences on brain structure in twins with and without ASD.

**Methods:** Same-sex monozygotic (MZ) and dizygotic (DZ) twin pairs in which at least one twin was diagnosed with ASD or both were neurotypical controls (aged 6-15 years) were recruited to participate. T1 (n=164), diffusion-weighted (n=168), and <sup>1</sup>H proton spectroscopy (n=106) MRI data were collected and processed with FreeSurfer, FSL Diffusion Toolbox, and LCMoDel, respectively, in order to examine brain structure based on grey matter morphometry (cortical thickness-CT; surface area-SA; volume-VOL; curvature-CURV), white matter microstructure (fractional anisotropy-FA; mean diffusivity-MD), and neurochemical markers of neuronal integrity (N-acetylaspartate-NAA). Intra-class correlations (ICC) were computed within twin

pairs and ACE modeling for broad sense heritability ( $a^2$ =additive genetics) and environmental influences ( $c^2$ =shared family environment,  $e^2$ =unique environment) was examined to provide estimates for the proportions of variation associated with genetic versus environmental factors.

Results: Brain structure was predominantly genetically-mediated in control twins, with variation in cerebral and cerebellar grey matter (CT, SA, VOL), white matter (FA, MD), and neurochemical levels (NAA) primarily associated with genetic factors, i.e., higher ICCs in MZ versus DZ twin pairs and larger  $a^2$  versus  $c^2/e^2$  estimates. The only measures that were predominantly environmentally-mediated in control twins were CURV and some region-specific CT and MD that may be associated with adaptive plasticity. Similarly, genetic factors also accounted for the majority of variation in brain structure in twins with ASD, potentially to a larger extent for deep brain structures like subcortical VOL and commissural FA, yet there were also significantly greater environmental influences in twins ASD, especially in the frontal lobe and cerebellum. For instance, variation in global and regional CT as well as cerebellar (VOL and FA) and cerebral white matter (FA in projection and association fibers) were primarily associated with environmental factors in twins with ASD. Additionally, twin pair differences in brain structure were also related with twin pair differences in ASD diagnosis and core symptom presentation and severity.

Conclusions: As previously reported, brain structure appears to be primarily genetically-mediated during typical development, with some regional and measure-specific environmental influences that most likely represent changes from adaptive plasticity. However, children and adolescents with ASD exhibit a markedly different and more pervasive pattern of environmental influences on brain structure. Brain-behavior relationships suggest that genetic susceptibility for ASD may primarily contribute to a diagnosis of the disorder whereas environmental exposures may more directly influence some of the extreme heterogeneity in symptom presentation and severity across individuals. These results are promising because they suggest that treatments targeting the early environment could potentially alter brain development to provide some clinical benefits in the core symptom domains.

Background:

Autism spectrum disorder (ASD) is highly heritable, with 4:1 prevalence in males versus females, suggesting that sex-differential phenotypes that track with familial risk could inform ASD's neurodevelopmental underpinnings. Language represents a candidate sex-differential marker of heritable ASD risk given: 1) a previously reported female advantage in early language acquisition, 2) evidence for language being an ASD endophenotype, 3) comorbidity of language delay and ASD, and 4) shared neural correlates with ASD.

Objectives:

1. To quantify infant sex differences in receptive and expressive language measures in a population at high and low familial risk of ASD.
2. To examine whether early language trajectories differ by sex as a function of familial ASD risk and diagnostic outcome.

Methods:

We evaluated sex differences in language in participants from the Infant Brain Imaging Study (IBIS) at ages 6, 12, and 24 months. Participants received a 24-month clinical best estimate diagnosis and were stratified by familial ASD liability into three risk-diagnostic groups: HR+ (ASD and a sibling with ASD), HR- (no ASD and a sibling with ASD), and LR- (no ASD and no first-degree family history). Receptive and expressive language scores were obtained from the Mullen Scales of Early Learning (MSEL), a direct assessment, and the Vineland Adaptive Behavior Scales (VABS), a parent-report measure. Sex differences were indexed by Cohen's *d*, with positive effect sizes reflecting lower male scores, aligning with greater ASD-related features in males. We used repeated measures ANOVA to examine risk-based sex differences in 6- to 24-month language development.

#### Results:

When comparing males and females in each group, significant sex differences were observed at 6 months such that HR+ males had lower VABS expressive language scores ( $p=0.004$ ,  $d=0.75$ ) (Table 1). At 12 months, HR+ males exhibited lower VABS expressive ( $p=0.01$ ,  $d=0.71$ ) and receptive ( $p=0.003$ ,  $d=0.81$ ) language scores, with trend-level differences on MSEL expressive ( $p=0.065$ ,  $d=0.50$ ) and receptive ( $p=0.1$ ,  $d=0.43$ ) language. At 24 months, small sex differences were observed in the HR- group only, with males exhibiting significantly lower scores in MSEL and VABS expressive language and lower trend-level differences on MSEL and VABS receptive language. Significant interaction effects of age by group (LR-, HR-, HR+) indicated decreased scores in the HR+ group for both males and females on all measures compared to HR- and LR- groups (Figure 1). Relative declines in language emerged earlier for HR+ males than females, whose group-level scores began to diverge from the LR- and HR- groups between 6 and 12 months. HR+ females did not exhibit a language decline until the period between 12 and 24 months.

#### Conclusions:

We observed that male sex, a known ASD risk factor, was associated with 6- to 12-month differences in language, an ASD endophenotype. These were detected by direct assessment and parent-report, with the latter showing larger differences. This observation supports the role of developmentally sensitive, sex-moderated factors in the emergence of ASD. Language declines during infancy may arise sooner for males versus females at elevated familial ASD risk, highlighting the importance of tracking infant language for early identification and intervention.

**Background:** Previous research reports that increased attention towards social stimuli (i.e., Social Attention, SA) in autistic females may modulate exposure to social contingencies, thereby reducing social interaction difficulties and symptom severity. Therefore, heightened SA could relate to specific manifestations of Autism in females, in relation to symptom intensity and socio-cognitive skills.

**Objectives:** This research aims to investigate the second-by-second changes of SA in autistic compared to neurotypical individuals and their relation to symptomatology and sex, as measured by eye-tracking during a dynamic video rich in social information.

**Methods:** 388 autistic (M:F ratio=2.68; mean age=16.7, SD=5.8; mean IQ=96.8, SD=19.9) and 271 neurotypical participants (M:F ratio=1.9; mean age=17.2, SD=5.9; mean IQ=103.8, SD=18.9) took part in the study. Participants' eye-movements were recorded via eye-tracking while watching medium close-up shots of 1-2 people talking to the camera. Each gaze sample was scored 0/1 if it fell within the area of the face, and averaged every 0.5-second since the onset of an individual face, within a 3-seconds time-window. The obtained Proportional Looking Time (PLT) was used in 3 separate Growth-Curve Mixed Models,

with 2nd order polynomials as predictors to capture PLT second-by-second change, and each including the neurotypical, autistic and female participants separately. We report the unstandardised effect sizes ( $\beta$ ) of sex/diagnosis on average and second-by-second change of PLT. Further, we extracted individual  $\beta$  from the models, and tested the partial correlations with autism symptom intensity (SRS-2), and, exploratively, neural event-related responses during a face processing task, measured by the Global Field Power (GFP) of brain microstates, representing quasi-stable topographies switching across time.

Results: Average PLT was higher in females than males, both in neurotypical (Model 1;  $\beta=0.06$ ,  $SE=0.01$ ,  $p\text{-value}<0.01$ ) and autistic group (Model 2;  $\beta=0.04$ ,  $SE=0.02$ ,  $p\text{-value}=0.02$ ; Fig. 1A). The second-by-second change of PLT configured a parabolic shape, with final net increase, that was sharper in autistic females than autistic males ( $\beta=-0.05$ ,  $SE=0.02$ ,  $p\text{-value}=0.002$ ). Average PLT was lower in autistic females compared to neurotypical females (Model 3;  $\beta=-0.09$ ,  $SE=0.02$ ,  $p\text{-value}<0.01$ ; Fig. 1B). Despite no significant association with symptom intensity, we found a negative correlation with GFP of the early microstate, in autistic (N=46; Intercept:  $\rho=-0.30$ ,  $p\text{-value}=0.04$ ; Slope:  $-0.35$ ,  $p\text{-value}=0.02$ ) and neurotypical females (N=47; Intercept:  $\rho=-0.33$ ,  $p\text{-value}=0.03$ ; Slope:  $-0.31$ ,  $p\text{-value}=0.03$ ; Fig. 1C), but not in males.

Conclusions: This task was able to elicit robust sex differences; autistic females showed lower SA compared to neurotypical females, possibly suggesting concurring adaptation/compensation. Further, higher interest in faces associated with smaller GFP in females only, suggesting that the process at work may influence face-processing abilities.

**320.003 (Oral) Differential Impact of Autism on Eating Problems in Females and Males – a Co-Twin Control Study**  
**K. Lundin<sup>1</sup>, J. Neufeld<sup>2</sup>, J. Isaksson<sup>1</sup> and S. Bolte<sup>3</sup>, (1)Karolinska Institutet, Stockholm, Sweden, (2)Center of Neurodevelopmental Disorders (KIND), Centre for Psychiatry Research; Department of Women's and Children's Health, Karolinska Institutet, & Stockholm Health Care Services, Region Stockholm, Srockholm, Sweden, (3)Center of Neurodevelopmental Disorders (KIND), Centre for Psychiatry Research; Department of Women's and Children's Health, Karolinska Institutet, & Stockholm Health Care Services, Region Stockholm, Stockholm, Sweden**

---

Background:

Eating problems are common in autism, and include selective eating, sensory issues related to food and inflexible routines around mealtimes. While recent research suggests that gender might play a role in the association between autism and eating problems, few studies have investigated potential gender differences in the impact of autism on different aspects of eating problems. Furthermore, there is a paucity of research exploring the genetic and environmental influence on the link between autism and eating problems.

Objectives:

We aimed to **a)** investigate the relation between autism and both total and specific aspects of eating problems; **b)** explore potential gender differences in these associations; and **c)** examine the influence of genetic and shared environmental factors on the association between autism and eating problems, using a co-twin control design.

Methods:

A sample of twins (N = 192) aged between 15 and 33 years, including 28 individuals diagnosed with autism, participated in the Roots of Autism and ADHD Twin Study in Sweden (RATSS). Participants self-reported eating problems on the Swedish Eating Assessment for Autism spectrum disorders (SWEAA), including for instance selective eating, sensory sensitivity concerning food, and symptoms of eating disorders, and participated in neurodevelopmental assessments conducted by experienced clinicians. Parent-reported autistic traits on the Social Responsiveness Scale-2 (SRS-2) were also collected. Linear regression models within the Generalized Estimating Equations (GEE) framework were conducted, which account for the clustering in the sample (i.e. the twin-pairs). Autistic traits were used as the exposure and eating problems as the outcome. Regression models included the interaction term autistic traits by gender and were adjusted for age, IQ, and ADHD. Significant associations were followed-up using autism diagnosis as exposure to ensure the clinical relevance of the findings. Lastly, within-pair analyses were conducted using conditional linear regression within GEE, which control for factors shared within twin-pairs, including ~50% of genes among dizygotic (DZ) pairs and 100% of genes among monozygotic (MZ) pairs.

Results:

Autistic traits, as well as autism diagnosis, were associated with an increase in total eating problems, and both were associated with more self-reported problems in several aspects of eating problems, including selective eating and sensory sensitivity

regarding food. A significant interaction effect between autistic traits and gender showed that autistic traits were associated with increased total eating problems particularly among females (see Figure 1). In addition, both traits and autism diagnosis predicted more self-reported problems with eating in social situations for females but not males. In the within-pair analyses, the association between autistic traits and total eating problems remained within DZ-pairs but not MZ-pairs, suggesting a common genetic influence on both variables.

#### Conclusions:

Autistic traits predict increased eating problems, and the association might be influenced by genetic factors common to both variables. Furthermore, autistic traits appear to predict eating problems particularly among females. Potentially, issues around eating might increase the risk of social isolation for autistic females. The often-overlooked area of eating problems could be a relevant target for intervention among autistic adolescents and adults.

#### 320.004 (Oral) Friend Matters: Autistic Girls Talk More about Friends during Diagnostic Interviews

*M. L. Cola<sup>1,2</sup>, L. D. Yankowitz<sup>1</sup>, K. G. Tena<sup>1</sup>, S. Plate<sup>1</sup>, L. Bateman<sup>3</sup>, A. S. Russell<sup>1</sup>, C. J. Zampella<sup>1</sup>, L. S. Cubit<sup>1</sup>, J. Pandey<sup>1</sup>, R. T. Schultz<sup>1</sup> and J. Parish-Morris<sup>1</sup>, (1)Center for Autism Research, Children's Hospital of Philadelphia, Philadelphia, PA, (2)PsyD Doctoral Program, LaSalle University, Philadelphia, PA, (3)The Center for Autism Research/CHOP, Philadelphia, PA, (4)Clinical and Social Sciences in Psychology, University of Rochester, Rochester, NY*

---

**Background:** Individuals with autism spectrum condition (ASC) are characterized by social communication challenges. Girls are diagnosed with ASC less often than boys<sup>1</sup> even when their symptoms are equally severe<sup>2</sup>. This may be due, in part, to insufficient understanding of the way ASC manifests in girls. Research suggests that autistic girls and boys present distinct symptom profiles in a variety of domains, including language<sup>3,4</sup>. Closely analyzing boys' and girls' language use during semi-structured clinical assessments could shed light on potential sex differences in the behavioral presentation of autistic individuals, revealing clinically meaningful variations in social phenotype that could ultimately inform the development of personalized supports.

**Objectives:** Compare the frequency of social word production in verbally fluent girls and boys with ASC during the conversation and reporting section of the ADOS-2 Module 3, and measure associations with clinical phenotype. Social words are words that make reference to other people (e.g., him/her, girlfriend, dad).

**Methods:** School-aged girls and boys with ASC (N=101, 25 females) were administered the ADOS-2. Participants were matched on age, IQ, and parent/clinician ratings of autism symptom severity (Table). Recordings of the conversation and reporting section of the ADOS-2 were orthographically transcribed<sup>5</sup> and processed using Linguistic Inquiry and Word Count (LIWC) software<sup>6</sup>. Word frequency was normalized per 1000 words to account for varying word production across participants. The effect of sex on participant word use was modeled using generalized linear regressions with a Poisson distribution, after controlling for age and clinician speech. Tukey-corrected comparisons of estimated marginal means assessed the directionality of effects.

**Results:** There was a significant main effect of sex on social word production (estimate: -.13,  $z=-6.11$ ,  $p<.007$ ), such that boys used fewer social words than girls (Fig.A). To clarify the kinds of social words being used, additional categories of "friend" and "family" words were analyzed. There was a significant effect of sex on "friend" words, with boys using fewer friend words than girls (estimate: -.20,  $z=-2.37$ ,  $p=.02$ ). There was no effect of sex on family words (estimate: -.14,  $z=-1.82$ ,  $p=.07$ ), suggesting that sex differences in social word production may be driven by girls talking more about friends. To assess relationships with clinical phenotype, we modeled ADOS-2 social affect (SA) scores as a function of social word production. After accounting for age, sex, and clinician speech, social word production significantly predicted ADOS-2 SA scores (estimate: -.01,  $z=-3.19$ ,  $p=.001$ ), indicating that participants who used fewer social words were rated as more socially impaired by clinicians (Fig.B).

**Conclusions:** Autistic girls used significantly more social words than boys during a diagnostic assessment – despite being matched on age, IQ, and autism symptom severity. Sex differences in linguistic markers of social phenotype in autism are especially important in light of the late or missed diagnoses that disproportionately affect autistic girls. Specifically, heightened talk about social topics could complicate ASC referral and diagnosis when observers expect a male-typical pattern of reduced social attention, which autistic girls do not always exhibit.

## ORAL SESSION — OTHER - MULTIPLE TOPIC AREAS

### Oral 327 - Understanding Behavioral and Biological Heterogeneity in Autism

**327.001** (Oral) Clinically-Relevant ASD Subgroups Based on Neural and Behavioral Characteristics Revealed through Similarity Network Fusion

*Y. Xiao<sup>1</sup>, M. V. Lombardo<sup>2</sup>, L. Eyles<sup>3</sup>, T. H. Wen<sup>1</sup>, D. Goel<sup>1</sup>, K. Pierce<sup>1</sup> and E. Courchesne<sup>1</sup>, (1)Autism Center of Excellence, Department of Neurosciences, University of California, San Diego, La Jolla, CA, (2)Center for Neuroscience and Cognitive Systems, Laboratory for Autism and Neurodevelopmental Disorders, Istituto Italiano di Tecnologia, Rovereto, Italy, (3)Department of Psychiatry, University of California, San Diego, La Jolla, CA*

#### Background:

ASD is heterogeneous in risk genes, behaviors, neural features and clinical outcomes. Understanding clinically-relevant subgroups of ASD toddlers could help discover etiological pathways and lead to more tailored treatments. A common subgrouping approach is unimodality stratification into experimenter-defined subgroups<sup>1-3</sup>. A novel unbiased, data-driven approach is similarity network fusion (SNF)<sup>4</sup> and clustering that integrates multiple kinds of measures (e.g., fMRI, clinical) from each individual to identify clusters of patients whose measures are maximally similar to each other and maximally different from patients in other clusters. In this approach, the similarity in patterns drives subgroup clusters independent of diagnosis revealing bio-behavioral dimensionality.

#### Objectives:

Identify homogeneous neurofunctional and clinical subgroups within a large sample of ASD and control toddlers and determine how they differ with respect to attention to social stimuli and trajectories of language and social development.

#### Methods:

We collected fMRI responses to a female speaker reading nursery rhymes<sup>2,5,6</sup> from 112 ASD and 64 Controls aged 13–46 months during natural sleep. Toddlers were clinically tested<sup>7-9</sup> at longitudinal clinic visits; eye-tracking tested each toddler's attentional preference for social images<sup>10</sup>. fMRI preprocessing used AFNI<sup>11</sup> and included motion correction, normalization to Talairach space, and smoothing. Statistical analyses used SPM8, controlling for age, gender and head motion. Percent signal changes (Speech vs. Rest) were calculated for frontal and temporal language regions using Neurosynth ROIs<sup>12</sup>. SNF constructed similarity networks for fMRI and clinical data and Louvian<sup>12</sup> clustering identified fused neural-clinical subgroups. These neural-clinical subgroups were tested for differences in social attention during eye tracking and gains/losses in social and language abilities across early development.

#### Results:

Network fusion and clustering found 6 neural-clinical subgroups, 4 with 100% ASD toddlers and 2 with ~90% TD and other control toddlers. One large subgroup with 100% ASD toddlers showed moderate brain activation to language and good cognitive scores (i.e., ASD good) while another large subgroup with ~88% ASD toddlers stands at opposite ends of the neural-social-language spectrum with hypoactivation and low cognitive scores (i.e., ASD poor). The ASD good subgroup had significantly greater eye tracking-based attention towards social stimuli than the ASD poor subgroup. They also showed substantial gains in language between initial clinical detection and later clinical outcome, while ASD poor subgroup had substantial declines.

#### Conclusions:

Using SNF/clustering methods, 6 neural-clinical subgroups were identified, and collectively suggest that biological and behavioral heterogeneity within ASD, TD and other control toddlers is dimensional. This data-driven approach replicated the finding of two different neurofunctional ASD subgroups—one with good language activation and the other with hypoactivation—that we previously identified using an experimenter-defined language stratification approach<sup>12</sup>. Consistent with the theory that infant attention to social stimuli drives language learning<sup>13</sup>, the ASD good subgroup with greater eye-tracking attention to social stimuli and greater language activation than the other subgroup, had greater gains in social and language across time, while the other subgroup had losses across time. Findings provide novel evidence of neural-clinical ASD subgroups that clarifies understanding of ASD heterogeneity and opens new avenues for discovery of early-age diagnostic and prognostic

biomarkers.

**327.002 (Oral)** Predictors of Adaptive Functioning in a Heterogenous Autism Spectrum Disorder Cohort: A Conditional Random Forest Analysis

---

**Background:** Higher cognitive ability predicts better functional outcomes for individuals with Autism Spectrum Disorder (ASD), yet many individuals exhibit a discrepancy between cognitive ability and adaptive functioning. Identifying clinical and demographic predictors of this discrepancy in community-representative samples would improve measurement of response to treatment across the heterogeneous range seen in ASD.

**Objectives:** This study implemented a conditional random forest (CRF) machine learning algorithm to identify clinical and demographic predictors of adaptive functioning in a heterogeneous cohort of individuals affected by ASD.

**Methods:** Participants included N=469 individuals aged 2 to 60 years old from the Rhode Island Consortium for Autism Research (RI-CART) patient registry. Participants varied with respect to presence or absence of a community diagnosis of ASD prior to study enrollment. For this analysis, inclusion criteria were individuals with an available IQ score and at least one diagnostic indicator of ASD: an elevated score in the Autism or ASD range on the Autism Diagnostic Observation Schedule, 2<sup>nd</sup> Edition (ADOS-2) and/or a prior community ASD diagnosis. This allowed for two levels of diagnostic certainty: ASD-confirmed (N=246: Elevated ADOS-2 score *and* community diagnosis) or ASD-inclusive (N=223: Community diagnosis *without* elevated ADOS-2 or elevated ADOS-2 *without* community diagnosis).

The primary outcome was the discrepancy between IQ (standard scores on Peabody Picture Vocabulary Test or the Kaufman Brief Intelligence Test) and adaptive functioning (AF; standard composite scores on the Vineland Adaptive Behavioral Scales), IQ-AF. Participants were stratified by IQ level (IQ < 85; 85-114;  $\geq$ 115). CRF analysis allowed us to simultaneously model many interrelated predictors and complex interactions among variables. Predictors included IQ strata, autism symptoms (Social Responsiveness Scale, 2<sup>nd</sup> Edition; SRS-2), diagnostic certainty, number of psychiatric and medical conditions, demographic variables (maternal age, ethnicity, family income), and age of enrollment. Permuted variable importance identified the most prominent predictors that were then used to plot a representative conditional inference tree to probe complex interactions among predictors.
