**Results:** IQ strata, autism symptoms, age of enrollment, minority status, and co-occurring medical conditions were among the top predictors of IQ-AF (See Fig. 1a). Partial dependence plots (Fig. 1b) show that the IQ-AF was highest and positive (i.e., IQ>AF) for individuals with IQ $\geq$ 115, and smaller and generally negative for individuals with IQ<85. IQ-AF was positively associated with age of enrollment and social communication deficits on the SRS-2. The representative tree in Fig. 1c illustrates interactions among predictors. For IQ $\geq$ 115, social communication deficits and older age predicted greatest IQ-AF. For IQ<85, the highest discrepancy was found for individuals aged 9-15 years with social communication scores >75 and restricted and repetitive behavior scores <87 on the SRS-2. For 85 $\leq$ IQ<115, social communication deficits, older age, and having >2 medical comorbidities predicted high IQ-AF.

**Conclusions:** Findings highlight the clinical utility of considering IQ-AF discrepancy when assessing functional outcomes and underscore how core symptom domains of ASD, particularly social communication deficits, and minority status differentially impact adaptive functioning outcomes across the range of IQ and age. Results also highlight the importance of considering co-occurring medical conditions when assessing functional outcomes in ASD.

**327.003 (Oral)** Clinical and Biochemical Predictors of Severity and Response to Applied Behavioral Analysis in Children with Autism Spectrum Disorder: An Outpatient Registry-Based Prospective Study

**S. Gulati<sup>1</sup>**, S. Sharma<sup>2</sup>, P. K. Panda<sup>3</sup>, S. Badal<sup>4</sup>, J. Gupta<sup>5</sup>, R. Sihna<sup>6</sup>, G. Kamila<sup>6</sup>, S. Singh<sup>6</sup>, S. Khan<sup>7</sup>, A. Meena<sup>6</sup> and C. Narayan<sup>7</sup>, (1)Centre of Excellence and Advanced Research for Childhood Neurodevelopmental Disorders, Child Neurology Division, Department of Pediatrics, All India Institute of Medical Sciences, New Delhi, India, (2)Child Neurology Division, Department of Pediatrics, All India Institute of Medical Sciences, New Delhi, New Delhi, India, (3)Child Neurology Division, Department of Pediatrics, All India Institute of Medical Sciences, Rishikesh, India, (4)Pediatrics, AFMC, Pune, India, (5)Child Neurology Division, department of pediatrics, All India Institute of Medical Sciences, New Delhi, New Delhi, India, (6)All India Institute of

**Background:** Applied behavior analysis (ABA) is the standard of care behavioral therapy for children with Autism Spectrum Disorder (ASD). However, literature determining clinical and biochemical predictors of severity and response to ABA among children with ASD is scarce.

**Objectives:** To determine clinical and biochemical predictors of severity and favorable/unfavorable response to ABA in children with ASD aged 2-18 years

**Methods:** Children with ASD (DSM V criteria) between age 2-18 years, who were provided ABA with the help of caregivers, along with various medications as and when indicated, were enrolled in the study and prospectively followed at 1-3 monthly intervals between January 2017 and November 2020. They were reevaluated for symptom severity and behavioral co-morbidities by performing Childhood Autism Rating Scale (CARS), Autism Behavior Checklist (ABC), and Childhood Behavior Check List (CBCL) and compared with the baseline values. Various predictors of response to ABA were identified by univariate and multivariate logistic regression analysis. In children with epilepsy or suspicion of ESES (n=122), sleep EEG was performed. Screening for Fragile X syndrome, Rett syndrome, chromosomal microarray, and next-generation sequencing was performed for children with complex autism/ significant clinical suspicion. Six oxidative biomarkers were analyzed in a subgroup (n=100) and compared with healthy controls (n=50).

**Results:** A total of 1148 children with ASD (911 boys, median age of presentation 4.2 years, IQR 3-6 years, CARS 36.78±4.92, ABC 84.01±16.92) were enrolled. Out of these, 688 (60%) children had significant behavioral co-morbidities (irritability, hyperactivity, disruptive/self-injurious behavior were most common), 122(11%) had epilepsy (31% had epileptiform abnormality-either focal/multifocal discharges or ESES), and 675(59%) had development quotient <50. Forty-four children had complex autism, with clinical suspicion of the underlying neurogenetic syndrome, and definite etiology was detected in 14 (31%) of them. Predominant antipsychotics administered were risperidone, followed by aripiprazole. Predominant anti-seizure medications used were valproate, followed by levetiracetam. At least one year follow up was completed in 965(84%) children, with a median duration of follow up being 1.5 years, and post-ABA institution, CARS was 32.88±2.72 (p<0.001, as compared to baseline reflecting the effectiveness of ABA).

Children with age of ABA institution <4 years had a better response to ABA than older children (p=0.03). No difference was identified between both sexes. Children with a longer duration of ABA had a better reduction in symptom severity (p=0.04). In contrast, those with DQ<50, behavioral co-morbidities, and epilepsy had a relatively less favorable response (p=0.01, 0.02, and 0.04, respectively). The baseline CARS score was also higher in these three subgroups, suggesting more severe illness (p=0.03, 0.03, and 0.04, respectively). Only serum homocysteine and dityrosine level were higher in ASD cases than controls (p=0.01 and 0.001, respectively).

**Conclusions:** Younger age at institution of ABA, higher SES of parents, absence of co-morbidities like epilepsy or hyperactivity, and longer duration of ABA are essential predictors for a favorable response to ABA in children with ASD.

**327.004 (Oral) Depi: A Platform Designed to Enable Precision Medicine in Neurodevelopmental Disorders**  
**L. Perez-Cano<sup>1</sup>, E. Guney<sup>1</sup>, F. Sirci<sup>1</sup>, D. Charvin<sup>2</sup> and L. Durham<sup>2</sup>, (1)Discovery and Data Science (DDS) unit, STALICLA SL, Barcelona, Spain, (2)STALICLA SA, Geneva, Switzerland**

---

**Background:**

Today, patients diagnosed with Autism Spectrum Disorder (ASD) account for 1-1.5% of the world population and the condition remains a high unmet medical need. The repeated failures of investigational drug clinical trials conducted in the general ASD population has highlighted the urgent need to shift from a “one-size-fits-all” approach towards drug development programs that start with dissecting the molecular and genetic heterogeneity that manifest in patients with ASD. While many areas of medicine have achieved major therapeutic strides by biologically parsing specific subgroups of patients, this effort has remained limited in Autism.

**Objectives:**

In order to fill this gap, STALICLA has developed DEPI, a first-in-class integrative systems biology and multi-omics platform for precision medicine discovery in the neurodevelopmental disorders (NDD) space. The main goals of the platform are: i) to identify and characterize more homogeneous and clinically actionable subgroups of patients within highly heterogenous

populations with NDDs, including ASD; and ii) to discover and develop precision medicine candidates that can efficiently target the identified subpopulations.

#### Methods:

DEPI leverages proprietary NDD-tailored knowledge bases and the access to genetic and clinical data from large-scale NDD cohorts, to identify non-behavioral biomarkers characterizing NDD patients (a.k.a. endophenotyping). These endophenotypes are then used as features to cluster patients using machine learning, allowing the identification of more homogeneous subgroups of patients eligible for precision medicine. On the other hand, DEPI uses network endopharmacology to identify fast-track drug candidates that can efficiently target these clinically actionable NDD subgroups.

#### Results:

In just over 3 years, DEPI has already proven successful in expediting and de-risking drug development for a first subgroup of patients with ASD and identifying four additional subgroups eligible for precision medicine trials. The first group, ASD phenotype 1 (ASD-Phen1), is characterized by non-behavioral clinical signs and symptoms and is estimated to represent approximately 25% of the ASD population. DEPI also allows systematic multi-omics data-driven screening of thousands of preclinical and phase II/III compounds to delineate their effect on biological pathways of each subgroup-specific pathophysiological mechanisms. The platform has enabled the identification of a therapeutic option that could compensate for the proposed molecular perturbations in ASD-Phen1, STP1, which has entered clinical trial in Q4 2020. DEPI has also enabled the identification of subgroup of patients with a high probability of responding to third-party drug candidates.

#### Conclusions:

DEPI has been designed to make a shift in the field, providing the tools to match the right NDD patients with the right drug treatments.

## POSTER SESSION — PEDIATRICS

### Poster 437 - Pediatrics Posters

**437.001** (Poster) A Mobile Game Platform for Improving Social Communication in Children with Autism: A Semi-Randomized Clinical Trial

*Y. Penev<sup>1</sup>, K. Dunlap<sup>2</sup>, A. Husic<sup>1</sup>, C. Hou<sup>2</sup>, P. Washington<sup>1</sup>, E. Leblanc<sup>1</sup>, A. Kline<sup>1</sup>, J. Kent<sup>2</sup>, A. Ng-Thow-Hing<sup>2</sup>, M. Tsou<sup>2</sup> and D. P. Wall<sup>1</sup>, (1)Stanford University, Stanford, CA, (2)Pediatrics, Stanford University, Stanford, CA*

Background: Autism Spectrum Disorder (ASD) is among the most pressing public health challenges in the U.S. and around the world. Many children with ASD are unable to receive timely in-person diagnosis and therapy, particularly during the COVID-19 pandemic. Mobile interventions can fill the gap by allowing all families with access to a smartphone to receive treatment.

Objectives: To evaluate the therapeutic potential of *GuessWhat*, a mobile game designed to improve social communication in children with ASD using any Android- or iOS-based smartphone.

Methods: We conducted a semi-randomized controlled trial where treatment participants received the *GuessWhat* intervention and control participants received treatment as usual. Families of children ages 3-12 years with parent-reported formal ASD diagnosis were recruited remotely and participated in the intervention from home. Participants were asked to play *GuessWhat* for three 90-second game sessions per day, three days per week, for four weeks. Families who had not started playing the game within one week of baseline data collection were asked to refrain from playing it and were assigned into the control cohort. To balance the number of participants in each arm of the study, control participants who had completed the same clinical measures over a similar timeframe as part of a randomized controlled trial previously reported by our lab were also included in the analysis. Two parent-reported socialization outcome measures, Social Responsiveness Scale – 2 (SRS-2) and Vineland Adaptive Behavioral Scales – II (VABS-II), were assessed between treatment and control groups using two-tailed paired sample T-tests. The measures were completed digitally immediately prior to and up to one month after the intervention.

Results: 168 children (85% male, mean age 7.75 years) were enrolled; 100 assigned to treatment, 68 to control. The 61 treatment completers showed significant improvements in SRS-2 Total (3.59,  $p < 0.001$ ) and VABS-II Socialization Standard (6.29,  $p = 0.01$ ) scores whereas the 41 control completers showed no change (1.34,  $p = 0.22$ , and  $-0.62$ ,  $p = 0.64$ , respectively). The improvements were sustained among all treatment participants following a mixed-effects linear-regression model. Children who played during all four weeks ( $N = 11$ ) or over 28 game sessions ( $N = 17$ ) demonstrated even higher improvements.

Conclusions: Participants who received the mobile game improved significantly on SRS-2 and VABS-II scales, while participants who received treatment as usual showed no changes. The results suggest that *GuessWhat* can engage children with autism in therapeutic gameplay from the comfort of their homes. The intervention presents a feasible approach to improving the efficacy and accessibility of pediatric behavioral therapies.

**437.002** (Poster) Evaluation of the Relationship of Sleep Disturbances to Severity and Common Behaviors in Autism Spectrum Disorder

*S. Miner, Case Western Reserve University, Cleveland, OH*

Background: First described in 1940, autism spectrum disorder (ASD) remains one of the most puzzling disorders of childhood. The underlying neurological disruptions as well as the heterogeneity of its symptoms are poorly understood. ASD is associated with an increased incidence of comorbid inflammatory disorders, psychological disorders, and sleep disturbances. Recent studies have indicated that these comorbidities and associated symptoms, historically attributed to the ASD diagnosis, may in fact be contributing to the behavioral symptoms of the disorder.

Disturbed sleep in children can have many detrimental health consequences including decreased cognition, decreased focus, performance problems, and changes in mood and behavior. These symptoms are common in ASD. Disturbed sleep patterns, such as increased sleep latency (time falling asleep), nighttime waking and early arousal, have been identified in up to 80% of children with ASD. Recent evidence suggests children with ASD experience an increased sensitivity to disturbed sleep that may ultimately increase the severity of the disorder.

**Objectives:** This study explored how disturbed sleep influences the severity of behavioral symptoms common to ASD. Children ages 6-12 with ASD were invited to participate through University Hospitals Autism Center and Connecting for Kids. Actigraphy and an accompanying sleep diary captured disturbed sleep patterns in this population. Participants wore a GT3X actigraphy monitor for 7 nights to collect data on patterns of increased sleep latency, nighttime or early morning waking, and sleep efficiency. Parents completed a sleep diary for their child during actigraphy collection, as well as a medical history and the Autism Spectrum Rating Scale (ASRS) questionnaire.

**Methods:** A descriptive analysis was used to report the characteristics of nighttime sleep and sleep efficiency as well as sleep disturbances of sleep latency, wake after sleep onset, and early morning wake in participants with ASD. Pearson's  $r$  determined the relationships between the number of sleep disturbances experienced by a child with ASD and the severity of specific ASD behavioral scores and ASD diagnostic severity (determined by the ASRS).

**Results:** Of the 24 participants in this study almost 92% had one or more sleep disturbances. A positive correlation was present between the number of sleep disturbances and the severity of delays in social and communication symptoms ( $r = .59, p < .01$ ). No other correlated variables met statistical significance, however, a moderate effect size was found between the number of sleep disturbances and unusual behaviors in ASD ( $r = -.38, p = .07$ ), suggesting a possible, unanticipated, inverse relationship.

**Conclusions:** Exploring the relationship of disturbed sleep to behavior and symptom severity in children with ASD can provide an understanding of how poor sleep influences ASD symptoms. This study identified distinct differences in symptom severity between and within individual participants. This knowledge will be useful to guide efforts to provide patient specific interventions, mitigate ASD symptoms, and improve the likelihood of success of therapeutic and behavioral interventions in this population.

**437.003 (Poster)** Examining Health Indicators Among Children with and without Autism Spectrum Disorder  
**K. L. Staples<sup>1</sup>, E. A. Pitchford<sup>2</sup> and L. R. Ketcheson<sup>3</sup>,** (1)School of Health Promotion and Kinesiology, Texas Woman's University, Denton, TX, (2)Department of Kinesiology, Iowa State, Ames, IA, (3)Department of Kinesiology, Health and Sport Studies, Wayne State University, Detroit, MI

---

**Background:** Children with ASD experience disproportionately higher rates of obesity compared to neurotypical children of the same age. Although there are multiple factors that contribute to obesity, the emphasis of public health initiatives has largely been focused on participation in moderate to vigorous intensity physical activity (MVPA). However, previous interventions have had little to no long-term impact on obesity or MVPA among children with ASD. To develop interventions that will promote positive trajectories of health for children with ASD, we must also consider additional health indicators that may collectively have a greater impact on promoting positive trajectories of health for children with ASD.

**Objectives:** The purpose of this study was to develop a more comprehensive understanding of differences in health indicators for children with and without ASD across early and middle childhood.

**Methods:** This study included 48 children with ASD (37 boys) and 49 neurotypical controls (37 boys) between the ages of 3 and 9 years. To examine age-related differences among health indicators, children were divided into two age groups: 3 to 5 and 6 to 9 years of age. Health indicators included body composition, MVPA, motor skill competence, physical fitness, and quality of life (QOL). Measurements included body mass index (BMI) percentiles, GT3X+ accelerometers, the Test of Gross Motor Development – 3<sup>rd</sup> edition, 4 items from the Brockport Physical Fitness Test, and the Pediatric Quality of Life Inventory.

**Results:** Based on BMI percentiles, 48% of children with ASD were classified as overweight or obese compared to 6% of neurotypical children. MVPA was not significantly different between children with and without ASD for either age group. However, 3 to 5 year old children with ASD had significantly poorer musculoskeletal fitness and QOL ( $p < .001, r_g^2 > .61$ ) compared to same aged children with neurotypical development. By 6 to 9 years of age, children with ASD had significantly poorer FMS competency, cardiorespiratory and musculoskeletal fitness, and QOL ( $p < .001, r_g^2 > .53$ ).

**Conclusions:** The findings of this study demonstrate that across early and middle childhood, children with ASD experience poorer health across a variety of indicators. For children with ASD, significantly lower levels of QOL will have a cumulative impact on other areas of health and development. These findings underscore the need for longitudinal and intervention research to understand the competencies children with ASD need to acquire early in development to be active and improve health outcomes. Given the differences in health indicators that emerge with increasing age, early childhood is a critical time for intervention to promote positive trajectories of health and quality of life during sensitive periods of development.

**437.004 (Poster)** How Has the COVID-19 Pandemic Affected School Aged Children with Autism: A Parental Report

**Background:** In the spring of 2020, school closures were widespread across the USA in an effort to control the spread of COVID-19. These shutdowns impacted millions of school aged children, and have had significant psychosocial implications. Children with autism are a vulnerable population with unique educational and social needs. Prolonged school closures due to the ongoing pandemic are likely to have had a unique disruptive effect on the social and emotional functioning of children with autism and their families compared to their neurotypical peers.

**Objectives:** The objectives of the current study was to compare experiences of the COVID-19 Pandemic on children with autism compared to neurotypical peers. Given social differences and preferences for consistency in children with autism, we predicted that children with autism would experience more stress related to disruptions in daily routines, and less stress related to social isolation. In comparison, we expected neurotypical peers to report more stress associated with social isolation. We also explored unique stressors present in children with autism, such as difficulty in meeting therapeutic and academic goals during the shutdown.

**Methods:** A sample of 311 parents of school aged children, ages of 4-15 years old, participated in an online survey via REDCap. The majority of the respondents (62%) were from the Northeast region of the United States and 65% were parents of children with autism and 35% were parents of neurotypical children. The children were 69% male, and 74.6% were non-Hispanic white. Parental perspectives were collected using the Covid-19 Adolescent Symptom and Psychological Experience Questionnaire (CASPE), as well as an exploratory measure meant to identify stressors specific to children with autism, the Parental Stress Survey (PSS).

**Results:** Parents of children with autism reported more overall disruptions for their child on average compared to the parents of neurotypical peers ( $t=4.38$ ,  $df=286$ ,  $p = 0.000$ ). The top three stressors reported by parents of children with autism were not attending school, schedule disruption, and having to stay at home. In comparison, the top three stressors reported by parents of neurotypical children were not seeing friends, not attending school, and having to stay home. In terms of unique stressors present in the autism children, parents of children with autism reported that they spent more time assisting their child with academic work compared to parents of neurotypical children ( $t=3.81$ ,  $df=286$ ,  $p = 0.000$ ). Parents of children with autism expressed concerns regarding reductions in meeting therapeutic, social and academic goals during the shut down.

**Conclusions:** The effects of the COVID-19 pandemic and prolonged school closures have disrupted the lives of all children, but these circumstances have presented unique challenges to children with autism. These results indicate children with autism are a vulnerable group for negative changes due to the pandemic. These findings represent the need for specific clinical and educational intervention to mitigate the effects of the COVID-19 pandemic in children with autism in the years ahead.

**437.005 (Poster) Identification of Sex Differences across Comorbidities in 59K Autism Spectrum Disorder Patients**  
*A. Gutierrez<sup>1</sup>, C. Sáez<sup>1,2</sup>, C. De Niz<sup>1</sup>, N. Jalali<sup>1</sup>, T. N. DeSain<sup>1</sup>, R. Kumar<sup>1</sup>, J. M. Zachariasse<sup>1,3</sup>, K. P. Fox<sup>1</sup>, N. Palmer<sup>1</sup>, I. Kohane<sup>1</sup> and P. Avillach<sup>1</sup>, (1)DBMI - Harvard Medical School, Boston, MA, (2)Instituto Universitario de Tecnologías de la Información y Comunicaciones (ITACA), Universitat Politècnica de València (UPV), Valencia, Spain, (3)Department of General Paediatrics, Erasmus MC - Sophia Children's Hospital, University Medical Center, Rotterdam, Netherlands*

---

**Background:** Autism spectrum disorder (ASD) is 3-4 times less prevalent in females than in males. Although sex dimorphism is a consistent and recognized feature of ASD, additional clinical correlates could help to identify potential ASD subgroups; this could shed light on some of the complexities of ASD that remain poorly described and help informing parents. Autism in females can present with phenotypic categories that are distinct from those considered characteristic of the disorders, being the sex an important specifier that could help in defining ASD subgroups and identifying mechanisms for disease, and such phenotypic categorization could help clinicians in guidance and specialist referrals appropriate for the specific anticipated comorbidities. Researchers have long recognized a discrepancy in the ratio ASD presentation in males and females. Yet, these sex differences and their related comorbidities have been incompletely characterized, hindering more accurate diagnosis.

**Objectives:** The purpose of this study is to identify phenotypic categories that occur uniquely in females with ASD, those significantly distinct from males with ASD and females without ASD.

**Methods:** In this work, using large-scale real-world data we characterize developmental and age-specific differences in related comorbidities, developmental, age-specific differences in females with ASD compared to males with the same diagnosis, as well as neurotypical girls. We performed a systematic comorbidity analysis on 1,860 groups of comorbidities exploring the all spectrum of known disease in 59,140 individuals (11,440 females) with ASD, in four age groups. We explored ASD sex

differences in real-world datasets, across all potential comorbidities by comparing 1) females with ASD versus males with ASD and 2) females with ASD versus females without ASD. We used electronic health record (EHR) data from a pediatric hospital to replicate the analysis.

**Results:** Through this analysis, we identified 27 different comorbidities that appeared significantly more frequently in females with ASD. Consistent with prior findings, we identified neurological (e.g., epilepsy, OR>1.8, ages 3-18), congenital (e.g., chromosomal anomalies, OR>2, ages 3-18), and mental disorders (e.g., intellectual disability, OR>1.7, in children aged 6-18). In addition, we found evidence of ten novel phenotypic categories, including endocrine-metabolic (e.g., failure to thrive, OR=2.5, in children aged 0-2), digestive disorders (GERD, OR=1.7 in children aged 6-11 and constipation OR>1.6 in children aged 3-11) and sense organs (strabismus, OR>1.8 in children aged 3-18), that mark a differential, gender-related indicator for children with ASD.

**Conclusions:** This study uniquely contributes to the growing body of research regarding sex-based comorbidity analysis in an ASD population. Our findings provide insights into female-enriched ASD comorbidities that might be important in diagnosis, as well as the identification of distinct comorbidity patterns influencing anticipatory treatment or referrals.

**437.006 (Poster)** Increase in Referrals of Children with Suspected Autism Spectrum Disorder (ASD) from Child Health Surveillance to Specialized Services, in Uruguay, Based on Changes in Health Policies  
*N. Tailanian<sup>1</sup>, C. Carvallo<sup>2</sup>, N. Davezak<sup>2</sup> and G. Garrido<sup>3</sup>, (1)MONTEVIDEO, Hospital Pereira Rossell, MONTEVIDEO, Uruguay, (2)ASSE, Montevideo, Uruguay, (3)Universidad de la República, Montevideo, Uruguay*

---

Background: ASD have increased their prevalence worldwide in recent years, detection and a precocious diagnosis are essential to initiate treatment as early as possible. Child health surveillance carried out by pediatricians, in primary health care, represents an important step in detection. Timely referral to specialists for diagnostic confirmation and initiation of early interventions is crucial. Recently [Montiel-Nava et. al 2020] in a survey study, estimated age of first first parents concerns in Uruguay was found at 21 months, and age of ASD diagnosis at 49. In our country, policy efforts have been made to shorten this time gap. In 2005, an integrated national health system (NHIS) was created. This system allows a greater coverage of medical care for the general population. Since 2008, the universal and mandatory use of the child control booklet is implemented. This booklet includes developmental alerts aimed at caregivers. Moreover, a National guide for development monitoring was designed and begun implementation in 2010. This guide is used in child health surveillance visits in pediatric consultation in primary health care for the evaluation of every child under 5 years of age. Furthermore, training programs for the correct implementation of the guideline were carried out for medical personnel. The ASD specialized outpatient clinic, created in 2005 in the pediatric hospital of national reference (CHPR) receives patients from the first level of care from across the country. Our interest is to analyze the characteristics of the referrals and their trends since its creation.

Objectives: To examine and compare the characteristics of patients referred from pediatric visits in children and adolescents who are referred to the ASD outpatient clinic at CHPR, and their trends during the 2005-2018 period.

Methods: Observational, descriptive study from anonymized patient records. Patients visiting for the first time, referred from pediatric consultation in the first level of care, during the period January 2005-July 2018 were analyzed. Data were analyzed using SPSS. The study is approved by the research ethics committee.

Results: In the period 2005-July2018, 331 patients who consulted had referral data. 12% corresponded to patients referred by pediatricians, occupying the 3rd place after psychiatrists and neuropediatricians. It is reported that in 59% of cases it was the family who detected the first symptoms. A statistically significant 8 fold increase ( $p < 0.05$ ) is observed in patient referrals by pediatricians in the 2015-June2018 period (Graph1). In other variables studied (Table1), no statistically significant differences were observed, maintaining temporal stability in the studied years.

Conclusions: The significant increase of referrals from pediatricians may be related with the impact of healthcare strategies. Despite this, the increase is not associated with a lower age of referral, age of identifying first symptoms or age of ASD diagnosis. A limitation is that the ASD outpatient clinic is not part of the primary healthcare system, so the impact of strategies for earlier detection and diagnosis could be shown with less sensitivity or need more time to be detected. We consider that it is important to keep monitoring in order to observe the impact of implemented strategies.

**437.007 (Poster)** Is Meeting the 24-Hour Movement Guidelines Associated with Weight Status and Quality of Life in Children with and without Autism Spectrum Disorder?

**Background:** Children with autism spectrum disorder (ASD) experience higher rates of overweight and obesity and lower quality of life (QOL) than children without ASD. The 24h movement guidelines for children include recommendations for physical activity (60 minutes of moderate to vigorous intensity PA and more than 2 hours of structured and unstructured light intensity PA), sleep (9 to 11h), and sedentary behavior (< 2h of recreational screen time). Examining the 3 recommendations collectively across 24 hours, allows us to move beyond 60 minutes of MVPA to understanding how behaviors throughout the whole day influence the health and well-being of children with ASD.

**Objectives:** The purpose of this study was to determine whether 6 to 9-year-old children with and without ASD were meeting the individual and collective recommendations outlined in the 24h movement guidelines and examine how meeting the 24h movement guidelines influenced their body composition and QOL.

**Methods:** This study included 25 children with ASD (21 boys) and 23 children without ASD (19 boys) between the ages of 6 and 10 years. Physical activity was objectively measured using GT3X accelerometers worn on the hip for 7 days. Screen time, sleep, and QOL were determined by parent report. The Pediatric Quality of Life inventory was used to estimate health-related QOL and included summary scores for physical and psychosocial QOL. The recommendations were examined for week and weekend days. Body fat percentage was estimated using bioelectrical impedance analysis. Independent sample *t*-tests were used to examine how meeting the 24h guidelines influenced body fat and QOL.

**Results:** Children with ASD had significantly higher body fat percentages and lower QOL ( $p < .001$ ). Looking at the individual recommendations, children with ASD engaged in less physical activity, had fewer hours of sleep, and had significantly more screen time than children without ASD. During the week, 16% of children with ASD and 52% of children without ASD met the 24h movement guidelines. Overall, children with ASD met fewer recommendations on the weekend. Children who met the 24h movement guidelines had significantly lower body fat percentage ( $p = .001$ ,  $d = 0.93$ ) and higher estimates of physical ( $p = .038$ ,  $d = 0.61$ ) and psychosocial QOL ( $p = .023$ ,  $d = 0.75$ ).

**Conclusions:** Children with and without ASD who met the 24h movement guidelines were more likely to have a healthier body composition and higher estimates of QOL. By examining the recommendations collectively and across the whole day, we begin to understand which behaviors require targeted intervention. The results of our study demonstrate that to improve the health of children with ASD, we need to understand movement behaviors throughout the whole day and the whole week.

**437.008 (Poster) Mental Health Screening in Pediatric Primary Care for Children with Autism**

N. A. Stadnick<sup>1,2,3</sup>, E. Lane<sup>2,4</sup>, K. Martinez<sup>5,6</sup>, D. P. Gizzo<sup>7</sup>, K. Coleman<sup>8</sup>, B. Lin<sup>8</sup>, B. Dub<sup>8</sup>, S. Walpole<sup>9</sup>, D. Walters<sup>10</sup>, R. Ireland<sup>11</sup>, G. A. Aarons<sup>1,2,3</sup> and L. ---

**Background:** Co-occurring mental health problems among children with autism spectrum disorder (ASD) are highly prevalent and require lifespan, transdisciplinary and community participatory care approaches (e.g., Gotham et al., 2020). Pediatric primary care is a principal point of contact for children's healthcare and can be instrumental in first identifying and responding to mental health concerns (e.g., Van Cleave et al., 2018). Yet, limited research has examined mental health screening rates or prevalence for children with ASD in primary care.

**Objectives:** This study reports on mental health screening and patterns in pediatric primary care as part of a larger program of implementation research piloting Access to Tailored Autism INtegrated Care (ATTAIN), an integrated pediatric care model promoting timely identification of mental health needs and care linkage for children with autism (Stadnick et al., 2019).

**Methods:** Data were extracted from the pilot study testing ATTAIN feasibility in six primary care clinics within two healthcare organizations. The two organizations were: Organization 1: a linked health system serving families with private insurance and Medicaid; Organization 2: a large integrated health care system. Demographics and screening data from the Pediatric Symptom Checklist-17 (PSC-19; Jellinek et al., 1999), a brief mental health screener for children ages 4-16 years, were collected during the

four-month pilot, partially during the COVID-19 pandemic. The PSC-17 screening occurred during annual well-child visit appointments.

**Results:** A total of 166 children with ASD were eligible during the pilot period across both organizations (n=81 in Organization 1; n=85 in Organization 2). Eligible children were an average of 9.08 years ( $SD=3.46$ ) of age, 58% Latinx (n=47) and 84% male (n=68) in Organization 1 and an average of 8.00 years ( $SD=3.94$ ), 47% Latinx (n=40) and 81% male (n=69) in Organization 2. Screening rates were similar with 53% (n=43) of eligible children screened in Organization 1 and 55% (n=47) of eligible children screened in Organization 2. In Organization 1, 47% (n=20) screened positive, as evidenced by an elevated PSC-17 Total Score, while 36% (n=17) screened positive in Organization 2. For both organizations, children who had positive screens had clinically elevated scores on the Externalizing and Attention subscales but not on the Internalizing subscale.

**Conclusions:** In this feasibility pilot of ATTAIN, slightly over 50% of eligible patients with ASD were screened using the PSC-17. This screening rate was lower than expected due to changes in practice responsive to the COVID-19 pandemic but also suggests opportunities to refine implementation strategies to boost screening. Positive screening rates differed between organizations (47% versus 36%) but were generally high, reinforcing the co-occurring nature of mental health needs in children with ASD. Those who had positive screens also scored above the clinical cutoffs for both Externalizing and Attention subscales, confirming typical trends in co-occurring challenging behavior presentations in school-age children with ASD (Brookman-Frazee et al., 2017). Next steps are to conduct additional analyses to understand demographic and clinical patterns in screening rates and outcomes and to enhance strategies to improve screening in primary care in order to better provide more relevant and personalized treatments.

**437.009 (Poster)** Prevalence of Broad Autism Phenotype in Parents of Children with Autism Spectrum Disorder Using Autism Spectrum Quotient (AQ) in an Indian Sample Its Impact on Adaptive Behaviours, Behavioural Issues and Severity Children with ASD

*H. Dayal<sup>1</sup> and M. Juneja<sup>2</sup>, (1)Pediatrics, Maulana Azad Medical College, New Delhi, India, New Delhi, India, (2)Maulana Azad Medical College, New Delhi, India*

---

**Background:** This study aimed to find prevalence of BAP in parents of children with ASD in a diverse Indian sample and to determine if presence of BAP in parents affected child severity

**Objectives:** The primary objective of the study was to find **prevalance of BAP** and association of BAP in parents with severity of ASD. Secondary objectives were to find association of BAP in Parents with Behavioral problems and Adaptive behaviors in children with ASD

**Methods:** 95 children, ages of 2-12 years, newly diagnosed with ASD and their 95 mothers and fathers each, were enrolled from 1<sup>st</sup> April, 2019 to 15<sup>th</sup> February, 2020. Children were administered Childhood Autism Rating Scale-2 (CARS-2), Child Behaviour Checklist (CBCL), Vineland II Adaptive Behaviour Scale (VABS-II) for severity of ASD, behavioral problems and adaptive behavior and respectively. Autism spectrum Quotient (AQ) was administrated to all parents. AQ was translated to Hindi and piloted, before commencement of the study. Few questions were adapted to suit cultural requirements.

**Results:** Prevalence of BAP (AQ scores  $\geq 23$ ) was 50% in mothers, and 47% in fathers. Mean maternal AQ was 22.4 and mean paternal AQ was 21.8.

Mean child age was  $65.02 \pm 30.71$  months with the male: female ratio of 2.8:1. 65.3% of the children had severe autism, while 32.6% had mild to moderate autism. The mean CARS-2 score was  $38.87 \pm 5.39$ .

Significant positive correlation was found between CBCL externalizing T- score and communication subdomain of AQ score in both parents. Significant negative correlation was found between VABS-II motor domain standard score with both parents' total AQ score. Regression analysis revealed father AQ communication subdomain score as a significant predictor of VABS motor skill subdomain ( $\beta = -0.276$ ,  $p = 0.034$ ). No association was found between severity of ASD in children and BAP in parents.

**Conclusions:** Most global studies show lower BAP prevalence and lower total mean AQ scores in both mothers and fathers as compared to present study. No significant difference was seen between mothers and fathers in any of the AQ subdomain, in contrast to western population. The higher all-over prevalence of BAP and higher AQ scores may be explained by? higher genetic loading needed for ASD symptoms to manifest. In view of more child centred rearing practices & traditions (especially in joint families) or the cohort consisted of more severe children with more BAP manifestations in the parents.

Children with the best motor functioning are shown to have to lowest cognitive impairment and ASD severity, as per studies analysing Artificial Neural Networks. Impaired parenting skills such as poor encouragement of child's play can thus impact severity in children.

Correlation between communication subdomain of AQ of both parents and more severe child externalizing behaviour can either be attributed to behavioural problems being marker of genetic risk; or to the lack of effective two way communication in such triads.

Defective parent-child interactions may affect parent mediated interventions, which are a norm in ASD management especially in developing country like India. Parents with BAP may require additional support for the successful delivery of parent-mediated interventions.

**437.010 (Poster)** The Association between Parent Concern about Child Weight and Parental Use of Restrictive Feeding Practices in Typically Developing Children and Children with Autism Spectrum Disorder.

**K. M. Rancano<sup>1</sup>**, C. Curtin<sup>2</sup>, L. G. Bandini<sup>3</sup> and A. Must<sup>4</sup>, (1)Nutrition Communications, Interventions, and Behavior Change, Friedman School of Nutrition Science and Policy, Tufts University, Boston, MA, (2)University of Massachusetts Medical School, Waltham, MA, (3)Eunice Kennedy Shriver Center, University of Massachusetts Medical School, Worcester, MA, (4)Tufts University School of Medicine, Boston, MA

---

Background: Parents concerned about child overweight may use restrictive feeding practices, which may contribute to the development of unhealthy eating behaviors in children (e.g., emotional eating and overconsumption of restricted foods). Parents of children with autism spectrum disorder (ASD) must often balance feeding challenges (e.g., food selectivity) and behavioral concerns in addition to concerns about health, such as child overweight. The relationship between concern about child overweight and use of restrictive feeding practices may therefore be different between parents of typically developing (TD) children and children with ASD.

Objectives: To compare the association between parent concern about child overweight and use of restrictive feeding practices between TD children and children with ASD.

Methods: We examined a diverse convenience sample of children (3-8 yo) and their parents from the Children's Mealtime Study, which recruited TD children and children with intellectual disabilities (ID). Children with ID with scores  $\geq 65$  on the on the Autism Rating Scale were classified as having probable ASD. Included in this analysis are 59 TD children and 34 children with ASD. Parents completed the Comprehensive Feeding Practices Questionnaire which included two domains capturing restrictive feeding practices: restriction of less healthy foods/sweets and restriction to decrease/maintain the child's weight. Parents reported their level of concern about their child "becoming overweight" and "being overweight," separately on a 5-point Likert scale. The two items were combined and dichotomized to represent "any concern" about child overweight where "any concern" ranged from "a little" to "very" concerned. Linear regression models adjusted for child weight status (0 "no overweight/obesity" 1 "overweight/obesity") were used to examine the association between parent concern about child overweight and restrictive feeding practices. Interaction terms were used to examine group differences.

Results: Nearly 70% of parents of children with ASD reported being concerned about their child's current or future weight status compared to 31% of parents of TD children ( $p < 0.001$ ). Among children with ASD, having any concern about child overweight was not associated with restrictive feeding practices ( $p > 0.05$ ). Conversely, among TD children, parents with any concern about child overweight were more likely to restrict child food intake to maintain or decrease child weight ( $\beta = 0.52$ ;  $p = 0.015$ ) and to restrict child intake of less healthy foods and sweets ( $\beta = 0.80$ ;  $p = 0.007$ ) compared to parents with no concern. Group interaction terms (TD vs. ASD) were not statistically significant ( $p > 0.05$ ).

Conclusions:

Significant associations between parental concern about child overweight and restrictive feeding practices were observed among parents of TD children but not among parents of children with ASD. Compared to TD children, associations among parents of children with ASD were weaker and may not have reached statistical significance due to the small sample size and young age of the sample (i.e., parental concern about overweight in younger children may be less influential). Future studies are needed to confirm these results. Understanding the drivers of parental feeding practices is important for developing recommendations and interventions that align with the needs and concerns of parents of children with ASD.

**437.011 (Poster)** The Complex Relationship between Greenspace and Wellbeing in Children with Autism, Children with Special Healthcare Needs (CSHCN), and Typical Children

**B. Barger<sup>1</sup>, L. Larson<sup>2</sup>, J. Torquati<sup>3</sup>, E. Moody<sup>4</sup> and S. Rosenberg<sup>5</sup>,** (1)Georgia State University, Atlanta, GA, (2)LR.Larson@ncsu.edu, NC State, Raleigh, NC, (3)U of Nebraska, Lincoln, NE, (4)Wyoming Institute for Disabilities, University of Wyoming, Laramie, WY, (5)University of Colorado Anschutz Medical Campus, Aurora, CO

---

**Background:** There is a sizeable body of research on the impact of natural environments for typically developing children and those with ADHD. However, only two studies have examined whether natural environments impact metrics of wellbeing in children with autism spectrum disorder (ASD): One study found greenspace predicted lower conduct problems in children with ASD and another found greenspace associated with increased anxiety in children with ASD. Both studies were limited by their use of binary outcome variables.

**Objectives:** This study investigated the effects of zip-code level greenspace and greyspace (i.e., constructed non-natural surfaces) on a metric of wellbeing from the 2012 National Survey of Children's Health (NSCH).

**Methods:** The 2012 NSCH is a large cross-sectional public health survey of U.S. children birth to 17 years old. It includes a 5-item metric of wellbeing and caregivers reported on whether their child has an ASD. Greenspace and greyspace metrics were derived from the National Land Cover Database (NLCD). Data from the 2012 NSCH and the NLCD were merged at the zip-code level and data were analyzed with survey weighted and stratified regression models using R's survey package. Co-variables included children with special healthcare needs (CSHCN) status; whether they had anxiety, conduct problems, depression, or learning disabilities; sex, age, race/ethnicity, socio-economic status, maternal education, insurance status, and metropolitan size.

**Results:** The study sample includes 65,593 typically developing children, 1,393 children with autism, and 14,947 non-autistic CSHCN age 6 and older. Multi-variate models with just greenspace and greyspace showed that greenspace had a negative ( $p < 0.001$ ) and greyspace a null ( $p = 0.18$ ) relationship with child wellbeing. Follow-up analyses revealed complex greenspace X conduct problems X diagnostic interaction effects. For typically developing children, trend lines and 95% confidence intervals were non-overlapping; children without conduct problems had higher wellbeing scores than those with conduct problems, displaying little change in relationship to greenspace; typical children with conduct problems displayed a negative relationship indicating that as greenspace increases wellbeing decreases. For children with ASD, trend lines and 95% confidence intervals were non-overlapping; children with ASD and no conduct problems had higher wellbeing scores than those with conduct problems, and displayed a negative relationship indicating that as greenspace increases wellbeing decreases; children with ASD and conduct problems displayed a negative relationship indicating that as greenspace increases wellbeing decreases. For CSHCN, trend lines and 95% confidence intervals were non-overlapping; CSHCN and no conduct problems had higher wellbeing scores than those with conduct problems, and displayed a positive relationship indicating that as greenspace increases wellbeing increases; CSHCN and conduct problems also displayed a positive relationship indicating that as greenspace increases wellbeing decreases.

**Conclusions:** In typical populations, the literature largely supports that natural environments positively impact wellbeing; however, these data suggest that the relationships may be more complex depending on the diagnostic traits of the population studied. A major limitation of this analysis is that greenspace was measured at the zip-code level; local measures are needed to draw firm conclusions.

**437.012 (Poster)** The Effects of Distraction on the Self-Regulation of Preschoolers with Autism Spectrum Disorder

**B. S. Kennedy<sup>1</sup> and S. Faja<sup>2</sup>,** (1)Faja Lab, Labs of Cognitive Neuroscience, Boston Children's Hospital, Boston, ME, (2)Boston Children's Hospital, Boston, MA

---

**Background:** Effortful control is the ability to self-regulate to achieve current and future objectives (Rueda, Posner, & Rothbart, 2005). The presence of distraction can assist with attention and impulsivity control in typically developing (TD) children but this relation between distraction and self-regulation has received less research attention among preschool-age children with autism spectrum disorder (ASD) (Mischel & Ebbsen, 1970). The error related negativity (ERN) is thought to be a neural index of error-monitoring, conflict detection, reinforcement learning, error-related distress, and the motivational significance of errors (Canen & Brooker, 2017).

**Objectives:** This study aimed to determine whether there are significant differences in the self-regulation of preschool-age children with (ASD) as compared to TD preschool-age children using effortful control and delay tasks. Electroencephalography (EEG) tasks were additionally conducted to determine whether there is a correlation between the error-related negativity (ERN) waveform and behavioral measures of effortful control.

**Methods:** Preschoolers ranging from four to six-years-old ( $N = 20$ ) with and without ASD participated in this study ( $n = 14$  participants with ASD). The Delay of Gratification (Mischel & Ebbsen, 1970) and Rabbit-Turtle (Kochanska, Murray, & Harlan, 2000) tasks were used to evaluate self-regulation. This study compared the original tasks to an adapted condition with additional toys for distraction.

EEG was recorded during the Attention Network Test (ANT) for 12 of the above participants ( $n = 9$  participants with ASD). The ERN component was examined over Fz consistent with the prior reports (Brooker, Buss, & Dennis, 2011; Canen & Brooker, 2017).

**Results:** Data collection is ongoing. ASD and TD groups did not differ in completion of Delay of Gratification overall,  $F(1, 18) = 0.07, p = .79$ , or by distraction condition,  $F(1, 18) = 0.34, p = .57$ . Across groups, attention behaviors differed by distraction condition,  $F(1, 18) = 23.39, p < .001$ . The difference in Rabbit-Turtle reaction time was larger for the non-ASD group,  $F(1, 21) = 4.69, p = .042$ , and both groups had less slowing for the Turtle condition when distractors were present,  $F(1, 21) = 5.93, p = .024$ . Preliminary analysis of the ERN data indicates a trend effect of diagnostic group by condition (ERN/CRN) interaction, such that TD children had more negative ERN relative to CRN than the ASD group,  $F(1, 12) = 4.14, p = .065$ . Finally, children in both groups who were able to slow more for the Turtle condition of Rabbit-Turtle had longer delay times for the Delay of Gratification task,  $r(15) = .65, p = .009$ , and had less attention to the temptation,  $r(15) = .61, p = .017$ , without distractors present.

**Conclusions:** These preliminary results indicate that distraction impacts the self-regulation of preschoolers and can differ between ASD and TD groups, shown by both the individual tasks and the correlation between behavioral tasks. Additionally, the preliminary ERN data demonstrate a trend that the ERN is present in the TD group and is not in the ASD group. In future the analyses will account for IQ using the Mullen nonverbal developmental quotient and will investigate the relationship between ERN and the behavioral tasks.

**437.013 (Poster)** The Impact of COVID on Families' Wellbeing with Children with ASD

R. Nunez Pepen<sup>1</sup>, H. Park<sup>1</sup>, P. Fuch<sup>2</sup>, G. Fleurio<sup>1</sup>, A. Chu<sup>3</sup> and E. Feinberg<sup>1</sup>, (1)Boston Medical Center, Boston, MA, (2)Boston University School of Medicine, Boston, MA, (3)Boston University School of Public Health, Boston, MA

Background: The COVID-19 pandemic has disproportionately affected Black, Indigenous, and People of Color (BIPOC) and low-income families. It has disrupted the lives of young children in ways that could have lasting effects on long term outcomes. Potential mechanisms include financial hardship, caregiver stress, and exacerbation of behavioral symptoms. Children with Autism Spectrum Disorder (ASD) may be particularly vulnerable.

Objectives:

To explore the effects of the COVID-19 pandemic on BIPOC and low-income families with children with ASD.

Methods:

We sampled across our research team's previous studies that recruited low-income, racially and ethnically diverse families of young children with psychosocial and developmental risk, including ASD. We administered the Epidemic-Pandemic Impacts Inventory (EPII) to families via phone. The EPII 92-item tool assesses the effects of financial hardship and changes in family dynamics. We examined descriptive statistics and results from chi-square tests comparing the reported financial hardship, family conflict and child behavioral symptoms among families of children with and without ASD.

Results:

To date, the study has enrolled 76 families; 54.0% identified as Black/African-American, 31.1% as Hispanic, 16.2% as white, 8.1% as mixed-race, 5.4% as Asian, and 2.7% as American Indian/Alaska Native. The majority (71.6 %) received public health insurance; 47.3% of families were unemployed. Twenty-one percent of families had a child with ASD, ascertained by evaluation that included administration of the ADOS.

A large proportion of families reported financial hardship, defined as experiencing difficulty accessing sufficient food and paying important bills (49%); 61.8% reported being laid off from work and/or reduced work hours during the pandemic. There were no differences among ASD and non-ASD families.

Reports of increased child behavioral and sleep difficulties were common. However, families of children with ASD were disproportionately affected; 87% of ASD families vs 58% of non-ASD families reported an increase in child behavior and sleep difficulties ( $p = 0.030$ ). Families of children with ASD also experienced an increase in physical conflict among the children in the home compared to non-ASD families (31% vs 11%,  $p=0.056$ ). Overall, there was a marked increase in family conflict but these changes did not affect families of children with ASD differentially. 34.2% of respondents reported increased verbal and physical argument or conflicts with adults at home and 44.7 % reported more conflict with their children or more harshly disciplining children. There were some positive changes associated with the pandemic: 92.0% of families reported spending more quality time with their children.

#### Conclusions:

Overall, this sample of low-income, largely BIPOC families of young children reported profound effects of the COVID pandemic on their financial wellbeing, conflict in the home, and child behavior. Families of children with ASD experienced a disproportionate increase in child behavioral problems and physical conflict between children compared to non-ASD families. The cumulative effects of increased material hardship and family conflict may result in levels of toxic stress, which have lasting impacts. Study data collection is ongoing and will assess family impacts longitudinally during the pandemic and recovery post pandemic.

#### **437.014** (Poster) The Impact of COVID-19 on the Autism Service Delivery System in Alberta

**D. B. Nicholas<sup>1</sup>, R. Zulla<sup>2</sup>, O. Conlon<sup>3</sup> and L. Zwaigenbaum<sup>1</sup>, (1)University of Calgary, Edmonton, AB, Canada, (2)School of Public Health, University of Alberta, Edmonton, AB, Canada, (3)University of Alberta, Edmonton, AB, Canada**

---

#### Background:

For children with autism, the COVID-19 pandemic has resulted in significant changes to daily life. These changes have variably resulted in anxiety and other challenges (e.g., depression, sleep disruption) with unknown long-term impact. While social, psychological and economic implications are anticipated, coping may be affected in varying ways, including some children having great difficulty adapting and others experiencing less struggle. Mental health issues, parental anxiety, economic instability, lack of access to services, and financial strain encompass factors that may exacerbate personal and family strain. Further study is needed to understand the impact of COVID-19 on children with autism and their families, and service providers.

#### Objectives:

As part of a larger study, this qualitative sub-study explored the lived experiences of children with autism and their families during the COVID-19 pandemic, along with that of service providers who provide child and family support.

**Methods:** Three focus groups were convened during the pandemic with service providers in Edmonton, Canada. Sixteen service providers in areas of professional or para-professional service (e.g., occupational therapy, psychology, education) participated in focus groups, using Zoom technology. Focus group questions focused on how the pandemic impacted children/youth/families as well as service providers and their practice.

#### Results:

Analysis revealed differential impacts of the pandemic on children and families as well as service providers. Service providers reported pivoting from *in-person* to *online* to *in-person* in some instances (e.g., home visits) and a hybrid of *online and in person* services. Service providers reported requisites of continual sanitization and PPE often in families' homes (e.g., wearing masks, repeatedly wiping down equipment), periodic social distancing, and some requiring quarantine. These shifts resulted in a range of responses from children and families, with some being able to readily adapt to changes such as social distancing, and some positive parent reports of appreciation for more time to engage with their child. On the other hand, these shifts were reported as devastating in varying degrees for many, with some families having negligible resources when they viewed these resources as most needed. Of further concern, social determinants of health barriers were described to heighten family stress such as multiple children with autism in a family, and complex social needs. Shifts in service delivery were viewed to offer new ways to connect with families (e.g., online), with increased access to families' natural surroundings (e.g., home environment), yet simultaneously imposed struggles such as, in some cases, less access to or engagement with some children and families. For some families, online service delivery increased their sense of engagement while for others, it was viewed as less effective than in person alternatives. For service providers themselves, the shifting service delivery environment reportedly resulted in personal/professional stress. They reported exhaustion from revised practice approaches (e.g., social distancing in homes and

classrooms). Service providers also reported fatigue due to working longer hours, having heavier workloads, and often struggling with finding a life/work balance.

Conclusions:

Findings reveal challenges and means by which autism service delivery can better provide care to families in a pandemic.

**437.015** (Poster) Understanding Behavioral Inflexibility and Anxiety in ASD during the COVID-19 Pandemic  
*A. R. Dallman<sup>1</sup>, C. M. Perry<sup>2</sup>, J. Goldblum<sup>3</sup>, L. Lecavalier<sup>3</sup>, B. A. Boyd<sup>4</sup> and C. Harrop<sup>2</sup>, (1)Occupational Therapy & Occupational Science, Towson University, Towson, MD, (2)Department of Allied Health Sciences, University of North Carolina at Chapel Hill, Chapel Hill, NC, (3)Ohio State University, Columbus, OH, (4)Juniper Gardens Children's Project, University of Kansas, Kansas City, KS*

---

**Background:** The COVID-19 Global Health Pandemic has presented unique challenges to individuals with Autism Spectrum Disorder (ASD) and their families. Behavioral inflexibility (BI), a prominent feature of ASD, is commonly associated with anxiety and requires families with ASD individuals to undertake extensive planning in order to ensure that daily life runs smoothly (Sethi et al., 2019). Due to the pandemic's unprecedented nature, families faced the inability to make necessary preparations, causing upended daily routines. Understanding both BI and anxiety during the COVID-19 pandemic is important to understand well-being for those on the spectrum during this time.

**Objectives:** Our study aims to (1) Characterize BI in ASD during/following the COVID19 pandemic and compare to prior BI data and to (2) Examine how parents of ASD adolescents describe their child's BI in response to the pandemic.

**Methods:** This convergent-parallel mixed-methods research study (Creswell & Piano Clark, V., 2017) was completed in two phases. During *Phase One*, parents of ASD children (N=46) who originally participated in Project BIDD completed the Behavioral Inflexibility Scale (BIS) (Lecavalier et al., 2020), the Parent Rated Anxiety Scale for ASD (PRAS-ASD) (Seahill et al., 2018), and the Parenting Stress Index (PSI) (Abidin, n.d.). In *Phase Two*, a subset of parents of ASD adolescents (N=11) participated in one of four virtual WebEx focus groups to help increase our understanding of ASD adolescent BI. To examine the association between relevant variables, linear regression and Pearson's correlations were used. Qualitative data was transcribed verbatim and analyzed using thematic analysis. Quantitative (based on n=46) and qualitative findings (based on n=11) were merged by using qualitative and quantitative data simultaneously to explain findings. Key results are presented below.

**Results:** Three organizing themes were identified: relative stability of BI during COVID-19, anxiety and BI during the COVID-19 pandemic, and the multiple new roles of caregivers. Caregivers reported negligible decreases in their child's BI during the pandemic in surveys (Change in BIS Sum  $M = -0.38$ ,  $sd=23.38$ ,  $t = -0.80$ ,  $p = 0.43$ ). In focus groups, caregivers discussed how their child's inflexibilities were magnified during the start of the pandemic, but returned to baseline as parents found new routines and adaptations. Child BI was moderately correlated with child anxiety ( $r = 0.65$ ,  $p < .001$ ). During focus groups, caregivers shared stories of children's anxieties increasing when preferred restaurants and activities were no longer available. Interestingly, BI was not related to caregiver stress ( $r = 0.26$ ,  $p = 0.09$ ). During focus groups, caregivers reported high stress levels, (PSI  $M = 90.56$ ), which may be explained by the fact that participants reported taking on new and multiple roles to help their child during this time. Additional themes and findings from the mixed-methods analysis will be presented.

**Conclusions:** BI remains a prominent concern for ASD individuals and their families during the COVID-19 pandemic. Though BI levels remained relatively stable during COVID-19, parents experienced high levels of stress likely due, in part, to the multiple roles now required of them. Implication of these findings for research and clinicians will be discussed.

## Postmortem Studies

### POSTER SESSION — POSTMORTEM STUDIES

#### Poster 438 - Postmortem studies Posters

**438.001** (Poster) Prefrontal and Primary Somatosensory Cortex in Fragile X Patients Is Characterized By Decreased Number of Parvalbumin-Expressing Interneurons

*P. Juarez<sup>1</sup>, B. Dufour<sup>2</sup> and V. Martinez-Cerdeno<sup>3</sup>, (1)Department of Pathology and Laboratory Medicine, University of California Davis, Sacramento, CA, (2)Pathology and Laboratory Medicine, University of California, Davis, Sacramento, CA, (3)Pathology & Laboratory Medicine, UC Davis School of Medicine; Institute for Pediatric Regenerative Medicine and Shriners Hospitals for Children of Northern California, Sacramento, CA*

#### Background:

Fragile X syndrome (FXS) is a genetic neurodevelopmental disorder that is characterized by the deficiency or absence of the fragile X mental retardation 1 protein (FMRP). FXS is the most common single gene disorder that accounts for up to 6% of all Autism Spectrum Disorder (ASD) cases. Many behavioral deficits that characterize FXS, such as cognitive impairment and sensory hypersensitivity, closely overlap with those seen in ASD. It is therefore reasonable to suggest that the underlying brain circuitry in these two populations may undergo similar cellular and molecular cortical modifications during and after neurodevelopment.

Recent findings in ASD postmortem brains from our laboratory show a 50% loss of one of the three major types of cortical GABAergic interneurons in the prefrontal cortex (PFC), the Parvalbumin (PV)+ interneuron. However, there have not been any large-scale human studies that have investigated changes in the 3 cortical GABAergic expressing interneuron populations in FXS postmortem brains.

#### Objectives:

Investigate cortical areas with potential role in the FXS phenotype. These include dorsolateral PFC (Brodmann Area (BA) 46), primary somatosensory cortex (BA3), temporal cortex (BA22), anterior cingulate cortex (BA24), primary visual cortex (BA17) and primary motor cortex (BA4). Our objectives are to: 1) evaluate changes in the PV+ cortical interneuron population across cortical regions and 2) determine if these changes are similar to those previously seen in ASD.

Methods: We will perform triple immunostaining for three interneuron subtypes (CR+, CB+ and PV+) in postmortem human cortical tissue. The total number of cases to be included in this study are 9 Fragile X and 9 control cases. Immunopositive CR+, CB+ or PV+ cells from each selected BA will be quantified from a 3-mm wide bin that is parallel to the pial surface and extends through the entire length of cortical gray matter, using the 40x objective on a light microscope. We will compare total cell numbers and cell ratios using ANOVA.

Results: We have so far quantified the total number of a set of Fragile X (n= 6-7) and control cases (n= 5). At the time of this writing, quantification in BA46, BA3, and BA22 have been performed by blind researchers, while quantification in BA24, BA4 and BA17 are ongoing. Preliminary results indicate a decrease of 38% ( $\pm 6.4$ ) of PV+ cells in BA46 and 30% ( $\pm 5.6$ ) in BA3. However, the total number of CB+ and CR+ cells did not differ in neither of these two cortical regions. Interestingly, there was no notable changes in any of the three interneuron populations within BA22.

Conclusions: Our findings in FXS brains demonstrate that the magnitude of reduced PV+ interneurons in BA46 and BA3 is very similar to that seen in human ASD brains. Furthermore, we show that the decreases in PV+ interneurons are consistent across multiple Brodmann Areas, thereby implicating potential cortical wide deficits in the PV+ population. Collectively, these findings provide us a better understanding of notable interneuron population changes that occur in FXS brains.

## Rare Genetic Disorders

### POSTER SESSION — RARE GENETIC DISORDERS

#### Poster 439 - Rare genetic disorders Posters

**439.001** (Poster) 18p Deletion Syndrome with Co-Occurring Autism Spectrum Disorder and Average Verbal Comprehension Abilities: A Case Study

*J. Hangauer, Psychology, Johns Hopkins All Children's Hospital, St Petersburg, FL*

Background: 18p deletion syndrome is a well-established rare chromosomal syndrome affecting approximately 1 in 50,000 live births worldwide. The genetic disorder involves deletion of a part or the entire short arm of chromosome 18 first described by Jean de Grouchy and colleagues in 1963. To date, the vast majority of empirical studies and case reports focus on medical complications rather than developmental and neuropsychological functioning. This case report details the unique characteristics of a 10 year old female patient with confirmed 18p deletion syndrome via chromosomal microarray and co-occurring autism spectrum disorder (ASD) requiring substantial support with mild intellectual disability. The patient demonstrated average verbal comprehension abilities, significant deficits in adaptive behavior and nonverbal cognitive functioning, mild language impairment within the context of ASD/co-occurring mild intellectual disability. Previous case reports have found far more severely impacted verbal abilities in individuals with 18p deletion syndrome with or without co-occurring ASD.

Objectives: To contribute to the growing body of literature on the heterogeneity of 18p deletion syndrome and co-occurring disorders (e.g., autism spectrum disorder and attention-deficit/hyperactivity disorder).

Methods: Parent consent and patient assent were obtained. Patient completed a comprehensive psychological evaluation consisting of the ABAS-3, ADHD-5, ADOS-2, BASC-2, BRIEF-2, CPT-3, WIAT-III, and WISC-V. A psychometrician who was blinded to the referral concerns and prior diagnoses administered cognitive and achievement measures. The psychometrician achieved 95% or greater interrater reliability on each measure prior to administration. Other measures were administered and interpreted by a licensed psychologist with significant experience assessing for autism spectrum disorder. Prior chromosomal microarray analysis (4x180K G3 CGH+SNP) was completed by a physician board certified in clinical genetics confirming presence of 18p deletion.

Results: Patient met DSM-5 diagnostic criteria for autism spectrum disorder requiring substantial support with accompanying intellectual disability (mild severity) and language impairment. Additionally, DSM-5 criteria for provisional other specified attention-deficit/hyperactivity disorder with elevated symptoms of inattention without impulsive/hyperactive symptoms was met. The results of the WISC-V found significant deficits in visual spatial, fluid reasoning, working memory, and processing speed performance but average verbal comprehension abilities in contrast to other case reports on 18p deletion syndrome. Knowledge of word definitions was not identified as a restricted interest in the patient.

Conclusions: The results of the present case study correlate with extant results of previous findings related to 18p deletion syndrome related to co-occurring mild intellectual disability. The present case study also found far stronger verbal comprehension abilities versus other areas of intellectual functioning in a 10 year old female patient with co-occurring autism spectrum disorder which other case reports have not found. The present case study contributes to the literature on autism spectrum disorder and co-occurring rare genetic disorders for which there is a paucity of information while informing treatment recommendations.

**439.002** (Poster) Absence of 40-Hz Auditory Steady State Response (ASSR) in 15-Years Old Girl with Microduplication in 22q13.33

*A. Neklyudova<sup>1</sup>, V. Voinova<sup>2</sup> and O. V. Sysoeva<sup>1</sup>, (1)Institute of Higher Nervous Activity and Neurophysiology, Moscow, Russian Federation, (2)Research Clinical Institute of Pediatrics, Moscow, Russian Federation*

#### Background:

Abnormalities in the SHANK3 gene located in 22q13.33 are highly associated with autism spectrum disorder (ASD). A few cases with microduplication of the SHANK3 gene reported in the literature include intellectual disabilities, mild dysmorphic features, ASD, delayed speech and language development, as well as attention deficit and hyperactivity disorder.

SHANK3 encodes scaffold protein involved in postsynaptic receptor density in glutamatergic synapses, including those in the parvalbumin(PV)+ inhibitory neurons – the key players in generation of sensory gamma oscillations, such as 40-Hz auditory steady-state response (ASSR).

### Objectives:

Our goal was to examine if ASSR is atypical in patients with microduplication affected SHANK3 gene.

### Methods:

Here we describe a clinical and neurophysiological phenotype of a 15-years old girl (SH01) with microduplication of 16389 bp in 22q13.33, affecting the SHANK3 gene revealed with high resolution molecular karyotyping (SNP Array).

Clinical assessment was conducted by experienced clinicians. In addition, most subjects' parents (n = 9), including SH01's, filled Russian translation of Social Responsiveness Scale (SRS). All TDs' SRS were less than 59 T-score.

Age-matched group of typically-developing children (TD) (N=11, 5 females, age=14.9±1.5(12.6-18.0)) was used as a comparison sample.

All participants took part in the EEG experiment (Neurotravel 32-channels system). During the study they watched silent videos while stimuli were presented via earphones. Auditory stimuli were 40Hz-click trains presented binaurally for 500 ms with inter-trial intervals varied between 500 and 800 ms (N=150 trains). Data were segmented into 1000 ms epochs (-200-800 ms). To calculate ASSR, EEG signal was filtered at 35-45 Hz, while to obtain auditory event-related potential (ERP) at 1-30 Hz. Then, trials with amplitude within 3 STD of the mean were averaged. To better characterize ASSR we used the envelope of filtered signal (Hilbert transform). Baseline correction for the -200 0 ms were applied.

The study was approved by the institutional ethical committee and all participants and their guardians provided informed consent.

### Results:

SH01 was diagnosed with mild mental retardation and learning disabilities (F70.88). She has problems with reading and writing, and pronouncing long and complex words, as well as smaller vocabulary than TD peers. Her face is elongated and auricles are protruding, resembling the phenotype of previously described patients with 22q13.33 microduplication. SH01's SRS equals 63 T-scores, which referred to mild autistic symptoms, while neither psychiatric assessment nor the Autism Diagnostic Interview-Revised (ADI-R) suggest ASD. No seizures or MRI abnormalities were reported.

SH01's ASSR did not exceed the baseline values for the whole period of stimuli presentation with the mean value of -0.015 mkV. It was significantly smaller than in TD peers ( $p < 0.05$ ), whose values were above 0.053 mkV for all children with mean equals 0.232 (SD=0.107) mkV. At the same time the amplitudes of SH01's ERP components were unremarkable.

### Conclusions:

Absence of 40-Hz ASSR in patient with microduplication, affected SHANK3 gene, indicates deficient temporal resolution of the auditory system, that might underlie language problems, and represent neurophysiological biomarker of SHANK3 abnormalities.

#### 439.003 (Poster) Autism Symptom Severity and Self-Injurious Behavior Among Individuals with ASD-Associated Disruptive Mutations

*E. C. Kurtz-Nelson<sup>1</sup>, A. S. Wallace<sup>1</sup>, E. E. Eichler<sup>2,3</sup>, R. A. Bernier<sup>1</sup> and R. K. Earl<sup>1</sup>, (1)Psychiatry and Behavioral Sciences, University of Washington, Seattle, WA, (2)Department of Genome Sciences, University of Washington, Seattle, WA, (3)Howard Hughes Medical Institute, Seattle, WA*

#### Background:

Previous research examining associations between autism symptom severity and self-injurious behavior (SIB) is limited and inconclusive, with variable results across studies and samples (Gulsrud et al., 2018; Richman et al., 2013; Steinfeldt-Kristensen et al., 2020). Identification of SIB correlates in monogenetic syndromes may clarify mechanisms of SIB in ASD (Minshawi et al.,

2015). Individuals with disruptive mutations to ASD-associated genes exhibit variable autism symptom severity and may or may not meet full diagnostic criteria for ASD (Beighley et al., 2020; Guo et al., 2018); this heterogeneity allows for examination of associations between ASD severity and other phenotypic characteristics in the context of genetic risk.

#### Objectives:

To determine whether autism symptom severity is associated with SIB status and severity among individuals with ASD-associated disruptive mutations.

#### Methods:

Participants were 124 individuals (mean age = eight years, 48.4% female) with a likely pathogenic mutation to one of eight high-confidence ASD-associated genes. 66.9% of participants met DSM-5 criteria for ASD. Participants completed assessments including the Autism Diagnostic Interview—Revised (ADI-R; Lord et al., 1994), Autism Diagnostic Observation Schedule, Second Edition (ADOS-2, Lord et al., 2013); Repetitive Behavior Scale—Revised (RBS-R; Bodfish et al., 2000), Social Responsiveness Scale-2 (SRS-2; Constantino & Gruber, 2012), and a cognitive assessment. A dichotomous current SIB variable was created from the ADI-R per Dempsey and colleagues (2016), while the self-injury subscale of the RBS-R was used as a measure of SIB severity. ADOS-2 calibrated severity scores (CSS) for Social Affect (SA) and Restricted and Repetitive Behaviors (RRB; Hus et al., 2014; Hus & Lord, 2014) and SRS-2 subscales were used as measures of autism symptom severity. Logistic regression was used to determine whether autism symptom severity predicted SIB status after controlling for age and full scale IQ (FSIQ), while linear regression was used to determine whether autism symptom severity predicted SIB severity after controlling for age and FSIQ. A Bonferroni corrected significance level of  $\alpha = .01$  was used for SRS-2 subscale analyses.

#### Results:

ADOS-2 SA CSS, ADOS-2 RRB CSS, and ASD diagnosis were not associated with SIB prevalence or severity. SRS-2 social communication impairment was modestly associated with SIB status ( $\beta = 0.10$ ,  $p = .006$ , OR = 1.11) and SIB severity ( $\beta = 0.42$ ,  $p < .001$ ,  $\Delta R^2 = .17$ ) after controlling for age and FSIQ. RRB severity as measured by the SRS-2 was also modestly associated with SIB status ( $\beta = 0.07$ ,  $p = .005$ , OR = 1.08) and SIB severity ( $\beta = 0.31$ ,  $p = .004$ ,  $\Delta R^2 = .09$ ) after controlling for age and FSIQ.

#### Conclusions:

Caregiver-reported social communication challenges and RRBs were modestly associated with SIB status and severity among individuals with ASD-associated disruptive mutations, while clinician-observed symptoms and ASD diagnosis were not associated with SIB. Associations between autism symptom severity and SIB may be present but minor or related to measurement factors (caregiver report vs. clinician judgment; Richman et al., 2013), which could account for discrepant results across studies. Future research should examine factors that may better account for SIB in ASD-associated genetic disorders.

#### **439.004 (Poster)** Autonomic Nervous System Function Early in Development Predicts Later ASD and Anxiety Symptoms in Both Fragile X Syndrome and Typical Development

**A. L. Hogan<sup>1</sup>**, E. Hunt<sup>1</sup>, K. D. Smith<sup>1</sup>, C. J. Black<sup>1</sup>, K. Bangert<sup>2</sup>, J. Klusek<sup>3</sup> and J. Roberts<sup>1</sup>, (1)Department of Psychology, University of South Carolina, Columbia, SC, (2)University of South Carolina, Columbia, SC, (3)Communication Sciences and Disorders, University of South Carolina, Columbia, SC

Background: Autonomic nervous system (ANS) dysfunction is thought to underpin a variety of psychiatric problems, including ASD and anxiety. For example, studies utilizing cardiac indices of ANS function have documented that poorer parasympathetic nervous system regulation (e.g., lower respiratory sinus arrhythmia [RSA]) is associated with both anxiety and ASD, though the relationship between elevated general arousal (e.g., shorter interbeat interval [IBI]) and anxiety or ASD is less clear. It also remains poorly understood how the maturation of ANS function across early development influences the development of anxiety and ASD symptoms later in childhood. Fragile X syndrome (FXS) is a genetic disorder highly associated with ASD and anxiety symptoms. Previous studies have reported shorter IBI and lower RSA in FXS. However, almost nothing is understood about the developmental maturation of ANS function in infants with FXS or the cascading developmental repercussions of early ANS dysfunction on later anxiety and ASD symptoms.

Objectives: To (a) determine whether children with FXS exhibit atypical ANS maturation across infancy and early childhood; and (b) investigate whether ANS maturation early in life predicts ASD or anxiety symptoms in childhood.

Methods: Participants included 73 males with FXS and 79 age-matched typically developing (TD) males. Baseline heart activity (IBI, RSA) was recorded via electrocardiogram (ECG) at multiple assessments between 3 and 83 months of age, resulting in 372 observations (FXS  $n=175$ ; TD  $n=197$ ). ASD and anxiety symptoms were assessed at one timepoint at or after 24 months in a subgroup of participants (FXS  $n=28$ ; TD  $n=29$ ). ASD symptoms were quantified by the Autism Diagnostic Observation Schedule (ADOS-2) calibrated severity score. Anxiety symptoms were measured by the Spence Preschool Anxiety Scale (PAS) total t-score.

Results: Linear mixed models revealed a significant group\*age interaction for both IBI,  $F(1,116)=9.25, p=.003$ , and RSA,  $F(1,109)=12.01, p=.001$ , with the FXS males exhibiting smaller increases across age in both indices. Post-hoc analyses indicated groups differed significantly on IBI by 29 months,  $t(139)=-2.12, p=.036$ , and on RSA by 24 months,  $t(150)=-2.10, p=.037$ . Subject-specific slopes and intercepts were extracted for IBI and RSA and included in multivariate general linear models as predictors of later ASD and anxiety symptoms along with group and IQ. IBI intercept and slope significantly predicted later anxiety symptoms,  $F_s \geq 4.91, p_s \leq .005$ , but not ASD symptoms. RSA intercept predicted later ASD symptoms,  $F(1,48)=5.30, p=.026$ , but not anxiety symptoms. RSA slope did not predict later ASD or anxiety symptoms,  $F(2,47)=1.46, p=.242$ .

Conclusions: Findings indicate that developmental maturation in ANS function, as indexed by IBI and RSA, is slower in males with FXS than TD males across early development. Shorter IBI (i.e., faster heart rate), which indicates elevated physiological arousal, predicted higher anxiety symptoms in both groups, whereas lower RSA, which indicates poorer parasympathetic regulation, predicted higher ASD symptoms in both groups. These findings are in line with converging evidence of lower baseline RSA in children with ASD and anxiety. These results also suggest that different facets of ANS dysfunction early in life may confer risk for different psychiatric symptoms later in childhood.

**439.005 (Poster)** Characteristics of Individuals with Parent-Reported Diagnosis of Autism Spectrum Disorder within Pitt Hopkins Syndrome

**H. K. Root<sup>1</sup>, C. H. Morgan<sup>2</sup>, K. C. Guest<sup>3</sup> and S. E. O'Kelley<sup>3</sup>**, (1)University of Alabama at Birmingham, Birmingham, AL, (2)Psychology, The University of Alabama at Birmingham, Birmingham, AL, (3)The University of Alabama at Birmingham, Birmingham, AL

Background: Pitt Hopkins Syndrome (PTHS) is an extremely rare genetic disorder which has historically been closely associated with autism spectrum disorder (ASD). While individuals with PTHS have been observed to exhibit symptoms that closely mirror ASD (de Winter et al., 2016; van Balkom et al., 2012; de Pontual et al., 2009; Sweatt, 2013), there have been few studies which have specifically examined ASD-like symptomatology in this population. This issue is further complicated by the severe nature of cognitive impairments typically described in PTHS (Sweatt, 2013; Van Balkom, Vuijk, Franssens, Hoek & Heenekam, 2012). A recent study indicated that only 33% of parents reported that their child with PTHS had a diagnosis of ASD (Guest et al., in press), despite this close association.

Objectives: To examine differences between individuals with PTHS whom have a parent-reported ASD diagnosis versus those who do not.

Methods: Participants included primary caregivers of individuals with PTHS ( $M_{age}=8$  years,  $SD=4.91$ ) who participated in a comprehensive demographic interview ( $n=33$ ) and completed standardized measures ( $n=24$ ) including the Modified Checklist for Autism in Toddlers-Revised (MCHAT-R), Communication and Symbolic Behavior Scales-Infant Toddler Checklist (CSBS-ITC), Repetitive Behavior Questionnaire (RBQ), Short Sensory Profile-Second Edition (SSP-2), Parental Stress Index-Fourth Edition (PSI-4), and Vineland Adaptive Behavior Scales, Second Edition (Vineland-II). Two groups of individuals with PTHS were created, those whose caregiver reported an additional diagnosis of ASD ( $n=11$ ; ASD group) and those who did not ( $n=22$ , non-ASD group).

Results: Independent samples t-tests and Pearson chi-square tests were used to compare characteristics between ASD and non-ASD groups within this PTHS sample. No significant differences were found on demographic variables (e.g., age, age of diagnosis of PTHS), number of communication types, vocabulary size, loss of language or motor skills, tantrums, sensory preoccupations, unusual listening responses, aggression, food selectivity, Vineland composite scores, CSBS and MCHAT total raw scores, PSI scores, RBS domain scores, and RBQ domain scores ( $p's > .05$ ). The ASD group had significantly greater total diagnoses endorsed, higher scores on the DBC Disruptive/Antisocial domain, and higher scores on the DBC Social Relating Score ( $p's < .02$ ).

Conclusions: Individuals with PTHS whose parents reported an additional diagnosis of ASD in addition to PTHS did not differ on many domains commonly associated with ASD. Specifically, groups did not differ on restricted repetitive behaviors via RBS and RBQ, red flags for ASD via CSBS and MCHAT-R, adaptive skills via Vineland-II, parental stress via PSI-4, and other parent reported characteristics such as communication, sensory sensitivities/preoccupations, and regression of skills. The ASD group did

have higher numbers of total diagnoses, which may suggest that they have more severe presentations, resulting in a diagnosis of ASD. However, results suggest that more nuanced and gold-standard measures must be used to fully differentiate ASD in this complex population.

**439.006** (Poster) Characterizing the Family Experience of Children with *CHD8* Using an Innovative Online Platform  
*K. P. Ahlers, E. C. Kurtz-Nelson and R. K. Earl, Psychiatry and Behavioral Sciences, University of Washington, Seattle, WA*

---

Background:

Disruptive mutations to *CHD8* are strongly associated with autism spectrum disorder (ASD; Bernier et al., 2014). Due to the rarity of *CHD8* mutations, affected families are dispersed internationally. We used an online app, Groopit, as a secure data collection tool to engage families of children with *CHD8* mutations. This project utilizes a participatory approach, operating from the framework that incorporating stakeholders as collaborators helps to ensure that research yields meaningful benefits to the community being studied (Fletcher-Watson et al., 2019).

While there is no known research regarding *CHD8* caregiver experiences, extensive research has demonstrated that parents of children with developmental disabilities (DD) are at heightened risk for psychological stress (Ashford et al., 2019). Assessing the benefits associated with caring for children with DD can also inform the caregiver experience (Hastings, 2016).

Objectives:

To partner with caregivers of children with *CHD8* mutations to characterize parenting experiences using an innovative online platform.

Methods:

Participants were nine parents of children (ages 2-11 years;  $M = 6.9$ ;  $SD = 3.5$ ) with disruptive *CHD8* mutations recruited from a Facebook family group. Parents identified top research priorities via Groopit, including caregiver stress and resilience. Participants provided background information and completed measures of parental stress related to rare genetic disorders (Genetic Syndromes Stressors Scale [GSSS]; Griffith et al., 2011) and caregiver resilience (Positive Gain Scale [PGS]; Pit-ten Cate, 2003).

Results:

Consistent with a *CHD8* phenotype (Beighley et al., 2020), the majority of children (85.7%) were previously diagnosed with ASD and/or global developmental delay/intellectual disability. Most parents (80%) reported that their primary motivation for participating in research via Groopit was for “us [parents] and the world to learn more about the *CHD8* mutation.”

Participants identified multiple sources of stress associated with their child’s rare genetic disorder. Common sources of high stress included: not having access to professionals with knowledge of their child’s condition (66.7%), an educational placement that doesn’t meet their child’s needs (66.7%), and worrying about their child’s future given a lack of adult specialist services (77.8%). Parents, on average, reported a high level of positive gain associated with having a child with a rare genetic disorder. All parents reported that raising their child helped put life into perspective and helped them learn new skills.

Conclusions:

Consistent with past research on parents of children with DD, parents of children with *CHD8* mutations identified parenting stress associated with their child’s genetic disorder. They identified their child’s current care and future receipt of services (e.g., services available in adulthood) as primary sources of stress; this may reflect limited professional understanding of rare ASD-associated genetic disorders and a lack of research on adult outcomes in these disorders. A better understanding of parenting experiences can inform future research priorities (e.g., adult outcomes) and practical resources to help with stress management and respond to parents’ specific concerns (e.g., *CHD8*-specific information packets for providers). Despite these sources of stress, all parents identified positive parenting experiences, highlighting the importance of considering positive gain in future research on caregiver experience in rare ASD-associated mutations.

**439.007** (Poster) Child and Maternal Predictors of Dysfunctional Parent-Child Interactions in Families of Boys with Fragile X Syndrome

**Background:** Fragile X syndrome (FXS) is a genetic disorder characterized by executive deficits including poor inhibitory control (IC), the ability to suppress a dominant response. Additionally, approximately 61% of children with FXS meet DSM-5 criteria for autism spectrum disorder (ASD). Mothers of children with FXS, who carry the *FMR1* premutation, are at heightened risk for depression and parenting stress. Child ASD symptoms and executive deficits have been associated with maternal distress and negative parent-child interactions in other neurodevelopmental disorders, but these relationships have not been studied in FXS.

**Objectives:** This study examined whether boys with FXS exhibit elevated IC deficits, and mothers of boys with FXS report higher depression symptoms or more severe parent-child dysfunctional interactions (PCDI), relative to typically developing boys and their mothers. Within FXS mother-child dyads, we explored whether child IC and maternal depression interact to predict PCDI, controlling for child ASD symptoms.

**Methods:** Participants included 71 males with FXS ( $M(SD)$  age = 44.03(15.09) months) and 52 chronological age-matched male controls ( $M(SD)$  age = 42.79(14.29) months) and their mothers. IC was measured via the Early Childhood Behavior Questionnaire (18-36 months) or the Children's Behavior Questionnaire (>36 months). Maternal depression and PCDI were assessed via the Beck Depression Inventory-2 and Parenting Stress Index-4, respectively. ASD symptoms were assessed via the Childhood Autism Rating Scale-2. Between-group differences were analyzed using independent-samples *t*-tests. Within the FXS group, a hierarchical multiple linear regression predicting PCDI from child and maternal characteristics was run.

**Results:** Boys with FXS exhibited greater IC deficits, ( $t(121)=6.09, p<.001$ ) and ASD symptoms ( $t(88.72)=12.62, p<.001$ ). Mothers of boys with FXS reported higher depression symptoms ( $t(103.99)=4.44, p<.001$ ), and greater PCDI ( $t(120.89)=8.28, p<.001$ ). Results of a hierarchical multiple linear regression predicting PCDI revealed a significant main effect of maternal depression ( $t(67)=2.68, p=.009, b=0.83$ ), and a marginally significant main effect of IC ( $t(67)=-1.72, p=.090, b=-1.82$ ). A child IC\*maternal depression interaction was also indicated ( $t(67)=-1.95, p=.055, b=-0.18$ ), with FXS families with lower child IC and higher maternal depression demonstrating more severe PCDI. Controlling for ASD symptoms did not significantly improve the model fit, and ASD symptoms did not significantly predict PCDI ( $t(66)=1.44, p=.156$ ).

**Conclusions:** Consistent with previous research, our results indicate that boys with FXS demonstrate impaired IC, mothers of boys with FXS exhibit higher depression symptoms, and FXS mother-child dyads evidence greater PCDI, compared to control families. Further, child IC and maternal depression interact to predict PCDI in FXS families, suggesting maternal and child characteristics influence each other and impact interaction quality. Whereas high child IC and low maternal depression may be protective, mothers of boys with FXS with IC deficits and with high depression symptoms may be particularly vulnerable to dysfunctional interactions, which may exacerbate psychological symptoms. Of note, ASD symptoms did not account for additional variance in PCDI beyond child IC and maternal depression. Together these findings suggest that interventions that target child IC and maternal depression may improve interactions in families of children with FXS, irrespective of child ASD status.

**439.008 (Poster)** Developing Angelman Syndrome-Specific Clinician-Reported and Caregiver-Reported Measures to Support Holistic, Patient-Centered Drug Development

**S. Connor<sup>1</sup>, M. Chladek<sup>2</sup>, T. Willgoss<sup>1</sup>, L. Newton<sup>3</sup>, T. Symonds<sup>4</sup>, J. Tjeertes<sup>4</sup>, B. Vincenzi<sup>5</sup> and F. McDougall<sup>5</sup>, (1)F. Hoffmann-La Roche Ltd., Welwyn Garden City, United Kingdom, (2)Clinical Outcomes Solutions, Chicago, IL, (3)Clinical Outcomes Solutions, Folkestone, United Kingdom, (4)F. Hoffmann-La Roche Ltd, Basel, Switzerland, (5)Genentech, South San Francisco, CA**

---

Background:

Valid and reliable measures reporting key symptoms and functional impairments of Angelman syndrome (AS) are required to support the development of patient-centered therapies. Yet, no disease-specific measures have been published to date which meet these criteria.

Objectives:

The main objective was to develop disease-specific measures for use in clinical trials which incorporate the most important symptoms and functional impairments for the treatment of AS. Specifically, to develop clinician-reported measures capturing AS symptom severity and change, and caregiver-reported measures capturing the impact of AS and change.

## Methods:

Best practice guidance for measure development was followed throughout with input from expert clinicians, patient advocates, and caregivers at multiple points during content generation and refinement. Initial measurement concepts were identified from a patient-centered conceptual model of the symptoms and impacts of AS, derived from interviews with caregivers and clinicians. Feedback from clinical and measurement experts was then sought to iteratively refine items and ensure wording was age-appropriate and captured AS-specific symptoms, as well as associated impacts and functional abilities. Importantly, items were phrased differently between the clinician-reported and caregiver-reported measures to maximize relevance and suitability.

Two rounds of cognitive debriefing (CD) interviews were performed; all participants were based in the United States. Five experienced, practicing AS clinicians debriefed the clinician-reported measures; 5 patient advocates along with 15 caregivers debriefed the caregiver-reported measures. To ensure relevance to the spectrum of AS severities and functional abilities, caregivers of children with AS were recruited for all genotypes and a broad age range (1-12 years). These CD interviews were conducted to explore concept relevance and comprehension.

Results: The Symptoms of Angelman Syndrome Clinician Global Impression (SAS-CGI) measure and the Caregiver-reported Angelman Syndrome Scale (CASS) were developed to capture global assessments for: seizures; sleep problems; maladaptive behaviors; expressive communication difficulties; fine motor skills impairment; gross motor skills impairment; cognitive impairment; and impairment in activities of daily living. In addition, a global item was included for assessing overall AS symptoms. In addition to assigning a rating for severity, impact, or change, a free text field is included in the SAS-CGI for clinicians to describe the clinical features. The CD interviews confirmed the measures covered the key concepts of AS for clinicians and caregivers. Second round interviews with clinicians and patient advocates demonstrated that the measures' instructions, items, response options, and recall period were all largely clear and appropriate. Adjustments to the wording of instructions and items were made based on interview feedback.

## Conclusions:

The SAS-CGI and CASS were designed to capture the most important concepts of AS. Robust development in collaboration with AS caregivers, advocates, and clinicians has resulted in content-valid measures. These measures have been incorporated into interventional and non-interventional studies for AS, which will allow the evaluation of their psychometric properties and determine whether further measure refinements are needed.

### **439.009 (Poster)** Developmental, Social and Emotional Characteristics of Girls and Young Women with *DDX3X*-Linked Intellectual Disability

**E. Ng-Cordell<sup>1</sup>, S. O'Brien<sup>2</sup>, D. Astle<sup>2</sup>, G. Scerif<sup>3</sup> and K. Baker<sup>2</sup>,** (1)Psychology, University of British Columbia Vancouver, Vancouver, BC, Canada, (2)MRC Cognition & Brain Sciences Unit, University of Cambridge, Cambridge, United Kingdom, (3)Experimental Psychology, University of Oxford, Oxford, United Kingdom

---

Background: Pathogenic variants in the *DDX3X* gene are a relatively common cause of intellectual disability (ID) in females, accounting for an estimated 1-3% of cases. Emerging characterization of *DDX3X*-linked ID based on collated clinical information points towards considerable variability in the range and scope of neurodevelopmental features associated with *DDX3X* variants. Previous studies have suggested potentially elevated rates of autism spectrum characteristics in individuals with *DDX3X*-linked ID. However, few studies to date have carried out post-diagnostic, standardized assessments to delineate the range and specificity of the developmental, social and emotional phenotype associated with *DDX3X*-linked ID.

Objectives: This study's objectives were two-fold. First, we set out to describe systematically the developmental, social and emotional features of a group of females with *DDX3X*-linked ID (n = 20). Second, we aimed to isolate potentially discriminating phenotypes, by comparing the characteristics of females with *DDX3X*-linked ID to those of females with pathogenic variants in other ID-associated genes (ID-comparison group; n = 22).

Methods: We collected systematic phenotyping data for individuals with ID, ascertained from clinical genetics services across the UK. Adaptive ability, autism spectrum characteristics and emotional-behavioural features were assessed via standardised questionnaires and interviews administered to parents, and researcher observations. We first described the characteristics of the *DDX3X* group, then drew comparisons between the *DDX3X* and ID-comparison groups using non-parametric statistical analyses.

Results: The *DDX3X* group demonstrated a range of abilities and difficulties across all of the domains we assessed. The majority of females with *DDX3X*-linked ID experienced significant autism-relevant social challenges. On average, adaptive abilities, autism-spectrum characteristics and overall emotional-behavioural difficulties were comparable across the *DDX3X* and ID-

comparison groups. However, the DDX3X group showed higher levels of anxiety ( $U = 138.50, p = .043, \eta^2 = .097$ ), and engaged more frequently in self-injurious behaviour ( $\chi^2 = 4.38, p = .036, \eta^2 = .10$ ), compared to the ID-comparison group. Parents of individuals with DDX3X-linked ID often reported that self-injurious behaviour is a response to anxiety or distress.

**Conclusions:** In this study, we highlight the heterogeneity of developmental, social and emotional characteristics in DDX3X-linked ID, as well as features that might differentiate this disorder from other causes of ID. Overall autism likelihood does not seem to differ from other causes of ID, but specific social and emotional characteristics may be associated with DDX3X-linked ID. In particular, females in this group may be more vulnerable to suffering from anxiety and engaging in self-injurious behaviour compared to those with other causes of ID. Future studies should investigate the development, onset and presentation of anxiety and self-injurious behaviours, and the mechanisms underlying phenotypic variability in this disorder.

**439.010 (Poster)** EEG Resting State Spectral Differences between SCN2A, Idiopathic ASD, and Typically Developing Controls  
**L. T. Hall<sup>1</sup>, C. L. Sargent<sup>1</sup>, W. R. Ganz<sup>1</sup>, R. K. Earl<sup>1</sup>, E. E. Eichler<sup>2</sup>, R. A. Bernier<sup>1</sup>, S. J. Webb<sup>1</sup> and C. M. Hudac<sup>3</sup>,** (1)Psychiatry and Behavioral Sciences, University of Washington, Seattle, WA, (2)Department of Genome Sciences, University of Washington, Seattle, WA, (3)Psychiatry and Behavioral Sciences, University of Washington, Seattle, AL

**Background:** The *SCN2A* gene modulates voltage-gated ion channels<sup>1</sup> with recent investigations finding that mutations may cause neurodevelopmental disorders (NDDs)<sup>2</sup>. Diverging phenotypes indicate that disruptions that generate a loss of *SCN2A* function exhibit ASD/ID, whereas disruptions that generate a gain of *SCN2A* function exhibit infantile epileptic encephalopathy (IEE)<sup>3,4</sup>. Given the diverse phenotypes found in individuals with ASD and high-risk mutations, resting state EEG may serve as a unique tool to identify targeted treatments for NDDs. Previous work in NDDs utilizes resting state electroencephalography (EEG) as a potential biomarker for certain clinical populations; for example individuals diagnosed with idiopathic seizures exhibit higher power in delta, theta, and alpha bands<sup>5</sup>. Moreover, exploration of such neural mechanisms of *SCN2A* have yet to be thoroughly investigated, thus warranting exploration into EEG resting state power.

**Objectives:** We explored differences in EEG band power for individuals with a *SCN2A* genetic mutation with IEE (+IEE) versus without IEE (-IEE) as a behavioral marker of loss versus gain of *SCN2A* function.

**Methods:** Data from 90 children (Table 1) were included in analyses. First, *SCN2A* gene groups were categorized by presence or absence of IEE characterized by seizures present before 1 year of age<sup>4</sup>. Second, we included comparison groups of children with ASD with no known genetic mutation (idiopathic) with either low nonverbal cognition (NVIQ<70; ASDLow, or average nonverbal cognition (NVIQ 85-115; ASDAve), as well as typically developing children (TD).

During a resting state EEG, children watched screensaver-like videos that were presented for two and a half minutes. Medial electrodes in the frontal, central, posterior, occipital regions were included. Group differences in EEG frequency bands were compared using repeated-measures linear mixed effects models with Bonferroni-correction.

**Results:**

Results revealed significant group by frequency interactions for absolute power across all frequency bands (Figure 1). For delta ( $F(4, 639)=29.179, p<.0001$ ) and theta ( $F(4, 639)=52.57, p<.0001$ ) bands, -IEE individuals exhibited higher power than all other groups, while +IEE exhibited higher power than ASDAve, ASDLow, and TD. For alpha, +IEE individuals exhibited higher power than ASDAve, ASDLow, and TD groups ( $F(4, 639)=3.973, p<0.01$ ). For beta, -IEE individuals exhibited higher power than the ASDAve group, while +IEE individuals exhibited higher power than ASDAve and TD groups ( $F(4, 639)=5.53, p<0.001$ ).

**Conclusions:**

This is the first resting state EEG study of this size examining spectral profiles of individuals with a *SCN2A* gene mutation. Results demonstrated differences in EEG spectral profiles for *SCN2A* groups when compared to idiopathic ASD and TD individuals. Within *SCN2A*, participants without IEE have higher power for delta and theta frequencies than those with IEE. Elevated power in delta, theta, and alpha bands for individuals with *SCN2A* mirrors prior work characterizing spectral profiles in adults with idiopathic generalized epilepsy<sup>6</sup>. Future studies should focus on aggregating more individuals with *SCN2A* with diverse phenotypes<sup>4</sup>.

**439.011 (Poster)** Features of Autism and Social Disability in 3q29 Deletion Syndrome

**J. Pincus<sup>1</sup>, E. Sefik<sup>2</sup>, M. M. Murphy<sup>3</sup>, C. Klaiman<sup>4</sup>, C. A. Saulnier<sup>4</sup>, S. P. White<sup>5</sup>, S. Shultz<sup>1</sup> and J. G. Mulle<sup>3</sup>,** (1)Department of Pediatrics, Emory University School of Medicine, Marcus Autism Center, Atlanta, GA, (2)Graduate Division of Biological and Biomedical Sciences, Emory University, Atlanta, GA, (3)Department of Human Genetics, Emory University School of Medicine, Atlanta, GA, (4)Marcus Autism Center, Children's Healthcare of Atlanta and Emory University School of Medicine, Atlanta, GA, (5)Department of Pediatrics, Emory University, Atlanta, GA

---

**Background:** 3q29 deletion syndrome (3q29Del) is a rare genetic disorder caused by a 1.6 MB typically de novo deletion. 3q29Del is associated with a ~20-fold increased risk for autism spectrum disorder (ASD), in both males and females (Sanchez Russo et al., 2020). Prior research suggests that 3q29Del individuals without ASD also exhibit marked features of social disability (Pollak et al., 2019). This prior research further reports that the profile of ASD in 3q29Del is distinct from non-syndromic ASD (nsASD). These prior data rely on self-report measures, which can introduce limitations. Here, we seek to understand phenotypes of ASD and social disability in 3q29Del using data from direct evaluation by trained clinicians.

**Objectives:** To investigate features of ASD-related social disability in 3q29Del using gold-standard clinical assessment tools.

**Methods:** 31 individuals with 3q29Del (mean age 14.5, range 4-39) were assessed for ASD symptoms with the Autism Diagnostic Observation Schedule-2 (ADOS-2) and the Autism Diagnostic Interview, Revised (ADI-R). Clinician best-estimate diagnosis of ASD was made after comprehensive assessment. 51 individuals with nsASD (mean age 9.04, range 4-16) were also administered the ADOS-2. Since ADOS-2 scores from these samples span modules 2-4, social affect (SA) and restricted and repetitive behaviors (RRB) scores were converted. On modules 2 and 3, SA and RRB raw scores were converted to calibrated severity scores (CSS) (Hus et al., 2014). On module 4, SA and RRB raw scores were calculated and then converted to CSS (Hus & Lord, 2014). We compared SA-CSS and RRB-CSS between 3q29Del with ASD (3q29Del-ASD), 3q29Del without ASD (3q29Del-noASD), and nsASD. We also performed item-level analyses between these groups for 19 items that are consistent across modules 2-4. We tested for between-group differences in SA and RRB symptom severity and between-group differences at the ADOS-2 item level.

**Results:** 38.5% of 3q29Del study subjects qualify for an ASD diagnosis. 3q29Del-ASD and nsASD show similar RRB severity ( $p=.73$ ), but 3q29Del-ASD show significantly more severe SA symptoms than nsASD ( $p<.01$ ). 3q29Del-noASD exhibit low-to-moderate severity on SA symptoms (mean SA-CSS 3.84) and RRB symptoms (mean RRB-CSS 4.79). Item level analyses reveal that 3q29Del-noASD and 3q29Del-ASD score similarly on the Conversation item, as well as all items related to stereotyped behaviors and restricted interests (all  $p>.05$ ). Item level analyses further reveal that 3q29Del-noASD and nsASD score similarly on various items pertaining to language and communication (items 1, 5 and 6), the Amount of Social Overtures item, and all items related to stereotyped behaviors and restricted interests (all  $p>.05$ ) (Figure 1).

**Conclusions:** We find that 3q29Del-ASD and 3q29Del-noASD both exhibit autism spectrum-related symptoms, replicating previous findings. 3q29Del-noASD converges with 3q29Del-ASD and nsASD on symptoms related to repetitive behaviors in particular. These data suggest that 3q29Del-noASD have ASD-related social disability and may benefit from therapy to reduce vulnerability and strengthen social skills. Future directions will compare symptom profiles between groups to determine the extent to which ASD symptoms in 3q29Del overlap or diverge with those observed in nsASD. These findings have important implications for the clinical treatment of social disability in 3q29Del.

#### **439.012 (Poster) Gene Functional Networks and Autism Spectrum Characteristics in Young People with Intellectual Disability: A Dimensional Phenotyping Study**

**K. Baker<sup>1</sup>, E. Ng-Cordell<sup>1,2</sup>, D. Brkic<sup>1</sup>, S. O'Brien<sup>1</sup>, D. Astle<sup>1</sup> and G. Scerif<sup>3</sup>,** (1)MRC Cognition & Brain Sciences Unit, University of Cambridge, Cambridge, United Kingdom, (2)Psychology, University of British Columbia Vancouver, Vancouver, BC, Canada, (3)Experimental Psychology, University of Oxford, Oxford, United Kingdom

---

**Background:** The relationships between specific genetic aetiology and phenotype in neurodevelopmental disorders are complex and hotly contested. The potential for dual diagnosis of intellectual disability (ID) and autism spectrum disorder (ASD) recognises that autism characteristics vary within the ID population and are not an inevitable consequence of low cognitive ability and adaptive impairments. Understanding autism within the ID population is important, because autism predicts the complexity of educational, occupational and social support needs, and influences the well-being of family carers. One factor which can influence behavioural phenotypes, including autism, is the aetiology of each individual's ID. Genes associated with intellectual disability (ID) can be grouped into networks according to known molecular and cellular functions of genetic variants.

**Objectives:** In this study, we explored whether individuals with ID show differences in autism spectrum characteristics (ASC), depending on the functional network membership of their rare, pathogenic *de novo* genetic variants. We set out to establish (1) whether the distribution of autism characteristics within a sample of young people with ID was categorical, unidimensional or

multidimensional, (2) whether gene functional network group membership influenced likelihood of ASC, and (3) whether the predictors of ASC were the same or different between functional network groups, reflecting shared or distinct underlying mechanisms.

Methods: Children and young people with ID of known genetic origin were allocated to two broad functional network groups: synaptic physiology (n=29) or chromatin regulation (n=23). We applied principle components analysis to the Social Responsiveness Scale to map the structure of ASC in this population, then used Akaike Information Criterion (AIC) to test the best fitting models for predicting ASC components, including demographic factors (age, gender), non-ASC behavioural factors (global adaptive function, anxiety, hyperactivity, inattention) and gene functional networks.

Results: When mapping the structure of ASC, we identified three components – Inflexibility, Social Understanding and Social Motivation. We found that, when other factors are accounted for, the chromatin regulation group showed higher levels of Inflexibility. We also observed contrasting predictors of ASC within each network group. Within the chromatin regulation group, Social Understanding was associated with inattention, and Social Motivation was predicted by hyperactivity. Within the synaptic group, Social Understanding was associated with hyperactivity, and Social Motivation was linked to anxiety.

Conclusions: In this exploratory study, the genetic cause of an individual's ID (classified by functional network) did not predict overall likelihood of autistic features, but did influence dimensional autism characteristics and co-occurrences. These results indicate that genetic diagnosis is clinically relevant to understanding the social abilities and difficulties of individuals with ID, but only if genetic diagnosis is considered in the context of a multi-faceted assessment, encompassing dimensions within and beyond the autism spectrum. It is not yet known whether valuable outcomes such as social inclusion and mental health could be improved if these underlying mechanisms were to be considered targets for intervention. Future research should seek to replicate and extend these findings, and investigate the molecular, neural, cognitive and interpersonal mechanisms contributing to the development of social function for individuals with ID.

**439.013 (Poster)** How Do Parenting Stress and Child Autism Symptoms Relate to Caregiver Self-Efficacy during the COVID-19 Pandemic?

**R. Felicichia<sup>1</sup>**, K. C. Okoniewski<sup>2</sup>, A. Wheeler<sup>2</sup> and B. Kelleher<sup>1</sup>, (1)Psychological Sciences, Purdue University, West Lafayette, IN, (2)Center for Newborn Screening, Ethics, and Disability Studies, RTI International, Research Triangle Park, NC

---

Background: Caregivers of children with neurodevelopmental disorders experience increased stress and challenges related to parenting. Specifically, caregivers who have a child diagnosed with autism report high levels of parenting stress compared to other neurodevelopmental disorders (Craig et al., 2016). These stressors may be further amplified in families of children with autism symptoms and a co-occurring neurogenetic syndrome (NGS) due to increased cognitive impairment, co-occurring medical features, and sensorimotor impairments common to some of these conditions. Caregiver self-efficacy is important in the mental health and wellbeing of parents. However, it is unclear which caregivers might be struggling with self-efficacy during COVID-19, limiting understanding of how to intervene. The present study aims to address this gap by examining predictors of caregiver self-efficacy in a cohort of parents surveyed both prior to and during the COVID-19 pandemic.

Objectives: Our goal is to explore whether caregivers' current levels of self-efficacy during COVID-19 were related to pre-pandemic levels of parenting stress and child autism features.

Methods: Participants were caregivers of children with neurogenetic syndromes (n=35) enrolled in a longitudinal early phenotype study (PEPS) who provided data both before and after the COVID-19 pandemic began. At the time of their post-pandemic assessment, children were ages 1 to 6 years (mean=4) diagnosed with Angelman (n=9), Down (n=2), Fragile X (n=3), Prader Willi (n=8), and Williams (n=13) syndromes. As part of PEPS, families contributed measures of parenting stress (Parenting Stress Index, PSI; Abidin, 1995) and child autism behaviors (Child Behavior Checklist, CBCL; Achenbach, 2001). After the pandemic, we measured parenting self-efficacy using the Parenting Sense of Competence Scale (PSOC; Ohan et al, 2000). We hypothesized that parents with lower self-efficacy post-pandemic would be those with greater parenting stress and child autism symptoms pre-pandemic.

Results: We used multiple regression analyses to predict caregivers' current sense of competency from pre-pandemic parenting stress and challenging behaviors; we ran correlations to ensure that age was not a covariate. The multiple regression model with both predictors was significant with  $R^2=.179$ ,  $F(2, 32)=3.498$ ,  $p<.05$ . Overall parenting stress was a significant predictor of parenting self-efficacy ( $\beta = -.46$ ,  $p = .017$ ), but child behaviors related to autism were not ( $\beta = .09$ ,  $p = .626$ ). We also ran exploratory effects with overall challenging behaviors (CBCL Total) to probe for impact of general challenging behaviors, which were also not predictive of self-efficacy.

**Conclusions:** These results suggest caregivers who entered the COVID-19 pandemic with higher parenting stress may be at greater risk for poorer-self efficacy. These findings highlight the importance of implementing parenting support services and interventions in NGS caregivers, especially in periods of elevated stress such as COVID-19. Our results also suggest that parenting interventions should be targeted to caregivers' level of need rather than child symptomatology alone, as self-efficacy was not related to child symptomatology. **Background:** Caregivers of children with neurodevelopmental disorders experience increased stress and challenges related to parenting. Specifically, caregivers who have a child diagnosed with autism report high levels of parenting stress compared to other neurodevelopmental disorders (Craig et al., 2016). These stressors may be further amplified in families of children with autism symptoms and a co-occurring neurogenetic syndrome (NGS) due to increased cognitive impairment, co-occurring medical features, and sensorimotor impairments common to some of these conditions. Caregiver self-efficacy is important in the mental health and wellbeing of parents. However, it is unclear which caregivers might be struggling with self-efficacy during COVID-19, limiting understanding of how to intervene. The present study aims to address this gap by examining predictors of caregiver self-efficacy in a cohort of parents surveyed both prior to and during the COVID-19 pandemic.

**Objectives:** Our goal is to explore whether caregivers' current levels of self-efficacy during COVID-19 were related to pre-pandemic levels of parenting stress and child autism features.

**Methods:** Participants were caregivers of children with neurogenetic syndromes (n=35) enrolled in a longitudinal early phenotype survey study (PEPS) who provided data both before and after the COVID-19 pandemic began. At the time of their post-pandemic assessment, children were ages 1 to 6 years (mean=4) diagnosed with Angelman (n=9), Down (n=2), Fragile X (n=3), Prader Willi (n=8), and Williams (n=13) syndromes. As part of PEPS, families contributed measures of parenting stress (Parenting Stress Index, PSI; Abidin, 1995) and child autism behaviors (Child Behavior Checklist, CBCL; Achenbach, 2001). After the pandemic, we measured parenting self-efficacy using the Parenting Sense of Competence Scale (PSOC; Ohan et al, 2000). We hypothesized that parents with lower self-efficacy post-pandemic would be those with greater parenting stress and child autism symptoms pre-pandemic.

**Results:** We used multiple regression analyses to predict caregivers' current sense of competency from pre-pandemic parenting stress and challenging behaviors; we ran correlations to ensure that age was not a covariate. **Conclusions:** These results suggest caregivers who entered the COVID-19 pandemic with higher parenting stress may be at greater risk for poorer-self efficacy. These findings highlight the importance of implementing parenting support services and interventions in NGS caregivers, especially in periods of elevated stress such as COVID-19. Our results also suggest that parenting interventions should be targeted to caregivers' level of need rather than child's symptomatology alone, as self-efficacy was not related to child symptomatology.

#### **439.014 (Poster) Joint Attention in Children with Adnp Syndrome**

**H. Walker<sup>1</sup>, S. B. Guillory<sup>2</sup>, B. Lerman<sup>3</sup>, S. Barkley<sup>3</sup>, K. Keller<sup>4</sup>, A. Rouhandeh<sup>5</sup>, T. Levy<sup>2</sup>, J. D. Buxbaum<sup>6</sup>, A. Kolevzon<sup>2</sup>, P. M. Siper<sup>2</sup> and J. H. Foss-Feig<sup>7</sup>,** (1)Seaver Autism Center, Department of Psychiatry, Icahn School of Medicine at Mount Sinai Hospital, New York, NY, (2)Seaver Autism Center for Research and Treatment, Department of Psychiatry, Icahn School of Medicine at Mount Sinai Hospital, New York, NY, (3)Icahn School of Medicine at Mount Sinai, New York, NY, (4)Department of Psychiatry, Icahn School of Medicine, Seaver Autism Center, New York, NY, (5)Clinical Psychology, Yeshiva University, New York, NY, (6)Department of Psychiatry, Icahn School of Medicine at Mount Sinai, New York, NY, (7)Psychiatry, Icahn School of Medicine at Mount Sinai, New York, NY

**Background:** ADNP syndrome is a rare neurodevelopmental disorder that is highly associated with autism spectrum disorder (ASD) and intellectual disability. While autism traits including deficits in social interaction can be observed clinically, objective tools such as eye-tracking can provide more refined insight into deficits in processing and response to social stimuli. Previous eye-tracking studies have been used to quantify clinically observed deficits in joint attention, or orienting one's attention to an object in response to another person's eye-gazing, in children with ASD. However, such studies have yet to explore whether joint attention to visual stimuli is impacted in children with ADNP syndrome.

**Objectives:** To examine the association between experimental metrics of joint attention with clinician-rated measures of social symptoms of ASD broadly and joint attention skills more specifically.

**Methods:** Eye-tracking data was collected during a visual joint attention task from four children with ADNP syndrome (2 female; ages 7-10; additional data from n=5 participants expected by April, 2021). The task consisted of 16 pseudo-randomized trials in which a woman seated at the center of the video frame directs her attention at one of two objects on screen (lower right, lower left). Experimental variables of interest include: a) proportion of trials where the first saccade is to the target b) average saccade latency for the target object, and c) average proportion of time spent looking at the target (versus distractor) object. We calculated the correlation between these experimental variables and the following items on the ADOS-2 Module 1: ADOS Social Affect (SA) Domain and Response to Joint Attention (RJA).

**Results:** Despite the small sample size, a number of trends were observed between the experimental variables and the clinical data. Moderate relationships were observed between the proportion of correct looks to the target and SA ( $r = -.698$ ) and RJA ( $r = -.595$ ). There was a significant correlation observed between saccade latency and SA ( $r = .961, p = .039$ ) (Fig. 1), while RJA was trending ( $r = .874$ ). Lastly, there is a moderate association between target dwell time and SA ( $r = -.852$ ) (Fig. 2) and RJA ( $r = -.784$ ).

**Conclusions:** Our early findings identify promising trends for associations between eye-tracking metrics of joint attention and clinical observations of social functioning and response to joint attention. These associations suggest this paradigm may offer a valid, objective assessment of joint attention in children with ADNP syndrome. Overall, children with greater impairments in social affect and joint attention followed the on-screen model's gaze to target less often and more slowly, as well as spent less overall time looking at the gazed-at target versus the ignored distractor. Children that had higher social affect responses to joint attention scores tended to saccade to the target item before the distractor item less frequently. This preliminary investigation provides early evidence of joint attention deficits in ADNP syndrome that mirror those seen in ASD and associate with clinical symptoms. We are continuing to collect data to verify these findings, as well as incorporate data from typically developing and idiopathic ASD controls.

#### **439.015 (Poster) Reduced Sensitivity to Eye Contact in Williams Syndrome**

**J. L. Kleberg<sup>1,2</sup>, D. M. Riby<sup>3</sup>, A. Nordgren<sup>4</sup> and C. Willfors<sup>5</sup>,** (1)Department of Clinical Neuroscience, Karolinska institutet, Stockholm, Sweden, (2)Department of Molecular Medicine and Surgery, Karolinska institutet, Stockholm, Sweden, (3)Department of Psychology, Durham University, Durham, United Kingdom, (4)Karolinska institutet, Stockholm, Sweden, (5)Dept of Molecular Medicine and Surgery, Karolinska institutet, Stockholm, SWEDEN

---

**Background:** Williams syndrome (WS) is a rare genetic disorder associated with high social motivation and interest in faces as well as an intellectual disability and challenges in complex social cognition. Research on Williams syndrome can contribute to our understanding of the developmental pathways leading from genes to social attention and motivation. Attention to others' eyes is crucial for adaptive social understanding. Consequently, eyes trigger quick and automatic gaze shifts in typically developing individuals. It is not known whether this process is atypical in WS.

**Objectives:** To examine visual attention to others' eyes in Williams syndrome.

**Methods:** Individuals with WS (n = 35; mean age 23.5 years) were compared to controls (n = 167) in stratified age groups (7 month: n = 37, 8-12 years: n = 44, 13-17 years: n = 36, adults: n = 50). Participants were cued to look at either the eyes or the mouth of human faces. The latency and likelihood of a first gaze shift from or to the eyes was measured with eye tracking. The study was pre-registered. Data were analyzed using both standard frequentist and Bayesian statistics.

**Results:** Individuals with WS were both less likely, and slower to orient to the eyes than typically-developing controls in all age groups from eight years of age, but did not differ from 7-month-old infants (see fig.1). These effects were supported by both frequentist and Bayesian statistics, with medium to large effect sizes, and Bayes factors indicating very strong evidence. In contrast to typically developing participants, individuals with Williams syndrome did not show a bias to orient to the eyes rather than to the mouth. Individuals with Williams syndrome had reduced peak saccadic velocity compared to controls, suggesting that hypo-arousal may be an underlying cause of the observed pattern of atypical social attention. No group differences were found in the speed or likelihood of orienting away from the eyes, once they were fixated.

**Conclusions:** Despite the hyper-social behavioral phenotype, WS is associated with reduced attention to others' eyes. This could contribute to the difficulties with complex social cognition observed in this group.

**439.016 (Poster)** Symptoms of Autism Spectrum Disorder and Behavioral Phenotype in Children with CLN2 Disease  
**J. F. Scherr<sup>1</sup>, C. Albright<sup>2</sup>, P. Vandana<sup>3</sup>, E. Butter<sup>3</sup> and E. de los Reyes<sup>3</sup>, (1)Behavioral Health, Nationwide Children's Hospital, Columbus, OH, (2)Nationwide Children's Hospital, Westerville, OH, (3)Nationwide Children's Hospital, Columbus, OH**

---

**Background:** CLN2 disease is a rare, fatal, autosomal recessive, neurodegenerative lysosomal storage disease caused by a deficiency in the enzyme TPP1. Symptoms of CLN2 disease emerge early, usually by 3 years of age, and progress rapidly including seizure onset and the loss of motor, language, and vision functioning. Children with CLN2 disease present with behavioral disturbances and language delay, which are also characteristic symptoms of Autism Spectrum Disorder. However, no research has specifically examined ASD symptomology in children with CLN2 disease.

**Objectives:** The present study aims to examine symptoms of ASD and behavior in children with CLN2 disease with and without a clinical diagnosis of ASD.

**Methods:** Data was collected as part of an ongoing, longitudinal, clinical study. Participants included in the current study included 27 children between the ages of 2-18 years with a diagnosis of CLN2 disease. This sample was characterized to include children with CLN2 disease that received a clinical diagnosis of ASD (N = 7; 25%) and children without a diagnosis of ASD (N = 21; 75%). Symptoms of ASD and behavioral functioning were assessed using raw and T-scores from scales on the CBCL in children 2-5 and 6-18 years of age. Item-level analysis of symptoms of ASD on the CBCL were also analyzed on ASD specific domains.

**Results:** Descriptive data in children 6-18 years of age with CLN2 disease (N = 11) indicate the highest T-scores on the attention problems (M = 62.7, SD = 5.3), social problems (M = 62.6; SD = 5.3), and somatic complaints (M = 60.2; SD = 6.2) scales of the CBCL. Descriptive data in children 2-5 years of age with CLN2 disease (N = 16) indicate the highest T-scores on the attention problems (M = 66.8, SD = 8.6), withdrawn (M = 65.2, SD = 8.9), and the DSM 5 autism spectrum problems (M = 64.1, SD = 8.5) scales of the CBCL. There were statistically significant group differences in children ages 2-5 years with CLN2 disease across DSM-5 oriented scales assessing autism spectrum ( $t(14) = -2.2, p < .05$ ), ADHD ( $t(14) = -4.1, p < .005$ ), and oppositional defiant ( $t(14) = -2.7, p < .05$ ) problems and children with ASD were reported to demonstrate more problems in comparison to children with CLN2 disease without ASD.

**Conclusions:** This preliminary investigation suggests that children with CLN2 disease may be at increased risk for behavioral problems including attention problems, social difficulties, and aggression. Additionally, children with CLN2 disease may be at higher risk for ASD with 25% of the current sample reporting a co-occurring diagnosis of ASD. Increased behavioral difficulties were reported by parents in children with CLN2 disease and ASD. It is critical to gain a better understanding of how behavioral symptoms present and change over time in children with CLN2 disease in order to better inform diagnostic decisions and treatment efforts. Behavioral intervention may help improve skill acquisition and maintenance, as well as enhance the quality of life for children and their families

**439.017 (Poster)** The Impact of Stress, Alcohol Consumption, Social Media Use, and Exercise on Sleep in Caregivers of Children with NGS during COVID-19

**T. F. Prothro<sup>1</sup>, S. P. Lane<sup>2</sup>, M. J. George<sup>3</sup>, E. A. Richards<sup>3</sup> and B. Kelleher<sup>1</sup>, (1)Psychological Sciences, Purdue University, West Lafayette, IN, (2)RTI International, Cary, NC, (3)School of Nursing, Purdue University, West Lafayette, IN**

---

**Background:** Caregiver well-being is essential in supporting the development of children with neurogenetic syndromes (NGS). Sleep is critical for well-being and health, and NGS caregivers frequently report compromised sleep. Social and physical constraints of COVID-19 have likely further disrupted caregiver sleep, directly due to stress and indirectly due to coping behaviors caregivers may engage in to combat stress. Caregivers may be managing stress using coping mechanisms sometimes reported to negatively impact sleep, like social media and alcohol use. Caregivers may have less time or access to health behaviors that reduce stress and improve sleep, like exercise. However, the impacts of COVID-19 on NGS caregiver sleep, stress, and health behaviors is unclear, limiting understanding of how to intervene and best support caregiver health and well-being.

**Objectives:** We used an experience sampling approach to examine how stress, alcohol consumption, social media use, and exercise impact sleep in NGS caregivers during COVID-19. We hypothesized that daily stress and health behaviors would relate to caregivers' nightly sleep duration and quality.

**Methods:** Participants included 50 caregivers of children ages 1 to 7 (M = 4.61) and diagnosed with Angelman (n = 13), Down (n = 9), fragile X (n = 4), Prader Willi (n = 9), and Williams (n = 15) syndromes; 14% were also diagnosed with autism. Using ExpiWell, caregivers completed four surveys per day across four seven-day periods across seven weeks. We focus on five

variables: (1) self-reported stress at the morning assessment, (2) previous night sleep duration and quality, previous day (3) alcohol use and daily (4) exercise and (5) social media use.

Results: Table 1 details descriptive statistics. Analyses include 5975 observations across 50 caregivers. Data completion ranged from 69-74% per variable. Preliminary Spearman correlations indicated that increased stress was correlated with reduced sleep quality ( $r = -.33$ ,  $p < .0001$ ) and duration ( $r = -.18$ ,  $p < .0001$ ). Wilcoxon signed rank tests indicated that sleep quality did not vary whether caregivers exercised ( $Z = -.66$ ,  $p = .507$ ,  $r = .02$ ), however those who exercised slept significantly longer ( $Z = 2.39$ ,  $p = .017$ ,  $r = .08$ ). When caregivers drank alcohol, they reported significantly better sleep quality ( $Z = 2.63$ ,  $p = .009$ ,  $r = .08$ ) and duration ( $Z = 4.32$ ,  $p < .0001$ ,  $r = .14$ ) than those who did not drink at all. There was no association between social media use and sleep quality ( $r = .01$ ,  $p = .770$ ) or duration ( $r = .01$ ,  $p = .728$ ). Final analyses will use mixed effects models to how patterns cluster within and across caregivers over time.

Conclusions: Our results suggest that caregivers' momentary ratings of stress during COVID-19 significantly relate to previous night sleep quality, and sleep was generally better when caregivers exercised. Alcohol consumption was generally low in our sample but did relate to higher sleep quality, whereas social media use did not predict sleep. These results begin to clarify the active ingredients that may be targeted in interventions to reduce caregiver stress during COVID-19 and beyond.

**439.018 (Poster)** Visual Engagement and Attention Differences in Children with FOXP1 Syndrome Parallel Those in Autism Spectrum Disorder

**B. Lerman<sup>1</sup>**, T. Levy<sup>2</sup>, C. McLaughlin<sup>3</sup>, S. B. Guillory<sup>2</sup>, H. Grosman<sup>3</sup>, K. Keller<sup>4</sup>, H. Walker<sup>5</sup>, L. Tang<sup>2</sup>, P. M. Siper<sup>2</sup>, A. Kolevzon<sup>2</sup>, J. D. Buxbaum<sup>3</sup>, M. P. Trelles<sup>2</sup> and J. H. Foss-Feig<sup>6</sup>. (1)Icahn School of Medicine at Mount Sinai, New York, NY, (2)Seaver Autism Center for Research and Treatment, Department of Psychiatry, Icahn School of Medicine at Mount Sinai Hospital, New York, NY, (3)Seaver Autism Center, Department of Psychiatry, Icahn School of Medicine at Mount Sinai Hospital, New York, NY, (4)Department of Psychiatry, Icahn School of Medicine, Seaver Autism Center, New York, NY, (5)Department of Psychiatry, Icahn School of Medicine at Mount Sinai, New York, NY, (6)Psychiatry, Icahn School of Medicine at Mount Sinai, New York, NY

**Background:** FOXP1 syndrome is a rare genetic neurodevelopmental disorder characterized by intellectual disability and speech and attention deficits. Moreover, *FOXP1* is a risk gene for autism spectrum disorder (ASD), which is associated with poor socialization and abnormal eye-contact and reciprocal gaze. Previous eye-tracking studies in idiopathic ASD (iASD) suggest that visual attention deficits are more attributed to global delays in reorienting of attention than to particular deficits in socialization. No studies have tested whether attentional deficits in FOXP1 syndrome follow this same paradigm.

**Objectives:** We investigated whether children with FOXP1 syndrome a) show similar patterns of visual attention engagement and disengagement to those we previously observed in iASD and b) are impacted by the social versus non-social nature of visual stimuli.

**Methods:** Eye-tracking data were collected from age- and sex-matched groups of individuals with FOXP1 syndrome ( $n=8$ ) and typically-developing (TD) controls ( $n=17$ ), ages 3-17. The FOXP1 cohort received consensus ASD diagnoses based on gold-standard diagnostic assessments (ADOS-2, ADI-R), DSM-5 criteria, and clinical impressions of licensed psychologists and psychiatrists. During the eye-tracking task, a central stimulus was presented for 1s, followed by presentation of a peripheral stimulus on the left or right. The central stimulus either remained on screen ("overlap") or disappeared 250ms before the peripheral stimulus appeared ("gap"). Central and peripheral stimuli were either social (20 child faces) or non-social (20 objects, e.g., ball, globe) and were presented in grayscale. We measured saccade latency to the peripheral stimulus and calculated gap effect (difference between average "overlap" and "gap" saccade latencies) for each participant overall and for each social/non-social condition. Reduced gap effect reflects deficits in engagement of visual attention.

**Results:** A Mann-Whitney U-test revealed a lower gap effect in FOXP1 relative to TD participants, with results approaching significance ( $p=0.091$ ) and of large effect size (Cohen's  $d=0.86$ ). Average saccade latency in the gap condition was higher in FOXP1 compared to TD ( $p=0.027$ ), whereas saccade latencies in the overlap condition did not differ ( $p=0.38$ ). There was no group-by-condition interaction for gap effect ( $p=0.56$ ), suggesting attention engagement was not differentially affected by the social or non-social nature of stimuli. Interestingly, a Mann-Whitney U-test revealed that there was no difference in gap effect between FOXP1 participants with ( $n=3$ ) and without ( $n=5$ ) consensus ASD diagnoses ( $p=0.39$ ).

**Conclusions:** We found a trend toward reduced gap effect in FOXP1 individuals compared to TD individuals, driven by slower latencies in the gap condition. Mirroring our previous findings in iASD, these results suggest that deficits in attention in FOXP1 may be driven by delays in the anticipation or reorientation of attention. As in iASD, there were no differences in engagement

with social versus non-social stimuli among FOXP1 individuals, demonstrating that deficits in visual attention in FOXP1 are independent of stimulus type. These findings lend support to the notion that attentional deficits in FOXP1 may be similar to those in iASD, despite only ~25% of FOXP1 individuals receiving formal ASD diagnoses. This work provides important insight into shared mechanisms of attentional differences across idiopathic and genetic forms of ASD.

## POSTER SESSION — SENSORY PHYSIOLOGY

### Poster 440 - Sensory physiology Posters

**440.001** (Poster) Altered Visual Evoked Potentials to Illusory Contour Integration Among Children on the Autism Spectrum  
*E. J. Knight<sup>1</sup>, E. J. Myers<sup>2</sup>, Z. Cao<sup>3</sup>, L. A. Oakes<sup>4</sup>, E. P. Nicholas<sup>3</sup>, E. G. Freedman<sup>4</sup> and J. J. Foxe<sup>1</sup>, (1)Developmental and Behavioral Pediatrics, University of Rochester Medical Center, Rochester, NY, (2)601 Elmwood Ave, University of Rochester Medical Center, Rochester, NY, (3)Neuroscience, University of Rochester Medical Center, Rochester, NY, (4)The Ernest J. Del Monte Institute for Neuroscience, University of Rochester Medical Center, Rochester, NY*

#### Background:

Individuals on the autism spectrum often exhibit atypicality in their sensory perception, but the neural underpinnings of these perceptual differences remain incompletely understood. One proposed mechanism is an imbalance in the integration of sensory inputs with prior experiences, leading to an increased propensity to focus on local object features over global context.

#### Objectives:

We explored this theory using electroencephalography (EEG) during passive perception of visual stimuli that formed illusory contours in autistic children and neurotypical controls. Specifically, we tested the hypotheses that autistic individuals would have attenuated or delayed visual evoked potential responses to illusory contour stimuli and that these differences in contour-integration mechanisms would correlate with perceptual reasoning ability.

#### Methods:

EEG was continuously acquired in 18 autistic (ASD) and 28 neurotypical (NT) children (age 6-17 years) while they viewed a random series of Kanizsa figure stimuli, each consisting of four equidistant 'Pac-Man' inducers that were either oriented at random rotational angles (non-contour configuration) or aligned such that contour integration would form a square (illusory contour configuration). Of note, the paradigm included both central and eccentric stimulus presentations to the left or right of fixation; data considered here are from central stimulus presentations only. Concurrently with Kanizsa figure stimulus presentation, participants engaged in an unrelated task identifying red-green color change in a centrally-located fixation dot to ensure foveation, which was further verified with eye tracking. Illusory contour integration is typically marked by a negative deflection in the visual evoked potential occurring between 90 and 200ms post-stimulus onset, termed the illusory contour effect. This difference in visual evoked potentials to illusory contour vs. non-contour stimuli was compared between autistic and neurotypical children. All participants also underwent a phenotyping battery consisting of the Weschler Abbreviated Scale of Intelligence-2<sup>nd</sup> Edition, Peabody Picture Vocabulary Test-4<sup>th</sup> Edition, and Social Responsiveness Scale-2<sup>nd</sup> Edition. ASD participants were additionally assessed with the Autism Diagnostic Observation Schedule-2<sup>nd</sup> Edition.

#### Results:

Autistic children had a reduced amplitude illusory contour effect most pronounced over the right posterior occipital region (electrode PO4 in the 10-20 convention) as compared to neurotypical children ( $\text{mean}_{\text{ASD}} = -1.551 \pm 3.048 \mu\text{V}$ ,  $\text{mean}_{\text{NT}} = -4.374 \pm 2.923 \mu\text{V}$ ,  $t(44) = 3.144$ ,  $p = 0.003$ ). There was no significant difference in the latency of the illusory contour effect between groups ( $\text{mean}_{\text{ASD}} = 152 \pm 43 \text{ms}$ ,  $\text{mean}_{\text{NT}} = 161 \pm 32 \text{ms}$ ,  $t(44) = -0.802$ ,  $p = 0.427$ ). No significant correlation between the amplitude of the difference wave and an individual's perceptual reasoning index has emerged in the data collected to date ( $r(34) = -0.180$ ,  $p = 0.294$ ).

#### Conclusions:

Autistic children demonstrate attenuated neural responses to illusory contour stimuli as compared to neurotypical controls, suggesting possible reduced deployment of predictive feedback mechanisms in visual processing of global stimulus features. It remains unclear the relationship of these differences in neurophysiologic mechanisms to specific behavioral phenotypes.

**440.002** (Poster) Attention Mediates Brain-Behavior Relationship of Sensory Processing in Autism Spectrum Disorders

**J. E. Crasta<sup>1</sup>, W. J. Gavin<sup>2</sup> and P. L. Davies<sup>3</sup>, (1)Physical Medicine and Rehabilitation, Kennedy Krieger Institute, Baltimore, MD, (2)Human Development & Family Studies, Colorado State University, Fort Collins, CO, (3)Colorado State University, Fort Collins, CO**

---

**Background:** Attention is a fundamental ability that impacts everyday sensory and social behaviors in ASD. Research on the neural basis of attention and sensory processing in autism spectrum disorder (ASD) is increasing. However, there is limited translational research bridging neuroscience and daily participation issues.

**Objectives:** This study used structural equation modeling to examine the relationship between brain measures of sensory processing and behavioral measures of attention, sensory processing, and social responsiveness in young adults with ASD and neurotypical peers.

**Methods:** Participants included 24 young adults with ASD (M age=23.3 years, SD=3.8) and 24 age-matched neurotypical adults. To assess neural sensory processing, electroencephalography (EEG) data were recorded while participants heard random presentations of 4 auditory stimuli (50 ms in duration) at two frequencies (1 and 3 kHz) and two intensities (50 and 70 dB). Participants completed two attention conditions; the passive condition involved only listening to the stimuli, followed by the active condition, wherein participants were instructed to press a button only to the 1 kHz 50 dB tone. For each condition, participants heard 80 trials of each tone in a pseudo-random order with a two-second inter-stimulus interval. Participants completed the self-report forms, the Adolescent/Adult Sensory Profile (AASP), and Social Responsiveness Scale 2 (SRS-2) and were administered the Test of Everyday Attention (TEA), a performance-based attention measure.

**Analysis:** Latent variable mediation analysis was used to examine the hypothesis that attention (TEA total score) mediates the relationship between brain measures of sensory processing (EEG) and behavioral measures of sensory processing (low registration quadrant score), which in turn predict social responsiveness (SRS-2 total score). EEG measures (N1 latency) derived from high-frequency tones of passive and active conditions were combined to obtain a latent variable describing brain measures of sensory processing. Analysis included participants from both groups.

**Results:** The ASD group had significantly delayed N1 latencies during both attention conditions than neurotypical peers. The latent EEG measure significantly predicted attention scores,  $\beta = -.49, p = .03$ , and attention abilities significantly predicted behavioral sensory processing,  $\beta = -.55, p < .0005$ . These results support the mediational hypothesis. The direct effect of EEG measure predicting sensory processing,  $\beta = -.04$ , was not significant but the indirect coefficient was significant,  $\beta = .16, p = .047$ . Lastly, sensory processing significantly predicted social responsiveness,  $\beta = .83, p < .0005$ . This model yielded excellent fit statistics,  $\chi^2(13) = 13.47, p = .41, RMSEA = .03, 90\% CI [.00, .15], p = .53; CFI = .99; SRMR = .06$ .

**Conclusions:** In young adults with and without ASD, attention abilities mediated the relationship between brain measures of sensory processing and behavioral sensory processing, specifically low registration. Thus, attention abilities can facilitate brain mechanisms to better process sensory stimuli to perform everyday sensory processing activities and social skills. Data suggest that statistical modeling can be beneficial in interpreting the nature of brain-behavior relationships in ASD. The results indicate that therapy emphasizing attention skills in ASD can potentially modify sensory and social participation in young adults with ASD.

#### **440.003 (Poster) Atypical Tactile Psychophysics in a Clinical Neurodevelopmental Disorder Cohort**

**H. Powell<sup>1</sup>, M. A. Rowe<sup>2</sup>, J. L. He<sup>1</sup>, R. Schaaf<sup>3,4</sup>, P. Mukherjee<sup>5</sup>, E. J. Marco<sup>6</sup> and N. A. Puts<sup>1</sup>, (1)Institute of Psychiatry, Psychology and Neuroscience, London, United Kingdom, (2)Radiology, University of California, San Francisco, San Francisco, CA, (3)Occupational Therapy, Thomas Jefferson University, Philadelphia, PA, (4)Jefferson Autism Center of Excellence, Thomas Jefferson University, Philadelphia, PA, (5)Department of Radiology and Biomedical Imaging, University of California, San Francisco, San Francisco, CA, (6)Neurodevelopmental Medicine, Cortica Healthcare, San Rafael, CA**

---

**Background:**

Touch plays an important role in human development, both in perception and development of social function. There is ample evidence to suggest that tactile processing is impaired in those with ASD and that it may contribute to the autism phenotype. Recent work using physiological measures, has shown that differences in low-level tactile function are associated with the clinical manifestation of ASD, including social deficits. Psychophysical approaches allow for differentiation of neural-mediated functions (e.g. detection, discrimination). However, it remains unclear to what extent these alterations in tactile perception are specific to ASD or associated with clinical sensory phenotype (e.g. over-responsivity).

**Objectives:**

To investigate whether children with neurodevelopmental disorders (NDD), including ASD, show atypical tactile perception and compare data relative to previously published cohorts. We will also investigate whether those with tactile sensory over-responsivity (TAC SOR) show worse tactile thresholds than those without. In the future we will investigate whether tactile perception differs between NDDs.

#### Methods:

23 children with NDD, 8-12 years old (6 with ASD, 18 with ADHD, 12 with anxiety; 16 male) were included. For reference, we used published data from 100 ASD and 200 TD children. Vibrotactile detection, discrimination, and order judgement were assessed using a Cortical Metrics stimulator (see Fig. 1), to better understand physiological differences. Children were included in the TAC SOR cohort if they scored >2 standard deviations on the Short Sensory Profile Tactile Sensitivity section (parent report measure) and/or >5 on the Sensory Processing 3 Dimensions (SP3D) TAC SOR section (OT-administered direct assessment). Student's T-tests were used to compare groups within this study and between this study and prior data. Spearman correlations were run between the SP3D TAC SOR score and psychophysical measures.

#### Results:

For the NDD cohort, mean static detection threshold was  $10.49 \pm 4.4 \mu\text{m}$ ; mean dynamic detection threshold (indicative of sensory gating) was  $6.38 \pm 2.71 \mu\text{m}$ ; the difference between static and dynamic detection (indicative of feed-forward inhibition) was not significant ( $p > 0.05$ ). Mean amplitude discrimination threshold (indexing lateral inhibition) was  $61.82 \pm 40.4 \mu\text{m}$ ; mean temporal order judgement threshold was  $69.65 \pm 60.80 \text{ ms}$ . These thresholds are significantly higher than previously published TD data ( $p < 0.05$ ) but consistent with previous ASD data (See Fig 1). We found a significant difference in amplitude discrimination between those with and without TAC SOR ( $p = 0.048$ ). Individual differences in amplitude discrimination also correlated with SP3D TAC SOR total score ( $r_s = -0.48, p = 0.03$ ).

#### Conclusions:

In an NDD cohort, we found significant differences in tactile physiology consistent with prior work, suggesting that low-level sensory abnormalities in tactile threshold are robust. We found that amplitude discrimination differed and correlated with TAC SOR score. We previously showed that amplitude discrimination was associated with autism severity. Large variation could reflect the heterogeneity and differentiation of NDDs compared to ASD-only. While larger samples are needed, our results suggest that impaired discrimination could impact SOR. Worse ability to distinguish stimuli at the physiological level may lead to inconsistencies in tactile encoding, contributing to SOR.

#### 440.004 (Poster) Closing the Species Gap: How to Study Sensory Processing Differences Relevant for Autism Spectrum Disorder in Both Rodents and Humans

**K. Scott<sup>1</sup>, D. Moehrl<sup>2</sup>, S. E. Schulz<sup>3</sup>, J. Oram Cardy<sup>3</sup>, B. Allman<sup>1</sup>, R. A. Stevenson<sup>1</sup> and S. Schmid<sup>5</sup>,** (1)Anatomy and Cell Biology, Western University, London, ON, Canada, (2)University of Western Ontario, London, ON, Canada, (3)Western University, London, ON, Canada, (4)Brain and Mind Institute, University of Western Ontario, London, ON, Canada, (5)Anatomy and Cell Biology, University of Western Ontario, London, ON, Canada

**Background:** The study of sensory phenotypes has great potential for increasing research translation between species, a necessity to decipher the neural mechanisms that contribute to higher-order differences in Autism Spectrum Disorder (ASD). Over the past decade, despite separate advances in our understanding of the structural and functional differences within the brain of individuals with and without ASD and in rodent models for ASD, researchers have been unable to directly translate the findings in murine species to humans, mostly due to incompatibility in experimental methodologies used to screen for ASD phenotypes. Focusing on sensory phenotypes offers an avenue to close the species gap because sensory pathways are highly conserved across species and are affected by the same genetic and environmental risk-factors as other diagnostic domains of ASD.

**Objectives:** To design and implement a framework to study sensory processing similarly in both rodents and humans.

**Methods:** First, electrophysiological and behavioural techniques that have been used to study and assess sensory phenotypes consistently across species were reviewed. Next, we identified those paradigms that could provide accessible, translatable, valid, and reliable metrics across species. We designed a framework focused on assessing auditory processing through the collection of evoked-potentials, acoustic startle paradigms, and psychophysical detection/discrimination paradigms. Lastly, to implement this framework, new behaviours were created in order to collect data on auditory processing in a coordinated and systematic fashion across species.

**Results:** We were able to collect the same metrics in both humans and rodents that can provide information about auditory processing in ASD. By simplifying task design by stripping stimuli down to their basic characteristics (e.g., for acoustic stimuli modulating intensity *or* temporal structure *or* frequency) and using as few instructions as possible in tasks of detection or discrimination, i.e. using implicit or very simple behaviours, we were able to remove potentially confounding cognitive variables such as motivation, distractibility, or the understanding of instruction. Importantly, these metrics scale similarly in humans and rodents and therefore results can be translated with a higher degree of confidence.

**Conclusions:** Using this framework across a variety of sensory domains (e.g. vision, olfaction, touch) will reduce the heterogeneity among protocols between and within human and animal research. Through careful protocol design and collaboration, sensory processing phenotypes can be harnessed to bridge the gap that exists between pre-clinical animal studies and human assessment and testing. Only then can we determine the mechanisms contributing to ASD, untangle gene/environment interactions, or assess intervention (e.g. drug) efficacy.

**440.005 (Poster) EEG Indices of Sensory Gating Are Associated with Atypical Perceptual Modulation and Interoception**  
*D. A. Trevisan, T. C. Parker, A. Naples, E. Cummings, S. Kala, A. Bagdasarov and J. McPartland, Child Study Center, Yale University School of Medicine, New Haven, CT*

---

Background:

Sensory habituation is the process of filtering out repeated sensory stimuli in the environment to prioritize attentional resources towards the most relevant sensory information (Grunwald, 2003), such as blocking out background noises to listen to a conversational partner. Compared to typically developing (TD) comparison groups, individuals with ASD exhibit reduced habituation to repeated auditory stimuli presentation (Williams et al., in press). It is possible that atypical sensory habituation is a basic mechanism that contributes to ASD symptoms relevant to atypical perception of external stimuli (e.g., sights, sounds) and internal stimuli (i.e., interoceptive senses). However, the clinical relevance of auditory sensory habituation is not well understood.

Objectives:

- To examine electroencephalography (EEG) indices of sensory habituation in relation to autistic traits.
- To evaluate relationships among EEG indices of sensory habituation and clinical measures of perceptual modulation and interoceptive awareness.

Methods:

Preliminary data has been collected in 19 typically developing adults (18-40 years old) with no history of psychiatric diagnosis. Data collection is ongoing and will include adults with ASD matched on age and sex. Sensory habituation was assessed using a validated P50 Sensory Gating EEG task (Wan et al., 2007) that administered two auditory clicks spaced 500ms apart. The auditory P50 event-related potential (ERP) was examined over central regions of the posterior scalp electrode sites, a brain area thought to be responsible for pre-attentive processes. Sensory habituation was calculated as: "P50 Gating Ratio=Click 2 amplitude/Click 1 amplitude," with the assumption that higher P50 Gating Ratios (reduced difference between Click 1 and Click 2 amplitude) represents reduced sensory habituation. P50 Gating Ratios were correlated with questionnaires including the Broader Autism Phenotype Questionnaire (BAPQ; Hurley et al., 2007), the Perceptual Modulation subscale of the Sensory Gating Inventory (SGI; Hetrick et al., 2012) which includes items such as "At times I have feelings of being flooded by sounds," and the Interoceptive Sensory Questionnaire (ISQ; Fiene et al., 2018), which includes items such as, "I am confused about my bodily sensations."

Results:

There was a marginal relationship between P50 gating ratios and the BAPQ, but the relationship was nonsignificant ( $r=.294$ ,  $p=.118$ , one-tailed). P50 gating ratios were significantly correlated with the Perceptual Modulation subscale of the SGI ( $r = 0.42$ ,  $p = .035$ , one-tailed) (Figure 2a) and with the ISQ ( $r = 0.40$ ,  $p = .049$ , one-tailed) (Figure 2b).

Conclusions:

The pattern of findings suggests reduced sensory habituation as measured by neural response to auditory stimuli is associated with real-world difficulties modulating and accurately perceiving external and internal stimuli. The findings establish the clinical relevance of an EEG index of sensory processing by linking variability in P50 gating ratios with clinical symptoms related to atypical interoception and sensory sensitivities that are common in ASD.

**440.006 (Poster)** Interoceptive Awareness and Its Relationship to Social and Sensory Processing in Youth with Autism Spectrum Disorder

**K. K. Cummings<sup>1</sup>**, G. Patterson<sup>2</sup>, J. Jung<sup>3</sup>, N. J. Okada<sup>3</sup>, S. Y. Bookheimer<sup>3</sup>, M. Dapretto<sup>3</sup> and S. A. Green<sup>3</sup>, (1)Semel Institute of Neuroscience and Human Behavior, University of California, Los Angeles, Los Angeles, CA, (2)University of Denver, Denver, CO, (3)Dept of Psychiatry and Biobehavioral Sciences, University of California, Los Angeles, Los Angeles, CA

---

**Background:** Interoception, or the ability to accurately perceive one's internal physiological cues, is often measured both through interoceptive accuracy (which is dependent on behavioral performance, such as on a heartbeat-tracking task), and interoceptive awareness (IA), which is a metacognitive understanding of how accurate one is on such a behavioral interoception task (Garfinkel et al., 2015). Individuals with Autism Spectrum Disorders (ASD) have been found to have atypical interoception (for review, see DuBois et al., 2016). Interoception is also associated with ASD symptoms, including atypical sensory processing (Schauder et al., 2016) and social awareness, as greater IA may allow one to identify and describe their own emotions better, resulting in increased empathy for others' emotions (Mul et al., 2018).

**Objectives:** To examine the association between interoceptive accuracy, interoceptive awareness (IA), and both social and sensory symptoms in youth with ASD compared to typically-developing (TD) peers.

**Methods:** Participants were 41 (9F) ASD and 36 TD (11F) youth, aged 8-17 years. Participants completed three trials of a heartbeat tracking task where they were asked to silently count their heart beats for a period of time (25/35/45 seconds intervals), without using their hands to feel their pulse, while an examiner recorded their true heart rate (HR). After estimating their HR for each interval, participants also rated how confident they were in their count on a scale of 1-10. Accuracy scores were calculated for each participant and then accuracy and confidence ratings within each interval were correlated within participants, to create a measure of IA (Garfinkel et al. 2015). Parents reported on social awareness and sensory over-responsivity (SOR) using parent-report on the Social Responsiveness Scale (SRS-2; Constantino, 2005) and Sensory Over-Responsivity Inventory (Schoen, Miller, & Green, 2008). Anxiety was measured using parent-report on The Screen for Child Anxiety Related Disorders (SCARED, Birmaher, 1999), and was covaried in the SOR analyses to examine the unique effect of sensory processing over and above anxiety.

**Results:** Independent-samples t-tests showed no significant diagnostic group differences in accuracy, confidence, or IA. Neither accuracy nor IA were independently associated with social awareness; however, a hierarchical regression showed that the interaction between accuracy and IA significantly predicted social awareness over and above the main effect of either one ( $R^2$ change=0.08,  $p=.038$ ). Additionally, within the ASD group, accuracy was significantly associated with SOR, after controlling for anxiety ( $R^2$ change=.07,  $p=.049$ ), indicating that youth with higher SOR had lower accuracy.

**Conclusions:** Despite no significant diagnostic group differences on either heartbeat tracking accuracy or interoceptive awareness, both interoception measures were associated with ASD symptomatology. Notably, both accuracy and IA interacted to predict social awareness, suggesting that *both* the ability to process one's own internal cues *and* awareness of one's own interoceptive abilities are important to social awareness. Moreover, within ASD, accuracy was significantly associated with SOR suggesting that reduced awareness of internal cues may play a role in increased responsivity to sensory stimulation. Results will be discussed in terms of implications for interventions.

**440.007 (Poster)** The Physiological Mechanisms of Habituation and Generalization to Mildly Aversive Sensory Stimulation in Youth with Autism and Anxiety Disorders

**J. Jung<sup>1</sup>**, T. D. Zbozinek<sup>2</sup>, K. K. Cummings<sup>3</sup>, F. H. Wilhelm<sup>4</sup>, M. Dapretto<sup>1</sup>, M. G. Craske<sup>5</sup>, S. Y. Bookheimer<sup>1</sup> and S. A. Green<sup>1</sup>, (1)Dept of Psychiatry and Biobehavioral Sciences, University of California, Los Angeles, Los Angeles, CA, (2)Div of the Humanities and Social Sciences, California Institute of Technology, Pasadena, CA, (3)Semel Institute of Neuroscience and Human Behavior, University of California, Los Angeles, Los Angeles, CA, (4)Dept of Psychology, University of Salzburg, Salzburg, Austria, (5)Dept of Psychology, University of California, Los Angeles, Los Angeles, CA

---

**Background:**

Sensory over-responsivity (SOR), an extreme aversive response to sensory stimulation, is common in both Autism Spectrum Disorders (ASD) and Anxiety Disorders (ANX; Tavassoli et al., 2013; Conelea et al., 2014). While SOR and anxiety symptoms are highly correlated (Green et al., 2010), their unique contributions to physiological arousal during sensory stimulation are not well understood. Here, we examined the unique effects of SOR and anxiety symptoms on physiological habituation and generalization of responses to sensory stimulation, both of which are essential to intervention approaches such as exposure therapy.

#### Objectives:

To investigate how SOR and anxiety symptoms uniquely predict physiological responses during exposure to two similar but distinct sets of mildly aversive sensory stimuli, across ASD and ANX youth.

#### Methods:

Participants were 28 ASD, 21 ANX, and 21 typically-developing (TD) youth matched on sex, IQ, and age (8-18 years). Parents reported on their child's SOR severity (composite of tactile/auditory subscales from Short Sensory Profile and Sensory Over-Responsivity Inventory; Dunn, 1999; Schoen et al., 2008), and anxiety symptoms (Screen for Child Anxiety and Related Disorders; Birmaher et al., 1995). Participants experienced six 15-sec Exposure blocks of mildly aversive tactile+auditory stimulation (white noise and scratchy material rubbed on the inner wrist) and four 15-sec Generalization blocks of new, but similar, stimuli. Heart rate (HR) was collected during a 2-min baseline period and throughout the sensory stimulation. Repeated-measures ANOVAs were used to test the effect of diagnostic group as well as SOR and anxiety symptoms on HR across the Exposure blocks and across the last Exposure block through the four Generalization blocks (to examine change from the end of Exposure into Generalization).

#### Results:

There were no diagnostic group differences in mean HR during Exposure, but within the ANX and ASD groups, there was a trend-level trial\*SOR interaction ( $F(1,42)=3.30, p=.077$ ) indicating that SOR was associated with faster increases in HR across the Exposure phase. For the subsequent Generalization phase, there was a significant diagnostic group\*trial interaction ( $F(2,63)=4.63, p=.01$ ) showing that, compared to TD, the ASD and ANX groups had reduced change in HR (flatter slope) to the new stimuli. Additionally, when SOR and anxiety symptoms were entered simultaneously in the model, there were significant trial\*SOR ( $F(1,61)=11.81, p<.01$ ) and trial\*anxiety ( $F(1,61)=8.54, p<.01$ ) interactions, indicating that both symptoms were positively associated with the reduced change in HR response.

#### Conclusions:

Results suggest that SOR is associated with initial increases in autonomic arousal to sensory stimulation, over and above anxiety. However, both SOR and anxiety symptoms uniquely predicted a reduced change in HR response to the new set of stimuli, regardless of diagnosis. The reduced rate of change suggests SOR and anxiety may be associated with an atypical orienting response, which could lead to greater arousal and dysregulation (Bradley, 2009), as well as potentially reduced discrimination of novel stimuli. Notably, results suggest that SOR and anxiety symptom severity may be more important than diagnostic status in predicting these atypical responses; further, the fact that both symptoms were uniquely involved calls for an integrated treatment approach targeting both symptoms.

#### **440.008** (Poster) "Neural Noise" in and Habituation of Auditory Responses in Young Autistic and Typically-Developing Children

**P. Dwyer<sup>1</sup>, Z. J. Williams<sup>2</sup>, S. Vukusic<sup>3</sup>, C. D. Saron<sup>3</sup> and S. M. Rivera<sup>1</sup>, (1)Department of Psychology, University of California, Davis, Davis, CA, (2)Medical Scientist Training Program, Vanderbilt University School of Medicine, Nashville, TN, (3)Center for Mind and Brain, UC Davis, Davis, CA**

Background: There are several competing explanations for atypical autistic sensory perception, such as the hypothesis that inter-trial variability (ITV) of sensory responses ("neural noise") is elevated in autism (Haigh, 2018). However, this account struggles to explain reports of enhanced perception in autism (see Mottron et al., 2006). Alternatively, prior studies do suggest diminished habituation of sensory responses in autism (Hudac et al., 2018; Kolesnik et al., 2019; Matsuzaki et al., 2014).

**Objectives:** The present study used 61-channel EEG to quantify and compare ITV and habituation of auditory responses in young autistic and typically-developing children. We expected habituation to be reduced in autism but expected no group differences in ITV.

**Methods:** Usable EEG was recorded from 127 autistic (20 female) and 79 TD (27 female) participants 2-5 years of age. While watching a quiet video, participants heard, via headphones, complex tones randomly varying in intensity (50, 60, 70, or 80 dB SPL). ~1100-1200 trials were collected at an ISI of 1-2s. EEG was sampled at 1000 Hz and average-referenced. An intensive data processing pipeline including Second-Order Blind source Identification (SOBI; Belouchrani et al., 1997) was used to remove signals of putatively non-neural origin. To compare habituation across groups, we computed ordinal slopes of changes in single-trial EEG amplitudes over the experiment for each participant separately by intensity; mean slopes were then averaged over frontocentral channels in time windows associated with the P1 ( $\pm 50$  ms of grand average ERP peak latency for each intensity) and N2 (201-350 ms) components and analyzed using mixed ANOVA (group x hemisphere x intensity). Correlations between habituation and scores from the Sensory Profile Hyperacusis Index (SPHI; Williams et al., 2019) were also explored. To examine ITV, we computed median absolute deviations (MADs) of amplitudes across trials within intensities. We also estimated, within intensities, inter-trial phase coherence (ITPC) in frequencies between 6-40 Hz (2 Hz steps) using Morlet wavelets with 1-3 cycles (linearly increasing, Delorme & Makeig, 2004). Cluster-based permutation *t*-tests (Maris & Oostenveld, 2007) were used to compare MADs and ITPC across groups at all channels between 1-350 ms.

**Results:** Habituation of the P1 response was greater in autism than TD,  $F(1,204) = 4.63, p = .03$ , but habituation of the N2 was greater in TD than autism,  $F(1,204) = 16.43, p < .0001$ . There was no correlation between habituation and SPHI score estimates. MADs did not differ across groups (all  $p \geq .26$ ). However, ITPC was significantly *elevated* in autism in the 50 dB ( $p = .05$ ) and 60 dB ( $p = .03$ ) conditions, suggestive of *decreased* ITV in autism.

**Conclusions:** As predicted, we found greater habituation of the N2 response in TD than autism; however, unexpectedly, habituation of the P1 was greater in autism than TD, raising questions regarding the time course of habituation of neural responses in autism. Furthermore, as expected, our data did not support the theory that ITV is elevated in autism. Surprisingly, high ITPC suggested ITV is *decreased* in autism, although most of our ITV analyses demonstrated no significant group differences.

## Sensory, Motor, and Repetitive Behaviors and Interests

### PANEL DISCUSSION — SENSORY, MOTOR, AND REPETITIVE BEHAVIORS AND INTERESTS

#### Panel 207 - Bodies, Faces, and Limbs: Measuring Movement in the Context of Autism

**Panel Chair:** Mary Beth Nebel, *Center for Neurodevelopmental and Imaging Research, Kennedy Krieger Institute, Baltimore, MD*

**Discussant:** Stewart Mostofsky, *Center for Autism and Related Disorder, Kennedy Krieger Institute, Baltimore, MD*

Recent evidence suggests that autism-associated motor deficits may be grossly underestimated; yet, motor traits specific to autism remain elusive. A key factor contributing to these disparate findings is the lack of rigorous methods for assessing subtle differences in the vast array of motor behaviors that emerge during typical and atypical development. Symposium speakers will present tools to improve measurement feasibility and accuracy for early motor behaviors and to test hypotheses regarding the role motor skills play in the development of social behaviors central to autism. Speaker #1 will present quantitative, body sensor-based measures of early infant leg movement that are more sensitive to clinical risk for autism than standard motor batteries. Speaker #2 will discuss efforts to develop robust computer vision-based methods to measure infant facial movement and to quantify infant-caregiver synchrony. Speaker #3 will provide an overview of studies validating a mobile app using computer vision analysis to assess a range of early motor differences in toddlers with and without autism. Speaker #4 will discuss efforts to expand our understanding of the interplay of early motor and social behaviors to African pediatric populations.

**207.001** (*Panel Discussion*) Quantitative Characterization of Early Motor Differences in Autism

**R. B. Wilson<sup>1</sup>, B. A. Smith<sup>2</sup>, T. Safari<sup>3</sup>, D. Elashoff<sup>1</sup> and S. Vangala<sup>1</sup>,** (1)UCLA Medical Center, Los Angeles, CA, (2)Children's Hospital Los Angeles, Los Angeles, CA, (3)Semel Institute for Neuroscience and Human Behavior, Los Angeles, CA

**Background:** Motor dysfunction is one of the first signs of atypical development in infants at high familial risk for autism spectrum disorder (ASD). Quantitative measures of motor in early infancy may improve identification of subtle movement differences that underlie motor dysfunction and are potentially specific to ASD. One promising measure is complexity of infant movement. The ability to execute a complex repertoire of spontaneous movements emerges in early infant development and is a key feature of healthy neuromotor maturation. We hypothesize that motion complexity could have a direct mechanistic link to atypical motor behavior in ASD because (1) poor motion complexity could be related to later motor delays and repetitive motor behaviors and, (2) the expression of healthy motion complexity depends on the integrity of cortical connectivity and aberrant cortical connectivity has been reported in neurobiological studies of ASD.

**Objectives:** Develop a quantitative measure of motion complexity from motor activity evaluated in high risk (HR; defined as having an older sibling with ASD) and low risk (LR; no elevated concern for ASD) infants. Evaluate the relationship of motion complexity to autism outcomes.

**Methods:** Full day quantitative measurement of spontaneous leg movements was obtained utilizing the opal wearable sensor at 3, 6, and 9 months of age from 7 HR infants and 12 LR infants. From the data, we constructed the motion complexity measure. A minimally complex movement pattern is one fully described by a singular periodic function (e.g., a sine wave with a specified frequency). In contrast, high complexity indicates that motion is best described by a superposition of waves of varying frequencies. Therefore, we defined our complexity measure in terms of the variability of the frequency components underlying the observed infant movements. ASD symptoms were measured at 24 and 36 months of age with the Autism Diagnostic Observation Schedule (ADOS).

**Results:** The motion complexity score at each visit time point showed a range of results in the 7 HR infants and 12 LR infants: 3 months, HR: (0.373-0.676, M: 0.528, SD: 0.134) and LR: (0.291-0.902, M: 0.578, SD: 0.191); 6 months, HR: (0.395-1.041, M: 0.703, SD: 0.217) and LR: (0.392-0.883, M: 0.657, SD: 0.162); 9 months, HR: (0.325-1.027, M: 0.645, SD: 0.268) and LR: (0.196-0.864, M: 0.582, SD: 0.208). HR infants that went on to develop a diagnosis of ASD (2/6) showed lower motion complexity compared to those that did not at all time points.

**Conclusions:** HR infants with later ASD diagnosis showed lower motion complexity scores compared to those that did not. We did not find that motion complexity scores show a clear pattern of change with age. Both HR and LR infants showed a large

range of motion complexity, likely representing the variability of typical motor development. Further evaluation of our quantitative measure of motion complexity may lead to a promising early motor measure to detect risk for later ASD diagnosis. These data will be expanded to a larger sample size of HR and LR infants and those with outcomes at the time of the INSAR conference.

**207.002** (*Panel Discussion*) Computational Analysis of Interactional Synchrony: A Novel Measure of Autism Risk  
*C. J. Zampella, E. Sariyanidi, L. S. Cubit, M. Drye, M. Fecher, L. K. Steinbeck, L. A. Wang, K. Bartley, B. Tunc, R. T. Schultz and W. Guthrie, Center for Autism Research, Children's Hospital of Philadelphia, Philadelphia, PA*

---

**Background:** Interactional synchrony, or social-motor coordination, is a fundamental, early-emerging developmental process that may provide a novel lens for understanding social and motor differences in ASD. Computational analysis of synchrony offers a scalable, granular, objective new direction for assessing early autism risk, possibly before overt symptoms emerge. However, current computer vision tools, developed nearly exclusively on adult samples, are not appropriate for quantifying infants' social movements. They fail to accurately quantify facial expressions in the context of head pose variation – a particular problem for infants who move around during natural interactions. They also fail to account for facial morphology differences between infants and adults. This abstract focuses on critical first steps for developing robust computational methods to measure synchrony in infants.

**Objectives:** (1) Develop computer vision methods that accurately quantify infant facial movements by accounting for head movement/orientation and morphology differences; (2) Collect pilot interactional synchrony data on 12-month-old infants at high and low familial risk for ASD.

**Methods:** To quantify the effect of head movement on facial expression measurement, we synthesized 1000 neutral face videos with varying head poses. We quantified facial expressions using state-of-the-art computer vision methods claiming to accurately separate facial pose and expression. Given that all face images were neutral, any detected expressions were spurious, allowing us to measure the degree to which head pose caused inaccurate measurement. To address differences in infant facial morphology, we used a public dataset (N=900) to develop a novel method that estimates face shape using simultaneous input from multiple image frames, and compared it to standard methods that process each frame independently. By taking multiple frames into account, it is possible to separate features that remain stable (morphology) from those that change (expressions), thus more accurately reconstructing an individual's unique face shape. Pilot synchrony data were then collected during brief natural interactions between infants and caregivers, using a bidirectional camera to measure movements in both partners.

**Results:** Head movements generated systematic errors in facial expression measurement that were large enough to be visibly apparent and to frequently mislead standard facial analysis systems; even 10-15° head rotations led to a 30% false positive rate, and errors were extreme (~70%) with larger rotations (30-40°). Our novel method for estimating face shape was 26% more accurate than standard methods. Pilot interactional synchrony data were successfully collected on 30 infant-caregiver dyads, with two sessions recorded to measure reliability across repeated assessments.

**Conclusions:** Results confirm that current computer vision programs yield significant inaccuracies in infant facial estimates due to head movement and differences in facial morphology. Our novel methods account for these confounds, allowing for more robust measurement of infant social movements within natural contexts. In light of these computational advances, digital capture of interactional synchrony holds particular promise for identifying early social-motor biomarkers that can be leveraged for screening. Future directions are to develop a screening threshold based on synchrony features that maximizes specificity for predicting ASD, to test relationships between synchrony and traditional clinical assessments, and to identify synchrony-based latent developmental profiles.

**207.003** (*Panel Discussion*) Computational Approaches to the Assessment of Early Motor Behavior in Autism  
*G. Dawson<sup>1</sup>, K. L. Carpenter<sup>1</sup>, Z. Chang<sup>2</sup>, J. M. Di Martino<sup>2</sup>, S. Espinosa<sup>2</sup>, S. Perochon<sup>2</sup>, P. R. Krishnappa Babu<sup>2</sup> and G. Sapiro<sup>2</sup>,*  
*(1)Department of Psychiatry and Behavioral Sciences, Duke Center for Autism and Brain Development, Durham, NC,*  
*(2)Department of Electrical and Computer Engineering, Duke University, Durham, NC*

---

**Background:** Early detection of autism spectrum disorder (ASD) is an essential first step toward access to intervention which can impact long term outcomes. Although ASD screening questionnaires are useful, they require literacy and have lower performance with caregivers from minority racial/ethnic backgrounds and lower education. Thus, there remains a need for feasible, accurate, and scalable methods for directly observing and quantifying early autism symptoms. We have developed a digital assessment tool for early ASD symptom detection and monitoring that can be delivered on widely-available devices by designing an application (app) consisting of several brief movies shown on an iPhone or iPad while the child's behavior is recorded via the frontal camera embedded in the device, and using computer vision analysis to quantify behavior. This

presentation will discuss how this computational approach can be useful for assessing early motor skills in toddlers with ASD. Numerous studies have documented deficits in motor coordination as an early feature of ASD.

**Objectives:** Describe a computational approach to the assessment of early motor behaviors in two independent samples of toddlers with and without ASD.

**Methods:** Participants in Study 1 were 104 toddlers, 16-31 months, 22 of whom were diagnosed with ASD, and in Study 2 were 910 toddlers, 17-37 months, 37 of whom were diagnosed with ASD. Both studies were conducted in primary care clinics. The app was administered on an iPhone or iPad while toddlers sat on their caregiver's lap and consisted of a series of brief movies designed to elicit a wide range of ASD-relevant behaviors. A novel bubble-popping game was added to the app in Study 2. During app administration, the child's name was called three times. This presentation will focus on computer vision analysis of motor behavior, including latency of the child's head turn in response to name and postural stability while watching the movies. Furthermore, during the bubble popping game, machine learning algorithms were used to assess motor accuracy, prospective motor control, and sensorimotor timing and integration.

**Results:** In both studies, toddlers with ASD oriented to their name significantly less frequently than non-ASD toddlers and mean latency to orient to name was significantly longer. In both studies, toddlers with ASD exhibited significantly more postural sway as evident by more frequent head movements while watching movies. Preliminary analyses of the bubble popping game showed that toddlers with ASD demonstrated lower fine motor control and accuracy than non-ASD toddlers. This was reflected in the median error (the distance between the center of the popped bubble and the child's touch) and accuracy variability (standard deviation of the accuracy when touching the screen) across all touches.

**Conclusions:** Results of these two studies demonstrate the ability of digital phenotyping deployed on widely-available devices to assess differences in motor skills between toddlers with and without ASD, many of which would be difficult to detect without the fine resolution of computer vision analysis. These findings have far-reaching potential for developing scalable autism screening tools that are feasible in natural settings and enable datasets amenable to machine learning.

**207.004 (Panel Discussion) Towards a Scalable Multidimensional Approach to Identifying Early Markers of Autism Among Toddlers in Sub-Saharan Africa**

Ellison<sup>4</sup>, (1)Institute of Child Development, University of Minnesota, Minneapolis, MN, (2)Psychiatry, Makerere University, Kampala, Uganda, (3)Pediatrics, University of Utah, Park City, UT, (4)University of Minnesota, Minneapolis, MN**

---

## Background

Motor skills afford children opportunities to interact with people and objects, and develop essential social skills. While evidence has demonstrated strong associations between motor and social skills in typically developing children and those with atypical trajectories such as autism and developmental coordination disorder, the majority of research examining the interplay of early motor and social behaviors has focused on western populations. The cultural appropriateness of new tools designed to quantify these behaviors has not been examined in African settings.

## Objectives

To begin to fill these gaps, we pilot tested the implementation of a multidimensional parent-report assessment in an African setting. We investigated associations between early motor, repetitive and reciprocal social behaviors in toddlers attending well-child clinics in urban Uganda. We hypothesized that more advanced motor behavior would be associated with fewer repetitive behaviors as well as more advanced reciprocal social behaviors in the target population.

## Methods

To assess motor skills, repetitive behaviors, and reciprocal social behaviors in our target population, we translated and cross-culturally validated Ugandan versions of the Early Motor Questionnaire, the Repetitive Behavior Scale for Early Childhood, and the Video-Referenced Rating of Reciprocal Social Behavior, respectively. These questionnaires were administered digitally to parents of toddlers (12-30 months of age) by a team of trained study nurses in two Central Ugandan hospitals. In this early look at the data, we summarize the sample ascertained and report correlation coefficients between key variables, while accounting for chronological age.

## Results

Two hundred and forty-six toddlers (121 females) between the ages of 12 and 30 months participated. The majority of parent respondents were biological mothers of the children (91.1%, n=224), and a high proportion were unemployed (72.8%, n=179). We explored associations between gross motor, fine motor, perception-action, reciprocal social behaviour and repetitive motor behaviour whilst controlling for age. As expected, we observed a positive correlation between reciprocal social behaviour and the frequency of repetitive motor behavior ( $r = .48, p < 0.001$ ), suggesting less sophisticated social responsiveness is associated with more repetitive motor behaviour. We also observed that gross motor skills were negatively correlated with reciprocal social behavior, albeit moderately ( $r = -0.14, p = 0.026$ ). Finally, we observed rather anomalous associations between the frequency of repetitive motor behavior and gross motor skills ( $r = 0.168, p = 0.008$ ), fine motor skills ( $r = 0.24, p < 0.001$ ), and perception action skills ( $r = 0.35, p < 0.001$ ).

## Conclusions

We explored associations between autistic traits (reciprocal social behavior and repetitive behavior) and motor development in a reasonably sized group of urban Ugandan toddlers. Toddlers displaying more repetitive behavior displayed less advanced reciprocal social behavior. Counter to our expectation, toddlers with more advanced gross motor, fine motor, and perception-action skills demonstrated a greater frequency of repetitive motor behaviors. This analysis represents a critical first step toward establishing normative data on autistic traits and motor development in urban Ugandan toddlers. Future work will characterize psychometric integrity of the assessments and derive profiles of risk that may augment future screening efforts.

## PANEL SESSION — SENSORY, MOTOR, AND REPETITIVE BEHAVIORS AND INTERESTS

### Panel 227 - Conceptualizing Motor Impairments within the Broader Framework of Autism Spectrum Disorder (ASD): Their Value in Early Diagnosis and the Diagnostic Process.

**Panel Chair:** Anjana Bhat, *Department of Physical Therapy, University of Delaware, Newark, DE*

**Discussant:** Rebecca Landa, *Center for Autism and Related Disorders, Kennedy Krieger Institute, Baltimore, MD*

Motor delays are one of the earliest identifiable markers in at-risk infants who eventually develop Autism Spectrum Disorder (ASD, Landa & Garrett-Mayer, 2006) and increase in magnitude across development (Lloyd, Macdonald & Lord, 2013). Motor impairments in children with ASD are closely linked to their social communication impairments as well as comorbidities in communication, cognition, and function (Licari et al., 2019). A better understanding of motor impairments can provide greater insight into the neural substrates underlying motor performance as well as the neuropathology of ASD. However, motor impairments are currently not part of the diagnostic criteria or specifiers for ASD within the DSM-V. This diverse panel of clinician scientists will present data on motor delays and impairments across the entire developmental spectrum from at-risk infants to children to adults affected by ASD. They will make a case for the pervasive nature of motor impairments in individuals affected by ASD; their association with core characteristics of ASD, and their impact on level of impairment and adaptive functioning. We hope to make a case for why and how motor impairments are intimately linked to the neuropathology of ASD and why they should be considered within the defining criteria or specifiers for ASD.

**227.001 (Panel)** Prevalence of Motor Impairment in Children on the Autism Spectrum and Early Motor Prognostic Markers in Infancy

**M. K. Licari<sup>1</sup>, J. Reynolds<sup>2</sup>, G. A. Alvares<sup>1</sup> and A. O. Whitehouse<sup>1</sup>,** (1)Telethon Kids Institute, University of Western Australia, Perth, WA, Australia, (2)Telethon Kids Institute, Nedlands, WA, Australia

#### Background:

Motor impairment is not currently included in the diagnostic criteria or evaluation of autism. This likely reflects motor impairment sitting outside the traditional social-cognitive conceptualisation of autism and the lack of large-scale studies demonstrating its prominence to advocate for change.

#### Objectives:

The objective of this presentation is to present a summary of our research program investigating the prevalence of motor impairment in large scale cohorts, including evaluating the relationship between motor impairment, core autism symptomatology and other prominent clinical features. Findings from our infant studies examining motor impairment and its potential as an early prognostic marker in infants will also be presented.

## Methods:

Prevalence of motor impairment has been evaluated in the Western Australian Autism Register (N = 2084; 2-6 years; 81.2% male, 18.8% female) and the Australian Autism Biobank (N = 514; 2-6 years; 80.0% male, 20% female). Motor impairment was identified based on scores from the motor subscales of the Vineland and then compared to other domains of functioning (i.e., communication, daily living, socialization), the DSM criteria, intellectual level, age, and gender.

Prevalence of motor impairment and its potential as an early prognostic marker has also been investigated in an infant cohort showing early signs of autism (N=96; recruited 9-14 months; 68.7% male, 22.3% female). Infants were evaluated longitudinally at baseline and three follow-up time points using the Mullen Scale of Early Learning up to three years of age. Utilising similar methodology, our research team are currently conducting a longitudinal high-risk birth cohort with movement being assessed from one month of age.

## Results:

Findings from our large-scale cohort studies have revealed that 26-35% of children on the autism spectrum have clinically significant motor impairment, a rate almost as common as intellectual impairment (29-37%). Even though motor impairment was a common clinical feature, it was not regularly reported (<1.5% cases reported). Motor impairment was more prevalent in children with intellectual impairment (40-52%,  $p<0.001$ ), but still common in those without intellectual impairment (20-29%). Motor impairment was a clinical feature that increases in severity with age and more prevalent in children meeting diagnostic criteria for impairments in non-verbal behaviour and presence of restricted and repetitive behaviours ( $p<0.001$ ).

Motor impairment was a clinical feature common in our infant cohort study. Gross motor impairment was more common (66%), but these resolved in two-thirds of infants at follow-up. Fine motor impairment was less common (30%) but more likely to persist. More than half of the infants with persistent fine motor impairment were classified in the moderate-to-high risk of autism.

## Conclusions:

Findings from our research highlight the need for further consideration of motor impairment within the diagnostic process for autism, along with the potential clinical value of including an evaluation of motor skills within early autism surveillance measures.

**227.002 (Panel) Quantitative Measures of Average and Peak Acceleration Differentiate Infants at High and Low Familial Risk for ASD and Are Related to Developmental Status.**

**R. B. Wilson<sup>1</sup>, M. Tsang<sup>2</sup>, B. Smith<sup>1</sup>, T. Safari<sup>1</sup> and D. Elashoff<sup>1</sup>, (1)UCLA Medical Center, Los Angeles, CA, (2)UCLA David Geffen School of Medicine, Los Angeles, CA, (3)University of Southern California, Los Angeles, CA**

---

## Background:

Motor development in the first year of life is fundamental in allowing an infant to 1) build environmental experiences that support cognitive skills, 2) develop a repertoire of complex motor behaviors through movement mistakes and achievements (Piaget, 1952). Impairments in motor development have been posited to be the first sign of atypical development in infants at high-risk for ASD (HR infants). Thus, there is interest in describing the nature of these impairments, which ones are predictive of developmental outcomes, and whether they are amenable to intervention. Quantitative measures of infant motor function may answer these questions by identifying subtle and specific motor impairments in early infancy. Lower movement acceleration has been described in infants at risk for developmental delays due to prematurity or white matter injury, and has been associated with poor locomotor, cognitive, and language outcomes. Thus, this movement feature could be a clinically relevant measure in HR infants.

## Objectives:

To utilize quantitative wearable sensors to identify motor differences in HR infants compared to low-risk (LR) infants, and to identify the relationship of motor activity to developmental domains.

## Methods:

Thirteen LR infants and 24 HR infants participated. HR infants had one older sibling with ASD. LR infants had no elevated concern for ASD. Full day quantitative measurement of spontaneous leg movements was obtained utilizing the wearable sensor at 3 and 6 months of age. Three quantitative features of the leg movement data were assessed: number of leg movements per hour awake and average and peak acceleration. Developmental status was measured at 3 & 6 months of age with the Mullen Scales of Early Learning (MSEL) subscales of gross motor (GM), fine motor (FM), and receptive and expressive language (RL, EL respectively).

#### Results:

There was no significant difference in average and peak acceleration at 3 months of age. At 6 months of age, HR infants showed significantly lower average and peak acceleration of leg movement compared to LR infants [both  $p=0.03$ ]. No difference was found in amount of leg movements between HR and LR infants at both ages. At 3 and 6 months, average acceleration showed a positive but not significant correlation with MSEL GM ( $p=0.08$ ), FM ( $p=0.06$ ), and RL ( $p=0.09$ ) and a significant correlation with EL ( $r=0.30, p=0.04$ ). At 3 and 6 months of age, peak acceleration showed a positive significant correlation with MSEL GM ( $r=0.30, p=0.04$ ), FM ( $r=0.31, p=0.03$ ), RL ( $r=0.30, p=0.04$ ), and EL ( $r=0.32, p=0.03$ ).

#### Conclusions:

Average and peak acceleration differentiated HR and LR infants at 6 months but not 3 months of age. These findings suggest variable motor skills by 6 months. Larger average and peak acceleration values were associated with higher GM, FM, RL and EL abilities. These findings support the hypotheses that quantitative measures of movement acceleration could be used for early identification of ASD, and higher acceleration is related to development of motor and language abilities in ASD. Further work is needed to determine whether acceleration could serve as a useful target for intervention or a marker of development.

**227.003 (Panel)** The Nature and Severity of Motor Impairment in a Large Sample of School-Age Children with Autism Spectrum Disorder (ASD): A SFARI-SPARK Dataset Analysis.

*A. Bhat, Department of Physical Therapy, University of Delaware, Newark, DE*

---

#### Background:

Eighty-seven percent of a large sample of children with Autism Spectrum Disorder (ASD) from the SFARI-SPARK study are at risk for motor impairment based on their performance on the Developmental Coordination Disorder Questionnaire (DCD-Q) (Bhat, 2020). In spite of the high prevalence for motor impairment in children with ASD, it is not considered among the diagnostic criteria or specifiers within DSM-V. The DSM-V provision of co-diagnosing motor impairment as DCD was only used in 15% of the children in this sample. In short, motor impairments in school-age children with ASD are under-recognized and remain unaddressed through a lack of motor screening, assessment, and intervention.

#### Objectives:

Three different analyses of the SFARI-SPARK dataset in school-age children with ASD were conducted to study the prevalence of risk for motor impairment and to conceptualize how motor impairments fit within the broader framework of ASD.

#### Methods:

The SFARI-SPARK study dataset ( $n=13,887$ ) was analyzed to examine associations between risk for motor impairment using the Developmental Coordination Disorder-Questionnaire (DCD-Q), social communication impairment using the Social Communication Questionnaire (SCQ), repetitive behavior severity using the Repetitive Behaviors Scale – Revised (RBS-R), and parent-reported current level of cognitive, functional, and language impairments (i.e., ASD specifiers). Next, I analyzed the subdomains of DCD-Q to determine whether gross-motor (visuomotor and multi-limb), fine-motor, or general coordination skills (e.g., moves quickly, fatigues easily, etc.) are better associated with ASD diagnostic criteria or specifiers. Third, I analyzed a subset of children with ASD in the SFARI-SPARK cohort ( $n=1477$ ) who completed both, the DCD-Q and the Purdue Pegboard Test (PPT) to relate DCD-Q data with motor performance on the PPT, a standardized test of bimanual dexterity.

#### Results:

Analysis shows that upon including children with ASD with cognitive impairments, 88.2% of the SPARK sample is at risk for motor impairment using the DCD-Q. The relative risk ratio for motor impairment in children with ASD was 22.2 times greater

compared to the risk in the general population (4%, Rivard et al., 2014) and that the risk for motor impairment further increased as a function of social communication (5.7), functional (6.2), cognitive (3.8), and language (1.6) impairments as well as repetitive behavior severity (5.0). Additionally, the magnitude/severity of risk for motor impairment (including fine- and gross-motor) increased as a function of all impairment types and their levels (i.e., social communication, cognition, language, function, and repetitive behaviors) with medium to large effects. The associations between the DCD-Q and PPT data are currently being analyzed and will be reported in the final presentation.

#### Conclusions:

These findings highlight the multisystem nature of ASD, the need to recognize motor impairments as one of the diagnostic criteria or specifiers for ASD, and the need for appropriate motor screening and assessment of children with ASD. ASD interventions must address not only the social communication and cognitive/behavioral challenges of children with ASD but also their motor function and participation (Kaur & Bhat, 2019; Srinivasan et al., 2015).

#### **227.004 (Panel) Age-Associations, Neural Correlates, and Familiarity of Atypical Sensorimotor Behaviors in ASD**

*M. W. Mosconi<sup>1</sup>, K. E. Unruh<sup>2</sup>, W. S. McKinney<sup>3</sup>, R. J. Lepping<sup>4</sup>, E. K. Bojanek<sup>4</sup>, S. E. Kelly<sup>5</sup>, L. Martin<sup>6</sup> and J. A. Sweeney<sup>7</sup>, (1)Clinical Child Psychology Program, Schiefelbusch Institute for Life Span Studies, University of Kansas, Lawrence, KS, (2)Kansas Center for Autism Research and Training (K-CART), University of Kansas, Lawrence, KS, (3)Hoglund Brain Imaging Center, University of Kansas, Kansas City, KS, (4)Clinical Child Psychology Program, Schiefelbusch Institute for Life Span Studies, Kansas Center for Autism Research and Training (K-CART), University of Kansas, Lawrence, KS, (5)Kansas Center for Autism Research and Training (K-CART), University of Kansas, Lawrence, KS, (6)Hoglund Brain Imaging Center, University of Kansas Medical Center, Kansas City, KS, (7)Psychiatry and Behavioral Neuroscience, University of Cincinnati College of Medicine, Cincinnati, OH*

---

#### Background:

Individuals with ASD frequently demonstrate sensorimotor issues, and these issues may be central to the disorder(s). The nature and severity of sensorimotor issues vary considerably across individuals, however, suggesting that determination of their primacy to ASD requires analysis of multiple different behaviors and their relation to key clinical and demographic characteristics. To better understand the role of sensorimotor behaviors in core pathophysiological processes of ASD, neural mechanisms also must be defined, as well as their heritability.

#### Objectives:

This talk has two objectives: 1) To characterize age and clinical associations of multiple different sensorimotor behaviors in ASD, and; 2) To describe neural correlates and familial mechanisms of sensorimotor issues with the goal of informing understanding of pathophysiology.

#### Methods:

Three sets of studies will be presented. In study 1 (behavioral study), 109 individuals with ASD and 101 age-(range: 5-35 years) and sex- matched typically developing (TD) controls completed tests of precision gripping force and visually guided saccadic eye movements. Grip force variability and saccade accuracy were examined. In study 2 (fMRI study), 41 individuals with ASD and 28 matched controls completed two functional magnetic resonance imaging (fMRI) runs while performing a test of precision gripping force with their right (run 1) and left hands (run 2). In study 3 (family study), 105 unaffected parents of individuals with ASD and their children (41 trios) as well as 78 age-, sex-, and IQ-matched TD controls completed tests of precision gripping force and visually guided saccades.

#### Results:

In our behavioral study, individuals with ASD showed increased gripping force variability and reduced saccade accuracy compared to controls. Differences in gripping force variability were more severe at younger ages for individuals with ASD, whereas reductions in saccade accuracy were more severe at older ages in ASD. Both grip force variability and saccade accuracy were associated with clinically rated social-communication symptom severity. During the fMRI study, individuals with ASD showed greater activation than controls in contralateral motor cortex (M1) during right-hand gripping, but reduced contralateral M1 and ipsilateral cerebellar activation during left-hand gripping. Results from our family study indicated that, similar to individuals with ASD, parents of individuals with ASD show increased gripping force variability and reduced saccade accuracy.

## Conclusions:

We found that individuals with ASD demonstrate both precision manual and oculomotor issues, but these issues show distinct age associations implicating separate neurodevelopmental processes. Imaging results indicate neural correlates for right and left hand gripping are different suggesting different brain alterations for dominant and nondominant hand movements. Our family study demonstrates that sensorimotor issues in ASD also are evident in unaffected parents, and their impairment is related to that of their affected offspring. We consistently find moderate associations between different sensorimotor issues and core ASD symptoms suggesting they are interrelated aspects of neurodevelopmental mechanisms in ASD.

## ORAL SESSION — SENSORY, MOTOR, AND REPETITIVE BEHAVIORS AND INTERESTS

### Oral 321 - Developmental Patterns and Subgroups

**321.001** (Oral) Comprehensive Assessment of Visual Perceptual Skills in Autism Spectrum Disorder  
*A. DiCriscio, J. Smith and V. Troiani, Geisinger Autism & Developmental Medicine Institute, Lewisburg, PA*

**Background:** Previous studies have demonstrated a perceptual bias to local vs. global features in individuals with autism spectrum disorder (ASD); however, results across this area of research are mixed and suggest that a local bias may not be present in all individuals with ASD across all contexts. Current methods commonly utilize paradigms that specifically assess local/global processing (i.e. Navon figures, embedded figures) and little is known regarding performance of individuals with ASD on standardized tests of visual perception. Previous studies have found that individual differences in autism-like traits in the general population were associated with improved performance on the Test of Visual Perceptual Skill Figure-Ground (TVPS-FG) subtest, which requires an individual to locate a smaller figure within a larger, more complex figure (See Figure 1A).

**Objectives:** The purpose of this study was to assess variability in visual perceptual skills using all 7 TVPS subtests, a standardized assessment of visual perception, across children with and without ASD.

**Methods:** Children with (n=48) and without (n=39) ASD completed the 7 subtests of the TVPS. Children were evaluated for ASD by clinicians that specialize in ASD assessment; IQ assessments were also included at the time of testing. ASD symptoms were additionally quantified in children via parent-report on the Broader Autism Phenotype Questionnaire (BAP-Q). We assessed performance across subscales of the TVPS, item-level response variability, and the linear relationship of these metrics with quantitative measures of ASD symptoms. Stimuli across the TVPS subtests are presented in a specified order, with each consecutive trial increasing in difficulty relative to the previous stimulus/trial. We computed a response dispersion index (RDI) that quantifies variability by weighting each stimulus according to its difficulty, with stimuli earlier in the test weighted more than those later in the test. An RDI for each subtest is then calculated by summing the weight of items missed for each individual, with lower RDI scores reflecting more efficient/less variable responses.

**Results:** Children with ASD did not demonstrate better overall performance on any of the 7 TVPS subtests compared to children without ASD, including the TVPS-FG subtest (see Figure 1B). However, when examining individual differences in autism traits, we find that higher BAP-Q scores are associated with better performance on the TVPS-FG subtest. Performance on the TVPS-FG improved as autism traits increased ( $p=0.003$ ; See Figure 1C), an effect that was specific to this subtest. Additionally, results of our item-based analysis indicate a significant relationship between RDI scores on the TVPS-FG and BAP-Q scores, with less variable response patterns being associated with increased ASD symptoms.

**Conclusions:** Results reported here emphasize the need for quantitative assessment of autism traits and may explain why findings regarding a local bias in ASD are mixed, as they may be influenced by the trait distribution of a given sample of participants. We show that the TVPS-FG captures important visual perceptual differences that are associated with the presence of autism traits using both overall and item-level performance metrics. Further, this work provides normative TVPS data in the largest ASD cohort to date.

**321.002** (Oral) Measurement of Subcategories of Restricted and Repetitive Behaviors across Age and Intellectual Functioning in a Large ASD Sample

---

**Background:** Restricted and repetitive behaviors (RRBs) comprise a diverse set of behaviors from repetitive sensory motor behaviors (RSMB) to ritualized and rigid behaviors, restricted or circumscribed interests, commonly referred to as insistence on sameness (IS). The Repetitive Behavior Scale-Revised (RBS-R) is one of the most commonly used parent/caregiver-reported measures of RRBs in individuals with Autism Spectrum Disorder (ASD). Despite its widespread use in clinical, neurobiological and genetic research, as well as in clinical practice, studies on the measurement structure of the RBS-R have produced inconsistent findings, impeding progress in the conceptualization and measurement of RRBs in ASD.

**Objectives:** Here we present a comprehensive approach to determine the factor structure of the RBS-R in a large pooled ASD sample using Multidimensional Item Response Theory (MIRT). The size of this sample allowed -- for the first time -- age- and IQ-stratified analyses to assess the scale structure across developmental stages and levels of intellectual functioning. We also assessed the implications of the scale structure through clinical trial simulations to inform intervention designs and endpoint selection.

**Methods:** Item-level data on 3,430 clinically-diagnosed individuals with ASD (519 females, 2,911 males) was combined from four data sources. Children with  $IQ \geq 70$  formed the largest group, ( $N=1,860$ ; Mean age=10.9,  $SD=5.7$ ). The average IQ of the total sample was 89 ( $SD=24$ ; IQ range 12-167). The MIRT analysis was split into four parts. First, the dimensionality of the data was established through an exploratory MIRT using the strata with the highest sample size (children with  $IQ \geq 70$ ). Next, a hierarchical cluster analysis was performed to identify the number of substantive components (i.e. latent factors) that were supported by the data. Third, deviations in structure were assessed in smaller groups stratified by age and IQ. For clinical trial simulations, we calculated power vs. sample size curves using model-based delta and SD of change from baseline scores assuming an effect on only one of the constructs identified (normalized effect size=0.3).

**Results:** We identified a 3-factor solution, comprising repetitive sensory motor behaviors (RSMB), insistence on sameness (IS) behaviors, and self-injurious (SI) behaviors. This structure was broadly consistent across different ages, from children compared to adolescents and adults (all  $IQ \geq 70$ ), and across levels of IQ (comparing  $IQ \geq 70$  vs.  $< 70$ ). While factor correlations between RSMB and IS behaviors were similarly high across different age and IQ strata (all  $r$ 's  $< .5$ ), the strength of association between SI and IS/RSMB factors showed more variability, from low to moderate, across IQ/age comparisons. Clinical trial simulations indicated that using all RBS-R items yields higher power to using effect-specific item subsets, particularly for RSMB and SI, but not IS behaviors.

**Conclusions:** Using the largest sample to date, we confirmed a 3-factor solution of the RBS-R that is consistent across age and levels of IQ. The results therefore support meaningful comparisons in the factors identified across different sub-populations (i.e. age and IQ). Our clinical trial simulations instruct the use of RBS-R total scores, rather than subscale-specific scores, as a clinical endpoint to maximize power to detect a treatment effect.

**321.003 (Oral)** Sensory Features and Associations in the Autism and Developmental Disabilities Monitoring Network, 2006–2014

A. V. Kirby<sup>1</sup>, D. A. Bilder<sup>2</sup>, J. Davis<sup>3</sup>, L. Wiggins<sup>4</sup>, M. M. Hughes<sup>5</sup>, J. A. Hall-Lande<sup>6</sup>, L. C. Lee<sup>6</sup>, C. Kingsbury<sup>7</sup>, W. M. McMahon<sup>2</sup> and A. V. Bakian<sup>2</sup>, (1)University of Utah College of Health, Salt Lake City, UT, (2)Psychiatry, University of Utah, Salt Lake City, UT, (3)Educational Psychology, University of Utah, Salt Lake City, UT, (4)Centers for Disease Control and Prevention, Atlanta, GA, (5)UCEDD, University of MN, Minneapolis, MN, (6)Department of Epidemiology, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, (7)Children with Special Health Care Needs, Utah Department of Health, Salt Lake City, UT

---

Background: Sensory features are highly prevalent among autistic children and include over- and under-responsivity to sensations as well as unusual or repetitive sensory interests. Existing literature suggests sensory features may be present in 54–94% of autistic children (Baranek et al., 2006; Jussila et al., 2019; Tomchek & Dunn, 2007), yet most studies use clinical or

convenience samples which may have limited generalizability. Studies also show associations between sensory features and problems in daily activities including sleeping and eating (Mazurek & Petroski, 2015; Mazurek et al., 2013). Studies from larger and more diverse samples are needed to expand our understanding of sensory features among autistic children.

**Objectives:** The objectives of this study are to use a population-based sample of children from the Autism and Developmental Disabilities Monitoring Network (ADDM) to determine the prevalence of sensory-related features among autistic children, examine differences in sensory features by demographic and functional characteristics, and explore relationships between sensory features and abnormalities in eating and sleeping.

**Methods:** We used data from the ADDM Network for study years 2006–2014, including cohorts of 4-year-old (N=2,915) and 8-year-old (N=22,717) autistic children identified at surveillance sites in the United States. The outcome variable of sensory features was captured through expert review of developmental evaluations in clinical and educational records and described as “odd responses to sensory stimuli.” We first calculated the prevalence of sensory features, with 95% confidence interval (CI) for the sample. We applied multi-level logistic regression modeling (accounting for study year and study site) to examine associations of demographic (age, sex, race/ethnicity, maternal education) and functional variables (cognition, adaptive behavior) with the presence/absence of sensory features. Finally, we examined associations of sensory features with the presence/absence of eating/drinking and sleeping problems, accounting for demographic and functional variables.

**Results:** The sample was 82% male and 55% White, non-Hispanic. The majority (74%; CI: 73.5-74.5%) of the children studied had documented presence of sensory features in their record. Full regression models included 8,442 children, due to missing data. Age of the cohort was not associated with sensory features, but male and White, Non-Hispanic children were more likely to have documented sensory features (Table 1). Children of mothers with >12 years of education and children with adaptive behavior standard scores ≤70 were also more likely to have documented sensory features (Table 1). Children with the presence of sensory features were approximately two or more times more likely to have eating/drinking and sleeping problems (Table 2).

**Conclusions:** Our results from a large, population-based sample support existing literature suggesting a high prevalence of sensory features in autistic children, as well as relationships among sensory features and eating/drinking and sleeping problems. However, they also suggest potential disparities in the documentation of sensory features, which may correspond with reduced access to supports for sensory features and related functional and health problems. Although the ADDM data do not capture a standardized sensory measure, these analyses complement and reinforce knowledge about the presence and impacts of sensory features among autistic children and offer avenues for future research.

### **321.004 (Oral) Developmental Trajectories of Sensory Patterns from Infancy to School Age in Children with ASD and Non-ASD Conditions**

**Y. J. Chen<sup>1</sup>, J. Sideris<sup>1</sup>, L. R. Watson<sup>2</sup>, E. Crais<sup>2</sup> and G. T. Baranek<sup>1</sup>,** (1)Chan Division of Occupational Science and Occupational Therapy, University of Southern California, Los Angeles, CA, (2)Department of Allied Health Sciences, University of North Carolina at Chapel Hill, Chapel Hill, NC

**Background:** Past research has demonstrated the early emergence of atypical sensory patterns (e.g., hyper/hypo-reactivity) in infants at-risk for ASD, and their potential utility in predicting ASD outcomes. Whereas previous findings highlighted the cross-sectional differences of sensory patterns across age and clinical groups, there is less research on their longitudinal changes from infancy to school age as differentially related to ASD or other clinical outcomes. More systematic investigations are needed to better understand the development of sensory patterns and heterogeneous outcomes in infants at-risk for ASD among a general population.

**Objectives:** This study aimed to identify developmental trajectories of sensory patterns, which include hyper-responsiveness (HYPER), hypo-responsiveness (HYPO), and sensory interests, repetitions and seeking behaviors (SIRS), from 1 to 6 years of age in a community sample, and to determine their associations with diagnostic outcomes and the effects of demographic factors.

**Methods:** This study used a longitudinal design with person-based analytic approaches. A large community sample of infants (N=1,517) was recruited through the state birth registry. Caregivers completed surveys regarding their child’s sensory patterns and other developmental concerns during infancy (6-19 months; Time1), pre-school years (3-4 years; Time2), and school years (6-7 years; Time3). Sensory patterns were measured by items extracted from the First Years Inventory-v3.1 at Time1 and the Sensory Experiences Questionnaire (SEQ)-v2.1 at Time2 and Time3. Children were classified into four clinical groups – ASD; sensory processing disorder (SPD) and/or sensory-related concerns; other non-ASD/SPD diagnosis/concerns (OD); and no diagnosis/concerns (ND) – based on the Developmental Concerns Questionnaire, Social Responsiveness Scale-2 and SEQ collected at Time2 and Time3. Longitudinally comparable scores of HYPER, HYPO and SIRS based on item-response theory

were included as indicators for multivariate latent growth curve modeling (LGCM). Child's sex, race, and parents' education levels were included as predictors of latent growth factors.

Results: Linear LGCM (CFI=.98, TLI=.96, RMSEA=.035) indicated highly variable trajectories of sensory patterns over early childhood in this community sample. HYPER and SIRS decreased while HYPO increased as mean trends. Child's sex and race were respectively significant predictors of the initial levels of HYPO and SIRS. Parents' education levels predicted the slopes of HYPER and HYPO, and initial levels of HYPO and SIRS ( $p$  all < .01, Figure1). The slopes of HYPO and HYPER were highly associated with autism severity at age 6 ( $r$  = .54 to .55,  $p$  < .0001). The trajectories by clinical group revealed differential patterns across children with ASD and non-ASD conditions (Figure2). The slope of HYPER seemed to best differentiate ASD from other clinical outcomes.

Conclusions: These results demonstrated the heterogeneous nature of sensory patterns from early infancy to school age, and the differential associations of sensory trajectories to specific clinical outcomes among a community sample. The change in hyperresponsiveness across this period had particular utility for differentiating ASD versus non-ASD groups, which may have implications for early intervention. Parents' education levels (relative to child's sex and race) accounted for more of the variability in sensory trajectories. Intervention strategies specifically addressing infant's sensory behaviors over time, with tailored family approaches, should be considered in future research.

## POSTER SESSION — SENSORY, MOTOR, AND REPETITIVE BEHAVIORS AND INTERESTS

### Poster 441 - Sensory, Motor, and Repetitive Behaviors and Interests Posters

**441.001** (Poster) A Comparison of Restricted Interests in Toddlers with Autism, Developmental Delay, and No Delay  
*M. Frisch<sup>1</sup>, K. L. Coulter<sup>1</sup>, R. P. Thomas<sup>1</sup>, M. Barton<sup>1</sup>, D. L. Robins<sup>2</sup> and D. A. Fein<sup>1</sup>, (1)Psychological Sciences, University of Connecticut, Storrs, CT, (2)A.J. Drexel Autism Institute, Drexel University, Philadelphia, PA*

Background: Restricted interests are a symptom of autism spectrum disorders (ASD) and individuals with ASD may show preferential attention to objects, over the social world (Baron-Cohen & Wheelwright, 1999). Parents of children with ASD more frequently endorse the presence of restricted interests than their developmentally delayed (DD) peers on the Repetitive Behavior Scale- Revised (Joseph et al., 2013). Studies of school-age children and adults indicate that compared to typically developing (TD) peers, the restricted interests of individuals with ASD differ in nature and intensity (Gutermuth Anthony et al., 2013; Turner-Brown et al., 2011). Categorizations of specific interests in ASD exist; however, no empirical work has examined the specific interests that are common in toddler age children with ASD.

Objectives: This analysis aims to understand the specific restricted interests of toddlers with ASD, compared to toddlers with DD, and TD.

Methods: Participants were parents of 294 toddlers age 12-36 months ( $M$  = 19.20) who received a developmental/diagnostic evaluation due to a positive screener or pediatrician concern. Of these, 72 children were diagnosed with ASD; 131 were DD, and 91 were TD. The TASI, a semi-structured interview (Coulter et al.), was used to elicit caregiver report of the child's behavior. Caregivers responded to two questions about their child's restricted interests: "Is there anything that your child seems interested in that seems like all he/she wants to do?" and "Does your child enjoy carrying around or playing with items that differ from most children his/her age?" and described endorsed interests. Categories of restricted interest were developed drawing from previous coding schemes (Baron-Cohen & Wheelwright, 1999; DeLoache et al., 2007; Klin et al., 2007) and examination of the current data set (Table 1). Each interest category was coded as "endorsed" or "not endorsed" for each respondent. Interests that fit in multiple categories were endorsed for both categories. Sensory interests not tied to a specific object were excluded from analysis (e.g., interest in "loud noises" was excluded, an interest in "vacuum cleaner noises" was included).

Results: Overall, the ASD group endorsed significantly greater frequency of restricted interests (79%) compared to the DD (36%) and TD (33%) groups. Across all groups, the highest endorsed category was household objects (e.g., spoons, keys). Chi-square tests revealed more frequent interests in vehicles,  $X^2(2, 294) = 12.76, p = .0017$ , and household objects,  $X^2(2, 294) = 31.22, p < .0001$ , within the ASD group compared to the other groups (Table 2). No other significant differences were found.

Conclusions: Restricted interests are present in children with DD and TD diagnoses but are significantly more common in toddlers diagnosed with ASD. Specifically, toddlers with ASD display greater interest in vehicles and household objects compared to DD and TD peers. However, there is little qualitative difference between the restricted interests of diagnostic groups, suggesting that a singular interest is common in young children and may not indicate risk for ASD. Future research

should explore differences in engagement with objects of interest and the longitudinal persistence of the interest across diagnostic groups.

**441.002** (*Poster*) A Cultural Comparison of the Latent Structure of Autistic Traits and Sensory Sensitivities in Typically Developing Populations

*E. J. Millington and D. R. Simmons, School of Psychology, University of Glasgow, Glasgow, United Kingdom*

---

**Background:**

There is considerable heterogeneity in the phenotype of autism within both the clinical and typically developing populations. This heterogeneity is similarly expressed in sensory experiences, with notable variation between modalities. It is known that there are also cultural variations in the presentation of autism. When these variations are confirmed by standard questionnaires, it is unclear if the results are real or represent differing translations and practices.

**Objectives:**

The aim of this exploratory analysis was to investigate the latent structure of autistic traits and sensory sensitivities, especially whether they are better represented as a continuum or separate groups, and if these structures are common between cultures.

**Methods:**

Researchers with published papers using the Autism Spectrum Quotient (AQ) and Glasgow Sensory Questionnaire (GSQ), measures of autistic traits and sensory sensitivities respectively, were asked to share their datasets. When combined with unpublished data from our lab, the final sample contained 2814 participants living in China, Japan, and the UK, as well as other unknown English-speaking countries.

**Results:**

The first analysis used a Gaussian graphical model to estimate the network of connections between the subscales of the two questionnaires. This showed autistic traits and sensory sensitivities forming two connected but distinct clusters of traits. The notable exception to this was the “attention-to-detail” subscale which was only loosely related to both clusters. Country-level analyses suggested that this network structure applied to all countries.

The second analysis used a Factor Mixture Model to explore the latent factors and groups using all items and participants. The best-fitting model found three groups based on ten factors, with each of the groups near-perfectly corresponding to the participants’ resident country. As expected, the strongest factor represented the autistic phenotype with strong, positive loadings on nearly every item, while the second factor loaded onto items from the GSQ. The subsequent factors were more unusual, with two factors loading onto attention-to-detail and a factor with strong loadings on a variety of items which appear to be culturally specific.

**Conclusions:**

This exploratory study suggests that the interactions between different autistic traits and sensory experiences are consistent between the countries studied. The factor and network structures both suggest three significant dimensions: autistic traits, sensory sensitivities, and attention. At the same time, countries formed their own distinguishable distributions on the measures. This means that scores of individual participants in different countries are not directly comparable. This result is also not necessarily evidence of replicable cultural differences, as subsequent analysis finds that the most notable items have slightly different translations. However, it does indicate that previous research comparing simple means on these questionnaires should be treated with some scepticism.

The size of the difference between the countries meant that the Factor Mixture Model was not sensitive enough to pick up smaller groupings which have previously been identified. While global in nature, the participants were also largely recruited from populations adjacent to the researchers’ universities, so the findings may not be universal.

**441.003** (*Poster*) A Network Analysis of Repetitive Thinking in Autistic Adults

**Background:** While repetitive behaviors are widely studied in autism and considered a core feature of the condition, much less work has been conducted to understand repetitive thinking in autistic people. Passive, repetitive negative thinking (rumination) is robustly associated with the onset of depressive disorders in non-autistic individuals, and preliminary work has suggested that increased rumination may contribute to the higher rates of depression seen in the autistic population.

**Objectives:** We used network analysis to examine the correlational structure of repetitive thinking based on a novel survey battery curated from multiple relevant self-report instruments. We aimed to identify particularly influential symptoms and compare network structures between subgroups of autistic individuals.

**Methods:**  $N=762$  autistic adults ( $M_{Age} = 30.90$  years, 54.4% Female, 10.1% non-binary, 79.5% non-Hispanic White) were recruited from the Simons Foundation's SPARK database (Feliciano et al., 2018). These individuals completed an online survey battery including 58 Likert items drawn from forms such as the Analytical Rumination Questionnaire, Perseverative Thinking Questionnaire, and Negative Event Rumination and Reflection Questionnaire. A regularized partial correlation network then was computed using the graphical LASSO to estimate the functional relations among these items. After combining redundant items into single nodes, we examined the community structure of the network using the walktrap algorithm. Node centrality (i.e., how strongly a specific node is connected to the remainder of nodes in the network) was quantified using one-step expected influence. Permutation tests were used to compare network structures between birth-assigned sex and groups based on age of autism diagnosis (before or after age 18).

**Results:** After node reduction, a total of 39 nodes were included in the exploratory network (Table 1). The walktrap algorithm grouped these nodes into four communities (Figure 1), which we interpreted as (1) General Negative Repetitive Thinking (brooding, worry, and perseveration), (2) Perceived Positive Benefit / Positive Repetitive Thoughts, (3) Adaptive Responses/Positive Reframing, and (4) Obsessive-Compulsive Thinking Patterns. The nodes with the highest expected influence included (a) reviewing past events to make sure one did not do anything wrong (*review*), (b) intrusive thoughts (*ies.intr*), and (c) repetitive thinking about negative events (*mnt*). A case-dropping bootstrap procedure indicated that one-step expected influence estimates were highly stable ( $CS = 0.778$ ). Additionally, permutation tests found no significant differences in overall network structure or global strength values between groups based on gender or age of diagnosis ( $ps > 0.420$ ).

**Conclusions:** Repetitive cognition in autistic adults is composed of several symptom clusters, each of which may be uniquely related to psychopathology in this population. Of the cognitive patterns operationalizing this construct, those most influential ("central") to the structure of the network included searching for errors in past events, experiencing thoughts as intrusive, and responding to negative events with repetitive thoughts. Although node centrality does not itself guarantee that a symptom is a meaningful intervention target, future work in this area should determine whether interventions targeting these central repetitive thinking constructs are effective in reducing the burden of depression and other psychopathology in the autistic population.

**441.004 (Poster)** A Prospective Perception-Action Strategy in Children with Autism during Smart-Tablet Gameplay  
**S. C. Lu<sup>1</sup>**, **D. Lee<sup>2</sup>**, **A. Anzulewicz<sup>3</sup>**, **K. Sobota<sup>4</sup>**, **P. Rowe<sup>5</sup>**, **C. Tachtatzis<sup>6</sup>**, **I. Andonovic<sup>6</sup>** and **J. Delafield-Butt<sup>1</sup>**, (1)Laboratory for Innovation in Autism, University of Strathclyde, Glasgow, United Kingdom, (2)University of Edinburgh, Edinburgh, United Kingdom, (3)Faculty of Psychology, University of Warsaw, Warsaw, Poland, (4)Harimata Sp. z.o.o., Kraków, Poland, (5)Department of Biomedical Engineering, University of Strathclyde, Glasgow, United Kingdom, (6)Department of Electronic and Electrical Engineering, University of Strathclyde, Glasgow, United Kingdom

---

**Background:** Motor differences between children with autism spectrum disorders (ASD) and those with typical development (TD) have been identified in various activities such as pointing (Torres et al., 2013) and placing (Crippa et al., 2014). Kinematic differences have also been observed in goal-oriented swipe kinematics during smart-tablet gameplay (Lu et al., 2019, 2020). General Tau Theory has been used to describe goal-oriented perception-action strategies (Lee, 2009), which proposes an intrinsic action guide generated by the nervous system coupled to the motor command to guide the physical movement. The coupling constant between the two is assumed to be set by the brain to coordinate the kinematic profile of the goal-oriented action. Here, an exploration to surface a potential difference in the tau-coupling during smart-tablet gameplay in children with ASD is presented.

**Objectives:** To test whether or not the perception-action strategy employed by children with and without ASD differ during goal-oriented swipes in smart-tablet gameplay.

**Methods:** Goal-oriented swipe data were extracted from a study of smart-tablet gameplay for young children (Anzulewicz et al., 2016). Only those swipes that proceeded directly from start to finish without overshooting the target were included. A total of 500 swipes were obtained from 32 children with ASD (aged 33-79 months), and 1426 swipes were obtained from 44 children with TD (aged 36-74 months). The percentage of tau-coupling in each swipe, its duration and distance, and the tau-coupling constant were determined utilising the time and x- and y-coordinates data.

**Results:** Children with ASD demonstrated  $97.90 \pm 10.49$  (mean  $\pm$  SD) % while children with TD demonstrated  $98.98 \pm 7.54$  % of tau-coupling movement, indicating a significantly weakening (t-test,  $p = 0.01$ ) and more variable (F-test,  $p < 0.01$ ) tau-coupling pattern in children with ASD. The coupling constant was  $0.40 \pm 0.93$  for the ASD group and  $0.41 \pm 0.15$  for the TD group. Children with ASD demonstrated a significantly wider range of the coupling constant than children with TD (F-test,  $p < 0.01$ ) while the mean values were similar.

**Conclusions:** The findings indicate that, in comparison to children with TD, children with ASD demonstrated significantly less tau-coupling with higher variability during swipes whilst engaging in smart-tablet gameplay. It should be noted that the coupling constant in ASD was significantly more variable, however, the mean value was similar to what was observed in TD. The results of the coupling constant imply that, for the overall movement, children with ASD and TD used similar strategies to perform the goal-oriented swipes while greater fluctuations were observed in ASD. These findings are consistent with previous reports indicating that individuals with ASD have difficulties in controlling goal-oriented movement efficiently with increased subsecond motor variability during the travel of the movement (Torres et al., 2013). Increased acceleration and jerk amplitudes noted in adults with ASD (Cook et al., 2013) suggests sensorimotor and timing are disrupted at the level of the brainstem integration (Delafield-Butt & Trevarthen, 2017). Therefore, disruption to efficient perception-action regulation by tau-coupling might be a critical motor disruption in ASD.

#### **441.005 (Poster) Adaptive Behaviors Predicted By Sensory Profiles in Toddlers at-Risk for Autism**

**E. Worthley<sup>1</sup>, R. Grzadzinski<sup>2</sup>, K. Botteron<sup>3</sup>, S. R. Dager<sup>4</sup>, A. M. Estes<sup>5</sup>, H. C. Hazlett<sup>6</sup>, R. T. Schultz<sup>7</sup>, L. Zwaigenbaum<sup>8</sup>, J. Piven<sup>9</sup>, J. J. Wolff<sup>10</sup> and .. The IBIS Network<sup>10</sup>,** (1)University of Minnesota, Minneapolis, MN, (2)University of North Carolina Chapel Hill, Chapel Hill, NC, (3)Washington University School of Medicine, St. Louis, MO, (4)Radiology, University of Washington, Seattle, WA, (5)Speech and Hearing Sciences, University of Washington, Seattle, WA, (6)\*co-senior author, University of North Carolina, Chapel Hill, NC, (7)Center for Autism Research, Children's Hospital of Philadelphia, Philadelphia, PA, (8)University of Alberta, Edmonton, AB, Canada, (9)\*Co-senior author, University of North Carolina, Chapel Hill, NC, (10)University of North Carolina, Chapel Hill, NC

**Background:** Atypical sensory responsivity is prevalent and problematic for children with autism and may have cascading developmental effects, particularly concerning deficits in adaptive behavior development (Lane et al., 2010; Liss et al., 2006). Previous work has shown that elevated sensory profiles (i.e. hypo, hyper, and seeking) have been shown to predict later adaptive behavior skills in elementary school aged children with ASD (Williams et al., 2018) What is not yet known is whether these findings generalize to infants and toddlers with ASD.

**Objectives:** The objective of the current study was to determine to what extent sensory profiles predict adaptive behaviors among infants and toddlers at high risk for developing ASD.

**Methods:** Data were collected as part of an ongoing longitudinal study of high-risk infant siblings. Of the high-risk sibling group ( $n=215$ ), 59 toddlers received an ASD diagnosis based on clinical best estimate at 3 years of age (HR-ASD). This study analyzed parent report data on sensory responsivity, collected at 12 months of age (Sensory Experiences Questionnaire; SEQ 2.1) and a semi-structured assessment of adaptive behavior collected at 36 months of age (Vineland Adaptive Behavior Scales; Vineland-II). A series of multiple linear regressions were computed using sensory profiles (hyperresponsivity, hyporesponsivity, and sensory seeking) to predict adaptive behaviors (communication, socialization, daily living skills, and motor skills). Other model variables included sex and an IQ proxy (Mullen Early Learning Composite; MSEL-ELC).

**Results:** We found significant negative main effects of hyperresponsivity, hyporesponsivity, and sensory seeking scores at 12 months of age on socialization at 36 months of age ( $\beta_{hyper} = -9.32, p < .001$ ;  $\beta_{hypo} = -4.38, p = .012$ ;  $\beta_{seeking} = -4.33, p = .003$ ). Autism diagnosis, MSEL-ELC and sex also had significant negative main effects on socialization. We also found significant negative main effects of hyper- and hyporesponsivity on communication ( $\beta_{hyper} = -5.22, p = .021$ ;  $\beta_{hypo} = -4.09, p = .016$ ). We found significant negative main effects of hyperresponsivity and sensory seeking on motor skills in which ASD diagnosis had an additional negative main effect in the sensory seeking model ( $\beta_{hyper} = -5.38, p = .011$ ;  $\beta_{seeking} = -2.85, p = .037$ ). Lastly, sensory seeking had a significant negative main effect on daily living skills ( $\beta_{seeking} = -2.77, p = .038$ ).

**Conclusions:** Results suggest that the predictive relation of sensory profiles with later adaptive function reported in school-age children with ASD extends to familial high-risk infants later diagnosed with ASD. Given that early sensory symptoms influenced

adaptive function in the HR group as a whole suggests that extreme sensory responsivity may have implications for the broader autism phenotype. In particular, sensory hyporesponsivity in late infancy was strongly related to socialization ability at preschool age. These results suggest that early differences in sensory responsivity could have downstream developmental consequences related to social development and communication, though further research is necessary to explore this possibility (Baranek et al., 2018). If a causal link between early sensory responsivity and adaptive behavior development is found, it would have potentially important implications for early intervention.

**441.006** (Poster) Altered Salience Processing during Visual Exploration in Autism Spectrum Disorder

*N. Bast<sup>1</sup>, L. Poustka<sup>2</sup>, T. Banaschewski<sup>3</sup> and C. M. Freitag<sup>4</sup>, (1)Department of Child and Adolescent Psychiatry and Psychotherapy, University Hospital Frankfurt, Frankfurt, Germany, (2)Child and Adolescent Psychiatry and Psychotherapy, University Medical Center Goettingen, Goettingen, Germany, (3)Department of Child and Adolescent Psychiatry, Central Institute of Mental Health, University of Heidelberg, Mannheim, Germany, (4)Autism Research and Intervention Center of Excellence Frankfurt, Department of Child and Adolescent Psychiatry, Psychosomatics and Psychotherapy, University Hospital Frankfurt, Goethe University, Frankfurt, Germany*

---

**Background:** Reduced attention to social stimuli is a well-replicated in Autism Spectrum Disorder (ASD). This altered visual exploration has been explained by reduced social motivation (top-down approach), although neurobiological evidence is conflicting. An alternative explanation suggested cognitive research with altered profiles of salience processing in ASD (bottom-up approach). Salience describes aspects that stand out from the sensory input stream. The activity of the Locus Coeruleus Norepinephrine (LC-NE) System modulates salience processing via neuronal regulation of sensory selectivity and can be measured by pupillary responses. It remains to be explored whether altered salience processing in ASD translates from cognitive research to visual exploration of dynamic scenes, which typically evoke attenuated social attention.

**Objectives:** Quantify salience processing during visual exploration of dynamic scenes in ASD compared to neurotypically-developed controls (NTC).

**Methods:** We presented 9 movie clips and recorded eye tracking in a sample of participants with ASD (n=164) and NTC (n=164) that were matched for age ([m/SD]; ASD: 16.2y/5.6y, NTC: 16.5y/6.0y), IQ (ASD: 102.1/18.1, NTC: 105.2/16.9), and gender distribution ([female/male]; ASD: 42/122, NTC: 53/111). Movie clips were segmented based on camera cuts into 98 dynamic scenes. The first 8 seconds (i.e. median scene duration) of each scene were analysed. We applied validated computational models of visual attention to estimate two salience maps for each scene frame: Low-level salience (colour, contrast, contour) was computed by the spectral residual approach (Hou & Zhang, 2007), motion salience was computed by the Gaussian mixture-based segmentation model (Zivkovic, 2004) (see figure). Pupillary reactivity was applied as measure of sensory selectivity and related to temporal profiles of corresponding gaze salience. We estimated linear mixed models in a per-trial analysis between groups.

**Results:** Pupillary reactivity during gaze behavior increased with higher low-level and motion salience across groups, which indicated that sensory selectivity was sensitive to low-level and motion salience. Interestingly, the temporal profiles of this association significantly differed between groups: In NTC, pupillary response over time was negatively associated with salience. In ASD, pupillary responses over time was – in contrast – positively associated with salience (see figure).

**Conclusions:** This is the first empirical study to quantify salience processing during dynamic social scenes in ASD compared to NTC. We found different temporal profiles of pupillary reactivity to computational models of salience that indicate different salience processing between groups: In NTC, the sensory selectivity to salience decreases over the course of a scene, where in ASD, the sensory selectivity to salience increases over the course of a scene. We conclude that ASD visual exploration of dynamic scenes is associated with increased sensory selectivity to low-level and motion salience. This might impair sensory selectivity to semantic salience (e.g.: objects, people) and underly attenuated social attention.

Our findings will be extended by an area-of-interests analysis in the coming months and thus we will be able to relate low-level and motion salience processing to social attention during visual exploration.

**441.007** (Poster) An Analysis of Gender Differences in Autism Spectrum Disorder Diagnostic Symptom Presentation in a Tertiary Care Clinic

*J. J. Cottle<sup>1</sup>, Z. E. Arnold<sup>2</sup>, H. K. Root<sup>3</sup>, K. C. Guest<sup>4</sup> and S. E. O'Kelley<sup>1</sup>, (1)Psychology, The University of Alabama at Birmingham, Birmingham, AL, (2)Department of Psychiatry, Rush University Medical Center, Chicago, IL, (3)University of Alabama at Birmingham, Birmingham, AL, (4)The University of Alabama at Birmingham, Birmingham, AL*

---

Background: Females are diagnosed with Autism Spectrum Disorder (ASD) at a relatively low rate, with an estimated female to male ratio of 1:3 (Loomes et al., 2017). A recent meta-analysis contradicted the previously proposed view that females are at reduced risk for developing ASD, instead suggesting that females with ASD are often missed in the diagnostic process (Loomes et al., 2017). This underestimation of ASD among females may be due to gender differences in ASD symptoms and behavioral profiles, as gold-standard diagnostic measures for ASD have been developed using predominantly male samples (Ratto et al., 2018). ASD symptom severity and adaptive skills are two common concerns in the ASD referral and diagnostic process, and research has produced mixed findings regarding gender differences in these areas, including greater Restricted and Repetitive Behaviors (RRBs) in males with ASD (van Wijngaarden et al., 2014; Allely et al., 2019; Kaat et al., 2020). However, the majority of research has focused on individuals with a confirmed diagnosis of ASD, thereby excluding those who may be missed by diagnostic measures that are based on the male ASD phenotype.

Objectives: To assess gender differences in ASD symptoms and adaptive skills in a clinical sample of individuals referred for an ASD diagnosis.

Methods: The participants for this study were from a database composed of children referred and clinically evaluated for an ASD diagnosis at a tertiary care clinic between 2013-2020. ASD symptom severity was evaluated using *Autism Diagnostic Observation Schedule, Second Edition (ADOS-2) Comparison scores* as well as domain-level calibrated severity scores in RRBs and Social Affect (Hus, Gotham & Lord, 2014). Adaptive skills were assessed using either the *Vineland-II/3* or *Adaptive Behavior Assessment System, Second/Third Edition (ABAS-II/3)*. Factorial ANOVAs were conducted to examine the interaction and main effects of gender and ASD diagnosis on ASD symptom severity and adaptive skill mean group differences.

Results: Participants included 456 total individuals (78.9% male;  $M_{\text{age}} = 5.17$  years,  $SD = 3.18$ ), with 47.7% of the sample diagnosed with ASD; non-ASD diagnoses included Language Disorder, ADHD, Global Developmental Delay, and others. Although the factorial ANOVA indicated significant main effects of ASD diagnosis on adaptive skills and ASD symptoms across domains, the only main effect of gender was in the RRB domain ( $F(1, 260) = 5.13, p = .024$ ), such that males referred for an ASD evaluation ( $M = 5.61, SD = 3.16$ ) exhibited significantly more RRBs than females referred for an ASD evaluation ( $M = 4.71, SD = 3.35$ ).

Conclusions: In a clinical sample of individuals referred for an ASD evaluation, males exhibited significantly more RRBs than females. This aligns with recent research on gender differences in RRBs (Kaat et al., 2020), expanding upon those findings to include those who may be mis- or under-diagnosed by current diagnostic procedures. These findings suggest that the female presentation of ASD is quantifiably different than the male presentation. As a result, clinicians should consider these differences when contemplating an ASD diagnosis.

**441.008 (Poster)** Associations between ASD-Related Traits, Restricted and Repetitive Behaviors, and Sensory Reactivity in Children with and without ASD

**S. Soker-Elimaliah<sup>1,2</sup>** and **J. B. Wagner<sup>1,2</sup>**, (1)*The Graduate Center, City University of New York, New York, NY*, (2)*College of Staten Island, City University of New York, Staten Island, NY*

---

Background:

Hypo- and hyper-reactivity to sensory input is a sub-criterion of restricted and repetitive behaviors (RRB) for ASD diagnosis. Hypo-reactivity patterns have been found to distinguish children with ASD from their typically-developing (TD) peers (Ben-Sasson et al., 2009), and sensory reactivity is correlated with RRB (e.g., Gabriels et al., 2008), particularly hyper-reactivity (e.g., Boyd et al., 2010). Recent research suggests that these types of associations might also be found in children and young adults without ASD (Schulz & Stevenson, 2019).

Objectives:

The current study expands on recent work to further examine the relationships between ASD-related traits, RRB, and sensory reactivity in children with and without ASD.

Methods:

The current sample included 13 children ( $M_{\text{age}} = 6.63$  years,  $SD = 2.14$ ; range: 3.83-10.91; TD:  $n = 11$ ; ASD:  $n = 2$ ). As part of a larger study, parents filled out 1) the Social Responsiveness Scale, Second Edition (SRS-2; Constantino & Gruber, 2012), to assess ASD-related traits, 2) the Repetitive Behavior Scale-Revised (RBS-R; Bodfish et al., 1999), to measure RRB frequency and intensity, 3) the Short Sensory Profile, Second Edition (SSP-2; Dunn, 2014), to assess overall sensory reactivity, and 4) the

Sensory Experiences Questionnaire (SEQ; Baranek et al., 2006), to assess hypo- and hyper-reactivity patterns. Correlational analyses first examined associations in the full sample, then participants were divided into groups low and high on ASD-related traits based on SRS-2 cutoff scores (low traits: T-score  $\leq 59$ ,  $n = 8$ ; high traits: T-score  $> 59$ ,  $n = 5$ ), and groups were then compared on RRB and sensory reactivity.

#### Results:

Positive correlations were found between SSP-2 and SRS-2 scores ( $r(11) = .76$ ,  $p = .003$ ; Figure 1) and between SSP-2 and RBS-R ( $r(11) = .76$ ,  $p = .003$ ). RBS-R was also positively correlated with both SEQ hypo- and hyper-reactivity subscales ( $ps < .042$ ). When children with ASD were excluded, associations remained significant between SSP-2 and SRS-2 ( $p = .039$ ), but RBS-R was no longer related to SSP-2 or the SEQ subscales ( $ps > .078$ ). Results from independent samples t-tests comparing groups high and low on ASD-related traits are summarized in Table 1. In comparison to those low on traits, the high traits group showed significantly higher SSP-2 scores and marginally higher RBS-R and SEQ hyper-reactivity scores, but no trend was seen for hypo-reactivity patterns. When excluding the children with ASD, groups still differed on SSP-2 ( $p = .038$ ), but marginal findings with RBS-R and SEQ hyper-reactivity became non-significant ( $ps > .490$ ).

#### Conclusions:

Overall, atypical sensory processing was associated with more ASD-related traits and more RRB. When the sample included children with ASD, in agreement with past work (Boyd et al., 2010), more RRB were related to hyper-reactivity patterns, but also to hypo-reactivity. Although children with more ASD-related traits exhibited greater atypical sensory processing, hypo-reactivity did not distinguish children high and low on ASD-related traits. Data collection for the current study has transitioned online, which will lead to an increased sample size. Additionally, future work will examine the underlying physiological measures that might play a role in RRB and sensory reactivity.

**441.010 (Poster)** Comparing Age-Related Sensory Processing Differences in Children with Autism Spectrum Disorder, Down Syndrome, Other Developmental Disabilities, and Typically Developing

*E. Isralowitz, G. T. Baranek, J. Sideris, L. I. Duker (Stein) and S. A. Cermak, Chan Division of Occupational Science and Occupational Therapy, University of Southern California, Los Angeles, CA*

**Background:** Atypical sensory processing impacts children with a wide range of developmental disabilities (DD). Three categories of sensory processing have been identified: and sensory interests, repetitions, and seeking behaviors (SIRS). Sensory difficulties significantly impact development and learning across multiple domains, including , motor, and adaptive behavior. Previous research suggests age-related changes in sensory processing patterns for children with DD, including those with ASD. It is unclear if these age-related trajectories extend to other clinical groups such as children with Down syndrome (DS) and how sensory processing differs in these groups.

**Objectives:** The current study compared patterns of sensory processing patterns and age-related trajectories in children with ASD, DS, other DD, and typically developing (TD).

**Methods:** This analysis was conducted on cross-sectional data from a longitudinal study of sensory characteristics in children with ASD. The sample ( $m = 5.06$ ). Assessments included caregiver questionnaires, the and Sensory Experience Questionnaire (SEQ), and an observational measure – Sensory Processing Assessment (SPA). Group HYPO, HYPER, and SIRS means were compared using an ANCOVA and contrasts. Multiple regression was used to assess the impact of age on sensory scores. Covariates included IQ, maternal education, sex, and, for the ANCOVA, age.

Results: All group comparisons were significant, except the SPA **HYPER** between the ASD and DS groups , Table 1. \*Denotes non-significant trend.

**HYPO**responsivity. On the SP and SEQ, we found For the SPA, researchers observed **ASD > TD  $\geq$  DS  $\geq$  DD\*** ( $F = 15.95$ ,  $p < .01$ ).

**HYPER**responsivity. While scores on the SEQ and SPA indicated **ASD > DS  $\geq$  DD > TD** ( $F = 21.76$ ,  $p < .01$ ), on the SP, the DS group demonstrated lower symptoms than the DD group, **ASD > DD** ( $F = 19.66$ ,  $p < .01$ ).

**SIRS.** Based on caregiver report – SP ( $F = 16.42$ ,  $p < .01$ ) and the SPA ( $F = 24.18$ ,  $p < .01$ ), we observed **ASD > DD > DS  $\geq$  TD\***. In contrast, SEQ scores were **ASD > DS** ( $F = 18.21$ ,  $p < .01$ ).

Sensory trajectories. Graphical analysis showed atypical sensory behaviors in the ASD, TD, and DS groups decreased with age, Table 2. In contrast, the other DD group exhibited increased **HYPO** on the SPA and SP, **HYPER** on the SEQ and SP, and **SIRS** on the SP. Age-related group sensory trajectories were significantly different between the ASD and DD groups for the SPA and SP **HYPO** and SP **HYPER** and from the TD group on the SEQ **SIRS**.

**Conclusions:** In this study, participants with ASD demonstrated more atypical sensory behaviors than their TD, DS, and other DD peers. Per caregiver report, children with DS and other DD showed relatively more atypical sensory processing features compared to TD peers. Across the HYPO measures and parent-reported HYPER measures, children with another DD demonstrated increasing age-related trajectories of atypical sensory behaviors. In contrast, children in the other groups showed stable or decreasing trajectories.

Inconsistencies were observed across caregiver reports and researcher observations. While previous research with a non-distinct DD group found no differences between DD and ASD groups for HYPO and HYPER measures, the current study highlights the need to distinguish between different diagnostic groups such as children with DS.

#### **441.011 (Poster) Component Analysis of a Novel Measure of Rigidity in Individuals with ASD**

**C. J. Ferretti<sup>1</sup>, V. Zemon<sup>2</sup>, B. P. Taylor<sup>3</sup>, E. Eule<sup>3</sup>, F. Bolognani<sup>4</sup> and E. Hollander<sup>1</sup>,** (1)Albert Einstein College of Medicine, Psychiatric Research Institute at Montefiore-Einstein, Bronx, NY, (2)Ferkau Graduate School of Psychology, Yeshiva University, Bronx, NY, (3)Neuroscience and Rare Diseases (NRD), Roche Pharma Research and Early Development, Roche Innovation Center, Basel, Switzerland, (4)VectivBio Holding AG, Basel, Switzerland, Basel, Switzerland

---

#### **Background:**

Restrictive and repetitive behaviors (RRBs) cause significant distress to individuals with ASD and their families, impacting functioning on multiple levels. Current instruments measuring RRBs are mostly self- and caregiver-reported, have significant informer bias, and do not serve well as outcome measures in clinical trials. The Montefiore-Einstein Rigidity Scale-Revised (MERS-R) is a clinician-rated assessment developed by Bonnie Taylor, PhD and Eric Hollander, MD to measure insistence on sameness and rigidity. Hoffmann-La Roche included this measure in their ORBITING study, which examined outcome measures of RRBs in ASD.

#### **Objectives:**

We examined the MERS-R's component properties using the ORBITING study data.

#### **Methods:**

Participants. A total of 95 children/adolescents and adults with ASD completed the ORBITING study ( $N = 95$ ,  $M = 16.36$  years,  $SD = 7.45$ ; range 5 – 36).

Study Design. The study design mimicked that of a drug intervention study. Participants attended four in-person clinic visits, Screening, Baseline, Week 2, and Week 12, and completed phone visits at Week 6 and Week 8.

Measures. For the purposes of this analysis, focus is solely on the MERS-R, a clinician-administered scale designed to assess three domains of rigid behavior in children/adolescents and adults, (1) Behavioral Rigidity, (2) Cognitive Rigidity, and (3) Protest Domain using all available information including clinical observations and participant/caregiver interviews. It was completed at Baseline, Week 2, and Week 12.

#### **Results:**

The assumptions of sampling adequacy ( $KMO = .843$ ), multicollinearity and factor ability ( $\chi^2[66] = 595.145$ ,  $p < .001$ ) were met. The initial Principal Component Analysis (PCA) solution on the MERS-R Baseline data, calculated using the Kaiser Criterion, resulted in three components with eigenvalues greater than 1, explaining 67.8% of the variance. The items of the Behavioral Rigidity subscale clustered together in a separate component, while the items from the Protest Domain subscale and all but one of the items from the Cognitive Rigidity subscale (Time Spent) clustered in a single component. The Cognitive Rigidity Time Spent item fell into its own component. All items had component loadings greater than 0.4, with the majority above 0.7. The correlations between components were .525 (RC1:RC2), .35 (RC1:RC3) and .113 (RC2:RC3), indicating that the promax oblique

rotation was appropriate. The scree plot inflection point for this PCA also presented a three- or four-component model as the best fit for the data.

### Conclusions:

This is the first PCA completed on the MERS-R scale. With the removal of a single item, the expected three-dimensional structure was identified, which directly corresponded to the already identified subscales, Behavioral Rigidity, Cognitive Rigidity and Protest Domain. The Cognitive Rigidity Time Spent item was identified as an independent component in a four-component solution and its removal increased the Cronbach's  $\alpha$  for the measure. Overall, the PCA structure is in line with the literature and theory behind the instrument, which identifies two separate but related constructs of rigidity, behavioral and cognitive, with protest being the resulting behavioral response to environmental and interpersonal challenges in either of these domains.

#### 441.012 (Poster) Development and Validation of the Parent-Rated Sensory Reactivity Scale for Children with Autism Spectrum Disorder

**M. Eyuboglu<sup>1</sup>**, D. Eyuboglu<sup>2</sup>, N. E. Unal<sup>3</sup>, F. Yaylaci<sup>4</sup>, E. Karadag<sup>5</sup> and D. Arslantas<sup>6</sup>, (1)Child and Adolescent Psychiatry, Eskisehir Osmangazi University Medical School, Eskisehir, Turkey, (2)Child and adolescent psychiatry, Eskisehir Osmangazi University Medical School, Eskisehir, Turkey, (3)Child and adolescent psychiatry, Eskisehir Osmangazi University Medical School, Eskisehir, Turkey, (4)Bursa Dortcelik Children Hospital, Bursa, Turkey, (5)Akdeniz University Faculty of Education, Antalya, Turkey, (6)Public Health, Eskisehir Osmangazi University Medical School, Eskisehir, Turkey

---

**Background:** Unusual reactions to sensory stimuli are mostly experienced by children with autism spectrum disorder (ASD) and became part of the diagnostic criteria for ASD in the DSM-5. Therefore, it is important to accurately assess these symptoms with reliable and valid scales. Even a number of instruments have been designed internationally to gauge parents' perception and description of sensory behaviors in autism, none has been particularly developed for the Turkish sample. Hence, to address this gap, the current study investigated the psychometric properties of a new parent-rated scale to assess sensory reactivity.

**Objectives:** This study examined the reliability and validity of the new parent-report assessment, the Eyuboglu Sensory Reactivity Scale (ESRS) in children with ASD. It was also aimed to investigate the factor structure of the new ESRS, and its reliability and concurrent validity with previously validated measures. The ESRS designed to assess various sensory behaviors in children with ASD compatible with DSM-5.

**Methods:** A total of 167 children (male:133, age 6.4±4.1) with ASD and their families were included in the study. Parents were asked to fill in the ESRS and the Autism Behavior Checklist (ABC). In addition, the Childhood Autism Rating Scale (CARS) was administered by the clinician to evaluate autism severity. The psychometric properties of the scale were examined through reliability and validity analyses. Cronbach's  $\alpha$  was used to calculate internal consistency and the correlation coefficient was performed to assess concurrent validity and discriminant validity. Bivariate analysis was performed to explore the relationship between the ESRS, ABC, and CARS.

**Results:** According to the confirmatory factor analysis, our results suggest that the ESRS consist of a 15 five-point Likert-type have acceptable internal consistency and good validity for children ages 2 through 18. The Cronbach alpha value of the scale was 0.85. The scale also showed significant associations with both ABC ( $r=.72$ ) and CARS scores ( $r=.42$ ) that indicate good concurrent and external validity.

**Conclusions:** In this study, we have demonstrated that parent-rated ESRS is a psychometrically valid tool to assess sensory reactivity in children with autism. The ESRS has potential as a measure of unusual sensory reactions and can be used to follow up the outcome of sensory interventions in children with ASD. Moreover, the scale is suitable to be used in scientific research and clinical practice.

#### 441.013 (Poster) Do Males and Females with Autism Spectrum Disorder Show Distinct Age-Related Patterns of Restricted Repetitive Behaviors from Early Childhood to Adulthood? Trends across 16,000 Individuals

**S. S. Kuo<sup>1,2</sup>**, C. van der Merwe<sup>2</sup>, C. E. Carey<sup>2</sup>, S. Bishop<sup>3</sup> and E. B. Robinson<sup>1,2,4</sup>, (1)Stanley Center for Psychiatric Research, Broad Institute of MIT and Harvard, Cambridge, MA, (2)Analytic and Translational Genetics Unit, Massachusetts General Hospital, Boston, MA, (3)University of California San Francisco, San Francisco, CA, (4)Department of Epidemiology, Harvard School of Public Health, Boston, MA

---

**Background:** Repetitive restrictive behaviors (RRBs) are cardinal features of autism spectrum disorder (ASD) that emerge in early childhood and often persist into adulthood. However, given that RRBs have rarely been examined across these

developmental periods and that prior research is mixed with regards to sex differences in RRBs, it remains unclear the points in development at which these behaviors become most salient for males and for females.

**Objectives:** We aimed to characterize age- and sex-related differences in RRBs in a large cross-sectional study of individuals with ASD.

**Methods:** We aggregated three cohorts from clinic and community settings across the United States: Autism Genetic Resource Exchange (N=1,436), Simons Simplex Collection (N=2,752), and Simons Foundation Powering Autism Research (N=12,392), yielding a total sample of 16,580 participants with ASD (80.0% male), aged 3 to 20 years (mean=9.0, s.d.=4.2 years). Caregivers provided behavioral ratings using the Repetitive Behavior Scale-Revised (RBS-R; Bodfish et al., 2000). We charted scores for each RBS-R behavioral domain (Self-Injurious, Restricted, Stereotyped, Compulsive, Ritualistic, and Sameness), then modeled these scores by age, age<sup>2</sup>, age<sup>3</sup>, sex, and cohort in simultaneous regression analyses. For RRB domains which were significantly predicted by age<sup>2</sup> or age<sup>3</sup>, we further extracted ages of highest and lowest RRB domain scores.

**Results:** Males and females with ASD showed both largely overlapping age-related patterns in RRBs observed by their caregivers. Specifically, males and females only differed in restrictive behaviors, with females showing fewer restrictive behaviors than males. Of the lower-order motor behaviors, self-injurious behaviors were stable across age, whereas restricted and stereotyped behaviors generally declined steadily for males and females until age 16, when these behaviors rose slightly through age 20. Of the higher-order cognitive behaviors, compulsive behaviors followed similar trends to restricted and stereotyped behaviors, whereas ritualistic and sameness behaviors increased from age 3, peaked at age 8, then declined until at least age 16.

**Conclusions:** To our knowledge, this is the largest study to date characterizing both age-related and sex-related differences in RRBs for ASD. Our findings illustrate that the nature and intensity of RRBs are largely consistent between males and females yet shift substantially from ages 3 to 20. Restricted, stereotyped, and compulsive behaviors first peaked early in childhood whereas more complex ritualistic and sameness behaviors first peaked later in childhood, suggesting that different behavior domains may track with distinct aspects of cognitive, social, and emotional development. Furthermore, all RRBs except for self-injurious behaviors showed another increase after age 16 particularly for males, though this interaction did not reach significance. Notably, males and females with ASD demonstrated similar levels of RRBs across ages and across domains except for restrictive behaviors, which were more heightened in males than females. In clarifying developmental and sex-specific phenotypes for a core diagnostic symptom domain in ASD, our findings may bear relevance for refining clinical assessments and intervention targets.

**441.014 (Poster) Do You Sense What I Sense? a Comparison of Caregiver- and Self-Reports of Sensory Sensitivities in Children and How They Relate to Autistic Traits**

**D. R. Simmons and E. J. Millington, School of Psychology, University of Glasgow, Glasgow, United Kingdom**

**Background:** The Glasgow Sensory Questionnaire (GSQ; Robertson & Simmons, 2013) is a 42-item self-report questionnaire which measures the frequency and severity of sensory difficulties (both hyper- and hypo-responsiveness), giving a score ranging from 0 (no sensory issues) to 168 (Extremely severe and frequent issues in all sensory modalities). Research with this questionnaire in adult populations has shown that there are strong correlations of sensory score with self-reported autistic traits and significant differences in sensory scores between diagnosed autistic and control populations. We have previously shown, however, that the correlation with autistic trait level is less strong in children (INSAR, 2015) using an adapted version of the GSQ with added pictures and simplified questions. Here we aim to replicate this result on a new population of children whilst simultaneously collecting data from their caregivers for comparison.

**Objectives:** To re-investigate the dependence of GSQ sensory score on autistic trait level in children using both self- and caregiver-reports.

**Methods:** The questionnaire was completed by 166 children (mean age 10.0 years, age range 6-15 years) during the course of a public workshop at a local “hands-on” science museum and at similar workshops run at local schools and community groups. The caregiver of the child was asked to complete the Children’s version of the Autism Spectrum Quotient Questionnaire (AQ-Child; Auyeung et al, 2009) and a caregiver version of the GSQ (P-GSQ; Smees et al, 2020). Due to attrition we only have data from 157 caregivers.

**Results:** Overall results showed a non-significant correlation between the self-report GSQ data from children and the caregiver-report AQ score (Pearson’s  $r(157) = 0.05$ ,  $p = 1$ ). The Caregiver-report GSQ showed a much stronger and significant correlation (Pearson’s  $r(152) = 0.47$ ,  $p < 0.01$ ,  $R^2 = 0.22$ ) with caregiver-reported AQ score. The correlation between children’s self reports

and their caregiver's reports of sensory features was significant but not strong (Pearson's  $r(150) = 0.23$ ,  $p = 0.01$ ,  $R^2 = 0.05$ ). Cronbach's alpha for children's GSQ (0.84) and parent's GSQ (0.75) revealed a good degree of internal consistency.

Conclusions: These results are curious given the multiply-replicated highly significant correlations between GSQ sensory scores and autistic trait levels found in adults (16+) and the similar relatively high correlations between caregiver-reported sensory scores and AQ scores found here. There is clearly a mismatch between what children consider their own sensory sensitivities are and what their caregivers think they are, possibly reflecting the "sensitivity-reactivity" divide frequently discussed in recent literature on sensory aspects of autism. One plausible explanation is that all young people have mild difficulties with sensory stimulation: the difference is how they *react* to it, and this "sensory reactivity" is what is picked up in caregiver questionnaires. Alternatively, young people may lack the insight necessary to self-report on their own sensory difficulties and/or the difficulties that they experience may be qualitatively different from those that adults experience. Whatever the explanation, the clear implication is that sensory experiences of autistic children, and adults, should be investigated as far as possible using self-report and first-person data.

**441.015 (Poster)** Effects of Creative Movement Interventions on Fine-Motor, Gross-Motor, and Functional Skills of Children with ASD

C. Cleffi<sup>1</sup>, S. Srinivasan<sup>2</sup>, W. C. Su<sup>3</sup> and A. Bhat<sup>4</sup>, (1)Physical therapy, University of Delaware, Newark, DE, (2)Department of Kinesiology, University of Connecticut, Storrs, CT, (3)Physical Therapy, University of Delaware, Newark, DE, (4)Department of Physical Therapy, University of Delaware, Newark, DE

---

Background:

Recently, we reported that 87% of school-age children with Autism Spectrum Disorder (ASD) are at risk for motor coordination impairments.<sup>1</sup> In our past studies, musical or yoga-based interventions led to generalized and task-specific improvements in gross-motor performance.<sup>2,3</sup> The present study expands on this work by comparing the effects of a Creative Movement (CM) intervention combining music, dance, and yoga to a standard-of-care, Sedentary Play (SP) intervention on the fine and gross-motor coordination and functional performance of children with ASD. Before COVID-19, a subset of children with ASD received face-to-face (F2F) intervention; however, after the pandemic, we are offering the intervention remotely through videoconferencing.

Objectives:

To compare the effects of CM or SP interventions on fine-motor, gross-motor and functional performance of children with ASD. We will also compare F2F and telehealth-based intervention delivery in both groups.

Methods:

24 children with ASD between 6 and 14 years. The study will last for 10 weeks with pretests and posttests conducted during the first and tenth weeks. Children will be matched on age, gender, and level of functioning and then randomly assigned to either CM or SP groups. Each child will receive 8 weeks of training @ 2 sessions/week. The CM group will engage in whole-body, music, dance, and yoga-based activities promoting interpersonal synchrony, visuo-motor, bilateral, and multilimb coordination as well as balance skills. The SP group will engage in tabletop activities such as reading, building, and arts and crafts to promote social interactions and fine motor skills. The Bruininks-Oseretsky Test of Motor Proficiency,<sup>4</sup> the Test of Gross-motor development,<sup>5</sup> and the 2-minute-walk/shuttle-run tests will be administered as a pre- and post-test. We will also code training-specific changes in motor coordination (unilateral, dual-limb, multilimb coordination) across an early, mid, and late training session.

Results:

Preliminary data from a subset of 7 children suggests significant generalized training improvements in running speed and agility (CM pretest =13.42(10.63); CM posttest=19.86(13.50),  $p<0.05$ ), bilateral coordination (CM pretest =18.57(5.41); CM posttest=20.86(4.18),  $p<0.01$ ), strength (CM pretest =9.71(5.50); CM posttest=15.57(4.65),  $p<0.05$ ), as well as locomotor (CM pretest =35.71(6.05); CM posttest=42(5.72),  $p<0.001$ ) skills on the BOT & TGMD standardized motor assessments. We hypothesize that irrespective of mode of intervention delivery (face-to-face or online), the CM group will demonstrate more gross-motor improvements on standardized and training-specific outcomes compared to the SP group who will demonstrate more fine-motor improvements.

Conclusions:

This study will highlight the fact that CM interventions can be used to promote gross-motor coordination in children with ASD. Moreover, we will also compare the effectiveness of delivering CM interventions using a telehealth platform versus F2F interventions and provide best practice guidelines. Movement clinicians working with children with ASD should use CM approaches to target their clients' motor coordination skills. This work will provide the support for inclusion of whole body movement experiences in the standard-of-care for ASD and for OTs/PTs to be motor advocates of their clients with ASD.

**441.016** (Poster) Evaluation of Fine Motor Skills in Preschool-Aged Boys and Girls with ASD

*A. Acosta<sup>1</sup>, B. G. Travers<sup>2</sup>, D. G. Amaral<sup>1</sup>, M. Solomon<sup>1</sup>, S. J. Rogers<sup>1</sup> and C. W. Nordahl<sup>1</sup>, (1)Department of Psychiatry and Behavioral Sciences, The Medical Investigation of Neurodevelopmental Disorders (MIND) Institute, UC Davis School of Medicine, University of California Davis, Sacramento, CA, (2)University of Wisconsin - Madison, Madison, WI*

---

Background: Motor impairments are commonly reported in Autism Spectrum Disorder (ASD) and have been shown in previous studies to be related to more severe autism symptoms (Travers et al 2015) and difficulties with social communication skills (McPhillips et al 2014). We sought to replicate and extend these findings by examining fine motor skills in a large cohort of 2-4 year old boys and girls with ASD.

Objectives: 1) To test for sex differences in fine motor skills. 2) To investigate associations between fine motor skills and autism severity. 3) To evaluate correspondence between parent report and direct observation measures for fine motor skills in preschool-aged children.

Methods: Participants include 381 children with ASD (263 males, 118 females) and 165 typically developing controls (95 males, 71 females) (mean age 36.68 months). Fine motor skills were assessed using standard scores from both parent report (Vineland Adaptive Behavior Scales- 2<sup>nd</sup> Edition [VABS-II]) and direct observation (Mullen Scales of Early Learning [MSEL]). Sex by diagnosis interactions for fine motor skills were investigated using ANOVA. Pearson's correlation was used to investigate associations between fine motor scores and autism severity (ADOS Calibrated Severity Score [CSS]) as well as parent report and direct assessment.

Results: There was a significant sex by diagnosis interaction for VABS fine motor standard score ( $p = .0005$ ). Pairwise associations revealed that while TD females and males did not differ, females with ASD had lower fine motor scores than males with ASD. In females, but not males with ASD, there was a significant association between increased fine motor skills and reduced autism severity ( $r = .24, p = .01$ ). Fine motor ability as measured by parent report (VABS-II) was highly correlated with direct observation (MSEL) ( $r = .69, p < 0.0001$ ) across both diagnostic group and sex. However, analyses of MSEL fine motor t-scores revealed no significant sex by diagnosis interaction, but there was an association with autism severity in both males and females with ASD (females  $r = -.42$ ; males  $r = -.23, p < .01$ ).

Conclusions: In this cohort of preschool-aged children, sex differences in fine motor ability were observed when using parent report of fine motor skills but not direct assessment. Females with ASD exhibited greater impairments in fine motor skills than all other groups and females with weaker fine motor skills had more severe ASD symptoms. Interestingly, although scores for parent report and direct assessment of fine motor skills were highly correlated, we did not observe sex differences in fine motor ability using direct assessment, and lower fine motor scores were associated with increased autism severity in both boys and girls. Thus, there are differences between parent report measures, which may focus more on adaptive living skills, and direct assessment of fine motor skills that should be considered when evaluating motor function in young children with autism.

**441.017** (Poster) Examining the Factor Structures of the Childhood Routines Inventory-Revised and the Adult Routines Inventory in Autistic Children, Adolescents and Adults

*D. V. Crawley<sup>1</sup>, J. Tillmann<sup>1</sup>, J. K. Buitelaar<sup>2</sup>, T. Charman<sup>3</sup>, E. J. Jones<sup>4</sup>, E. Loth<sup>5</sup>, D. Murphy<sup>6</sup>, J. F. Hipp<sup>1</sup> and D. W. Evans<sup>6</sup>, (1)Neuroscience and Rare Diseases (NRD), Pharma Research & Early Development, Roche Innovation Center Basel, F. Hoffmann-La Roche AG, Basel, Switzerland, (2)Department of Cognitive Neuroscience, Donders Institute for Brain, Cognition and Behaviour, Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands, (3)Department of Psychology, Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, United Kingdom, (4)Centre for Brain and Cognitive Development, Birkbeck, University of London, London, United Kingdom, (5)Department of Forensic and Neurodevelopmental Sciences, Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, United Kingdom, (6)Department of Psychology, Bucknell University, Lewisburg, PA*

---

Background: The Childhood Routines Inventory-Revised (CRI-R) and Adult Routines Inventory (ARI) are two companion questionnaire instruments designed to measure restricted, repetitive behaviours (RRB) in typical development and across a range of neurodevelopmental conditions, including autism, from childhood through to adulthood. These measures could provide valuable tools to quantify RRBs in autism spectrum disorder for basic research, clinical trials, and in clinical practice. However,

their factor structure and convergent validity with other autism symptom measures in a clinically ascertained autism sample remains unknown.

**Objectives:** The aims of this study were to (i) explore the factor structures of the CRI-R and ARI for the first time in well-characterised autism cohorts and (ii) examine the factor structures in relation to age, sex, IQ and additional symptomatology measures.

**Methods:** The CRI-R and ARI were administered to 275 autistic children, adolescents and adults aged 6-33 ( $M=16.4$ ,  $SD=6.1$ ;  $N=178$  CRI-R;  $N=79$  ARI) as part of the EU-AIMS Longitudinal European Autism Project (LEAP) and the oRBiting study. Item-level data were analysed using exploratory factor analysis. Reliability was assessed using Cronbach's alpha and item response curves. Convergent validity was established by relating the derived factors to the Repetitive Behavior Scale-Revised (RBS-R) and the Short Sensory Profile (SSP). Derived factor scores were interrogated in terms of associations with age, IQ and sex comparisons (Multivariate Multiple Regression; MMR).

**Results:** Both measures yielded five-factor measurement structure, four of which were common to the CRI-R and ARI and interpretable as: 'Just right' behaviors, Routines and Sameness behaviors, Sensory and Motor behaviors and Restricted Interests/Stereotypies. Each measure then showed an additional unique factor, interpretable as Food Rigidities on the CRI-R and Detail Focus/Sensory Sensitivities on the ARI. The novel factors showed good-to-excellent internal consistency ( $\alpha$  range: 0.82-0.94) and reliability across the trait range. No sex differences were observed on any factors ( $p>.1$ ). Higher scores on the CRI-R Restricted Interests/Stereotypies, Food Rigidities and Sensory & Motor behaviours factors showed significant, moderate associations with younger ages ( $r$  ranging -0.22 to -0.35, all  $p<.004$ ). Higher scores on the CRI-R Restricted Interests/Stereotypies and Food Rigidities factors also showed significant, moderate associations with lower IQ ( $r=-0.34$ ,  $p<.001$ ;  $r=-0.19$ ,  $p=.01$ ). The MMR model for the CRI-R factors showed a significant interaction between age and IQ for Restricted Interests/Stereotypies ( $p=.009$ ,  $b=-0.03$ ), such that older adolescents showed a stronger association with lower IQ than children. Higher scores on the ARI Routines & Sameness behaviours and Detail focus/Sensory Sensitivities factors showed moderate associations with older ages ( $r=0.35$ ,  $p=.0004$ ;  $r=0.30$ ,  $p=.003$ ). The Detail focus/Sensory Sensitivities factor also showed a moderate association with higher IQ ( $r=0.24$ ,  $p=.01$ ). Convergent validity of the novel CRI-R factor structure was demonstrated through expected associations with phenotypically similar subscales on the RBS-R/SSP.

**Conclusions:** We identified novel five-factor measurement structure for the CRI-R and ARI that demonstrate strong psychometric properties and convergent validity in ASD. The findings also indicate important developmental differences in RRB subtypes. These factors can be utilized in a range of future studies across a wide age range and highlight the importance of more research in adulthood.

**441.018 (Poster)** Examining the Hierarchical Structure of Parent-Reported Sensory Features in Autism Using Bifactor Models **Z. J. Williams<sup>1</sup>, J. I. Feldman<sup>2</sup> and T. G. Woynaroski<sup>1</sup>**, (1)Medical Scientist Training Program, Vanderbilt University School of Medicine, Nashville, TN, (2)Department of Hearing and Speech Sciences, Vanderbilt University Medical Center, Nashville, TN

**Background:** Research to date has grouped the sensory features of autism into four response patterns: hyperreactivity (HYPER), hyporeactivity (HYPO), sensory seeking (SEEK), and enhanced perception (EP), all of which can occur in multiple sensory modalities. Though available measures almost exclusively combine responsiveness patterns across multiple sensory modalities (e.g., auditory, visual, tactile, olfactory, gustatory) into unified "overall [HYPER/HYPO/SEEK/EP]" scales (e.g., Ben-Sasson et al., 2009; 2019), some researchers recommend measurement of sensory features within each modality separately (e.g., Tavassoli et al., 2019). However, there is little evidence to suggest which level of measurement and analysis is more appropriate for these constructs.

**Objectives:** Using modern psychometric techniques, the current study aimed to assess the degree to which the five canonical sensory response patterns listed above combine to form valid and interpretable superordinate constructs.

**Methods:** Parents of autistic children aged 2–12 years ( $n = 708$ ,  $M_{Age} = 7.95$  years, 83% male, 73.3% non-Hispanic White) were recruited from the Simons Powering Autism Research Knowledge (SPARK) participant pool (Feliciano et al., 2018) as part of a study on the genetic underpinnings of sensory differences in autism (RM0035Woynaroski). Modality-specific unidimensional measures of HYPER, HYPO, SEEK, and EP were derived from the Sensory Experiences Questionnaire Version 3.0 (SEQ-3.0). For each sensory response pattern, we first used exploratory regularized structural equation modeling (Scharf & Nestler, 2019) to assign items to specific factors. Factor solutions from these models were then used to construct pseudo-confirmatory bifactor models, which were fit to the data using a limited-information (WLSMV) estimator. To assess the strength of the general "overall [HYPER/HYPO/SEEK/EP]" factor in each case, we calculated (a) coefficient omega hierarchical ( $\omega_H$ ), (b) explained common variance (ECV) of the general factor, and (c) the proportion of items with poor loadings ( $<0.3$ ) on the general factor. For each

sensory response pattern, values of  $\omega_H \geq 0.8$ ,  $ECV \geq 0.60$ , and  $< 10\%$  poor loadings were established *a priori* as evidence of a strong general factor, supporting the combination of response patterns across modalities without much loss of information.

Results: A total of 17 HYPER, 12 HYPO, 19 SEEK, and 10 EP items were drawn from the SEQ-3.0 across the five selected modalities. Bifactor models fit the data well for each response pattern (HYPER: 4 specific factors; HYPO: 3 specific factors; SEEK: 5 specific factors; EP: 2 specific factors; all  $CFI_{cML} > 0.971$ , all  $RMSEA_{cML} < 0.055$ , all  $SRMR_u < 0.027$ ). Overall, bifactor indices failed to demonstrate a strong general factor for HYPER ( $\omega_H = 0.482$ ,  $ECV = 0.333$ , 25% poor loadings), HYPO ( $\omega_H = 0.436$ ,  $ECV = 0.294$ , 33.3% poor loadings), SEEK ( $\omega_H = 0.640$ ,  $ECV = 0.400$ , 15% poor loadings), or EP ( $\omega_H = 0.631$ ,  $ECV = 0.555$ , 10% poor loadings), indicating that all four response patterns were better analyzed at the single-modality level.

Conclusions: Multimodal “general reactivity” factors failed to account for large portions of common variance in each sensory responsiveness pattern, suggesting that these commonly used superordinate constructs do not adequately capture the patterns of sensory behaviors seen in autism. Future work should attempt to parse these constructs into single-modality response patterns such as tactile hyperreactivity or visual sensory seeking, which may better represent individual sensory phenotypes.

**441.019** (Poster) Examining the Relationship between Stereotypy and Attentional Problems and Diagnoses in Individuals with ASD

*J. E. Nauman and B. R. Ingersoll, Psychology, Michigan State University, East Lansing, MI*

---

Background: Motor stereotypies are a subcategory of restricted and repetitive behavior commonly associated with Autism Spectrum Disorder (ASD). However, motor stereotypy is not exclusive to ASD, and a visual description of the motor behavior is not enough to distinguish between stereotypy in those with and without ASD (Freeman et al., 2010). Individuals without ASD who have motor stereotypy are often diagnosed with another neurodevelopmental disorder, commonly Attention Deficit-Hyperactivity Disorder (ADHD), and have problems with attention and executive function, suggesting motor stereotypy may be related to attentional challenges (Mahone et al., 2014). Individuals with ASD often have comorbid ADHD and report issues with attention (Lyll et al., 2017). However, studies have not examined whether attention problems in ASD are related to measures of motor stereotypy. Understanding whether this is the case will help determine the mechanisms behind motor stereotypy.

Objectives: The goal of this study is to examine the relationship between restricted and repetitive behaviors in ASD and measures of attention problems and comorbid ADHD diagnosis.

Methods: Data were collected through the Simons Simplex Collection (SCC), a permanent repository of behavioral and genetic samples from 2,600 simplex families. Our sample included 2,550 children ages 4-18 years ( $M_{age} = 9.03$  years,  $SD_{age} = 3.56$  years) who had a diagnosis of ASD and complete data for the measures of interest. Stereotypy was measured using the Stereotypy factor derived in a prior factor analysis (Russell et al., 2019) from the Repetitive Behaviors Scale – Revised (RBS-R). Attention problems were measured using the Attention Problems T-Score from the Child Behavior Checklist (CBCL). Proband ADHD and current ADHD medication use were assessed via parent report. We conducted two hierarchical linear regressions to examine the relationship between attention problems and ADHD diagnosis and participants’ stereotypy. For both analyses, sex, age, and IQ were included in Step 1, and whether participants were currently on ADHD medication was included in Step 2. Step 3 included either ADHD diagnosis or attentional problems, depending on the analysis. Given the large sample size, we used a p-value of  $\leq .001$ .

Results: An ADHD diagnosis was not a significant predictor of stereotypy after controlling for age, sex, IQ, and medication use. In contrast, the Attention Problems T-Scores on the CBCL were significantly associated with increased stereotypy ( $p = .000$ ), even after controlling for the other variables. Interestingly, medication use was associated with a lower stereotypy ( $p = .001$ ), but only after controlling for attention problems in Step 3.

Conclusions: This research highlights a link between attentional problems and stereotypy in ASD. Further investigation of this link may offer important information on the mechanisms that influence stereotypy in children with ASD as well as other conditions.

**441.020** (Poster) Exploring Sensory Phenotypes in Autism Spectrum Disorder

*N. E. Scheerer<sup>a</sup>, K. Curcin<sup>b</sup>, B. Stojanoski<sup>c</sup>, E. Anagnostou<sup>d</sup>, R. Nicolson<sup>e</sup>, E. Kelley<sup>f</sup>, S. Georgiades<sup>g</sup>, X. Liu<sup>h</sup> and R. A. Stevenson<sup>g</sup>, (1)Psychology, Western University, London, ON, Canada, (2)Western University, London, ON, Canada, (3)Autism Research Center, Bloorview Research Institute, Holland Bloorview Kids Rehabilitation Hospital, Toronto, ON, Canada, (4)University of Western Ontario, London, ON, Canada, (5)Queen’s University, Kingston, ON, Canada, (6)McMaster Autism Research Team,*

#### Background:

Atypical reactions to the sensory environment are often reported in autistic individuals, with a high degree of variability across sensory modalities. As our everyday lives are spent functioning in complex and unpredictable sensory environments, these sensory-processing differences have been shown to promote challenging behaviours and distress in autistic individuals. In addition, these sensory issues have been shown to have downstream effects on other functions including motor, social, and cognitive abilities.

Preliminary research suggests that specific sensory differences may cluster together within individuals creating discrete sensory phenotypes. However, the manner in which these sensory differences cluster, and whether the resulting phenotypes are associated with specific motor, social, and cognitive challenges is unclear.

#### Objectives:

The objective of this research was to gain a better understanding of how sensory differences cluster together within autistic individuals, and to determine whether there are distinct sensory phenotypes within the autistic population. A second aim of this research was to determine whether these sensory phenotypes are differentially associated with adaptive behaviour, social communication, repetitive behaviours, attention deficit and hyperactivity, and obsessive and compulsive traits.

#### Methods:

Data from 598 children between the ages of 1 and 21 years, with a clinical diagnosis of Autism, were extracted from the Province of Ontario Neurodevelopmental Disorder Network database. Data from the seven subscales of the short sensory profile was subjected to a K-means cluster analysis. The Bayesian Information Criteria and previous literature were used to determine meaningful sensory phenotypes. Follow-up ANOVAs were used to compare adaptive behaviour, social communication, repetitive behaviours, attention deficit and hyperactivity, and obsessive and compulsive traits across the resultant phenotypes.

#### Results:

The five-cluster model was found to minimize error variance and produce five meaningful sensory phenotypes: (1) sensory adaptive, (2) generalized sensory differences, (3) taste and smell sensitivity, (4) under-responsive and sensation seeking, and (5) movement difficulties with low energy (see Figure 1). Age, adaptive behaviour, obsessive and compulsive traits, restricted and repetitive behaviours, social communication, and attention deficits and hyperactivity traits were found to be significantly different across the five clusters (all  $p < .001$ ). IQ and gender were not found to differ across clusters. Notably, pairwise comparisons indicated that cluster 3 and 4 were significantly younger than other clusters. Also, cluster 2 had significantly poorer adaptive behaviour, and significantly greater obsessive compulsive traits and repetitive behaviours than other clusters. Children in cluster 1 were reported to have significantly less repetitive behaviours, obsessive compulsive traits, ADHD traits, and scored the lowest on the social communication questionnaire (indicative of less autistic traits; all comparisons significant at  $p < .05$ ; see Figure 2).

#### Conclusions:

These findings suggest that sensory difficulties in autistic individuals can be clustered into meaningful sensory phenotypes, representing a meaningful way to parse the heterogeneity in sensory issues in autism. These discrete sensory phenotypes are associated with unique behavioural/clinical profiles. Given that these sensory phenotypes do not differ in IQ, these results suggest that sensory issues may provide a novel, meaningful way to understand behavioural heterogeneity in Autism.

**441.021** (Poster) Functional Brain Mechanisms of Rapid Motor Control in Individuals with Autism Spectrum Disorder  
**K. E. Unruh<sup>1</sup>**, J. Bartolotti<sup>1</sup>, W. S. McKinney<sup>1</sup>, M. B. Trost<sup>1</sup> and M. W. Mosconi<sup>2</sup>, (1)Kansas Center for Autism Research and Training (K-CART), University of Kansas, Lawrence, KS, (2)Clinical Child Psychology Program, Schiefelbusch Institute for Life Span Studies, University of Kansas, Lawrence, KS

---

**Background:** Sensorimotor issues are present in the majority of individuals with ASD and are associated with core symptoms. We previously have demonstrated reduced accuracy of initial force output characterized by rapid target overshoot and increased variability of sustained force in ASD, though functional brain processes associated with these behavioral issues in ASD have not been determined.

**Objectives:** Using a rapid visually-guided precision gripping task during functional neuroimaging (fMRI), we examined cortical-cerebellar networks associated with visuomotor control.

**Methods:** Twenty-five individuals with ASD (10-33 years) and 18 typically developing (TD) controls matched on age and IQ completed a test of precision gripping during fMRI. Participants pressed with their right thumb and forefinger on a force transducer while viewing a green FORCE bar that moved upwards with increased force toward a fixed white TARGET bar. Individuals were instructed to maintain the FORCE bar at the level of the TARGET bar for two seconds, alternating with two second rest periods. Two runs were administered in which target force levels were set at 20% or 60% of each participant's maximum voluntary contraction (MVC). Accuracy and trial-to-trial variability of initial and sustained force output were analyzed. Brain activation and functional connectivity (FC) also were examined.

**Results:** Individuals with ASD showed greater initial force output at 20% MVC and reduced initial force output at 60% MVC relative to controls. A significant force x group interaction revealed a pattern of reduced trial-wise variability of initial force output in ASD relative to controls at 20% MVC but increased trial-wise variability at 60% MVC, though post-hoc comparisons did not reach statistical significance. Accuracy and trial-wise variability of sustained force was similar across groups in both conditions. No between group differences in brain activation were seen at 20% MVC. At 60% MVC, compared to controls, individuals with ASD showed increased activation in right primary motor (M1) and somatosensory (S1) cortices and bilateral paracentral lobule. At 20% MVC, increased activation in left M1 and right cerebellar lobules IV-VI each were related to reduced initial force variability as well as increased initial and sustained force accuracy in controls, but not in ASD. For individuals with ASD, increased variability of initial force output was related to reduced severity of clinically rated symptoms. Results of FC analyses are pending.

**Conclusions:** Atypical control of initial force output in ASD suggests reduced integrity of internal action representations that are consolidated and stored within cerebellum and is consistent with previous reports of structural and functional cerebellar abnormalities in ASD. Individuals with ASD showed increased activation in ipsilateral M1 compared to controls which may reflect decreased hemispheric lateralization during precision manual motor actions. Trial-to-trial variability of initial and sustained force output each were associated with activation in contralateral M1 and ipsilateral cerebellar IV-VI in TD but not ASD indicating motor issues also may reflect reorganization of cortical-cerebellar motor systems. These findings collectively suggest cortical-cerebellar dysfunctions may contribute to precision sensorimotor issues and core clinical symptoms of ASD.

**441.022 (Poster)** Genetic Clustering of Repetitive Symptoms, Oppositional Defiant Disorder and Language Disorder and Delay in People with Autism: A Multivariate Genetic Variance Analysis of Genetic Relationship Matrices in the SPARK Sample  
**L. de Hoyos<sup>1</sup>, M. Barendse<sup>2</sup>, M. M. van Donkelaar<sup>1</sup>, E. Verhoef<sup>1</sup>, S. E. Fisher<sup>1,3</sup>, D. Rai<sup>4,5</sup> and B. ---

**Background:**

Autism spectrum disorders (autism) are complex, heritable and highly heterogeneous neurodevelopmental conditions. The majority of genetic variance and nearly half of the total variance in ASD liability can be attributed to common genetic variation. Clinical symptoms often co-occur with other conditions and there is mounting evidence for a considerable genetic heterogeneity between diagnostic subcategories of autism. Recent research showed that common risk variants appear to be similarly relevant to both high- and low-functioning autism, as well as to people with and without *de novo* mutations, involving at least partially distinct aetiological mechanisms. Here, we investigate whether clusters of co-occurring autism symptoms vary in their common genetic architecture and manifest as multiple, distinct, overarching genetic factors. We disentangle autism heterogeneity through multivariate genetic analysis of co-occurring autism symptoms using a case-only design, studying a representative sample of individuals with an autism diagnosis.

**Objectives:**

In this Simons Foundation-funded study, we aim to identify (1) evidence for genetically predictable symptom heterogeneity and (2) evidence for genetically predictable overarching symptom clusters.

### Methods:

Co-occurring autism symptoms were collected through online assessment. A total of 46 phenotypes related to cognitive, motor, social and language abilities and coexisting psychiatric diagnoses were selected from the Basic Medical Screening Questionnaire (BMS), the Background History Form (BGHX), the Lifetime Social Communication Questionnaire (SCQ), the Repetitive Behavior Scale-Revised (RBSR), and the Developmental Coordination Disorder Questionnaire (DCDQ). Approximately 5300 unrelated individuals with autism of Caucasian ancestry had phenotypic and genome-wide genetic data (Infinium Global Screening Array-24 v.1.0; Simons Foundation Powering Autism Research for Knowledge, SPARK). All measures were adjusted for age, age squared, sex and principal components. Univariate and bivariate genetic variance analyses were conducted using Genome-wide Complex Trait Analysis (GCTA) software, where SNP-heritability (SNP- $h^2$ ) estimates capture autism symptom heterogeneity, and genetic correlations ( $r_g$ ) among symptoms reflect shared underlying genetic influences. Overarching shared genetic factors, as captured by genetic relationship matrices (GRM), were subsequently modelled with multivariate structural equation models (SEM) (GRMSEM), analogous to twin modelling techniques. The best-fitting model was identified using likelihood ratio tests.

### Results:

The strongest evidence for genetically predictable symptom heterogeneity in autism was found for quantitatively assessed ritualistic behaviour using the RBSR scale (SNP- $h^2=0.38$ (SE=0.12),  $p=0.00093$ ) though the underlying genetic variation was largely shared across the repetitive RBSR symptom spectrum. Repetitive symptoms were genetically also related with multiple other symptoms. Using GRMSEM, the best-fitting structural equation model identified evidence of a shared genetic factor contributing to RBSR symptoms, behavioural problems/Oppositional Defiant Disorder (ODD), and language delay/disorder, corresponding to at least 50% of the respective SNP- $h^2$  estimates. Replication of these findings in the Simons Simplex Collection is planned.

### Conclusions:

Our findings suggest that symptoms in autism can be understood as complex quantitative traits, where symptom heterogeneity, especially across repetitive behaviours, can be predicted by common genetic variation. Furthermore, repetitive symptoms were genetically linked to ODD and language abilities, consistent with the existence of an overarching aetiological mechanism.

**441.023** (Poster) Girls or Boys, Does the Repetitive Behaviors in Young Autistic Children Differ during Object Exploration? **K. Sotelo<sup>1,2</sup>, V. Courchesne<sup>2</sup>, L. Mottron, M.D.<sup>2</sup> and C. Jacques<sup>1,2</sup>**, (1)University of Quebec in Outaouais, Gatineau, QC, Canada, (2)Autism Research Group, CIUSSS du Nord-de-l'Île-de-Montréal, Montréal, QC, Canada

---

### Background:

Sex differences in repetitive behaviors and interests are reported in the developmental trajectory of autistic children. However, few sex differences were described in young autistic children (Harrop et al., 2015; Knusten et al., 2019). In our previous observational study using the Montreal Stimulating Play Situation (MSPS) (Jacques et al., 2018), we showed that three behaviors, namely *Arm movements*, *Hand flapping* and *Close gaze at objects* were significantly more prevalent in our sample of autistic preschoolers. Regarding interests, the objects explored did not significantly differ between autistic and typical children, but objects related to literacy tended to be more explored by autistic children. The differences between girls and boys of our sample was not explored.

### Objectives:

Document sex differences in prevalence, frequency and duration of repetitive behaviors and objects exploration in young autistic children (18-70 months) during the MSPS.

### Methods:

The MSPS includes 40 objects of interest for autistic children and is coded using a repertoire of 48 repetitive behaviors (Jacques et al., 2018). Age matched Autistic ( $n=78$ ; F:15; M:63) and typical ( $n=71$ ; F:26; M:45) children were exposed to the MSPS and

their repetitive behaviors and object exploration were coded using *Noldus Observer XT 11*. Mann-Whitney U and Fisher's test were conducted to compare the prevalence, frequency and duration of repetitive behaviors and objects explored. Bonferroni corrections were applied.

### Results:

Only *Pressing on objects* was marginally significant in proportion in typical boys compared to autistic boys: ( $p=0.009$ ). *Arm movement*, *Putting object in mouth*, *Close gaze at object*, *Lateral glances at object*, *Wiggling fingers* and *Hand-flapping* were found in a greater proportion of autistic boys compared to typical boys (significant or marginally significant,  $ps<0.001-0.009$ ). Frequency and duration of *Covering ears* was also marginally greater in autistic boys compared to typical boys (both  $p=0.008$ ). None of the objects were significantly more explored in either groups of boys. However, the frequency of *Literacy* related object exploration was marginally greater in autistic boys ( $p=0.007$ ).

None of the repetitive behaviors were found in a greater proportion of autistic girls compared to typical girls or had a significantly higher frequency and duration. Although the proportion of autistic and typical girls exploring each object did not significantly differ, *Balls with lights and sounds* was significantly more explored by autistic girls in frequency ( $p<0.001$ ).

### Conclusions:

Our preliminary results suggest that young autistic boys differ more from typical boys, in repetitive behaviors and objects explored, than autistic girls compared to typical girls. It suggests that our previous results mostly characterized the boys in our sample. When studying boys separately, in addition to the three behaviors that were more prevalent in autistic compared to typical children (*Arm movement*, *Close gaze at objects* and *Hand flapping*), three additional behaviors significantly differ in prevalence: *Putting objects in mouth*, *Lateral glances* and *Wiggling fingers*. None of these differences in prevalence were found in girls. Interest for literacy related objects also seems to distinguish only autistic and typical boys. A larger sample is warranted to further document sex differences in autistic preschoolers.

#### 441.024 (Poster) Interoceptive Awareness Is Associated with Autism Trait Severity

*M. E. Johnson, D. A. Trevisan, T. C. Parker, E. Cummings, J. M. Wolf, C. C. Cukar-Capizzi, C. E. Finn, L. Pisani, C. J. Stevens, A. Naples and J. McPartland, Child Study Center, Yale University School of Medicine, New Haven, CT*

---

### Background:

Interoception is broadly understood as the perception of the internal state of the body, including physiological sensations such as hunger, thirst, and temperature (Murphy et al., 2017). Recent research suggests that atypical interoception may be associated with autism spectrum disorder (ASD), although some findings are inconclusive (DuBois et al., 2016; Quattrocki & Friston, 2014). The current study investigates the relationship between interoceptive awareness and autism trait severity in order to better understand the link between interoception and ASD.

### Objectives:

To explore the relationship between interoceptive awareness and autism trait severity by examining group differences in a sample of adults with ASD and typically developed (TD) adults, and by examining how interoceptive awareness is correlated with autism traits within these groups.

### Methods:

*Participants.* This study uses preliminary data collected via questionnaire; collection is in progress. Participants were adults aged 18-40 (ASD  $n=11$ ; TD  $n=41$ ). ASD diagnoses were confirmed by clinicians with the Autism Diagnostic Observation Schedule-2 (ADOS; Lord, et al., 2000).

*Procedure.* As part of a larger study, participants completed two questionnaires. The Interoception Sensory Questionnaire (ISQ) assessed interoceptive awareness; an example item is "It is difficult for me to describe what it feels like to be hungry, thirsty, hot, cold or in pain" (Fiene, Ireland & Brownlow, 2018). Participants also completed the Social Responsiveness Scale (SRS; Constantino & Gruber, 2012) to assess autism trait severity.

### Results:

As variances were unequal, Mann-Whitney U tests were conducted to examine group differences. Participants with ASD exhibited higher total scores on the SRS ( $M=68.36$ ,  $SD=30.84$ ) than TD participants ( $M=35.09$ ,  $SD=19.37$ ),  $U=84.5$ ,  $p=.001$  one-tailed. Participants with ASD also exhibited higher total scores on the ISQ ( $M=41.54$ ,  $SD=22.82$ ) than TD participants ( $M=29.52$ ,  $SD=11.39$ ),  $U=138.5$ ,  $p=.031$  one-tailed.

As distributions were non-normal, Spearman's rank-order correlation tests were run to explore the relationship between interoceptive functioning and autism trait severity within both groups. Within both the TD and ASD groups, higher scores on the ISQ were associated with higher scores on SRS-Social Cognition, SRS-Social Communication, SRS-Social Motivation, and SRS-Restricted Interests and Repetitive Behavior. There was no significant association between the ISQ and the Social Awareness subscale in either group (see Table 1). Associations between the ISQ and SRS subscales were weaker within the TD group (ASD significant associations ranged from  $r=.708$  to  $r=.846$ , and TD significant associations ranged from  $r=.338$  to  $r=.393$ ; see Table 1).

#### Conclusions:

Participants with ASD scored lower on interoceptive awareness than TDs and demonstrated a strong positive association between interoceptive difficulties and autism trait severity in the domains of social cognition, social communication, social motivation, and RRBs. This association suggests that interoceptive difficulties are related to ASD trait severity. Within the TD group, the correlations between ASD traits and interoceptive awareness were weaker but still significant. In both groups, interoceptive awareness was not significantly associated with social awareness. As interoceptive challenges are higher in ASD and are related to core social-communicative and RRB symptomology, future research should evaluate whether interoceptive difficulties represent a meaningful intervention target for improving developmental outcomes in individuals with ASD.

**441.025 (Poster)** Investigating Perceptual Sensitivities and Sensory Atypicalities during Development in Children with an Elevated Familial Likelihood for Autism.

**R. Arthur<sup>1</sup>**, T. Bazelmans<sup>2</sup>, M. Johnson<sup>3</sup>, E. J. Jones<sup>4</sup>, T. Charman<sup>5</sup> and *& The BASIS Team<sup>6</sup>*, (1)Kings College London, London, United Kingdom, (2)King's College London, Institute of Psychiatry, Psychology and Neuroscience, London, United Kingdom, (3)Department of Psychology, University of Cambridge, Cambridge, United Kingdom, (4)Centre for Brain and Cognitive Development, Birkbeck, University of London, London, United Kingdom, (5)Department of Psychology, Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, United Kingdom, (6)Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, United Kingdom

---

#### Background:

Children diagnosed with Autism Spectrum Disorder (ASD) often show atypical responses to sensory stimuli, such as hyposensitivity, hypersensitivity, and sensory seeking behaviour. Apparently similar atypicalities have been found in infants and toddlers at an elevated likelihood for developing ASD. For example, some studies have reported increased levels of perceptual sensitivity – the ability to respond to and show an awareness of their surroundings – in individuals with ASD, but it's unclear whether these alterations reflect early-emerging manifestations of diagnostic sensory symptoms. In this study, we explored the relationship between infant perceptual sensitivity and sensory atypicalities in mid-childhood.

#### Objectives:

Our overarching goal is to evaluate the relationship between sensory atypicalities and perceptual sensitivity over development. We compare parent reported levels of perceptual sensitivity across development, from 4 months to 10 years, to see if there are any differences in perceptual development between groups who display typical vs elevated symptoms of ASD, and sensory atypicalities at mid-childhood.

#### Methods:

Children were tested as part of an ongoing longitudinal study of infants with an older sibling with ASD ( $n = 81$ ), or typical development ( $n = 52$ ). Parents completed the infant (4, 8, 14 months), early childhood (24 months) and children's (mid-childhood, 7-10 years) behaviour questionnaires which included a sub-scale on perceptual sensitivity. At mid-childhood parents completed the Short Sensory Profile (SSP), and Social Responsiveness Scale (SRS) measuring sensory sensitivity and ASD symptoms. We then split the sample into groups of low vs high sensory atypicalities and ASD symptoms based on the SSP total scores and SRS T-scores, respectively. We used t-tests to examine mid-childhood differences in sensory profiles by high or low

levels of ASD traits. We used mixed models to test differences in perceptual sensitivity over early development between groups with high vs. low sensory atypicalities or ASD symptoms in mid-childhood.

#### Results:

Children with elevated ASD traits had significantly more sensory atypicalities in mid-childhood ( $t(115) = 8.98, p < .001$ ; Figure 1). *Grouping by sensory atypicalities*: 34 children showed an elevated number of sensory atypicalities in mid-childhood. However, in the infant data these sensory groups did not differ on overall perceptual sensitivity or its change over time (Figure 2). *Grouping by ASD traits*: 30 children showed an elevated number of ASD symptoms in mid-childhood. Perceptual sensitivity scores varied significantly between those with high and low symptoms over time ( $p = .009$ ). The elevated ASD symptoms group showed significantly lower perceptual sensitivity at 4 months ( $p = .023$ ) and higher perceptual sensitivity at 24 months than other infants ( $p = .037$ ).

#### Conclusions:

Although children with higher levels of ASD traits showed alterations in the developmental trajectory of perceptual sensitivity over time, this was not found to be the case for children with higher level of sensory symptoms in mid-childhood. Our work finds some evidence consistent with the idea that perceptual sensitivity is altered in infants who go on to have high levels of ASD traits, but this doesn't seem to map onto later sensory symptoms, as readily as previously assumed. Further analyses are needed to investigate possible hypo/hypersensitivity differences.

#### 441.026 (Poster) Lower Verbal IQ Is Associated with Higher Presence of Repetitive Use of Objects with Autism Spectrum Disorder

*S. Mussarrat<sup>1</sup>, B. Rozumny<sup>2</sup> and E. Hanson<sup>3</sup>, (1)Boston Children's Hospital, Boston, MA, (2)Developmental Medicine, Boston Children's Hospital, Boston, MA, (3)Boston Children's Hospital/Harvard Medical School, Boston, MA*

---

#### Background:

Restrictive and repetitive behaviors (RRBs) are a core feature of Autism Spectrum Disorder (ASD) and can be extremely impairing for individuals and their families (Richler et al., 2010). Previous studies have shown that RRBs related to object use (OBJ-USE) at an early age is associated with ASD in a prospective sample (Ozonoff et al., 2008) and these behaviours are observed to decrease over time (South et al., 2005). The correlation of Verbal IQ (VIQ) and OBJ-USE has not been explored.

#### Objectives:

VIQ is correlated with greater presence of OBJ USE in children with ASD with and without controlling for Nonverbal IQ (NVIQ).

#### Methods:

We used previously gathered Behavior and Sensory Interest Questionnaire (BSIQ) data from the Simons Simplex Collection and Boston cohort of the Autism Consortium analyzing the BSIQ parent measure. BSIQ items are coded on a 0-3 scale with 0= not present and 1-3 = present and increasing degree of impairment There were 280 children (males=240, females=40) groups using BSIQ item B4 which includes repetitive spinning (SPIN), repetitive watching of items fall (FALL), repetitive banging (BANG), repetitive throwing (THROW), and lining up objects (LINE) (Hanson et al., 2016). OBJ-USE included individuals with a code of "1, 2 or 3" on any of the five items and NO-OBJ-USE included individuals with a code of "0" on all five items). Additionally, there were three NVIQ clusters: HIGH = <110, AVG= 90-109 LOW = >89.

Using descriptive statistics, we analyzed the relationship between OBJ-USE and NO-OBJ-USE and VIQ, with and without using NVIQ. We then analyzed the occurrence of the five specific OBJ-USE behaviors in our population.

#### Results:

OBJ-USE group showed significantly lower VIQ than those in the NO-OBJ-USE group ( $p < 0.01$ ). OBJ-USE group also showed significantly lower VIQ than NO-OBJ-USE in two of the NVIQ clusters, HIGH ( $p < 0.01$ ), AVG ( $p < 0.01$ ) and although for the LOW NVIQ cluster the difference didn't reach significance ( $p = 0.1$ ).

Preliminary analysis looked at the occurrence of specific OBJ-USE items in our population. LINE=32%, SPIN=24%, FALL=14%, BANG=10% and THROW=6%. In subsequent analysis, we will run a regression analysis to find the correlation between each individual OBJ-USE and VIQ.

#### Conclusions:

This preliminary analysis supported our hypothesis OBJ-USE is correlated with lower VIQ. Additionally, we found that LINE was the most common OBJ-USE behavior in our population. Subsequent analysis will identify whether VIQ is related to specific OBJ-USE and other RRB's. Limitations included using parent report alone and not combined with direct observation. Future directions include using this information to aide in program planning.

---

Background: Sensorimotor impairments, including feedforward and feedback deficits of manual motor behaviors, are prevalent in individuals with autism spectrum disorder (ASD). Oculomotor issues previously have been documented in unaffected relatives of individuals with ASD. The extent to which manual motor control is disrupted in unaffected parents of individuals with ASD has not yet been determined.

Objectives: To examine the familiarity of manual motor control issues in ASD using a family trio study of individuals with ASD and their unaffected biological parents.

Methods: Fifty-four children with ASD (probands; ages 5-17 years) and 100 parents of children with ASD (ASD parents; ages 29-54 years) were studied. Thirty-five typically developing (TD) controls were matched to probands on age and nonverbal IQ. Forty-five controls were matched with ASD parents on age, sex, handedness, and nonverbal IQ. Participants completed two tests of precision grip force in which they pressed opposing load cells with their thumb and index finger. Participants viewed a static red/green target bar and a white force bar. They were instructed to press the load cells when the target bar turned green, so the force bar reached the level of the target bar. To assess feedforward control, participants completed a two second "rapid" test. We measured the accuracy of the initial force output and the peak rate of initial force increase. To assess feedback control of visuomotor behavior, participants completed an eight second "sustained" test. We measured the force variability and complexity of the force time series (approximate entropy). Both tests were completed at 15%, 45%, and 85% of each participant's maximum voluntary contraction (MVC).

Results: During the rapid test, probands showed reduced accuracy relative to TD controls including greater overshooting at 15% MVC and greater undershooting at 85% MVC; this was especially true at younger ages (group x age x force level interaction,  $p=0.004$ ). Probands also showed a higher peak rate of force increase than TD controls (group main effect,  $p=0.005$ ). During the sustained test, probands showed greater sustained force variability than TD controls; this difference scaled with force level and was more severe at younger ages (group x age x force level interaction,  $p=0.047$ ). ASD parents showed greater force variability than controls at 85% MVC using their dominant hand and at 45% MVC using their non-dominant hand (group x force level x hand,  $p=0.004$ ). Probands showed reduced dominant hand sustained force complexity relative to TD controls, but similar non-dominant hand complexity (group x hand interaction,  $p=0.005$ ).

Conclusions: We found that children with ASD show disruptions in feedforward mechanisms supporting precision motor control. However, feedforward motor control appeared to be intact in ASD parents suggesting that it may not be familial. We also found that children with ASD and their parents show increased sustained force variability which indicates that reduced motor control in response to sensory feedback may be familial. These studies implicate cortico-cerebellar circuits involved in sensory feedback control of precision motor behaviors in the pathophysiology of ASD and suggest sensorimotor issues may serve as important candidate intermediate phenotypes in ASD.

#### **441.028 (Poster) Measuring Multisensory Integration and Autistic Traits**

**J. W. Hagon<sup>1</sup>, S. E. Schulz<sup>2</sup> and R. A. Stevenson<sup>3</sup>,** (1)University of Western Ontario, London, ON, Canada, (2)Western University, London, ON, Canada, (3)Brain and Mind Institute, University of Western Ontario, London, ON, Canada

---

## Background:

Issues in multisensory integration are increasingly apparent in autism spectrum disorder (ASD). Atypical lower-level perceptual processes, like multisensory integration, can have cascading consequences for higher-level forms of cognition, like social and communication skills. However, no clear delineation exists between typically-developed adults with high levels of autistic traits and autistic adults. Thus, many adults experiencing social and behavioural issues associated with autism are overlooked because of their exclusion from the categorical definition of autism. This study seeks to fill this gap by testing whether integration issues seen in clinical ASD samples will be reflected across the broader spectrum of autistic traits.

## Objectives:

Determine the relationship between multisensory integration and autistic traits, specifically relating to social behaviour and communication.

## Methods:

Participants completed a battery of questionnaires on autistic traits including restricted interests and repetitive behaviours (RRBs) and social communication. Multisensory integration was assessed through a two-part behavioural experiment. First, each individual's psychophysical threshold level was identified using a psychophysical staircase procedure. Auditory stimuli consisted of 70 pure tones presented at every half decibel ranging in volume from 35-69.5 dB SLP. Visual stimuli consisted of 70 sinusoidal luminance gratings (Gabor patches) ranging in contrast-luminance from 0.0-0.1 Michelson contrast. In the second phase, stimuli were presented in auditory, visual, and audiovisual modalities within a small range around each participant's specified threshold, identified in phase one, to measure multisensory integration. Participants completed a detection task, with detection rates and response times recorded. Multisensory integration was measured as (1) the increase in detection rate and (2) the speed of response times during audiovisual relative to unisensory trials. Multisensory enhancement in detection rates and response times were then correlated with autistic traits.

## Results:

Multisensory enhancement was successfully indicated by both detection rates and response times. RRBs were significantly associated with increased multisensory detection rates, ( $r(113)=.21, p<.022$ ), but not multisensory response times ( $r(70)=-.03, p<.826$ ). Similarly, issues with social communication were significantly associated with detection rates, ( $r(113)=-.19, p<.042$ ), but not response times, ( $r(70)=-.08, p<.482$ ). No significant relationship was observed between pragmatic language and multisensory integration.

## Conclusions:

We expected to see decreased levels of multisensory integration associated with higher autistic traits, however we found mixed results. Social communication was negatively associated with detection rates, supporting the hypothesis that increased deficits in communication relate to reduced multisensory integration. Associations between RRBs and detection rates were positive. While this runs contrary to previous research, we hypothesize that this may be a result of matching for behavioural thresholds. Individuals with higher autistic traits exhibited lower thresholds, i.e. they were able to detect dimmer/quieter stimuli, and multisensory enhancement is commonly found to be strongest with weak stimuli, a phenomenon known as inverse effectiveness. These findings support the broader theory that sensory processing issues have cascading impacts on autism symptomatology, in this case, RRBs and social communication. These findings also indicate a potential relationship/interaction between the multiple sensory issues associated with autism, specifically sensory sensitivities and multisensory integration, which should be accounted for in future research.

### **441.029 (Poster)** Microstructural Brain Correlates of Parent-Reported Sensory Symptom Severity in Children with ASD and Typical Development.

**B. G. Travers<sup>1</sup>, O. J. Surgent<sup>1</sup>, A. Riaz<sup>1</sup>, K. K. Ausderau<sup>1</sup>, D. C. Dean<sup>2</sup> and A. L. Alexander<sup>3</sup>,** (1)University of Wisconsin - Madison, Madison, WI, (2)Pediatrics & Medical Physics, University of Wisconsin - Madison, Madison, WI, (3)Medical Physics & Psychiatry, University of Wisconsin - Madison, Madison, WI

Background: Children with autism spectrum disorder (ASD) often demonstrate differences in sensory responsivity compared to typically developing (TD) peers (Baranek et al., 2006). This atypical sensory responsivity can significantly impact overall quality of life (Ismael, Lawson, & Hartwell, 2018). A study of infants at high risk for ASD identified the genu of the corpus callosum

and the cerebellar peduncles as white matter tracts associated with sensory symptom severity (Wolff et al., 2017). However, it is unclear if these associations remain after infancy. Further, we do not know the degree to which the neural correlates of sensory symptom severity are similar or distinct in children with ASD and TD.

**Objectives:** Identify areas where white matter microstructure is 1) associated with sensory symptom severity and 2) distinctly related to sensory symptom severity based on diagnostic status.

**Methods:** 153 children (6-10 years old) completed a diffusion-weighted imaging (DWI) scan and sensory measures (57 children with ASD, 96 children with TD). Overall sensory symptom severity was assessed using the parent-reported Sensory Experience Questionnaire Version 3 (Ausderau et al., 2013). Multi-shell DWI was performed on a 3T GE Scanner with a 32-channel head coil and isotropic 1.8mm voxels. Voxel-based analysis with general linear modeling was used to identify brain areas where T-SPOON corrected fractional anisotropy (FA) was associated with sensory symptom severity (FA~sensory symptom severity\*diagnostic group + age + sex + average head motion). False discovery rate ( $p < .05$ ) was used for multiple comparisons with a cluster threshold of  $k > 10$  contiguous voxels.

**Results:** VBM analyses revealed 7 clusters (sizes: 20-195 voxels) where FA was similarly associated with sensory symptom severity across groups (i.e. sensory symptom severity main effects; Figure 1). Clusters with positive FA-severity correlations were located in the left and right middle cerebellar peduncle, left and right middle temporal white matter, and the right superior corona radiata. Clusters with negative FA-severity correlations were in the left inferior corticospinal tract and the body of the corpus callosum. Analyses also revealed 34 clusters (sizes: 10-436 voxels) where the relationship between FA and sensory symptom severity was dependent upon diagnostic status (i.e. sensory symptom severity x diagnosis interactions; Figure 2). These clusters showed a negative association in the TD group and a positive association in the ASD group. They included the left and right superior cerebellar peduncles, left cerebral peduncle, left and right internal and external capsules, corpus callosum splenium, and left and right superior parietal white matter.

**Conclusions:** Results corroborated previous work demonstrating an association between cerebellar peduncles microstructure and sensory symptom severity but also identified several additional neural correlates of sensory symptoms. Intriguingly, there were more diagnostic-specific neural correlates of sensory symptoms than trans-diagnostic neural correlates of sensory symptoms, potentially indicating a unique role of white matter in the sensory processing network of children with ASD. Many areas identified in these analyses have been associated with sensory gating and integration and thus may suggest that white matter microstructure contributes to sensory symptom severity via altered sensory gating and integration in key brain regions.

**441.030 (Poster)** Misophonia, Hyperacusis, and the Relationship with Quality of Life in Autistic and Non-Autistic Adults  
**T. Q. Boucher<sup>1</sup>**, N. E. Scheerer<sup>2</sup>, G. Iarocci<sup>1</sup>, B. Bahmei<sup>3</sup>, S. Arzanpour<sup>3</sup> and E. Birmingham<sup>4</sup>, (1)Psychology, Simon Fraser University, Burnaby, BC, Canada, (2)Psychology, Western University, London, ON, Canada, (3)Mechatronic Systems Engineering, Simon Fraser University, Surrey, BC, Canada, (4)Faculty of Education, Simon Fraser University, Burnaby, BC, Canada

---

**Background:**

Sound sensitivity in people diagnosed with Autism Spectrum Disorder is well documented but the precise sensitivities, and how they impact quality of life, are not well understood (Stiegler & Davis, 2010). Misophonia (sensitivity to specific sounds, often human-produced, such as chewing) and hyperacusis (reduced tolerance to sound) have been investigated in populations of non-autistic adults and may cause negative emotional, behavioural, and physiological reactions (Jastreboff & Jastreboff, 2014). However, their prevalence and associated impairments are not sufficiently understood in autistic populations.

**Objectives:**

Investigate the presence of misophonia and hyperacusis symptoms in autistic and non-autistic adults and assess the relationship between symptom severity and mental health, quality of life, and autism symptoms.

**Methods:**

Sixty-two autistic ( $M_{age} = 33.10$ ,  $SD = 11.83$ ; 12 non-binary, 10 men, 40 women) and ninety-nine non-autistic adults ( $M_{age} = 37.14$ ,  $SD = 12.34$ , minimum; 10 non-binary, 4 men, 85 women) completed a series of online questionnaires. All participants completed the Autism Spectrum Quotient (AQ; Baron-Cohen et al., 2001) assessing autistic traits, Misophonia Questionnaire (MQ; Wu et al., 2014) assessing misophonia symptoms, Inventory of Hyperacusis Symptoms (IHS; Greenberg & Carlos, 2018)

assessing hyperacusis symptoms, Patient Health Questionnaire (PHQ-4; Kroenke et al., 2009) assessing depression and anxiety, and the World Health Organization Quality of Life–Brief (WHOQOL-BREF; WHOQoL Group, 1998). Autistic participants also completed the Autism Quality of Life Questionnaire (ASQoL; McConachie et al., 2018).

#### Results:

Relative to non-autistic participants, autistic participants had higher misophonia (MQ;  $t(159)=-3.266, p<.001$ ) and hyperacusis symptoms (IHS;  $t(159)=-5.201, p<.001$ ), and higher autistic traits (AQ;  $t(159)=-7.678, p<.001$ ). Autistic participants had lower quality of life in the Environment domain of the WHOQOL-BREF ( $t(159)=2.680, p=.008$ ). Fifty-three percent of autistic participants scored higher than the cutoff for clinical presence of hyperacusis symptoms compared to 23% of non-autistic participants. Forty-seven percent of autistic participants scored higher than the cutoff for clinically significant misophonia symptoms compared to 24% of non-autistic participants. MQ and IHS scores were significantly correlated in autistic ( $r(60)=.723, p<.001$ ) and non-autistic ( $r(97)=.840, p<.001$ ) participants. AQ scores significantly correlated with IHS scores in both autistic ( $r(60)=.316, p=.012$ ) and non-autistic participants ( $r(97)=.637, p<.001$ ). AQ scores were only correlated with MQ scores for non-autistic participants ( $r(97)=.550, p<.001$ ). The IHS was correlated with the PHQ ( $r(60)=.266, p=.037$ ) and ASQoL ( $r(58)=-.314, p=.015$ ) for autistic participants. For non-autistic participants, the PHQ was significantly correlated with IHS ( $r(97)=.536, p<.001$ ) and MQ ( $r(97)=.479, p<.001$ ) scores. IHS symptoms negatively correlated with all WHOQoL domains for non-autistic participants (Physical, Psychological, Social, and Environment), but only with the Environment domain for autistic participants ( $r(60)=-.377, p=.003$ ).

#### Conclusions:

The results suggest that both misophonia and hyperacusis are more common and severe in autistic adults, and are significantly related with one another. These sound sensitivities are related to lower environmental satisfaction (WHOQOL-BREF) and increased depression and anxiety (PHQ-4) in autistic and non-autistic adults. As the results are correlational in nature, additional research is needed to understand possible causal relationships between sound sensitivities, mental health, and quality of life.

**441.031 (Poster)** Motor, Praxis and Social Impairments in Children and Adolescents with Autism Spectrum Disorder, Developmental Coordination Disorder, and Typical Development  
*E. Kilroy<sup>1</sup>, P. A. Ring<sup>1</sup>, A. A. Nalbach<sup>2</sup>, A. A. Hossain<sup>1</sup>, C. Butera<sup>3</sup>, L. A. Harrison<sup>4</sup>, A. **Background:** For children with Autism Spectrum Disorder (ASD), social-communication impairments are part of the diagnostic criteria, although motor deficits also are present. Similarly, for children with Developmental Coordination Disorder (DCD), motor impairments are essential diagnostic criteria although social-emotional deficits may be present.

**Objectives:** This study examined social and motor/praxis deficits unique to ASD and DCD, and the relationships between them.

**Methods:** Tests included a motor skills assessment, Movement Assessment Battery for Children-2 (MABC-2) and two praxis measures: Postural Praxis test (PPr) of the Sensory Integration and Praxis Tests, and Florida Apraxia Battery (FAB) modified for children. Social measures included: Theory of Mind (ToM) and Affect Recognition (NEPSY-II subscales), Social Responsivity Scale-2 (SRS-2), Interpersonal Reactivity Index (IRI), and Empathy Quotient for Children and Adolescents (EMQ). Analyses controlled for age, sex, and IQ.

#### Results:

**Motor and Praxis Skills.** The ASD and DCD groups performed significantly worse than the TD group on all motor and praxis measures. The ASD and DCD groups did not differ on the MABC-2 nor the PPr. However, the ASD group performed worse than the DCD group on several FAB sections.

**Social Skills.** On the **SRS-2**, all three groups were significantly different (ASD>DCD>TD). On **ToM** Total and Verbal, the ASD group performed worse than DCD and TD groups. On **IRI** Perspective Taking (PT), the ASD group scored significantly worse than the TD group.

Relationship Among Social and Motor Skills. There were different significant correlations within groups.

TD. MABC-2 Total was correlated with IRI-PT. MABC-2 Manual Dexterity (MD) was negatively correlated with EMQ Cognitive Empathy; Balance was correlated with EMQ Cognitive Empathy and IRI-PT. MABC-2 Catching and Aiming was negatively correlated with ToM Total and Verbal. On the FAB, Gesture to Command was significantly correlated with SRS-2 Restricted and Repetitive Behaviors (RRB), and Tool Use was significantly correlated with ToM Total and Verbal. PPr was significantly negatively correlated with EMQ Prosocial.

ASD. MABC-2 Total and MD showed significant negative correlations with SRS-2 RRB; MD was also significantly correlated with SRS-2 Social Communication. Balance was significantly correlated with IRI PT. On the FAB, Imitation was significantly positively correlated with SRS-2 social motivation measures.

DCD- The only significant correlation between social and motor was MABC-2 MD with ToM Total.

Conclusions: Consistent with the literature, both DCD and ASD groups performed worse than TD on motor and praxis tests. However, the primary difference between clinical groups was the ASD group performed worse than the DCD group on the FAB. Thus, comparable motor impairments are present in both ASD and DCD groups, but praxis, which is considered to have a greater social-communicative value, was most impaired in the ASD group. In ASD, motor performance skills (MABC-2) were related to repetitive and restrictive behaviors, while praxis skills are related to social motivation. These relationships were not found in the DCD group suggesting that there are unique clinical implications for social and motor impairments for each group.

**441.032 (Poster)** New Device for Tip-Toe Behavior Treatment in ASD: A Proof of Concept Study Based on Sensory Impairment Pattern

Grossi<sup>2</sup>, (1)Program in Physical Therapy, University of Milano-Bicocca, School of Medicine and Surgery, Monza, Italy, (2)Autism Research Unit, Villa Santa Maria Foundation, Tavernerio, Italy*

---

Background:

Toe walking is a possible finding in individuals with ASD. In a previous study, we documented the presence of this behavior also during the maintenance of standing position from which the term “tip-toe behavior” (TTB). In a further study, using the Short Sensory Profile (SSP) tool we found different patterns of sensory profile in TTB ASD individuals with two opposite forms: “Under responsive/Seeks sensation” or “tactile hypersensitivity” Since in a pilot study we found a TTB decreasing during standing on a mattress when compared on a hard surface, we have developed a device to be worn within shoes consisting in a special insole for subjects with tactile hypersensitivity.

Objectives:

The study aim is to offer a proof of concept behind a rational approach to TTB treatment based on individual sensory profile.

Methods:

The ASD diagnosis followed the DSM-5 criteria, and a diagnosis confirmation was performed using ADOS-2. Two subjects (subject A: male, 15 years; subject B: male, age: 10,5 years) were selected among a sample of 14 TTB ASD subjects to whom the SSP tool was administered. Subject A expressing a “definite difference” in “Under responsive/seeking sensation” section and a typical performance in “Tactile Sensitivity” section, while subject B expressing a “definite difference” in “Tactile Sensitivity” section and a typical performance in “Under responsive/seeking sensation” section.

We developed an insole made of soft material such as cellular rubber to be inserted inside each shoe. This insole has a constant thickness between 2.0 and 12.0 millimeters which is adapted to individual needs and a density between 0.10 and 0.20 g/cm<sup>3</sup>.

Both subjects wore the device for 48 weeks, 6 hours a day, five days a week. At baseline (T0) and every four months (T1, T2, T3) TTB intensity during standing position was assessed using video recordings taken during a static task (playing in front of a playing table for 90 seconds) without shoes and with socks, using a standardized methodology previously described. The test was repeated in three different days. An independent therapist not involved in test operation analyzed the videos of the static task trials by calculating the cumulative time in seconds spent along ninety seconds on full feet support versus one foot on toes versus

both feet on toes. The mean time of the three trials was then calculated for the three conditions. In this study, we considered as outcome measure the mean percentage of cumulative time spent with a foot on the tips plus both feet on the tips.

Results:

In subject A no changes in TTB intensity was found (T0 value = 71%; T1-T3 average value = 79%), while in subject B a marked reduction in TTB intensity was found (T0 value = 72%; T1-T3 average value = 36,3%) (Figure 1).

Conclusions:

The results obtained in these case reports constitute a proof of concept for the development of special devices to treat TTB according to sensory profile expressed. In particular in presence of “tactile hypersensitivity”, an intervention with special rubber insole seems rationale.

**441.033** (Poster) Parent Perspectives: Sensory Sensitivities Impact the Transition to Adulthood in Young Adults with ASD  
**R. Hantman<sup>1</sup>** and **H. Tager-Flusberg<sup>2</sup>**, (1)*Boston University, Boston, MA*, (2)*Department of Psychological and Brain Sciences, Boston University, Boston, MA*

---

**Background:** Sensory sensitivities are prevalent in individuals with autism spectrum disorder (ASD; Baranek et al., 2006; Tomcheck & Dunn, 2007). Most studies focus on sensory symptoms in younger individuals (Ben-Sasson, 2019), although they likely impact older individuals. Parents of young adults with ASD express concerns regarding their children’s transition to adulthood from vocational, daily living skills, and service perspectives (Cheak-Zamora et al., 2017; Cribb et al., 2019; Laxman et al., 2019), but it is unknown how parents conceptualize their children’s sensory sensitivities in relation to their transition to independence.

**Objectives:** We aim to examine the intersection of sensory sensitivities and the transition to adulthood from parental perspectives.

**Methods:** Participants were parents, mostly mothers (97%), of young adults with ASD (aged 16;0-25;11), who still live at home, and who, from a screener, have sensory sensitivities. 38 participants completed questionnaires about their children and a semi-structured interview about how their children’s sensory behaviors impact their transition. A composite variable was calculated to determine child independence based upon education, high school graduation plan, employment, driver’s license, and z-score transformed daily living skills standard score from the Vineland Adaptive Behavior Scales. Higher scores indicated greater independence. The Adult/Adolescent Sensory Profile determined if child sensory behavior severity was less than, similar to, or more than most people. The interviews were transcribed, and three questions were thematically analyzed, taking a qualitative approach regarding:

1. The intersection of sensory sensitivities and the transition to adulthood,
2. Sensory sensitivities as a mechanism towards independence, and
3. The sensory sensitivities’ impact on parental expectations for their child’s transition.

Derived themes were examined for frequency and in relation to independence, age, and sensory behavior severity.

**Results:** 84% of parents reported that their children’s sensory sensitivities intersected with their transition, mostly due to daily functioning (56%) and limiting job opportunities (25%). Over half (53%) of parents believed that their children’s sensory sensitivities were obstacles towards independence, citing daily functioning interference, anxiety, and job options. Only 5% of parents considered sensory sensitivities to be vehicles *helping* their child towards independence (e.g., facilitating vocations), 24% considered them to be both, and 18% considered them to be neither. Almost two-thirds (63%) of parents reported that their children’s sensory sensitivities impacted their expectations for their children’s independence, positively (4%) and negatively (33%). 29% of parents felt their children’s sensory sensitivities hindered independence (Table 1). 65% and, with some caution, 100% of parents who endorsed that their children’s sensory sensitivities were obstacles or vehicles towards their independence, respectively, had more independent children. Otherwise, neither independence nor age largely differentiated parental beliefs. Over half (53%) of parents who said their children’s sensory sensitivities intersected with their transition had children with more severe low registration (i.e., under-responsive) sensory behaviors (Table 2).

**Conclusions:** Parents strongly believe that their children’s sensory sensitivities impact their children’s transition to adulthood, primarily regarding daily functioning and job opportunities. Identifying how sensory sensitivities impact the transition to

independence may be important in determining relevant familial supports. Future work should examine these issues directly from individuals with ASD.

**441.034** (Poster) Perceptual Processing Links Autism and Synesthesia: A Twin Study

*T. M. van Leeuwen<sup>1</sup>, L. Wilsson<sup>2</sup>, H. Nobel Norrman<sup>2</sup>, M. Dingemans<sup>3</sup>, S. Bolte<sup>4</sup> and J. Neufeld<sup>5</sup>, (1)Donders Institute for Brain, Cognition and Behaviour, Radboud University, Nijmegen, Netherlands, (2)Center of Neurodevelopmental Disorders at Karolinska Institutet (KIND), Stockholm, Sweden, (3)Centre for Language Studies, Radboud University, Nijmegen, Netherlands, (4)Center of Neurodevelopmental Disorders (KIND), Centre for Psychiatry Research; Department of Women's and Children's Health, Karolinska Institutet, & Stockholm Health Care Services, Region Stockholm, Stockholm, Sweden, (5)Center of Neurodevelopmental Disorders (KIND), Centre for Psychiatry Research; Department of Women's and Children's Health, Karolinska Institutet, & Stockholm Health Care Services, Region Stockholm, Stockholm, Sweden*

---

**Background:** Synesthesia is a non-pathological condition where sensory stimuli (e.g. letters or sounds) lead to additional sensations (e.g. color). It occurs more commonly in individuals diagnosed with Autism Spectrum Condition (ASC) and is associated with increased autistic traits and autism-related perceptual processing characteristics, including a more detail-focused attentional style and altered sensory sensitivity. In addition, autistic traits correlate with the degree of synesthesia (consistency of color choices on an objective synesthesia test) in non-synesthetes.

**Objectives:** We aimed to investigate whether the degree of synesthesia for graphemes is associated with autistic traits and perceptual processing alterations within twin pairs, where all factors shared by twins (e.g. age, family background, and 50-100% genetics) are implicitly controlled for, and across the cohort.

**Methods:** We investigated a predominantly non-synesthetic twin sample, enriched for ASC and other neurodevelopmental disorders, NDDs (n=65 individuals including 22 complete pairs, 14-34 years, 60% female, 12 with NDD diagnosis), modelling the linear relationships between the degree of synesthesia (=dependent variable) and autistic traits, sensory sensitivity, and visual feature integration (as independent variables), both within-twin pairs and across the entire cohort. The degree of synesthesia was assessed using a gold standard synesthesia consistency test where participants chose colors for digits and the letters of the alphabet three times. The score was calculated as the mean of the Euclidean distances in CIELUV color space between participant responses for the three different trials per item (Rothen et al. 2013), with lower consistency scores indicating higher levels of synesthetic color consistency (= more similar colors chosen). Autistic traits were assessed with the Autism Quotient (AQ, Baron-Cohen et al., 2001), sensory sensitivity with the Sensory Profile (Brown and Dunn, 2002) and visual feature integration ability with the Fragmented Pictures Test where participants identified incomplete (fragmented) images with as little visual information as possible (Kessler et al., 1993).

**Results:** Within twin pairs, a higher degree of synesthesia (= lower score) was associated with increased autistic traits only within the attention to details domain ( $\beta(95\%CI)=-.66 (-1.21, -.11)$ ,  $SE=.28$ ,  $p=.019$ ), with sensory hyper- ( $\beta(95\%CI)=-.60 (-1.14, -.06)$ ,  $SE=.28$ ,  $p=.031$ ), but not hypo-sensitivity and with being better in visual feature integration ( $\beta(95\%CI)=.47 (.08, .85)$ ,  $SE=.20$ ,  $p=.017$ ). Similar associations were found across the sample, although standardized regression coefficients were only about half the size and only the association with sensory sensitivity reached significance ( $\beta(95\%CI)=-.35 (-0.68, -.01)$ ,  $SE=.17$ ,  $p=.044$ ).

**Conclusions:** Consistent with previous findings, the results support an association between the degree of synesthesia and autistic traits within the attention to details domain and sensory hyper-sensitivity. Better visual feature integration in more synesthetic individuals indicates that they might be able to overcome a by default more detail-focused attentional style if task instructions demand it. Further, the results indicate that a twin design can be more sensitive for detecting these associations.

**441.035** (Poster) Pressing a Button and Drinking from a Cup: Upper Extremity Movements during Activities of Daily Living in Children with Autism Spectrum Disorder

*N. E. Fears, T. Templin and H. L. Miller, University of North Texas Health Science Center, Fort Worth, TX*

---

**Background:**

Children with Autism Spectrum Disorder often struggle with activities of daily living (ADLs) even when their cognitive ability is average, possibly due to differences in motor development. Specifically, as many as 90% of children with ASD have clinically significant, persistent motor delays or dysfunction, which correlate with difficulties in performing ADLs. Upper extremity motor skills play a crucial role in children's ability to perform ADLs. Current standardized motor assessments and caregiver reports of ADLs reduce complex behaviors down to success or failure, potentially neglecting clinically-significant information that could

help to explain how children complete tasks, or why they may fail. Conversely, while laboratory tasks can improve our understanding of underlying motor mechanisms using quantifiable, objective measures, it is difficult to link performance on customized tasks to functional ability in daily living. To bridge this gap, we are evaluating two ADLs, pressing a button and drinking from a cup, using motion capture technology to objectively quantify how movement impacts the performance of ADLs.

### **Objectives:**

The objective of the current study was to quantify differences between children with ASD and typically developing (TD) children in the execution of upper extremity movements during ADLs. Specifically, we used spatial (e.g. path length) and speed (e.g. velocity, acceleration, jerk) based characteristics of movements to analyze differences in motor mechanisms that may disrupt performance of upper extremity ADLs in children with ASD.

### **Methods:**

Twelve age-matched pairs of children with ASD and TD children ( $M_{age}=9.31$ ,  $SD_{age}=3.43$ ,  $Range_{age}=4-14$ ) reached to press a button and to drink from a cup while instrumented for upper-body motion capture and binocular mobile eye-tracking (Figure 1). Participants completed 8 trials for each task, 4 per hand. The button and cup placement was standardized to the participant's 2<sup>nd</sup> metacarpophalangeal joint when their arms were stretched out in front of them. Participants in the TD group did not have a diagnosis of ASD, nor any first-degree relatives with a diagnosis of ASD.

### **Results:**

Preliminary analysis of the data indicated that children with ASD made less fluid movements when performing ADLs compared to TD children. Specifically, children with ASD showed increased jerk, an indicator of decreased fluidity, when reaching toward the button or cup compared to TD children. Figure 2 illustrates a pair of 5-year-old children with ASD and TD reaching to pick up and drink from a cup. Subsequent analyses include assessment of group differences between children with ASD and TD children in measures of movement fluidity during reaching to press a button and reaching to pick up a cup.

### **Conclusions:**

Results suggest that differences between children with ASD and TD children's performance of ADLs may be due to decreased spatial efficiency and fluidity of movements by children with ASD. By measuring movement during upper extremity ADLs, we can begin to understand why children with ASD succeed on some tasks but fail on others. The new data provided by this study will inform the development of interventions specifically tailored to the unique motor challenges observed in ASD.

**441.036 (Poster)** Relationships between Visual Fixation and Goal-Directed Body Movement Differ between Autism Spectrum Disorder, Developmental Coordination Disorder, and Typical Development.

*H. L. Miller, N. E. Fears and N. L. Bugnariu, University of North Texas Health Science Center, Fort Worth, TX*

---

**Background:** Individuals with Autism Spectrum Disorder (ASD) exhibit significant sensorimotor differences. Notably, children with ASD have documented difficulties with oculomotor and postural control, as we and others have previously demonstrated. Despite these documented difficulties, few studies have quantified the relationship between vision and movement together in children with ASD, and most studies have focused on quiet standing rather than dynamic postural control. Further, few studies of sensorimotor control have compared ASD to other neurodevelopmental conditions with motor symptoms (e.g., Developmental Coordination Disorder, DCD). Here, we examined how children with ASD, children with DCD, and typically-developing (TD) children use visual information to guide goal-directed body movements.

**Objectives:** The first objective of this study was to quantify the relationship between oculomotor movements and dynamic postural control in children with ASD. Specifically, we examined where children were looking while completing the task (e.g., to the target object or the user-controlled object), and how long children used to complete the task. The second objective of this study was to determine whether oculomotor control and dynamic postural control differed between children with ASD, children with DCD, and TD children.

**Methods:** Thirty children (ASD  $n = 10$ ,  $M_{age} = 9.50$  years,  $SD_{age} = 1.51$  years,  $Range_{age} = 7-12$ ; DCD  $n = 10$ ,  $M_{age} = 9.30$  years,  $SD_{age} = 1.25$  years,  $Range_{age} = 8-12$ ; TD  $n = 10$ ,  $M_{age} = 9.60$  years,  $SD_{age} = 1.57$  years,  $Range_{age} = 7-12$ ) completed a goal-directed body movement task in a virtual environment while instrumented for full-body motion capture and binocular mobile eye-tracking. Participants moved a user-controlled object (blue ball) laterally to a target (green rectangle) at each of 4 positions

(near/far, right/left) for a total of 16 trials (Figure 1). The user-controlled object translated along a horizontal axis based on the position of a marker placed on the 7<sup>th</sup> cervical vertebra. All participants scored >70 on the nonverbal domain of the WASI-II. Participants in the DCD and TD groups did not have a diagnosis of ASD or any first-degree relatives with ASD.

**Results:** Preliminary analysis of 12 participants (ASD=4, DCD=4, TD=4) indicated differences in the mean proportion of time fixating the target object (ASD=0.15, TD/DCD = 0.20; Figure 2A) and the user-controlled object (ASD=0.05, DCD=0.12, TD=0.02; Figure 2B). The ASD group also had greater variability in task completion time compared to the TD/DCD groups (standard deviations: ASD=6.33, DCD=2.10, TD=3.41; Figure 2C), though the overall rate of task success was similar across groups (ASD=87.5%, DCD=79.7%, TD=81.3%).

**Conclusions:** These results suggest that differences in the use of visual information underlying goal-directed movement in ASD, DCD, and TD influence movement efficiency. Individuals with ASD may exhibit greater variability in task completion time due to inefficiency of motor planning and execution. Individuals with DCD may make a larger proportion of fixations to the user-controlled object relative to their peers due to difficulty mapping the relationship between their movements in the real world and the virtual world. Further work is necessary to clarify the role of visual input and motor output in atypical development.

#### **441.037 (Poster)** Repetitive and Restricted Behaviours and Anxiety in Autism Spectrum Disorder: A Systematic Review and Meta-Analysis

**T. J. Sellick<sup>1</sup>, K. Williams<sup>2</sup> and A. Ure<sup>3</sup>,** (1)School of Psychological Sciences, Monash University, Clayton, VIC, Australia, (2)Department of Paediatrics, Monash University, Melbourne, VIC, Australia, (3)Department of Paediatrics, Monash University, Clayton, VIC, Australia

---

##### Background:

Many individuals with Autism Spectrum Disorder (ASD) experience anxiety, which compounds ASD related difficulties and inhibits daily functioning. However, identifying and treating anxiety in this population is challenging due to its atypical presentation and its overlap with the core features of ASD. Repetitive and restricted behaviours (RRBs) have been found to be positively associated with anxiety and could be used as observable markers to help clinicians identify anxiety in this population. Yet our understanding of the direction and magnitude of the association between anxiety and RRBs remains unclear.

##### Objectives:

Through a systematic review and meta-analysis, this study aimed to 1) assess the association between RRB subtypes and anxiety symptoms in individuals with ASD; 2) assess the association between the RRB subtypes in the context of the anxiety-RRB relationship; and 3) identify factors associated with both RRBs and anxiety symptoms.

##### Methods:

We systematically searched bibliographic databases, clinical trial registries, and dissertation databases as per the Preferred Reporting Items for Systematic Reviews and Meta-Analyses guidelines. Titles, abstracts, and full texts were reviewed by two independent reviewers, whilst data extraction and risk of bias assessments were conducted by one reviewer. Random-effects meta-analyses were then conducted to calculate the pooled association between anxiety and RRB subtypes and the distinct RRB subtypes, whilst the risk factors associated with the anxiety-RRB relationship were narratively reported.

##### Results:

The systematic search identified 3,160 publications. Of these, 42 studies were included in the review. A significant, positive association was found between anxiety and repetitive movements, restricted interests, insistence on sameness, and sensory processing abnormalities ( $r = .22 - .47$ ). Among RRB subtypes, a strong association was identified between insistence on sameness and restricted interests ( $r = .69$ ), whilst there was no association between repetitive movements and restricted interests ( $r = .25$ ). Moderate associations were identified between all other RRB subtypes ( $r = .31 - .41$ ). Finally, this review collated 22 factors which may influence the anxiety-RRB relationship and found evidence for the influencing role of other RRB subtypes, social communication deficits, and intolerance of uncertainty.

##### Conclusions:

This was the first review to examine the association between anxiety and the four subtypes of RRBs in individuals with ASD. We found significant positive associations between anxiety and all RRB subtypes, and that these relationships are influenced by the presence of additional RRBs, intolerance of uncertainty, and the severity of social communication deficits. The identification of autistic traits does not rule out coexisting anxiety and the type and severity of these traits may assist clinicians to identify those at increased risk of anxiety, thus enabling early identification and intervention. However, further work is needed to understand the mechanisms underpinning these relationships. There are likely multiple, inter-twining causal pathways. Clinicians should strive to conduct comprehensive functional assessments of RRBs and anxiety and monitor if interventions targeting RRBs reduce anxiety or vice versa. Intervention studies targeting the factors thought to be involved in the RRB-anxiety relationship may improve outcomes for individuals with ASD.

**441.038** (Poster) Sensorimotor and Cortical-Cerebellar Lateralization in Autism Spectrum Disorder

**W. S. McKinney**<sup>1,2</sup>, **K. E. Unruh**<sup>1,2</sup>, **M. H. Campbell**<sup>1,2</sup> and **M. W. Mosconi**<sup>1,2</sup>, (1)Kansas Center for Autism Research and Training (K-CART), University of Kansas, Lawrence, KS, (2)Clinical Child Psychology Program, Schiefelbusch Institute for Life Span Studies, University of Kansas, Lawrence, KS

---

**Background:** Sensorimotor abilities are disrupted in most individuals with autism spectrum disorder (ASD). Atypical lateralization of sensorimotor functioning has been documented, implicating reduced hemispheric specialization of motor networks. Lateralization of sensorimotor brain function during behavior has not been systematically assessed in ASD, limiting insights into neurodevelopmental mechanisms. In the present study, we examined sensorimotor behavior and brain activation during left- and right-handed precision gripping in individuals with ASD to assess lateralization of sensorimotor behavior and brain function.

**Objectives:** To (1) characterize precision sensorimotor behavior across right and left hands in ASD, and (2) define functional brain networks associated with right- and left-hand precision sensorimotor control in ASD.

**Methods:** Forty-one individuals with ASD, including eight left-handed individuals, and 28 typically developing (TD) controls, including three left-handed individuals, matched on age (range: 10-34 years) and sex completed a visually guided precision gripping task during functional MRI (fMRI). During the task, participants gripped a force transducer while viewing two horizontal bars. Their task was to press on the transducer to move the lower “force” bar upwards to the height of the static “target” bar. The target bar was set at 45% of each individual’s maximum voluntary contraction (MVC). Participants completed three 26-s blocks of gripping separated by rest blocks. They completed separate runs for right and left hands. Mean force, force complexity, and force variability were examined separately for each hand. Percent BOLD signal change during gripping vs. rest was examined in cortical and cerebellar sensorimotor regions of interest (ROIs), including bilateral primary motor cortex (M1), somatosensory cortex (S1), inferior parietal lobule (IPL), cerebellar lobules V/VI, and cerebellar Crus I.

**Results:** Individuals with ASD showed reduced mean force, reduced force complexity, and greater force variability compared to TD controls across both hands. Both individuals with ASD and TD controls showed increased brain activation during gripping compared to rest across all ROIs, though group differences in activation varied as a function of hand and hemisphere. During right-hand gripping, individuals with ASD showed increased left M1 and left S1 activation relative to TD controls. During left hand gripping, individuals with ASD showed reduced activation in right M1, right S1, bilateral IPL, and left cerebellar lobules V/VI relative to TD controls. In TD controls only, increased activation in left M1 during right hand gripping and increased left cerebellar lobules V/VI activation during right and left gripping each were associated with increased force complexity.

**Conclusions:** Force variability and regularity each were elevated in individuals with ASD compared to controls during both right- and left-hand gripping suggesting bilateral sensorimotor disruptions. Individuals with ASD showed increased contralateral cortical activation relative to controls during right hand gripping, but decreased contralateral cortical and ipsilateral cerebellar activation during left hand gripping suggesting that brain mechanisms associated with reduced precision sensorimotor control in ASD vary as a function of effector side. Our finding that increased activation in left M1 and cerebellar lobules V/VI were associated with increased force complexity in TD controls only further suggests lateralized reorganization of sensorimotor networks in ASD.

**441.039** (Poster) Sensorimotor Gating in Autistic Children and Adolescents and Their Typically-Developing Peers

**K. R. Henderson**<sup>1</sup>, **S. E. Schulz**<sup>1</sup>, **R. Phillips**<sup>2</sup>, **A. Seif**<sup>3</sup>, **S. Schmid**<sup>3</sup> and **R. A. Stevenson**<sup>4</sup>, (1)Western University, London, ON, Canada, (2)University of Western Ontario, London, ON, Canada, (3)Anatomy and Cell Biology, University of Western Ontario, London, ON, Canada, (4)Brain and Mind Institute, University of Western Ontario, London, ON, Canada

---

**Background:** Sensory gating refers to the ability to focus on the most important aspects of one’s environment by filtering out extraneous stimuli from awareness. Sensory gating, often assessed as sensorimotor gating, is hypothesized to function atypically in autistic individuals. Key measures of sensorimotor gating include habituation/sensitization and prepulse inhibition of the startle

response. Habituation refers to a decrease in response to a novel stimulus after being exposed to it repeatedly. While sensitization is an indication of the opposite, suggesting an increase in response to a repeated stimulus. Prepulse inhibition refers to when perception of a weaker pre-stimulus produces an attenuated response to the startle-inducing stimulus. Recent findings suggest developmental changes in sensorimotor gating in ASD such that autistic children display higher startle reactions possibly due to slower habituation/stronger sensitization, and atypical prepulse inhibition. However, the development of sensorimotor gating in autistic children has not been well mapped.

**Objectives:** To measure sensorimotor gating within autistic children/adolescents and the broader autism phenotype (BAP) relative to their typically-developing peers.

**Methods:** Autistic children/adolescents, their siblings, and typically developing controls between the ages of 4-16 (N=32), completed an auditory startle task to assess the acoustic startle response, prepulse inhibition, and habituation/sensitization. Participants passively listened to a series of pulses ranging from 65-105 dB while viewing a silent film and their startle eye-blink response was measured by means of electromyography. Prepulse inhibition trials included an 85 dB prepulse 120 ms prior to a 105 dB pulse. In statistical analyses, autistic children/adolescents and their siblings were combined into one broad autism phenotypes (BAP) group and compared against the control group. This was done to increase the sample size of the ASD group and was justified on the basis that siblings of autistic individuals are considered higher risk for developing ASD and exhibiting autistic traits.

**Results:** A MM-ANOVA suggested individuals in the BAP group habituated more to the startle stimulus throughout the experiment, with a medium effect size,  $\eta^2=.120$ , as shown in Figure 1A. Although pulse intensity affected the amplitude of participants' startle responses,  $\eta^2=.347$ , this effect showed minimal differences between groups,  $\eta^2=.025$ , as shown in Figure 1B, suggesting individuals with the BAP have a typical acoustic startle response. Lastly, prepulse inhibition had a small effect size,  $d=.40$ , suggesting individuals in the BAP and control group did not differ in response inhibition.

**Conclusions:** These findings show that autistic children/adolescents and those with the BAP, display some differences in sensorimotor gating, specifically habituation. Previous work has suggested that there are sensory differences in ASD. However, our results do not support this. Since autistic children/adolescents and those with the BAP showed increased habituation, this suggests that their ability to filter redundant sensory information may actually be enhanced.

**441.040 (Poster) Sensory Mechanisms of Atypical Motor Variability and Regularity in Autism Spectrum Disorder**  
**R. L. Shafer**<sup>1,2</sup>, Z. Wang<sup>3</sup>, J. Bartolotti<sup>1,4</sup> and M. W. Mosconi<sup>5</sup>, (1)Life Span Institute, University of Kansas, Lawrence, KS, (2)Kansas Center for Autism Research and Training, University of Kansas, Lawrence, KS, (3)Department of Occupational Therapy, University of Florida, Gainesville, FL, (4)Kansas Center for Autism Research and Training (K-CART), University of Kansas, Lawrence, KS, (5)Clinical Child Psychology Program, Schiefelbusch Institute for Life Span Studies, University of Kansas, Lawrence, KS

---

**Background:** Deficits in sensorimotor integration are highly prevalent in persons with Autism Spectrum Disorders (ASD). Our prior studies of precision gripping demonstrate that increased motor variability and regularity are exacerbated when visual feedback is either enhanced or degraded in individuals with ASD, suggesting that they are over-reliant on visual feedback during basic motor actions. Other studies indicate over-reliance on proprioceptive feedback during motor learning in ASD, suggesting separate sensory feedback processes may be selectively altered in ASD.

**Objectives:** Given the pervasiveness of sensorimotor behavioral differences in ASD, understanding sensory and motor control processes is important for identifying physiological mechanisms and determining new targets for interventions. To clarify sensory mechanisms of increased motor variability and regularity in ASD, we characterized precision gripping behavior during conditions in which visual and proprioceptive feedback were altered.

**Methods:** Participants with ASD (N=43, 11F) and controls (N=23, 12F) matched on age (10-20 years) and non-verbal IQ completed tests of precision gripping. Participants pressed on force sensors with their index finger and thumb so that a moving bar corresponding to their force output reached and stayed as stable as possible at the level of a stationary target bar. Visual feedback was manipulated by changing the visual gain of the force bar (low, medium, high), which moved more per change in force output at higher gains. Proprioceptive feedback was manipulated by applying 80Hz tendon vibration at the wrist to induce an illusion of muscle contraction. This was compared to a condition with the tendon vibrator turned off. Force variability (standard deviation) and regularity (sample entropy) were examined.

**Results:** Controls showed increased force variability with the tendon vibration turned on compared to off (3.372,  $p < 0.001$ ); however, the ASD group showed no difference in force variability between the tendon vibration conditions ( $t = -0.960$ ,  $p =$

0.338). Individuals with ASD showed stronger age-associated reductions in force variability relative to controls across tendon vibrator and gain conditions (Group x Age:  $t = -4.05$ ,  $p < .001$ ). Individuals with ASD also showed greater age-associated increases in force regularity relative to controls, especially at higher gain levels (Group x Gain Level x Age:  $t = -3.22$ ,  $p = 0.001$ ). Unlike the ASD group for whom regularity increased with age in both tendon vibration conditions, controls only showed age-related gains when the tendon vibrator was off (Group x Vibration Frequency x Age:  $t = 2.46$ ,  $p = .014$ ).

Conclusions: Force output in controls was affected by disrupted proprioceptive and visual feedback, indicating that they integrate both sources to adjust fine motor behavior. However, persons with ASD did not change their force output when proprioceptive feedback was disrupted, suggesting that they rely primarily on visual feedback. Additionally, controls showed minimal change in force regularity and variability with increased age while persons with ASD showed age-associated improvements through adolescence suggesting sensorimotor issues may be more prominent in early development. Our findings help clarify the sensory integration deficits that contribute to motor issues in individuals with ASD and implicate distinct, atypical neurodevelopmental mechanisms in patients.

**441.041** (Poster) Sensory Phenotypes in Autism and Their Relationship with Anxiety

**Z. Ding<sup>1</sup>**, N. E. Scheerer<sup>2</sup>, C. Yang<sup>3</sup>, B. Stojanoski<sup>4</sup>, E. Anagnostou<sup>4</sup>, R. Nicolson<sup>5</sup>, E. Kelley<sup>6</sup>, S. Stevenson<sup>9</sup>, (1)Western University, London, ON, Canada, (2)Psychology, Western University, London, ON, Canada, (3)Western University, London, ON, Canada, (4)Autism Research Center, Bloorview Research Institute, Holland Bloorview Kids Rehabilitation Hospital, Toronto, ON, Canada, (5)University of Western Ontario, London, ON, Canada, (6)Queen's University, Kingston, ON, Canada, (7)McMaster Autism Research Team, McMaster University, Hamilton, ON, Canada, (8)Genomics, Queen's Genomics Lab at Ongwanada, Kingston, ON, Canada, (9)Brain and Mind Institute, University of Western Ontario, London, ON, Canada

---

Background: Sensory processing difficulties and high levels of anxiety are commonly found in autistic children, with these issues showing a high level of heterogeneity in the autistic population. When it comes to treating these sensory and anxiety issues, the treatments often do not account for the individual differences in the type and degree of sensory and anxiety issues. As a result, generic treatments are being applied to specific problems, potentially reducing the efficacy of these treatments. In an attempt to parse some of the heterogeneity in sensory and anxiety issues, studies have begun to focus on identifying patterns within these sensory and anxiety issues. However, the relationship between these sensory and anxiety issues remains unclear.

Objectives: The objective of this research is to examine whether anxiety issues in autistic children will cluster into meaningful phenotypes, and if so, whether there is a relationship between these anxiety phenotypes and sensory issues.

Methods: The present study used a secondary dataset collected via from the Province of Ontario Neurodevelopmental Disorders Network (POND). Data from 302 participants who had primary diagnoses of autism and had Short Sensory Profile (SSP) and Revised Child Anxiety and Depression Scale (RCADS) scores were included. A K-means cluster analysis was conducted on the subscale scores of SSP and the RCADS to determine whether meaningful sensory and anxiety phenotypes, respectively, could be generated. Follow-up ANOVAs were conducted to examine whether anxiety issues were related to specific sensory phenotypes.

Results: The cluster analysis of the anxiety symptoms did not yield meaningful phenotypes, rather the resultant phenotypes varied in anxiety severity but not anxiety subtype (see Figure 1). The cluster analysis of sensory data yielded a five-cluster model that minimized error variance and produced five meaningful sensory phenotypes, similar to previous research. These phenotypes can be generalized as (1) sensory adaptive, (2) generalized sensory differences, (3) sensory seeking, (4) low energy/weak, and (5) taste and smell sensitivity (see Figure 2a). Importantly, analysis of anxiety levels across these phenotypes revealed significantly differential results (see Figure 2b). "Sensory adaptive" phenotype showed significantly lower anxiety level than "generalized sensory differences" and "low energy/weak" phenotypes. The "generalized sensory differences" phenotype showed significantly higher anxiety levels than all phenotypes except the "low energy/weak".

Conclusions: Whereas meaningful sensory phenotypes could be identified, anxiety issues cluster based on the severity. The absence of a categorical organization of anxiety issues suggests that although different kinds of anxiety disorders have been found in ASD children, there is no identifiable pattern of co-occurrence of anxiety symptoms. Levels of anxiety did vary across the discrete sensory phenotypes, however. The "generalized sensory difference" phenotype, with the most severe sensory symptoms, was associated with the highest degree of anxiety. That is consistent with previous findings on the positive relationship between severity of sensory processing and anxiety problems in autism. Overall, identifying sensory phenotypes contributes to parse the heterogeneity of sensory characteristics and to develop more targeted treatment for ASD children. And anxiety problems should be given different consideration across five sensory phenotypes.

**441.042** (Poster) Sensory Processing, Prediction, and Anxiety in Autistic Children: Behavioral and Neurophysiologic Correlates

**Background:**

Atypical sensory processing is common in autism and can influence a host of behavioral domains. Unfortunately, the behavioral and neural correlates of atypical sensory processing remain somewhat elusive, which limits the effectiveness of supports for individuals who need them.

The brain's ability to predict upcoming sensory events, based on past experience, is central to sensory function and mental health, and has been implicated in autism. For instance, long-term irregularities in prediction of sensory events could lead to development of an intolerance of uncertainty (IU) and anxiety. Examining prediction could provide a useful perspective regarding behavioral and neural correlates of sensory processing in autistic children.

Atypical functioning of both sensory cortices and neural processing outside of these areas (i.e., supramodal) could contribute to aberrant sensory responsivity. For instance, differences in cerebellar and amygdala processing have been shown in autism studies and have been connected to sensory and higher order neural processes. Because the cerebellum and amygdala are highly connected to cortical sensory regions and play an important role in prediction and anxiety, we propose that irregular function and connectivity in these regions likely contribute to atypical sensory processing, IU, and anxiety in autistic persons.

**Objectives:**

We aimed to examine the relationship between behavioral measures of sensory processing, IU, and anxiety, and the association between these measures and functional connectivity between sensory and supramodal brain regions. We hypothesized that the autistic participants would demonstrate significant relationships between sensory processing, IU, and anxiety, and that these measures would correlate with hypo-connectivity between sensory cortices, the cerebellum, and amygdala.

**Methods:**

Participants were 30 children with a confirmed diagnosis of autism (27 male; mean age=9.13 years) and 26 nonautistic peers (19 male; mean age=9.38). All participants underwent a resting-state functional magnetic resonance imaging scan (rs-fMRI). Parents also completed several questionnaires: Short Sensory Profile<sup>s</sup> (SSP), Intolerance of Uncertainty Scale (IUS-12), and the Screen for Child Anxiety Related Disorders (SCARED). One-way analysis of variance (ANOVA) was used to test between-groups differences for each behavioral questionnaire. Furthermore, relationships between the behavioral questionnaires were calculated using regression and mediation analyses. Finally, between-groups differences in functional connectivity were calculated and associations between functional connectivity and behavioral results were evaluated via regression analysis.

**Results:**

Results revealed that autistic children presented with significantly more sensory atypicalities, greater IU, and heightened anxiety, compared to nonautistic children. Additionally, regression revealed a significant predictive effect of SSP scores on anxiety scores. Mediation analysis showed that IUS-12 scores significantly mediated this relationship. Associations between these behavioral correlations and functional connectivity between sensory cortices, the cerebellum, and the amygdala will also be presented.

**Conclusions:**

Our study suggests that heightened sensory processing irregularities in autistic children may be related to increased anxiety, an association that is mediated by IU. These findings provide evidence that irregular predictive abilities could play a role in behavioral phenomena common to autism. These results also implicate certain brain regions, such as sensory cortices, the cerebellum, and amygdala, which could eventually become targets for supportive action, improving services for autistic individuals.

**441.043 (Poster)** Sensory Responsivity in Social and Non-Social Contexts of Toddlers at Risk for Autism Spectrum Disorder  
**J. Gunderson<sup>1</sup>, E. Worthley<sup>1</sup>, R. Grzadzinski<sup>2</sup>, K. Botteron<sup>3</sup>, S. R. Dager<sup>4</sup>, A. M. Estes<sup>5</sup>, H. C. Hazlett<sup>6</sup>, R. T. Schultz<sup>1</sup>, L. Zwaigenbaum<sup>6</sup>, J. Piven<sup>6</sup> and J. J. Wolff<sup>6</sup>, (1)University of Minnesota, Minneapolis, MN, (2)University of North Carolina Chapel Hill, Chapel Hill, NC, (3)Washington University School of Medicine, St. Louis, MO, (4)Radiology, University of Washington, Seattle, WA, (5)Speech and Hearing Sciences, University of Washington, Seattle, WA, (6)\*co-senior author, University of North**

**Background:** Children with ASD present with a variety of sensory behaviors that overall differentiate them from their typically developing peers. The 'social brain' of individuals with ASD may underlay specific deficits in the processing or perception of social stimuli or stimuli situated within a social context (Pelphrey, Shultz, Hudac, & Wyk, 2011). However, empirical evidence of sensory responsiveness in young children who later develop ASD remains relatively limited, and it is unclear whether contextual aspects of sensory responsivity are meaningful to the expression of sensory features in children with ASD.

**Objectives:** The primary goal of this study was to examine whether social versus non-social context impacted the expression of sensory response patterns in infants at high risk for ASD and to examine if responsivity in social or nonsocial contexts were associated with severity of ASD symptoms.

**Methods:** Participants were from the Infant Brain Imaging Study, an ongoing longitudinal study of infants at high and low familial risk for ASD. The Sensory Experiences Questionnaire 2.1 (SEQ; Baranek et al., 2006) was collected for participants at 12 (n=292) and 24 (n=276) months of age. Linear mixed-effects models were used to examine SEQ social and non-social scores across 12 and 24 months of age for infants who did (HR-ASD=77) and did not develop ASD (HR-Neg=263). Correlations were examined to identify the strength of association between SEQ social and non-social scores and the Autism Diagnostic Observation Schedule severity scores (ADOS; Lord et al., 2000), Mullen early learning scales composite scores (MSEL-ELC; Mullen, 1995) and Vineland adaptive behavior scales-II composite scores (Vineland-II ABC; Sparrow, Balla, & Cicchetti, 2005).

**Results:** Significant differences in sensory responsivity across both social ( $F(2,338)=44.19, p<.001$ ) and non-social contexts ( $F(2,338)=24.05, p<.001$ ) were observed for HR-ASD infants relative to HR-Neg infants starting at 12 months of age. Group differences in responsivity scores for both social and non-social contexts widened by 24 months of age ( $F(2,226)=16.68, p<.001$ ). The results were relatively consistent when examine the influence of responsivity patterns (hypo responsivity, hyper-responsivity, sensory seeking) on social and nonsocial scores. However, within the non-social domain the effect of Group by Time was accounted for by the sensory seeking items ( $F(2, 225)=13.92, p<.001$ ). The social and non-social scores were negatively associated with adaptive behavior, but not significantly associated with IQ or ASD severity.

**Conclusions:** High-risk infants who later meet diagnostic criteria for ASD showed elevated sensory responsiveness in both social and non-social contexts at 12 months of age. Differences between groups expanded over the second year of life. Higher responsivity in both contexts for individuals with ASD indicates that there are generalized effects in sensory responsivity and/or registration that is not necessarily particular to socially salient information or social contexts. In addition, associations related to ASD severity and adaptive functioning were comparable between both social and non-social contextual scores, adding to the evidence that social versus non-social context is not particularly meaningful in the expression of sensory responsivity in ASD.

#### **441.044 (Poster) Sensory-Phenotype Clusters across Children with Autism and ADHD**

---

**Background:** Sensory-processing issues in Autism are heterogeneous, occurring across modalities and presenting in seemingly unique ways across individuals. Previous research has shown that certain sensory symptoms tend to cluster together in Autistic individuals, creating meaningful sensory phenotypes. Sensory issues are not unique to Autism but are also seen in other neurodevelopmental disorders including Attention-Deficit/Hyperactivity Disorder (ADHD). Despite their distinctions in diagnostic criteria, these disorders share many overlapping sensory issues (i.e. tactile sensitivity, low energy and movement difficulties). It is unclear whether the sensory symptoms across these clinical diagnoses cluster similarly, or whether Autism and ADHD have distinct sensory phenotypes.

**Objectives:** 1) Validate sensory phenotypes in Autism and identify novel, meaningful sensory phenotypes for ADHD; 2) Examine potential overlap in sensory phenotypes across diagnoses.

**Methods:** Data from 570 children with a primary clinical diagnosis of Autism Spectrum Disorder ( $M_{age}=10.0$  years,  $SD_{age}=4.48$  years) and 439 children with a primary clinical diagnosis of ADHD ( $M_{age}=10.0$  years,  $SD_{age}=3$  years) were extracted from the Province of Ontario Neurodevelopmental Disorder Network. The Short Sensory Profile, a well-validated questionnaire consisting of seven sensory subscales (tactile sensitivity, taste/smell sensitivity, movement sensitivity, under-responsive/seeking sensation, auditory filtering, low energy/weak, and visual/auditory sensitivity) was used to assess sensory issues. Data from the seven subscales of the Short Sensory Profile were subjected to a K-means cluster analysis for each disorder group. The Bayesian Information Criteria and previous literature were used to determine meaningful sensory phenotypes. Final cluster solutions were then compared across diagnostic groups.

**Results:** A five-cluster model was found to minimize error variance in both Autism and ADHD. These five meaningful sensory phenotypes can be described as Sensory Adaptive, Generalized Sensory Differences, Taste and Smell Sensitivity, Under-responsiveness and Sensory Seeking, and Low Energy/Weak (see Figures 1 and 2). Interestingly, for the Autism group, the Low Energy/Weak phenotype also showed movement difficulties, while for the ADHD group movement difficulties were not apparent in the Low Energy/Weak phenotype.

**Conclusions:** Sensory issues in Autism and ADHD cluster into meaningful sensory phenotypes. These phenotypes showed a high degree of overlap across diagnostic groups. Aside from the Low Energy/Weak phenotype where movement difficulties were also present for the Autism group, but not the ADHD group, the phenotypes were virtually identical. Importantly, these results suggest that sensory issues are qualitatively similar across both Autism and ADHD. These results support previous research suggesting that, while sensory issues are more severe in Autism than ADHD, they follow the same pattern of presentations. These results suggest that sensory issues are transdiagnostic and that these issues may result from similar mechanisms and cognitive underpinnings. Future research will explore how these phenotypes relate to other characteristics of Autism and ADHD.

**441.045 (Poster)** Somatosensory Profiles of Children with ASD, Carriers of a 16p11.2 Deletion and Typically Developing Children Using a Multi-Method Approach

*J. M. Almeida Osório, B. Rodríguez-Herreros, P. Yu, D. Romascano, V. Junod, S. Richetin, N. Chabane, M. Jequier Gyax and A. M. Maillard, Lausanne University Hospital, Lausanne, Switzerland*

---

**Background:** Sensory processing difficulties are frequent in neurodevelopmental disorders (NDD), and particularly in Autism Spectrum Disorder (ASD). Individuals present different sensory processing profiles, even within disorders. Considering the heterogeneity of clinical symptoms in ASD, it is challenging to outline a clear picture of the sensory profile of this disorder and its neural correlates. Carriers of the 16p11.2 deletion share a predisposing factor for NDD, including ASD. This genetically defined cohort offers a unique opportunity to identify specific sensory profiles in a population with more homogeneity and to compare sensory profiles across NDD. Additionally, the sensory phenotype of del16p11.2 carriers has not been assessed to date.

**Objectives:** The aim of this study is to assess and compare the sensory profiles in carriers of a 16p11.2 deletion, children with idiopathic ASD, and typically developing children and using a multi-method approach.

**Methods:** Participants included 121 ASD children, 17 carriers of the 16p11.2 deletion (del16p11.2) and 45 typically developing (TD) children. All participants were aged between 2 to 12 years. Behavioral responses to sensory stimuli were assessed using a parent-report questionnaire (SPM: Sensory Processing Measure). A small subset of this sample was additionally assessed using a lab-based observational paradigm (TDDT-R: Tactile Defensiveness and Discrimination Test-Revised) and underwent an EEG protocol to investigate neural responses to passive somatosensory stimuli. Statistical analyses included MANCOVA and regression analyses, as well as exploratory ERP analyses.

**Results:** ASD children show significantly higher levels of sensory processing difficulties, as rated by parents on the SPM questionnaire. Del16p11.2 also scored higher than TD on all subscales except for tactile and olfactory/taste processing, in which they score similarly to TD. The TDDT measure differentiated ASD and del16p11.2 on the Seeking but not on Tactile Defensiveness Scales. The exploratory analysis of somatosensory ERPs showed a differentiated pattern in P1 and N2 components in ASD children, suggesting that the neural processing of tactile stimulation might be different in ASD, compared to the other two cohorts.

**Conclusions:** Behavioral responses to touch and olfaction/taste stimuli seem to be particularly affected in ASD, as measured by parent-report. Lab-based observation suggests that there are potential differences across clinical groups in terms of the pattern of response to tactile stimuli. Exploratory findings from the somatosensory ERPs hint at further differences between the groups. These results highlight the importance of using a combination of methods to assess different levels of sensory processing. This is a much-needed approach to achieve a better comprehension of sensory phenotypes and their impact on daily functioning.

Defining sensory profiles in ASD and other NDD and will help tailor therapies in order to alleviate the impact of sensory processing difficulties in children's overall functioning and quality of life.

**441.046** (Poster) Temperament and Self-Injurious Behavior Among Infant Siblings of Children with Autism

**A. F. Dimian<sup>1</sup>, A. M. Estes<sup>2</sup>, J. T. Elison<sup>3</sup>, L. Zwaigenbaum<sup>3</sup>, J. Piven<sup>4</sup> and J. J. Wolff<sup>1</sup>.** (1)University of Minnesota, Minneapolis, MN, (2)Speech and Hearing Sciences, University of Washington, Seattle, WA, (3)University of Alberta, Edmonton, AB, Canada, (4)\*Co-senior author, University of North Carolina, Chapel Hill, NC

---

**Background:** Temperament characteristics, such as negative affectivity, regulatory/effortful control, and surgency have been identified as predictive of externalizing behavior in neurotypically developing children (e.g., Eisenberg et al., 2005). Similarly, among children with autism spectrum disorder (ASD), high negative affectivity, high surgency, and low effortful control has been found to predict problem behavior (Adamek et al., 2011; Korb et al., 2020). Specific types of problem behavior, such as self-injurious behavior (SIB), have not been examined in relation to early temperament characteristics.

**Objectives:** The purpose of this study was to examine temperament at 6 and 12 months of age among children at high risk for ASD. The specific research questions included: 1) Are there differences in temperament factors at 6 and 12 months of age between children with and without SIB? 2) What temperament characteristics at 12 months predicted SIB at 36 months?

**Methods:** Participants were from a longitudinal study of infants at familial risk for ASD. The present sample included 114 high-risk infants (65% male, 23% ASD) who completed the following assessments at 6,12,24, and 36 months of age: Infant Behavior Questionnaire (IBQ-R), Mullen scales of Early Learning (MSEL), and Repetitive Behavior Scales-Revised (RBS-R). The RBS-R was used to identify SIB and the IBQ-R was used to characterize temperament. SIB endorsement (i.e., any SIB endorsement verses none at 36 months) was used to group participants. Descriptive analyses, independent samples t-tests, and a hierarchical multiple regression model were utilized to examine 12 month predictors for SIB at 36 months.

**Results:** SIB prevalence estimates at 12, 24, and 36 months were 38%, 31%, and 17%, respectively. Mean SIB severity scores were 1.63 (0.95), 1.94 (1.73), and 3.26 (3.93). Statistically significant mean differences were observed between SIB and no SIB groups for surgency at 6 months (SIB group, mean=-2.05, sd=4.49; NoSIB group, mean= 0.42, sd= 3.71) and 12 months of age (SIB group, mean= -1.73, sd=3.97; NoSIB group, mean= 0.35, sd= 3.62). The regression model was used to evaluate the contribution of 12 month negative affect, regulatory capacity, and surgency to severity of SIB at 36 months. Mullen scores were entered at Step 1 and temperament characteristics were entered at Step 2. The first step resulted in 4.6% of the variance being accounted for,  $F(1,111) = 5.39, p = .02$ . Step 2 accounted for 8.8% variance,  $F(4, 108) = 2.62, p = .04$ . None of the temperament characteristics were found to independently predict the severity of SIB at 36 months.

**Conclusions:** SIB was less prevalent at 36 months but more severe compared to 12 and 24 months of age. Children with SIB endorsement at 36 months had lower surgency at 6 and 12 months than children without SIB. Our previous study indicated that children with a diagnosis of ASD also exhibited lower surgency at 12 months compared to children without a diagnosis (Paterson et al., 2019). Overall, the models accounted for very little variance. Temperament may need to be assessed with other early behavioral characteristics to better predict SIB and inform early intervention targets.

**441.047** (Poster) The First Fundamental Movement Skill Intervention Delivered As Applied Behavior Analysis: Preschoolers with ASD Gain the Equivalent of 2.5 Years of Skills

**I. T. Felzer-Kim<sup>1</sup>, J. L. Hauck<sup>2</sup> and J. B. Plavnick<sup>3</sup>,** (1)College of Human Medicine, Department of Kinesiology, Michigan State University, East Lansing, MI, (2)Department of Kinesiology, College of Education, Michigan State University, East Lansing, MI, (3)Counseling, Educational Psychology, and Special Education, Michigan State University, East Lansing, MI

---

**Background:** It is increasingly clear that motor skill deficits are intertwined with autism symptomatology. Researchers have gained interest in the motor delays in children with Autism Spectrum Disorder (ASD) and resultant motor intervention programs yield promising results. However, these programs are largely delivered by highly trained motor experts in movement-friendly environments.

**Objectives:** The purpose of this study was to assess the preliminary efficacy of fundamental movement skill (FMS) training integrated in early intensive behavioral intervention (EIBI) centers, an ecologically valid environment with wide reach. Intervention feasibility was a secondary aim.

**Methods:** Fourteen preschoolers with severe ASD and thirteen EIBI behavior technicians participated in this randomized controlled trial. Baseline data included ADOS-2, Mullen Scales of Early Learning, and Vineland Adaptive Behavior Scales – 3. The intervention consisted of daily, 15-minute, discrete trial training sessions targeting motor skills over 20 weeks. The

behavioral technicians regularly engaged in Applied Behavior Analysis (ABA) therapy together with the preschoolers for thirty-five hours per week. Blinded motor assessment via the Test of Gross Motor Development – III occurred pre-intervention, post-intervention, and at 4-week follow-up. Feasibility outcomes were assessed using a survey of behavior technician implementers delivered post-intervention.

Results: Motor scores significantly improved compared to the control group in FMS relative to the control group across 3 repeated measurements ( $F(1, 12) = 4.983$ ;  $p = 0.016$ ;  $ES = 0.312$ ). Behavior technicians implementing the study expressed polarized views on the feasibility of the intervention, rating the intervention low in feasibility overall despite high intervention efficacy.

Conclusions: These results hold relevance for interventionists attempting (a) movement programs with children with severe ASD, and (b) implementation in EIBI centers.

#### **441.048 (Poster)** The Impact of ADHD Symptoms and Age on Sensory Features in Autism

*E. C. Masters<sup>1</sup>, E. P. McKernan<sup>2</sup>, J. Kopec<sup>2</sup>, E. A. Kaplan-Kahn<sup>1</sup>, E. L. Cary<sup>1</sup>, E. Matsuba<sup>1</sup>, A. Rodrigues<sup>1</sup>, C. MacKenzie<sup>1</sup> and N. Russo<sup>1</sup>, (1)Department of Psychology, Syracuse University, Syracuse, NY, (2)Psychology, Syracuse University, Syracuse, NY*

---

##### Background:

Children with Autism Spectrum Disorder (ASD) exhibit differences in sensory processing patterns compared to typically developing peers. Differences in sensory processing patterns have also been reported in children with Attention-deficit/hyperactivity disorder (ADHD). Given the substantial overlap between features of ASD and ADHD, the purpose of the current study was to examine the extent to which ADHD symptoms and age, separately and together, impact sensory processing patterns associated with ASD traits in a sample of children with ASD aged 6-17 years.

##### Objectives:

The current study sought to examine sensory processing patterns using the Sensory Profile in children with ASD while controlling for ADHD symptoms, and age. In examining the extent to which ADHD symptoms, and age, impact sensory processing patterns reported in children with ASD across each of the four sensory quadrants in Dunn's (1997) theoretical framework, we sought to gain insight into whether, and which, sensory features are uniquely related to ASD after controlling for age and co-occurring ADHD symptoms.

##### Methods:

Participants included 61 children aged 6-17 years with ADOS-2 and ADI-R confirmed ASD. Extant data was used that included participants' scores on various caregiver questionnaires. Sensory features were assessed using the Sensory Profile, ADHD symptoms were measured using the Hyperactivity and Attention Problems T-scores on the Behavior Assessment System for Children, Second Edition (BASC-2), and ASD traits were measured using the Autism Spectrum Quotient (AQ). Our measure of sensory features included the four following constructs: sensation avoiding, sensation seeking, registration, and sensory sensitivity.

##### Results:

Hierarchical multiple regression analyses indicated no significant effects of age. The addition of ADHD symptoms to the prediction of Autistic traits led to a statistically significant increase in  $R^2$  of .107,  $F(2, 57) = 3.425$ ,  $p = .039$ ; adjusted  $R^2 = .065$ , in which Hyperactivity was significantly associated with Autistic traits ( $p = .012$ ). The addition of sensory features to the prediction of Autistic traits further led to a statistically significant increase in  $R^2$  of .276,  $F(4, 53) = 5.987$ ,  $p < .001$ ; adjusted  $R^2 = .307$ . Sensory features accounted for a significant portion (30.7%) of the explained variance in Autistic traits after controlling for the significant effect of ADHD symptoms. Specifically, after controlling for age and ADHD symptoms, the sensory feature Sensitivity was significantly predictive of Autistic traits ( $p = .025$ ).

##### Conclusions:

Results suggest that of all sensory features associated with ASD, sensory sensitivity is the strongest predictor of ASD traits, even after controlling for comorbid ADHD symptoms as well as age. These findings provide implications for Autism theories that have linked sensory hypersensitivity to enhanced perception in ASD. Our findings further emphasize the importance of strengths-

based conceptualizations of the unique sensory perceptual experiences in ASD for earlier identification and individualized support.

**441.049 (Poster)** The Relationship between Body Language, Enjoyment, and Performance during Motor Skill Tasks in Children with Autism Spectrum Disorder (ASD)

**I. D. Naiman<sup>1</sup>**, K. P. Arbour-Nicopoulos<sup>2</sup>, J. A. Brian<sup>3</sup> and V. Wright<sup>4</sup>, (1)Rehabilitation Sciences Institute, University of Toronto, Toronto, ON, Canada, (2)Faculty of Kinesiology and Physical Education, Mental Health and Physical Activity Research Centre, University of Toronto, Toronto, ON, Canada, (3)Holland Bloorview Kids Rehabilitation Hospital, Toronto, ON, Canada, (4)Bloorview Research Institute, Holland Bloorview Kids Rehabilitation Hospital, Toronto, ON, Canada

---

Background: Autism spectrum disorder (ASD) affects approximately 1 in every 66 children in Canada and is characterized by deficits in social communication and restricted interests. Motor skill deficits are less-recognized, but can have potentially serious additional consequences on participation in recreational activities. Motor skill acquisition occurs through a child's development and is greatly aided by practice during physical activity with peers. However, children with ASD are often less involved in physical activities with other children, relative to typically developing peers. Reasons for this include the presence of stereotypic behaviours that might influence their ability to participate, lack of interest, fear of getting hurt, and physical activity instructors having limited knowledge about ASD and how to engage children with ASD. To address these participation barriers, it is important to understand the motivation, confidence, affect, and physical ability of a child with ASD to participate (i.e., their physical literacy).

Objectives: To understand the relationship between body language, enjoyment, and gross motor skill performance of children with ASD aged 6-12 years.

Methods: Thirty-one participants were recruited who: (a) were 6-12 years of age, (b) had a diagnosis of ASD, (c) had no contraindications to participate in physical activity, and (d) could understand/respond to complex 3-step instructions. Participants completed the *Ignite Challenge* (videotaped), a 13-item advanced gross motor skills assessment suitable for children with ASD, followed by the *Personalized Enjoyment Scale*, a visual analogue scale developed for this study that assessed *Ignite Challenge* item enjoyment using personalized pictorial format anchor points. The first author scored the *Ignite Challenge* videos using the *Body Language Coding Scale (BLCS)* to measure the body language displayed during the assessment. The *BLCS* was developed by our team, and is divided into positive, negative, and neutral cues. The number of cues shown per *Ignite Challenge* item was recorded and totalled for each of the positive, negative, and neutral cue sections.

Results: Data from twenty-eight participants (mean age 9.0 years [SD 1.7]; 5 females) were analysed. The *Ignite Challenge* mean total score was 41/60 [SD 8.0; item score range 1.5-3.3/4]. The *Personalized Enjoyment Scale* mean total score was 91.6/130 [SD 19.6; item score range 6.0-8.15/10], and *BLCS* mean score for positive body language cues observed was 52.5% [SD 16.1%; range 41.0%-74.0%] and 33.4% [SD 16.3; range from 17%-44%] for negative body language cues observed. There was a moderate positive correlation (minimum  $r = 0.40$ ,  $p < 0.05$ ) between *Ignite Challenge* and *Personalized Enjoyment Scale* scores for 4 of 13 *Ignite Challenge* items, but an unexpected moderate negative correlation ( $r = -0.5$ ,  $p = 0.04$ ) between enjoyment and body language for the overall assessment.

Conclusions: There was a positive association between higher motor skill performance scores and higher ratings of enjoyment on some items. However, the *BLCS* scores were not associated with individual enjoyment or motor performance scores. This begs the question: do children with ASD display feelings in ways that are easily observed and/or match how they feel in conventional ways, or were there measurement issues with our *BLCS* tool? Further investigation is underway.

**441.050 (Poster)** The Relationship between Developmental Coordination Disorder and Concurrent Deficits in Social Communication and Repetitive Behaviors Among Children with Autism Spectrum Disorder

**L. R. Ketcheson<sup>1</sup>**, E. A. Pitchford<sup>2</sup> and C. Wentz<sup>3</sup>, (1)Department of Kinesiology, Health and Sport Studies, Wayne State University, Detroit, MI, (2)Department of Kinesiology, Iowa State, Ames, IA, (3)Department of Kinesiology, Wayne State University, Detroit, MI

---

Background: Children with Autism Spectrum Disorder (ASD), characterized by core deficits in social communication and restrictive behaviors, can exhibit concurrent motor incoordination and/or intellectual disability (ID). While pervasive delays in motor behavior are common, formal diagnosis of Development Coordination Disorder (DCD) is uncommon. It is not clear how DCD and ID impact core deficits in ASD.

Objectives: This study utilized the Simons Foundation SPARK cohort to describe the scope of motor incoordination among children with ASD and examine the interrelationships between DCD risk, ID, and ASD core deficits.

Methods: 10,234 children with ASD, between the ages of 5 and 15 years, were included in the analysis. Parents completed online versions of the DCD Questionnaire (DCD-Q), Social Communication Questionnaire (SCQ) and Restrictive Behavior Scale (RBS-R). 85% of children with ASD had DCD-Q scores consistent with being at-risk for DCD, but only 14% reported a formal diagnosis.

Results: Children with ID exhibited significantly greater motor incoordination compared to children without ID ( $p < .001$ ). Significantly greater core deficits were identified in both children at-risk for DCD ( $p < .001$ ) and with ID ( $p < .001$ ). However, the effects of DCD risk were independent of ID and exhibited a medium effect size for SCQ ( $\eta^2_p = .063$ ) and a small effect size for RBS-R ( $\eta^2_p = .04$ ) scores.

Conclusions: Collectively, study outcomes reinforce the pervasiveness of motor incoordination among children with ASD, both with and without concurrent ID, and provide further justification for the inclusion of motor behavior in the early intervention and prescription for children with ASD.

**441.051 (Poster)** The Relationship between Sensory Reactivity Differences and Mental Health Symptoms in Preschool-Age Autistic Children

*T. Rossow<sup>1</sup>, K. MacLennan<sup>2</sup> and T. Tavassoli<sup>2</sup>, (1)Centre for Autism, School of Psychology & Clinical Language Sciences, University of Reading, Reading, United Kingdom, (2)Centre for Autism, School of Psychology & Clinical Language Sciences, University of Reading, Reading, United Kingdom*

---

Background: Children with an autism spectrum condition (ASC) often have sensory reactivity differences, such as being overwhelmed by sounds, which can elicit distress in their everyday life. Furthermore, autistic children often present with a greater frequency of mental health symptoms compared to their typically developing peers. However little research has examined the impact or relationship of these sensory reactivity differences on broader mental health symptoms.

Objectives: This study set out to explore the relationship between sensory reactivity and mental health symptoms in pre-school aged autistic children.

Methods: Data from parent-reported and observational measures of sensory reactivity (Sensory Processing Scale Inventory - SPSI, and Sensory Assessment of Neurodevelopmental Differences - SAND) and parent-reported measure of mental health symptoms (Behavioural Assessment System for Children – 3, BASC-3) were collected for 54 preschool-aged children with an Autism Spectrum Condition (ASC) (41 males and 13 females, 3 - 5 years,  $M = 4.02$ ,  $SD = 0.77$ ). Correlational analyses were used to analyse the data.

Results: Our results showed a relationship between sensory reactivity and mental health symptoms in autistic preschool-aged children. At a sensory construct level, our results indicate a positive relationship between sensory seeking and externalising symptoms, including for hyperactivity ( $r_s = 0.62$ ,  $p < 0.01$ ) and aggression ( $r_s = 0.46$ ,  $p = 0.01$ ). This relationship was seen in both children who were verbal, and those with few to no words. We also found that hyper-reactivity was significantly positively related to internalising problems in autistic pre-schoolers, including for symptoms of anxiety ( $r_s = 0.30$ ,  $p = 0.03$ ), depression ( $r_s = 0.33$ ,  $p = 0.02$ ) and somatisation ( $r_s = 0.52$ ,  $p < 0.001$ ). However, this relationship only held in participants with few to no words. Further, we found little evidence of a relationship between hypo-reactivity and mental health symptoms outside of anxiety.

Conclusions: For the first time this study has revealed a relationship between sensory hyper-reactivity, as well as sensory seeking, and mental health symptoms outside of anxiety in autism. Of note, this relationship appears to be driven by those with few to no words, and has both research and clinical implications in understanding the drivers underlying mental health symptoms in different autistic phenotypes, as well as the possible role of functional communication in mitigating the development of mental health symptoms.

**441.052 (Poster)** The Relationship between Sensory Sensitivity and Fine Motor Function across Neurodevelopmental Disabilities: A Case for the Research Domain Criteria (RDoC) Framework

*Z. E. Arnold<sup>1</sup>, R. Gahan<sup>1</sup>, T. Hilty<sup>1</sup>, S. E. O'Kelley<sup>1</sup> and K. C. Guest<sup>1</sup>, The University of Alabama at Birmingham, Birmingham, AL*

---

Background: Sensory sensitivity (SS) was recently included as a diagnostic symptom in autism spectrum disorder (ASD) (APA, 2013). Additionally, individuals with ASD often have fine motor delays early in life (Licari et al., 2020). These two deficits have potential to be linked in ASD given neurobiological evidence that sensory processing and motor output are highly integrated (Salinas & Abbott, 1995). However, motor and sensory difficulties also exist in other neurodevelopmental disabilities (NDDs) (Soorya et al., 2018; Hen-Hebst et al., 2020), suggesting these symptoms are not unique to ASD. In fact, recent findings have

suggested that SS, with other factors, best predicted motor ability in children regardless of diagnostic category (Surgent et al. 2020). Thus, there may be value in researching sensorimotor behaviors and responses as individual differences within ASD and NDD phenotypes rather than discrete diagnostic categories.

**Objectives:** To determine if an ASD diagnosis or ASD symptom severity (ASD-SS) will improve the predictive ability of the relationship between SS and fine motor function (FMF) in a clinical sample. Based on the heterogeneity of our clinical sample, we predicted that an ASD diagnosis and ASD-SS would not significantly add predictive value to FMF.

**Methods:** The participants for this study were from a database composed of children referred and clinically evaluated for an ASD diagnosis at a tertiary care clinic between 2006-2020. Participants were identified as having sensory concerns and diagnostically characterized as non-ASD (i.e. ADHD, developmental delay, language delay/impairment, etc.) or ASD. ASD-SS was evaluated using comparison scores (CS) of the ADOS, SS was measured via the total score (TS) of the Short Sensory Profile (SSP), and FMF was assessed via the fine motor quotient (FMQ) of the Peabody Developmental Motor Scales 2nd Edition (PDMS-2). Two hierarchical regressions (HR) on the PDMS-2 FMQ were computed with SSP TS as a step 1 predictor, and then either ASD diagnosis or ADOS CS were the step 2 predictors.

**Results:** Participants included 72 individuals (86% male;  $M_{age}=4.04$  years,  $SD=1.22$ ) and 40% of the sample had ASD. The two groups significantly differed on ADOS CS ( $M_{ASD}=6.621$ ,  $M_{nonASD}=3.070$ ,  $t(70)=7.615$ ,  $p<.001$ ). As predicted, step 1 of both HRs was significant for SSP TS being a significant predictor of PDMS-2 FMQ ( $R^2=.073$ ,  $F(1, 70)=5.472$ ,  $p<.05$ ). With the addition of either an ASD diagnosis or ADOS CS, the change in  $R^2$  was not significantly different from 0 ( $R^2=.074$ ,  $F(1, 69)=.103$ ,  $p=.750$ ;  $R^2=.121$ ,  $F(1, 69)=3.784$ ,  $p=.056$ ). At step 2, the HR became insignificant for ASD diagnosis ( $F(2, 69)=2.752$ ,  $p=.071$ ) and remained significant for ADOS CS ( $F(2, 69)=4.737$ ,  $p<.05$ ).

**Conclusions:** In a clinical sample of children with NDDs who had a sensory concern, neither ASD diagnosis nor ASD-SS added predictive value to our model of FMF from SS. Additionally, ASD-SS was predictive with SS in predicting FMF, but ASD diagnosis was not. Findings support the Research Domain Criteria (RDoC) framework of investigating individual differences among all individuals with NDDs and deemphasizing diagnostic criteria to ensure a greater understanding of the underlying symptomatology regardless of diagnosis.

**441.053 (Poster) Towards Mechanistic Quantification of Motor Challenges in Autism during a Functional Dressing Task**  
**A. Ardalan<sup>1</sup>**, A. H. Assadi<sup>2</sup> and B. G. Travers<sup>3</sup>, (1)Zuckerman Institute, Columbia University, New York, NY, (2)University of Wisconsin-Madison, Madison, WI, (3)University of Wisconsin - Madison, Madison, WI

---

**Background:** Sensorimotor challenges have been shown to relate to poorer daily living skills in individuals with autism spectrum disorder (ASD) (Jasmin et al., 2009; Travers et al., 2017) even after controlling for key variables like age and IQ (Travers et al., 2017). In particular, dressing -as an integral part of individuals' daily routines- is an area for caregiver concern for adolescents with ASD based on the increased duration of time required to complete the task (Bagatell, et al., 2016; Campbell et al., 2015; Tomchek et al., 2017). However, to our knowledge no study has quantitatively and systematically studied the motor mechanisms underlying the increased dressing time in youth with ASD compared to their typically developing (TD) peers. This would inform what aspects of movement may be different in ASD during a functional tasks, which could potentially inform intervention targets.

**Objectives:** 1) To use a controlled and quantifiable dressing task to establish that dressing time is different between ASD and TD; 2) To quantify movement during a dressing task by capturing kinematic and postural sway data; and 3) To examine whether the movement and postural sway measures mechanistically account for longer dressing times in ASD.

**Methods:** 49 participants with ASD and 31 age-matched TD participants (7-17 years-old) underwent motor (BOT-2) and diagnostic testing and completed our Motor Rainsuit Assessment During Dressing (M-RADD) task in which participants put on a clear rain suit (pants and a jacket) over their clothes while we recorded whole-body kinematics using a Kinect camera and postural sway using a Wii Balance Board. We compared these measures across the ASD and TD groups, while controlling for age and BMI. Finally, mediation analyses examined which measures explain slower dressing times in youth with ASD.

**Results:** The ASD group took significantly longer to complete the dressing task compared to the TD group,  $t(79) = -4.46$ ,  $p < .001$ . The ASD group had significantly larger postural sway areas during dressing (both in terms of ellipse area [ $p = .02$ ], and X-Y interquartile ranges [ $p = .01$ ]). However, angular tilt of midline structures during dressing (median and interquartile range of the angle from upright) did not differ between the groups,  $p$ 's  $\geq .24$ . Mediation analyses demonstrated that standardized motor scores accounted for group differences in dressing time, but the postural sway measures during dressing did not.

**Conclusions:** These findings show that youth with ASD take longer to dress and exhibit larger shifts in balance during dressing. However, our measures of gross motor movements during dressing (i.e., kinematics) did not differ between the groups. Mechanistically, the composite motor score (which includes fine and gross motor assessment) fully mediated the relationship between diagnostic status and longer dressing times, but the larger shifts in balance during dressing did not. Overall, these findings more directly suggest the important role of motor skills for dressing in youth with ASD. Future analyses will examine gross motor versus fine motor contributions to this functional task to more precisely define potential intervention targets.

**441.054 (Poster)** Understanding the Non-Social Domain of Autism in Autistic Adults

**R. Grove<sup>1</sup>, S. Begeer<sup>2</sup>, A. M. Scheeren<sup>2</sup>, R. F. Weiland<sup>2</sup> and R. A. Hoekstra<sup>3</sup>,** (1)University of Technology Sydney, Sydney, NSW, Australia, (2)Vrije Universiteit, Amsterdam, Netherlands, (3)Department of Psychology, King's College London, London, United Kingdom

---

**Background:** The social domain of autism has been studied in depth, and shown to be a unitary construct. However, the relationship between the non-social traits of autism has received less attention. The Diagnostic and Statistical Manual of Mental Disorders (DSM-5) outlines four criteria that make up the non-social domain including repetitive motor movements, insistence on sameness, restricted interests and sensory sensitivity. It is important to consider whether the non-social traits of autism should be conceptualised as a unitary or multidimensional construct. In addition, the majority of this research has been conducted with autistic children and adolescents. There is a lack of research into the relationship between the four DSM-5 non-social criteria for autism.

**Objectives:** This study aimed to evaluate the relationship between the non-social traits of autism in a large sample of autistic adults. It explored whether these traits are best conceptualised as four distinct factors, or exist along a single dimension.

**Methods:** Participants included autistic adults from the Netherlands Autism Register. The sample consisted of 833 autistic adults (478 females and 355 males). The four components identified within the DSM-5 non-social domain were measured by items from the Adult Routines Inventory, the Autism Spectrum Quotient short and the Sensory Perception Quotient short. Confirmatory factor analysis, as well as exploratory factor analysis and exploratory structural equation modelling was implemented to examine the relationship between these four criteria.

**Results:** The one-factor model evaluating whether the non-social traits of autism fall along the same unitary dimension did not provide a good fit to the data, highlighting that the non-social domain of autism is not a unitary construct. Additional two and three factor models consisting of repetitive motor movements, insistence on sameness and restricted interests factors had goodness of fit values outside the recommended thresholds, indicating that they did not provide a good fit. Overall, the results indicated that a four-factor model provided the best fit, mapping onto the DSM-5 criteria, including repetitive motor movements, insistence on sameness, restricted interests and sensory sensitivity. These four factors were moderately correlated, suggesting that four distinct, yet related factors best describe the non-social domain of autism.

**Conclusions:** This study provided evidence for the multi-dimensional nature of the non-social domain of autism. Given only two of the four criteria within the non-social domain need to be endorsed for a diagnosis of autism, there is room for substantial variation across individuals, who will have a unique profile within the non-social domain. The results have implications for our understanding of the heterogeneous nature of autistic traits, as well as for how we conceptualise autism as a diagnostic category. This is important for the provision of diagnosis and support within research and clinical practice.

**441.055 (Poster)** White Matter Microstructural Correlates of Parent-Reported Sensory Hyporesponsivity, Hyperresponsivity, Sensory Seeking, and Enhanced Perception in Children with ASD and Typical Development

**A. Riaz<sup>1</sup>, O. J. Surgent<sup>1</sup>, K. K. Ausderau<sup>1</sup>, D. C. Dean<sup>2</sup>, A. L. Alexander<sup>3</sup> and B. G. Travers<sup>1</sup>,** (1)University of Wisconsin - Madison, Madison, WI, (2)Pediatrics & Medical Physics, University of Wisconsin - Madison, Madison, WI, (3)Medical Physics & Psychiatry, University of Wisconsin - Madison, Madison, WI

---

**Background:** Sensory responsivity differences are common across neurodevelopmental disorders and are especially prevalent in autism spectrum disorder (ASD; Baranek et al., 2006; Ausderau et al., 2014). These sensory differences in ASD have been associated with lower IQ, poorer motor performance, and impaired adaptive behaviors (Sans Cerva et al., 2015; Ismael et al., 2020; Surgent et al., 2020). Recently, there have been preliminary investigations into the neural basis of the specific sensory response patterns (hyporesponsiveness, hyperresponsiveness, sensory seeking behaviors, and enhanced perception) using a variety of neuroimaging methodologies (Wolff et al., 2017; Tavassoli et al., 2019; Simon et al., 2017). However, it is still unclear what the specific microstructural neural correlates of sensory response patterns are in children with ASD and how they might differ from children with typical development (TD).

Objectives: Determine the microstructural correlates of sensory response patterns in children with ASD and children with TD.

Methods: 153 children (6-10 years old) completed a brainstem-optimized diffusion-weighted imaging (DWI) scan and sensory measures (57 children with ASD, 96 children with TD). Overall sensory symptom severity was assessed using the parent-reported Sensory Experience Questionnaire Version 3.0 (Ausderau et al., 2013). Multi-shell DWI was performed at 3T with isotropic 1.8mm voxels. Voxel-based analyses with general linear modeling was used to identify brain areas where TSPOON corrected fractional anisotropy (FA) was associated with each response pattern severity (FA ~ response pattern severity +age+sex+average head motion) within the ASD and TD groups separately. False discovery rate ( $p < .05$ ) was used for multiple comparisons with a cluster threshold of  $k > 10$  contiguous voxels.

Results: The TD group showed a high degree of similarity among FA associations with sensory severity across response patterns (Figure 1). In the TD group, sensory response patterns were all associated with the posterior parietal white matter, frontal white matter, and bilateral internal capsules. In the ASD group, hyporesponsiveness, hyperresponsiveness, sensory seeking behaviors, and enhanced perception generally mapped onto different, non-overlapping brain areas (Figure 2). For example, seeking behaviors were highly associated with FA in the splenium of the corpus callosum, whereas hyperresponsiveness was associated FA in the superior corona radiata. The exception was the middle cerebellar peduncle where hyporesponsiveness, hyperresponsiveness, and seeking behaviors were associated with FA and posterior parietal cortex where all response patterns were similarly associated with FA.

Conclusions: While sensory response patterns in TD were largely associated with similar white matter areas, sensory response patterns in ASD were largely associated with unique white matter areas. These results provide evidence for altered neural mechanisms of sensory responsiveness in children with ASD and TD. Given the role that the internal capsule plays in transmitting sensory and motor information between cortical and subcortical areas, its robust cross-pattern associations in TD and minimal associations in ASD suggest that the internal capsule may be highly involved in mitigating atypical sensory driven behaviors. Additionally, the cross-pattern associations with the middle cerebellar peduncle in ASD may suggest a brainstem-specific compensatory mechanism for sensory responsivity in children on the autism spectrum.

## Service Delivery/Systems of Care

### PANEL SESSION — SERVICE DELIVERY/SYSTEMS OF CARE

#### Panel 214 - Using Novel Implementation Tools for Evidence-Based Practice Delivery (UNITED) for Under Resourced Settings

**Panel Chair:** Jill Locke, *Speech & Hearing Sciences, University of Washington, Seattle, WA*

**Discussant:** David Mandell, *Penn Center for Mental Health, University of Pennsylvania, Philadelphia, PA*

There is a growing number of evidence-based practices for children with autism, but few are successfully implemented in under resourced communities and with families from traditionally disenfranchised groups. Conducting research in community-based settings creates opportunities to build capacity in existing service systems to ensure evidence-based practices are readily accessible, relatively low-cost, and sustainable. In order to have a lasting impact, autism research must focus on broadening access, expanding reach, and facilitating widespread availability of services in the community. Utilizing implementation strategies defined as “methods or techniques used to enhance the adoption, implementation, and sustainment of a clinical program or practice” is critical to support organizations and providers use evidence-based practices. We will present data from four studies that use novel implementation strategies to facilitate evidence-based practice delivery and enhance access to care in under resourced community settings. The four studies engage different implementation strategies (e.g., multi-system training, parent navigation, remote training, use of advisory boards and stakeholder workgroups) to: 1) promote earlier access to specialized intervention for toddlers with autism; 2) support parents of newly diagnosed children with autism; 3) increase the use of JASPER in community settings; and 4) adapt a disruptive behavior intervention for school-aged children with autism.

**214.001 (Panel)** A Multi-System Approach to Improving Access to Early Detection and Intervention for Toddlers in Underserved Communities

*W. L. Stone<sup>1</sup> and L. V. Ibanez<sup>2</sup>, (1)Psychology, University of Washington, Seattle, WA, (2)UW READi Lab, Seattle, WA*

**Background:** Early detection of ASD is the critical first step to providing children with the highly specialized treatment required to optimize outcomes. Yet, many obstacles limit access to early, evidence-based treatments for children with ASD. First, primary care providers (PCPs) often lack knowledge about the early signs of ASD and/or fail to use validated screening tools as recommended by the American Academy of Pediatrics. Second, in the publicly-funded Part C Early Intervention (EI) system, which offers treatment for toddlers with developmental delays, few providers have specialized training in ASD. Third, many evidence-based interventions are expensive and time-consuming to learn and implement, rendering them unrealistic for use within the EI system, where providers may spend only one hour/week with families due to heavy caseloads. This lack of specialized ASD intervention services in the community further creates a disincentive for PCPs to screen or identify children with ASD.

**Objectives:** We developed the Screen-Refer-Treat (SRT) model to address these service access challenges. This model comprises a multi-system health care intervention designed to increase capacity across the primary care and early intervention sectors *within the same community*. We provided evidence-based tools that were tailored for each group of providers, with the goal of mitigating practical challenges to ASD screening and specialized intervention, and measured their use of these tools as well as changes in their practices and self-efficacy 18 months post-intervention.

**Methods:** The SRT model was implemented in four underserved counties in the East, West, and Central regions of the state. PCPs (n=59, from 10 practices) and EI providers (n=87, from 9 programs) received surveys at 2 time points prior to the SRT intervention and 3 times following the intervention (i.e., 6, 12, and 18 month follow-ups). PCPs received a 2-hour office-based workshop describing the early features of ASD, how to talk to parents about concerns, and local ASD resources. They also received a REDCap-based version of the Modified Checklist for Autism in Toddlers Revised/with Follow-up (i.e., the webM-CHAT-R/F) that automatically presents follow-up interview questions when indicated, and were encouraged to use it universally during 18-month well-child visits. Training for EI providers included a full-day workshop on implementing an inexpensive, play-based, easy-to-use ASD-specialized intervention, Reciprocal Imitation Training (RIT).

**Results:** At the 18-month follow-up, PCPs reported significantly higher levels of knowledge regarding the early features of ASD, as well as higher levels of self-efficacy in providing care for these children and families. The majority of practices continued their use of the webM-CHAT-R/F well after the conclusion of the study. EI providers reported higher levels of self-efficacy for recognizing signs of ASD, discussing ASD concerns with caregivers, and providing treatment services to families of children

with ASD symptoms. The majority of EI providers were using RIT with children (84%) and had coached parents in its use (73%).

**Conclusions:** Relatively brief training activities designed to mitigate common obstacles to ASD screening and intervention can increase the use of evidence-based tools by PCPs and EI providers in community practice.

**214.002 (Panel) Remote Supports for Practitioners and Parents: Community Jasper Implementation**

**S. Y. Shire<sup>1</sup>, L. Baker Worthman<sup>2</sup> and C. Kasari<sup>3</sup>,** (1)University of Oregon, Eugene, OR, (2)Department of Health and Community Services, St. John's, Newfoundland and Labrador, Canada, (3)University of California, Los Angeles, Los Angeles, CA

---

**Background:** For rural and remote communities, few specialists and large geographic service areas limit regularly scheduled in-person interventions (CDC, 2016). Remote tools are one option to provide both direct services to families of children with autism and professional development for providers.

**Objectives:** To examine the use of remote implementation strategies to support community delivery of the Joint Attention, Symbolic Play, Engagement, and Regulation (JASPER: Kasari et al., 2006) intervention. Study 1 focuses on training practitioners through a randomized comparison of Peer Feedback versus Intensive Refresher with a supervisor on interventionists' fidelity and children's social communication and play skills. Study 2 focuses on remote parent coaching through a concurrent multiple baseline study examining caregivers' fidelity and children's social engagement.

**Methods:** Study 1: Thirty community interventionists working in urban and remote regions of Atlantic Canada, served 37 boys and 14 girls with ASD ( $M=4.78$  years,  $SD=1.52$  years). Interventionists were supervised by five local JASPER supervisors. Interventionists were randomized to either (a) Peer Feedback: local interventionist at fidelity provides feedback for 12 weeks or (b) Intensive Refresher: a 12-hour supervisor led training.

Interventionists' fidelity was scored from ten-minute adult-child interactions. Each video was coded for 32 items rated on a Likert scale from 0 (low quality/accuracy) to 5 (high) strategy implementation. Children received assessments at baseline and exit including: (a) Structured Play Assessment (SPA: Sigman & Ungerer, 1981) and (b) Early Social Communication Scales (ESCS: Mundy et al., 2003). Assessments were video recorded and delivered by masked community assessors (fidelity  $M=81.87\%$  ESCS,  $M=93.05\%$  SPA). Independent, reliable coders blinded to timepoint and condition coded number of spontaneous: (a) unique play acts; and (b) initiations of joint attention and requesting.

Study 2: Six caregivers and their male children with autism ( $M=4.44$  years,  $n=2$  Inuit) from rural communities in Atlantic Canada were included. A concurrent multiple baseline design across participants was applied to examine the effects of synchronous remote caregiver coaching on children's joint engagement with caregivers and caregivers' strategy implementation.

Each session, caregivers completed a 10-minute unsupported interaction with their child using a standard toy set (separate from intervention materials). Independent, reliable coders scored the videos for children's joint engagement (total seconds) and caregivers' implementation (see study 1).

**Results:** Study 1: Interventionists receiving Peer Coaching made significantly greater gains in fidelity than those in Intensive Refresher ( $F(1,126)=4.23, p=0.042$ ), reaching means of 85.44% and 87.32%, respectively by exit. Children paired with interventionists in either group made significant gains in initiations of joint attention and requesting ( $F(1,25)=4.94, p=0.036$ ) and total play types ( $F(1,23)=4.78, p=0.039$ ). There were no significant between group differences for children.

Study 2: Children demonstrated greater time jointly engaged (baseline  $M=41.71$  seconds; intervention  $M=315.04$  seconds) and caregivers demonstrated greater use of strategies (baseline  $M=38.79\%$ ; intervention  $M=71.05\%$ ) showing shift in level and trend in intervention over baseline phases (Tau-U= 0.94-1.00).

**Conclusions:** Synchronous remote caregiver coaching and mixed remote/in-person professional development show promise for community intervention implementation and children's outcomes. Weekly peer discussions offer a less costly and more efficient training option.

**214.003** (Panel) Mind the Gap, a Caregiver-Engagement Focused Intervention for Traditionally Underserved Families with a New Autism Diagnosis

**S. Iadarola<sup>1</sup>, M. Pellecchia<sup>2</sup>, A. C. Stahmer<sup>3</sup>, A. Gulsrud<sup>4</sup>, H. S. Lee<sup>5</sup>, W. I. Shih<sup>5</sup> and C. Kasari<sup>5</sup>,** (1)University of Rochester Medical Center, Rochester, NY, (2)University of Pennsylvania, Philadelphia, PA, (3)UC Davis MIND Institute, University of California, Davis, Sacramento, CA, (4)UCLA Semel Institute for Neuroscience & Human Behavior, Los Angeles, CA, (5)University of California, Los Angeles, Los Angeles, CA

---

Background: Early service access is critical for children with autism spectrum disorder (ASD) and their families. Children may experience access disparities based on race, ethnicity, and family income (Mandell et al. 2009). Caregivers are key advocates for their children's services, but many feel underprepared to effectively navigate complex service systems. Through a community-partnered participatory research process, we developed an intervention, Mind the Gap (MTG), which aims to address barriers and needs for under-represented families. MTG explicitly focuses on implementation strategies (e.g., community engagement, user-centered design, flexibility) to support caregiver engagement, to thereby increase retention in children's treatment (Ingoldsby, 2010) and improve child outcomes (Haine-Schagel & Walsh, 2015).

Objectives:

1. Describe a community-partnered process for developing a caregiver-focused intervention (i.e., Mind the Gap)
2. Report on the feasibility of the MTG intervention and the relationship between demographics and family social networks to baseline service access in our sample.

Methods: Mind the Gap is an intervention to support families from low-income households post ASD diagnosis. It includes features designed to enhance implementation in real-world settings. First, MTG was developed with a community partnership of key stakeholders. Content includes modules that partners indicated would be important post-diagnosis. Second, MTG utilizes a flexible, modular design, such that intervention content and targets are individualized. The intervention is delivered flexibly, driven by participants' individual needs (e.g., location: home or community and modality: in-person or virtually). Third, MTG utilizes a peer navigator model (i.e., other parents of children with ASD) to build trust with families. Fourth, parent engagement strategies increase relevance of MTG to under-represented communities (e.g., translation, matching navigators with participants based on key characteristics).

Participants were parents of children with new ASD diagnosis who were under 8y/o and from low-income households. We first conducted a pre/post pilot study design (n=7) without concurrent comparison across four recruitment sites. Data from the pilot informed an RCT: 118 families were randomized to receive MTG or enhanced information. We explored how demographics and social networks predicted services access.

Results: In the pilot, retention was high (79%), and we had high attendance (M=85% sessions) and completion of measures (range 86-100%). For the RCT (n=118), we recruited a diverse sample and characterized their family social networks and service use. At baseline in the RCT, families received a mean of 1.95 (SD = 1.54) (i.e., number of identified services) and had social networks of 5.15 (2.41) people. Social network size positively predicted service access; demographic characteristics were not predictive. English speakers were more likely to have services in 3 of 4 sites; at one site non-English speakers had more services.

Conclusions: MTG was developed in partnership with community stakeholders. Given previous literature on family-mediated interventions, our use of implementation strategies (e.g., home visits, parent-driven, peer navigators) likely influenced outcomes. MTG is a promising way to improve child and family outcomes post-diagnosis by capitalizing on caregiver leadership. Baseline data from the RCT can inform research and clinical services for under-represented families, with an emphasis on engagement strategies and opportunities to expand social networks.

**214.004** (Panel) Using Advisory Boards and Stakeholder Workgroups to Adapt the Rubi Program for Use in Educational Settings

**J. Locke<sup>1</sup> and K. Bearss<sup>2</sup>,** (1)Speech & Hearing Sciences, University of Washington, Seattle, WA, (2)Psychiatry and Behavioral Sciences, University of Washington, Seattle, WA

---

Background: There is a need to improve community-viable, empirically supported interventions targeting disruptive behavior for children with autism in schools. RUBI is a proven-efficacious intervention that addresses disruptive behavior in children with autism. Although RUBI is an empirically supported intervention for children with autism and disruptive behavior, adaptations are needed for its use in schools.

**Objectives:** The goal of this presentation is to discuss a novel implementation strategy – engaging advisory boards and stakeholder workgroups – to collaboratively redesign a proven-efficacious intervention, RUBI, with targeted end users for use in a novel context, schools, with different end users, educators. We use the Discover, Design/Build, Test (DDBT), a human-centered design and implementation science framework to enhance the usability, contextual fit, uptake, and effective implementation of an intervention, to iteratively redesign the RUBI intervention to improve the likelihood that it is useful and useable in elementary schools.

**Methods:** Thirty-five school staff (administrators, general and special education teachers, paraeducators, school counselors, and speech pathologists) that support a child with autism in general and special education classrooms from 22 elementary schools were included in this study. In the first stage, we used a day-long observation and retrospective think-aloud interview protocol to identify the contextual constraints and work processes relevant to the management of disruptive behavior in the classroom. In the second stage, we used an in-depth intervention demonstration of RUBI paired with behavioral rehearsal, a prospective think-aloud interview protocol, and structured assessment methods to identify targets for RUBI redesign (adaptation or pruning needs related to RUBI content and structure). In the third phase, we engaged in collaborative redesign feedback sessions to iteratively adapt RUBI content and procedures with our advisory boards and stakeholder workgroups, and we measured the usability, feasibility, acceptability, and appropriateness of the redesigned RUBI intervention, which we named RUBI in Educational Settings (RUBIES).

**Results:** Conventional content analysis was used to code qualitative data. Feedback from stakeholders suggested: 1) special education teachers feel adequately prepared to use behavioral management strategies; 2) general education teachers reported having little time to actively intervene one to one with children with ASD; 3) challenging behaviors are a key prognostic indicator that disrupts inclusion; 4) the target end user for RUBIES ought to be paraeducators as they are best suited to support the transition from special to general education settings due to their consistent contact and access to the child across classrooms; and 5) paraeducators are in need of targeted training in classroom behavioral management strategies given their minimal autism-specific behavior management training but extensive time with children with ASD. Quantitative ratings (on a 5-point scale) indicated that while RUBI was usable (4.1), acceptable (4.7), and appropriate (4.3), there were some concerns around feasibility (3.9). Recommendations were provided for which RUBI sessions should be retained, eliminated, or modified to address the needs of the school context and end-users.

**Conclusions:** The use of a human-centered design and implementation science approach driven by community stakeholders to redesign a proven-efficacious intervention may provide greater usefulness and usability in real-world contexts.

## PANEL SESSION — SERVICE DELIVERY/SYSTEMS OF CARE

### Panel 221 - Bridging the Gap: Mitigating Barriers to Autism Service Access in Rural Populations

**Panel Chair:** **Hannah Morton**, *Binghamton University, Binghamton, NY, Geisinger, Lewisburg, PA, Binghamton University, Binghamton, NY, Geisinger, Lewisburg, PA*

**Discussant:** **Zachary Warren**, *Vanderbilt University Medical Center, Nashville, TN*

Families in rural communities experience barriers to accessing diagnostic evaluations and evidence-based interventions for Autism Spectrum Disorder (ASD). These include high service cost, lack of autism-specific service providers, and a far geographic travel distance to access services. This panel presents findings from a variety of novel delivery methods that seek to increase access to autism services in rural areas. The first paper identifies predictors of parent follow-through with a pediatrician referral for neurodevelopmental assessment at a rural hospital clinic and examines the impact of a virtual intake appointment to increase retention. The second paper presents a novel training program for early intervention providers in rural locations to increase recognition of ASD symptoms and facilitate telediagnostic evaluation. The third paper describes use of a mobile autism clinic and telehealth modalities for ASD assessment and parent psychoeducation in a rural community. The fourth paper reports on implementation of a consultation intervention to increase use of evidence-based practices for ASD in rural schools. Dr. Zachary Warren (discussant) will draw on his expertise adapting and implementing evidence-based autism services in a rural community to make recommendations for application of novel delivery methods to reduce barriers to care and directions for future research.

**221.001 (Panel) Barriers to Engagement with the Neurodevelopmental Diagnostic Assessment: Predictors of Retention in a Rural Hospital Clinic**

**H. E. Morton<sup>1,2</sup>, L. Walsh<sup>2</sup>, D. Welsh<sup>2</sup>, M. Mitchell<sup>2</sup>, H. R. Fisher<sup>2</sup>, C. M. Taylor<sup>2</sup> and S. M. Myers<sup>2</sup>, (1)Binghamton University, Binghamton, NY, (2)Geisinger, Lewisburg, PA**

---

**Background:** Children can be diagnosed with developmental disabilities, such as Autism Spectrum Disorder (ASD), as young as two years-old; however, the average age of ASD diagnosis in the United States is not until age five. An ASD diagnosis facilitates access to services, which are associated with positive outcomes. Later age of ASD diagnosis may occur via lack of follow-through with assessment referrals and is also related to female gender, lower socioeconomic status (SES), difficulty finding a psychology provider, and limited parent English-language proficiency. These factors may be especially salient in rural communities, where there are relatively fewer opportunities for services.

**Objectives:** Identify barriers to retention with the neurodevelopmental diagnostic assessment process for families in rural Pennsylvania; and examine the impact of an initial in-person or virtual intake appointment on completion of the evaluation process.

**Methods:** Participants were 975 families of children <72 months of age (72.56% Male, 73.87% White, non-Hispanic) who were referred to a rural specialty hospital clinic in central Pennsylvania for a neurodevelopmental evaluation, including ASD diagnostic assessment, by their primary care provider. Families ( $n=285$ ) were contacted to schedule an evaluation after completing a questionnaire packet that was mailed to their home. To increase engagement, the procedural approach was modified such that referred families were scheduled for an intake interview prior to completing diagnostic questionnaires ( $n=690$ ). During COVID-19, intakes were conducted virtually. An ordinal logistic regression model was used to identify predictors of retention with the neurodevelopmental assessment (i.e., initial intake, clinical evaluation).

**Results:** Participating in the intake interview significantly increased likelihood to attend the neurodevelopmental evaluation visit ( $M=84.49\%$ ,  $SD=36.22\%$ ) compared to completing a questionnaire packet prior to scheduling this appointment ( $M=76.84\%$ ,  $SD=45.42\%$ ;  $t(973)=2.85$ ,  $p = .002$ ). Conducting the intake virtually versus in-person had no impact on retention ( $t(688)=2.19$ ,  $p=0.99$ ). Predictors of assessment retention were older child age (Odds Ratio (OR)=1.93, 95% Confidence Interval (CI): 1.13, 3.29), already receiving services (OR=4.59, 95% CI: 1.89, 11.20), and shorter latency since first developmental concern (OR=0.95, 95% CI: 0.91, 0.99). Child male sex also trended towards predicting retention (OR: 2.21, 95% CI: 0.92, 5.31). There was no impact of race/ethnicity, language spoken, SES, or distance from clinic on retention.

**Conclusions:** Rural families' engagement with the neurodevelopmental assessment process was improved by scheduling an intake interview following pediatrician referral. Completion of the intake virtually, during COVID-19, maintained this improved retention rate. Parents with less recent first developmental concern, whom have younger children, or are not already receiving services may require additional support to remain engaged with the assessment process. Families may also benefit from psychoeducation regarding neurodevelopmental concerns in girls. Evaluation of clinic procedures is limited by non-random assignment of families to conditions (i.e., questionnaire packet, intake, virtual intake). Development of additional procedures and programs that increase autism and developmental service access and retention for rural families is needed.

**221.002 (Panel) Engaging Part C Services Providers As Facilitators of Early Identification and Evidence-Based Intervention Services for Children with ASD in Rural and Under Resourced Communities**

**A. Stainbrook<sup>1</sup>, M. Fleck<sup>2</sup>, K. Simcoe<sup>1</sup>, L. Corona<sup>2</sup>, L. Wagner<sup>3</sup>, A. S. Weitlauf<sup>4</sup>, J. F. Hine<sup>4,6</sup>, P. Juárez<sup>1</sup> and Z. Warren<sup>4</sup>, (1)Vanderbilt University Medical Center- Treatment and Research Institute for Autism Spectrum Disorder, Nashville, TN, (2)Vanderbilt University Medical Center- Treatment and Research Institute for Autism Spectrum Disorder, Jackson, TN, (3)Vanderbilt University Medical Center - Treatment and Research Institute for Autism Spectrum Disorder, Nashville, TN, (4)Vanderbilt University Medical Center, Nashville, TN, (5)Vanderbilt Kennedy Center, Vanderbilt University Medical Center, Nashville, TN, (6)Dept of Pediatrics, Vanderbilt University Medical Center- Treatment and Research Institute for Autism Spectrum Disorder, Nashville, TN**

---

**Background:** Families of young children with autism spectrum disorder (ASD), especially those in rural areas, experience barriers to accessing diagnostic evaluations and evidence-based early intervention services [1-4]. Many of these families turn to their state's Part C system for support, but these service providers vary in training, skill set, and familiarity with ASD [5-7]. Telemedicine presents a unique opportunity to involve Part C providers in the diagnostic process while also building their capacity to support and educate families [9-12]

**Objectives:** We will present the development and preliminary outcome data from a novel telemedicine model of service delivery designed to support early identification and follow-up behavioral intervention for children with ASD via Part C providers in rural locations. The model builds on a more established model that has served more than 700 families through both traditional and

telemedicine models of service delivery over the past 6 years [13, 14]. This extension includes training Part C providers in two critical areas: 1) screening young children for ASD and facilitating telediagnostic consultation and 2) providing support and education to caregivers in how to implement evidence-based intervention practices in the natural environment.

**Methods:** Participants included 11 Part C providers and families of children < 36 months of age showing symptoms of ASD. Providers participated in training on a play-based ASD screening tool to increase understanding of recognizing and eliciting ASD symptoms. They then participated in an ongoing monthly virtual learning community focused on evidence-based practices for supporting caregivers. Each service provider then had the opportunity to refer families for telediagnostic evaluation of ASD, participate in and observe those telediagnostic visits and mediate follow-up behavioral consultation services offered by a remote Behavior Analyst. We assessed parent and provider satisfaction with the model as well as child outcomes.

**Results:** Data collection and analysis of this model are ongoing. However, preliminary results align with findings from our more established model that includes both traditional (N = 49) and tele delivery (N = 46) of diagnostic and intervention services but with more limited involvement from Part C providers. Those findings suggest caregivers report satisfaction with the service model, service provider and service outcomes (see Table 1) with no significant differences in caregiver satisfaction emerging between groups. Community providers (N = 40) also report high levels of satisfaction with most reporting they would recommend participation in the intervention model to other families (90% endorsed “strongly agree”).

**Conclusions:** These results provide preliminary support for the feasibility of providing diagnostic and intervention services via telemedicine and in partnership with Part C providers in rural regions. Both models were developed by listening to the concerns of the providers already in these communities, engaging them in both the development and implementation of each component, and emphasizing sustainable modalities for ongoing training and practice. Building this model within an existing, large-scale system for young children has helped not only in sustaining the model but also in its ability to be replicated and grown over time.

### **221.003 (Panel) Novel Methods of Delivering Autism Assessment and Psychoeducation in Rural Southwest Virginia: A Pilot Study**

**J. R. Bertollo**<sup>1,2</sup> and **A. Scarpa**<sup>1,2</sup>, (1)Virginia Polytechnic Institute and State University, Blacksburg, VA, (2)Virginia Tech Autism Clinic & Center for Autism Research, Blacksburg, VA

---

**Background:** Early detection and intervention facilitate optimal outcomes for youth with autism spectrum disorder (ASD); however, service access is often reduced in rural communities. The later average age of diagnosis in rural areas puts children at a disproportionately high risk for missed intervention opportunities and poorer outcomes. In rural Southwest Virginia specifically, caregivers report several major barriers to accessing ASD services, including few providers knowledgeable in ASD, high cost of services, and geographic remoteness. Additionally, caregivers report not receiving ASD resources or educational materials after an ASD diagnosis, leaving families ill-equipped to seek proper services for their child.

**Objectives:** (1) To evaluate the relative feasibility of two novel delivery formats of evidence-based ASD assessment: mobile assessment and tele-assessment; and (2) to assess the effects of our assessment and psychoeducation protocol on caregiver empowerment and ASD knowledge.

**Methods:** Participants included 30 children between 1.7 and 14.9 years of age ( $M=8.43$ ,  $SD=3.85$ ; 80% male; 83.3% white) and one or both primary caregivers ( $n=34$ ) ages 24 to 61 ( $M=37.44$ ,  $SD=8.71$ ; 91.2% female). To address the aforementioned barriers, the current pilot study assessed the feasibility of delivering ASD assessment to children through a Mobile Autism Clinic ( $n=15$ ). During COVID-19, the study then shifted to assess the feasibility of ASD teleassessment ( $n=15$ ). After a diagnostic feedback session, caregivers were randomized to attend psychoeducation sessions or receive psychoeducation materials about ASD. Caregivers then completed a satisfaction measure of the services received. Caregivers also reported on their ASD knowledge and empowerment throughout the study, utilizing the Autism Stigma and Knowledge Questionnaire and Family Empowerment Scale, respectively. Repeated measures ANOVA was conducted for each of the two caregiver outcome metrics. Time (i.e., intake, post-feedback, post-psychoeducation) was entered as the within-subjects factor, and psychoeducation condition (i.e., sessions or materials) and assessment type (i.e., mobile or teleassessment) were included as between-subjects factors.

**Results:** While flexibility in scheduling was necessary, all families completed the assessment and psychoeducation protocol. The primary reason for rescheduling mobile assessments included weather-related cancellations. Primary reasons for rescheduling teleassessments during COVID-19 included family emergencies and work-related scheduling conflicts. Caregivers rated high satisfaction of both assessment formats; t-tests revealed slightly higher general satisfaction with mobile assessments ( $p<.05$ ; see Table 1). Caregiver empowerment within the family and community improved with time, as did total ASD knowledge and knowledge of ASD treatment ( $\eta^2=.114-.235$ ,  $ps<.05$ ; see Table 2); no interaction effects were significant in this sample.

**Conclusions:** The current pilot study demonstrates high feasibility and satisfaction with two novel assessment delivery methods that are both affordable and accessible for families in this underserved, low-resource region, surmounting aforementioned barriers of geography and limited providers. Additionally, receiving a comprehensive assessment and ASD psychoeducation, whether face-to-face or through educational materials, improved aspects of caregiver knowledge and empowerment over time. Teleassessment has been relied upon to an unprecedented degree during COVID-19 and is likely to be needed throughout future waves of this pandemic, while both mobile and teleassessment can be used regularly to overcome access-to-care barriers in rural or other hard-to-reach locales.

**221.004 (Panel) Compass: Considerations for Implementing an Evidence-Based Consultation Intervention in Rural Schools**  
**L. N. Ogle<sup>1</sup>, L. A. Ruble<sup>1</sup> and J. H. McGrew<sup>2</sup>, (1)Special Education, Ball State University, Muncie, IN, (2)Psychology, Indiana University - Purdue University Indianapolis, Indianapolis, IN**

---

Background:

Consultation interventions such as the Collaborative Model for Promoting Competence and Success (COMPASS) are ideal for promoting the use of EBPs in rural schools. COMPASS starts with a parent-teacher consultation facilitated by a consultant producing goals and intervention plans individualized to the student with ASD, teacher, and environmental context using an evidence-based practice in psychology framework (McGrew, et al., 2015). This is followed by coaching organized around teaching plan implementation fidelity feedback and student progress monitoring. Three previous studies found that COMPASS doubled the IEP progress of students with ASD, but in each of these studies the developers served as the consultants.

Objectives:

The current study sought to develop and validate a training and supervision package for school-based consultants in both rural and urban areas. A secondary objective was to understand how much and what type of coaching (written feedback vs. face-to-face problem solving) is needed by teachers to achieve implementation fidelity and maximize student goal attainment progress.

Methods:

COMPASS training consisted of a 2-day in person training complemented by a web-based training website and data-driven supervision. Twelve consultants (age 24-60) were trained in three cohorts and each worked with 2-4 teacher-parent dyads. Eleven worked in rural schools. Thirty-one teachers (age 23-55) were recruited, along with one student (n=31, age 4-13) with ASD and their parent randomly chosen from their caseload. Each parent-student dyad received a 3-hour initial consultation. Teachers were then randomly assigned to one of four follow-up conditions: 1) four coaching sessions, 2) two coaching sessions, 3) four written performance feedback emails of student's goal attainment progress and teacher intervention plan adherence, or 4) no follow-up, initial consultation only. Consultants received data-driven supervision via video conferencing and written performance feedback following each initial consultation and follow-up coaching session that rated the consultant's adherence to protocol and teacher/parent satisfaction. Teaching plan quality, teacher adherence to plan, and student goal attainment progress were also rated.

Results:

Satisfaction with the COMPASS training package (10-items, 1=Strongly Disagree - 5=Strongly Agree) was high for both days of training (M=4.71 and M=4.63). Parent and teacher satisfaction with the consultation (M= 4.76, 5=Strongly Agree) and teacher satisfaction with coaching were also high (M=4, 4=Strongly Agree). Consultant adherence to the COMPASS consultation and coaching protocols and teaching plan quality increased with practice and supervision by the researchers. However, researcher assessment of adherence did not correspond to self-report assessment. Teacher adherence to the teaching plans and students' goal attainment progress increased relative to the amount of coaching or written feedback they received. No differences were observed in rural vs. urban schools.

Conclusions:

COMPASS is an effective intervention in rural schools with high satisfaction that helps support and strengthen the relationships between consultants, teachers, and parents. Rural school administrators were more open to trying COMPASS. However, rural schools were also more likely to either not have a designated ASD consultant or have consultants in multiple roles within the school. Special considerations for consultation in rural schools will be discussed.

## PANEL SESSION — SERVICE DELIVERY/SYSTEMS OF CARE

### Panel 228 - Decentralizing ASD Knowledge, Resources, and Services Away from ASD Specialists into Diverse Communities

**Panel Chair:** Serene Habayeb, *Children's National Hospital, Washington, DC*

**Discussant:** Sarah Dababnah, *University of Maryland, Baltimore, Baltimore, MD*

ASD awareness has increased, internationally and in historically disenfranchised communities, at a faster rate than has the growth of the specialized ASD workforce (Zhang and Cummings, 2019). In turn, there is a paucity of ASD specialists providing evidence-based resources to those who require them. Further, many traditional ASD clinics report lengthy wait times delaying children with/suspected to have ASD from receiving necessary services (Gordin-Lipkin, Foster, and Peacock, 2016). This panel will describe the benefit of decentralizing the receipt of ASD resources from specialized ASD professionals to community stakeholders in order to increase equitable access of these tools and supports. This panel will highlight projects that have successfully engaged diverse community stakeholders, including early childcare providers and parents, to disseminate evidence-based ASD knowledge, resources, screening protocols, and treatments to children and families. Projects will share examples from different timepoints along a family's diagnostic journey, beginning with monitoring for atypical development through receiving therapy once a diagnosis has been made. Presentations will emphasize how stakeholder engagement in resource dissemination can decrease health disparities among ethnic and racial minority youth and improve access to needed services in historically underserved communities in the US and internationally.

**228.001 (Panel)** Bridging the Gap: Increasing Access to ASD Knowledge and Resources through Hospital-Community Partnerships Focused on Training and Supporting Early Childhood Education Community Providers

**S. I. Habayeb<sup>1</sup>**, A. Inge<sup>2</sup>, Y. Myrick<sup>1</sup>, A. Hastings<sup>1</sup>, O. Soutullo<sup>1</sup>, R. Williams<sup>3</sup> and L. Godoy<sup>1</sup>, (1)Children's National Hospital, Washington, DC, (2)Center for Autism Spectrum Disorder, Children's National Hospital, Rockville, MD, (3)Child Health Advocacy Institute, Children's National Hospital, Washington, DC

**Background:** Early childhood education (ECE) providers ("educators") play a critical role in identifying Autism Spectrum Disorder (ASD) in young children and connecting families to resources. While developmental monitoring and screening is increasing in ECE settings, educators continue to report limited knowledge about ASD and related resource navigation. Limited research has investigated how consultation and training, specifically for ASD-related concerns, may impact educators.

**Objectives:** The primary objective of this mixed-methods feasibility pilot is to improve community-based educator knowledge of ASD using a train-the-trainer model to maximize sustainability and dissemination.

**Methods:** ASD specialists from a children's hospital (psychologists and a parent professional) developed replicable trainings to increase educators' knowledge about ASD, engage families in care, and navigate local services, using input from community stakeholders and national resources. Trainings were provided to two groups of educator participants (Training 1 N = 62; Training 2 N = 19). Several participants then co-facilitated a training with the ASD specialists for other ECE stakeholders (N = 19) via a train-the-trainer model and co-led a four-part webinar series for educators (N = 254 registered from 20 community agencies). Trainings were assessed using pre- (Time 1) and immediate post-training (Time 2) ratings of ASD knowledge and measures of feasibility and acceptability. Four to six months post-training, endpoint questionnaires (Time 3) were collected, and focus groups (2) and interviews (7) were conducted with participants who co-led trainings.

**Results:** Following the three in-person trainings, over 90% agreed or strongly agreed that trainers were effective and topics covered were relevant to their work. All but one participant felt somewhat (47.6%) or very (51.2%) prepared to share the information with their community sites, and 100% would recommend the training to other ECE professionals. Participants reported increased knowledge, confidence, and behaviors, in all domains assessed, at Time 2 and Time 3 (Figure 1). Following the webinars, over 90% of educators agreed or strongly agreed that they had the knowledge to recognize atypical development and to identify and connect families with community ASD resources, understood developmental monitoring and screening, and had the confidence to engage parents in conversations about their child's development. At Time 3, participants identified challenges they continued to face in ASD care, including lack of timely access ASD evaluations (64%) and treatment (36%) and limited family engagement in services/stigma (42%). They also identified ways to improve ASD care, including increased care/peer navigation (68%), more ASD-focused trainings (35%), and technical/individualized support (35%). Key focus group and interview themes included: 1) the training and technical assistance increased knowledge and positively impacted practices, 2) family education and engagement are keys to quality ASD care, 3) greater knowledge increases equitable access, but current systems are unable to handle demand, and 4) educators should be more involved in ASD work.

Conclusions: Findings suggest that brief trainings are feasible and can improve educator knowledge of ASD and resource navigation in a community setting while also maximizing dissemination. Based on findings, a city-wide collaborative was launched and is currently developing workplans to address community needs identified in this study.

**228.002** (Panel) Addressing Health Disparities in Early Detection of ASD: Bilingual Screening in Part C Early Intervention  
*A. S. Carter<sup>1</sup>, R. C. Sheldrick<sup>2</sup>, A. Eisenhower<sup>3</sup>, T. Mackie<sup>4</sup>, F. Martinez-Pedraza<sup>5</sup>, N. A. Hoch<sup>6</sup> and S. M. Brunt<sup>7</sup>, (1)Department of Psychology, University of Massachusetts Boston, Boston, MA, (2)Boston University School of Public Health, Boston, MA, (3)University of Massachusetts Boston, Boston, MA, (4)Institute for Health, Health Care Policy and Aging Research, School of Public Health, Rutgers Univer, New Brunswick, NJ, (5)Center for Children and Families, Florida International University, Miami, FL, (6)Clark University, Worcester, MA, (7)Psychology Department, University of Massachusetts Boston, Boston, MA*

Background: Whether suspected of ASD or not, a high percentage of children who are referred to and engage in Part C Early Intervention (EI) services will ultimately receive an ASD diagnosis. Even after a positive pediatric ASD screener, developmental concerns (e.g., language delays) are acknowledged without referral to ASD diagnostic evaluation. Families who successfully connect to EI services may still face access barriers associated with health disparities in early diagnosis and ASD-tailored interventions. We partnered with community-based EI agencies to implement multi-stage ASD screening and referral to university-based diagnostic evaluation to increase access to early detection of ASD, minimizing health disparities in rates of diagnosis.

Objectives: To determine if a community-based, EI-administered multi-stage screening protocol administered in English and Spanish coupled with referral to university-based diagnostic evaluation increases rates of ASD diagnosis and minimizes health disparities access to ASD diagnosis. Assess parent experiences of EI-based screening and the diagnostic evaluation.

Methods: A mixed methods approach was employed. Quantitative analyses involved tracking 4943 children (mean age: 22.0 months; 62.9% boys, 73.3% children of color, 34.9% non-English-primary language, 64.5% publicly-insured) who were eligible for screening through the multi-stage screening and diagnostic protocol. Stage 1 screening included the Brief Infant-Toddler Social Emotional Assessment and Parent Observations of Social Interactions, Second stage screening involved the Screening Tool for Autism in Toddlers. A positive questionnaire screener or parent or provider concern determined eligibility for further screening/diagnostic evaluation. State-level administrative demographic and diagnostic data from the Department of Public Health were used to conduct difference-in-difference analyses comparing rates of diagnosis in partner screening sites relative to contrast sites with similar trajectories of diagnostic rates in the pre-intervention period. Qualitative analyses of 65 longitudinal interviews with 22 parents provide insight into parent experiences of the multi-stage screening process.

Results: Screening and diagnostic evaluation participation were high (64.9% and 65.3% at first-and second-stage screening, 84.6% at diagnostic evaluation), with 83.7% of children participating in a diagnostic evaluation receiving an ASD diagnosis. Difference-in-difference analyses document that rates of diagnosis improved significantly at each partner screening EI site relative to comparison sites (See Figure). Spanish speaking families showed relatively stronger diagnostic benefits. Logistic regressions identified the following predictors of ASD diagnosis relative to the full screen eligible sample: children receiving diagnoses were older [Exp(B)=1.03, p=.004, 95% C.I.=1.01-1.05], more likely to be boys [Exp(B)=0.40, p < .001, 95% C.I.=0.31-0.52], and more likely to be children of color than all other eligible children [Exp(B)=1.39, p=.026, 95% C.I.=1.04-1.86]. No differences in language [Exp(B)=0.96, p=.71, 95% C.I.=0.75-1.21] or insurance [Exp(B)=1.20, p=0.16, 95% C.I.=0.93-1.54] were observed. Parents reported the written and observational screening tools facilitated understanding their child's behaviors within an ASD interpretive framework in unique and synergistic ways, facilitating shared decision-making with the EI provider.

Conclusions: Our EI-implemented multi-stage screening model increased rates of ASD diagnosis and addressed linguistic health disparities in receipt of ASD diagnosis. Expanding screening to EI settings affords opportunities to aid parents in understanding their children's ASD symptoms and facilitates shared decision-making and access to ASD-tailored interventions.

**228.003** (Panel) Evaluation of a Novel Remote Cascade Training Curriculum of the Who/As Caregiver Skills Training Program (CST) in Response to the COVID-19 Pandemic

*A. Ibrahim<sup>1</sup>, H. R. Pickard<sup>2</sup>, A. Kiafar<sup>3</sup>, A. Yusuf<sup>4</sup>, P. Dixon<sup>5</sup>, S. Dababnah<sup>6</sup>, A. Shih<sup>7</sup>, A. Pickles<sup>8</sup>, M. Elsabbagh<sup>9</sup>, S. Y. Shire<sup>8</sup> and T. W. CST Team<sup>9</sup>, (1)McGill University, Montreal, QC, Canada, (2)Social, Genetic and Developmental Psychiatry, King's College London, London, United Kingdom, (3)Neurology and Neurosurgery, McGill University, Montreal, QC, Canada, (4)Wayne State University, Ann Arbor, MI, (5)University of Maryland, Baltimore, Baltimore, MD, (6)Autism Speaks, New York, NY, (7)King's College London, Institute of Psychiatry, Psychology and Neuroscience, London, United Kingdom, (8)University of Oregon, Eugene, OR, (9)Department of Mental Health and Substance Abuse, World Health Organization, Geneva, Switzerland*

**Background:** The Caregiver Skills Training Program (CST), a caregiver-mediated intervention model, was developed by the World Health Organization and Autism Speaks to offer an open access and relatively low dose package for use by trained non-specialists. Intervention fidelity - i.e., the degree the intervention is implemented the way it was designed maintaining all components - has been a long-standing challenge in the translation of research into wider community benefits. CST approaches this challenge by using a cascade training and supervision model beginning with the training of Master Trainers (MTs), who in turn deliver the intervention with caregivers. However, to date very few studies have examined the extent to which fidelity can be achieved when training professionals in community settings before implementation. Significant barriers to training have been introduced with the COVID-19 pandemic, limiting in person professional development activities.

**Objectives:** Pre pandemic, all MTs had participated in a 5-day in person didactic and skills-based training. This would typically be followed by in person CST practice with children. We developed a remote cascade training curriculum to substitute this practice. The extent to which CST scoring reliability and MTs' perceived knowledge/confidence improved relative to the baseline was examined over the course of 12 weeks of training.

**Methods:** We enrolled 19 Master Trainers in the MT training curriculum (adapted for COVID-19) from Canada (n=11), USA (N=1), Argentina (n=3), Egypt (n=1), Ethiopia (n=2) and Iran (n=1). Participating MTs were professionals providing autism intervention services in their communities. Of the 19 MTs, 11 completed all modules and their rates of attendance in structured group interactions was very high. The MTs' skills on scoring adult-child interactions were assessed by CST experts using the 11-item CST Fidelity Rating Measure at baseline, midpoint and at the end of training. Each item was scored from 0 (not yet) through 4 (high quality, consistent implementation). The focus was to achieve scoring reliability on this measure. Adapted training included (a) 7 weekly group meetings to discuss MTs' independent scoring reliability of one adult-child interaction video and (b) independent coding of 10 new videos followed by two scoring discussions. We also evaluated perceived knowledge/confidence using the "MTs Perspectives on CST" survey.

**Results:** Repeated measures ANOVA revealed a significant effect of training on scoring reliability ( $F(2, 20) = 3.562, p = 0.04$ ). Post-hoc analyses using paired *t*-tests showed that the mean CST scoring reliability rating at midpoint ( $M = 4.08, SD = 2.25$ ) was significantly higher than at baseline ( $M = 2.62, SD = 0.76$ ) ( $t(12) = -2.33, p = .038$ ). However, no significant difference was found between midpoint and post training reliability scores. In contrast, MTs Perspectives on CST increased significantly over time from baseline to midpoint to post-training ( $F(2, 10) = 6.28, p = .017$ ).

**Conclusions:** The results provide evidence for increase of MTs' CST skills as a result of a newly developed remote training curriculum. Results also suggests increase of MTs' knowledge and perceived confidence of CST during the course of the training, including all modules.

**228.004 (Panel) Revisiting a Parent Education Program for Latinx Families: Are Positive Effects Maintained Overtime?**  
**S. Magaña<sup>1</sup>, W. Zeng<sup>1</sup> and K. Lopez<sup>2</sup>, (1)Steve Hicks School of Social Work, University of Texas at Austin, Austin, TX, (2)Arizona State University, Phoenix, AZ**

---

**Background:**

Latinx children with ASD and their families experience disparities in information and treatment. Parents Taking Action (PTA) is a culturally tailored parent education intervention that was developed to address disparities faced by Latinx families of children with ASD. Parent peer-leaders delivered the 14-session program through face-to-face home visits after receiving training on the content and intervention protocol. A randomized waitlist-control trial found positive parent and child outcomes for the treatment group compared to the control between baseline and four months across two sites: Illinois and California.

**Objectives:**

The purpose of this study is to examine the maintenance of intervention effects from baseline to eight-months post baseline to determine longer-term effects of the intervention.

**Methods:**

The participants were 93 (intervention=41, control=52) Latinx mothers of children with ASD aged 8 years or younger, who completed assessments at three timepoints: baseline, four months, and eight months. Parent and child outcomes included family empowerment (Family Outcome Scale; FOS), mother's confidence in using evidence-based (EB) strategies, and frequency of using EB strategies; child challenging behaviors, child social communication (Social Communication Questionnaire; SCQ), and the number of services received. We assess maintenance of intervention effects by conducting repeated measures analysis of

covariance (ANCOVA) models for all parent and child outcomes between baseline and eight months. Maternal education was controlled for since it was the only significant between-group demographic variable. We also analyzed differences in intervention effects by site by running OLS regression models at eight months.

#### Results:

Compared to control mothers, intervention mothers achieved 4.4 points higher in confidence ( $F_{[1, 90]}=8.61, p<.001$ ), and 3.8 points higher in frequency ( $F_{[1, 90]}=3.83, p=.02$ ) of using EB strategies scales between baseline and eight months. Children whose mothers were in the intervention groups on average received 1.4 additional services ( $F_{[1, 90]}=3.16, p=.04$ ) across these two timepoints. Overall, there were no significant treatment differences in family empowerment, the child's challenging behaviors, or SCQ scores. When analyzed by site, however, we found significant treatment differences in FOS' *assessing community resources* subscale ( $F_{[1, 23]}=7.33, p=.002$ ) and in child's SCQ scores ( $F_{[1, 23]}=9.08, p<.001$ ) in the California sample, but not in the Illinois sample.

#### Conclusions:

Intervention mothers at both sites reported greater confidence in and frequency of using EB strategies eight-months post baseline compared to the control. Additionally, our findings indicated greater receipt of services by children of mothers in the intervention groups compared to those in controls eight-months post intervention. Together, these findings suggest that the content, structure, and delivery mode of PTA may contribute to maintenance of effects beyond the timeframe of the intervention program. We found differences in some outcomes between the two sites. Policy and service differences in each state may contribute to these differences. Therefore, the intervention may show more robust improvements for families depending on state policies and availability of services.

## ORAL SESSION — SERVICE DELIVERY/SYSTEMS OF CARE

### Oral 314 - Measuring and Maximizing Access to Services

**314.001** (Oral) Service Experiences of Autistic People and Family Carers in Europe: Access-EU Study  
**J. Man<sup>1</sup>, R. Holt<sup>2</sup>, T. Parsons<sup>2</sup>, A. N. Ruigrok<sup>3</sup>, C. Allison<sup>1</sup>, A. Baranger<sup>4</sup>, J. Cusack<sup>5</sup> and S. Baron-Cohen<sup>1</sup>**, (1)Autism Research Centre, Department of Psychiatry, University of Cambridge, Cambridge, United Kingdom, (2)Autism Research Centre, University of Cambridge, Cambridge, United Kingdom, (3)University of Cambridge, Cambridge, United Kingdom, (4)Autism Europe, Brussels, Belgium, (5)Autistica, London, United Kingdom of Great Britain and Northern Ireland

**Background:** The worldwide prevalence of autism is approximately 1-2%, leading to estimates of seven and a half million autistic people in Europe. Many of those people, as well as their families, rely on a variety of services, yet many report difficulties with service access.

**Objectives:** This study is the first of its kind to explore a broad range of service experiences across Europe and the aim is to consider the state of service quality and access to services for autistic people. Findings will be used to inform European policy makers with a view to improving service experiences for autistic people and their families.

**Methods:** Autistic people and family carers were invited to take part in an online survey (available in English and seven European languages) which asked about their experiences with services within the past two years. The survey included a range of services such as physical and mental health services, social care, education, employment and therapy/allied health services.

**Results:** Initial findings based on UK data consist of 558 participants, of whom 358 were autistic people, and 200 were family carers reporting on behalf of an autistic person. Approximately half (52%) of all the autistic participants (self- and carer-report combined) identified as male, 40% as female, and less than 10% as non-binary or 'other'. 80% were adults, and 20% were under 18 years old. Mental health, therapy/ allied health and autism diagnostic services were reported to be the most difficult services to access. Long wait times were commonly reported for autism diagnostic services, with 87% waiting more than one month, 59% more than six months and 40% more than 12 months. Of those attempting to access mental health services in the last two years, 80% reported being successful at least once, but 40% reported being unsuccessful at least once. A similar pattern was seen for therapy services/ allied health services (68% successful and 43% unsuccessful) and for diagnostic services (85% successful, 22 unsuccessful). Overall, one of the most frequently reported barriers to service access was the service not being suitable (or not being deemed eligible for the service). The most frequently reported suggestions for improvements to diagnostic, mental health and therapy/allied health services involved improving resources, specifically including funding. Improving autism-related training was also commonly suggested for mental health and therapy/ allied health services.

**Conclusions:** Autistic people experienced many barriers to service access. A majority of those receiving services within the past two years stated that the service needed to improve. Some suggested improvements included a need to adapt to the specific needs of autistic people, improve the autism expertise of those providing the services and improve resources of services. Here we include preliminary data from this survey, subsequently we will provide a more in depth exploration including investigation of other service types and data from additional European language versions.

**314.002** (Oral) Changes in Equitable Access to Autism Services in Utah after Transitioning to Telehealth during the COVID-19 Pandemic: Identifying Socio-Demographic Gaps

*M. E. Villalobos<sup>1</sup>, P. Carbone<sup>2</sup> and A. L. Stuart<sup>3</sup>, (1)Pediatrics, University of Utah, Park City, UT, (2)University of Utah, Salt Lake City, UT, (3)General Pediatrics, University of Utah, Salt Lake City, UT*

---

**Background:** The University of Utah Child Development Program (CDP) serves families across the Intermountain West with developmental concerns, most frequently related to autism. While some telehealth visits were done prior to the pandemic, when the options for in-person visits became more limited at the onset of the pandemic (March 2020), CDP pivoted towards more telehealth-based assessments. It has been suggested that telemedicine may simultaneously open doors for families previously unable to access specialized services, such as those in rural/frontier communities and create barriers to care for those without adequate resources (Ameis, 2020). To date, changes in socio-demographic characteristics of families accessing care at an autism evaluation clinic preCV19 and during CV19 have not been described.

**Objectives:** To compare socio-demographic characteristics and rurality of patients served by CDP prior to the pandemic (July 2018 -February 2020) and since March 1, 2020.

**Methods:** We compared characteristics of children (age, race/ethnicity, sex) and families (location [urban/rural/frontier], medically underserved area/population [MUA/P] status, primary language, insurance type) and visit type (telehealth vs in-person). We also compared the proportion of families seen via telehealth. We examined associations between telehealth and equitable access for underserved populations. Logistic regression was used to estimate factors that influenced whether a person was able to access telehealth. All scheduling and productivity of clinicians remained unchanged during the pandemic.

**Results:** The transition to telehealth that is occurring during the pandemic, compared with in-person visits that predominated pre-pandemic appears to increase access for urban, English speaking families and for commercial insurance carriers. Access did not appear to be impacted by sex, race, or rurality; however, a trend towards decreased rural access was noted. Less equitable access was observed based on ethnicity (Hispanic families), insurance (MCAID) and language (See Table 1). Further, a significant decrease in age at first visit was observed during the pandemic suggesting that access to telehealth may decrease wait time (See Table 2).

**Conclusions:** Results from our study suggest specific targets for increasing equitable access to autism services during the pandemic based on socio-demographic variables. With telehealth CDP, was able to maintain pre-pandemic capacity for serving families of children with developmental concerns. Children seen during the pandemic are younger suggesting that children with developmental concerns can be evaluated in a timelier manner via telehealth. The telehealth technology used during the pandemic was associated with improved access for families living in urban areas but worsened access for non-English speaking families and those with MCAID. Telehealth did not appear to adversely impact rural access to care; however, we will be examining this further as we continue to collect data. This suggests that disparities in access to care that were present prior to the pandemic remain present and possibly more resilient. Previous research has identified socio-demographic issues as barriers to care for underrepresented families (Colbert et al., 2017). However, these issues are complex and not well understood especially during a pandemic. It behooves us to remain vigilant and build equitable systems of care as we move into this new era of telemedicine.

**314.003** (Oral) Autistic Adults' Experiences with Palliative Care and End-of-Life Services

*J. Lowe<sup>1</sup>, B. Rumbold<sup>2</sup> and C. Dissanayake<sup>3</sup>, (1)Public Health Palliative Care Unit and Olga Tennison Autism Research Centre, La Trobe University, Melbourne, VIC, Australia, (2)Public Health Palliative Care Unit, La Trobe University, Melbourne, VIC, Australia, (3)Olga Tennison Autism Research Centre, La Trobe University, Melbourne, VIC, Australia*

---

#### **Background:**

Australia's National Palliative Care Strategy (2018) recognises the importance of identifying and respecting the needs of people from under-served population groups and improving their access to culturally appropriate palliative care services. However, to date there have been no studies on the service experiences, preferences or needs of autistic adults with Autism Spectrum Disorder (Level 1) regarding palliative care.

## Objectives:

The aim in this study was to examine autistic adults': 1. understanding of and attitudes towards death as a concept; 2. experiences with palliative care and end of life services; 3. experience of and adjustment to grief due to bereavement; and 4. explore potential relationships between autism, death anxiety, attachment and grief.

## Methods:

The study, conducted by an autistic researcher, used a concurrent mixed methods design including semi-structured interviews with autistic adults (n=20) and health care and service professionals (n=22) from palliative care services, autism services, funeral providers and bereavement specialists. Interview data was analysed using grounded theory (Charmaz, 2014) including initial and focused coding and conceptual categories. An online survey was also conducted to examine potential relationships between autistic traits, death anxiety, adult attachment styles and indicators of prolonged grief disorder (PGD). A total of 298 survey responses were analysed and open-ended questions about respondents experiences with end of life service contexts were also included in the online survey.

## Results:

Grounded theory analysis resulted in 92 initial codes, 79 focused codes and 8 conceptual categories: concept of death, death anxiety and desire, autism is invisible, information needs, interaction with others, core components of palliative care, memorialisation practices and grief and bereavement. The survey results support qualitative findings, and also revealed the following: Autistic traits were correlated with avoidant ( $r = .36$ ) and anxious ( $r = .45$ ) attachments; Anxious attachment was correlated with death anxiety ( $r = .38$ ) and cognitive, emotional and behavioural symptoms > 6 months after bereavement ( $r = .30$ ); Cognitive, emotional and behavioural symptoms were correlated with separation distress > 6 months after bereavement ( $r = .36$ ).

## Conclusions:

There is a lack of autism awareness and education across palliative care and end of life services, including the funeral industry and specialist bereavement support services. Autistic adults' experiences with palliative care and end of life services indicate that the presence of autistic traits influences the delivery and quality of palliative care provided. The expression of grief due to bereavement presents uniquely in autistic adults and health care professionals need to be aware of the nuances of autistic responses to grief and loss. The presence of separation distress and/or cognitive, behavioural and emotional symptoms more than 6 months after bereavement are indicators of PGD. Autistic adults with an anxious attachment style and high levels of death anxiety may be at higher risk of developing PGD.

### 314.004 (Oral) Identifying Components of Autism Friendly Healthcare: A Modified Delphi Study

*B. O'Hagan<sup>1</sup>, S. King<sup>1</sup>, A. Friedman<sup>1</sup>, L. Bartolotti<sup>1</sup>, O. Abubakare<sup>2</sup>, S. Broder-Fingert<sup>2</sup> and M. Augustyn<sup>1</sup>, (1)Developmental and Behavioral Pediatrics, Boston Medical Center, Boston, MA, (2)Boston Medical Center, Boston, MA*

Background: Individuals with Autism Spectrum Disorder (ASD) are reported to have higher rates of healthcare services utilization<sup>1-3</sup>. However, despite higher utilization rates, individuals with ASD and their families are also more likely to report lower satisfaction with the care that they receive<sup>4,5</sup>. Currently, there is no definitive set of "best practice" standards in providing care for patients with ASD.

Objectives: This study aims to identify the components of what would make a healthcare practice "Autism Friendly" according to key stakeholders (i.e., professionals whose interests include ASD or who regularly works with individuals with ASD, individuals with ASD, and family members of individuals with ASD).

Methods: We conducted a modified three-round Delphi<sup>6</sup> study. A list of statements about possible components of an "Autism Friendly" healthcare practice was compiled using insights from the Autism Friendly Initiative at Boston Medical Center's steering committee, which consists of researchers, clinicians, hospital staff, and parents of individuals with ASD. These statements were entered into an electronic survey, which was distributed to selected members of our professional networks and families/patients mailing list.

In the first two rounds, participants were asked to score statements from a scale of 1-9 in terms of their importance as a component of Autism Friendly healthcare (1 = not important at all; 9 = very important). Scores were analyzed and statements with low scores (i.e., bottom 50%) across all stakeholder groups were eliminated. In the first round, participants had the

opportunity to add new statements if there were other components of an Autism Friendly healthcare practice that were not represented in the original list. Newly added statements were integrated with the higher-ranked statements from the first round. In the second round, participants had the opportunity to “rescue” eliminated statement(s) for the final round. “Rescued” statements that received more than three votes were included in the final list. In the third round, participants were asked to rank statements from most important to least important.

Results: In the first round, 78 participants scored 37 statements on a scale of 1-9. After analysis and integration of newly suggested statements, 21 statements were presented in the second round and scored by 51 participants. To date, 29 participants (20 professionals; 9 individuals with ASD and family members of individuals with ASD) have responded to the final round of the survey, which consists of 16 statements. The top 10 statements to date in the final round are presented in Table 1.

Conclusions: Themes that emerged from the highly ranked statements include patient advocacy for individuals with ASD, staff training to support patients with ASD in healthcare settings, and environmental or operational modifications to accommodate the needs of patients with ASD. In all three rounds, there appear to be differences in scores provided by professionals and non-professionals (e.g., individuals with ASD and family members of individuals with ASD). More research is needed to explore avenues to implement the findings of this study as well as the differences in perspectives of professionals and families/individuals with ASD about Autism Friendly healthcare practice.

## ORAL SESSION — SERVICE DELIVERY/SYSTEMS OF CARE

### Oral 328 - Access to Primary and Preventive Care

**328.001** (Oral) National Inpatient Hospitalizations in Autistic Youth in the U.S.

**J. Rast<sup>1</sup>, A. Roux<sup>1</sup>, S. J. Fernandes<sup>1</sup>, V. D'Silva<sup>2</sup> and L. Shea<sup>3</sup>, (1)A.J. Drexel Autism Institute, Drexel University, Philadelphia, PA, (2)Children's Crisis Intervention Services, Robert Wood Johnson Barnabas Health Monmouth Medical Center, Long Branch, NJ, (3)A.J. Drexel Autism Institute, Philadelphia, PA**

Background: Addressing healthcare needs is complex in autistic youth for many reasons. Increased inpatient care that has been noted in this population may be a marker of inadequate primary and outpatient care.

Objectives: The goal of this study is to examine characteristics of inpatient hospital stays for autistic youth, examine racial and ethnic differences in experiences, and compare to youth with other mental, behavioral, or neurodevelopmental disorders (MBND). The aims are to 1) present demographic and inpatient stay characteristics of autistic and MBND youth, 2) examine the most common reasons for inpatient hospitalizations in autistic youth by race and ethnicity and by MBND youth, and 3) describe the cost and length of inpatient stays among autistic and MBND youth. This research builds on existing literature to underscore the need to prioritize policies and programs that incentivize treatment of ambulatory care sensitive conditions (ACSC) to prevent unnecessary hospitalizations.

Methods: This study used data from hospital inpatient discharges from the Healthcare Cost and Utilization Project (HCUP), Agency for Healthcare Research and Quality (AHRQ) National Inpatient Sample (NIS) 2017. NIS 2017 captured more than 7 million stays from 47 states plus the District of Columbia, covering 97% of the U.S. population. The prevalence, average length of stay, and average cost per day of the 10 most common principal diagnoses for index stay were calculated for autistic youth (ages 0-17) overall (n=7890) and by race and ethnicity. Comparisons were made to youth with mental, behavioral, and neurodevelopmental disorders (MBND) (n=70,150).

Results: Of every 1000 stays, 7.3 were for autistic youth and 65.2 for youth with MBND, the rate varied by U.S. region and zip code-level household income. The most common principal diagnosis in autistic youth was mood disorders, as in youth with MBND. Nearly all top 10 principal diagnoses for autistic youth were for ACSCs. Race and ethnicity impacted the rate of principal diagnosis in autistic youth: mood disorders were more common in white, non-Hispanic youth (19%) than black, non-Hispanic (13%) and Hispanic (8%) youth; while asthma and schizophrenia were more common in black youth (8% and 4%) than in white (both 2%) and Hispanic (4% and 1%) youth. The highest average cost per day for autistic youth was for physical injuries (\$4320 per day) followed by epilepsy (\$3480 per day) (Figure 1). Average length of stay varied by race and ethnicity in autistic youth for schizophrenia, conduct disorders, and mood disorders, but cost per day did not vary greatly (Figure 2).

Conclusions: High occurrence of ACSCs in autistic youth suggest that primary care many not adequately address health and mental health needs. Long length of stay suggests that clinical complexity and autism characteristics may be impacting care received in the hospital. Care complexity also appears to be impacted by race and ethnicity in autistic youth, unsurprising due to

more common mis- and under-diagnosis and misinterpretation of ASD associated behaviors in minority youth. More work is needed on improving systems of care to prevent unnecessary hospitalizations and providing optimal care to vulnerable populations.

**328.002** (Oral) Specialized Primary Care Center for Autistic Adults Is Linked with Increased Receipt of Preventive Care Services

*B. N. Hand<sup>1</sup>, D. Gilmore<sup>2</sup>, D. Coury<sup>3</sup>, A. Darragh<sup>4</sup>, S. Moffatt-Bruce<sup>5</sup>, C. Hanks<sup>6</sup> and J. Garvin<sup>7</sup>, (1)Health and Rehabilitation Sciences, The Ohio State University, Columbus, OH, (2)The Ohio State University, Columbus, OH, (3)Nationwide Children's Hospital, Columbus, OH, (4)Division of Occupational Therapy, The Ohio State University, Columbus, OH, (5)Department of Surgery, The Ohio State University, Columbus, OH, (6)The Ohio State University Wexner Medical Center, Hilliard, OH, (7)Health Information and Management Systems, The Ohio State University, Columbus, OH*

---

**Background:** Preventive healthcare services, like immunizations, disease screenings, and behavioral counseling, are a critical component of health maintenance. However, autistic adults face barriers to healthcare at the patient, provider, and systems levels, resulting in autistic adults receiving significantly fewer preventive services than non-autistic peers. As the population of autistic adults grows, there is an urgent need to address this disparity in the receipt of preventive services by developing and testing evidence-based models of healthcare delivery that may better meet this population's needs. The Center for Autism Services and Transition (CAST) at The Ohio State University is a patient-centered primary care clinic aiming to remove many barriers to care for autistic adults. For example, CAST patients may receive modifications to the standard patient workflow (e.g., bypass the waiting room due to sensory sensitivity) and are seen by physicians with extensive experience working with the autistic adult population.

**Objectives:** To compare the receipt of preventive services among patients who receive care through CAST to US national samples of autistic adults with private insurance or Medicare.

**Methods:** We conducted a cross-sectional retrospective study of medical billing data. The sample included CAST patients (N=490) who were propensity score matched to national samples of Medicare-enrolled autistic adults (N=980) and privately insured autistic adults (N=980) using demographic characteristics. The primary outcome measure was the receipt of any preventive service, as defined by the Medicare Learning Network and AAPC (formerly the American Academy of Professional Coders). Secondary outcome measures included receipt of five specific preventive service types (i.e., general health and wellness services; screenings; counseling and therapies; vaccinations; and sexual/reproductive health services). We used logistic regression to compare CAST patients to national samples of autistic adults with Medicare or private health insurance on the odds of receiving any preventive service, as well as the odds of receiving each of the five specific types of preventive services.

**Results:** CAST patients had significantly greater odds of receiving any preventive service than Medicare-enrolled (OR=10.3; 95% CI=7.6-13.9) and privately insured (OR=3.1; 95% CI=2.3-4.2) autistic adults. CAST patients were also significantly more likely to receive screenings and vaccinations than either Medicare beneficiaries (screenings OR=20.3; 95% CI=14.7-28.0; vaccinations OR=5.5; 95% CI=4.3-7.0) or privately insured autistic adults (screenings OR=2.0; 95% CI=1.6-2.5; vaccinations OR= 3.3; 95% CI=2.6-4.1).

**Conclusions:** Our findings support a specialized, patient-centered approach in the care of physicians who are knowledgeable about autism as a promising solution to improve healthcare delivery for this population. There are a number of characteristics of CAST that may be responsible for the increased receipt of preventive care services, screenings, and vaccinations such as care coordination and patient-centeredness. CAST, however, differs from other patient-centered approaches in its customization for autistic adults and it may, in fact, be these customizations that contribute to the observed increase in receipt of preventive care. In future work, it will be important to identify the most significant drivers of CAST patient outcomes in preparation for replication in other communities.

**328.003** (Oral) Feasibility of a Telediagnostic Model for ASD Evaluation in Clinically-Referred Young Children

*E. Fox and J. Gerds, University of Washington, Seattle, WA*

---

**Background:** In response to the COVID-19 pandemic, U.S. federal and state-level governments have created policies that promote and facilitate the use of telehealth tools to provide healthcare services to patients. Diagnostic services for autism spectrum disorder (ASD) were in high demand prior to the pandemic, and the temporary closing and then limited in-person re-opening of diagnostic centers during this public health crisis have increased already lengthy wait times for evaluations (Solomon & Soares, 2020). Delays in diagnosis restrict access to treatment, and this is particularly problematic for young children with

ASD, who particularly benefit from early identification and intervention. Telehealth diagnostic (telediagnostic) models for assessing ASD are being piloted and may provide a critical service to families during the pandemic.

**Objectives:** To explore the feasibility of a telediagnostic model piloted at the Seattle Children's Autism Center (SCAC) for young children referred for ASD diagnostic evaluation.

**Methods:** Figure 1 summarizes the SCAC telediagnostic pilot protocol. Figure 2 shows complete screening data. Of the 300 patients interested and reached from the waitlist aged approximately two to four years, 35.6% ( $n=107$ ) screened in. Patients were most often screened out due to the child having too much language per recommended TELE-ASD-PEDS (Corona et al., 2020) guidelines or family preference for in-person evaluation. Data from 80 patients were available based on intakes completed to date. Patients ranged in age from 22-59 months ( $Mean=37.3$  months, 68.8% male). Sixty percent of patients identified as Non-White and 26.9% identified as Hispanic/Latino. Patients resided in 13 counties throughout WA State, ranging from 0 to 159 miles from clinic.

**Results:** After accounting for patients lost to follow-up, most patients (88%) completed their diagnostic evaluation entirely via telehealth. Approximately 11% of patients had to return to clinic for additional evaluation (7.5% of patients after intake, 3.3% after teleassessment). Common reasons included issues with technology, medical or psychosocial complexity, language barriers, and discrepancy between parent report and clinician observation. Sixty-one patients have been seen for teleassessment to date using the TELE-ASD-PEDS and ABAS-3, and 96.7% of these evaluations were completed entirely via telehealth. The majority of patients ( $n=54$ , 93%) with diagnostic outcome data available received an ASD diagnosis. Total TELE-ASD-PEDS score was significantly higher ( $M=16.3$  vs. 9.0,  $p<.001$ ) and ABAS-3 General Adaptive Composite significantly lower ( $M=70.8$  vs. 82.8,  $p=.04$ ) in patients diagnosed with ASD versus without ASD. Provider confidence in providing a diagnosis via telehealth was high ( $Mean=4.6$ , range=3-5).

**Conclusions:** A telediagnostic model for a focused ASD assessment appears feasible in young children referred to an ASD specialty clinic for diagnostic evaluation. Providers reported feeling confident in using a telediagnostic model, and 88% of patients completed their assessment from start to finish via telehealth. Patient and provider satisfaction data are being evaluated. Telehealth has played a critical role in maintaining patients' access to services during the COVID-19 pandemic, and results from this study suggest that it can be used sufficiently for diagnostic purposes. Further study is needed, but this modality may also expand access to care and decrease physical barriers to services.

**328.004 (Oral) Physician Voices on the Impact of Echo Autism in a LMIC Setting- a Qualitative Study of a Telementoring Model to Build Physician Capacity in Diagnoses and Management of Pediatric ASD**

**K. Sengupta<sup>1</sup>, L. Lobo<sup>2</sup>, V. Krishnamurthy<sup>2</sup> and K. Sohl<sup>3</sup>, (1)Ummeed Child Development Center, Mumbai, Maharashtra, INDIA, (2)Ummeed Child Development Center, Mumbai, Maharashtra, India, (3)Department of Child Health, University of Missouri, School of Medicine, Columbia, MO**

**Background:** A significant treatment gap exists in Low & Middle-Income Countries (LMICs) for children with Autism Spectrum Disorder (ASD), ranging from delays in initial detection to inadequate access to effective management of commonly associated psychiatric and medical co-morbidities. Possible solutions include training first-line and specialist physicians using sustainable, evidence-based models.

**Objectives:** To explore physician perspectives about process and perceived impact of ECHO Autism - a tele-mentoring model to increase physician access to best-practice care for children with ASD in a LMIC context.

**Methods:** The Extension for Community Healthcare Outcomes (ECHO) framework shown to be effective in improving self-efficacy and ASD-specific practice parameters of primary care physicians in the U.S. was culturally modified based on initial feasibility results and feedback from a pilot cohort conducted by a "hub" team of multi-disciplinary experts and a parent at a child-development center in Mumbai. In the current study, 13 bi-weekly sessions focused on best practice methods in screening, early diagnoses of autism, principles of intervention, management of challenging behaviors, psychiatric and medical co-morbidities were conducted using secure video-conferencing technology. Specific adaptations included increasing duration of didactic component, including more videos of clinical features and intervention techniques and a strong focus on strengths-based, family-centered approach woven in across the sessions. Across two cohorts, 64 "spokes" participated-including primary care and developmental pediatricians, psychiatrists and neurologists working with children with ASD in India and other LMICs. On completion of the program, qualitative data was collected from 28 physicians who volunteered to participate. 6 focus groups were conducted online by trained moderators, using an interview guide with open-ended questions about the process and impact of ECHO. Audio recordings were transcribed, all data was coded using iterative and reflexive sifting by two coders and

discrepancies were resolved consensually. Using principles of thematic analysis, themes were identified inductively from the categories.

**Results:** Participants represented a broad geographic reach across 15 cities in 4 countries-India, Nepal, Turkey and Ethiopia. Common themes reflected the andragogical processes of ECHO Autism that participants considered beneficial, yet different from previous training experiences (accessible format, interactive case-based discussion, peer-learning, “expert” guidance, layering of topics, access to resources, respectful mentoring, parent as “expert” and cultural relevance) and the perceived impact of the program on their work (shift in clinical practice to structured, transdisciplinary, comprehensive care, change in attitude, increase in self-efficacy and direct impact on children and families). Participants’ recognition of need for ongoing developmental monitoring, parents as partners-in-care and importance of caregiver mental health emerged strongly. Disruptions in internet connectivity, scheduling conflicts and limited access to therapy services in certain settings were cited as challenges.

**Conclusions:** ECHO Autism has emerged as a model that can potentially improve both access and quality of care in pediatric ASD for underserved communities. The model reinforces the need for local stakeholders in leading such initiatives to enable emphasis on locally relevant issues and challenges in LMICs, thereby enhancing cultural congruence and ensuring sustainability. Such initiatives also create opportunities for meaningful collaboration between global teams and valuable cross-cultural learning.

## POSTER SESSION — SERVICE DELIVERY/SYSTEMS OF CARE

### Poster 442 - Service Delivery/Systems of Care Posters

**442.001 (Poster)** A Collaborative Psychiatric-Genetics Inpatient Service and Outpatient Clinic Improves Accessibility to Genetics Evaluation and Testing for Patients with Autism Spectrum Disorder and Intellectual Disability  
*A. Shillington<sup>a</sup>, M. Lamy<sup>a</sup>, C. A. Erickson<sup>a</sup>, K. Dominick<sup>a</sup> and R. Hopkin<sup>a</sup>, (1)Cincinnati Children's Hospital Medical Center, Cincinnati, OH, (2)Division of Child and Adolescent Psychiatry, Cincinnati Children's Hospital Medical Center, Cincinnati, OH*

**Background:** Genetic testing is indicated for children with neurodevelopmental disorders, including autism spectrum disorder and intellectual disability. Much of this testing is initiated by genetics physicians in the outpatient setting. Children with neurodevelopmental disorders with more severe behavioral phenotypes receive much of their care by neurodevelopmental psychiatrists, who are a key source of referrals for genetic testing. Unfortunately, many patients in this population who are referred to genetics are lost to follow up after inpatient or outpatient psychiatric evaluation.

**Objectives:** A psychiatric genetics collaboration was established at Cincinnati Children’s Hospital in March of 2019 to provide genetic evaluation and genetic testing to children with neurodevelopmental disorders in the psychiatric inpatient setting, as well as the psychiatric outpatient clinic, in order to improve care for this population of patients. Our goals were to reduce both the wait time to see a geneticist, and to reduce the number of patients who were lost to genetics follow up after an outpatient referral for evaluation was placed.

**Methods:** A retrospective chart review was conducted on all patients at Cincinnati Children’s Hospital that were evaluated by neurodevelopmental psychiatrists and referred to genetics from July 1, 2010 to October 31, 2020. Patients were divided into two groups; those that were referred to genetics prior to the psychiatric genetics collaboration (March 1, 2019), which forms our pre-collaboration cohort (N=40) and those who were referred to genetics after the initiation of the psychiatric genetics collaboration, which forms our post-collaboration cohort (N=51). We analyzed the time to genetics evaluation after a referral was placed, and the percentage of patients lost to follow up in each group.

**Results:** Patients in the pre-collaboration group had an average wait time of 393 days before they were seen in the genetics clinic after a referral was placed, which was significantly higher than the average wait time of 29 days experienced by post-collaboration patients. 32% of patients in the pre-collaboration group were lost to follow up and did not present to their referred genetics evaluation. This was significantly higher than the 6% of post-collaboration patients who were lost to follow up for genetics evaluation.

**Conclusions:** After implementation of a collaborative psychiatric genetics program for children with neurodevelopmental disorders in the care of psychiatry, we noticed a decrease in wait time to genetics evaluation, as well as a decrease in patient attrition due to lost follow up. Some of the reasons for the improved patient care include accessibility to genetics evaluation in the inpatient setting, accessibility to genetics evaluation in the outpatient psychiatric clinic, improved communication between psychiatric and genetics physicians for joint care management decisions, convenience for families to receive care in a

multidisciplinary fashion, and ability to deliver care in the psychiatric care setting allowing for additional behavior supports increasing family comfort and patient ability to tolerate more familiar settings for evaluation.

**442.002 (Poster)** A Systematic Review of Healthcare Professionals' Knowledge, Self-Efficacy and Attitudes Towards Working with Autistic People

*K. Corden<sup>1</sup>, R. Brewer<sup>1</sup> and E. Cage<sup>2</sup>, (1)Department of Psychology, Royal Holloway, University of London, Egham, United Kingdom, (2)Department of Psychology, University of Stirling, Stirling, United Kingdom*

---

**Background:** Healthcare professionals play a vital role in identifying and supporting their patients on the autistic spectrum. Dependent on context, this could include the diagnostic process itself, in addition to managing the high levels of physical and psychological difficulties often co-occurring in this population. It is necessary for health workers to be knowledgeable of the core characteristics of autism and how they present to provide high quality care tailored to the needs of autistic people and their families. However, relatively little is known about healthcare professionals' knowledge of autism, or their self-efficacy and attitudes to providing care to this group. The existing literature demonstrates significant variability in method, measures and results, which is difficult to interpret across disparate studies.

**Objectives:** The present study aimed to systematically review the available empirical research examining healthcare professionals' knowledge, self-efficacy and attitudes to working with autistic people, in addition to the factors potentially associated with these elements.

**Methods:** An initial database search was conducted using SCOPUS, PsychInfo, PubMed and Web of Science, followed by manual searches of the included articles. Studies were included in the date range of 1994 to the present, to reflect the substantial changes in diagnostic criteria and prevalence rates of autism during this time. Unpublished and qualitative research was excluded. Thirty-five studies were included in the final total out of the 2574 identified by the initial search. The included studies sampled a wide range of countries of origin (such as the USA, UK, Nigeria, Pakistan, Australia) and professional backgrounds (such as medical students, occupational therapists, nurses, general practitioners and doctors).

**Results:** A modified quality assessment tool found the overall quality of the included studies was moderately good. A narrative synthesis of the results was performed. The results indicated that healthcare professionals continue to report only moderate levels of knowledge (ranging between 47% to 71% correct knowledge) and moderate self-efficacy related to working with autistic people. Several negative beliefs about autism were noted in some studies, such as viewing autistic patients as difficult or feeling uncomfortable working with them. There were also some beliefs and attitudes highly incongruent with current research and medical guidance, particularly concerning potential causes of autism. Variation in knowledge, self-efficacy and attitudes both within and between countries and professional background were not adequately explained by demographic factors, such as gender or age. However seven studies reported greater autism knowledge was associated with increased experience.

**Conclusions:** These results indicate that autism knowledge, self-efficacy and attitudes are highly variable across samples and individuals working in healthcare, and even in samples with reasonable knowledge scores, there is still room for improvement. Even within individual countries, there was substantial disparity of results, suggesting autism knowledge is highly variable irrespective of country. The reviewed evidence suggests that health professionals' limited knowledge, and self-efficacy in working with autistic people continues to be a challenge to the provision of high quality healthcare for autistic individuals.

**442.003 (Poster)** Adaptation and Piloting of the Who Caregivers Skills Training Programme for Remote Delivery

*C. Ferrante<sup>1</sup>, P. Sorgato<sup>1</sup>, S. Ghersi<sup>2</sup>, A. Salandin<sup>2</sup>, S. Rizzo<sup>2</sup>, T. W. CST Team<sup>3</sup>, M. L. Scattoni<sup>4</sup>, C. Servili<sup>2</sup> and E. Salomone<sup>1</sup>, (1)Department of Psychology, University of Milan-Bicocca, Milan, Italy, (2)Fondazione Paideia, Turin, Italy, (3)Department of Mental Health and Substance Abuse, World Health Organization, Geneva, Switzerland, (4)Istituto Superiore di Sanità, Rome, Italy*

---

**Background:** The Caregiver Skills Training (CST) is a caregiver-mediated program for neurodevelopmental disorders developed by WHO (Salomone et al. 2019). Based on principles of behavioural and developmental science and positive parenting, the program consists of 9 group sessions and 3 home visits. Due to the COVID-19 emergency in Italy in-person participation to CST, previously found to be feasible and acceptable, was suspended. A remote adaptation of CST was developed to respond to families' needs.

**Objectives:** The study reports on the process of adapting CST to online delivery and examines feasibility and acceptability data.

**Methods:** Clinical psychologists with experience of CST implementation and a WHO CST Team member adapted the program for online delivery through group and individual videocalls ('Group Sessions' and 'Home Visits'). Core contents remained

unchanged; adaptations were based on principles of active learning. The live modelling of strategies was replaced with pre-recorded videos based on the manuals' scripts. Caregiver role play was substituted by enhanced planning of the home practice with additional time dedicated to discussion of scenarios in small groups. Sharing of a videorecording of a play/home routine with the child was added after Sessions 3 (play) and 7 (daily living skills), with feedback provided the following session. Caregivers of children (4-6 years,  $M=4.88$ ) with a clinical diagnosis of ASD ( $n=8$ ; extra-EU nationality,  $n=5$ ; high-school diploma,  $n=5$ ) and two program interventionists completed adapted WHO CST feasibility and acceptability measures (5-point scales; 'satisfactory' = 3, 'good' = 4). Observers completed fidelity ratings. Data is available for sessions 1-3; data collection is ongoing. At baseline, 5 caregivers had previous experience of telehealth and considered it as less valuable than in-person consultations.

Results: All recruited caregivers attended the first three sessions (via a smartphone,  $n=4$ ). Usability ratings of the videocalls were high across sessions. Feasibility ratings for all sessions were above satisfactory levels across standard and adapted activities. Fidelity ratings were excellent (range = 3.5-4). Caregivers reported practising with strategies on average 3.5 times/week (range = 3-5). For the adapted activities, caregivers' ratings of comprehensibility and relevance and interventionists' ratings of caregivers' involvement and interest were good for at least 6 caregivers across sessions. Caregiver-reported confidence levels were above satisfactory levels for 6 out of 8 caregivers across sessions. All sessions were rated as having the same value of face-to-face consultations by at least 5 out of 8 caregivers.

Conclusions: Preliminary feasibility ratings of CST delivered online through simple technology were high and comparable with those of in-person implementation, including for the adapted components. The sessions were highly acceptable and relevant, and considered as valuable as in-person contacts, despite a negative attitude towards telehealth at baseline. Advantages of this adapted remote delivery model include reducing barriers to attendance and facilitating additional contact (videorecordings); however, potential challenges (in-home distractions, group dynamics) should be monitored. Full data, including measures of therapeutic alliance and uptake of intervention strategies, will be examined to explore the usefulness of this delivery method beyond the current health emergency and the potential for use in other contexts.

**442.004** (Poster) Applied Behavior Analysis Disparities for Medicaid-Enrolled Individuals with Autism: A Multilevel Analysis

---

Background: Studies have demonstrated that children with ASD from rural areas and those who are Black or Hispanic/Latinx experience *diagnostic and service access* disparities.

Objectives: Examine whether disparities also exist in *service use* for traditionally underserved children with ASD who receive services within a publicly funded system.

Methods: Medicaid claims from one region of a midwestern state in the U.S. from April of 2017 through March of 2018 for 1,028 youth with ASD under age 21 were analyzed. The individuals were treated by 69 agencies (42% rural) that provide applied behavior analysis (ABA) services. Youth were predominantly White (71%), non-Hispanic (88%) and male (80%), with an average age of 7.56 years. Racial and ethnic groups in the sample were unevenly distributed. Thus, a single race/ethnicity variable with four categories was coded: 1) White, non-Hispanic; 2) Black, Hispanic or non-Hispanic; 3) Other Race, non-Hispanic; or 4) Hispanic (non-Black). Agency rurality was defined according to HRSA.

The outcome variable was the number of 30-minute billing units of one-on-one ABA sessions per month. A series of multilevel models using restricted maximum likelihood were used to predict hours of ABA as a function of either race/ethnicity or agency rurality, controlling for age and sex. Random effects included an intercept variance to account for nonindependence due to agency.

Results: Three models were estimated. Model 1 predicted ABA as a function of agency rurality (effects coded), sex (effects coded), age (grand mean centered), and racial/ethnic minority status (effects coded). We could not include agency rurality and each racial/ethnic group within the same model because there were only 8 observations of Black individuals served by a rural agency. Model 2 predicted hours of ABA as a function of the four categories of race/ethnicity (categorical coding), sex (effects coded), and age (grand mean centered). Model 3 was identical to Model 2 but only included non-rural agencies.

In Model 1, hours of ABA were predicted as a function of age, sex, minority status, and agency rurality. The analysis indicated a significant main effect of agency rurality,  $F(1, 122) = 7.89, p = .006$ , as well as a significant effect of age,  $F(1, 862) = 105.12, p < .001$ . The effects of sex and minority status were not significant. Holding sex, minority status, and age constant, youth that received services from rural agencies received an average of 10.86 fewer hours of ABA per month compared to those in non-rural areas. Younger children received more ABA. See Table 1 for regression coefficients.

Model 2 indicated a significant main effect of age,  $F(1, 964) = 118.28, p < .001$ , but not for race/ethnic group or sex. Results from Model 3 (non-rural agencies only) were nearly identical with Model 2. See Table 2 for estimated marginal means.

Conclusions: Publicly funded service systems such as the Medicaid system may provide more equitable provision of services to individuals of racial/ethnic minority backgrounds. Service systems must address challenges for families from rural regions, increase the healthcare workforce in rural areas, and consider rurality in policies.

**442.005 (Poster)** Assessing Child Life Specialists' Knowledge, Competency, and Comfort Levels Caring for Pediatric Patients with Autism Spectrum Disorder

**K. Lavery<sup>1</sup>, A. A. Weimer<sup>1</sup> and K. R. Warnell<sup>2</sup>,** (1)School of Family and Consumer Sciences, Texas State University, San Marcos, TX, (2)Department of Psychology, Texas State University, San Marcos, TX

---

Background: Healthcare environments involve many factors that can be stressors to children with autism spectrum disorders (ASD), such as bright lights, strongly-scented cleaning products, and interactions with many unfamiliar adults (Johnson et al., 2012). Understanding how children with ASD cope with hospitalization is especially important given that children on the spectrum are more likely to be hospitalized than their typically-developing (TD) peers (Zwaigenbaum et al., 2016). One important way that hospitals promote positive pediatric outcomes is via Certified Child Life Specialists (CCLS). CCLS play a vital role on interdisciplinary healthcare teams as they aid in positive coping, promote psychosocial care, and reduce the risk of healthcare-related trauma. Previous research has found that CCLS interventions improve outcomes for hospitalized TD children (Thompson et al., 2018), but little work has directly examined the interaction between CCLS and pediatric patients with ASD (Jensen et al., 2019). Thus, an important research step is to identify how well-prepared CCLS are for providing care to children with ASD.

Objectives: The present study investigated knowledge, competency, and comfort levels in caring for pediatric patients with ASD amongst CCLS healthcare professionals.

Methods: Participants included a total of 131 practicing CCLS (100% female, 94% White). Most held a graduate degree (68.4% Graduate, 30.1% Bachelor's). Participants completed an online survey that assessed (1) their experience and previous training regarding challenging or maladaptive behaviors common in ASD (e.g., self-harm or throwing objects) and (2) their perceived competency and comfort levels in managing these behaviors.

Results: Almost all participants (96.99%,  $n=129$ ) reported having experienced one or more challenging behavior when working with children with ASD in a healthcare setting. On 7-point Likert scales assessing self-reported competence and comfort in working with such behaviors, average scores were slightly above the midpoint for both competence ( $M = 5.27, SD = .56$ ) and comfort ( $M = 5.40, SD = .55$ ). Very few CCLS reported high levels on both scales (i.e., fewer than 15% with average scores above 6). As hypothesized, knowledge about childhood autism positively correlated with perceived competence ( $r(130) = .20, p < .05$ ) and comfort ( $r(130) = .23, p < .01$ ) in managing challenging behaviors. The perceived competency of CCLS in managing challenging behavior was significantly higher if the participant had gained their knowledge through academic education ( $M = 5.38, SD = .49$ ) compared to other domains such as professional development or training outside of work ( $M = 5.12, SD = .56; t = 2.09, p < .05$ ). However, only 17.3% of those who reported receiving training received theirs via academic coursework, and 13.5% had received no training in working with children with ASD at all.

Conclusions: Results suggest that Child Life programs should focus more on ASD care and behavioral management, as such training directly results in more comfort with handling challenging behaviors. Increasing ASD-specific training will equip CCLS to accommodate the unique support needs that often correspond with ASD, leading to better overall health outcomes, as well as reduced stress and anxiety for pediatric patients with ASD experiencing hospitalization.

**442.006 (Poster)** Caregivers-Mediated Intervention in Brazil through Who CST Program Implementation in Public and Universal Health Care System.

**E. Matos<sup>1</sup>, C. C. Rauenz<sup>2</sup>, G. M. S. Doria<sup>3</sup>, M. D. F. J. Minetto<sup>4</sup>, A. M. Choinski<sup>5</sup>, R. Massuda<sup>6</sup>, C. Geyer<sup>6</sup>, S. ---

Background:

Neurodevelopmental disorders (ND) and autism cause significant losses to child's and family members' quality of life. Training parents to promote the acquisition of their children's skills is a viable and effective alternative in less favored scenarios, since recommended treatments have a high cost. The Caregivers Skills Training (CST) program trains families of children (2 to 9 years) with ND to apply stimulation techniques.

#### Objectives:

This study aimed to adapt the CST to the Brazilian socio-cultural context, to verify the acceptability and feasibility of the program implementation, as well as to measure the impacts (goals / outcomes) on children and caregivers.

#### Methods:

The Phase 1 was the adaptation of the program to the Brazilian context. It included consultation with specialists, translation and revision of materials and two Focal Groups with professionals and families. The Phase 2 evaluated feasibility and acceptability by caregivers (n = 10) and Master Trainers (MT) (n = 4). Quantitative data were obtained by the World Health Organization recommended measures and qualitative data were obtained through Focal Groups and analyzed by the Descending Hierarchical Classification. The Phase 3 is expected to be completed by December 2020, it was adapted to happen remotely, due to the COVID-19 pandemic. It started with 50 caregivers divided into five groups, with two facilitators each, and one MT supervisor. Quantitative measures will be evaluated through questionnaires that assess both children and caregivers' changes with the program. Qualitative data will be obtained by six Focal Groups (one with all the facilitators and MT and five with the family groups) after the program.

#### Results:

Phase 1 was completed with a positive perception from the caregivers. In Phase 2, the parents' results showed an improvement of behaviors on all children, an improvement on parental knowledge and skills on 77.77% out of the 36 questions and that the sessions were understandable, relevant, acceptable and useful. From the MT's perceptions, the caregivers showed agreement with ideas, engagement, relevance of contents and acceptability. The program implementation fidelity average was 2.71 (ranging from 1 to 3). Regarding qualitative data, five themes emerged from the caregivers' Focal Group: changes in caregivers' behavior, support for caregivers, development of the child's skills, challenges of inclusion and treatments and understanding. From the MT's qualitative data emerged the themes: supervision, method and material, field activity, achievements and planning. Phase 3 is still being implemented.

#### Conclusions:

Both qualitative and quantitative, showed consistent initial results, which demonstrates that the implementation of CST in Brazil is feasible, acceptable, relevant and it meets a local need. Participant's data suggest that group sessions and home visits were well accepted and valued in the local context. The practical issues were the main obstacles to participation in training and that the organization of handouts and supervision of trainers needs to be improved. The program test demonstrated positive changes in caregivers, creation of a support network and improvement of symptoms in children with ND. These findings in Brazil may be relevant for countries with few resources and similar socio-cultural characteristics.

**442.007 (Poster)** Cost-Benefit and Cost-Effectiveness of a Specialized, Patient-Centered, Primary Care Clinic Designed with Autistic Adults and Their Caregivers

**B. N. Hand<sup>1</sup>, C. Hanks<sup>2</sup> and J. Garvin<sup>3</sup>, (1)Health and Rehabilitation Sciences, The Ohio State University, Columbus, OH, (2)The Ohio State University Wexner Medical Center, Hilliard, OH, (3)Health Information and Management Systems, The Ohio State University, Columbus, OH**

---

Background: Autistic adults are significantly more likely to have mental health conditions than non-autistic peers. With inadequate care, these conditions can lead to emergency department visits or hospitalizations for mental health conditions and increase healthcare costs. Primary care management of mental health conditions increases access to services and reduces stigma, but there are currently few patient-centered, holistic approaches to primary care for autistic adults. The Center for Autism Services and Transition (CAST) is a patient-centered clinic that was co-designed with autistic adults and their caregivers to minimize barriers to care. For example, CAST offers accommodations to best meet the needs of autistic adults (e.g., patients with anxiety may bypass the waiting room) and has providers with extensive experience providing care for this population.

Objectives: To determine whether CAST is more cost-effective and cost-beneficial than primary care provided to national samples of autistic adults.

**Methods:** We conducted a cross-sectional retrospective study with data from our institutional Information Warehouse, IBM MarketScan, and Medicare Standard Analytic Files. The sample included CAST patients (N=524) who were propensity score matched to national samples of privately (N=1048) and publicly insured autistic adults (N=1048) using demographic characteristics. Our outcome variables were: (1) costs, quantified by direct charges billed for primary care (i.e., general medicine, internal medicine, pediatric, geriatric, family medicine, or preventive care providers); (2) benefits, quantified by direct charges billed for mental health-related inpatient hospitalizations and emergency department visits, collectively termed “admissions”; and (3) effectiveness, quantified by the number of mental health admissions. We calculated incremental cost-benefit ratios and cost-effectiveness ratios to compare CAST patients to each of the other samples. To estimate variability in our outcomes, we obtained 95% confidence intervals by bootstrapping with 50% subsamples 500 times. We performed two-sample t-tests on the estimates from the bootstrapping analysis to compare CAST patients to each of the other two samples.

**Results:** Table 1 provides sample characteristics and bootstrapped estimates. Average per-person primary care costs were lowest for Medicare beneficiaries (\$722), followed by CAST patients (\$886), and privately insured autistic adults (\$943). On average, CAST patients had significantly fewer and lower cost of mental-health related admissions than either national sample. Compared to care provided to privately insured autistic adults, every \$38 spent on CAST is associated with a 10-visit decrease in the number of mental health admissions and \$2000 decrease in cost of mental health admissions. Every \$48 spent on CAST primary care above the cost of care provided to Medicare-enrolled autistic adults is associated with a 10-visit decrease in the number of mental health admissions and \$578 decrease in cost of mental health admissions.

**Conclusions:** CAST is more cost-effective and cost-beneficial than primary care provided to a national sample of privately insured autistic adults. Relative to primary care provided to a national sample of Medicare-enrolled autistic adults, CAST is more expensive but yields significant savings by reducing the number and cost of mental health admissions. Overall, the findings support patient-centered approaches, like CAST, as promising models of primary care delivery for autistic adults.

**Background:** The global COVID-19 pandemic has had an unprecedented impact on European health and social care systems, with demands on testing, hospital and intensive care capacity exceeding available resources in many regions. This has led to concerns that some groups, including autistic people and those with intellectual disability (ID), may become excluded from services.

**Objectives:** To assess COVID-19 health and social care provision for autistic people.

**Methods:** A two-step methodological approach was implemented. First, COVID-19 health and social care policies from 15 European member states (Figure 1) - published March-July 2020 - were collated and reviewed by researchers, clinicians and non-profit groups from AIMS-2-TRIALS network and a panel of five representatives from the autism community. Policies were reviewed across three priority areas: 1) access to COVID-19 tests; 2) provisions for treatment, hospitalisation and access to intensive care units (ICU); and 3) changes to standard health and social care. Second, Autism-Europe provided de-identified secondary data from their large-scale survey of the impact of COVID-19 on the lived experiences of 1,301 autistic people and caregivers.

**Results:** Autistic people and those with ID experienced significant barriers accessing COVID-19 services. First, despite these groups being at elevated risk for severe illness due to co-occurring health conditions, there was a lack of accessibility to COVID-19 testing. Second, many COVID-19 outpatient and inpatient treatment services were reported to be inaccessible - predominantly resulting from individual differences in communication needs. Third, ICU triage protocols in many European countries (directly

or indirectly) resulted in discriminatory exclusion from lifesaving treatments. Last, interruptions to standard health and social care left over 70% of autistic people without everyday support.

**Conclusions:** The COVID-19 pandemic has further exacerbated healthcare inequalities for autistic people and those with ID, likely contributing to disproportionate increases in morbidity and mortality in these groups (Public Health England; 12th November 2020). Current policies and guidelines regarding the accessibility of COVID-19 services require revision to prevent the widespread exclusion of autistic people and those with ID from services, which represents a violation of international human rights law. To our knowledge, this is the first analysis of inequalities in access to COVID-19 health and social care services for autistic people and those with ID across Europe. Based on this evidence, we provide specific recommendations for informing an aligned European strategy on the fair allocation of resources in public health emergencies, which include strategies for enhancing the accessibility of testing, hospital/ ICU care and mitigation measures for the continued safe and effective delivery of health and social care services for potentially vulnerable groups.

**442.009 (Poster) Disruptions to Services Accessed By Families of Autistic Individuals during the COVID-19 Pandemic**

McMorris<sup>4</sup>,** (1)University of Calgary, Calgary, AB, Canada, (2)Psychology, York University, Toronto, ON, Canada, (3)University of British Columbia, Vancouver, BC, Canada, (4)Department of Paediatrics, University of Calgary, Calgary, AB, Canada

---

*Background:*

Prior to the COVID-19 pandemic it was well-established that caregivers of autistic individuals were particularly vulnerable to heightened stress and mental health concerns. Autism is often accompanied by associated conditions, including mental health concerns, attention-deficit/hyperactivity disorder, intellectual disability, language disorders, and disordered sleep, which require support from a range of supports. The unique needs of autistic children, coupled with barriers families often face in accessing services to address their needs, can contribute to high levels of caregiver stress. These challenges are likely exacerbated by the effects of social distancing guidelines and regulations in place due to COVID-19. Many face-to-face social, educational, and therapeutic programs were paused, cancelled, offered less frequently, or modified (e.g., offered virtually). These interruptions in routines have likely been distressing for families and have led to caregivers adopting multiple additional roles and responsibilities.

*Objectives:*

The main goals of the present study are: 1) to describe service use patterns and disruptions to services experienced by families during COVID-19; 2) to determine whether there is a relation between service disruptions and perceived parental stress levels and family distress/crisis; and 3) to identify the current service needs and priorities of families.

*Methods:*

A sample of 635 Canadian caregivers (59% mothers) completed an online questionnaire between June and July 2020 that included demographic information, information related to parent and child well-being, and information about disruptions and difficulties due to the COVID-19 pandemic. Caregiver stress was measured using the Perceived Stress Scale (PSS-10), and family distress or crisis was measured using the Brief Family Distress Scale (BFDS). Caregivers were asked to identify services accessed prior to the pandemic and changes to these services experienced due to the pandemic. Finally, caregivers were asked to select up to five services that they currently wanted or needed, as well as up to five services that they predicted they would want or need in the future (post-quarantine and moving forward) from a list of 26 services.

*Results:*

95% of families surveyed were accessing services prior to the pandemic, with the most popular being speech-language therapy (37%), behavioural therapy (30%), and occupational therapy (29%). A vast majority of families (88%) experienced a change (e.g., face-to-face to virtual) or disruption to at least one service. The most frequently changed/disrupted being behavioural therapy, with 81% of families accessing that service reporting that it had been changed or interrupted in some way. Additional analyses will investigate the association between service disruption, caregiver stress and family distress.

*Conclusions:*

The current study will describe the impact of the physical restrictions of COVID-19 pandemic on the service utilization of autistic individuals and their families. Further, the study will provide insight into whether service disruptions contribute to caregiver stress and family distress, which may have implications for how families, who are already vulnerable to stress and mental health concerns, can be better supported during this time.

**442.011** (Poster) Do Family Characteristics Influence Providers' Use of Evidence-Based Practices?

*L. Tomczuk and M. Pellecchia, University of Pennsylvania, Philadelphia, PA*

---

**Background:** Evidence-based mental health treatments have been underutilized in community settings, especially in under-resourced communities (Brookman-Frazee, Taylor, & Garland, 2010). Autistic children from racial and ethnic minority groups or low socio-economic backgrounds are more likely to experience delays in the onset of intervention services and are less likely to receive evidence-based practices (EBPs), as compared to their white peers (Nelson, 2002; Algeria, Vallas, & Pumariega, 2010). The reasons for these disparities in access to care are multi-layered and likely related to systemic- and individual-level barriers. Previous research has indicated that providers' attitudes and beliefs related to an intervention's fit with an individual family or client influence their use of those interventions (Stahmer & Aarons, 2009; Irvin, McBee, & Boyd, 2012; Siller et al., 2014). However, this research has never been applied to understanding the barriers to implementing evidence-based practices for autistic children in under-resourced community settings. Understanding how providers intend to implement evidence-based practices, and the factors that influence their decisions to implement EBPs for poor or ethnic minority children is a critical step in developing strategies to improve the implementation of EBPs in under-resourced settings.

**Objectives:** This study aimed to learn about community practitioners' experiences with and perspectives about using a particular evidence-based intervention, parent coaching. Specifically, the study sought to identify barriers and facilitators to implementing parent coaching with families of young autistic children within publicly funded early intervention systems.

**Methods:** Semi-structured interviews were conducted with 30 early intervention providers across two distinct geographic regions serving highly under-resourced populations within the United States. Interview questions probed about providers' use of evidence-based parent coaching strategies and barriers and facilitators to using these types of strategies with families. Transcripts were analyzed iteratively based upon an integrated approach incorporating both inductive and deductive features.

**Results:** Common themes relating to family characteristics, such as culture and home environment, were mentioned by providers as barriers to successfully implementing evidence-based parent coaching strategies. They often mentioned their belief that the intervention approach did not "fit" well with families who may be experiencing financial strife and living in poverty. Providers' use of evidence-based parent coaching strategies is influenced by the extent to which families are experiencing external stressors.

**Conclusions:** This study is one of the first to provide first-hand perspectives regarding community providers' use of evidence-based parent coaching strategies within under-resourced service settings. Early intervention providers described specific family characteristics that influence their use of evidence-based parent coaching. Specifically, they described the presence of characteristics that are most commonly ascribed to under-resourced or ethnic minority families (i.e., non-English speakers, chaotic households, and financial burdens) as influencing their decision to implement parent coaching. These findings highlight the need to improve culturally competent practices among these providers and develop implementation strategies to improve the use of evidence-based parent coaching for this population in order to improve equity and access to EBPs for ethnic minority and under-resourced families.

**442.012** (Poster) Does Hcbs Enrollment Bridge Racial-Ethnic Gap in Community-Based Service Use Among Autistic Adults?

*W. Song<sup>1</sup>, L. Shea<sup>2</sup> and S. Tao<sup>3</sup>, (1) Temple University, Philadelphia, PA, (2) A.J. Drexel Autism Institute, Philadelphia, PA, (3) Drexel University, Philadelphia, PA*

---

**Background:** Although no differences in prevalence by race or ethnicity have been found, Black children are less likely to be diagnosed and receive early intervention than white children (Maenner et al., 2020). A previous study on autistic children showed that Medicaid HCBS enrollment significantly reduced the likelihood of having unmet needs among Black autistic children compared to white children (LaClair et al., 2019). However, there has been no research on racial and ethnic differences in the use of Home and Community-based Services (HCBS) among autistic adults.

**Objectives:** To provide a preliminary exploration of (1) the HCBS enrollment status by race and ethnicity and (2) the Medicaid paid amount of HCBS by racial and ethnic groups among autistic adults enrolled in the HCBS.

**Methods:** Data from the Medicaid Analytic eXtract 2012 were used. The sample included adults with ASD who were 18 years old or older. All HCBS utilization and associated costs were assessed. Race and enrollment status were the primary independent

variables. There was three enrollment status: (1) enrolled, (2) not enrolled, and (3) status change during 2012. HCBS enrollment included programs for intellectually disabled/developmentally disabled or autism/autism spectrum disorder. Four racial and ethnic groups – non-Hispanic white, non-Hispanic Black, Hispanic/Latino, and Asian, were examined.

Results: Our sample had 88,513 adults with ASD, with most of them being male (74.8%) and an average age of 28.27 (SD=10.88). Most of the sample were non-Hispanic white (60.5%), followed by non-Hispanic Black (15.9%), Hispanic/Latino (6.8%), Asian/Pacific Islander (2.6%), and other (14.2%). At the national level, among the HCBS enrollees, the proportion of Asian adults (55.8%) was higher than the other groups, followed by 43.9% of Hispanic/Latino, 40.2% of non-Hispanic Black, and 38.9% of non-Hispanic white. A smaller proportion of Hispanic/Latino autistic adults (38.0%) were not enrolled in the HCBS than the other three groups. No considerable differences were found among those who changed enrollment status during 2012. Please see Table 1 for selected states. Regarding the Medicaid paid amount of HCBS, the average payment per person were relatively higher for non-Hispanic white (M=58350.91) than the other three groups, followed by non-Hispanic Black (M=53516.7), Asian (M=43882.1), and Hispanic/Latino adults (M=41744.9). For specific services, Non-Hispanic white had a higher average payment of round-clock services and home-based services, while non-Hispanic Black had a higher average cost of day services. The Asian group had the lowest amount in all three services.

Conclusions: This study showed some preliminary results demonstrating the racial and ethnic differences in terms of HCBS enrollment and the average Medicaid paid amount. Although a smaller proportion of non-Hispanic white adults were enrolled compared to other groups, the differences varied in different states. Although a higher proportion of Asian adults was enrolled in HCBS, Asian waiver enrollees had the lowest Medicaid paid amount. Other individual characteristics (e.g., ASD severity, comorbidities, and service planning) need to be considered to explain the racial/ethnic differences. Since the current analysis is unadjusted, regression analyses will be performed in the next step to adjust for other individual characteristics.

**442.013** (Poster) Echo Autism: Characterizing Children Diagnosed with Tier 1 Autism By Echo Graduates in Missouri  
**B. Gois<sup>1</sup>, K. Sohl<sup>1</sup>, J. Reken<sup>2</sup> and T. Hanson<sup>3</sup>,** (1)Department of Child Health, University of Missouri, School of Medicine, Columbia, MO, (2)Child Health, University of Missouri, Columbia, MO, (3)Child health, University of Missouri-Columbia School of Medicine, Columbia, MO

---

Background: The Extension for Community Healthcare Outcomes (ECHO) Autism STAT is a new program aimed at increasing the local expertise regarding autism among Missouri pediatricians. It uses telehealth to connect pediatricians to an interdisciplinary team of autism experts, increasing the number of providers who can evaluate, diagnose, and manage children with Autism Spectrum Disorder.

Objectives: Since there are no data on the patients diagnosed by the program graduates, the focus of this study was to determine key demographic and clinical diagnostic characteristics of children with Tier 1 autism in Missouri. By understanding these key identifiable characteristics, we hope to not only learn what types of children can be diagnosed reliably by Tier 1 Providers but also work towards establishing a clinical decision algorithm that will help clinicians more accurately diagnose these children.

Methods: Retrospective chart reviews of 69 patients evaluated by four graduates of the ECHO Autism STAT Program were completed. Data regarding the patient's age at evaluation, ethnicity/race, testing scores, and DSM-5 criteria were collected and analyzed using STATA R software.

Results: Following the national trend, the children evaluated through STAT ECHO were prominently male and identified as Non-Hispanic White. Unlike the national trend, however, the age of patients diagnosed through our program were 1.9 years younger than the national average. There was no distinction in the two most prominent behavioral concerns between Tier 1 and Non-Tier 1 patients, both groups reporting high prevalence of aggression and self-harm. When comparing Tier 1 to Non-Tier 1 patients, a statistical significance was present in all criteria for DSM-5 diagnosis, except B2 and B4. Lastly, we found that the MCHAT, a test highly relied upon by pediatricians to screen for Autism, only had a positive predictive value of 33%.

Conclusions: We can say with confidence that the ECHO autism program has the promise to improve the prognosis of children through diagnosis at an earlier age. Unfortunately, given the low power and lack of major statistically significant findings, no conclusions can be made in regard to specific behaviors that distinguish Tier 1 and non-Tier 1 Patients at this time. Future research is imperative to better understanding the types of patients that can be diagnosed through the program versus those that be referred to a next level diagnostic provider.

**442.014** (Poster) Echo Autism: Innovations in Workforce Development to Bridge the Specialty to Generalist Gap and Optimize the Continuum of Autism Care.

**K. Sohl<sup>1</sup>, R. Brown<sup>2</sup>, N. C. Cheak-Zamora<sup>3</sup>, V. Nanclares-Nogues<sup>4</sup> and M. O. Mazurek<sup>5</sup>,** (1)Department of Child Health, University of Missouri, School of Medicine, Columbia, MO, (2)KUMC, Wichita, KS, (3)Health Sciences, University of Missouri, Columbia, MO, (4)Pediatric Developmental Center, AIMMC, Advocate Children's Hospital, Chicago, IL, (5)University of Virginia, Charlottesville, VA

---

#### Background:

Advances in autism diagnostic accuracy and understanding of autism co-occurring conditions have led to earlier, more effective diagnostic and intervention practices. However, these advances tend to be limited to highly specialized professionals. There continue to be increasing service gaps for individuals with autism and their families. Standard professional development curriculum for general clinicians often lacks specificity in core elements critical for serving the autism population and lack the adaptability to address professional's clinical and learning demands.

ECHO Autism is an innovative approach that scales the dissemination of scarce specialist knowledge through virtually training generalist clinicians using de-identified, case-based learning (an "all-teach, all-learn" collaborative model). The ECHO Autism model originated in 2015 and first focused on pediatric primary care. It has since expanded to train a much broader range of professionals serving individuals with autism.

#### Objectives:

- Describe ECHO Autism as a workforce development tool to support generalist clinicians to build clinical expertise and increase capacity to serve the ASD community.
- Discuss generalist clinician outcomes demonstrated across ECHO Autism programs highlighting impact of the program on the professional workforce to scale knowledge dissemination and address the gaps in the continuum of care.

#### Methods:

ECHO Autism programs are uniquely designed to fill specific professional/workforce development gaps in the autism care continuum. Evaluation measures are designed for each ECHO Autism program to assess changes in self-efficacy, knowledge, barriers to care and practice patterns while participating in ECHO Autism. Post-ECHO Autism session qualitative comments are also collected for ongoing program evaluation. Mixed methods review of existing program data was analyzed for professional type, frequency of attendance per ECHO Autism program, and satisfaction with ECHO Autism model.

#### Results:

To date, ECHO Autism has set up 27 training hubs across the United States and provided more than 13,700 hours of learning to approximately 2,300 generalist clinicians.

Results consistently show improvement in generalist clinician self-efficacy in understanding autism, resource utilization, medical and psychiatry co-morbidity management. Additionally, results demonstrate promising improvements in key quality indicators across the life course including screening practices for early identification of autism and elements of healthcare transition. Perceived barriers to care are also reduced following ECHO Autism participation.

#### Conclusions:

Since 2015, ECHO Autism has trained approximately 2,300 professionals in the United States through case-based learning. ECHO Autism's unique blend of evidence-based, high quality professional development with collegial, iterative learning collaboration is building the workforce capacity across the autism care continuum. While barriers to systematic changes to professional accreditation requirements persist, ECHO Autism is an acceptable, feasible and effective model to scale the dissemination of clinical skills and knowledge to equip professionals to serve individuals with autism. Future directions include economic analysis and partnership with payors and professional accrediting organizations to consider sustainable workforce development strategy.

**442.015 (Poster)** Echo Education: Autism in Schools – Pilot Data from a Teleconsultation Model Providing Educational and Behavioral Supports to Educators of Students with Autism

*R. E. Nevill, G. E. Lovette and M. O. Mazurek, University of Virginia, Charlottesville, VA*

---

**Background:** Many special educators have limited training and background on supporting students with autism within the classroom. Displaying challenging behavior in the classroom can limit students' opportunities to make educational gains and form positive social connections with teachers and peers.

**Objectives:** Presenters will share results from a pilot study testing the effects of a teleconsultation program using the ECHO model to provide behavioral and educational consultation to educators of students with autism in K-12 settings across Virginia.

**Methods:** Participants in the pilot study were educators of children with autism in Virginia's K-12 schools ( $n = 9$ ). Educators were delivered a combination of case-based problem solving opportunities and workshops through an 8-session network. Data collection was comprised of pre- and post-test measures of participants' autism knowledge, autism self-efficacy, beliefs about behavior, and self-confidence. Program satisfaction data were also collected at post-test.

**Results:** This presentation will report on the participant group's demographics, changes from pre- to post-test in participants' outcomes, and program satisfaction. Effect sizes for significant improvements in outcomes will be shared. Finally, we will provide descriptive information about case presentations to better characterize the types of challenges for which educators most commonly requested support. Pilot data showed significant improvements in autism self-efficacy and confidence in managing challenging behavior ( $ps < .05$ ), with a small effect on confidence and moderate effect on autism self-efficacy.

**Conclusions:** The ECHO Education: Autism in Schools is a promising model for delivering support and consultation to educators of students with autism in K-12 settings. Advantages of this model are that it can be offered at zero cost and can increase participants' sense of social support and connectedness with colleagues. To conclude, we will present our follow-up plans to evaluate this program using larger participant groups and a waitlist control design. To conclude, this presentation shares additional examples of other applications of the ECHO Autism model for professionals across Virginia.

**442.016 (Poster)** Emergency Department Utilization Among Youth with Autism Spectrum Disorder: Exploring the Role of Preventive Care, Medical Home, and Mental Health

*E. Sadikova, N. Badgett, M. Menezes and M. O. Mazurek, University of Virginia, Charlottesville, VA*

---

**Background:** Children with autism spectrum disorder (ASD) have complex medical, dental, and mental health care needs, which are often unmet. The continuum of care for youth with ASD begins with basic preventive healthcare. The medical home is an especially helpful healthcare delivery model for children with ASD, given its emphasis on coordinated, comprehensive, and family-centered primary care. Although emergency department (ED) services should be considered a "last resort" of the continuum of care in children, children and adolescents with ASD are at an especially high risk for ED utilization when compared to the general population. It's likely that the level of unmet need, access to preventive care and access to medical home are associated with ED use, yet no study to date has examined these associations.

**Objectives:** The aim of the study was to examine preventive care (dental, medical), unmet healthcare needs (medical, dental, mental health), and access to a medical home as predictors of the frequency of ED service use among children with ASD.

**Methods:** Using data from the 2016 National Survey of Children's Health (NSCH), children who had a current parent-reported diagnosis of autism were selected for these analyses ( $N = 1,131$ , Mean Age=11.22,  $SD=4.07$ ). A hierarchical ordinal logistic regression was used to examine the relationships among the dependent variable of ED utilization (i.e., 0, 1, 2+ past-year visits) and other levels of care. Step 1 were the covariates of child age, sex, race, ID, behavior problems, federal poverty level percentage, and insurance type. Step 2 were whether preventive dental care and preventive medical care were received in the past year. Step 3 were unmet medical needs, unmet dental care needs, and unmet mental health care needs. Step 4 was access to a medical home. Whether each step (i.e., block of variables) contributed significantly to the model was determined by Wald tests.

**Results:** The Wald tests indicated that demographic variables, unmet healthcare needs, and medical home blocks of variables provided significant contributions to the nested model; preventative care block of variables did not significantly contribute to the nested model. Unmet mental health care needs in children with ASD was associated with 3.33 times greater odds of visiting the ED. Having unmet dental and medical healthcare needs were not significantly associated with ED use. Children with a medical home had decreased odds of visiting the ED twice or more in a year by 73% as compared to once or zero times.

**Conclusions:** Given the association between unmet mental health care and ED use, it is essential that high-quality outpatient mental health services be accessible to this population to prevent the need for psychiatric-related ED visits. Furthermore, our findings indicated that although preventive care was not significantly associated with ED use, having a medical home decreased the likelihood of frequenting the ED twice or more in a year. This suggests that simple access to preventive care may not be enough to reduce the likelihood of ED use, but rather that a comprehensive and holistic medical home model is needed.

**442.017 (Poster)** Emergency Department Utilization By Adolescents and Young Adults with Autism Spectrum Disorder  
**D. A. Iannuzzi<sup>1</sup>, M. Hall<sup>2</sup>, N. Oreskovic<sup>3</sup>, E. Aryee<sup>4</sup>, S. broder-Fingert<sup>5</sup>, J. M. Perrin<sup>6</sup> and K. Kuhlthau<sup>6</sup>,** (1)125 Nashua Street, MassGeneral Hospital, Boston, MA, (2)National Association of Children's Hospitals, Lenexa, KS, (3)Pediatrics, Mass General Hospital, Boston, MA, (4)Boston Medical Center, Boston, MA, (5)Harvard Medical School, Boston, MA, (6)Massachusetts General Hospital, Boston, MA

---

**Background:** Adolescents and young adults (AYA) with autism spectrum disorder (ASD) often experience co-occurring medical and psychiatric conditions that can exacerbate the core symptoms of ASD. It has been well documented that individuals with ASD have increased rates of medical and psychiatric co-occurring conditions including epilepsy, gastrointestinal disturbances, sleep issues, anxiety, depression, and respiratory, food, and skin allergies, which may at times necessitate utilization of an emergency department (ED).

**Objectives:** This study examined ED utilization by adolescent and young adults (AYA) with ASD. We investigated principal reason for an ED visit, likelihood of hospital admission following an ED encounter of ASD, and the presence of an ambulatory care sensitive condition (ACSC), as compared to non-ASD cohort, controlling for age, sex, and demographic region. Ambulatory care sensitive conditions are illnesses or health conditions where appropriate ambulatory care can prevent or reduces the need for hospital admission.

**Methods:** We used data from the most recent 2016 Nationwide Emergency Department Data Sample (NEDS), Healthcare Cost and Utilization Project (HCUP), Agency for Healthcare Research and Quality (AHRQ). Information regarding principal diagnoses for the ED encounter were extracted using (ICD-10) codes and the Clinical Classification Software (CCS) categorization schema. The CCS developed by the Agency for Healthcare Research and Quality (AHRQ) collapses ICD10 diagnoses codes into clinically meaningful groups. An ED visit was considered to be for an individual between 12-30 years of age with ASD, if there was a documented diagnosis of ASD based on ICD-10 codes for Autistic disorder(F84.0); Rett's syndrome (F84.2); other childhood disintegrative disorder (F84.3); Asperger's syndrome (F84.5); other pervasive developmental disorders (F84.8); and pervasive developmental disorder, unspecified (F84.9). Other data extracted included sex, insurance, region of residence, the hospital's location, and median household income. Median household income was reported as estimated median household income of residents in the patient's ZIP Code.

**Results:** Among the Non-ASD group, the most frequent principal diagnoses were sprains and strains (6.5 %), superficial injuries and contusions (5.6%), and upper respiratory infections (5.2%). In contrast, for the ASD cohort, the most frequent ED principal diagnoses were, mood disorders (8.6%), epilepsy, and convulsions (8.6%), followed by attention deficit disorders (ADD) and conduct and disruptive behavior disorders (4.6%). In addition, the results indicated that the ASD cohort had more ACSC diagnoses as compared to the Non-ASD cohort. The relative risk of a hospital admission following an ED discharge in the ASD cohort was 3.7 times greater than in the non-ASD cohort.

**Conclusions:** These findings suggest that individuals with ASD may present to the ED with neurological and psychiatric symptoms, as well as, a higher proportion of ACSCs as compared to the non-ASD cohort. By definition, had these conditions been treated and managed through community-based outpatient care, these ED visits may have been avoided. Given that among AYA with ASD, ED visits are nearly four times more likely to result in an inpatient hospital admission as compared to the non-ASD cohort; increasing available community healthcare supports could potentially reduce both ED visits and inpatient admissions.

**442.018 (Poster)** Examining Sociodemographic Disparities in Amount and Type of Intervention Use  
**H. S. Durham<sup>1</sup> and A. J. Harrison<sup>2</sup>,** (1)Education, University of Georgia, Athens, GA, (2)Educational Psychology, University of Georgia, Athens, GA

---

**Background:** Research suggests that intervention in the preschool years plays a particularly vital role in beneficial outcomes (Zwaigenbaum et al., 2015). Unfortunately, many children do not receive intervention as early as they should for a myriad of reasons. Children from sociodemographic minority groups in the United States are at a particular disadvantage for receiving early interventions (Nguyen, Krakowiak, Hansen, Hertz-Picciotto, & Angkustsiri, 2016). Although there is emerging evidence

documenting disparities for some sociodemographic groups in Autism Spectrum Disorders treatment use, previous research has focused on a dichotomous variable of treatment receipt and typically examines a narrow definition of treatment types.

**Objectives:** The current study conducted a closer examination of a specific number of hours for multiple different types of intervention service usage per week across several sociodemographic groups. Importantly this study looked at service utilization for the classically studied under five-year-old group as well as for children ages six to twelve.

**Methods:** This study examined data collected from 2974 participants enrolled in the Simons Simplex Collection (SSC), a genetic and phenotypic database of individuals diagnosed with ASD (Fischbach & Lord, 2010). We examined the specific number of weekly hours of therapy in four different domains: Speech Therapy, Occupational Therapy, Intensive Therapy, and Classroom Intervention. We additionally examined Psychotropic Medication usage. We looked at two age groups, children under five and elementary aged children (five to twelve-years-old). We looked to see if either age group differed on amount of weekly therapy based on sociodemographic variables including, mother and father education, annual household income, family structure, race, ethnicity, relationship status, and occupation.

**Results:** Amount of Under 5 occupational therapy (OT) was significantly related to mother education  $F(7,167) = 3.89, p = .001$  and father education  $F(8,167) = 3.45, p = .001$ . Such that, individuals with an associate degree had significantly more hours of OT than individuals that did not complete high school  $p = .005$ . On average, individuals whose father had an associate degree received a mean of 3.49 hours of OT per week, whereas those with some high school only received a mean of .268 hours per week. Similarly, children with mothers who completed only some high school received significantly less OT hours than mothers with additional education (GED, some college, associates, or bachelor's; highest  $p = .002$ ). Amount of OT was not significantly related to any of the other examined independent variables. We did not find significant sociodemographic differences in any of the other types of therapy examined for either age group.

**Conclusions:** In alignment with disparity reduction models that call for a better understanding of the inequities (Kilbourne, 2006), this research helps to demonstrate the extent of the problem by quantifying in what types of treatment disparity is greatest and by how much, through an examination of group differences in total numbers of weekly treatment. We found that parent education specifically impacted number of weekly hours of OT.

**442.019 (Poster)** From Science to Service: Seeking Evidence for the Translation of Basic Research into Community-Based Practice

*P. Doehring, ASD Roadmap, Chadds Ford, PA*

---

**Background:** It is generally understood that basic research on the characteristics, trajectory, correlates, and possible causes of ASD will eventually translate into applied research to develop assessment and intervention tools, and then to demonstrate that these can be used to measurably improve outcomes in the community. We have designed a research roadmap that categorizes individual studies to track this progress. We have previously used such a roadmap to describe the distribution of research funding over a 8 year period in the United States intended to improve ASD diagnosis. Despite a shift over time in the proportion of applied research focused on community-based outcomes, almost 2/3s of funding was still directed towards basic research. It is possible that this evolution from basic to applied research takes place, however, over a longer period of time.

**Objectives:** We sought to apply a research roadmap to articles published over a 40 year period in the Journal of Autism and Developmental Disorders (JADD) to answer the following questions. Has applied research increased relative to basic research over this period, reflecting the translation of basic research into specific assessment or intervention practices? If not, could factors like shifts in the design of assessment or intervention research studies explain this? Has applied research sought to improve outcomes in the community, or to better understand factors influencing these outcomes?

**Methods:** We searched PSYCINFO for all articles published in JADD in 1979, 1989, 1999, 2009, and 2019, with "aut\*" in the title or abstract. We scanned abstracts to select original empirical research and exclude case studies. We distinguished between Basic and Applied Research, and between three stages of the latter (Assessment, Intervention, and Other Applied Research). Applied research seeks to directly achieve a specific clinical, behavioral, or educational outcome through services provided to a clinical population. For assessment and intervention research, we noted the study design sample size, and the reliance upon community-based programs or professionals. Other applied research documented community outcomes or examined factors influencing these outcomes.

**Results:** Of the 413 basic and 204 applied research studies identified, more than 90% were published since 2009 and 60% in 2019 alone (see Figure 1). Basic research remained steady throughout this period, peaking at about 80% in 1999 before dropping down to 67% in the decades since. Intervention research studies comprised about one quarter of research studies early on, dropping by one half later. Preliminary analyses suggest that this shift coincides with a relative increase in studies involving larger samples

and more complex designs. Few assessment and intervention research studies focused, however, on community-based service delivery.

Conclusions: Despite an explosion of research over the past two decades, there has been no appreciable shift over the past four decades in the proportion of research seeking to directly improve assessment and intervention. Combined with the relative lack of research on intervention, especially involving community-based programs, this suggests that specific efforts will be required to assure that basic research is translated into practice.

**442.020** (Poster) Health Related Quality of Life of Children with ASD Experiencing Inpatient Psychiatric Hospitalization  
*M. McCabe<sup>1</sup>, K. Bockek<sup>1</sup> and A. D. Desai<sup>2</sup>, (1)Seattle Children's Research Institute, Seattle, WA, (2)Department of Pediatrics, University of Washington, Seattle Children's Research Institute, Seattle, WA*

---

Background: Autism spectrum disorder (ASD) is a neurodevelopmental disorder characterized by social, behavioral, and communicative impairments. Approximately 72% of youth with ASD experience psychiatric comorbidities (Leyfer et al. 2006) putting this population at high risk for psychiatric hospitalization (Bhaumik et al. 2008). However, the effect of inpatient care for improving health-related quality of life (HRQL) outcomes is unknown in this population.

Objectives: The objective of this study was to describe HRQL outcomes before, on admission, and after hospitalization in patients with ASD admitted to a children's hospital psychiatric and behavioral medicine unit (PBMU) and compare these outcomes to hospitalized patients without ASD.

Methods: Parent-reported HRQL data were collected between 11/2017 and 03/2020 from a convenience sample of patients ages 5 – 25 to the PBMU at Seattle Children's Hospital. We administered either the Pediatric Quality of Life Inventory (PedsQL™) or the Functional Status II Revised (FS2R) Scale (for parents who reported their child had a severe disability) to obtain three HRQL assessments: before admission (baseline), during admission, and 6-12 weeks after hospital discharge. Patients were categorized as having ASD if they had an ICD-10 code for an autism spectrum disorder on admission or discharge, otherwise they were categorized as patients without ASD. We used t-tests to examine differences in HRQL between groups at each time point.

Results: We obtained HRQL data from 301 parents (52 patients with ASD and 249 patients without ASD) for all three assessments. Mean baseline scores (59.6 versus 65.6; difference -5.9 (95% CI -11.57, -.31,  $p < 0.05$ ) and admission scores (69.0 versus 78.1; difference -9.1 (95% CI -15.35, -2.92,  $p < 0.05$ ) for the PedsQL™ for patients with ASD were significantly lower than patients without ASD. Both groups showed increased HRQL after discharge with no significant differences between groups at these assessments.

Conclusions: Our findings suggest that HRQL outcomes in patients with ASD are lower than patients without ASD prior to admission and during inpatient admission. By examining health related quality of life (HRQL) before, during and after an inpatient stay, hospitals can establish a set of clinical outcomes for the ASD population. Future research should establish a more granular understanding of these disparities and work to target quality improvement strategies related to the care continuum for ASD patients requiring hospitalization.

**442.021** (Poster) How Can We Deliver Timely and High Quality Diagnostic Assessment for Children with Possible Autism in the UK: A Rapid Realist Review of Autism Service Delivery Literature.  
*V. J. Abrahamson<sup>1</sup>, W. J. Zhang<sup>1</sup>, W. Farr<sup>2</sup>, I. Male<sup>3</sup>, J. R. Parr<sup>4</sup>, L. Kenny<sup>5</sup>, V. Grahame<sup>6</sup>, A. Allard<sup>7</sup>, H. Gage<sup>8</sup>, V. Reddy<sup>9</sup>, G. Saunders<sup>10</sup>, P. Shaw<sup>7</sup>, P. Williams<sup>8</sup> and P. M. Wilson<sup>11</sup>, (1)University of Kent, Canterbury, United Kingdom, (2)Sussex Community NHS Trust, Haywards Heath, United Kingdom, (3)Mid Sussex Child Development Team, Sussex Community NHS Trust, Haywards Heath, United Kingdom, (4)Population Health Sciences Institute, Newcastle University, Newcastle upon Tyne, United Kingdom, (5)Centre for Research in Autism and Education (CRAE), London, United Kingdom of Great Britain and Northern Ireland, (6)Cumbria, Northumberland, Tyne and Wear NHS Foundation Trust, Newcastle upon Tyne, United Kingdom, (7)Council for Disabled Children, London, United Kingdom, (8)University of Surrey, Guilford, United Kingdom, (9)Cambridge and Peterborough NHS Foundation Trust, Peterborough, United Kingdom, (10)W Sussex Parent Carer Forum, Worthing, United Kingdom, (11)Centre for Health Service Studies, University of Kent, Canterbury, United Kingdom*

---

Background:

Referrals and waiting times for diagnostic assessment of possible autism in children have increased substantially within UK National Health Service (NHS) recently, delaying opportunities for intervention and frustrating families. Research exploring which service models could improve quality and timeliness of autism assessment is a key NHS priority.

## Objectives:

- Explore evidence from research and grey literature about which autism assessment pathways work well, for whom and under what circumstances, to deliver high quality and timely diagnosis.
- Inform subsequent stages of our Realist Evaluation/study.

## Methods:

We performed a Rapid Realist Review (RRR), a well-established approach to synthesising evidence to identify service delivery models achieving desired outcomes. RRRs seek to develop programme theories (PTs), or explanations, of how, why and in what contexts an intervention works. The focus was a clearly defined intervention (diagnostic pathway), specific outcomes (high quality and timely) within particular parameters (Autism diagnostic services in UK). This was carried out in five iterative stages (see figure). We collected 129 grey literature and policy/guidelines from the background search, and 220 articles from primary search (Jan 2011-Dec 2019; seven databases, terms: autism, diagnostic pathway, model of service provision, assessment process). Following duplicate removal and screening of abstracts, two researchers carried out data extraction by hybrid approach: basic details from each included article (n=79) were recorded in an Excel data extraction form; highly relevant articles (n=45) were coded in NVivo. PTs were developed by cross comparison and synthesis of evidence from the articles and findings were discussed with expert stakeholders.

## Results:

1. If frontline health/education professionals are confident in recognizing symptoms of autism, understand referral pathways and take parents' concerns seriously, then children and young people (CYP) will be referred appropriately, in a timely manner.
2. If services provide clear guidelines for referrers on what information is needed, time will be saved and fewer CYP will be assessed unnecessarily.
3. If a structured and consistent approach to service delivery is adopted, making best use of available staff and expertise then the number of assessments per individual may be reduced.
4. If feedback takes an assets-based approach and management plans are individualized, then parental expectations will be moderated.
5. If parents have a single point of contact, are provided explanations throughout and included in decision-making then diagnostic pathway may be less stressful.
6. If "experts" including CYP and parents work together and knowledge generated is embedded into local services, this will build capacity and support service planning.
7. If professionals have access to tailored training appropriate to their role, and services engage in development and evaluation, then there will be a higher degree of consistency.

## Conclusions:

This first theory informed review of childhood autism diagnostic pathways has identified important aspects that may contribute to more efficient, high quality and family friendly service delivery. We will test whether the resulting PTs are met, and how service design could be further enhanced through a national survey of current practice and in depth case study of exemplar services.

**442.022** (Poster) Impact of ASC/LD (Autistic Spectrum Disorder/Learning Disability) Specific Training for North West Prison and Probation Staff.

**H. Judge**<sup>e</sup> and C. Hughes<sup>s</sup>, (1)National Autistic Society, London, United Kingdom, (2)National Autistic Society, Northenden, United Kingdom of Great Britain and Northern Ireland

---

## Background:

In 2017 the National Prison and Probation Service began working with a national autism non-profit organisation on a project funded by the Ministry of Justice, aimed at improving services for offenders with learning disabilities and autism (HMI Probation & HMI Prisons, 2015). Building on previous work in 2017-2018 improving support for autistic offenders in a probation cluster, one key component was to roll out LD/ASC specific training to improve understanding of autism amongst 200 staff across five prisons and five probation clusters. Topics covered included introduction to LD/ASC in the criminal justice system, sensory issues, stress and anxiety, navigating the social care system and applying frameworks such as the care act.

A mixed method longitudinal evaluation of the training was undertaken over the course of a year.

Objectives:

The objectives were (1) To measure improvement in knowledge, understanding and confidence of staff (including sex offender treatment programme facilitators) before, concurrently and six months after delivery of training (2) To consult prisoners on their experience with transitions within the service along with their suggestions to improve future support.

Methods: A Theory of Change (ToC) was developed to identify the expected short and long term outcomes of the project; key elements of the ToC were used to inform the structure of questionnaire tools and topic guides; telephone interviews were undertaken with trainees before (n=56) and six months after training (n=31); questionnaires were completed during the training (n=208); participant information sheets and consent forms were provided for prisoners; prisoners (n=10) were consulted face to face; quantitative data collected via 10-point and 5-point scales in questionnaires and interviews was summarised; thematic analysis of qualitative data obtained was undertaken.

Results: Analysis revealed high satisfaction of delivery, format and relevancy amongst a cross section of trainees. Main themes identified included: deeper insight and confidence in distinguishing autism from co-occurring conditions, opportunity to consolidate current knowledge, feel more confident applying legislative frameworks, improved relationships with service users and confidence in educating/advising other staff. During COVID-19 lockdown periods some probation staff were able to make creative adjustments when delivering sex offender treatment programmes whereas others lacked opportunities to put knowledge into practice. Whilst there is some evidence of improvement in how knowledge is embedded across staff networks in prisons, there still needs to be more solid models of 'autism resource infrastructure' which can be upscaled nationally. A recurring theme was that it may be beneficial to schedule reflective practice sessions after training to reinforce confidence when applying new knowledge to cases.

Transitions within, between and out of prison can pose specific challenges for autistic prisoners. Recommendations included development of peer support, awareness of misinterpretation of behaviour from staffs' perspective and offering alternative mediums of communication.

Conclusions:

Compliance of staff and prisoners participating in telephone interviews, questionnaires and face to face consultations has enabled a rigorous mixed methods process, for in depth analysis and reporting to key stakeholders. Such evidence will be used to inform future proposals to maintain quality, funding and increase reach.

**442.023 (Poster)** Improving Health Care Access and Hospitalization Rates in Patients with Autism Spectrum Disorder and/or Intellectual Disability through Utilizing a Nurse Care Management Model

*A. Hogan<sup>1</sup>, M. Lamy<sup>2</sup>, L. Terhune<sup>2</sup>, C. Frye<sup>2</sup> and M. Zeinler<sup>2</sup>, (1)University of Cincinnati College of Medicine, Cincinnati, OH, (2)Division of Child and Adolescent Psychiatry, Cincinnati Children's Hospital Medical Center, Cincinnati, OH*

---

Background: Pediatric patients with autism spectrum disorders (ASD) and/or intellectual disability (ID) present with high complexity due to wide variation in symptom severity paired with additional medical and social complications. However, studies demonstrate this population possesses significant unmet medical needs and would benefit from improved care coordination. Nurse care management (NCM) models, employed with success in other populations, represent an opportunity for enhancing care access and reducing hospital utilization for patients with ASD and/or ID.

Objectives: 1) To better understand the chronic health conditions and social needs of the patients with ASD and/or ID who are enrolled in the nurse care manager program. 2) To assess patterns of patient access to both specialty and outpatient service providers through review of visits and referrals. 3) To assess the rates of emergency room visits, inpatient psychiatric and medical admissions, as well as hospital length of stay following program enrollment.

Methods: All patients with ASD and/or ID enrolled in the NCM program for at least one year were included in the retrospective chart review. Data regarding specialty care access, outpatient services access, and hospital utilization was extracted from the twelve months before and after enrollment in the program for comparison. The variables included number of diagnoses, specialty providers and visits, outpatient services, completed referrals, inpatient hospital admissions and emergency room visits. A signed rank test was completed for hospitalization variables to determine significance.

Results: A total of 79 patients met criteria for inclusion, including 55 males and 24 females. The average age at time of enrollment was 12.1, and a majority of patients were White/Caucasian (n=56) and from Ohio (n=61). Fourteen patients were diagnosed with ASD, 16 with ID, and 49 with both. All patients had at least one comorbid psychiatric diagnosis, and 74 patients had at least one comorbid medical diagnosis. Patients visited the emergency room for psychiatry-related concerns significantly less in the twelve months following program enrollment, with an average of 1.57±1.68 visits before and 1.08±1.48 after (p=0.011). The average number of inpatient psychiatric admissions decreased following enrollment, but this finding was not significant (p=0.085). Most patients accessed the same number of or more specialty providers (78.4%) and outpatient services (74.6%). Additionally, 76% had one or fewer incomplete referrals within the study period, indicating fulfillment of recommended care.

Conclusions: The NCM model provides a framework for improving specialty and outpatient service access and reducing psychiatry-related emergency room visits. Patients specifically demonstrated increase in access to therapy providers including psychologists, social workers and licensed counselors. They also demonstrated increased access of specific specialties, such as ophthalmology, audiology, endocrinology, and orthopedics, which meet unique health needs. The patients also showed increased access specifically for home-based healthcare and therapy services, enabling treatment outside of a hospital setting. This intervention may reflect enhanced ability of families to practice self-management of behavior with regular support from nurses and warrants further longitudinal study.

**442.024 (Poster)** Increasing Access to Diagnostic Evaluations and Ongoing Care for Autism across Washington State  
**A. Bravo<sup>1</sup>, J. Gerdtz<sup>1</sup>, J. Mannheim<sup>2</sup>, C. Mutti-Driscoll<sup>1</sup>, J. Mancini<sup>2</sup> and G. Stobbe<sup>2</sup>, (1)University of Washington, Seattle, WA, (2)Seattle Children's Autism Center, Seattle, WA**

---

Background: Project ECHO (Extension for Community Healthcare Outcomes) connects primary care providers (PCPs) with subject matter experts using a telementoring model. ECHO sessions consist of redacted PCP case presentations and expert-delivered didactic presentations to increase PCP capacity to provide specialized care. *ECHO Autism* has increased PCP self-efficacy in identifying and caring for individuals with autism spectrum disorder (ASD), adherence to ASD screening guidelines, and use of ASD-specific resources (Giachetto et al., 2019; Mazurek et al., 2017; 2019). Pilot data suggest that the model may be a feasible option for enhancing local access to ASD-specific care (Mazurek et al., 2019), thereby decreasing patient travel and wait times.

Objectives: *ECHO Autism Washington* launched its first cohort of 28 PCPs across Washington State in December 2019 to support participants in the diagnosis and management of ASD. The majority of participants are designated Autism Centers of Excellence (COEs) by the Washington State Health Care Authority. Although ASD diagnoses and treatment plans from COE providers are accepted by Medicaid insurance plans, COEs report care delivery barriers including a lack of knowledge about ASD resources, symptoms, and treatment.

Methods: Participants (n=28) received a questionnaire pre-ECHO participation (Time 1), halfway through *ECHO Autism Washington* (Time 2), and will receive it once more upon program completion (Time 3). 61% completed the questionnaire at Times 1 and 2 (n=17; 82% female). Three participants discontinued prior to Time 2 due to unforeseen circumstances. Respondents reported practice barriers to diagnosing and caring for individuals with ASD and completed a modified version of the Primary Care Autism Self-Efficacy survey (Mazurek et al., 2017). ASD screening items were replaced with ASD diagnosis items since the focus of *ECHO Autism Washington* is on diagnosis. This resulted in 56 items, not 57 items as originally published. Items are rated on a Likert scale ranging from 1 (no confidence) to 6 (highly confident/expert). Items yield a Total Score and six subscale scores: diagnosis across age groups, diagnostic criteria, referrals and resources, medical comorbidities, psychiatric symptoms, and additional aspects of care.

Results: A paired samples t-test compared PCP self-efficacy levels at Times 1 and 2. There was a significant increase in overall PCP self-efficacy levels from Time 1 (M = 196.94, SD = 37.37) to Time 2 (M = 228.41, SD = 35.88);  $t(16) = -4.30, p < .001$ . See Figure 1 for changes in subscale scores. Respondents reporting a lack of knowledge about ASD resources, a lack of prior training in ASD, and a lack of knowledge about ASD symptoms decreased from 47.1% to 17.6%, 41.2% to 11.8%, and 35.3% to 0%, respectively.

Conclusions: Participants reported a significant increase in self-efficacy levels related to ASD diagnosis and care and reduced barriers to completing diagnostic evaluations after 6-months participation. This suggests that telementoring models such as Project ECHO may be one way to build provider capacity and expand ASD expertise. Further results will be reported after data is collected at completion of the program in December 2020.

**442.025 (Poster)** Innovations in Caregiver Skills Training: Amplifying the Reach through Echo Autism and Virtual Delivery in Rural America.

*M. Tregnago<sup>1</sup>, P. Dixon<sup>2</sup>, A. Curran<sup>3</sup>, M. Mahurin<sup>3</sup>, T. W. CST Team<sup>4</sup>, C. Nava<sup>5</sup>, J. Marshall<sup>6</sup> and K. Sohl<sup>1</sup>, (1)Easterseals Midwest, Columbia, MO, (2)Wayne State University, Ann Arbor, MI, (3)Department of Child Health, University of Missouri, School of Medicine, Columbia, MO, (4)Department of Mental Health and Substance Abuse, World Health Organization, Geneva, Switzerland, (5)Psychological Science, University of Texas Rio Grande Valley, Edinburg, TX, (6)Easterseals Midwest, St. Louis, MO*

---

**Background:** A 9-week Caregiver Skills Training (CST) initially developed by the World Health Organization and Autism Speaks was adopted by Easterseals Midwest in partnership with ECHO Autism to be applicable to parents of children with autism living in rural Missouri. This CST program (ECHO Autism: CST) was then implemented via the traditional in-person method and virtually via videoconferencing. - This is the first study utilizing the CST model in a rural setting in the United States and the first to use the ECHO Autism model to train and provide a learning community for new master trainers and facilitators to engage in collaborative, interactive, iterative program implementation.

**Objectives:** The objectives of the pilot project were 1) to assess the feasibility of implementing the CST program in rural Missouri, 2) the feasibility and acceptance of implementing CST via telehealth methods, and 3) the impact of utilizing an ECHO Autism approach for training and supporting facilitators implementing the CST program.

**Methods:** Four families from Central Missouri completed the in-person pilot of the ECHO Autism: CST program. An additional 15 rural Missouri families completed the telehealth version of the ECHO Autism: CST program. Families completed pre- and post-surveys regarding their knowledge and perceptions of their child's behavior, as well as satisfaction surveys at the end of each session. An expert team of professionals or "Hub Team" who trained to be "Master Trainers" within CST supported the new parent trainers (facilitators) during weekly ECHO Autism sessions. Four new CST facilitators participated in weekly ECHO Autism sessions which reviewed content of the upcoming CST workshop and reviewed case studies to discuss recommendations regarding structure of the workshops and child strategies. These participants completed weekly surveys regarding the helpfulness of the ECHO Autism model in support the implementation of CST material and program goals.

**Results:**

Overall the program implementation was found to be feasible in rural Missouri. Families in both groups found the key information applicable to their children with average ratings of 4.7 out of 5 for telehealth surveys (n=99) and 4.94 for in person surveys (n=36).

The majority of facilitators who attended the weekly ECHO Autism sessions indicated that they felt "very confident" in their ability to demonstrate, explain, and coach parents in CST-specific strategies. CST facilitators engaged in ECHO Autism: CST reported that practicing presenting the concepts and reviewing session case studies were the most helpful and supported their implementation of CST via telehealth and in person.

**Conclusions:**

ECHO Autism enhanced Caregiver Skills Training model is a feasible and acceptable model for educating caregivers living with a young child with Autism Spectrum Disorder in rural Missouri. The model was found feasible in both an in-person and a telehealth format. ECHO Autism: CST is a promising innovation to accelerate the scale of Caregiver Skills in rural and underserved locations globally while maximizing fidelity to the content to ensure quality program implementation.

**442.026 (Poster)** Integrating Input from Service Providers and Service Recipients Relative to Autism Spectrum Disorder and Mental Health Issues: Toward Knowledge for Action.

*D. B. Nicholas<sup>1</sup>, W. Mitchell<sup>2</sup> and R. Zulla<sup>3</sup>, (1)University of Calgary, Edmonton, AB, Canada, (2)University of Calgary, Calgary, AB, Canada, (3)School of Public Health, University of Alberta, Edmonton, AB, Canada*

---

**Background:**

The prevalence of autism spectrum disorder (ASD) in Canada according to the 2018 National Autism Spectrum Disorder Surveillance System (NASS) Report is 1 in 66. Parents raising children with ASD require an array of services across sectors such as health, social services and education. Unfortunately, the system of care is often fragmented, suboptimal, and difficult to navigate. Particularly concerning are the 30-70% of individuals who present with ASD and a co-existing mental health problem

(dual diagnosis) (Moseley et al., 2011). These individuals and their families face additional challenges accessing appropriate and unified care, often encountering multiple barriers within and between systems of care.

#### Objectives:

As part of a larger study, the objective is to identify navigation processes that are working well, and barriers or challenges, as perceived by stakeholders.

#### Methods:

A Community Based Participatory Research orientation guided the interviews and focus groups that were conducted with 57 service providers and service recipients in relation to navigational services for children with a dual diagnosis in urban, rural and remote communities in Alberta. Interviews were based on a semi-structured interview guide. NVivo data management and analysis software was used. Analysis was comprised of 1) line-by-line coding, 2) review of codes for textual linkages both within and across transcripts and 3) examination of the emerging categorization of codes in yielding themes. Interrater review of data by leaders in the ASD and MH field verified themes.

#### Results:

Based on families experiences a multi-level model emerged consisting of four care levels (universal support, specialized services, complex care and crisis care). Crisis was often identified as a service catalyst for families. At every level, service providers and families indicated that there was a need to make information more assessable to families, that more coordinated services were needed, especially in rural areas, and that parents play a key role, although parental care, preparation for the long haul, and training are sorely lacking. Peer support for families was highly valued and recommended as it addresses parent isolation, is non-judgemental, and offers hope to families.

#### Conclusions:

Navigational support programming requires coordinated service network across sectors (health, social services, and education), particularly in rural and remote communities. There is also a need to involve people impacted by and /or with lived experience in service planning and policy development.

**442.027 (Poster)** Investigating Access to State-Funded, Part C Early Intervention Services in Children Evaluated for Autism Spectrum Disorder

*A. I. Mendez<sup>1</sup>, C. Klaiman<sup>2</sup>, A. Klin<sup>2</sup> and K. Pickard<sup>3</sup>, (1)Marcus Autism Center, Children's Healthcare of Atlanta and Emory University Department of Psychology, Atlanta, GA, (2)Marcus Autism Center, Children's Healthcare of Atlanta and Emory University School of Medicine, Atlanta, GA, (3)Emory University School of Medicine, Atlanta, GA*

---

#### **Background:**

Optimal developmental outcomes for individuals with autism spectrum disorder (ASD) rely on early detection and intervention. As ASD prevalence continues to increase, there is a growing need to make early intervention more accessible. The Part C, Early Intervention (EI) system may be one viable way to increase access to these services, as they can be received prior to a diagnosis: an important provision given that the average age-of-diagnosis is 51 months. Importantly, as many as 10% of children who receive EI services eventually obtain an ASD diagnosis, making it a first-line intervention. Unfortunately, service disparities are well-documented within the ASD field. To mitigate these disparities, we must first understand the extent to which these disparities exist within the EI system. Here, we evaluate how access to state-funded EI services is distributed among a population of children referred to an ASD-specific clinic. In doing so, we hope to identify children at higher-risk of being “missed” and where further resources should be allocated.

#### **Objectives:**

To examine whether access to state-funded, EI services differs on the basis of child race, ethnicity, primary home-language, insurance status, and age-of-first parental concern.

#### **Methods:**

Demographic information and parent-reported developmental data from N=3624 children seen at an ASD-specific clinic from March 2019 through October 2020 were extracted from intake forms. The sample was 38% White (n=1379), 36% African American (n=1309), and 13% identified as Hispanic or Latino (n=484). As part of intake, families indicated whether they accessed state-funded EI services at any point. Variables of interest included: race, ethnicity, home-language, insurance type, and age-of-first parental concern. Between-group differences were tested by t-tests and chi-squared analyses.

### Results:

Overall, results showed only 34% of all children accessed state-funded EI services. Chi-squared analyses revealed no significant differences in EI service access by race or ethnicity group (both  $p > 0.05$ ). Additional chi-squared analyses revealed a significant difference in insurance type among the groups,  $\chi^2(1, N=3293) = 22.84, p < 0.001$ . After re-coding home-language as English, Non-English, and Some-English, chi-squared analyses revealed no significant differences in home-language composition in the groups ( $p > 0.5$ ). Finally, a t-test revealed a significant difference in age-at-first parental concern among the groups ( $t=13.92, p < 0.001$ ).

### Conclusions:

Despite this sample being composed of individuals who eventually accessed an ASD-specific evaluation, the majority of families in the sample reported not receiving EI services. Here, race, ethnicity, and home-language did not predict access to these services. Results suggest that individuals with public health insurance are more likely to access EI services. Additionally, a lower age-of-first concern was observed in individuals who did access EI services, indicating that parental concern may be an important precursor to the receipt of these services. These findings begin to elucidate the extent to which children receive services within an important system of care and the extent to which disparities exist in accessing these services. Future work will use diagnostic data to evaluate whether a subsequent diagnosis predicts access to these services.

**442.028 (Poster)** Looking at the Big Picture: Stakeholder Perspectives on the Implementation Outcomes of a CBT Program for Students with ASD and Anxiety within Diverse Public Schools

**K. Pickard<sup>1,2</sup>, A. T. Meyer<sup>3</sup>, N. Reyes<sup>1</sup>, T. Tanda<sup>4</sup> and J. Reaven<sup>1</sup>,** (1)JFK Partners, University of Colorado Anschutz Medical Campus, Aurora, CO, (2)Emory University School of Medicine; Marcus Autism Center, Atlanta, GA, (3)JFK Partners, University of Colorado School of Medicine, Aurora, CO, (4)Developmental Pediatrics, Children's Hospital Colorado, Aurora, CO

Background: Cognitive behavioral therapy (CBT) for youth with ASD and anxiety is effective, but disparities exist in accessing these programs within clinic-based settings. Training interdisciplinary school providers to deliver CBT may help to address these disparities and may also build school capacity to implement and sustain these programs. To date, little is known about how CBT programs are implemented by interdisciplinary school providers within public schools, and the broader impact of these programs for diverse students. Established frameworks such as Reach, Effectiveness, Adoption, Implementation, and Maintenance (REAIM) can be used to examine broader outcomes (Glasgow et al., 2019). This study was part of an implementation trial that examined the effectiveness of a group CBT program for youth with ASD and anxiety [Facing Your Fears: School-Based; (FYF-SB)] implemented across 25 public schools (27 school teams) across three school districts.

Objectives: (1) To understand the broader impact of translating FYF-SB into public school settings by examining provider perspectives on the reach, effectiveness, adoption, implementation and intended maintenance of FYF-SB; and (2) To examine factors that providers perceive as impacting the implementation of FYF-SB in public school settings.

Methods: Sixty-five providers across 26 of 27 school teams participated in a semi-structured exit interview. School teams consisted of 2-4 interdisciplinary school providers who implemented FYF-SB together as a group. Interview questions were guided by the REAIM framework. All interviews solicited general perceptions of implementing FYF-SB in addition to: 1) the students *outside* of the research study who received FYF-SB (i.e., reach); 2) the *perceived* effectiveness of FYF-SB; 3) the process by which school teams implemented FYF-SB; 4) factors that impacted FYF-SB implementation; and 5) to what extent school teams planned to maintain their use of FYF-SB. Standard content analysis was used to analyze qualitative data (Hsieh & Shannon, 2005).

Results: Primary themes emerged across REAIM constructs in a way that suggested that FYF-SB had a pervasive positive impact. These themes included: 1) the delivery and fit of FYF-SB for students outside the scope of the research project and without ASD; 2) the perceived effects of FYF-SB on students' use of coping skills, bravery, and school participation and engagement, as well as providers' understanding and identification of anxiety symptoms; and 3) planned maintenance and expansion of FYF-SB in future years. Regarding the implementation of FYF-SB, participants consistently highlighted the program's accessibility for school providers without a mental health background. This was viewed as important given the

shortage of mental health staff within public schools. Finally, several school teams made adaptations to FYF-SB in response to perceived student needs and school context.

Conclusions: Results from this study suggest that FYF-SB may have a broader impact on school providers. It also highlights the importance of task sharing across interdisciplinary providers to overcome the challenges of staff shortages within public schools. Programs that can be implemented flexibly and adapted are also critical given the variability in school structures and student needs. Limitations and future directions will be discussed.

**442.029 (Poster)** Measuring the Association between Behavioural Interventions and Outcomes in Young Children with Autism Spectrum Disorder

---

Background: Behavioural interventions, defined as one-to-one structured programs, such as applied behaviour analysis, Discrete Trial Training or Pivotal Response Treatment, are widely used for autism spectrum disorder (ASD) in preschool-aged children. The design and the effectiveness of such early intervention programs depend on whether they are provided in a community or in a specialized clinical or research setting. Evaluating community-based interventions is challenging since both the treatment model and service delivery model may vary between jurisdictions and treatment fidelity may be uncertain.

Objectives: The objective was to examine the association between parent-reported, multi-jurisdictional, community-based behavioural interventions received by preschoolers and various outcomes during primary school years (ages 7 to 11) and determine which factors related to the child and family affect this association.

Methods: A cohort of 414 preschool-aged children diagnosed with ASD were enrolled at five Canadian sites (Nova Scotia, Quebec, Ontario, Alberta and British Columbia) and followed to 11 years of age. Children were assessed within four months of diagnosis (T1, mean age at enrollment = 39.9 months (SD = 9.04)), six months later (T2), 12 months later (T3), at school entry (T4), and then annually (T5-T8). An association between the receipt of behavioural interventions during preschool years (T1-T3) and outcomes at T6 or T8 related to intellectual ability, language, adaptive behaviour and autism severity was modelled using separate linear regressions adjusted for immigrant status, family income, child age at ASD diagnosis, site, sex, and baseline (T1) value of outcome measure. Missing data were addressed using multiple imputation methods.

Results: In total, 186 (68.4%) participants received behavioural interventions at least once during the preschool years and 58 (21.3%) received these interventions during T1, T2 and T3. Almost all of the children who got behavioural interventions also received developmental interventions or services which were not specialized for children with disabilities. The receipt of behavioural interventions differed significantly among the five sites. Higher household income was positively associated with the receipt of these interventions. Children who received behavioural interventions at least once at some point during preschool years did not have significantly different outcomes at T6 or T8 than children who did not receive any such interventions.

Conclusions: The variation in the structure of behavioural interventions for ASD and the heterogeneity in ASD symptoms and functional abilities hinder the ability to measure ASD program effectiveness. Given the importance of and challenges in estimating long-term effects of ASD interventions in different jurisdictions, it is recommended that prospective studies collect data on design, fidelity, eligibility, type, intensity and duration of the interventions, as well as demographic and clinical data, so that similar interventions could be compared between groups that are matched on or adjusted for demographic and baseline differences. Increasing sample size and taking steps to reduce attrition would facilitate examining the interactions between intervention types and effect modifiers and facilitate analysis to identify groups of children displaying similar patterns of response to interventions. Such studies would enhance the quality of evidence used to inform public ASD policy and service provision.

**442.030 (Poster)** Obtaining a First Diagnosis of Autism Spectrum Disorder: Process Characteristics and Parent Perceptions from a National Sample

**K. T. MacKenzie** and **S. M. Eack**, *University of Pittsburgh School of Social Work, Pittsburgh, PA*

---

**Background:** Parents of individuals with autism spectrum disorder (ASD) experience poor outcomes, such as stress and depression, at a higher rate than parents of typically developing children. One particularly salient challenge for parents is obtaining a formal ASD diagnosis for their children. However, while the diagnostic process is commonly cited as challenging and unsatisfying for parents, it also remains largely understudied in the United States.

**Objectives:** The purpose of this study was to better understand the process of obtaining a formal ASD diagnosis for American families.

**Methods:** A total of 406 parents of children with ASD were recruited across the United States using the SPARK (Simons Foundation Powering Autism Research for Knowledge) research registry. All parents had children aged 2 to 9 years who had been formally diagnosed with ASD in the last 3 years. Participants were administered a survey covering demographic information and detailed characteristics of the ASD diagnostic process.

**Results:** Sample participants were mostly mothers (93%) with a mean age of 36.41 years ( $SD = 5.88$ ). Their children were mostly boys (80%) with a mean age of 6.03 years ( $SD = 1.40$ ). Common early concerns were related to delays in social skills and communication. Average age of these concerns was prior to age 2 ( $M = 1.64$ ,  $SD = .88$ ). Parents most commonly sought initial help from pediatricians ( $N = 274$ , 67%), but sometimes consulted other professionals first. Average wait time for subsequent referral appointments was about 5 months and parents attended an average of 3-4 different appointments prior to obtaining a formal diagnosis. Formal diagnosis was made by a wide range of professionals, most commonly developmental psychologists ( $N = 110$ , 27%). Mean age at diagnosis was 3.26 years ( $SD = 1.29$ ). Average diagnostic delay (i.e. between first visit and final diagnosis) was 1.20 years ( $SD = 1.13$ ). Over 70% of parents reported being somewhat satisfied or very satisfied with the process, yet over 70% also indicated the process was somewhat stressful or very stressful.

**Conclusions:** Mean age of formal diagnosis was lower than in previous studies, perhaps reflecting a greater awareness of ASD and/or better referral systems in American pediatric care. However, parents continue to experience long diagnostic delays, attending many referral appointments and experiencing long wait times for these appointments. While parental satisfaction with the diagnostic process was notably higher than in previous studies, most parents still found the diagnostic experience stressful. These findings provide greater insight into the challenges experienced throughout the ASD diagnostic process. Researchers can use these findings to pinpoint specific areas where the process can be improved to ease the burden on families.

#### **442.031 (Poster) Occupational Therapy Service Utilization in Children with ASD**

**E. Campi<sup>1</sup>, J. Sideris<sup>1</sup>, A. Phillips<sup>1</sup>, A. M. Wiles<sup>2</sup>, V. H. Vera Carrasquero<sup>1</sup>, K. K. Ausderau<sup>3</sup> and G. T. Baranek<sup>1</sup>,** (1)Chan Division of Occupational Science and Occupational Therapy, University of Southern California, Los Angeles, CA, (2)Wesley College, Dover, DE, (3)University of Wisconsin - Madison, Madison, WI

---

**Background:** Demographic and personal characteristics, such as family income, parental education, and child's age (Cidav et al., 2013; McIntyre & Zemantic, 2016; Mire et al., 2015; Nguyen et al., 2016), impact the type and amount of therapy services received by children with autism spectrum disorder (ASD). The impact of ASD severity and other clinical features on service utilization, however, has mixed evidence (Bilaver et al., 2015; Zuckerman et al., 2017). Occupational therapists (OTs) commonly work with children with ASD to address challenges related to sensory processing and adaptive functioning (Case-Smith & Arbesman, 2008). However, there is limited evidence regarding factors that predict OT-specific service utilization, which may be useful to clinicians for making more informed decisions for assessment and intervention planning.

**Objectives:** This paper aims to explore clinical, demographic, and service history factors that are associated with OT service utilization for children with ASD. It is expected that severity of sensory processing and adaptive behavior challenges will be most strongly associated with OT service utilization, followed by history of receiving OT. Lower income and education are also expected to be associated with lower likelihood of receiving OT services due to access issues.

**Methods:** Participants included 703 2-12-year-old children with ASD. Data was collected as part of a longitudinal national survey across two time points, approximately 1 year apart. Measures of clinical characteristics included the Vineland Adaptive Behavior Scales (VABS, Sparrow et al., 2005), the Sensory Experiences Questionnaire v3.0 (SEQ, Baranek, 2009), and the Social Responsiveness Scale (SRS, Constantino & Gruber, 2005). Demographic and service use data was collected via a background information questionnaire. Hours of OT per week were tallied over one year. See Table 1 for sample demographics. Hierarchical Poisson linear regression was conducted to examine predictors of hours per week of OT services.

**Results:** Sensory interests, repetitions, and seeking (SIRS), VABS adaptive behavior composite, and age were the strongest predictors (Table 2). Non-significant demographic variables were not included in the hierarchy in order to avoid any attenuating effects on clinical factors of interest.

Conclusions: In contrast with previous studies, demographic factors were not significant predictors of hours of OT. This could be due to this predominantly school-aged sample, such that children might have access to services in school regardless of demographic differences. SIRS may be a strong predictor of amount of OT due to the potentially disruptive nature of such behavior that could prompt a referral to OT services. Adaptive behavior and ASD severity appear to overlap in prediction of hours of OT, potentially because severe ASD presentation and limited adaptive behavior could each warrant OT services. VABS score and age uniquely predicted hours of OT, suggesting that amount of OT services per week increases with lower age and lower adaptive behavior scores. This is consistent with the literature and underscores that children with lower adaptive behavior scores may be in particular need of OT services (Case-Smith & Arbesman, 2008; Cidav et al., 2013; McIntyre & Zemantic, 2016; Mire et al., 2015).

**442.032 (Poster) Outcomes Among Caregivers of Toddlers with ASD Concerns Following Implementation of Screen-Refer-Treat, a Novel Service Delivery Model for Early ASD Detection and Intervention**

*T. DesChamps<sup>1</sup>, H. Neiderman<sup>1</sup>, L. V. Ibanez<sup>2</sup>, C. C. Dick<sup>1</sup>, S. M. Attar<sup>3</sup> and W. L. Stone<sup>1</sup>, (1)Psychology, University of Washington, Seattle, WA, (2)UW READi Lab, Seattle, WA, (3)University of Washington, Seattle, WA*

---

Background: In line with the American Academy of Pediatrics guidelines for early ASD screening in primary care settings (Hyman et al., 2020) and evidence demonstrating that specialized early intervention leads to more optimal outcomes among children with ASD (Landa, 2018), ongoing implementation efforts are aimed at increasing ASD screening and access to evidence-based early intervention (EI) in the community (Broder-Fingert et al., 2019). Recently a novel service delivery model, Screen-Refer-Treat (SRT; Ibañez et al, 2019), was developed to increase routine use of the M-CHAT-R/F (Robins et al., 2014) at 18-month well-child primary care visits and expedite delivery of ASD early intervention (i.e., Reciprocal Imitation Training [RIT]; Ingersoll, 2010) within Part C EI programs for toddlers who screen positive for ASD risk, but who have not yet received a formal ASD diagnostic evaluation. SRT was implemented within four Washington State counties by training primary care providers (PCPs) and EI providers on components of the SRT model. PCPs were trained to administer an online version of the M-CHAT-R/F (webM-CHAT-R/F) that automatically presents the follow-up questions. In addition to RIT, EI providers were trained on a Stage 2 screen (Screening Tool for Autism in Toddlers (STAT; Stone et al., 2004) to confirm ASD risk. Two separate cohorts of families were recruited to assess the effects of the SRT model on families of toddlers with ASD concerns.

Objectives: We sought to examine the effects of SRT on family-centered care, parenting stress, parent quality of life, and parenting self-efficacy.

Methods: 120 families with ASD concerns for their toddlers in the pre-SRT cohort (n=57) and the post-SRT cohort (n=63) completed caregiver measures at multiple timepoints to measure family-centered care, parenting stress, parent quality of life, and parenting self-efficacy. Preliminary analyses using independent samples *t*-tests were used to compare time-averaged scores from the pre-SRT and post-SRT cohorts on all outcomes.

Results: Preliminary findings revealed higher reported family centered care among the post-SRT cohort ( $M = 5.37, SD = 1.64$ ) compared to the pre-SRT cohort ( $M = 4.79, SD = 1.47$ );  $t(118) = -2.1, p = .042$ . Based on preliminary analyses, there were no apparent differences between the pre-SRT and post-SRT cohorts on measures of parenting stress, quality of life, or parenting self-efficacy ( $ps > .05$ ).

Conclusions: These preliminary findings suggest that SRT may be associated with improvement in family centered care for families of toddlers with ASD concerns. Given reported barriers to high quality care for families of children with ASD concerns leading up to a diagnostic evaluation, these preliminary findings further suggest that ongoing efforts to increase evidence-based ASD care in the community may improve families' experiences with care. Based on these findings, we plan to conduct a series of multi-level mixed models, accounting for the nested structure of the data and covariates, that also include outcome data from families of toddlers with non-ASD developmental concerns and no concerns to test the effects of SRT on ASD-related experiences.

**442.033 (Poster) Predictors of Service Priorities during COVID-19 and Beyond**

*M. Jimenez Munoz<sup>1</sup>, E. F. Ferguson<sup>1</sup>, H. Feers<sup>2</sup> and T. W. Vernon<sup>1</sup>, (1)University of California Santa Barbara, Santa Barbara, CA, (2)University of California, Santa Barbara, Santa Barbara, CA*

---

Background: The pandemic and subsequent stay-at-home orders have greatly impacted service provision for individuals on the autism spectrum (Pellicano & Stears, 2020). Prior to COVID-19, this difficulty finding adequate support services was especially salient for (a) families experiencing high levels of stress (Kazdin & Wassell, 2000), (b) autistic individuals with more serious challenging behaviors (Siegel, 2018) and (c) those with complex social-emotional profiles (Croen et al., 2017). To improve

service delivery during and after COVID-19, it is essential to learn more about characteristics of autistic individuals that contribute to caregiver-reported service priorities.

**Objectives:** To explore the effect of child emotion regulation, child age, child cognitive level and socioeconomic status on the likelihood of choosing specific service priorities during COVID-19.

**Methods:** Cross-sectional data were collected from caregivers via an online Qualtrics survey that was published from late May 2020 to early July 2020. Eligible participants ( $n = 339$ ) included parents or other legal guardians of autistic individuals (aged 2 or older) in the U.S. Binomial logistic regressions were performed to ascertain the effects of child's age, EDI dysphoria and reactivity scores, child cognitive scores and socioeconomic status on the likelihood of caregivers choosing a behavioral service (social skills, disruptive behavior, daily living skills, or "other" services) as their top service priority for their autistic child during and after COVID-19.

**Results:** Social skills services were the highest endorsed service priority by caregivers (39% of sample). The logistic regression models examining the likelihood of choosing services that target social skills ( $\chi^2 = 48.249$ ,  $df = 5$ ,  $p < .0001$ ), disruptive behaviors ( $\chi^2 = 57.514$ ,  $df = 5$ ,  $p < .0001$ ) and "other" services ( $\chi^2 = 20.521$ ,  $df = 5$ ,  $p < .000$ ) were statistically significant. Higher age and emotional reactivity scores, as well as lower cognitive scores, were associated with reduced likelihood of respondents choosing social skill services as their priority during COVID-19. On the other hand, higher emotional reactivity scores and lower child cognitive scores were associated with an increased likelihood of caregivers choosing disruptive behaviors services as their priority during COVID-19. Lastly, increasing age was associated with an increased likelihood of parents reporting a service not listed in the survey, such that a one-year increase in child's age increased the odds of a parent choosing "other" services by 87%.

**Conclusions:** Despite being the most popular service choice, the likelihood of selecting social skills services varied across caregivers. Increasing child's age and emotional reactivity scores, as well as lower perceived intellectual functioning, predicted lower likelihood of selecting social skills services as a top service priority. These findings add to the existing body of knowledge indicating the diverse service needs of autistic individuals (Chamak & Bonniau, 2016; Vivanti et al., 2014), and suggest that child's emotion regulation, perceived intellectual functioning, and age are important predictors of family's service priorities.

**442.034 (Poster) Project Echo Autism: Building Capacity Among Community Mental Health Providers**

*N. Dreiling<sup>1</sup>, M. L. Cook<sup>2</sup>, E. M. Lamarche<sup>3</sup> and L. G. Klinger<sup>1</sup>, (1)TEACCH Autism Program; Psychiatry, University of North Carolina, Chapel Hill, NC, (2)TEACCH Autism Program; Psychology & Neuroscience, University of North Carolina, Chapel Hill, NC, (3)Psychiatry, UNC TEACCH Autism Program, Chapel Hill, NC*

**Background:** Approximately 92% of autistic individuals are also diagnosed with co-occurring mental health (MH) conditions (Brookman-Frazee et al., 2018). Though community MH centers are one of the most prevalent and accessible service delivery options in the United States, serving more than 1 in 12 people across rural and urban locations (Rosenbaum et al., 2018), few autistic individuals receive services at these centers. Many community MH practitioners report they lack training to treat autistic individuals and instead refer out to specialty clinics, leaving families waiting up to two years to access specialized intervention (Smith-Young, Chafe, & Audas, 2020). With Medicaid reform that aims to integrate physical and behavioral health care and encourage the provision of services within individuals' home communities, a clear need has arisen to build capacity for community-based MH services for autistic individuals. Project ECHO Autism, a tele-mentoring platform which connects physicians to interdisciplinary ASD experts, has demonstrated improvement in primary care providers' ASD related knowledge, self-efficacy, and practice (Mazurek et al. 2017, 2019a, 2019b) and shows high potential to effect similar meaningful change for MH providers.

**Objectives:** Within the broader context of Medicaid transformation and the need for increased access to MH services for autistic individuals within their home communities, this study aimed to develop and implement an adaptation of Project ECHO Autism designed to increase rural MH providers' autism knowledge, self-efficacy, and knowledge application.

**Methods:** The Project ECHO Autism pilot program consisted of a 6-month ASD-focused curriculum for MH providers ( $N=41$ ) across 21 counties in North Carolina. Ten biweekly 90-minute sessions included a brief didactic (e.g. treatment for anxiety, ADHD) followed by provider case presentations. Providers received CEUs for participating. Pre/post assessments measured change in ASD knowledge via an Autism Knowledge test and provider self-efficacy via an adapted version of the Primary Care Autism Self-Efficacy (PCASE) survey (Mazurek et al., 2017). A subset of participants ( $n=35$ ) also provided written case conceptualizations in response to applied vignettes as a measure of provider knowledge application. Satisfaction surveys were collected at posttest.

**Results:** At posttest, providers demonstrated significant improvement in their knowledge of ASD ( $t(41)=7.12$ ,  $p<.001$ ), self-efficacy ( $t(41)=-14.57$ ,  $p<.001$ ), and clinical problem solving abilities ( $t(34)=5.25$ ,  $p<.001$ ). Additionally, participants reported

high satisfaction with their experience ( $M=1.34$ ,  $SD=.31$ ) on a 5-point scale with “1” indicating the highest degree of satisfaction. Follow up data was also collected to examine maintenance of knowledge and self-efficacy changes over time and will be summarized.

**Conclusions:** This study demonstrates that Project ECHO Autism may be an effective tele-mentoring model for improving MH practitioners’ knowledge and self-efficacy in treating autistic individuals with co-occurring MH conditions. This has important public policy implications as it suggests that this model could build capacity among rural community health providers and reduce unmet service needs for autistic individuals by increasing access to evidence-based services within their home communities.

**442.035 (Poster) Psychological Wellbeing and Service Satisfaction during COVID-19 and Beyond**

*E. F. Ferguson, M. Jimenez Munoz, H. Feerst and T. W. Vernon, University of California Santa Barbara, Santa Barbara, CA*

---

**Background:** In the early stages of COVID-19, parents of autistic children reported higher anxiety, meltdowns, and aggressive behaviors as a result of disruptions to routines (SPARK, 2020). The COVID-19 pandemic may particularly impact autistic individuals who experience emotion dysregulation, which has been implicated as a core feature of mood and anxiety disorders (Ameis et al., 2020; Mazefsky, Day, et al., 2018). This underscores the importance of targeting emotion regulation and coping skills in autism treatment services. It remains to be determined whether the families of autistic individuals who experience greater emotional distress are satisfied with autism support services during COVID-19.

**Objectives:** To explore child emotional distress and emotion regulation as predictors of parent-reported satisfaction with services during COVID-19.

**Methods:** Cross-sectional data were collected from caregivers via an online Qualtrics survey from late May 2020 to early July 2020. Participants included 339 parents or other legal guardians of autistic individuals ( $M = 13.7$  years,  $SD = 7.8$ ) residing in the U.S. The survey included: service access and satisfaction questions for each endorsed service; the *Perceived Stress Scale* (PSS; Cohen et al., 1994) for parent stress; and the *Emotion Dysregulation Inventory* (EDI; Mazefsky, Day, et al., 2018), a parent-report measure that captures emotional distress (Dysphoria) and problems with emotion regulation (Reactivity). Sociodemographic and child cognitive variables were not significantly correlated with satisfaction with services and were thus excluded from the following multiple linear regression models in SPSS 27.

**Results:** Child’s reactivity, dysphoria, age, and parent stress explained 9.8% of the variance in average service satisfaction ratings across all received services ( $R^2 = 9.8$ ;  $F_{4,196} = 5.32$ ,  $p < .001$ ). Higher child dysphoria significantly predicted lower parent-reported satisfaction in this model ( $B = -.204$ ,  $t = -2.32$ ,  $p = .022$ ). The next linear regression model examined satisfaction with ABA/ other behavioral therapy services specifically. Child’s reactivity, dysphoria, age, parent stress, and service delivery medium (telehealth, hybrid, or in person) accounted for 30.9% of the variance in behavioral service satisfaction ratings ( $R^2 = 30.9$ ;  $F_{6,72} = 5.37$ ,  $p < .001$ ). Higher dysphoria significantly predicted lower behavioral therapy satisfaction ( $B = -.312$ ,  $t = -2.57$ ,  $p = .012$ ). Parents reported significantly lower satisfaction for behavioral services delivered via telehealth ( $B = -.301$ ,  $t = -2.87$ ,  $p = .005$ ) or via a hybrid of in-person and telehealth ( $B = -.438$ ,  $t = -4.08$ ,  $p < .001$ ) as compared to services delivered in person.

**Conclusions:** Findings indicate that parents of autistic individuals experiencing greater emotional distress reported decreased satisfaction across all services that their children were receiving during COVID-19. Taking a closer look, parents of autistic individuals with higher dysphoria reported lower satisfaction with ABA/ behavioral therapy services, and satisfaction was also lower for behavioral services delivered via telehealth or a hybrid model. These findings suggest that child emotional distress is one important contributor to variance in satisfaction with services during COVID-19. Behavioral therapists and other service providers may renew their efforts to promote emotion regulation skills in order to improve child’s emotional distress and parental satisfaction.

**442.037 (Poster) Service and Support Needs in Families of Autistic Children during the COVID-19 Pandemic**

*J. Shim<sup>1</sup>, V. C. Fong<sup>2</sup> and G. Iarocci<sup>3</sup>, (1)Simon Fraser University, Vancouver, BC, Canada, (2)Psychology, Simon Fraser University, Vancouver, BC, Canada, (3)Psychology, Simon Fraser University, Burnaby, BC, Canada*

---

**Background:** The COVID-19 pandemic has amplified existing health and social inequities in our society. The impact on autistic children and their families is particularly striking due to the elimination of a network of essential school, family and community support services. Previous studies found that during health emergencies, children with disabilities experience greater negative psychological symptoms and are less likely to be prioritized in resource allocation (Fong & Iarocci, 2020). There is an urgent need to tackle this inequity by examining caregiver perceptions of service and support needs during the current pandemic. This will lead to research informed policy and planning that can prevent further hardship for autistic children and their families in the current public health emergency but also, helps to promote resilience in the longer term.

**Objectives:** Our research questions were three-fold: (1) What services and supports are prioritized by families? (2) What are families' schooling and educational needs for their child? and (3) What online supports do families need or find helpful?

**Methods:** The current study adopted a community engagement approach, collaborating with the executive director of a non-profit organization called ACT – Autism Community Training. Our partner was involved in all stages of the research process, including setting the research priorities, formulating the research questions, developing the online survey, recruitment, and disseminating research findings. Participants of the study included 238 caregivers living in British Columbia, Canada between the ages of 25 to 64 years ( $M=42.82$ ;  $SD=6.65$ ). Their autistic children were between the ages of 2 to 21 years ( $M=10.47$ ;  $SD=6.65$ ). The online survey comprised of open-ended questions, specifically “What Ministry of Children and Family Development supports did you need?”; (2) “What information, services, or supports did you need for your child's education that you did not have access to during this time?”; and (3) “Is there any form of online support that you believe could have helped you more during the COVID-19 outbreak? The online survey was hosted by Qualtrics from July 30 to September 26, 2020. Responses were independently coded by two authors blind to each other's coding decisions and inter-rater reliability across coders was calculated.

**Results:** Caregivers prioritized a number of areas related to government supports and services such as greater flexibility in funding, availability of respite, and mental health supports. Many families also reported being unaware of new policies and supports implemented during the pandemic. Education needs identified included more Educational Assistant support, social opportunities for students to interact online, and consistent communication between teachers and parents. Families prioritized online supports such as parental counselling and information related to child behavioural management.

**Conclusions:** Findings highlight the importance of understanding caregivers' service and support needs in order to improve families' capacity for resilience during the current and future pandemics. Results will help guide decision-makers in implementing policies that better address the needs of autistic children and their families.

**442.038 (Poster) Systematic Review of ASD Intervention Services and Treatment Programs in Africa**

**J. M. Pierucci**, A. M. Hernandez, H. Lucente, G. A. Aquino and G. Garcia, (1)Psychology, St. Mary's University, San Antonio, TX, (2)Research Imaging Institute, University of Texas Health Science Center - San Antonio, San Antonio, TX, (3)The University of Texas at Austin, Austin, TX, (4)Texas Tech University, Lubbock, TX

**Background:** Autism spectrum disorder (ASD) has become a global burden due to its increasing prevalence (Baxter et al., 2015). An estimate of one in 132 individuals throughout the world have ASD (Global Burden of Disease, 2010) with certain countries showing higher incidences (e.g., one in 54 American children; Center for Disease Control and Prevention, 2020). Access to and knowledge of intervention services and treatment programs provide the best outcome for individuals with ASD and their families. Yet, there is a paucity of ASD intervention services and treatment programs especially in low- and lower-middle-income countries (LAMICs) such as throughout Africa (Ruparella et al., 2016).

**Objectives:** This research systematically identified existing literature on ASD intervention services and treatment programs conducted in Africa's 54 countries.

**Methods:** The trained multidisciplinary research team used DISCOVER search engine and PsycINFO database to search the following keywords: 1) Autism or ASD or autism spectrum disorder; 2) intervention or services or treatment or therapy or programs; and 3) Africa or Sub Saharan Africa. Each of the 54 African countries was also searched in combination with the first and second set of aforementioned keywords. Publications' titles were screened according to the keywords. Then, three researchers screened abstracts of the selected publications using the keywords. In addition, reference lists of the selected publications were manually searched to identify additional relevant publications. Publications that met the keyword criteria were then read in full and coded. A standardized coding system was developed by the research team for data extraction from the full articles.

**Results:** A total of 1,269 publications populated during the searches when using the keywords. Additionally, 42 publications were identified from manual searching of the reference lists. Publications that were not in English, not accessible, or that were duplicates were excluded ( $n = 1176$ ). Abstracts of 135 publications were then screened to determine eligibility for full review. Twenty publications met criteria and were read in full. Eight articles were then excluded. See Figure 1. All articles were published since 2008. The 12 articles that met eligibility included various methodologies (e.g., pilot, feasibility, mixed-methods) from six African countries. See Figure 2. Intervention services and treatment programs targeted skills such as language and social development in young children ( $M_{age} = 7$  years). Synthesis of key findings is ongoing.

**Conclusions:** This systematic review provides critical information on intervention and treatment research in Africa for individuals with ASD – including suitable implementation methods. It highlights the six African countries that have published research and focused efforts on ASD intervention - although it is limited. It illustrates the sparsity of publications, further exemplifying the

dearth of empirical resources for individuals with ASD in Africa. Additionally, it provides a compelling case for policy makers and stakeholders to address the service gaps for Africans with ASD. Conclusively, intervention services and treatment programs have shown an array of short-term and long-term benefits (National Research Council, 2001); however, the service demands for ASD remain unmet in Africa, inclusive of multiple LAMICs, as this research encapsulates.

**442.039** (Poster) Systemic Racism Continues: Disparities in Eligibility for U.S. Public Health Programs and Spending Among Autistic Adults

**T. W. Benevides<sup>1</sup>, H. J. Carretta<sup>2</sup>, G. Rust<sup>3</sup> and L. Shea<sup>4</sup>, (1)Occupational Therapy, Augusta University, Augusta, GA, (2)Behavioral Sciences and Social Medicine, Florida State University College of Medicine, Tallahassee, FL, (3)Florida State University, Tallahassee, FL, (4)A.J. Drexel Autism Institute, Philadelphia, PA**

---

**Background:**

Research on children with autism spectrum disorder (ASD) historically revealed racial and ethnic disparities in access to care and health services utilization, often from Medicaid-only samples or privately insured samples. Parallel research to understand how disparities persist as individuals age into adult systems of care is understudied. With more autistic individuals aging into adult systems of care each year, it is essential to understand eligibility for public benefits in the U.S. via Medicare and/or Medicaid and underlying inequities in resource allocation.

**Objectives:**

RQ1: What racial and ethnic differences exist in eligibility for Medicare and/or Medicaid programs among adults with ASD?  
RQ2: What racial and ethnic differences exist in out-of-pocket and program spending for medical care among Medicare and/or Medicaid-enrolled adults with ASD?

**Methods:**

We conducted a cross-sectional study of U.S. autistic adults using 2012 Medicare-Medicaid Linked Enrollee Analytic Data Source. Adult ASD individuals aged 18+ years with records in either Medicare and/or Medicaid and complete race-ethnicity data were analyzed ( $n=172,071$ ). We used chi-square tests to evaluate differences in race-ethnicity and eligibility status (Medicare-only, Medicaid-only, Full-Dual). Adjusted logistic models were used to predict eligibility by race-ethnicity while controlling for age, gender, state of residence, and intellectual disability (ID) status. We describe spending using median annual spending in 2012 with 95% centile confidence intervals. General linear modeling with gamma distribution were used to analyze mean spending between race-ethnicity groups.

**Results:**

Demographics are shown in Table 1. In 2012, the majority of White adults (49.87%) were full-dual eligible for both Medicare and Medicaid. In contrast, only 37.53% of Black, 34.65% Asian/Pacific Islander (PI), and 35.94% of Hispanic individuals were full-dual eligible, with the majority only eligible for state-funded Medicaid. Adjusted models support bivariate findings, with Black, Asian/PI, and Hispanic individuals having significantly lower odds of being dual-eligible (aOR=0.64, SE=.01; aOR=0.82, SE=.03, aOR=0.80, SE=.02). Across these three eligibility types ( $n=168,638$ ), total spending among adults aged 18 and over with ASD in 2012 totaled \$10,494,060,057. Median annual spending per individual for White adults (\$59,013) was approximately 20-29% greater than median annual spending per individual as compared to Black (\$47,405), Asian/PI (\$42,097), and Hispanic (\$46,252) individuals.

**Conclusions:**

Black and Hispanic individuals were significantly less likely to be dual eligible for Medicare and Medicaid than White individuals after adjusting for age, gender, ID, and state. Black, Asian/PI, and Hispanic full-dual adults had significantly lower Medicare-Medicaid spending per individual than White individuals likely suggesting differences in care patterns. Overall, across all race-ethnicity groups, spending exceeded \$10.5 billion dollars in 2012, representing 1.3% of total Medicare and Medicaid spending in that fiscal year. Research focused on costs of care across all age groups are likely underestimates. As autistic adults age into public-payer systems such as Medicare and Medicaid, policy makers and healthcare administrators require sustained and collaborative efforts to reduce inequities, improve coordination across systems, prevent high-cost mental health crisis and emergency department care, and consider the effects that lack of regular employment, affordable housing, and qualified care

providers will have on the future health of autistic adults.

**442.040** (Poster) The Impact of COVID-19 on the IDD Community in California: Service Delivery and Regional Centers  
*G. B. Salinas, Y. Bolourian and J. Blacher, Graduate School of Education, University of California, Riverside, Riverside, CA*

---

**Background:** Within the State of California, services for children and youth with intellectual and developmental disabilities (IDD), such as behavioral and occupational therapy (OT), can be allocated through insurance, regional centers, medical clinics, and school settings. Due to COVID-19, parents and individuals with autism experienced a disruption in services, forcing them to quickly adapt to online services (i.e., telehealth) when offered. Little is known about the accessibility of services, whether online or in-person, to these families during the pandemic.

**Objectives:** The aim of this study was to capture how COVID-19 has disrupted service delivery and regional center services for the IDD community in the State of California.

**Methods:** This study is a secondary analysis of survey data provided by the Autism Society of California to understand the impact of COVID-19 on youth with IDD and their families. An electronic survey was disseminated in English and Spanish using Survey Monkey and was open for two weeks from May 9-19, 2020. Descriptive statistics and frequencies were run to analyze quantitative data.

**Results:** A total of 1,082 individuals responded to the survey, which included 40 individuals with a disability and 1,042 parents, family members, or guardians of a person with a disability. The diagnosis of the person with a disability or family member with a child with a disability included Autism Spectrum Disorder (ASD; n=794) and other IDD (n=288). Overall, 52% of the participants identified as White or Caucasian, 42.4% identified as Hispanic or Latino, 7.8% as Asian, 4.1% as Black, and 2.7% as American Indian. Respondents reported services obtained during COVID-19 such as ABA, communication therapy (CT; e.g., speech, language, or augmentative and alternative communication), OT, social skills groups, and physical therapy (PT). The most frequently reported services were: ABA (telehealth n=282; in person n=84), communication therapy (telehealth n=318; in person n=20), and OT (telehealth n=238; in person n=17). Respondents also reported receiving no services at all during the pandemic as follows: no ABA n=512, no CT n=533, no OT n=591. Most of the respondents reported being a regional center client (n=850) and were asked a series of questions regarding support provided by their regional center caseworker. Of those associated with a regional center, 72.1% (n=613) of respondents reported receiving adequate support from their caseworker since COVID-19 began; 27.9% (n=237) did not. Ongoing analyses will determine if services were equally offered across the state, ethnicity/race, and disability.

**Conclusions:** Individuals and families affected by COVID-19 have had to quickly adapt to changes due to COVID-19 such as adapting to telehealth or, unfortunately, experiencing dismissal of services. Regional Center clients received adequate support from their caseworkers but some reported a lack of support during the pandemic.

**442.041** (Poster) The Impact of Learning to Play the Piano on the Emotion and Behaviour Regulation of Autistic Teenagers.  
*R. Cowie<sup>1</sup>, S. Fletcher-Watson<sup>2</sup> and R. MacDonald<sup>1</sup>, (1)University of Edinburgh, Edinburgh, United Kingdom, (2)Salvesen Mindroom Research Centre, University of Edinburgh, Edinburgh, United Kingdom*

---

**Background:** In typically developing children, behavioural benefits of instrument learning have been demonstrated (Palmer, 2001; Herholz & Zatorre, 2012). However, the autism literature largely reports on interventions focused on music making and listening (Edgerton, 1994; Hammel & Hourigan, 2013). There is far less evidence about the impact of learning to play an instrument for autistic individuals, though personal accounts indicate benefits (Koleman, 2013).

**Objectives:** This research asks: does learning to play an instrument have a beneficial effect for autistic individuals? The research was conducted in two phases. The objective of phase one was to engage with experienced music teachers to gain a better understanding of good practice when teaching autistic adolescents. This information was used to design a one-to-one instrument lesson plan for autistic learners. The objective of phase two was to review the impact of these lessons on autistic adolescents by investigating pupil and teacher experiences, and parent perspectives.

**Methods:** Study 1 investigated teachers' (n=7) experiences of teaching beginner piano to adolescents, including teaching autistic individuals, through semi-structured interviews and questionnaires. All teachers had at least 10 years of experience of one-to-one instrument teaching. In study 2, nine autistic individuals (aged 12-15) received an average of ten beginner piano lessons over the course of 14 weeks. Semi-structured interviews were conducted with the pupil, their parents and the teachers at the start and end of the learning period. All data were transcribed and underwent thematic analysis.

**Results:** Study 1: Three themes were identified from teacher interviews: Individuality, Familiarity and Impact. Individuality refers to the need to engage with the pupil's own motivations and preferences, and to make adaptations that evolve over time. Familiarity refers to the need for the lesson structure to be consistent and that the teachers and pupils were clear about their expectations of each other. Teachers expressed that the lesson should be a safe space. Impact refers to the teachers' observations about how pupils can benefit from instrument learning in terms of emotional expression, attitude to learning and opportunities for community participation.

The evaluation of study 2 is ongoing at the time of writing, with lessons due to be completed in December 2020 and analysis completed by March 2021. A single case study pilot revealed evidence of pupil benefit from the weekly lessons. Being able to practice and go to the piano gave him a safe space to go and work through any emotions he was experiencing and helped calm him down when feeling overwhelmed. It also helped ease his anxiety and gave him the opportunity to engage with peers in social settings.

**Conclusions:** Teacher interviews indicate that autistic people can and do take part in instrument learning but may require enhanced understanding and some adaptations to gain maximum enjoyment. This information can be used to create a model for one-to-one lesson learning which shows very preliminary evidence of benefit.

**442.042 (Poster)** The Importance and Availability of Adjustments to Improve Access for Autistic Adults Who Need Mental and Physical Healthcare: Findings from a UK Survey

**S. Brice<sup>1</sup>, J. Rodgers<sup>1</sup>, B. Ingham<sup>1,2</sup>, D. Mason<sup>3</sup>, C. Wilson<sup>1</sup>, M. Freeston<sup>1</sup>, A. LeCouteur<sup>1</sup> and J. R. Parr<sup>1,2</sup>,** (1)Population Health Sciences Institute, Newcastle University, Newcastle upon Tyne, United Kingdom, (2)Cumbria, Northumberland, Tyne and Wear NHS Foundation Trust, Newcastle upon Tyne, United Kingdom, (3)Social, Genetic and Developmental Psychiatry Centre, Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, United Kingdom, (4)School of Psychology, Newcastle University, Newcastle upon Tyne, United Kingdom

---

**Background:** Autistic people are more likely to experience mental and physical health conditions than neurotypical people. Poor health predicts poorer quality of life. Life expectancy for autistic people is significantly lower than the general population. Autistic people frequently encounter barriers that prevent access to effective healthcare. Such barriers prevent autistic people from arranging and attending healthcare appointments. UK NHS clinical guidance recommends providers adjust their procedures to best meet the needs of autistic people - understanding how best to do this represents an autism community research priority. However, the importance and availability of specific adjustments to autistic adults across UK healthcare settings are currently unknown.

#### **Objectives:**

- Investigate autistic adults' views on the importance and availability of adjustments to mental and physical healthcare.
- Explore whether specific categories of adjustments can be empirically identified and to explore differences in their importance and availability between mental and physical healthcare.

**Methods:** Data were combined from two cross-sectional studies; one focused on mental health services and the other on physical health services. Autistic adults were recruited from the Adult Autism Spectrum Cohort- UK (ASC-UK; <https://research.ncl.ac.uk/adultautismspectrum/>), and invited to complete a survey about mental or physical healthcare. 537 (51% response) participants completed the mental health survey and 407 (49%) completed the physical health survey; 221 participants completed both surveys. Both surveys included an identical list of adjustments identified to improve accessibility and inclusivity of healthcare. Participants rated the importance and availability of each adjustment using a 5-point Likert scale. Exploratory factor analysis (EFA) was conducted to explore whether the adjustments could be empirically grouped in a meaningful way. Differences in adjustments between mental and physical healthcare were explored using McNemar's test to compare nominal data in the paired sample who completed both surveys.

**Results:** EFA identified three categories of important adjustments: *sensory environment, clinical and service context, and clinician knowledge and communication*. The adjustment rated as being most important was 'access to a clinician who understands autism' (rated as being important by 98.3% and 96.5% of participants in mental and physical healthcare respectively). Despite this high importance, this adjustment was rated as being 'rarely or never available' to 71.8% of autistic adults accessing mental healthcare and 73% accessing physical healthcare. This pattern of high importance and low availability was observed across the majority of adjustments. Only 'access to appointments with familiar clinicians and/or healthcare locations' were regularly available to over half of respondents. 'Access to a clinician who is willing to adjust their approach to suit my needs' was significantly more important in mental health compared to physical health settings ( $p = .001$ ). No other significant differences between healthcare settings were identified.

**Conclusions:** The limited availability of important adjustments for autistic people in current healthcare settings may lead to unmet health needs. To address this and reduce health inequalities currently faced by autistic people, healthcare providers should consider offering adjustments relating to the three identified factors, most of which are inexpensive to implement. Future research should focus on identifying and addressing service-provider barriers to implementation of adjustments.

**442.043 (Poster)** The Role of Advocacy and Empowerment in Shaping Service Development for Autism and Other Developmental Disorders

**Z. Szlamka<sup>1</sup>, B. T. Tekola<sup>2</sup>, C. Hanlon<sup>3</sup> and R. A. Hoekstra<sup>2</sup>,** (1)King's College London, London, United Kingdom, (2)Department of Psychology, King's College London, London, United Kingdom, (3)Addis Ababa University and King's College London, Addis Ababa, Ethiopia

---

**Background:** Empowerment of families with children with autism and advocacy for autism are essential to service development using a rights-based approach to disability. The World Health Organization (WHO) identified empowerment as key to the development of services for children with autism and other developmental disorders (DDs). Caregiver and professional advocacy is one of the key pillars of empowerment and include obtaining support or services for a child with autism, creating opportunities, and educating the child's environment and the broader community about the condition. Engaging in advocacy is described to be shaped by caregivers' access to social capital and resources.

**Objectives:** The aim of this study was to investigate advocacy and empowerment in a global context in relation to service development for families of children with autism and other DDs. We studied a) meanings of empowerment; b) stakeholder perceptions on the role that advocacy and empowerment play in service development; c) the use of evidence for advocacy and empowerment.

**Methods:** This qualitative study took a phenomenological approach. The study questions were applied to service development for caregivers of children with a DD and to a specific caregiver intervention, the WHO's Caregiver Skills Training (CST). This programme was chosen as it represents a global effort to make services available for caregivers irrespective of their socio-economic setting. Participants were clinicians, caregivers, researchers representing five continents, and representatives of WHO and Autism Speaks. All participants were involved in advocacy and caregiver interventions, like CST. First, two focus group discussions (FGDs) were conducted with 15 participants. After the preliminary analysis of FGDs, 25 semi-structured individual interviews were conducted. All data were analysed thematically. The codebook was developed by two independent coders. Themes were developed in iterations, using investigator, method, and data triangulation.

**Results:** Three themes were developed: a) Meanings of empowerment; b) Advocacy for services; c) Caregivers as active stakeholders in services. Many professional participants defined empowerment within the realms of their profession: for example, having skills to improve the child's symptoms or economic empowerment. They thought that an empowered caregiver has self-confidence, relies less on others and is knowledgeable about how best to help a child with a DD. Caregivers expressed that this expert-oriented view of empowerment fails to acknowledge the intuitive knowledge of caregivers. Professionals and caregivers thought that advocacy is a key to service development and that personal connections and being opportunistic were important aspects of advocacy. Informants agreed that caregivers can be powerful advocates and take an active role in shaping service development for DDs. Empowerment practices and participation in caregiver interventions can facilitate this role. Some thought that there is a gap between rights of caregivers and services and professionals available and added that one of the goals of empowerment is to overcome this gap.

**Conclusions:** Empowerment of caregivers and advocacy can contribute to service development for DDs in different contexts worldwide. Definitions of empowerment should take into account caregiver perspectives. Caregiver and professional advocacy can facilitate achieving an inclusive, rights-based approach to making services available for all families globally.

**442.044 (Poster)** Understanding Provider and Family Experiences with Telehealth Services for Children with Autism and Developmental Disabilities

**M. L. Luu<sup>1,2</sup>, G. Duhon<sup>1,2</sup>, L. N. Berry<sup>1,2</sup>, R. G. Voigt<sup>1,2</sup>, R. H. Fein<sup>1,2</sup>, S. Cash<sup>1,2</sup> and R. P. Goin-Kochel<sup>1,2</sup>,** (1)Baylor College of Medicine, Houston, TX, (2)Texas Children's Hospital, Houston, TX

---

**Background:** Telehealth is a platform of healthcare that delivers services through the use of technology. Although reported advantages of telehealth include improved access to clinical services, the rapid transition to telehealth in spring 2020 (due to COVID-19) may have occurred before consistent work flows and systems to fully support telehealth visits were developed, thereby creating challenges with subsequent delivery of and/or receipt of care. This may have especially affected diagnostic clinics for autism spectrum disorder (ASD) and related conditions that rely heavily on standardized, in-person assessments and behavioral observations. Given the likely permanence of some ASD-telehealth services, there is value in gauging acceptability and sufficiency of telehealth to guide quality-improvement efforts.

**Objectives:** To characterize telehealth visits for children with suspected ASD/developmental delays at a tertiary autism/developmental center in a large metropolitan area from both caregiver and provider perspectives.

**Methods:** REDCap surveys, adapted from the Vanderbilt Kennedy Center's Telemedicine Feedback form, were designed separately for providers (i.e., developmental behavioral pediatricians, psychologists, neurologists) and families and distributed via email with instructions to complete the form with a given appointment in mind. All families scheduled for a telehealth visit received an email within four hours following their scheduled visit. Providers were emailed a survey link within the same timeframe for every third visit to avoid response fatigue. Surveys were distributed regardless of whether the visit was completed, attempted, or no-showed. Up to two email survey reminders were sent to families every two days. Survey distribution spanned two months (5/18/2020-7/27/2020). Data were imported into SPSS and analyzed descriptively.

**Results:** A total of 90/637 (14.1%) caregiver surveys and 122/241 (50.4%) provider surveys were returned. The most common visit type was diagnostic intake (46.7%) and the most common telehealth format was Vidyo (video; 89.3%). 47/90 (53.2%) families stated that this was their first time working with their provider; 78/90 (86.7%) families said their provider recommended a subsequent follow-up visit, with 47/77 (61.0%) of these being an in-person visit. 79/121 (65.3%) provider surveys reported making a diagnosis via telehealth that was shared with the family. Although 71/90 (78.9%) caregivers agreed that equipment used for their telehealth visits worked well, 46/90 (51.1%) were neutral/disagreed that telehealth was more convenient compared to in-person and 8/15 (53.3%) open-ended comments about inconvenience specifically noted technical and/or communication issues. 48/121 (39.7%) provider surveys endorsed technical difficulties during telehealth visits; additionally, 7/34 (20.6%) reported lack of family preparedness (i.e., appointment reminders, visit readiness) in open-ended feedback about their telehealth visits. Further information about families' and providers' experiences with telehealth is provided in Tables 1 and 2.

**Conclusions:** Telehealth can provide a safe method of service delivery for children being evaluated for ASD during COVID-19. However, technological difficulties can make service provision inefficient or incomplete, thus leading to delayed diagnoses and recommendations for subsequent, in-person appointments. Moreover, telehealth may be perceived as less convenient because of technological or other logistical challenges. Qualitative analyses of caregiver and provider feedback are underway to provide a more complete understanding of challenges with the telehealth-service platform.

**442.045 (Poster)** Use and Intention to Use Mental Health Services Among College Students with Autism Spectrum Disorder  
**J. Anbar<sup>1,2</sup>, C. Cutshaw<sup>1</sup>, P. Haynes<sup>1</sup>, M. Barnett<sup>3</sup>, P. Glider<sup>4</sup> and S. Pettygrove<sup>1</sup>,** (1)Mel and Enid Zuckerman College of Public Health, University of Arizona, Tucson, AZ, (2)Southwest Autism Research & Resource Center (SARRC), Phoenix, AZ, (3)Norton School of Family and Consumer Sciences, University of Arizona, Tucson, AZ, (4)Campus Health, University of Arizona, Tucson, AZ

**Background:** Autism Spectrum Disorder (ASD) prevalence estimates have increased over time. Despite core and associated symptoms of ASD persisting beyond childhood, research exploring how adult individuals with ASD use mental health services is limited. With college serving as a major pathway for transitioning into adulthood, it is important to understand how individuals with ASD engage with mental health services in a higher education context.

**Objectives:** Identify whether use and intention to use mental health services differs among students with ASD, students with other diagnosed mental disorders, and students with no diagnosed mental disorder.

**Methods:** Participants were respondents from an annual cross-sectional, self-report survey conducted at a major university in the southwestern United States (n=4,580). Survey data were collected in-person and respondents answered questions about demographics, previously diagnosed mental disorders, and insurance status. ASD status and history of other mental disorders were based on self-report of whether the respondent had ever been diagnosed with ASD or another mental disorder. For the analyses,  $\chi^2$  - statistics and logistic regressions were used. Students who had a diagnosis of ASD were compared to a) students with a history of other mental disorders; and b) to students with no history of mental disorders.

**Results:** Of the respondents, 0.6% (n=29) reported ever being diagnosed with ASD, 34.3% (n=1,569) reported ever being diagnosed with at least one other mental disorder, and 65.1% (n=2,982) reported no history of mental disorder diagnosis. Chi square analyses showed that students with ASD were significantly more likely to have used professional mental health services in the last 12 months than students with no mental disorder (p<0.001). Respondents with ASD were significantly more likely to intend to seek out mental health services in the future than students with another mental disorder (p=.049). In controlling for demographics (e.g. race, gender) and insurance variables (including removing respondents who had insurance that specified what provider could or could not be seen), respondents with ASD had significantly greater odds of using professional mental health services than students without ASD (OR=22.7; 95% CI=9.1-57.0). Controlling for demographics and insurance variables also

eliminated the significant association between respondents with ASD and the intention to seek out mental health services in the future, compared to students with another mental disorder (OR=0.8; 95% CI=0.3-2.2).

**Conclusions:** College students with ASD were significantly more likely to use professional mental health services than students with no diagnosed mental disorder, which is consistent with data showing students with a diagnosed mental disorder are more likely to use mental health services than students without diagnosed mental disorders. Interestingly, students with ASD did not have different intentions to seek out mental health services in the future when controlling for demographics and insurance status. These results imply that students with ASD use services differently than students without ASD. Future research could explore what role other variables (e.g. mental distress, discrimination) play in determining what resources students with ASD use to address mental health challenges.

**442.046 (Poster)** Using the Telemedicine during the COVID-19: A Working Model to Meet the Needs of Parents and Children with Autism Spectrum Disorder

*A. Narzisi<sup>1</sup>, C. Blandino<sup>2</sup>, D. Di Stefano<sup>2</sup>, A. Rocchi<sup>2</sup> and M. Pinzino<sup>2</sup>, (1)IRCCS Stella Maris Foundation, Pisa (Calambrone), Italy, (2)CETRA, Calambrone (Pisa), Italy*

**Background:** The COVID-19 has had a profound impact on healthcare services. The institutions that deal with the diagnosis and intervention of children with autism spectrum disorder (ASD) required rapid functional adaptation to respond to patients' needs. The possibility of using technology to activate and manage diagnostic (preliminary diagnosis) and intervention processes was explored.

**Objectives:** The main aim of this contribute is to share telemedicine working models for preliminary diagnosis and intervention adopted at CETRA. CETRA is a highly specialized center for ASD (accredited by the Italian National Health Service and with a scientific agreement with IRCCS Stella Maris that is a tertiary referral hospital) sited in Pisa, Italy. Usually, it offers in-person services, including diagnosis and evidence-based parent-mediated interventions. The in-person working model of CETRA involves the use of video feedback with parents during the intervention (inspired by the PACT model of Green et al. (Lancet,2010)) and the analysis of the videos used during the diagnostic process. Additional clinical offerings include support groups for parents, training for therapists and clinical research. Since the beginning of the COVID-19 era, most of the clinical activities have been remotely reorganized, developing a working in telemedicine.

**Methods:** Two developed telemedicine working models for diagnosis and intervention, including synchronous and asynchronous transmissions, are presented. The diagnostic step (see Figure 1) is composed by two different and consecutive phases: (A) pre-specialistic consultation (PSC) and (B) specialistic assessment (SA). During the PSC, parents filled out questionnaires and they sent five short videos to the ASD team (see Figure 1). During the SA (three days) the ASD team watch the five asynchronous videos and also three synchronous connections (in real time) were carried out. In the first synchronous connection, the anamnesis, ADI-R and Vineland-II were acquired. In the other two synchronous connections the child with a parents were observed by the ASD team. The ADOS item, as suggested by Fusaro (PlosOne,2014) and DSM-5 checklist were used for the global clinical scoring of the synchronous and asynchronous videos. The intervention step (see Figure 2) implemented well-recognized evidence-based model (i.e. ESDM) for preschoolers, school-aged, and older children in an online format. Parents' support was also included.

**Results:** The 26,3% of assessed children were at their first diagnosis of ASD (ma=3,2 years; sd=1,1); 44,3% were follow-ups (ma=4,6; sd=1,9) and 29,4% were preschoolers engaged in intervention sessions. These last children (and their families) were engaged in the Early Start Denver Model (ESDM) one of few evidence-based treatment for children with ASD with a specific parent-coaching developed program.

**Conclusions:** The described working models have the purpose of carrying out preliminary specialistic answers to the families without aiming to replace preferable in-person assessment. Based on previous research findings, the telemedicine approach is accepted by parents, increases their sense of competence, increases the parent intervention adhesion and improves the social communication competencies for children with ASD. In conclusion, the presented working models should be considered partial and ethic responses to the current emergency status and at the same time as possible integrations into traditional approaches.

**442.047 (Poster)** Who Caregivers Skills Training Delivery Adaptation during COVID-19 Pandemic in a Public Service at Brazilian Health Care Context

*A. M. Choinski<sup>1</sup>, M. D. F. J. Minetto<sup>1</sup>, E. Matos<sup>2</sup>, G. M. S. Doria<sup>2</sup>, R. Massuda<sup>2</sup>, C. Geyer<sup>2</sup>, S. Antoniuk<sup>3</sup>, J. Braga Filho<sup>3</sup>, C. C. Rauen<sup>3</sup>, L. P. Santos<sup>3</sup>, V. Braga<sup>3</sup>, K. H. Nogara<sup>3</sup>, M. S. O. Alencar<sup>3</sup>, C. Guilhardi<sup>3</sup> and T. W. CST Team<sup>3</sup>, (1)Education, Federal University of Paraná, Curitiba, Brazil, (2)Founder, Ico Project Foundation, Curitiba, Brazil, (3)Psychiatry, Federal University of*

**Background:**

The Caregivers Skills Training (CST) is a program designed to help parents promote the acquisition of their children's skills, aimed at families of children with neurodevelopmental disorders. Originally CST was intended to have a face-to-face delivery, but due to the Covid-19 pandemic, that had to be adapted.

**Objectives:**

This study aimed to evaluate the CST adaptation to an online setting in the Brazilian context.

**Methods:**

CST in Brazil is on the pilot testing, it was translated and adapted to the Brazilian context, evaluated acceptability and feasibility and applied to a small sample size. Pilot phase started with 50 families, 10 facilitators and 4 master trainers, they were divided in 5 groups. Each group was accompanied by a research member, responsible to send the online questionnaires to the families and facilitators. Facilitators training happened with daily online classes and access to an online platform with the materials and daily tasks. The families training took place with weekly online sessions and access to a platform where the materials and questionnaires were available. The materials were also made available at the health center nearest to the family's home. The families were selected considering their availability to participate in the online training, those who couldn't were transferred to a waiting list. Sessions were recorded and if any parent couldn't make a session its video was sent to them. The scheduled home visits had to be adapted, the parent was requested to record a 5 to 10 minutes interaction with the child and send it to the facilitators, who watched it and talked about it to the parent on an online meeting.

**Results:**

The facilitator training happened without great problems. In the families training various difficulties appeared: almost none of the parents accessed the platform where the materials and questionnaires were, so the team switched to social network apps that proved more effective; as parents were home, some had to divide their attention between the training and the children or other home activities; technical difficulties arose, such as bad internet connection, learning how the videoconferencing app worked (especially in the first few sessions) and lack of (other people in the house were using it) or incompatibility of the devices; "visits" were greatly impacted by this change as the recorded video left out important aspects of the interaction; all sessions needed to be shorter, due to the strain of long hours of online sessions; the content of the sessions became more theoretical and lacked experience; and in some groups the families didn't interact much with each other, impacting the development of a support network. Despite these difficulties, there were some benefits: families that had transportation difficulties managed to participate and the availability of the recorded sessions was regarded as very important if the family missed some session.

**Conclusions:**

The administration of the CST online was impacted, but, as observed by the results of parental skills development and frequency child problem behaviors. Considering it all, it can be a viable alternative, especially with the facilitators training.

**442.049 (Poster)** "They Looked at Me As a Person, Not Just a Diagnosis": A Qualitative Study of Barriers and Facilitators to Care at a Specialized Patient Centered Primary Care Clinic for Autistic Adults

**B. N. Hand<sup>1</sup>, D. Gilmore<sup>2</sup>, L. Harris<sup>3</sup>, A. Darragh<sup>3</sup>, C. Hanks<sup>4</sup>, D. Coury<sup>5</sup>, S. Moffatt-Bruce<sup>6</sup> and J. Garvin<sup>7</sup>, (1)Health and Rehabilitation Sciences, The Ohio State University, Columbus, OH, (2)The Ohio State University, Columbus, OH, (3)Division of Occupational Therapy, The Ohio State University, Columbus, OH, (4)The Ohio State University Wexner Medical Center, Hilliard, OH, (5)Nationwide Children's Hospital, Columbus, OH, (6)Department of Surgery, The Ohio State University, Columbus, OH, (7)Health Information and Management Systems, The Ohio State University, Columbus, OH**

---

**Background:** The Center for Autism Services and Transition (CAST) is a patient-centered primary care clinic that aims to remove barriers to care for autistic adults. CAST patients may receive modifications to the standard patient workflow (e.g., bypass the waiting room due to sensory sensitivity) and are seen by physicians with expertise in providing care for autistic adults. In a previous study using survey data (Hand, Coury, et al., 2020), we demonstrated that CAST patients had significantly higher

satisfaction with the care they receive than a national sample of autistic adults. We conducted this study to add depth and context to our survey findings by describing factors that increased or decreased patient and caregiver satisfaction with CAST.

Objectives: To characterize factors that increased or decreased patient and caregiver satisfaction with CAST.

Methods: We used a phenomenological approach and conducted 30-60-minute semi-structured interviews with CAST patients (N=9) and caregivers of CAST patients (N=12). All interviews were transcribed verbatim and entered into NVivo. We conducted a thematic analysis following the steps in the qualitative data analysis process. Two researchers (BH and LH) began the analysis by identifying codes and grouping them into facilitators or barriers to satisfaction. The researchers independently coded the transcripts and met to calculate inter-coder agreement. The agreement rate for all codes was over 90%. To achieve trustworthiness of our qualitative findings, we: (1) used investigator and data triangulation; (2) checked for representativeness by only including final themes that were present in at least 30% of the interviews; (3) used audit trails; and (3) performed member checks by sending all participants a 1-page summary of the results to solicit views on the credibility of our interpretations.

Results: Factors that increased participants' satisfaction included: (1) CAST providers' experience with autism, which led to a more positive experience at CAST relative to experiences with other providers; (2) rapport between the provider and the patient or caregiver; and (3) spending less time waiting and more time with the provider. Factors that decreased participants' satisfaction included: (1) lack of access to services like on-site mental health counseling; (2) patients' difficulties communicating the way they're feeling to the provider; and (3) system-level barriers such as policies, practices, or procedures. Most participants confirmed that our interpretation was consistent with their experiences but wanted to point out that *"any negatives in no way outweigh the positives; not even close."*

Conclusions: Our findings demonstrate the importance of linking autistic patients with providers who are knowledgeable about autism to create positive healthcare experiences and rapport, thereby improving healthcare satisfaction. Additionally, we identified some aspects of CAST that can be targeted for continued improvement initiatives. In the short-term, our findings will help inform continued efforts to improve the quality of care provided to autistic adults who receive their healthcare through CAST. This work also adds to the growing body of literature demonstrating the effectiveness of patient-centered healthcare for autistic adults and the importance of having knowledgeable providers who are willing and able to care for this population.

## Social Cognition and Social Behavior

### PANEL SESSION — SOCIAL COGNITION AND SOCIAL BEHAVIOR

#### Panel 235 - Global Insights on Understanding and Reducing Autism Stigma

**Panel Chair:** Eilidh Cage, *Department of Psychology, University of Stirling, Stirling, United Kingdom*

**Discussant:** Jacqueline den Houting, *Macquarie University, Sydney, Australia*

Stigma involves the discrediting of an identity or a negative perception of differentness. Research shows that autism is a stigmatised identity, with non-autistic people holding both explicit and implicit negative biases against autistic people. Furthermore, stigma can be a life-limiting experience for autistic people: Exposure to stigmatising events and attitudes has been shown to relate to worse mental health outcomes and higher psychological distress for autistic people both in cross-sectional and longitudinal studies. Therefore, understanding stigma is an important endeavour within research, in order to reduce and prevent stigma. This panel brings together cutting-edge and novel research exploring autism stigma from the perspectives of non-autistic and autistic researchers, using a range of methods, in different settings, from multiple geographic regions. For example, the panel brings together research on stigma in educational settings in Scotland, the efficacy of a stigma-reducing intervention in non-autistic college students in the United States, qualitative experiences of stigma and community connectedness from a worldwide autistic sample, and a comparative cross-cultural study of stigma between the United States and South Korea. Insights from this panel will highlight means for reducing stigma and improving autism acceptance globally.

**235.001 (Panel)** “It’s Being a Part of a Grand Tradition, a Grand Counter-Culture”: A Qualitative Investigation of Autistic Community Connectedness, Stigma, and Identity

**M. Botha<sup>1</sup>, B. Dibb<sup>2</sup> and D. M. Frost<sup>3</sup>,** (1)*Psychology, University of Stirling, Stirling, United Kingdom,* (2)*School of Psychology, University of Surrey, Guildford, United Kingdom,* (3)*Thomas Coram Research Unit, University College London, London, United Kingdom*

**Background:** There is little research investigating the experiences of autistic community connectedness (ACC). This may be because autism is traditionally associated with lack of social motivation, or community. Yet, there are numerous social media groups, events, and community groups that autistic people use. Researchers, however, have yet to fully engage with the experiences that autistic people may have within this community. Studying community within minority groups is important because community may buffer against stigma.

**Objectives:** This study aimed to qualitatively investigate concepts of ACC in the autistic population.

**Methods:** Twenty autistic people were interviewed using a range of methods. Four formats for interviews were available – face to face, virtually using video-based software, over a text-based platform, or email. This was done to also allow for the inclusion of autistic individuals who struggled with face-to-face social interaction, who were situationally mute, or found text-based communication easier. We used critical grounded theory tools to guide study design and data analysis - including using theoretical sampling, and the constant comparative approach. Theoretical sampling means reviewing who has been included in a sample during data collection, and expressly aiming for particularly under-reached populations to ensure representative data. The constant comparative approach means continually reviewing the data as you collect it, and comparing it to what other participants are saying and what questions are being asked, and adapting the interview schedule according to data received by adding topics if they repeatedly come up. This allows the process to stay grounded in the data. The interviews were coded line by line, using grounded theory techniques to discern core categories, and sub-categories, and how they relate to each other.

**Results:** Core categories were ACC, stigma, and identity. Three elements of ACC were apparent in the data – belongingness, social, and political connectedness. Belongingness was described as a feeling of immense similarity to other autistic people. Social connectedness referred to the individual friendships formed within the community and included attending social events made by and for autistic people. Political connectedness referred to a connectedness to other autistic people as a minority group, and included activism around securing rights, reframing autism, reclaiming language, and combating stigma. Participants described the benefits of ACC as being increased self-esteem, a sense of direction, and access to a sense of community. Most participants were connected to the community in at least one way, yet two described themselves as completely unconnected. Stigma and discrimination seemed to push autistic people towards ACC, whereas an internalisation of that stigma seemed to push people away. The participants who were unconnected also did not consider autism central to their identity, unlike connected participants.

**Conclusions:** Despite autism being associated with a lack of motivation around friendships, there appears to be a vibrant autistic community. Three domains (belongingness, social, and political connectedness) appear to inform the broad construct of ACC. This community level togetherness may provide a form of social resource to help protect against stigma and discrimination, and work to further the political causes of the autistic community.

**235.002** (Panel) Investigating the Implicit and Explicit Attitudes of Primary School Educators in Scotland Towards Autism  
*E. Cage and T. Doyle, Department of Psychology, University of Stirling, Stirling, United Kingdom*

---

**Background:** In Scotland, autistic children and young people are most often taught in mainstream schools, with Scottish policy and legislation aiming for inclusion and equality. However, in recent years, issues with policy being reflected in reality have been highlighted, which has led to further efforts to improve the inclusion of autistic pupils. For example, the Scottish Government developed “The Autism Toolbox” in 2019 to support educator’s inclusive practices. Despite this, there have been few studies investigating the knowledge and attitudes of educators in Scotland towards autism, despite the fact that educator’s attitudes could be a significant barrier to effective inclusion.

**Objectives:** This study firstly aimed to investigate Scottish educator’s explicit and implicit attitudes towards autistic children. Secondly, we aimed to understand the relationships between educator’s attitudes, knowledge and experience.

**Methods:** Seventy primary school (i.e. elementary school) educators currently working in Scotland took part. The mean age was 43 and most were female ( $n = 64$ ), with an average 12 years of experience working in primary schools. Most participants were teachers (54%), but the sample also included other roles such as classroom support assistants (20%). The study was completed online and used both experimental and quantitative survey methods. Participants first completed a Single-Category Implicit Association Test (SC-IAT), designed to assess their implicit attitudes towards autistic children. They also completed two explicit attitude measures (behavioural intentions and cognitive attitudes towards educating autistic children), as well as measures of autism knowledge and their previous level of contact with autistic people.

**Results:** Overall, participants held positive attitudes towards autistic children in both explicit and implicit attitude measures. Some participants (24%) did express negative attitudes within the implicit measure – suggesting that they may have input socially desirable answers into the explicit measures. Correlation analyses indicated significant relationships between the explicit attitude measures (behavioural intentions and cognitive attitudes,  $p=.01$ ), but no relationships between the variables and implicit attitudes. Additionally, there were correlations between explicit attitudes, age and years of experience in education – such that older ( $p=.007$ ) and more experienced staff ( $p=.043$ ) had more negative attitudes. In regression analyses, only higher autism knowledge was a significant predictor of more positive explicit cognitive attitudes towards educating autistic children ( $p=.01$ ).

**Conclusions:** The findings indicate that in this sample, Scottish educators tended to have mostly positive explicit and implicit attitudes towards autism. Younger educators with less experience may in fact have more positive attitudes, perhaps reflecting societal changes in perceptions and greater exposure to autistic experiences in recent years. Enhanced knowledge also predicted more positive attitudes, replicating findings noted elsewhere in the literature. Together, these findings suggest that targeting knowledge may be an effective means of improving certain attitudes, and that Scotland’s educational policies do have the potential for supporting the inclusion of autistic children in schools. More work is needed with larger and more diverse samples of educators, as well as longitudinal research to monitor the ongoing effects of inclusive educational policy in Scotland.

**235.003** (Panel) Effects of Autism Acceptance Training on Explicit and Implicit Biases Towards Autism  
*D. R. Jones, K. M. DeBrabander and N. J. Sasson, University of Texas at Dallas, Richardson, TX*

---

**Background:** Despite efforts to improve autism awareness, stigma towards autistic people remains high (Gillespie-Lynch et al., 2020), with non-autistic (NA) individuals showing negative attitudes towards autistic people based on the behavioral and expressive differences that characterize autism (Sasson et al., 2017). These biases build exclusionary environments that contribute to poor personal and professional outcomes for autistic adults. However, because increased autism knowledge and familiarity are associated with more positive attitudes towards autistic people (Sasson & Morrison, 2019), training that targets these two factors may improve perceptions of autism.

**Objectives:** To determine whether training to improve autism knowledge and familiarity in NA adults is associated with more favorable attitudes about autism compared to general mental health awareness training and a no-training control condition.

**Methods:** 238 NA adults (mean age = 21.5) were randomly assigned to one of three conditions: 1) autism acceptance training (AAT), in which they viewed a 25-minute video featuring firsthand accounts from autistic adults (Boucher et al., 2020); 2) mental health training (MHT), in which they viewed a comparable video about mental health conditions other than autism; or 3) a

control condition, with no training video. After viewing the training, participants watched 20 brief videos of autistic adults and rated each on six social traits and provided their interest in interacting with them. Participants then completed measures assessing their autism knowledge, perceptions of autistic functional abilities, and autism stigma, as well as an implicit association task (IAT) to measure associations between autism and personal attributes.

**Results:** Participants in the AAT condition were less likely to agree with misconceptions about autism, including beliefs that autistic people are violent ( $p < .05$ ), do not show attachment ( $p < .01$ ), and are disinterested in friendship ( $p < .05$ ). AAT was also associated with more favorable explicit attitudes towards autistic people compared to both comparison conditions, including a higher desire to hang out with ( $p < .01$ ) or start a conversation with autistic adults ( $p < .05$ ), a greater openness to marry or date an autistic person ( $p < .05$ ), and greater perceptions of autistic social abilities ( $p < .05$ ).

In contrast, AAT was not associated with significant differences in implicit biases. Here, an association between autism and unpleasant personal attributes was detected ( $p < .001$ ) and did not differ significantly between training conditions.

**Conclusions:** While interventions to improve the social experiences of autistic adults have typically focused on encouraging autistic people to adopt more normative behaviors, the current study implements a training program focused on the behaviors of *non-autistic* adults. Here, we found that a brief video training was associated with more accurate autism knowledge and more favorable attitudes towards autism compared to both a general mental health training video and a control condition. However, the benefits of training were restricted to explicitly held attitudes, with negative implicit beliefs about autism present across training groups. It is unknown whether the training program would produce lasting effects or translate to increased inclusivity in real-world environments. Future studies investigating these effects are encouraged.

**235.004 (Panel)** A Cross-Cultural Comparison of Stigma Toward Autism in the US and South Korea

**S. Y. Kim<sup>1</sup>, J. E. Cheon<sup>2</sup>, K. Gillespie-Lynch<sup>3</sup> and Y. H. Kim<sup>2</sup>,** (1)Duksung Women's University, Seoul, Korea, Republic of (South), (2)Yonsei University, Seoul, Korea, Republic of (South), (3)Department of Psychology, College of Staten Island; CUNY Graduate Center, Brooklyn, NY

---

**Background:** Stigma, defined as an attribute that is deeply discrediting (Goffman, 1963), negatively influences autistic individuals by instigating poor mental health, social exclusion, and discrimination. People in cultures that are considered more collectivistic tend to report higher autism stigma than people in the United States (US) (Someki et al., 2018). However, recent work suggests that a different cultural dimension than collectivism, vertical orientation, or accepting competition as a natural part of human interactions, predicts heightened autism stigma (Gillespie-Lynch et al., 2019). Through interviews with mothers of autistic children in South Korea, Grinker and Cho (2013) provided evidence that autism stigma is heightened in South Korea. They speculated that Korean mothers might reject the autism label to separate their children from a diagnosis they believe is hereditary and to protect the marriageability of relatives while avoiding community concerns about how an autistic child might impact other children's academic productivity. Despite these intriguing findings, no previous studies have compared autism stigma in South Korea to other cultures. Therefore, we conducted a cross-cultural comparison of autism stigma (i.e., desired social distance) in South Korea, a relatively collectivistic and ethnically homogeneous country, and in the US, a relatively multicultural and individualistic country.

**Objectives:** We aimed to: 1) determine if autism stigma is higher in South Korea than in the US, 2) examine if predictors identified in previous autism stigma literature (i.e., gender, autism knowledge, pleasantness and quantity of previous contact, openness to experiences, vertical individualism, horizontal collectivism, and concerns about productivity and bloodline) and 3) the broader prejudice literature (i.e., cultural tightness, or strict belief in societal norms, in-group enhancement, and out-group derogation) are associated with autism stigma.

**Methods:** Two-hundred ninety-six American and 494 Korean participants completed online surveys using Amazon's MTurk and Data Spring, respectively. Table 1 presents participant characteristics and a complete list of variables measured. A multiple regression predicting stigma was conducted with variables that were significantly correlated with stigma entered as predictor variables.

**Results:** Koreans reported higher autism stigma than Americans. As expected, the belief that an autistic person negatively impacts the romantic prospects of family members was associated with heightened stigma. Unexpectedly, this belief was heightened in the US relative to Korea. Heightened vertical individualism, lesser accurate autism knowledge, less pleasant and frequent previous contact with autism, and higher cultural tightness predicted greater stigma (Table 2).

**Conclusions:** As Grinker and Cho (2013) predicted, Koreans reported heightened autism stigma but only partially due to the reasons suggested in their qualitative work. Unexpectedly, Americans more strongly viewed autism as hereditary and as negatively impacting romantic prospects than Koreans. Cultural tightness, which is believed to be activated by ecological

catastrophes and predicts prejudice towards a range of other minority identities (Jackson et al., 2019), was associated with autism stigma. Given the ecological catastrophes we are currently facing, efforts to increase autism knowledge and foster pleasant and frequent contact with autistic individuals are needed to combat potential tendencies toward increases in autism stigma in both the US and South Korea.

## POSTER SESSION — SOCIAL COGNITION AND SOCIAL BEHAVIOR

### Poster 443 - Social Cognition and Social Behavior Posters

**443.001** (Poster) A Cross-Cultural Comparison of the Relation between Autistic Traits and Adherence to Politeness Norms  
**K. R. Warnell<sup>1</sup>, J. M. Clegg<sup>1</sup> and R. Kok<sup>2</sup>,** (1)Department of Psychology, Texas State University, San Marcos, TX, (2)Department of Psychology, Education and Child Studies, Erasmus University Rotterdam, Rotterdam, Netherlands

**Background:** Recent research on autism spectrum disorders (ASD) has drawn attention to camouflaging, or deliberately enacting neurotypical social behaviors (e.g., Hull et al., 2017; Lai et al., 2017). Such literature suggests that heightened autistic traits may result in over-adherence to social rules, even in situations that neurotypical individuals think merit exceptions. A contrary hypothesis—stemming from more conventional literature on social cognition in ASD—is that increased levels of autistic traits should predict increased difficulty with social norms. The norm of prosocial lying (e.g., lying to be polite) presents an interesting test of these two perspectives, as prosocial lying is a complex behavior with strong culturally-influenced expectations (Szarota & Cantarero, 2019). Examining the relation between autistic traits and prosocial lying can offer insight into social understanding and deliberate social performance in ASD.

**Objectives:** We examined the relation between prosocial lying and autistic traits in the U.S. and the Netherlands, two countries which differ on norms surrounding lying to be polite.

**Methods:** American participants ( $N=261$ , 148 males, aged 21-71, mean=36.5y) and Dutch participants ( $N=178$ , 41 males, aged 19-78, mean=39.8y) completed an online survey in which they reported on their likelihood of telling prosocial lies versus blunt truths across various scenarios (e.g., receiving a disappointing gift; giving feedback about a bad drawing). Participants also completed the Autism Quotient (AQ; Baron-Cohen et al., 2001; Hoekstra et al., 2008) to assess autistic traits. Participants were from the general population given that camouflaging may impact a broad spectrum of individuals.

**Results:** We first examined cultural differences in prosocial lying tendencies, collapsing across social scenarios. Consistent with past work, we found that Americans were significantly more likely to report both outright lying and masking (e.g., changing the subject; Wice et al., 2019) than Dutch respondents (masking Cohen's  $d=.60$ ). For Americans, increased autistic traits were associated with increased masking ( $r=.18$ ,  $p=.003$ ), particularly when giving feedback and discussing politics. In contrast, for the Dutch sample, AQ scores were not related to any specific prosocial lying strategies, and the difference in correlations between cultures was significant ( $p<.05$ ). This cross-cultural patterns of results held when examining male and female participants separately.

**Conclusions:** In American culture, social norms emphasize avoiding blunt truths and Americans with more autistic traits showed increased adherence to this norm via increased prosocial lying and masking. In contrast, heightened ASD traits were not related to prosocial lying behaviors in a Dutch sample, a culture which does not have such strong prosocial lying norms. These results suggest that individuals with ASD may show an adherence to culturally-emphasized social norms exceeding that of neurotypical individuals, potentially due to internalizing scripts governing interaction (e.g., do not tell hurtful truths). Our results are contrary to the hypothesis that increased ASD traits would relate to decreased sensitivity to social rules, but results may vary in clinical populations. Future work should consider the real-world prevalence of prosocial lying, given clinical work on prosocial lying in ASD (Bergstrom et al., 2016), as well as interpersonal consequences of over-adherence to social norms.

**443.002** (Poster) ASD Traits Predict Preference Towards Social Mimicry in a Subclinical Sample  
**L. H. Tan<sup>1</sup>, R. M. Ford<sup>1</sup>, A. Morrison<sup>2</sup> and S. D. Stagg<sup>3</sup>,** (1)Psychology, Anglia Ruskin University, Cambridge, United Kingdom, (2)Sports and Exercise Science, Anglia Ruskin University, Cambridge, United Kingdom, (3)Anglia Ruskin University, Cambridge, United Kingdom

**Background:** Individuals on the autism spectrum (ASD) show reduced tendency to spontaneously mimic others during social interaction (Hamilton, 2008). Ability to naturally mimic the actions of others within the context social communication confers benefits. It helps individuals form meaningful connections (Ashton-James et al., 2007), and creates generally favourable impressions of social interactions (Chartrand & Bargh, 1990). To-date no research has investigated whether poor social mimicry

skills are specific to autism or are a part of broader autism phenotype. To investigate responses to social mimicry, we employed a novel paradigm based on first impression ratings of social interaction. The experiment contained two critical conditions. Actors engaged in social interaction with mimicry present or in social interaction with no mimicry present. We hypothesised that given social mimicry indicates increased empathy and friendship between engaged parties (Chartrand & Bargh, 1999), participants would rate images containing mimicry more favourably than images where mimicry was not present.

**Objectives:** The study aimed to determine if images of individuals engaged in social mimicry would be rated more favourably than those engaged in interaction with no social mimicry. Further we investigated whether responses were modulated by traits associated with ASD.

**Methods:** 35 participants were recruited with age ranging 18 to 55. Participants completed the Autism Quotient. Four conditions were used in the study. These include images of individuals interacting with observable acts of social mimicry and individuals interacting without social mimicry. Images in these two conditions was reversed so that the two actors in each picture were facing away. The study employed a within participant design and participants viewed all images. Each image was displayed for 500ms and were asked to rate on a 7-point Likert Scale with “How pleasant do you find the image?”.

**Results:** As predicted, participants rated social mimicry images more favourably ( $M = 4.71, SD = .58$ ) than interaction images ( $M = 4.17, SD = .54$ ) and the results was statistically significant, ( $p = .006$ ). Participants were divided using median split (mdn = 21) of the AQ scores. Low AQ group rated the mimicking images more favourably ( $M = 5.03, SD = .46$ ) than high AQ group ( $M = 4.45, SD = .55$ ) and the result was statistically significant ( $p = .002$ ). Correlation analysis, including all participants, demonstrated strong negative correlation ( $r = -.71, p < .01$ ) between first-impression rating of social mimicry images but not between AQ and interaction only images ( $r = -.13, p = .47$ ).

**Conclusions:** To our knowledge, our study is the first to show that social mimicry affects the impressions viewers, who are not part of the interaction. Importantly the study demonstrates that this appreciation of social mimicry is reduced in individuals who do not have autism but score high in autism traits. Our study suggests that individuals with high autistic traits may experience different perception of social interaction and are less likely to pick up cues that indicate positive/friendly interaction. Further research is needed to determine whether lack of appreciation for these cues results in alerted social attention.

**443.003 (Poster)** Application of the Joint Engagement Rating Inventory to Preschool- and School-Aged Children with Autism Spectrum Disorder and Typical Development during a Parent-Child Free Play Interaction

*M. Sabatos-DeVito<sup>1</sup>, A. Bey<sup>2</sup>, R. Simmons<sup>3</sup>, J. Troy<sup>2</sup>, C. Sullivan<sup>2</sup>, S. Compton<sup>4</sup>, K. L. Carpenter<sup>1</sup>, M. Spanos<sup>4</sup>, L. Franz<sup>5</sup>, N. O. Davis<sup>6</sup>, R. E. Aiello<sup>1</sup>, L. Sikich<sup>1</sup>, S. H. Kollins<sup>6</sup> and G. Dawson<sup>1</sup>, (1)Psychiatry and Behavioral Sciences, Duke Center for Autism and Brain Development, Durham, NC, (2)Duke University, Durham, NC, (3)Department of Biostatistics and Bioinformatics, Duke University, Durham, NC, (4)Department of Psychiatry and Behavioral Sciences, Duke Center for Autism and Brain Development, Durham, NC, (5)Duke Center for Autism and Brain Development, Department of Psychiatry and Behavioral Sciences, Duke University, Durham, NC, (6)Department of Psychiatry and Behavioral Sciences, Duke ADHD Program, Duke University Medical Center, Durham, NC*

Background:

Parent-child interactions (PCI) are used to measure social and communication development (e.g., Adamson et al., 2004, 2010). Engagement states coding (Bakeman & Adamson, 1984) quantifies joint attention and social communication of infants, toddlers, and young children with autism spectrum disorder (ASD) during PCIs (e.g., Kasari et al., 2010, 2015). The Joint Engagement Rating Inventory (JERI; Adamson et al., 2018) is a seven-point scale measuring the quantity and quality of engagement states, and child-specific and dyadic behaviors. To date, the JERI has been used with toddlers and preschoolers; less is known about the JERI as a measure of preschool- and school-aged children’s social engagement.

Objectives:

In two studies, we examined how the JERI performed as a measure of social behaviors of preschool- and school-aged children with ASD (Study 1 and 2) and typical development (TD; Study 2) during PCIs. In both studies, we examined relationships between JERI items and clinical measures in ASD children. In Study 2, we explored JERI-derived composites and compared scores in ASD and TD groups.

Methods:

Participants included children with ASD (Study 1: N=145, Mean (Range) Age=63.73 (27-95) months; Study 2: N=81, Age = 71.68 (41-99) months) and TD (Study 2: N=18, Age=66.5 (37-96) months). A six-minute, lab-based, parent-child free play was rated using JERI items (Study 1: seven items; Study 2, eleven items). Clinical measures included: Vineland Adaptive Behavior Scales (VABS); Differential Abilities Scale-II (DAS-II)/Mullen Scales of Early Learning (MSEL); Clinical Global Impressions – Severity (CGI-S); Aberrant Behavior Checklist (ABC); Pervasive Developmental Disorder Behavior Inventory (PDDDBI). Analyses include descriptive statistics and Spearman correlations of JERI items with clinical measures, and ANCOVA comparing ASD and TD groups.

#### Results:

Distributions of JERI scores vary for items and groups (Tables 1, 2). For both ASD groups, JERI items and composites correlate with clinical variables in similar patterns (Table 1, 2). In Study 1, older age correlates with higher coordinated and symbol-infused joint engagement (JE) and lower unengaged (UN) ratings. In Study 2, older age correlates with higher ratings of all JE items, expressive language level (ELL), dyadic fluency/connectedness (FC), and both composites. In both studies, higher nonverbal cognition (NVIQ) and higher VABS socialization and communication correlate with higher JE and attention to caregiver (ATC), and lower UN. In Study 2, higher NVIQ and VABS scores also positively correlate with ELL, FC, responsiveness to partner's communication (RPC), and composites. ASD/TD group differences include JE, supported JE, ATC, RPC, and composites ( $F_s = 10.96-19.36$ ,  $p_s = .0001-.001$ ). Remaining JERI items have main effects of age and/or group. A main group effect and group by age interaction were detected for FC.

#### Conclusions:

Results demonstrate that the JERI can be used in preschool- and school-aged children with ASD and TD with some coding modifications to accommodate for wider language, age and developmental levels. For both ASD groups, JERI items correlate with age, developmental level, and clinical measures. JERI items and composites also distinguish ASD from TD groups. Composite JERI variables should be assessed for their ability to measure change in response to ASD interventions.

**443.004** (Poster) Attentional Bias to Positive and Negative Social Scenes Differs Based on Traits Related to Social Anxiety  
**J. Burk<sup>1</sup>**, **G. Haffner<sup>1</sup>**, **C. Dintino<sup>1</sup>** and **C. L. Dickter<sup>2</sup>**, (1)William & Mary, Williamsburg, VA, (2)College of William and Mary, Williamsburg, VA

---

**Background:** The social avoidance behaviors exhibited by individuals with autism spectrum disorder (ASD) closely resemble phenotypes of social anxiety disorder (SAD), a condition often co-morbid with ASD. Individuals with ASD and SAD have consistently shown variance in their implicit attentional biases to emotional facial stimuli although less research has investigated attentional biases to social scenes.

**Objectives:** The purpose of this study was to test whether participants varying in traits related to autism and social anxiety experience an attentional bias related to positive and negative images depicting social and non-social scenes.

**Methods:** Undergraduate students ( $n=146$ ) completed a dot probe task. Images were selected from the International Affective Picture Systems. For each trial, two images were presented on either side of a computer screen. Whether the images were shown on the left or right was randomized, as well as where the dot was placed. In each trial, one image was always neutral, paired with either a positive or negative image. Images were presented for 500 ms before a dot appeared on one side of the screen. Participants then responded to where the dot was presented, and response time and accuracy were measured. Each participant then completed the Social Phobia and Anxiety Inventory (SPAI), Autism Quotient (AQ), and Broad Autism Phenotype Questionnaire (BAPQ).

**Results:** A 2 (Target Valence: Positive, Negative) x 2 (Target Subject: Person, Non-Person) x 2 (Non-Target Subject: Person, Non-Person) x SPAI mixed-model ANOVA with SPAI as a within-subjects variable was conducted. Results revealed a marginally significant 4-way interaction. When the analyses were conducted for Target Non-Person, there was no 3-way interaction. However, for Target Person, there was a marginally significant 3-way interaction,  $F(1, 138) = 2.82$ ,  $p = .095$ . For the positive target, there was not a 2-way interaction but for the negative target there was a significant Non-Target Subject x SPAI interaction,  $F(1, 138) = 4.72$ ,  $p = .032$ . For the condition in which the non-target did not depict a person there was not a significant correlation between social anxiety and attentional bias to the targets,  $r = -.10$ ,  $p = .242$ . When the non-target did show a person there was a significant correlation, such that participants with more social anxiety showed more attentional bias when there were negative targets depicting people when the non-target depicted a person,  $r = .21$ ,  $p = .011$ . There were no significant effects associated with measures of autistic behaviors.

Conclusions: The present results contribute to a growing literature that, although there is a clear correlation between autistic traits and social anxiety, these measures predict different outcomes on behavioral tasks. Therefore, it appears that there are underlying differential processing differences between mechanisms that contribute to autistic behaviors and those that contribute to social anxiety that need to be further elucidated. The present findings indicate that the SAD related traits showed more attentional bias towards stimuli that were negatively valenced that depicted people, fitting well into the existing literature that suggests anxiety in SAD is mediated by fear of negative evaluation by peers.

443.005 (Poster) Autism/Autistic Traits and Belief in a Just World  
A. Bertrams, University of Bern, Bern, Switzerland

---

### **Background:**

In the social psychology literature, “general belief in a just world” refers to a self-serving illusion whereby, in general, people get what they deserve. A strong belief in a just world can be beneficial to one’s subjective well-being, but it can also increase one’s tendency to unjustifiably blame victims for their fates. In sum, believing that the world is generally just is a fallacy with both positive and negative implications.

Formally diagnosed autistic people and undiagnosed people high in autistic traits may be less likely to believe that the world is generally just compared to non-autistic people and people low in autistic traits. The literature suggests four reasons for this: autistic people and people high in autistic traits perceive themselves to be treated less justly (i.e., they possess a weaker “personal belief in a just world”), have a higher external locus of control, tend to be less self-deceptive, and tend to be less influenced by their environments in terms of social norms.

### **Objectives:**

Two studies investigated the hypothesis that autistic people and people high in autistic traits are less likely to believe in a generally just world than non-autistic people and people low in autistic traits. In addition, potential reasons for this assumed relationship were analyzed.

### **Methods:**

Study 1: A diverse sample of 588 participants from the USA (including 60 with formal autism diagnoses) completed established psychometric scales on general belief in a just world and autistic traits. A subsample of 388 participants also completed scales on personal belief in a just world, locus of control, and the tendency for self-deception.

Study 2: A diverse sample of 249 participants from the USA (social norm: strong belief in a just world) and 241 participants from Great Britain (social norm: weak belief in a just world) completed scales on general belief in a just world and autistic traits.

In addition, in the two studies, control variables, such as cognitive ability, were assessed.

### **Results:**

Study 1: Formally diagnosed autistic participants were less likely to believe in a generally just world than non-autistic participants,  $p < 0.001$ ,  $d = 0.73$ . Among non-autistic participants, autistic traits correlated negatively with general belief in a just world,  $r = -0.23$ ,  $p < 0.001$ . As expected, these relationships were mediated by personal belief in a just world, locus of control, and the tendency for self-deception.

Study 2: As expected, the cultural environment moderated the negative relationship between autistic traits and general belief in a just world (USA:  $\beta = -0.25$ ,  $p < 0.001$ ; Great Britain:  $\beta = -0.07$ ,  $p = 0.24$ ); see Figure 1.

### **Conclusions:**

In cultural environments where general belief in a just world is relatively pervasive, autistic people and people high in autistic traits seem to be less likely to internalize the social norm of belief in a just world. These studies point to autistic strengths (realistic views and a low tendency for self-deception) and well-being risks (weak self-serving views). Self-honesty and views on justice may play relevant roles in autism-related therapies.

**443.006 (Poster)** Autistic Adults, but Not Non-Autistic Adults, Accurately Detect Social Interest of Conversational Partners  
*K. M. DeBrabander, K. E. Morrison, D. R. Jones and N. J. Sasson, University of Texas at Dallas, Richardson, TX*

---

**Background:** High meta-accuracy, or the degree to which individuals perceive how they are viewed by others (Vazire & Carlson, 2010), is associated with positive social interaction outcomes (Steinmetz et al., 2017). In autism, studies of meta-accuracy have produced mixed results, with those measuring it in real-world scenarios (Usher et al., 2018) failing to show the impairments reported from more indirect assessments (Locke & Mitchell, 2016; McMahon & Solomon, 2015; Sasson et al., 2018).

**Objectives:** The current study examines metaperceptive abilities of autistic and non-autistic (NA) adults during real-world social interaction.

**Methods:** Sixty-seven autistic males and 58 NA males comparable on race and IQ were assigned to one of three dyadic conditions: autistic only (22 pairs), NA only (23 pairs), or autistic and NA (25 pairs). Participants completed a 5-minute “get-to-know-you” conversation with an unfamiliar partner, then evaluated the interaction and their partner using The Social Interaction Evaluation Measure (SIEM) and the First Impression Scale (FIS), with both measures also reworded participants to assess metaperceptions. Finally, the Beck Depression Inventory (BDI) was completed to control for depression in analyses.

**Results:** Data were analyzed using dyadic analysis and the truth and bias model. Participants who rated the interaction as higher quality, and their partners as more attractive and trustworthy, predicted that their partners would rate them positively on these items. However, participants underestimated how their partner perceived the quality of the interaction ( $p < .001$ ) and overestimated how dominant/aggressive ( $p = .008$ ) they were perceived. NA’s metaperception for intelligence was negatively related to partner’s ratings, such that NA participants who perceived themselves to be more intelligent were rated as less intelligent by partners ( $b = -.038$ ,  $SE = .015$ ,  $p = .02$ ), but this relationship was not found for autistic adults ( $b = .18$ ,  $SE = .13$ ,  $p = .16$ ). An interaction of actor diagnosis with the partner’s social interest ( $p = .003$ ) revealed that autistic actors’ metaperception for social interest was related to how their partners evaluated them ( $b = .47$ ,  $SE = .17$ ,  $p = .007$ ), such that autistic adults were accurate in predicting their partners’ social interest (e.g., autistic adults who believed their partner would rate them low on social interest actually did rate them low). This did not occur for NA participants.

**Conclusions:** These findings indicate that for some traits and social interest, both autistic and NA adults use their own perceptions as a baseline for predicting how they are perceived by others. In contrast, meta-accuracy for social interest differed between the autistic and NA participants regardless of the diagnosis of their partner. Autistic adults, but not NA adults, accurately predicted when their partner expressed low interest in future interaction with them.

This higher level of meta-accuracy for social interest among autistic adults is inconsistent with a social cognitive deficit model and differ from the “self-enhancement bias” found in NA adults in which they tend to overestimate how others’ perceive them. Findings from this study suggest that social interaction difficulties for autistic adults are likely driven by complex and dynamic processes rather than a simple social deficit model.

**443.007 (Poster)** Autistic Community Connectedness As a Moderator of the Effect of Minority Stress on Mental Health in the Autistic Population

*M. Botha<sup>1</sup>, B. Dibb<sup>2</sup>, P. Rusconi<sup>3</sup> and D. M. Frost<sup>4</sup>, (1)Psychology, University of Stirling, Stirling, United Kingdom, (2)University of Surrey, Guildford, United Kingdom, (3)School of Psychology, University of Surrey, Guildford, United Kingdom, (4)Thomas Coram Research Unit, University College London, London, United Kingdom*

---

**Background:** Autistic people often have worse mental health than non-autistic people. Stigma, discrimination may play roles in mental health. The minority stress (MS) model predicts that socially marginalised groups will be exposed to an increased stress burden, while having fewer social resources with which to cope, resulting in health disparities. Previously, extending the MS model to understand mental health in the autistic community proved useful. In a cross-sectional study, exposure to MS explained a significant and large degree of the variance of mental, social, and emotional health. There was no non-autistic comparison group however, and the study did not take in to account potential community level coping resources, such as community connectedness. Intra-community connectedness may help to ease the burden of minority stress.

**Objectives:** This study aimed to investigate whether there are intergroup differences in mental health, wellbeing, and social resources (as the MS model hypothesized) between a comparative autistic and non-autistic sample. It also aimed to test whether MS predicted worse mental health in the autistic community, and whether ACC moderated the impact of MS on mental health.

**Methods:** A sample of 195 autistic and 188 non-autistic people was used. Validated scales of MS, social resources, mental health, and ACC were administered. While we administered measures of social resources to test whether there was a gap in social

resource scores, ACC was the only social resource we had interest in testing moderation for specifically because it is a community level resource. Focusing on individualistic social resources can result in victim blaming minorities for worse outcomes. It was hypothesized that the autistic cohort would have significantly lower mental health and social resource scores, that minority stress would predict a significant variance of mental health scores, and that higher ACC would moderate the impact of MS on mental health.

**Results:** The autistic sample were more likely to be above the threshold indicating severe psychological distress, higher depression, and lower psychological, social, and emotional wellbeing, and rated themselves as having significantly lower social resources compared to the non-autistic sample, with the exception of resilience (with medium to large effect sizes). Moderated hierarchical regression analysis showed that exposure to MS predicted a large degree of variance in mental health and wellbeing in the autistic sample, despite controlling for key demographics and general life stress, and lastly, that higher ACC moderated the impact of MS on mental health.

**Conclusions:** There are large disparities in the mental health, wellbeing, and social resources between autistic and non-autistic people. Autistic participants were more likely to have mental health scores suggestive of mental ill-health, and lower social resources. The MS model continues to provide a coherent theoretical and empirical model for understanding mental health in autism. Despite the autistic community being associated with a lack of community, this research demonstrates the utility of ACC. The results suggest that addressing systemic inequality that results in stigma, discrimination, while promoting autistic community connectedness MS may be key to addressing mental health disparities in the autistic community.

**443.008 (Poster)** Autistic Girls Smile More Than Autistic Boys during Natural Conversations: Insights from Computer Vision  
*C. J. Zampella, J. Parish-Morris, J. Foy, M. L. Cola, A. Riiff, M. Haley, A. Hutchinson, M. Leuzzi, L. S. Cubit, A. Hulick, K. Bartley, J. Pandey, R. T. Schultz and J. D. Herrington, Center for Autism Research, Children's Hospital of Philadelphia, Philadelphia, PA*

---

**Background:** Autism in females is understudied and poorly understood, leading to underdiagnosis and missed intervention opportunities. This may stem from autistic females displaying more contextually appropriate social cues, sometimes attributed to “camouflaging” or actively conforming to social expectations. We examined the effects of sex and autism diagnosis on a key social behavior that carries gendered expectations – smiling. We hypothesized that autistic females would conform to typical sex-based social norms, by smiling more often – and more typically – during social interactions compared to autistic males.

**Objectives:** (1) Use novel computational methods to characterize smiling behavior during brief, naturalistic conversations; (2) Test for sex differences in the magnitude and quality of smiling behavior using a 2 (autism/neurotypical) x 2 (male/female) design; (3) Examine how smiling behavior influences social partners’ perceptions of autistic males and females.

**Methods:** We used state-of-the-art computer vision to characterize smiling in 60 autistic (20 female) and 67 age- and IQ-matched neurotypical (25 female) participants during unstructured conversations with unfamiliar, non-expert adults. Immediately following the conversation, the adult completed a brief rating scale regarding his/her perception of the quality of the interaction. Autistic males and females were matched on autism characteristics per established clinical scales (ADOS-2, SCQ). Using automated facial analysis, smiling was digitized frame-by-frame and operationalized as the average magnitude (area under the curve) of the two standard facial movements that comprise a smile (lip corner pulling and cheek raising). Smile quality was operationalized as the degree of correlation between the activity in these two standard facial movements (because co-occurring activity across these two locations constitutes a prototypical smile).

**Results:** A diagnosis x sex ANOVA indicated that females smiled more than males ( $p=.01$ ,  $\eta^2=.09$ ) and neurotypical participants smiled more than autistic participants ( $p<.001$ ,  $\eta^2=.05$ ), with no diagnosis x sex interaction. Autistic females’ smiling was increased relative to autistic males ( $p<.01$ ), and was more comparable to neurotypical males. The same pattern emerged for smile quality – smiles were more prototypical in females relative to males ( $p=.02$ ,  $\eta^2=.05$ ) and in neurotypical participants relative to autistic participants ( $p<.001$ ,  $\eta^2=.09$ ), with no interaction. Spearman correlation indicated that the relationship between smile magnitude and interaction quality ratings approached statistical significance within the autism group as a whole ( $r_s=.27$ ,  $p=.067$ ). However, when the same analysis was broken down by sex, this pattern seemed to be driven only by autistic males ( $r_s=.30$ ,  $p=.108$ ) and not autistic females ( $r_s=-.07$ ,  $p=.80$ ).

**Conclusions:** Results suggest that sex-based societal display rules for normative facial expressiveness may leave autistic females appearing more typical in their social behavior than male peers. Failing to analyze autistic males and females separately (and compared to sex-matched peers) may mask important differences in their behavior, and in how they are perceived by social partners. Furthermore, the failure of established autism assessments to consider sex differences in core social behaviors may drastically reduce sensitivity for detecting autism in females. Objective, granular computational behavior analysis has vast

potential for detecting these underrecognized sex differences in autism.

**443.009 (Poster) Autistic Traits, Psychosocial Factors, and Depressive Symptoms**

**L. Camus<sup>1</sup>, E. O'Dowd<sup>2,3</sup>, K. Jones<sup>1</sup>, B. Auyeung<sup>3</sup>, G. Rajendran<sup>1</sup> and M. E. Stewart<sup>1</sup>,** (1)Psychology, Heriot-Watt University, Edinburgh, United Kingdom, (2)Discipline of General Practice, National University of Ireland, Galway, Ireland, (3)University of Edinburgh, Edinburgh, United Kingdom, (4)Heriot-Watt University, Edinburgh, United Kingdom of Great Britain and Northern Ireland

---

**Background:** Higher rates of depression and of depressed mood are associated with autism and autistic-like traits (Lever & Geurts, 2016; Lundström et al., 2011). In addition, both autistic traits and depressive symptomology are associated with social interaction factors, such as social self-efficacy (Rosbrook & Whittingham, 2010), social motivation (Corbett et al., 2014, Swain et al., 2015) and loneliness (Hedley et al., 2018; Reed et al., 2016). Those with autistic-like traits may differ in both their social motivation and social self-efficacy when interacting with others which may in turn have an impact on depression and loneliness. It is important to test the pathways between autistic-like traits, psychosocial difficulties and depressed mood.

**Objectives:** 1) Test whether autistic-like traits are correlated with social self-efficacy, social motivation, and loneliness; 2) Determine potential pathways linking autistic-like traits to depressive symptoms via psychosocial predictors.

**Methods:** 660 participants (529 women) completed measures of autistic-like traits (AQ), social self-efficacy (Social Self-Efficacy Scale), social motivation (Social Striving Assessment Scale), loneliness (UCLA Loneliness Scale) and depressive symptoms (Beck Depression Inventory II). Relationships between psychosocial factors and depressive symptoms were examined with linear regressions. The potential pathway of these relationships was then assessed using a mediation analysis.

**Results:** Autistic traits ( $\beta = .21, t(653) = 10.53, p < .001$ ) and loneliness ( $\beta = .45, t(594) = 7.34, p < .001$ ) were positively related to depressive symptoms, while social self-efficacy ( $\beta = -.28, t(602) = -11.4, p < .001$ ) and social motivation ( $\beta = -.37, t(531) = -7.33, p < .001$ ) were negatively related. The relationship between autistic traits and depressive symptoms was fully mediated by the other three factors ( $\beta[\text{indirect}] = .005, z = 2.63, p < .01$ ;  $\beta[\text{direct}] = .05, z = 1.58, p > .05$ ), forming a pathway from autistic-like traits, to social self-efficacy, to social motivation, to loneliness and finally to depressive symptoms.

**Conclusions:** Results indicate that autistic-like traits are related to depressive symptoms via social self-efficacy, social motivation, and loneliness. These results suggest that targeting social self-efficacy may break this pathway and disrupt this relationship. Interventions should consider the double empathy problem when addressing social domains to provide adapted support (Crompton et al., 2020; Milton, 2012).

**443.011 (Poster)** Behavioral Synchrony and Empathic Response to an Interaction Partner's Distress in Adolescents with and without ASD

*E. Zadok<sup>1</sup>, I. Gordon<sup>1,2</sup>, R. Navon<sup>1</sup>, S. J. Rabin<sup>1</sup> and O. Golan<sup>1</sup>, (1)Department of Psychology, Bar-Ilan University, Ramat-Gan, Israel, (2)Gonda Brain Research Center, Bar-Ilan University, Ramat Gan, Israel*

---

**Background:**

Behavioral synchrony, the spontaneous coordination and congruence of behaviors between interacting partners in both form and timing, is an important component of successful social interaction, which has been linked to perspective taking and expressions of empathy. Notably, it has been suggested that flexibly going in and out of synchrony reflects adaptive social reciprocity and fosters empathic response. Behavioral synchrony and flexibility in synchronization, as well as empathic behavior, has been shown to be altered in many individuals with ASD. However, findings are mostly based on questionnaires and computerized tasks, and further examinations using ecologically valid paradigms are needed.

**Objectives:**

To examine behavioral synchrony dynamics during social interaction in two contexts – friendly conversation, and empathic concern.

**Methods:**

Twenty-two adolescent males with ASD (clinical diagnosis verified using ADOS-2) with no intellectual impairment, and twenty-two typically developing (TD) male controls, matched on age and cognitive abilities, were video-recorded while participating in a social interaction sequence that included a friendly conversation with a confederate, a sudden expression of distress by the confederate (following a disturbing text message), and a return to a friendly conversation. Socio-emotional behaviors during these three stages were coded minute by minute by trained blind raters, for participants' commenting and asking questions, prosocial behavior and synchronization of nonverbal behavior. In addition, movement synchrony was analyzed using Motion Energy Analysis (MEA; Ramseyer, 2020), an automated method quantifying frame-to-frame difference.

**Results:**

On average, adolescents with ASD were rated as less synchronized with the social partner throughout the interaction. Group by stage interaction was found, revealing that while TD adolescents were less synchronized in the distress stage compared to the friendly stages, adolescents with ASD maintained constant, and lower, levels of synchrony (Figure 1). Contrarily, groups did not differ on empathic behavior ratings. MEA revealed diminished movement synchrony in the ASD group compared to controls, as well as an interaction effect: while TD adolescents showed less synchrony in the distress stage compared to the friendly stages, no such difference was found in the ASD group (Figure 2).

**Conclusions:**

Adolescents with ASD displayed lower levels of synchrony with the social partner. Moreover, whereas TD adolescents displayed shifts in synchrony when facing the social partner's distress, among adolescents with ASD such shifts were not observed. These patterns were found both for behavioral coding and for MEA analysis. Contrarily to previous studies, empathic behavior did not differ between groups. It is possible that adolescents with ASD relied adequately on social knowledge regarding *what* to say to the distressed other, but struggled with *how* to say it, i.e., with timing and coordinating the response with non-verbal aspects of communication, of one's own and of the social partner.

**443.012 (Poster)** Biological Motion and Action Perception in Autism: A Systematic Review

*Y. Bai<sup>1</sup>, E. Gowen<sup>2</sup> and E. Poliakoff<sup>2</sup>, (1)The university of Manchester, Manchester, United Kingdom, (2)Division of Neuroscience and Experimental Psychology, University of Manchester, Manchester, United Kingdom*

---

**Background:** Detecting and recognising the movements of other people is essential for understanding other's actions or intentions and giving appropriate reactions during social interaction. Biological Motion (BM) is Point-light displays (PLDs) are commonly used to test the BM which contained low-level form and kinematic information. Researchers found humans can easily recognise actions and emotions from these PLDs, and could easily recognise actions and the gender of actors from PLDs as well as emotions.

**Objectives:** Previous research suggests that autistic individuals have reduced biological motion perception compared to non-autistic individuals. The current review aimed to explore whether task and stimulus characteristics influence group differences in BM processing ability and whether BM processing ability in autistic individuals is related to non-biological motion processing ability.

**Methods:** This systematic review was conducted according to PRISMA guidance during June and July 2020 and searched five electronic databases. Following exclusion criteria, 33 articles that used behavioural methods to compare autistic and neurotypical individuals are included. Studies were separated into three categories ranging from least to most complex: detection of human motion, discrimination of action features, and recognition of human action. Within these categories, stimulus complexity was further considered according to the number of response choices, background distraction, and the number of target agents.

**Results:** For detection of human motion, Point Light Displays (PLDs) were widely used, and autistic children and adults reported less accuracy in BM detection than neurotypical individuals. Meanwhile, the performance is positive correlate with IQ score among autistic individuals. PLDs, pictures, and video clips were used in the discrimination and recognition task, and both groups performance equality in speed discrimination tasks. However, autistic individuals showed challenging to recognise actions in low context information stimuli and more than one actor's social interaction condition. For non-biological motion (non-BM), autistic individuals showed less accuracy in coherence motion compare with neurotypical individuals, and this may lead to the deficit for social interaction actions. Whereas, there is no group difference on the threshold for the non-BM task.

**Conclusions:** The children and adults showed more difficult on BM processing, and the performance highly depends on the IQ. Meanwhile, autistic individuals are more challenging to recognise low context information actions and difficult integrating local motion in non-BM. Further studies could more compare BM processing in a social environment with low or high context information.

**443.013 (Poster)** Camouflaging of Autistic Traits in Non-Autistic Adults Is Associated with Poorer Mental Health  
*M. Somerville<sup>1</sup>, S. Fletcher-Watson<sup>2</sup> and S. E. MacPherson<sup>3</sup>, (1)Psychology Department, University of Edinburgh, Edinburgh, United Kingdom, (2)Salvesen Mindroom Research Centre, University of Edinburgh, Edinburgh, United Kingdom, (3)Department of Psychology, University of Edinburgh, Edinburgh, United Kingdom*

---

Background:

Camouflaging refers to a range of coping strategies used by autistic people to minimise the visibility of traits or behaviours characteristic of autism. Camouflaging involves suppressing behaviours associated with autism, minimizing responses to sensory overstimulation, adopting a 'mask' or persona during social interactions, and developing explicit compensatory strategies to meet social and communication demands. Camouflaging is associated with poor mental health in autistic people. Camouflaging of autistic traits has also been reported in non-autistic people. A substantial body of research has demonstrated that elevated levels of autistic traits are associated with poorer mental health in non-autistic people, however the exact nature of this relationship remains unclear. Camouflaging may be an important variable in the relationship between mental health and autistic traits. Previous research has suggested that executive function resources may support camouflaging behaviours, however the relative importance of specific executive functions are unknown.

Objectives:

This study examined the manifestation of camouflaging in non-autistic adults. The primary objective was to examine the role of camouflaging in the known relationship between autistic traits and mental health problems in non-autistic people. The study also explored the association between different executive functions and camouflaging.

Methods:

Sixty-three non-autistic adults completed standardised self-report questionnaires which measured: autistic traits (Autism-Spectrum Quotient) , mental health symptoms (Depression, Anxiety, Stress Scales) (DASS), and camouflaging behaviours (Camouflaging Autistic Traits - Questionnaire). In addition, a subset (n=51) completed three tests of executive function measuring inhibition, working memory, and set-shifting. Multiple linear regression models were used to analyse data.

Results:

There was a significant positive relationship between autistic traits and a measure of mental health which incorporated anxiety, depressive and stress symptoms. However, when taking account of self-reported camouflaging in the regression model, the

relationship between autistic traits and mental health was no longer significant. Camouflaging instead emerged as a significant predictor of mental health, such that increased camouflaging was associated with increased symptoms of poor mental health when controlling for autistic traits. Closer analysis of the specific subscales of the DASS revealed a similar pattern of results across the three domains of anxiety, depression, and stress. Camouflaging did not correlate with any measure of executive function

#### Conclusions:

These findings have implications for understanding the relationship between autistic traits and mental health in non-autistic people and add to the growing development of theory and knowledge about the effects of camouflaging. The findings suggest that it is the camouflaging of autistic traits which is associated with poor mental health in non-autistic adults rather than autistic traits themselves. The role of autistic traits as an independent risk factor for poor mental health should be reconsidered in a framework incorporating the construct of camouflaging.

**443.014** (Poster) Can Autistic Children Discriminate Intentional from Incidental Pointing Gestures in a Word Learning Context?  
**P. Maes, F. Stercq and M. Kissine, ACTE — Center of research in Linguistics — ULB Neuroscience Institute, Université libre de Bruxelles, Brussels, Belgium**

---

**Background:** One early sign of Autism Spectrum Disorder (ASD) is a reduced response to joint attention characterized by, among other traits, a failure to follow someone's pointing (American Psychiatric Association, 2013). Studies have highlighted the fact that autistic children show impairments in using social cues to respond to joint attention (Dawson et al., 1998) and to acquire the meaning of words (e.g. Preissler & Carey, 2005). Nonetheless, the specific role of pointing following remains hard to isolate as it is often studied in combination with other cues such as eye gaze. One recent study has shown that autistic children are able to follow gaze and pointing cues, both combined or in isolation, to learn new words (Field, Lewis, & Allen, 2019). Interestingly, the authors reported that the children also mapped the new words to the new objects when the pointing cue was incidental (viz. speaker pointing at target while looking off into the distance towards the other direction).

**Objectives:** Using a stricter definition of incidental pointing, we seek to investigate if 3- to 5-year-old autistic (58) and typically-developing (61) children follow intentional pointing gestures and are able to differentiate them from incidental pointing gestures.

**Methods:** Stimuli were videos of a person sitting at a table while looking at the camera, displayed on a screen equipped with a mobile eye-tracker. During the first phase of the video, the actor uttered a pseudo-word while pointing intentionally with one finger towards one corner of the table and pointing incidentally towards the other corner of the table with his other arm (e.g. hand placed behind the neck and elbow pointing towards the corner of the table). The second phase consisted of a snapshot of the last frame of the video from the first phase. In both pointed corners of the table, a drawing of two different imaginary animals appeared in a cloud of smoke (see Figure 1).

**Results:** A Group x Time interaction on the relative distance between the children's fixations and the two pointed-at corners of the frame revealed that, upon hearing a novel word, TD children tend to be shifting their visual attention closer to the corner pointed intentionally, whereas no such trend is visible in the ASD group ( $\chi^2(1) = 24.26, p < .001$ ). Moreover, both verbal and nonverbal autistic children struggle with pointing gestures as no significant main effect of raw expressive vocabulary was found in the ASD group ( $p = .93$ ).

**Conclusions:** Unlike TD children, autistic children fail to discriminate between intentional and incidental pointing gestures in a word learning context when no other social cues are available. However, such difficulty doesn't seem to prevent some autistic children to acquire vocabulary as all of them, regardless of their level of language, attend to pointing gestures in the same manner.

**443.015** (Poster) Comparison of Social Skills Deficits and Strengths Profiles in Youth with Autism Spectrum Disorder and Attention Deficit Hyperactivity Disorder  
**J. A. Gates<sup>1</sup>, A. H. Gerber<sup>1</sup>, C. E. Miller<sup>2</sup> and M. D. Lerner<sup>1</sup>, (1)Department of Psychology, Stony Brook University, Stony Brook, NY, (2)University of British Columbia, Vancouver, BC, Canada**

---

**Background:** While impairments in social functioning are common for individuals with Autism Spectrum Disorder (ASD) and Attention Deficit Hyperactivity Disorder (ADHD), these challenges present differently across populations. Recent literature suggests that ASD youth may exhibit more acquisition deficits (i.e., lack of knowledge of what to do) and fewer performance

deficits (i.e., enacting known behaviors) than ADHD youth, while both populations should demonstrate fewer social skill strengths than typically developing (TD) peers (Mikami et al., 2019). A method for assessing within-person distributions of social skills deficits and strengths (Gresham et al., 2010) — or a Social Skills Deficit and Strengths Profile (SSDSP) — has recently been developed, and can test this hypothesis by systematically examining ASD and ADHD youth SSDSPs. Indeed, one recent study has used the SSDSP in youth with ADHD, discovering greater social skill performance deficits, fewer strengths, and equivalent acquisition deficits compared to TD youth (Aduen et al., 2018).

**Objectives:** The present study tested the aforementioned ASD/ADHD hypothesis using the SSDSP in ASD, ADHD, and TD youth.

**Methods:** Parents of 254 youth with and without ADOS-2 confirmed ASD completed the Social Skills Improvement system (SSIS; Gresham et al., 2010), and the aforementioned method was applied to create an SSDSP for each population (See Table 1). Data from 47 youth with ADHD were extracted from Aduen et al., (2018). Independent *t*-tests compared SSDSPs across ASD and TD youth and the extracted ADHD data. Paired *t*-tests investigated within-group distributions (Figure 1).

**Results:** Analyses revealed that ASD youth exhibited significantly more acquisition deficits than ADHD youth ( $p < .05$ ), and significantly more deficits and fewer strengths than TD youth (all  $p < .001$ ; Table 1). ASD and ADHD youth did not significantly differ on performance deficits or social skill strengths. ADHD youth had comparable acquisition deficits and skills strengths, but significantly more performance deficits ( $p < .001$ ), than TD youth. Though ASD acquisition deficits were *more* prevalent relative to ADHD and TD youth, they were still less prevalent than strengths; performance deficits were the most prevalent aspect within ASD group SSDSPs (all  $p < .001$ ; Figure 1).

**Conclusions:** As expected, ASD youth exhibit significantly more acquisition deficits than ADHD youth. Though past work suggests ASD youth should display fewer performance deficits and skill strengths than ADHD youth (Mikami et al., 2019), rates were comparable in these samples. Importantly, ASD and ADHD groups showed high rates of performance deficits relative to TD youth, suggesting they share a profile of learned social skills that are not being enacted. Notably, though ASD youth obtained about twice as many acquisition deficits as ADHD and TD youth, acquisition deficits remained the least prevalent aspect of the within-ASD SSDSP. This highlights that, while uniquely pronounced, difficulties in acquiring social skills do not categorically define social challenges in ASD. Indeed, they appear to exhibit a similar prevalence of social strengths as youth with ADHD. Utilization of the SSDSP offers promising opportunities for more nuanced examination of social difficulties across youth populations.

**443.016 (Poster) Concerns and Stress Among Autistic and Neurotypical Adolescents during the COVID-19 Pandemic**  
**T. Simantov and F. Uzefovsky, Ben-Gurion University of the Negev, Be'er-Sheva, Israel**

---

**Background:** Autistic individuals typically find disturbance to routines as aversive and disruptive (Glass, 2001), and might therefore be especially affected by the Covid-19 pandemic. This may result in exacerbated symptoms of stress and anxiety, which are more prevalent in autistic individuals as compared to neurotypicals (Gillott, Furniss & Walter, 2001). Additionally, In typical development adolescence is a time of increased awareness and interest in peer relationships (Steinberg & Morris, 2001), which may become compromised due to social-distancing.

**Objectives:** The current study aimed to assess levels of experienced and observed stress of youths, and to examine how this is related to the specific concerns youths with and without ASD have regarding Covid-19.

**Methods:** 155 parents of 10-16-year-old adolescents (mean age 13.47 years, N=57 autistic) participated in the study. Data was collected July-September 2020, two months after the end of the first lockdown due to Covid-19 and right before a second lockdown, as cases began to rise. Parent- and self-report regarding adolescents' pandemic-related concerns were collected using the Covid-19 Adolescent Symptom and Psychological Experience Questionnaire (CASPE; Pfeifer et al., 2020). Exploratory factor analysis showed best fit for four factors: health concerns; instrumental concerns; concerns about family relationships; and concerns about social relationships. All of which were used as predictors of parent and child-reports regarding adolescent's stress and negative impact (NE) of the pandemic on daily-life.

**Results:** Two ANOVA analyses (IVs: diagnosis, sex, controlled for age) showed that autistic adolescents experienced higher levels of stress and NE, based on parent-report, but not self-report (see Table 1). Parent- and self-report stress significantly correlated overall ( $r(122) = .309, p < .01$ ) and in the neurotypical group ( $r(78) = .350, p < .01$ ). Although the correlation was not significant in the autism group, the difference between correlations was not significant  $z = -.48, p = 0.6312$ . Linear regression were used to examine the relationships between youths' concerns and stress or NE. Age was controlled for in all analyses but was not significant. See all models in Table 2. Parent-reported stress was predicted by female sex, autism diagnosis, and higher health

concerns. Whereas self-reported stress was positively predicted by concerns about family relationships and the interaction between diagnosis and concerns about social relationships. An examination of the interaction effect shows a positive relationship between concerns about social relationships and higher levels of stress for autistic, but not neurotypical youth ( $r=.306$   $p$ -value $=.044$  and  $r=.030$   $p$ -value $=.795$ , respectively). Higher parent-reported NE was predicted by female sex, autism diagnosis, higher health-concerns, and concerns about social relationships. Conversely, only concerns about family relationships positively predicted self-reported NE.

Conclusions: Parents and youths' judgments about their stress levels are correlated, but seem to relate to different aspects of youths' experiences, although the majority of these relate to the social aspects of the pandemic. Parents of autistic youths find them to be more stressed than they perceive themselves to be, which emphasizes the need to better understand the subjective experiences of parents and children during crises and the cause of the gaps between those views.

**443.017 (Poster)** Correlation between Face-to-Face and Digital Social Interaction and Suicidality in Autistic and Socially Anxious Individuals

**D. Gifford<sup>1</sup>**, L. Parker<sup>1</sup>, S. Gilliat<sup>1</sup>, J. Wild<sup>1</sup>, C. Timpson<sup>2</sup>, D. Melanson<sup>1</sup>, J. A. Nielsen<sup>3</sup> and M. South<sup>4</sup>, (1)Neuroscience, Brigham Young University, Provo, UT, (2)Psychology, Brigham Young University, Provo, UT, (3)Brigham Young University, Provo, UT, (4)Psychology & Neuroscience, Brigham Young University, Provo, UT

---

Background: Research has consistently shown that social support has an important role in predicting suicidal ideation, especially in non-autistic samples. However, few studies have investigated suicidal fluctuations driven by day-by-day social interaction. Even fewer have done this with autistic samples. Some that have done daily analysis have found an inverse relationship between perceived social support and same-day and next-day suicidal ideation. Differences in this correlation between autistic and non-autistic socially anxious individuals have yet to be fully investigated.

Objectives: To analyze the predictive relationship between face-to-face or digital interactions and suicidal ideation in autistic and in socially-anxious non-autistic participants.

Methods: Each participant was administered daily surveys through the MetricWire application on their phone. Part of these surveys asked the participants to rate their social interactions experienced during the day on a scale of 0-100. They were also asked to rank the frequency and severity of suicidal thoughts. These scores were combined to create a singular suicidal index score. The social interactions and suicidal index scores were then compared with a linear regression both individually and on a group level.

Results: During the tracking period just 11% of non-anxious controls ever experienced a suicidal thought during the day, while 92% of autistic participants and 84% of anxious, non-autistic participants reported at least some suicidal thinking. However, the mean number of days with some suicidal ideation, the mean intensity of suicidal ideation, and the frequency of suicidal thoughts within the hour immediately previous to nighttime reporting were all significantly greater in the socially anxious than the autistic group. Contrary to our hypothesis, a significant linear regression model showed daily social interactions, whether face-to-face or digital, did not predict daily suicidal thinking. Rather group membership was the strongest predictor, with socially-anxious but non-autistic participants showing greater intensity and frequency of suicidal ideation, with no difference in intentionality to act on suicidal impulses. The trait measure of LSAS total score was the driving force in predicting the intensity of daily suicidal thoughts. The strength of correlations between LSAS score and intensity of suicidality were stronger for the socially-anxious than autistic group.

Conclusions: While daily social interactions, either face-to-face or digital, did not predict suicidal thinking on a daily basis, the frequency and intensity of the suicidal ideation were significantly higher in the socially anxious group than in the autistic group. No difference between the groups was seen in the intention to act on suicidal impulses, but the socially anxious group presented stronger intensity and frequency of suicidality.

**443.018 (Poster)** Determining What Factors Contribute to Atypical Social Motivation in ASD

**C. M. Hudac** and N. R. Friedman, Center for Youth Development and Intervention, Department of Psychology, University of Alabama, Tuscaloosa, AL

---

**Background:** The social motivation theory posits that autism spectrum disorder (ASD) deficits emerge from the downstream consequences caused by reduced social motivation (Chevallier et al., 2012) (i.e., desire and valuation of engaging with others). For instance, without an intrinsic desire to engage with others during early development, children may not orient to the social world, demonstrate their enjoyment in social experiences, or subsequently, work to engage and maintain social connections.

Despite evidence that social motivation problems are elevated in males (Sedgewick et al., 2016), age (Clements et al., 2018), and linked to particular genetic etiologies of ASD (Beighley et al., 2019), there is a lack of clarity regarding what factors contribute to social motivation problems.

**Objectives:** We aimed to determine if core ASD features related to social motivation in children with ASD by examining what factors predict social motivation.

**Methods:** Data were obtained from three large cohorts of children with a confirmed ASD diagnosis (see Table): two cohorts ascertained for ASD ( $n=2809$  from Simons Simplex Collection, Fischbach & Lord, 2010;  $n=127$  from ZEBRA study) and one cohort ascertained for an ASD or intellectual disability associated genetic etiology ( $n=117$  from TIGER study). Social motivation was measured via the Social Responsiveness Scale (SRS-2; Constantino & Gruber, 2012) subdomain.

**Results:** Linear mixed effects models included ASD severity symptoms, sex, age, nonverbal cognition, and genetic etiology (i.e., the presence or absence of a pathogenic likely-gene disrupting mutation (LGDM). Rather than inputting overall ASD severity via the overall calibrated severity score (CSS) on the ADOS-2 Rutter et al., 2012), separate scores for social affect and restricted and repetitive behavior to avoid collinearity. Increased social affect problem severity and age predicted increased social motivation problems,  $F(1,2288) > 40.53, p < .001$ , whereas lower nonverbal cognition and sex predicted decreased social motivation problems,  $F(1,2288) = 15.2, p < .001$ . Females were predicted to have fewer social motivation problems,  $F(1,2288) = 9.77, p = .002$ . Social motivation problems were not predicted by RRBs or the presence of an LGDM,  $F(1,2288) > 1.90, p = .17$  (see Figure).

**Conclusions:** Considering the association with social affect severity, our findings provide additional support for the social motivation hypothesis of ASD (Chevallier et al., 2012) and extend our understanding of the unique contributions across different factors. Importantly, both sex (significant predictor) and presence of LGDM (not a significant predictor) presented with large confidence intervals (2.7 & 2.6, respectively), suggesting areas of heterogeneity for future targeted analysis.

**443.019 (Poster)** Development of a Coding Scheme for Social Interactivity in ASD and Related Developmental Disorders  
*C. Rosensweig<sup>1</sup>, B. Gordon<sup>1,2</sup> and K. Davis<sup>1</sup>, (1)Cognitive Neurology/Neuropsychology, Department of Neurology, The Johns Hopkins University School of Medicine, Baltimore, MD, (2)Department of Cognitive Science, The Johns Hopkins University, Baltimore, MD*

Background: Learning in individuals with autism spectrum disorder (ASD), particularly those with severe intellectual deficiencies, is often impaired. Among the factors responsible might be social deficits, as social interactions are known to be vital for learning in typically developing individuals. Therefore, fostering social interactions might potentiate their learning. Necessary first steps for quantitatively testing this possibility are to create situations where social interactions and learning can occur for these individuals and to measure the interactions and the learning that may result. However, measuring such interactions can be a considerable challenge, as they are likely to be infrequent, transient, fragmentary, and, perhaps, atypical. Using classes developed specifically for such individuals and others with related developmental disorders, we developed a reliable measurement system we feel meets these challenges.

Objectives: We used video recordings of adults with ASD and other related disorders who took part in recreational and adaptive skills classes to develop a coding scheme to describe and measure their social behaviors and interactions.

Methods: Twelve adults were selected via purposive sampling, in part to achieve as wide a variation as possible in diagnoses (ASD level 3,  $n=4$ ; level 2,  $n=3$ ; level 1,  $n=2$ ; other diagnoses,  $n=3$ ) and in levels of adaptive functioning. Six classes were designed to foster recreational and adaptive skills (e.g., cooking, office skills, fitness), led by experienced instructors. Classes were held weekly for ten weeks; each class consisted of at least two participants. Sessions were video-recorded. Written informed consent was obtained in accordance with procedures approved by Hopkins' IRB.

A modified grounded theory approach (Strauss & Corbin, 1998) was used to develop the coding scheme based upon the recordings from all six classes. After initial open coding, the constant comparative method and iterative thematic analysis (Glaser, 1965) were used to combine initial codes and organize them into themes. This coding scheme was reviewed with the instructors and researchers to help establish construct validity (Leung, 2015). A negative case analysis was conducted to ensure that all situations could be coded by the scheme. As an initial test, reliability and validity of the resulting scheme were measured using a dataset from one class: fitness class.

Results: This process resulted in a coding scheme of 13 codes within four themes: (1) patterns of engagement (i.e. collaboration among participants, non-engagement, division of labor), (2) task format (i.e. community of learners, participant-led, instructor-

led), (3) participant behavior toward instructor (i.e. obeys, ignores, resists, reminds instructor of need for support), and (4) task performance (i.e. successful without support, successful with support, unsuccessful). For the fitness class, we assigned 4,979 codes to 769 minutes of video with strong inter-coder reliability ( $Kappa=0.8$ ).

Conclusions: It seems possible to develop a reliable and plausibly valid coding scheme for social interactions of individuals across the ASD spectrum based upon video recordings in relatively naturalistic settings (classes). This is a necessary first step to better determine whether such interactions contribute to learning, and if so, how they might be optimized.

**443.020** (Poster) Developmental Effects in Physiological Stress Response to Social Threat in Adolescents with and without Autism

**B. A. Corbett<sup>a</sup>, R. A. Muscatello<sup>a</sup>, A. Kim<sup>a</sup>, S. Vandekar<sup>b</sup> and K. Patel<sup>c</sup>,** (1)Psychiatry and Behavioral Sciences, Vanderbilt University Medical Center, Nashville, TN, (2)Department of Biostatistics, Vanderbilt University Medical Center, Nashville, TN, (3)Vanderbilt University, Nashville, TN

---

Background: Humans place high value on how they are socially evaluated by others. The Trier Social Stress Test (TSST) is a well-established measure of social evaluative threat that promotes activation of the hypothalamic pituitary adrenal (HPA) axis and release of cortisol. Higher cortisol responses in typically developing (TD) adolescents are influenced by age and pubertal development especially in later stages. Children with ASD have been shown to exhibit blunted cortisol in response to the TSST although adults with ASD show a more prototypical response. The current study examined physiological stress in early adolescents with ASD and TD. It was hypothesized that TD youth would show elevated cortisol in response to the TSST influenced by age and pubertal stage. In contrast, youth with ASD would show a more diminished stress response yet still show effects for age and pubertal development.

Objectives: The objective of the current study was to examine the developmental effects of age and puberty on physiological stress to social evaluative threat in youth with and without ASD.

Methods: The sample included a large, well-characterized sample of 241 early adolescents between 10 to 13 years of age, 138 with ASD (median age = 11.25) and 103 TD (median age=11.67). Standardized diagnostic assessments and gold-standard pubertal development (genital/breast (GB), and pubic hair (PH) stage) physical exams were performed. Salivary cortisol was collected at multiple timepoints before and after the TSST. Linear mixed effects models examined the effects of baseline cortisol, time, age, sex, pubertal stage, and diagnosis.

Results: We did not find an effect of early pubertal development stage (GB or PH) on cortisol response (all  $p>0.05$ ). There was an interaction between age and TSST timepoint, showing stronger effects for older children across the timeline especially during the stressor ( $p=0.0396$ ). Finally, there was a significant diagnosis by TSST timepoint interaction characterized by a blunted cortisol stress response in youth with ASD compared to TD participants who showed higher cortisol ( $p<0.0001$ ).

Conclusions: We found evidence that age contributes to an increase in cortisol in response to being socially evaluated by others during early adolescence. TD youth exhibit an adaptive elevated stress response to psychosocial threat whereas youth with ASD do not. The current study replicated and extended research showing increased stress sensitivity arising during adolescence for TD and ASD youth which is driven by age rather than puberty at least in early adolescents. The impact of pubertal effects on physiological stress as measured by cortisol may increase as the sample advances through stages of sexual maturation. The current findings suggest that there may be a developmental lag in the perception of and stress response to social evaluation which may emerge in older adolescents with ASD.

**443.023** (Poster) Effects of Creative Movement Interventions on Praxis, Imitation, and Interpersonal Synchrony Skills of Children with ASD

**W. C. Su<sup>1</sup>, C. Cleffi<sup>2</sup>, S. Srinivasan<sup>3</sup> and A. Bhat<sup>4</sup>,** (1)Physical Therapy, University of Delaware, Newark, DE, (2)Physical therapy, University of Delaware, Newark, DE, (3)Department of Kinesiology, University of Connecticut, Storrs, CT, (4)Department of Physical Therapy, University of Delaware, Newark, DE

---

Background:

Children with Autism Spectrum Disorder (ASD) present with impairments in social communication skills including imitation and interpersonal synchrony (IPS). We have previously reported greater improvements in imitation and IPS in children with ASD after receiving face to face (F2F) rhythm and yoga-based interventions compared to a sedentary play (SP), standard of care intervention (Kaur & Bhat, 2019; Srinivasan et al., 2015; Srinivasan & Bhat, 2013). In the current study, we combined various

musical activities including instrument play, dance, and yoga to develop a multimodal Creative Movement (CM) intervention and compared its effects to that of a SP intervention. A subset of children with ASD received F2F training; however, after the outbreak of the COVID-19 pandemic, we are offering the intervention remotely through videoconferencing.

#### Objectives:

The current study investigates the effects of CM and SP interventions on the imitation and IPS skills of children with ASD. We will also compare the effects of F2F and telehealth-based intervention delivery in both groups.

#### Methods:

Twenty-four children with ASD between 5 and 14 years will be recruited for the study. Children with ASD will be matched on age, gender, and level of functioning before being randomly assigned to the CM or SP group. Both groups will receive 16 training sessions (2 sessions/week) over 8 weeks. The CM group will engage in whole-body movements using music, dance, and yoga to promote IPS, imitation, coordination, and balance. The SP group will engage in tabletop activities such as reading, building, and art-craft to promote social interactions and fine-motor skills. Two tests will be administered before and after the intervention: a) The postural praxis and bilateral motor coordination subtests of the Sensory Integration and Praxis Tests (SIPT-PP and SIPT-BMC) (Ayres, 1989) and b) an IPS test to assess synchrony performance during whole-body swaying. We will also assess their training-specific IPS performance during an early and a late training session.

#### Results:

Our preliminary data from 7 children with ASD suggest positive results following CM training. From pretest to posttest, children reduced the number of spatial errors on the SIPT-PP subtest (mean error  $\pm$  SE pretest score:  $7.43 \pm 1.73$ ; posttest score:  $2.57 \pm 0.53$ ,  $p < 0.05$ ) and the number of temporal errors during the SIPT-BMC subtest (CM group's mean error  $\pm$  SE pretest score:  $17.57 \pm 4.00$ ; posttest score:  $4.90 \pm 1.85$ ,  $p < 0.05$ ). While results from the generalized test of sway synchrony did not significantly change with training, training-specific IPS with the social partner increased during a late training session compared to an early training session (mean in-synchrony duration in minutes  $\pm$  SE early session:  $10.15 \pm 3.60$ ; late session:  $23.53 \pm 5.48$ ,  $p < 0.05$ ).

#### Conclusions:

CM intervention has positive effects on generalized imitation skills and training-specific IPS and could be used to promote socially-embedded motor skills in children with ASD. This study will also shed light on the pros and cons of telehealth-based interventions compared to F2F interventions.

#### **443.024** (Poster) Effects of Creative Movement Interventions on Social Communication & Behavioral Skills of Children with ASD

S. Srinivasan<sup>1</sup>, C. Cleff<sup>2</sup>, W. C. St<sup>3</sup> and A. Bhat<sup>4</sup>, (1)Department of Kinesiology, University of Connecticut, Storrs, CT, (2)Physical therapy, University of Delaware, Newark, DE, (3)Physical Therapy, University of Delaware, Newark, DE, (4)Department of Physical Therapy, University of Delaware, Newark, DE

---

#### Background:

Children with Autism Spectrum Disorder (ASD) demonstrate social communication impairments and engage in restricted and repetitive behaviors (American Psychiatric Association, 2013). Our past work demonstrated the positive effects of whole-body movement experiences including rhythm and yoga interventions on social communication and affective skills of children with ASD (Kaur & Bhat, 2019; Srinivasan et al., 2016a, 2026b).

#### Objectives:

In the present study we compare the effects of a Creative Movement (CM) intervention that combines music, dance, and yoga activities to a standard-of-care, Sedentary Play (SP) intervention on social communication and affective skills of children with ASD. In light of COVID-19, we have been using face-to-face and telehealth-based intervention methods and also plan to compare the two methods within each group.

#### Methods:

24 children with ASD between 6 and 14 years will participate over 10 weeks with pretests and post-tests conducted during the first and tenth weeks. Children will be matched on age, gender, and level of functioning and then randomly assigned to either CM or SP groups. Each child will receive 8 weeks of training @2 sessions/week conducted with an expert trainer and an adult model. The CM group will engage in music, dance, and yoga-based activities promoting interpersonal synchrony, imitation, and gross-motor skills. The SP group will engage in tabletop activities such as reading, building, and arts-crafts to promote academic and fine-motor skills. The standardized Joint Attention Test (JTAT, Bean & Eigsti, 2012), administered at pretest and post-test, will assess changes in responsive joint attention with training. We will also code training-specific changes in duration of verbalization and positive affect across an early, mid, and late training session.

Results:

Preliminary data from 7 children with ASD suggest that 5 out of 7 children showed a trend for improvement in standardized JTAT scores from pretest to posttest. From an early to a late training session, 6 out of 7 children increased verbalization towards their trainers and reduced self-directed verbalization. CM interventions promoted greater spontaneous speech initiations compared to responsive verbalization in all children. Five out of 7 children also showed a reduction in negative affect and an increase in task-appropriate, interested affect from an early to a late training session. We hypothesize that the CM group, irrespective of mode of intervention delivery (face-to-face or online), will demonstrate greater improvements in target skills on standardized and training-specific outcomes compared to the SP group.

Conclusions:

This study will add to the mounting evidence on the value of socially-embedded CM therapies in alleviating the core impairments of ASD. Moreover, we will also assess the effectiveness of delivering CM training using telehealth platforms and provide best practice guidelines based on our experiences. ASD clinicians could use CM interventions to improve motor, social communication, and behavioral skills in children with ASD. This work will offer evidence for the inclusion of whole-body movement experiences in the standard-of-care for children with ASD.

**443.025 (Poster)** Effects of Sex, Condition, and Phenotype on Visual Attention to Social Interactive Scenes in Children: Autism Biomarkers Consortium for Clinical Trials

*C. Westerhold<sup>1</sup>, F. Shic<sup>2</sup>, A. Naples<sup>3</sup>, C. Sugar<sup>4</sup>, D. Senturk<sup>5</sup>, G. Hellemann<sup>6</sup>, J. Dziura<sup>6</sup>, H. Seow<sup>6</sup>, G. Dawson<sup>7</sup>, S. Jeste<sup>8</sup>, C. A. Nelson<sup>8</sup>, R. A. Bernier<sup>9</sup>, N. M. Kleinmans<sup>10</sup>, S. J. Webb<sup>9</sup> and J. McPartland<sup>3</sup>, (1)Child Health, Behavior and Development, Seattle Children's Research Institute, Seattle, WA, (2)Center for Child Health, Behavior and Development, Seattle Children's Research Institute, Seattle, WA, (3)Child Study Center, Yale University School of Medicine, New Haven, CT, (4)University of California, Los Angeles, Los Angeles, CA, (5)UCLA, Los Angeles, CA, (6)Yale University, New Haven, CT, (7)Department of Psychiatry and Behavioral Sciences, Duke Center for Autism and Brain Development, Durham, NC, (8)Developmental Medicine, Boston Children's Hospital, Boston, MA, (9)Psychiatry and Behavioral Sciences, University of Washington, Seattle, WA, (10)University of Washington, Seattle, WA*

**Background:** The Autism Biomarkers Consortium for Clinical Trials (ABC-CT) was designed to identify and validate promising eye-tracking (ET) biomarker candidates for ASD. One task examined by the ABC-CT was the Social Interactive Task (1). Previous work has shown greater differences between children with ASD and typically developing (TD) controls in attention to faces of child actors engaged in cooperative versus parallel play (1) as well as 3-way-interactions between group, play conditions, and sex (2).

**Objectives:** To replicate results of (1) and (2) in a large, well-powered sample while extending these results by controlling for and examining relationships with participant behavioral and experimental characteristics.

**Methods:** Participants were 6-to-11-year-old children with ASD (n females=65, male=215) and TD (n females=36, male=83) who were eye tracked while viewing social interactive paradigms drawn from (1) (including both cooperative (social) and parallel play ("non-social") conditions). The primary outcome variable was percentage of time looking at faces (%Faces), with factorial ANOVA of sex \* group \* condition to predict %Faces. Analyses were conducted without controls as well as controlling for IQ, Age, NEPSY memory for faces, and percentage of Valid ET Data.

**Results:** ANOVA without controls revealed interactions of group\*sex (p=.039) and group\*condition (p=.045), as well as main effects of group, condition, and sex (all ps<.01). Not other effects were identified.

%Faces in ASD was 28.0% (cooperative) and 20.5% (parallel), and in TD, 36.3% and 27.2%, respectively. Cooperative-parallel condition differences in %Faces in ASD were  $\Delta=7.5\%$  compared to  $\Delta=9.2\%$  in TD (both ps<0.0001). ASD-TD group differences

in %Faces were  $\Delta=8.3\%$  for cooperative and  $\Delta=6.7\%$  for parallel (both  $ps<0.0001$ ). Group differences in the cooperative condition were greater than the parallel condition ( $p=.045$ ).

Females (combining groups) had higher %Faces (29.8%) than males (26.2%) ( $\Delta=3.6\%$ ,  $p=0.004$ ). %Faces was 24.7% in ASD females and 23.7% in ASD males. %Faces in TD females was 34.9% compared to 28.6% in TD males. There was no significant female-male sex difference in %Faces observed in ASD participants ( $\Delta=1.0\%$ ,  $p=0.4911$ ), but there was in TD participants ( $\Delta=6.3\%$ ,  $p=0.0024$ ).

Inclusion of control variables revealed positive associations between %Faces and NEPSY memory for faces ( $t=6.47$ ,  $p<.001$ ) and Age ( $t=2.17$ ,  $p=.031$ ), and negative associations with IQ ( $t=-3.05$ ,  $p=.002$ ) and %Valid Data Acquired ( $t=-5.4$ ,  $p<.001$ ) but did not otherwise change the identified pattern of results.

**Conclusions:** Analyses replicated (1), with stronger group differences in cooperative versus parallel play, and sensitivity to condition present in both ASD and TD groups. Contrary to results from (2), which showed 3-way-interactions among group, condition, and sex, our results suggest interactions between sex and group (highlighting greater sex differences in TD) and condition and group (highlighting greater condition effects in TD) may be sufficient to describe interactions. New findings include identification of strong dependence of face looking with clinical characteristics including memory for faces, IQ, and broader experiment attention. These results will be discussed in terms of the methodological, sampling, and participant characteristics differences between current and prior work.

#### 443.026 (Poster) Empathic Disequilibrium in Autism

*I. Shalev<sup>1</sup>, P. Smith<sup>2</sup>, C. Allison<sup>3</sup>, S. Baron-Cohen<sup>3</sup> and F. Uzefovsky<sup>4</sup>, (1)Psychology, Ben-Gurion University, Jerusalem, Israel, (2)University of Cambridge, Cambridge, United Kingdom, (3)Autism Research Centre, Department of Psychiatry, University of Cambridge, Cambridge, United Kingdom, (4)Ben-Gurion University of the Negev, Be'er-Sheva, Israel*

---

#### Background:

Empathy is a core ability for effective and efficient social communication (Decety et al., 2016), and atypicalities in empathy are considered a hallmark of autism (Smith, 2009). Specifically, some studies suggest that autism is characterized by intact emotional empathy (EE; the ability to respond to another's mental states with appropriate emotion) and diminished cognitive empathy (CE; the ability to recognize what another person is feeling) (Baron-Cohen & Wheelwright, 2004). Yet mixed findings in this domain (e.g. Lombardo et al., 2016) led us to examine a novel conceptualization of empathy to autistic traits focusing on the gap between EE and CE, termed Empathic Disequilibrium (ED), as a more informative measure of autism.

#### Objectives:

ED was found to be predictive of autistic traits in a large neurotypical population even when controlling for total empathy scores (Shalev & Uzefovsky, 2020). We now extend these findings to examine ED in autism. Based on the previous findings and the theoretical framework of empathy in autism (Smith, 2009), we hypothesized that EE-dominance (EE higher than CE) will be related to autism diagnosis.

#### Methods:

Participants (1,905 with autism; 3,009 control) were recruited via the Cambridge Autism Research Database. Autistic traits were measured using the Autism Quotient (AQ; Baron-Cohen et al., 2001). EE and CE were measured using the Empathy Quotient (Baron-Cohen & Wheelwright, 2004). ED was calculated as the difference between CE and EE standardized scores. ANCOVA was conducted to predict ED by diagnosis (autism/control) and sex, controlling for total empathy. ED scores were used to classify participants to CE-dominant, EE-dominant, and balanced-empathy groups based on 1-SD from the mean. Chi-square tests were conducted to compare expected and observed proportions of autism diagnosis in each group. Finally, ANCOVA was conducted to examine autistic traits (using the AQ subscales) in each empathy group, controlling for overall empathy.

#### Results:

ED was predicted by diagnosis (autism/control) ( $p = 2 \times 10^{-47}$ ) and sex ( $p = 4 \times 10^{-7}$ ) (**Figure 1**). Higher rates of autism diagnoses were characteristic of individuals in the EE-dominant group (observed 51.4%; expected 39%;  $p = 5 \times 10^{-17}$ ). Importantly, autistic females showed higher rates of EE-dominance than autistic males (observed, 61%; expected 54%,  $p = 0.001$ ). Elevated autistic traits were found in the EE-dominant group for all AQ subscales (**Table 1**). Specifically, autistic individuals in the EE-dominance ED group showed elevated deficits in social skill ( $p = 0.0089$ ), communication ( $p = 6 \times 10^{-9}$ ) and attention-switching ( $p = 6 \times 10^{-9}$ ).

Conclusions:

Our findings suggest that the intra-personal imbalance between the emotional and cognitive might be informative for characterizing and understanding social deficits in autism and the broad autism phenotype. These findings imply the possibility of novel subgroup classification of autism based on the imbalance between EE and CE, rather by CE or EE separately, and that this is particularly informative for females. This promise to explain some of the mixed findings in the field.

**443.027 (Poster)** Examining Sex Differences in Social Responsiveness and Concurrent Verbal Intelligence Abilities of Young Individuals in Autism Spectrum Disorders

M. A. Cox<sup>1</sup>, K. Webb<sup>2</sup>, J. E. Blume<sup>3</sup> and A. Mastergeorge<sup>4</sup>, (1)Human Development and Family Sciences, Texas Tech Universities, Lubbock, TX, (2)Human Development and Family Sciences, Texas Tech University, Lubbock, TX, (3)Department of Human Development and Family Studies, Texas Tech University, Lubbock, TX, (4)Texas Tech University, Lubbock, TX

**Background:** Social and communication deficits are core behavioral symptoms of autism spectrum disorders (ASD), however these symptoms present in unique and sometimes conflicting patterns for males and females resulting in differential diagnosis and intervention trajectories and females are often diagnosed later in life or not diagnosed at all; this trend is exacerbated when females do not present with comorbid cognitive impairments (Dean et al., 2017; Shattuck et al., 2009). Recent studies challenge gender invariance assumptions (Frazier et al., 2014; Hiller et al., 2014). Other studies continue to indicate social communication deficits are roughly universal for both genders (Dean et al., 2014; Holtmann et al., 2007). Gender differences in ASD are also observed for IQ (Rivet et al., 2011; Banach et al., 2009), yet salient subsections of IQ assessments, have not been examined for the same effects. Moreover, research evaluating verbal IQ and social communication deficits in children with ASD support a strong negative relationship between the two (Wetherby, 2006). Since gender differences specific to this relationship have yet to be examined, we aim to explore the conditional effects of gender differences on patterns of association between IQ and core behavioral symptoms of ASD.

**Objectives:** In the current study, we will compare associations between specific dimensions of social responsiveness and concurrent verbal intellectual abilities in youth with ASD when controlling for age and gender.

**Methods:** This study utilized a subset of secondary data from the Autism Brain Imaging Data Exchange (ABIDE) I ( $n = 37$ , 8 females,  $M_{age} = 14.4$  yrs,  $SD_{age} = 1.6$ ). Dimensions of social responsiveness were measured with the *Social Responsiveness Scale* (SRS; Constantino & Gruber, 2007). Performance on the *Wechsler Intelligence Scale for Children* (WISC-III; Woogler, 2001) Verbal Intelligence Quotient (VIQ) yielded an index of verbal intellectual abilities. We utilized nested linear multiple regression models to compare the strength of the association between the SRS subscale scores as predictors (Table 1) and VIQ scores as the outcome variable, first in Model 1 controlling for age, then in Model 2 controlling for both age and sex.

**Results:** Results of Model 1 revealed a significant negative relationship between VIQ scores and SRS subscale scores when controlling for age, indicating higher ASD symptom severity is associated with lower verbal IQ performance (see Table 2). Further, SRS subscale scores explained 52.5% of the variance in VIQ scores, suggesting the model serves as a predictor of verbal IQ ( $p < .001$ ). Model 2 accounted for an additional 7.9% of variance ( $p < .001$ ).

**Conclusions:** The current study findings indicate a moderate, negative association between VIQ performance and social responsiveness deficits. Further, these findings highlight variability in this association specific to gender differences and emphasize the importance of making this distinction across core behavioral symptomology. These findings support further investigation of gender variance in verbal intelligence ability and social communication impairments to better understand unique gender profiles for diagnostic and intervention best practices. Future studies should expand evaluation of this relationship to include Full Scale IQ and additional social skills measures with a larger sample size.

**443.029 (Poster)** Exploring Behavioral Biomarkers of Children with ASD Based on Physiological Data in Practice of Conversation Initiation with a Social Robot

H. Do<sup>1</sup>, K. Welch<sup>1</sup>, J. T. Soriano<sup>2</sup>, R. Castelly<sup>2</sup>, S. Daisey<sup>2</sup>, G. M. Kuravackel<sup>3</sup>, R. Pennington<sup>4</sup>, G. Barnes<sup>3</sup> and D. Popa<sup>1</sup>, (1)Louisville Automation & Robotics Research Institute, University of Louisville, Louisville, KY, (2)Louisville Automation &

**Background:** Children with autism spectrum disorder (ASD) experience challenges with social conversation, a core impairment in ASD. This impairment limits these children in initiating and contributing to group conversations. Social robots with verbal conversation capabilities have great potential to provide therapeutic interventions of social conversation skills for children with ASD. The use of social robots for practices of conversation initiation could be highly beneficial for these children, to improve social conversation skills. Physiological cues can provide powerful tools in understanding responses and affective states of a child with ASD during conversations with a social robot. Therefore, exploring behavioral biomarkers based on physiological data may provide significant recommendations for further design of social robot-based intervention.

**Objectives:** This study aims to 1) explore physiological variation of children with ASD in response to different moments of scripted interactions with a social robot in order to understand their affective states and 2) provide recommendations for further design of social robot-based intervention that can adapt to the affective states of participants with autism.

**Methods:** Six children with autism (aged 8-12 years) participated in a social skills group. The group ran for 12 weeks, meeting once per week. During the last 10 group meetings, participants practiced conversation initiation with a social robot. As two small groups of three, participants entered a room with a humanoid NAO robot from SoftBank Robotics. Using two robots and two rooms, the participants completed the practice at the same time. One participant from each group wore an Empatica E4 wristband, measuring electrodermal activity and blood volume pulse. Each participant takes turns to initiate three trials of robot interaction. A complete trial consists of: 1) participant initiates interaction using one of five predefined questions; 2) robot animates, responds, and repeats the question; 3) participant responds; and 4) robot acknowledges. We analyzed physiological data from baseline recordings during quiet sitting in comparison to the robot interactions. We explored physiological variation to key moments in the participant's turn and others' turns.

**Results:** We have finished collecting data from 6 of 10 sessions of robot interaction. The preliminary analysis of the physiological data showed significant changes of physiological signals in response to the robot's questions, the latency in the robot's responses, and the performance of the robot in understanding the participants' questions.

**Conclusions:** Participants responded implicitly, with emotional behaviors, to different moments of social interactions with a social robot. Behavioral biomarkers have the potential to be used to design further social robot-based intervention that can adapt to the affective states of participants with autism. For example, the robot could monitor a participant's physiological signals to decide when to continue the intervention practice (e.g., when a participant's signals are within a margin close to baseline), or as feedback for how (e.g., introducing new questions based on the response to the robot's questions) the robot should adjust the intervention. In the future, the intervention could be further refined to adapt to subtle changes in behavioral biomarkers during interactions with a social robot.

#### 443.030 (Poster) Exploring the Role of Camouflaging Motivations and Consequences

C. Bernardin<sup>1</sup> and D. Bell<sup>2</sup>, (1)University of Missouri - Columbia, Columbia, MO, (2)University of Missouri, Columbia, MO

---

**Background:** Camouflaging (i.e., compensating for or masking autistic traits) is associated with poorer mental health and wellbeing in autistic and nonautistic individuals (Beck et al., 2020; Cassidy et al., 2020; Hull et al., 2017). However, camouflaging may also lead to some benefits, such as improved connections with others, increased ability to maintain employment, and avoidance of experiences of discrimination (Botha & Frost, 2019; Hull et al., 2017). It is important to understand why camouflaging may lead to poorer outcomes for individuals. This could allow researchers and clinicians to move toward supporting autistic individuals in maximizing the benefits of camouflaging while minimizing negative impacts on mental health and wellbeing.

**Objectives:** To examine the association between perceived positive and negative motivations and consequences of camouflaging (see example items below) and symptoms of anxiety and depression. This pilot study was conducted with a nonautistic sample to test whether the constructs may be related.

**Methods:** 283 undergraduate students (61% female; 84% Caucasian; *M* age = 19.28 years) completed measures of anxiety symptoms (GAD-7; Spitzer, 2006), depression symptoms (PHQ-9; Kroenke, 2001), levels of camouflaging (CAT-Q; Hull et al., 2019), and perceived camouflaging motivations and consequences. The items pertaining to perceived camouflaging motivations and consequences were developed based on qualitative research with autistic individuals (manuscript under review). Example items include "to gain positive perceptions" (positive motivation); "to avoid negative experiences" (negative motivation); "you fit in with others" (positive consequence); and "you feel inauthentic or like others don't you know the 'real you'" (negative

consequence). Hierarchical linear regression models were used to predict depression and anxiety starting with *gender* in step 1 and adding the *CAT-Q* and *positive and negative motivations* in subsequent steps. Post hoc analyses compared models predicting anxiety and depression using *gender* and *CAT-Q* to models predicting anxiety and depression using *gender* and *negative motivations and consequences*.

**Results:** Tables 1 and 2 include results for all steps of the hierarchical linear regression analyses for anxiety and depression, respectively. Negative camouflaging motivations ( $B = .19, t(272) = 3.43, p < .001$ ) and negative camouflaging consequences ( $B = .20, t(273) = 4.17, p < .001$ ) significantly predicted anxiety. Negative camouflaging motivations ( $B = .21, t(270) = 3.50, p < .001$ ) and negative camouflaging consequences ( $B = .25, t(273) = 4.36, p < .001$ ) also significantly predicted depression. Post hoc regression analyses indicated that combined, the nine items for negative camouflaging motivations and consequences explained more variance than the 24 items on the CAT-Q for both anxiety ( $R^2 = .10$  for *gender + CAT-Q*;  $R^2 = .16$  for *gender + negative motivations and consequences*) and depression ( $R^2 = .08$  for *gender + CAT-Q*;  $R^2 = .14$  for *gender + negative motivations and consequences*).

**Conclusions:** Results suggest that perceived camouflaging motivations and consequences may better predict anxiety and depression symptoms than camouflaging levels. However, these findings must be interpreted with caution, as this sample did not include autistic individuals. A crucial next step will be to replicate these analyses in an autistic sample.

#### 443.031 (Poster) Eye Will Remember You: Individual Differences in Face Fixation Patterns and Recognition Accuracy Amongst Autistic and Neurotypical Adults

*K. B. Parkington, Psychology, University of Waterloo, Waterloo, ON, Canada*

---

**Background:** Face recognition is a crucial building block for establishing and maintaining effective social relationships: we interact differently with people we know than with people we do not know. Many autistic adults experience difficulties attending to the eyes and recognizing others in their daily lives. These reports are substantiated by empirical investigations revealing face recognition impairments and reduced reliance on the eyes amongst autistic individuals, although intact recognition abilities and visual strategies have also been reported, signifying the heterogeneity of social abilities across the spectrum. The eye avoidance theory posits that atypical attention to the eyes in autism may limit the quality and quantity of social information that is processed, thereby leading to difficulties in higher-order social cognitive processes (e.g., face recognition). A link between the eyes and face recognition is emerging within the neurotypical literature, although a direct association has yet to be established in autism.

**Objectives:** The current study presents the first empirical investigation directly evaluating the eye avoidance theory of face recognition in autistic and neurotypical adults through a neurodiversity lens and an individual differences approach.

**Methods:** Adults with an autism spectrum disorder ( $n = 24$ ; 12 female, 9 male, 2 non-binary, 1 transgender) and age-, gender-, ethnicity-, and IQ-matched neurotypical adults ( $n = 21$ ; 11 female, 9 male, 2 non-binary) completed incidental and intentional measures of old/new face recognition while eye movements were recorded. Area-normalized fixation metrics were calculated for six facial regions (left eye, right eye, nasion, nose, mouth, and non-core features) during face encoding and  $d'$  measures of recognition accuracy were computed for each task.

**Results:** During encoding, the eyes and nasion were looked at significantly more often than other facial features, a pattern that was upheld for autistic and neurotypical adults alike, although individual differences were abundant for both groups. Manual inspection of individual heat maps revealed that the classic T-shaped pattern observed at the group level was a byproduct of averaging a variety of fixation patterns, rather than execution of a homogenous strategy across all participants. Autistic and neurotypical adults did not differ in face recognition accuracy, nor did performance vary across task demands, although intentional  $d'$  was negatively associated with autism symptomology, such that autistic adults with higher ADOS-2 scores performed more poorly than their autistic counterparts with better social adaptation skills. Fixation to the left eye also showed trending associations with face recognition accuracy, albeit on different tasks across groups, and was weakly related to ADOS-2 scores amongst autistic adults.

**Conclusions:** Autistic adults implement typical fixation patterns to internal facial features during face encoding and display face recognition abilities within range of their neurotypical peers. Individual-level analyses reveal the left eye may play a role in autistic and neurotypical face recognition, partially supporting the eye avoidance theory and highlighting the importance of adapting a neurodiversity perspective when evaluating autistic face recognition. This research advances our understanding of the neurocognitive mechanisms underlying face recognition, highlights the heterogeneity of autistic social behaviours, and has clinical implications for social skill programs in adulthood.

**443.032** (Poster) Gender Differences in Friendship Experiences, Peer Conflict, and Perceived Loneliness in Children with ASD  
*N. Libster, V. Auriel, A. Hovey and C. Kasari, University of California, Los Angeles, Los Angeles, CA*

---

**Background:** The social deficits associated with Autism Spectrum Disorder (ASD) impair children's ability to successfully interact with peers and develop friendships. Boys with ASD have difficulty playing with others and tend to isolate themselves from their peers, whereas girls attempt to fit in with their neurotypical peers by imitating their social behaviors. However, girls with ASD are often victims of relational aggression (Dean et al., 2017). The isolation experienced by boys with ASD is associated with social-cognitive loneliness (feeling alone and isolated), while the relational aggression experienced by girls with ASD is associated with emotional loneliness (not making close, emotional connections with others). Children with ASD have difficulty understanding the emotional, but not social-cognitive, dimension of loneliness (Bauminger & Kasari, 2000). Therefore, boys, but not girls, may perceive themselves as lonely. Furthermore, school-aged children with ASD report lower levels of loneliness compared to preadolescents and adolescents (Chamberlain et al., 2007). Therefore, perceptions of loneliness may vary across both gender and developmental status.

**Objectives:** Qualitatively analyze interviews from the Autism Diagnostic Observation Schedule (ADOS; Lord et al., 2012) to explore how friendship experiences, peer conflict, and perceived loneliness differ across gender and developmental status in children with ASD.

**Methods:** The current study was a secondary data analysis of 22 children (11 girls) with ASD who participated in five different studies conducted at the UCLA Center for Autism Research. Eight children (four girls) were school-aged (ages 7-9), 10 (five girls) were preadolescents (ages 10-13), and four (two girls) were adolescents (ages 14-15). Boys and girls were matched on age, IQ, and ADOS severity score. Participants had been administered Module 3 of the ADOS. A thematic analysis was conducted on the ADOS interviews addressing friends, social difficulties/annoyance, and loneliness.

**Results:** Boys and girls with ASD were equally likely to have friends and engage with their peers. However, the majority of boys reported being bullied or having trouble getting along with others at school. Several boys experienced conflict due to difficulties in playing and interacting with peers. Girls were less likely than boys to experience peer conflict, and none of the girls experienced difficulties in playing or interacting with peers. When boys and girls reported feeling lonely, both alluded to social-cognitive loneliness – however, boys reported feeling lonely more frequently than girls. Finally, the majority of school-aged children reported not feeling lonely, whereas the majority of preadolescents and adolescents reported feeling lonely.

**Conclusions:** Both girls and boys with ASD had positive relationships with their friends, yet girls were less likely than boys to experience peer conflict and to report feeling lonely. Although few girls reported instances of relational aggression, this may have been due to difficulty recognizing rejection from peers (Sedgewick et al., 2016). Perceptions of loneliness also varied across age, indicating that school-aged children with ASD may have trouble understanding loneliness. Our next steps will be to increase the sample size and compare friendship experiences, peer conflict, and perceived loneliness in boys and girls with and without ASD.

**443.033** (Poster) Global and Fine Social Perception in Children and Adults with ASD: An Eye-Tracking Study  
*A. Vinçon-Leite<sup>a</sup>, A. Cavalcanti Ferreira<sup>a</sup>, A. Saitovitch<sup>c</sup>, E. Rechtman<sup>d</sup>, V. Philip-Montillot<sup>e</sup>, A. Philippe<sup>e</sup>, N. Chabane<sup>e</sup>, H. Lemaître<sup>e</sup>, N. Boddaert<sup>e</sup> and M. Zilbovicius<sup>f</sup>, (1)INSERM U1000, Paris, France, (2)Inserm U1000, institut Imagine, UNICAMP, Paris, France, (3)INSERM, Paris, France, (4)INSERM U1000, Institut Imagine, Paris, France, (5)Necker Hospital, Paris, France, (6)Lausanne University Hospital, Lausanne, Switzerland, (7)Inserm U1000, institut Imagine, Université Paris Sud, Paris, France, (8)Hospital Necker, Paris, France, (9)Inserm U1000, institut Imagine, Paris, France*

---

**Background:**

Social perception abnormalities in ASD have been largely objectified with eye-tracking. Mainly two different types of stimuli have been used. Dynamic audio-visual stimuli presenting complex social scenes, which can evaluate fine social perception, has been widely applied. Nevertheless, the complexity of these stimuli prevent its use across languages or among non-verbal individuals. More recently, studies have investigated global aspects of social perception using less complex stimuli based on visual preference paradigms. However, the sensitivity of these stimuli and its congruence with more subtle aspects of social perception has not yet been established.

**Objectives:**

Here, we aimed to investigate a putative correlation between global social perception and fine social perception in a large cohort of individuals with ASD and with TD, across a wide age range.

## Methods:

We included 123 individuals, 46 with ASD (age 2-26 years) and 77 with TD (age 2-30 years). Eye tracking recordings were obtained using two types of stimuli 1) a visual preference stimuli, inspired by the original GeoPref test from Pierce et al. 2011, simultaneously showing videos of children in motion and videos with geometric figures in motion, 2) stimuli with videos containing complex social scenes from the film “Le petit Nicolas”, a paradigm developed in our lab (Saitovitch et al., 2016). The main data used were: 1) for the visual preference stimuli: the number of fixations in the video with the children in motion and the number of fixations in the video with geometric movement and 2) for the videos of social scenes: the number of fixations in the eye area, face and non-social regions (excluding faces).

## Results:

In the social scenes paradigm, a significant reduction in fixations to the face ( $F(1,119) = 19.1, p = 2.7e-05$ ) and to the eyes ( $F(1,119) = 14.4, p = 0.00023$ ) was observed in ASD group compared to TD group whereas a significant increase in fixation to non social background were found ( $F(1,119) = 24.5, p = 2.4e-06$ ). In the preferential viewing paradigm, significant reduced fixations in dynamic biological movements were observed in ASD group compared to TD group ( $F(1,119) = 24.2, p = 2.8e-06$ ). In the ASD group, as in the TD group, a significant positive correlation between number of fixations to faces of characters and number of fixations in the video with the children in motion was observed ( $F(1,118) = 30.2; p = 2.3e-07$ ). In addition, a significant positive correlation between number of fixations to the eyes and number of fixations in the video with the children in motion was observed ( $F(1,118) = 11.7; p = 0.0008$ ).

## Conclusions:

To the best of our knowledge, this is the first study investigating a correlation of two levels within social perception using eye-tracking. Our results indicate a significant correlation between the global social perception (tested by the visual preference stimulus) and the fine social perception (tested by the social video clip stimulus) in participants with ASD and with TD. Importantly, our results showed that this correlation exists in participants with ASD and with TD, suggesting a universal mechanism of social perception.

### 443.034 (Poster) Imagined Contact with Individuals with Autism Improves Typically Developing University Students' Attitudes Towards Autism

*C. L. Dickter<sup>a</sup>, J. Burk<sup>a</sup>, K. Carter<sup>a</sup>, K. Burton<sup>a</sup>, A. Allen<sup>a</sup>, S. Mallipeddi<sup>a</sup> and K. Fergus<sup>a</sup>, (1)College of William and Mary, Williamsburg, VA, (2)William & Mary, Williamsburg, VA*

---

#### Background:

More young adults diagnosed with autism are attending university than in the last decades. Attending university for individuals with autism is associated with increases in self-esteem, employment, and personal skills. However, students with autism may face challenges at university with making and maintaining friendships, despite a desire to do so. One reason for this is that college students with autism experience social exclusion more so than their typically developing (TD) peers who tend to evaluate individuals with autism negatively. While exposure to individuals with autism can improve TD individuals' attitudes towards autism, this contact is not always possible. Investigating ways to improve TD university students' attitudes using simulated interactions may be effective.

#### Objectives:

We sought to 1) examine the relationship between TD university students' contact with individuals with autism and their attitudes towards autism and 2) examine whether simulating contact with individuals with autism would improve attitudes towards this group. Labeling people engaging in atypical behavior associated with autism can lead to more positive perceptions as perceivers have an explanation for these behaviors. Therefore, we examined whether imagining an interaction with someone displaying behavior stereotypically associated with autism and labeled as having autism would affect subsequent attitudes.

#### Methods:

TD university students ( $n = 130$ ) read vignettes in which they imagined interacting with another university student who depicted behaviors associated with ASD (i.e., perseveration) or not and with a label of autism or not. This yielded a 2 (label) x 2

(perseveration) design. Participants then completed a Feelings Thermometer which measured their attitudes towards individuals with autism.

#### Results:

Participants with greater contact with individuals with ASD had more positive attitudes towards people with autism,  $r = .32, p = .001$ . In addition, a 2 (Label: ASD vs. non-ASD) x 2 (Behavior: Perseveration vs. No Perseveration) analysis of covariance (ANCOVA) with prior contact as a covariate revealed a significant Label x Behavior interaction,  $F(1, 111) = 4.53, p = .036, \eta_p^2 = .039$ . Planned comparisons demonstrated that, for the non-ASD condition, there was not a significant effect of Behavior,  $F(1, 60) = 0.70, p = .407, \eta_p^2 = .012$ . However, for the ASD condition, attitudes towards individuals with ASD were higher in those in the Perseveration condition than the No Perseveration condition,  $F(1, 50) = 4.77, p = .034, \eta_p^2 = .087$ .

#### Conclusions:

These findings are consistent with other evidence showing that having knowledge that a person is diagnosed with ASD may be helpful in allowing somebody to understand some of the behaviors associated with ASD that may otherwise be considered unusual. With this knowledge, attitudes toward individuals with ASD in general may become more positive. This finding suggests that the imagined contact procedure may be useful for improving attitudes toward individuals who display some behaviors of ASD that may otherwise be viewed in a more negative manner. Apart from vignettes, alternative methods of simulating imagined contact can be explored in the future to further understand how imagined contact changes attitudes.

#### **443.035** (Poster) Impact of COVID-19 on Implementation of Live Eye-Tracking Research Procedures and Social Attention in Toddlers

*M. Butler<sup>1</sup>, R. Foster<sup>1</sup>, C. Banarjee<sup>2</sup>, H. Feiner<sup>1</sup>, D. M. Goncalves Fortes<sup>1</sup>, E. Diamond<sup>1</sup>, E. Brennan-Wydra<sup>1</sup>, A. Boxberger<sup>1</sup>, S. Macari<sup>1</sup>, A. Verneti<sup>1</sup> and K. Chawarska<sup>1</sup>, (1)Child Study Center, Yale University School of Medicine, New Haven, CT, (2)University of Miami, Coral Gables, FL*

---

#### Background:

Screen-based eye tracking is a well-established method of investigating visual social attention in children with ASD (Guillon et al., 2014). Studies utilizing eye tracking methods in live, more ecologically valid contexts may provide more information regarding dynamics of social attention in ASD, but they are still limited (Thorup et al., 2018). Moreover, feasibility of live eye tracking in very young and disabled children has yet to be fully established. Finally, adopting COVID-19 safety measures may significantly impact feasibility and accuracy of live eye-tracking tasks.

#### Objectives:

**1)** Assess the preliminary feasibility of a live eye-tracking paradigm measuring social attention in toddlers with ASD, developmental delays, and typical development. **2)** Examine whether COVID-19 safety protocols alter calibration accuracy, participant affect, or amount of attention to the eye-tracking scene and to the experimenter.

#### Methods:

Eighteen toddlers (eleven pre-, seven during-COVID-19) interacted with an experimenter and toys in a live eye-tracking setting. During the pandemic, a plexiglass divider separated the child from the scene and experimenters wore masks. We examined calibration accuracy (degrees), participant affect (rated -1=negative, 0=neutral, 1=positive), proportion of valid looking at the scene (%Valid: duration looking at scene/total time), and proportion of looking at the examiner (%Examiner: duration looking at experimenter/duration looking at scene).

Two children from the pre-COVID-19 group were excluded because of low %Valid (<30%). Two additional participants, one pre- and one during-COVID-19, were excluded from the analysis of calibration accuracy only, due to unsuccessful calibrations. The final pre- and during-COVID groups did not differ in age ( $p=0.27$ ), Mullen Verbal DQ ( $p=0.76$ ), or ADOS-total scores ( $p=1.00$ ). Mean age for the entire sample was 27.82mo (SD=6.77).

#### Results:

For the combined sample, mean calibration accuracy was  $.42^\circ$  ( $SD=.95$ ), mean affect was  $-0.02$  ( $SD=0.26$ ), and mean %Valid was 61.81% ( $SD=14.08$ ).

A series of Wilcoxon rank sum tests, Bonferroni-adjusted, compared calibration accuracy, participant affect, %Valid, and %Experimenter pre- vs. during-COVID-19. Effect sizes were calculated via  $r=Z/\sqrt{N}$ . Calibration accuracy ( $Z=24.5$ ,  $p=1.00$ ,  $r=0.02$ ), participant affect ( $Z=32.0$ ,  $p=1.00$ ,  $r=0.01$ ) and %Valid ( $Z=29.0$ ,  $p=1.00$ ,  $r=0.07$ ) were not significantly different pre- vs. during-COVID-19. However, the group assessed during-COVID-19 had higher %Experimenter than the group assessed before the pandemic ( $Z=63.0$ ,  $p<.001$ ,  $r=0.83$ ).

Conclusions:

COVID-19 safety measures did not alter feasibility of data collection in toddlers with and without neurodevelopmental disabilities. Participant loss was comparable to published live eye-tracking studies of high and low-risk infants (Thorup et al., 2018). Calibration accuracy surpassed the field standard of  $.5^\circ$  (Nyström et al., 2013) and %Valid was well-above the upper cut-off (50%) used in the literature (Nyström et al., 2019). Introduction of safety measures also did not lead to greater negative affectivity in the toddlers. However, COVID-19 safety measures resulted in increased attention to social partners during a live eye-tracking scenario. It is not clear if toddlers were responding to the masks' novelty, or whether they were working to decode communicative and affective cues from a perceptually impoverished input. Accurate live-eye tracking data with minimal data loss from inattention can be collected under pre- and pandemic conditions in neurodevelopmentally diverse toddlers.

**443.036** (Poster) Meet Me in the Middle: The Link between Common Ground and Coordinated Joint Action in ASD and TD  
**E. Karin**<sup>1</sup>, **Y. Estrugo**<sup>2</sup>, **S. Bar Yehuda**<sup>1</sup>, **R. Geva**<sup>3</sup> and **N. B. Bauminger-Zviely**<sup>4</sup>, (1)School of Education, Bar - Ilan University, Ramat - Gan, Israel, (2)School of Education, Bar - Ilan University, Ramat-Gan, Israel, (3)Psychology Department, Bar-Ilan University, Ramat-Gan, Israel, (4)School of Education, Bar Ilan University, Ramat Gan, Israel

---

Background:

Common ground (CG) is generated when two interlocutors build shared knowledge and concepts during a reciprocal conversation. Coordinated joint action (CJA) is created when two confederates accomplish a shared goal by coordinating their social-motoric movement in time and space. Both processes rely on the ability to interpret beliefs and actions in others, which is considered a core deficit in cognitively able ( $IQ>70$ ) youngsters with autism spectrum disorder (CAASD). Nonetheless, the developmental trajectory of CG ability as well as its link with CJA have been under-investigated for children and adolescents with CAASD.

Objectives:

This study examined group and age differences in CG for children and adolescents with CAASD compared to age-matched controls with typical development (TD), as well as CG's links with CJA. Findings regarding this link may offer a unique viewpoint for understanding social-communicational deficits in CAASD.

Methods:

Participants:

Children and adolescents ages 6–16yrs included 80 with CAASD ( $M = 11.11$ yrs,  $IQ = 103.88$ ) and 64 with TD ( $M = 10.73$ yrs,  $IQ = 114.53$ ) in three age-groups: early-childhood (6–8), pre-adolescence (8–12), and early-adolescence (12–16). Group differences on age and IQ were non-significant.

Measures:

Background measures included the Autism Diagnostic Observation Schedule (ADOS) and the Wechsler Intelligence Scale for Children—Fifth Edition (WISC-IV). A linguistic CG task was executed in peer dyads paired by IQ and chronological age. Children described 10 different tangram shapes to each other, six times (changing roles as follower and leader). Shapes were placed behind a screen, unseen to followers. Time duration and number of words were computed for each turn. However, to reflect the efficiency of the dyadic CG generation process, the current abstract presents duration and word count results only for the final turn (#6) while controlling for duration and word count at baseline (turn #1). Shorter time duration and lower word count

reflect more efficient CG performance. In addition, participants performed four dyadic CJA tasks: two imitation tasks (side-by-side walking, face-to-face movement-mirroring) and two completion tasks (virtual-football kick-and-catch, corridor completion during virtual football). CJA performance was coded via *Interact* micro-analyses coding system, providing four major coordinated movement scores for each task.

#### Results:

Group and age differences were examined for CG's time duration and word count in turn #6 (controlling for turn #1) using ANCOVA. Significant main effects emerged for group (CAASD > TD) and for age (early-childhood > pre-adolescence and early-adolescence) on duration and word count (see Table 1). For both groups, significant negative correlations emerged between time duration for CG (in turn #6 controlling for turn #1) and the CJA imitation and completion scores. Similarly, word count for CG (in turn #6 controlling for turn #1) correlated negatively with the CJA completion score in both groups but only correlated with the CJA imitation score in the CAASD group (see Table 2). Overall, better CG performance was linked with higher social-motor coordination.

#### Conclusions:

Interventionists should consider the action-language link in treating ASD.

**443.037 (Poster)** Peer Match Rather Than Autistic Diagnosis Predicts Social Network Density and Strength in Real-World Peer Interaction Among Autistic and Non-Autistic Adolescents  
*Y. L. Chen and K. P. Koenig, Occupational Therapy, New York University, New York, NY*

---

#### Background:

Social connections are crucial to mental health and well-being. Research on the social relationships of autistic students in inclusive education has used social network analysis to quantify their social connections, suggesting that they have fewer peer connections and are often peripheral or isolated in their classroom social networks. However, previous studies primarily focused on group comparisons between autistic and non-autistic students' social network measures in isolation of the peer context. Given the bidirectionality of social connections, as well as recent findings on the role of interpersonal similarity on positive social outcomes, it is necessary to investigate autistic student's social networks in the context of peers' group affiliation.

#### Objectives:

To compare characteristics of same-group and cross-group peer connections among autistic and non-autistic adolescents in a real-world, longitudinal social networks of peer interactions in inclusive education, by examining (1) whether affiliation in the same group (autistic or non-autistic), besides autism diagnosis, predicts social network measures; (2) whether reciprocity of connections differs between autistic-to-autistic, non-autistic-to-non-autistic, and mixed-group social networks; and (2) whether the school club social networks demonstrates homophily based on group affiliation or social centrality.

#### Methods:

We plotted the longitudinal social network in an inclusive school club (Maker Club) across four months at a public middle school in a large, urban area, based on the rates of observed social behaviors among the autistic and non-autistic adolescents ( $N=12$ , 6 were autistic, between grade 6 to 8) enrolled in the club. For a total of eight observation sessions, we calculated social network measures (degree centrality, strengths, and reciprocity) for same-group and cross-group social networks, as well as the assortativity coefficients (level of homophily) of the club networks based on group affiliation and degree centrality.

#### Results:

Figure 1 illustrates the mean networks of high social interaction rates among students in the club. Mixed-methods modeling suggested that students' degree centrality, either the number of connections they made with peers or received, was not predicted by their groups (autistic or non-autistic) but the type of social network (same-group or cross-group). Social network strengths showed similar results, although total network strengths (total rates of social interaction with peers) were predicted by both student groups and network types. One-way ANOVA comparing the reciprocity of social initiations in autistic-to-autistic ( $M=0.65$ ,  $SD=0.20$ ), non-autistic-to-non-autistic ( $M=0.85$ ,  $SD=0.17$ ), and mixed-group social networks ( $M=0.51$ ,  $SD=0.26$ )

revealed significant differences between network types ( $F=4.90, p=.01$ , Figure 2), while no significant differences were found between reciprocity in social responses across the three network types. The average assortativity coefficient of the club social network over time showed that students tend to connect to peers within the same group ( $r=.23$  and  $.29$  for social initiation and response networks), but not those with similar social activity or popularity ( $r_s=.04$ ).

#### Conclusions:

This preliminary study explored the role of interpersonal similarity on autistic adolescents' social networks in natural peer interactions. The results showed that the numbers and strengths of connections were predicted by matches between student and peer groups but autism diagnosis, and the students tended to connect with their same-group peers.

**443.038** (Poster) Perceived Social Support By Typically Developing Children and Children with Autism Spectrum Disorder  
*M. Kaedbey<sup>a</sup>, H. Dahary<sup>b</sup> and E. M. Quintin<sup>c</sup>, (1)McGill University, Montreal, QC, Canada, (2)McGill University, Montreal, QC, Canada, (3)Educational & Counselling Psychology, McGill University, Montreal, QC, Canada*

---

Background: Social support is defined as, 'a multidimensional concept that includes the support actually received (informative, emotional and instrumental) and the sources of the support (friends, family, strangers). Social support from peers and teachers provide an index of social inclusion at school. Furthermore, social support has been demonstrated to be an important factor in the lives of those with ASD, yet very little research has investigated the extent of perceived social support available for children with ASD. Although it is common for teachers of children to provide information on child social support, adult perceptions of child social support do not always align with child perceptions. Gender differences in social support are not always discussed in the literature, but existing studies suggest that adolescent girls perceive more social support than adolescent boys. We compare self-reported perceptions of social support by children with ASD versus TD children, as well as investigate gender differences in perceptions of social support.

Objectives: The first aim of the study is to compare self-reported perceptions of social support by children with autism spectrum disorder (ASD) versus typically developing (TD) students. The second aim of the study is to investigate gender differences in perceptions of social support in children with typical development (TD).

Methods: Twenty-five children with ASD ( $n=12$ ) and TD children ( $n=13$ ) aged 8 to 12 years were recruited via a music intervention program (before the program) in an elementary school, in Gatineau, Quebec. The participants completed the Social Support Appraisal Scale with an examiner.

Results: An independent-samples t-test revealed that children with ASD reported having less social support from their peers compared to TD children ( $p<.05$ ). There was no significant group difference in self-reported teacher support ( $p>.05$ ). TD boys tended to report more peer support than TD girls, but there was no gender difference in self-reported teacher support ( $p>.05$ ).

Conclusions: The results of this study suggest that children with ASD self-report having less social support than their TD peers. We found that pre-adolescent boys tend to report higher peer support than girls, which contrasts research studies that have found the opposite trend in older children. Moreover, children with ASD are more likely to be excluded from social activities at school compared to TD children. Peer and teacher support systems are recognized as important resources that children use to bolster their ability to cope in stressful situations. Interventions that aim to facilitate the social inclusion of children with ASD should incorporate direct outcome measures of peer and teacher support. Given these points, findings support the need for interventions, targeted school activities, and research to ameliorate social support of students with ASD and TD girls, and to recognize the different social support needs of distinct populations.

**443.039** (Poster) Perspective-Taking, Mentalizing, and Attending to Others in Narratives from Roleplaying Games  
*D. Schena<sup>a</sup>, A. Hillier<sup>b</sup> and H. Carroll<sup>b</sup>, (1)University of Massachusetts, Lowell, Lowell, MA, (2)University of Massachusetts Lowell, Lowell, MA, (3)University of Massachusetts Lowell, Lowell, MA*

---

Background: Role-playing games (RPGs), in which a player interacts with an in-game world as character or avatar (Hitchens & Drachen, 2009), may be a useful tool for services for persons with autism spectrum disorder (ASD). These games may provide a fun way to practice a wide variety of skills, such as perspective-taking and "mentalizing" tasks such as assuming mental states, emotions and goals (Allen, 2003; Frith, 2001; Langdon & Coltheart, 2001). As these games tend to be played socially, gaming with players without ASD diagnoses may offer players with ASD a good way of meeting new acquaintances and practicing social skills while working on goals during and surrounding gameplay.

**Objectives:** As RPGs tend to be story-based, these games naturally produce narratives surrounding the player's experiences. We aimed to examine these narratives in order to gain insight into the narrator's experiences, comparing these experiences between those with ASD and an age matched group without an ASD diagnosis. Specifically, we looked at four "axes" of analysis: in-game perspective (whether or not the narrator told the story as their character would see it), references to individuals (such as references to oneself, others, a group including oneself, etc.), the use of words implying mental traits or activity, and the number of goals explicitly introduced.

**Methods:** We recruited five participants with ASD (2 female, 2 male, 1 gender nonbinary) and 12 participants without ASD (4 female, 8 male), all of whom had played an RPG within the past year. Sessions were conducted virtually, using Zoom, Skype, or Discord to interview participants. After participants arrived and informed consent was collected, a sample narration was offered to orient the participants to the task. After this sample, participants were asked to tell a story from an RPG they had played within the past year which we audio-recorded. Following the narrative participants completed a demographic form and the Autism Quotient Questionnaire, a 50-item questionnaire which assesses autism traits. Narratives were scored using a stanza, as well as sentence and word count of key words (such as "think" for the mental trait axis).

**Results:** Stanza analysis revealed that across participants, a relatively common four-part pattern emerged; an "introduction to the world" section, an in-game section, an in-game climax section, and an in-game and out-of-game conclusion and summary. Participants with ASD tended to produce shorter narratives (average of 241 words to 437 from non-ASD participants) and sometimes produced rambling or exceptionally short conclusions. However, comparisons based on ASD diagnosis as well as gender did not produce significant differences between the groups in narration or Questionnaire scores.

**Conclusions:** Current findings suggest that persons with ASD who play RPGs offer narratives which are largely similar to persons without an autism diagnosis. This suggests that RPGs may offer an environment where those with ASD are able to practice both social-communication and other skills while having fun. This work will be further examined with a larger participant group where the potential use of these games for mentalizing and perspective-taking practice will be specifically investigated.

**443.041 (Poster) Sex Differences in Social Competence from 6 to 36 Months in a Sample at High Familial Risk for Autism Spectrum Disorder**

**Background:**

While symptoms autism spectrum disorder (ASD) unfold over the first 2-3 years of life, the average age of diagnosis remains close to 5 years, missing a critical window for early intervention. Assessments of symptoms of ASD, particularly of social communication (SC), vary with child's language, motor and cognitive development, which has posed challenges for capturing variability in SC symptoms over time. Child sex may be an important predictor of SC symptoms, as females generally show more advanced SC skills than boys regardless of ASD diagnosis. Precise quantification of sex-specific SC symptoms and trajectories may inform early identification of ASD. Here, we use moderated nonlinear factor analysis (MNLFA; Bauer, 2017) to establish measurement invariance, a psychometric property crucial to determining whether a latent variable (e.g., SC) functions similarly across sex and diagnostic groups over time. We then test for differences in SC symptoms by sex and diagnostic group.

**Objectives:**

1. To evaluate measurement invariance on SC and derive an estimate of SC symptoms in infant-siblings of children with ASD from 6 to 36 months.
2. To evaluate sex and diagnostic group differences in SC, as well as their interaction, from 6 to 36 months.

## Methods:

This study prospectively examined infants at high-familial-risk (HR) for ASD at 6, 12, 24, and 36 months of age (total  $N_{\text{observations}}=1220$ ). Clinical best estimate diagnosis of ASD (HR-ASD;  $N= 88$ , 20 females) or no-ASD (HR-negative;  $N= 297$ , 142 females) was made at 24 months. Participants were assessed with the AOSI at 6 and 12 months, and the ADOS at 24 and 36 months, which are both clinician-administered behavioral observations of SC and other ASD-relevant behaviors. Features harmonized across assessments included Response to Name, Social Interest, Social Referencing and Eye Contact. MNLFA was applied to obtain an assessment of SC symptoms (where higher scores indicate higher symptoms), accounting for measurement invariance by age. ANOVA was then employed to examine differences in sex, diagnostic outcome (HR-ASD vs. HR-negative) and sex-by-diagnosis interaction over time.

## Results:

MNLFA results indicated measurement non-invariance (i.e., differential item functioning) by age on Response to Name, Social Interest, and Social Referencing items ( $p's < .0001$ ), suggesting that these items do *not* function similarly over development. All items functioned similarly by sex. In the ANOVA model, there were significant main effects of sex ( $p=.018$ ) and diagnosis ( $p < .001$ ). There was no significant interaction of sex and diagnosis ( $p > .05$ ) (Figure 1).

## Conclusions:

We used a novel method to precisely model SC from 6 to 36 months in a sample at high familial risk for ASD. Consistent with previous literature, we found a robust underlying factor of SC, with measurement differences by age and mean-level differences emerging in diagnostic and sex groups. Sex differences in SC were consistent across HR-ASD and HR-negative groups, providing evidence that sex differences in SC are not ASD-specific. Diagnostic group differences were present across development, suggesting that when assessing SC, employing methods that correct for measurement invariance could improve detection of early ASD-relevant behaviors.

### **443.042 (Poster)** Social Attention of Children with ASD during Live Interactions Around a High-Interest Object

**J. Yang<sup>1</sup>, V. O. Nacho<sup>2</sup>, J. Wiebe<sup>2</sup>, G. Iarocci<sup>2</sup> and E. Birmingham<sup>1</sup>,** (1)Faculty of Education, Simon Fraser University, Burnaby, BC, Canada, (2)Simon Fraser University, Burnaby, BC, Canada, (3)Psychology, Simon Fraser University, Burnaby, BC, Canada

## Background:

Previous research has demonstrated that social attention is reduced in school-aged children with Autism Spectrum Disorder (ASD) when compared with typical developing (TD) children. However, the majority of studies on this topic focused on computer-based stimuli. How school-aged children with ASD attend to social stimuli during real life interactions is not well understood.

## Objectives:

This study specifically investigated how social attention unfolds in the presence of objects that are of high interest to children with ASD, as previous studies suggest that these objects may compete for attention (Sasson & Touchstone 2014), but that high interest topics of conversation may improve social attention (Nadig et al 2010).

## Methods:

This study included 20 ASD and 30 TD school-aged children, matched on age (ASD  $M = 10.01$  years; TD  $M = 9.50$  years) and IQ (ASD  $M = 104.00$ ; TD  $M = 107.33$ ). Participants were asked to select their favourite object from a display of 5 objects that are commonly associated with circumscribed interests for individuals with ASD (Pokémon, dinosaur, train, spaceship, car), and 4 low-interest objects (yarn, flower, plastic cup, doll). After selecting a preferred object, participants engaged in a conversation with the experimenter about the object that they had chosen while their interactions were captured through a point of view head camera. Social attention was behaviorally coded from the video footage into 3 categories: 1) *Full face* consisted of video frames that contained all of the experimenter's major facial features (eyes, nose, and mouth); 2) *face out-of-view* captured frames in which the experimenter's face was not visible, because the participant was looking elsewhere; 3) *partial face* contained frames in which some but not all of the experimenter's facial features were visible. Coding was conducted on the first 60 seconds of the interaction and was further divided into three 20s segments to see if social attention behaviour changed over time as the interaction unfolded.

## Results:

Nonparametric analysis after Bonferroni correction revealed that the ASD group spent significantly less time viewing the experimenter's full face than the TD group, and this was true throughout the 60s second interaction (Mann-Whitney's U tests for 0-20s, 20-40s, 40-60s, ps all < .016). The ASD group also spent significantly less time in the partial face category than the TD group interaction (Mann-Whitney's U tests for 20-40s, 40-60s, ps all < .016). In contrast, the ASD group spent significantly more time than the TD group looking away from the experimenter's face (face out-of-view: Mann-Whitney's U test for 20-40s, 40-60s, ps all < .016). The TD group increased their social attention over time (Friedman's test for face full and out-of-view, ps < .016), but the ASD group did not (ps > .016).

## Conclusions:

Compared with the TD group, children with ASD showed less social attention in a real-life social interaction. While TD children increased their social attention over time, the social attention of children with ASD remained low. Our findings extend the literature on social attention in school-aged children with ASD to face-to-face interactions.

### **443.043** (Poster) Social Connectedness and Stress in Autistic Compared to Socially Anxious Adults

**D. Melanson<sup>1</sup>, D. Gifford<sup>1</sup>, L. Parker<sup>1</sup>, S. Gilliat<sup>1</sup>, J. Wild<sup>1</sup>, C. Timpson<sup>2</sup>, J. A. Nielsen<sup>3</sup> and M. South<sup>4</sup>,** (1)Neuroscience, Brigham Young University, Provo, UT, (2)Psychology, Brigham Young University, Provo, UT, (3)Harvard University, Cambridge, UT, (4)Psychology & Neuroscience, Brigham Young University, Provo, UT

---

## Background:

Autistic individuals often find social interactions to be stressful, in part due to a communication gap between autistic and neurotypical (NT) peers (Morrison et al., 2019). Feelings of everyday stress likely contribute to significantly elevated levels of anxiety in autism. Understanding how social interactions affect stress and anxiety is important when considering the well-being of autistic adults. Studies using ecological momentary assessment methods (EMA) are useful for tracking such relationships on a daily level more than one-time lab visits.

## Objectives:

The present study used EMA to measure daily social connections and stress. We hypothesized that the amount of tension associated with social interactions for autistic participants may lead to a positive association between these two. However, feelings of social connectedness, separate from the number of daily interactions, could correlate with better stress management.

## Methods:

Participants included adults participating in a longitudinal study of mental health in social anxiety and autism. Participants consisted of 100 adults in non-clinical (NOCLIN n =30), autistic (AUT n =35), and socially anxious (SOCANX n =35) groups. Daily phone surveys were delivered over the course of 6 months via MetricWire. Correlations were analyzed through the R studio package corrplot.

## Results:

Preliminary analysis of the correlations between the number of daily social interactions and reported daily stress varied across the three groups: the NOCLIN group showed significant positive correlation, there was no significant correlation in the SOCANX group, while the AUT group showed a *positive* correlation between social interactions and stress levels. Similar patterns were found for a question on negative affect. The NOCLIN and AUT groups also showed positive correlations between social connectedness and their perceived ability to manage their stress. All three groups showed strong correlations between social connectedness and a question on positive affect.

## Conclusions:

Data supported our hypothesis that increased numbers of social interactions may be associated with feelings of stress and negative affect in the autism group. Nonetheless feeling socially connected contributed to perceived ability to manage stress

across all groups. We are continuing our EMA research to better elucidate what aspects of social contact, compared to feelings of social connectedness, best predict stress and anxiety in autistic adults.

**443.044** (Poster) Social Functioning and the Presentation of Anxiety in Children with Autism and Co-Occurring Anxiety Disorders

**M. C. Hunsche<sup>1</sup>**, M. Cervin<sup>2</sup>, E. A. Storch<sup>3</sup>, P. Kendall<sup>4</sup>, J. J. Wood<sup>5</sup> and C. M. Kerns<sup>1</sup>, (1)University of British Columbia, Vancouver, BC, Canada, (2)Lund University, Lund, Sweden, (3)Baylor College of Medicine, Houston, TX, (4)Temple University, Philadelphia, PA, (5)Human Development & Psychology, University of California, Los Angeles, Los Angeles, CA

---

**Background:** Co-occurring anxiety in children with autism spectrum disorder (ASD) is associated with greater social impairment, including deficits in social ability (Duvekot et al., 2018; Lei & Ventola, 2018; McVey et al., 2018) and poorer peer relationship quality (Chou et al., 2020; Mazurek & Kanne, 2010; Wright & Wachs, 2019). Social difficulties may influence the presentation and impact of anxiety symptoms among children with autism, particularly social anxiety. Most research to date has investigated this topic using only single-informant, broad measures of social functioning, limiting our understanding of how different aspects of social functioning relate to one another and to anxiety in this population.

**Objectives:** The current study sought to extend prior work by using a novel Bayesian network analytic approach (Williams & Mulder, 2019) to examine how different facets of social ability (e.g., social communication ability, social motivation) and peer relationships (e.g., friendships, bullying) relate to one another and to anxiety severity and comorbidity in a large treatment-seeking sample of autistic children with co-occurring anxiety disorders. Additionally, this study sought to clarify the role of social functioning in the presentation of social and non-social anxiety symptoms in children with ASD.

**Methods:** Data were collected from 191 autistic children ages 7-13 and their caregivers who participated in intake interviews for the *Treatment of Anxiety in Autism Spectrum Disorder* trial. Interviews included the Anxiety Diagnostic Interview Schedule-Autism Addendum (ADIS/ASA), Social Responsiveness Scale-2 (SRS-2), Autism Diagnostic Observation Schedule (ADOS-2) and Child Behavior Checklist (CBCL).

**Results:** The network analysis demonstrated strong connections among the core social deficits of ASD (i.e., social motivation, social communication), and among measures of social integration (i.e., conflict with peers, bullying), though there was little overlap between these two clusters of social difficulties. Compared with other facets of social functioning, social motivation (i.e., level of interest and desire to engage in social interactions and relationships) demonstrated the strongest connections with nearly every facet of social ability as well as with peer relationship quality (posterior probabilities = 0.93 -1.00), suggesting that this domain of social functioning may play a central role in the social well-being of children with autism and comorbid anxiety. Logistic binary regressions indicated that ToM appeared to play a role in the presentation of anxiety symptoms, whereby marked impairment in ToM was most strongly associated with a distinct presentation of social anxiety (i.e., social fears without fear of negative evaluation) compared with social anxiety disorder (i.e., social fears with fear of negative evaluation) ( $\beta = 1.00, p = .041, OR = 2.71 [1.04, 7.05]$ ).

**Conclusions:** Findings suggest that difficulties in one area of social functioning are likely associated with difficulties in other, related areas—particularly social motivation, which may represent an optimal target for psychosocial intervention for children with autism and anxiety disorders. Further, ToM seemed to be a unique indicator of a distinct presentation of social fears in autistic children, suggesting that these children may particularly benefit from intervention strategies that target this social-cognitive skill.

**443.045** (Poster) Social Skills Interventions for Young Adults: Fitting into a Neurotypical World?

**J. Monahan<sup>1</sup>**, B. Freedman<sup>2</sup>, K. Pini<sup>1</sup> and C. Edmondson<sup>1</sup>, (1)University of Delaware, Newark, DE, (2)Center for Disabilities Studies, University of Delaware, Newark, DE

---

**Background:**

Social skills instruction is often cited as necessary for autistic individuals to be successful in higher education or employment. However, literature reviews of social skills curricula have shown mixed results of effectiveness and focus largely on younger populations. In recent years the autistic community has made clear that their involvement in the creation and evaluation of interventions is critical (Gowen et al., 2019). In the most recent literature review, the authors reported on autistic satisfaction, but did not address the level of autistic input used to inform the interventions. It is important to understand what researchers believe is the goal of social skill interventions, which requires a critical examination of the outcome variables used in studies. Thus, we conducted a systematic literature review to critically examine studies on social skills interventions for autistic young adults.

Objectives:

To understand:

- The literature base for social skills interventions for young autistic adults
- To what extent the interventions are formed by autistic input, researchers are collecting information about social validity, or acceptance of the intervention and how the success of interventions is measured

Methods: The ERIC and PSYCInfo databases were systematically searched for articles that examined the effectiveness of social skills interventions for young adults, were published in 1990 or later, written in English, and domestic. Two members of the research team then coded 505 abstracts for eligibility, 26 of which were included in the analysis.

Results:

Of the 26 interventions identified in this literature review, participants were mostly male (77.6%) and of the studies that reported on race, 75% of participants were white. While studies that examined participant satisfaction found high levels of satisfaction and positive experiences with the interventions, only three asked for autistic input when designing the intervention or determining which social skills to teach. The outcome variables measured varied by study and within randomized controlled trials (RCT) and single subject studies, there were a mix of measures completed by participants and parents or caregivers. In the RCTs the only measures that showed an improvement of social skills knowledge were those that were created specifically for the intervention. Most studies found no improvement in mental health variables, with mixed results for one intervention and its impact on loneliness. Single subject studies reported a functional relationship between the intervention and the targeted social skill for all or the majority of their participants.

Conclusions: The studies in the literature review found mixed results of effectiveness of group interventions. Only three of the studies asked autistic individuals to contribute to the intervention itself, which is a significant gap in the literature base. Opportunities for improvement appear important for social skills interventions for young adults on the spectrum, as the studies found very little change in mental health variables. Researchers should work with the autistic community in building interventions and focus on building inclusivity through interventions for non-autistic populations to better understand the communication differences of autistic peers.

**443.046** (Poster) The Factors Affecting Social Cognition in Children with ASD

**A. Q. Razaghzadeh<sup>1</sup>, J. C. Bullen<sup>2</sup> and P. Mundy<sup>3</sup>,** (1)School of Education, University of California, Davis, Davis, CA, (2)University of California, Davis, Davis, CA, (3)University of California at Davis, Sacramento, CA

---

Background: Problems on measures of theory of mind (ToM), or the ability to ascribe mental states to others, have been consistently reported for younger children with ASD with or without intellectual disabilities and for older children with intellectual disabilities. However, it is less clear whether older children without intellectual disabilities display problems on ToM measures (Scheeren et al., 2013), and whether these problems singularly reflect social cognitive processes or more general cognitive processes such as working memory, inferential thinking, or verbal IQ (VIQ) (Joseph & Tager-Flusberg, 2004).

Objectives: To address this issue, this study examined the performance of a large sample of verbal children and adolescents with ASD on both verbal and nonverbal measures of ToM compared to age and VIQ matched controls in order to test whether diagnostic groups differences on ToM could be explained in terms of variance on measures of working memory, inferential thinking, or VIQ.

Methods: The participants included 125 children between the ages of 8-15. 81 met diagnostic criteria (ADOS-2) for ASD but were not affected by intellectual disability (ASD-WoID group; M = 11.29 years, SD = 2.13) and 44 were in the Typical Development (TD) group (M = 11.59 years, SD = 2.25). IQ scores were obtained from the WASI-2 (Weschler, 2011). Working memory was assessed using the Story Memory subtest from the WRAML2 (Sheslow & Adams, 2003), inferential thinking using the QRI (Leslie & Caldwell, 2011), and ToM using the average of individual scores received on Strange Stories Task (Happé, 1994) and the Silent Films Task (Devine & Hughes, 2013). The ASD and TD samples were also matched on “higher VIQ” and “lower VIQ” subgroups based on a median VIQ split at 101.5 (see Table1).

Results: MANOVA revealed that the ASD group significantly differed from the TD group on the ToM, inferential thinking, and working memory measures ( $p < .001$ ), but there was no interaction of diagnostic group and VIQ group. Working memory and inferential thinking correlated with ToM in the ASD sample only. A stepwise logistic regression analysis indicated that performance on ToM measures correctly identified 82% of the ASD sample but only 49% of the TD sample ( $p < .001$ ). The

addition of Story Memory improved the identification of ASD slightly to 83.6%, but improved TD identification to 69.2% ( $p < .001$ ). The QRI did not contribute significantly on the 3<sup>rd</sup> step of regression ( $p < .20$ ). Thus, ToM performance significantly and independently differentiated many but not all ASD and TD participants above and beyond the effects of working memory and inferential thinking. Neither working memory nor inferential thinking measures impacted ASD identification, but the former also differentiated the diagnostic samples.

**Conclusions:** The findings were consistent with the hypothesis that ToM performance is associated with domain general cognitive abilities such as working memory and inferential thinking in ASD. However, the findings also support the idea that ToM deficits in ASD are not explained by impairments in more general cognitive abilities.

**443.047 (Poster)** The Influence of Autism Label on Face Recognition By Non-Autistic Adults

*M. I. Cargill, A. J. Lampi, Z. M. Sargent, K. M. Stockwell and V. K. Jaswal, University of Virginia, Charlottesville, VA*

---

**Background:** Labeling an individual can influence the inferences others make about them. For example, using a face-inversion paradigm, Civile et al. (2018) found the difference between memory for upright vs. inverted faces was larger for faces labeled "regular people" than those labeled "diagnosed with autism." Civile et al. suggested this could mean participants treated faces labeled as "diagnosed with autism" in a more objectified manner than faces labeled as "regular people."

**Objectives:** In two pre-registered studies, we attempted to replicate and extend Civile et al.'s (2018) findings. Study 1 was a close replication using the face inversion paradigm. Study 2 was a conceptual replication using an in-group vs. out-group recognition memory paradigm (Bernstein et al., 2006).

**Methods:** In Study 1, we recruited a sample of 140 adults via MTurk (Mage = 37.53 years, SD = 8.77; NMale = 62). Participants saw 64 faces at encoding: Half were upright and half were inverted. As in Civile et al.'s study, half of participants were informed the faces they would see were of "regular people" and half were informed the faces were of "people diagnosed with autism." At test, participants saw the 64 old faces (in the same orientation at encoding) and 64 new faces (half upright and half inverted), and made old/new judgments.

In Study 2, 147 undergraduates (Mage = 18.52 years, SD = 0.85; NMale = 40) in one of three conditions saw 40 faces at encoding. In "identity-first" and "person-first" conditions, half of the faces appeared on blue backgrounds and were labeled either "autistic person" or "person with autism," and half appeared on orange backgrounds and were labeled either "non-autistic person" or "person without autism." In a control condition, faces appeared on blue and orange backgrounds, but were not given a label. At test, all participants saw the 40 old faces on the same color backgrounds as at encoding and 40 new faces (half on blue and half on orange). No faces were labeled at test.

**Results:** Study 1: Figure 1 shows upright faces were remembered better than inverted faces  $F(1,276) = 56.04, p < .001$ , and faces labeled as "regular people" were remembered better than those labeled "people diagnosed with autism"  $F(1,276) = 4.48, p = .035$ . The interaction was not significant, indicating magnitude of the inversion effect was the same regardless of label.

Study 2: Figure 2 shows faces on blue backgrounds were remembered better than those on orange backgrounds,  $F(1,144) = 6.74, p = .01$ . Neither effect of condition nor interaction were significant, suggesting face recognition did not depend on presence or type of autism label provided at encoding.

**Conclusions:** Results from Study 1 suggested that faces with an autism label were less likely to be recognized than those without (though no difference of inversion effect magnitude, contrary to Civile et al., 2018). However, results from Study 2 suggested autism labels had no effect on recognition memory. It is possible that explicit measures of bias may reveal differences these implicit measures did not.

**443.048 (Poster)** The Role of Distractibility and Emotional Engagement in Imitation in Children with Autism

*A. Browngoehl, K. D. Kelly and G. Vivanti, A.J. Drexel Autism Institute, Drexel University, Philadelphia, PA*

---

**Background:**

It is critical to understand which circumstances facilitate imitation in children with ASD, so that targeted intervention can be informed accordingly. Critical factors modulating imitation performance in children without ASD include distractibility and

emotional engagement with the model (Micheletti et al., 2020; Vivanti et al., 2016). One plausible yet untested scenario is that children with ASD imitate more in response to a model who is socially engaging when there are no distractions in the environment.

Objectives:

The present study examines whether toddlers with ASD imitate more accurately in response to the following conditions:

A) whether the demonstrator is showing positive or neutral facial expression

B) whether the demonstration takes place in a distraction-free versus “busy” environment that includes distractors (e.g., posters on the wall).

Additionally, we used eye-tracking to examine the link between imitation and attention to the demonstration in response to these different scenarios.

Methods:

We examined video recorded sessions of 27 children with ASD (20–35 months) participating in an imitation task. Participants were shown videos of an unfamiliar adult performing object-directed actions with either a playful or neutral facial expression and with or without visual distractors. Distractors included posters on the wall, as well as plants and other objects designed to resemble the real-life scenario of a busy environment (e.g., classroom). During observation of the demonstration, gaze patterns in responses to the video-stimuli were recorded using a Tobii-Pro eye-tracking device. After watching the model, participants were given the same materials shown in the videos and were encouraged to interact with them. Their responses were rated on a scale from 0–3, with zero indicating no interaction and three indicating a full imitation of the action. The rater was blind to research hypotheses and achieved reliability and percentage agreement above 80% with a master rater.

Results:

Imitation performance was (a) not modulated by facial expression ( $p = .698$ ) and (b) more accurate when distractors were present ( $p = .004$ ). Eye-tracking data showed that children did not look longer at the demonstration when accompanied by playful affect compared to neutral affect ( $p = .196$ ). Conversely, they looked longer at the demonstration in the “busy” compared to the “distraction free” environment ( $p < .001$ ). Additionally, children looked longer at the action to imitate in stimuli with distractors in the background compared to stimuli without distractors ( $p = .001$ ).

Conclusions:

Attention and imitation of children with ASD were modulated by the presence or absence of distractions, but not by the affect (positive or neutral) shown by the demonstrator. Counter to predictions, children with ASD in this study imitated more accurately when the environment *was not* distraction-free, potentially because the presence of objects increased engagement with the task. Additionally, unlike children without ASD in previous studies (Micheletti et al., 2020) children with ASD in this study imitated actions to the same degree regardless of whether the model displayed playful or neutral affect. These results suggest that a more naturalistic versus distraction-free environment may facilitate imitation in young children with ASD.

**443.049** (Poster) To be Good or to be Right: Effects of Social Problem Solving Competence and Congruency on Social Functioning in ASD

*M. L. McNair<sup>1</sup>, E. J. Libsack<sup>2</sup>, V. Mondejar<sup>2</sup>, N. Mordekai<sup>2</sup>, N. Russo-Ponsaran<sup>3</sup> and M. D. Lerner<sup>1</sup>, (1)Department of Psychology, Stony Brook University, Stony Brook, NY, (2)Stony Brook University, Stony Brook, NY, (3)Rush University Medical Center, Skokie, IL*

---

Background: Children with autism spectrum disorder (ASD) demonstrate variable difficulty with social problem solving (SPS; Russo-Ponsaran, 2015). SPS challenges include generating effective, competent solutions (Ziv, 2014) and selecting prosocial responses (Bottema-Beutal, 2019) to social problems. Some ASD children generate competent, prosocial goals (e.g., make friends) and effective solutions to social problems (competent congruent [CC] SPS); others may have non-competent goals (e.g., hostile, retributive) but still generate effective solutions to achieve them (non-competent congruent [NCC] SPS). Although social skills and ASD symptoms relate to SPS abilities in ASD (Mazza, 2017), it is unknown whether it is the *competence* or *congruence* of SPS responses that is most responsible for these relationships.

**Objectives:** Evaluate the relationship between social skills, ASD symptomatology, and congruence of socially competent, or non-competent, SPS goals and solutions.

**Methods:** 58 children (44 male) ages 5-11 years ( $M=8.53$ ,  $SD=1.33$ ) with ADOS-2-confirmed ASD and  $IQ \geq 80$  ( $M=103.72$ ,  $SD=14.33$ ) completed SPS and affect recognition (AR) tasks within SELweb, a computerized, self-administered social cognition battery (Figure 1; McKown, 2015; Russo-Ponsaran, 2019); CC and NCC SPS response rates were calculated for each participant (Table 1; Figure 1). Social skills were assessed using the parent-report Social Skills Improvement System (SSIS; Gresham & Elliott, 2008), and ASD symptomatology was evaluated via ADOS-2 Comparison Score (CS; Lord, 2012), Social Responsiveness Scale, 2nd Edition (SRS-2; Constantino & Gruber, 2012), and Social Communication Questionnaire (SCQ; Rutter, 2003). Bivariate correlations were conducted to examine relationships between CC or NCC SPS and AR, social skills, and ASD symptomatology. Variables with significant correlations were entered in commonality analyses (Nimon, 2008) to specify the unique and common variance each contributes to CC or NCC SPS (Table 2).

**Results:** Greater SSIS ( $r(58)=.355$ ,  $p<.01$ ), lower SRS-2 ( $r(58)=-.355$ ,  $p<.01$ ), and lower ADOS-2 CS ( $r(58)=-.261$ ,  $p<.05$ ) were associated with CC SPS. Conversely, lower SSIS ( $r(58)=-.355$ ,  $p<.01$ ), greater SRS-2 ( $r(58)=.367$ ,  $p<.01$ ), higher SCQ ( $r(58)=.276$ ,  $p<.05$ ), and poorer AR ( $r(58)=-.262$ ,  $p<.05$ ) were associated with greater NCC SPS. Commonality analyses revealed variance common to SSIS and SRS-2 accounted for the greatest overall variance in CC SPS, while ADOS-2 CS contributed the greatest unique variance. Variance common to SSIS, SRS-2, and SCQ accounted for the greatest overall variance in NCC SPS, and AR contributed the greatest unique variance.

**Conclusions:** Most youth with ASD exhibited CC SPS responses and did not exhibit NCC, though considerable variation was evident. While social skills and ASD symptoms were related to SPS responses, these results suggest that competence, rather than congruence, of SPS related to greater skills and fewer symptoms. Results also revealed common rater variance of parent report to be most related to SPS, while unique variance of clinician-rated symptoms of ASD and AR each predicted CC and NCC SPS, respectively. More finely parsing the shared and unique contributions of social symptoms to SPS provides a more nuanced means of understanding social cognitive profiles in ASD (Keifer et al., 2020). Future work should further disentangle the role of specific elements of SPS in impacting social functioning in ASD, to provide more precise social cognition intervention targets.

#### **443.050 (Poster)** Use of the Children's Communication Checklist-2 in School-Aged Students with ASD: A Psychometric Analysis

**S. W. Nowell<sup>1</sup>**, B. Tomaszewski<sup>2</sup>, J. R. Steinbrenner<sup>3</sup>, A. Sam<sup>3</sup> and S. L. Odom<sup>4</sup>, (1)University of North Carolina - Chapel Hill, Chapel Hill, NC, (2)Frank Porter Graham Child Development Institute, University of North Carolina at Chapel Hill, Chapel Hill, NC, (3)Frank Porter Graham Child Development Institute, Carrboro, NC, (4)Frank Porter Graham Child Development Institute, University of North Carolina at Chapel Hill, San Diego, CA

#### **Background:**

Measurement of social-pragmatic communication skills is essential for clinicians and researchers working with school-aged autistic children. Many measures of these skills require time-intensive training and coding and are impractical for clinical assessment settings. In this poster session, we will examine the psychometric properties of the Children's Communication Checklist-2 (CCC-2; Bishop, 2006) as applied to children with ASD and completed by teachers, providing an updated report of the utility of this measure for clinicians and researchers.

#### **Objectives:**

- (1) To examine the reliability of the CCC-2 as a measure of social-pragmatic communication skills in children with ASD.
- (2) To explore the convergent and divergent validity of the CCC-2 as a measure of social-pragmatic communication skills in children with ASD.
- (3) To determine the factor structure of the CCC-2 for this sample of students with ASD and if the factor structure results differ by child biological sex, nonverbal IQ, ethnicity, or race.

#### **Methods:**

Using a sample of 299 school-aged autistic children ( $M=8.6$  years,  $sd=1.7$ , 27% female, 51% non-White) whose teachers completed the CCC-2, we evaluated the psychometric properties of the measure.

## Results:

Internal Consistency. Cronbach's alpha was .94 for the whole measure. Subscale alphas ranged from: .62-.86.

Convergent Validity. The CCC-2 GCC was highly correlated with the VABS Communication ( $r=.67, p<.01$ ) and Socialization ( $r=.61, p<.01$ ) domain standard scores. It was moderately correlated with the SSiS Social Skills Standard Score ( $r=.42, p<.01$ ).

Divergent Validity. The CCC-2 GCC did not show divergent validity with the VABS Daily Living Skills Domain ( $r=.61, p<.01$ ). It demonstrated divergent validity with the SSiS Problem Behavior Standard Score ( $r=-.31, p<.01$ ) and the SCQ restricted and repetitive behavior subscale ( $r=-.08, p<.28$ ).

Factor Structure. We conducted a series of CFAs and EFAs (See Table 1 for fit statistics) to determine the most parsimonious model fit. The final model was a 3-factor CFA on 38-items that met acceptable goodness of fit-criteria (RMSEA = 0.050, CFI = 0.896, TLI= 0.889, SRMR=.101). The factors were interpreted as (1) structural language (2) pragmatic communication and (3) pragmatic social. Nonverbal IQ was significantly associated with Structural Language ( $B= -.02, p < .001$ ) and Pragmatic Socialization ( $B= -.01, p < .001$ ), but not Pragmatic Communication. Individuals with higher nonverbal IQ scores had less difficulties with structural language and pragmatic social skills. Race and Ethnicity was associated with Structural Language ( $B = -.40, p < .001$ ), but not Pragmatic Socialization or Pragmatic Communication. Students who identified as White and Non-Hispanic/Non-Latino had fewer difficulties with structural language than students who identified as White, Hispanic/Latino, or multiracial in this sample.

## Conclusions:

Our results indicate strong psychometric properties for the CCC-2 with this population and a 3-factor model fit: Structural Language, Pragmatic Communication, and Pragmatic Social. Evidence of racial/ethnic bias was found for the structural language factor. Based on the results of this analysis, we will report several recommendations for use of these CCC-2 with school-aged autistic students as well as further interpretation of the factor analytic results.

### **443.051 (Poster)** Using Video Stimuli to Quantify Robust and Reliable Difficulties in Social Comprehension in Adults with Autism Spectrum Disorder

*T. M. Burns-Yocum<sup>1</sup>, L. Byrge<sup>2</sup>, U. Keles<sup>3</sup>, Y. S. Lograsso<sup>4</sup>, D. Kliemann<sup>5</sup>, R. Adolphs<sup>6</sup> and D. P. Kennedy<sup>1</sup>, (1)Psychological and Brain Sciences, Indiana University, Bloomington, IN, (2)University of North Florida, Jacksonville, FL, (3)California Institute of Technology, Pasadena, CA, (4)Division of Humanities and Social Sciences, California Institute of Technology, Pasadena, CA, (5)University of Iowa, Iowa City, IA, (6)Caltech, Pasadena, CA*

Background: Autism spectrum disorder (ASD) is characterized by impairments in social cognition that are especially apparent in complex social situations (Heavey et al., 2000). While some individuals with autism can accurately characterize simple emotions (e.g., happiness), they may stumble at deciphering complex emotions (e.g., playful) (Happé, 1994) or when making more advanced mental state judgments (Baron-Cohen et al., 1985), especially when those judgments are embedded in complex, dynamic situations (Dzoi bek et al., 2006). Real-world difficulties in social processing could arise from altered attention to faces, higher-order social cognitive differences, or a host of other domain specific and domain general processes. This underscores the importance of measuring and capturing these difficulties in the lab by using increasingly more complex, naturalistic stimuli.

Objectives: The current study investigated social cognition in autism with the use of complex audio-visual stimuli (a television show) together with a broad set of social cognition questions. Our aims here were to extend previous findings (Byrge et al., 2015) to a large sample comprised of data from two independent sites, with future plans to link these social cognition findings to eye-tracking and neuroimaging measures.

Methods: This multi-site study was comprised of ASD participants (Site 1  $n = 54$ ; Site 2  $n = 20$ ) and sex-, age-, and IQ-matched controls ( $n = 82$ ;  $n = 35$ ). Participants watched an episode of *The Office* while undergoing screen-based eye-tracking and answering 39 open-ended questions assessing their comprehension of the preceding segment of this video. One subset of these questions assessed characters' thoughts and feelings (13/39), while another subset assessed characters' motivations and intentions (18/39). Each question was answered aloud and recorded for later offline blind coding using a 0, 1, or 2 coding scheme, with high scores indicating better comprehension.

Results: For all categories across both sites, the autism group exhibited lower performance than the control group (see Figure 1 and Table 1). Although full-scale IQ was correlated to performance (ASD,  $r = 0.53$ ,  $p < 0.001$ ; Control,  $r = 0.27$ ,  $p < 0.01$ ) in each group, group differences persisted when IQ was included as a covariate ( $\beta = 0.11$ ,  $SE = 0.02$ ,  $p < 0.001$ ).

Conclusions: Overall, these results indicate that the stimuli used in this study are sensitive enough to pick up differences between groups in social judgments of videos, with differences replicated across two samples. Individuals with ASD were impaired overall, with the largest differences found for judgments of motivations/intentions. This is consistent with previous findings (Heavey et al., 2000; Byrge et al., 2015) indicating that people with ASD may have difficulty understanding behaviors motivated by complex mental states (i.e., intentions). Future analyses will link performance on this measure to eye movements on the same stimuli. Combining gaze and behavior may allow us to better understand the relationship between visual input and social comprehension in autism.

**443.052** (Poster) Video Game Use, Aggression, and Social Impairment in Adolescents with Autism Spectrum Disorder  
**K. Davis<sup>1</sup>**, **M. K. Krug<sup>1</sup>**, **A. M. Iosif<sup>2</sup>** and **M. Solomon<sup>3</sup>**, (1)Department of Psychiatry & Behavioral Sciences, UC Davis MIND Institute, Sacramento, CA, (2)Public Health Sciences, University of California Davis, Davis, CA, (3)Department of Psychiatry and Behavioral Sciences, The Medical Investigation of Neurodevelopmental Disorders (MIND) Institute, UC Davis School of Medicine, University of California Davis, Sacramento, CA

---

Background:

Adolescents with autism spectrum disorder (ASD) play video games more often and for longer periods of time than their typically developing (TD) peers (Mazurek & Wenstrup, 2013), and also exhibit increased rates of aggression (Mays et al., 2011; Kim et al., 2000). However, increased video game use is not associated with increased aggression in ASD (Alkhatat & Ibrahim, 2020), although research in this area has been limited (Mazurek & Engelhardt, 2013). Video games, however, may increase social functioning by offering social interaction that avoids nonverbal cues, reading facial expressions, and interpreting gestures (Walther, 2007). The relationship between video games and social functioning has not been fully examined yet within the ASD community.

Objectives:

1. Compare the frequency and amount of video game playing in adolescents with ASD and TD (in a FSIQ matched sample).
2. Examine the association between video game playing and aggression in adolescents with ASD.
3. Examine the association between video game playing and social impairment in adolescents with ASD.

Methods:

Participants included 89 adolescents with ASD (Mean age=12.69 years (SD=2.03)) and 89 with TD (Mean age=13.09 years (SD=1.99)) enrolled in two longitudinal studies. All individuals were diagnosed using the Autism Diagnostic Observation Schedule (ADOS) and Social Communication Questionnaire (SCQ). The ASD and TD groups were case-matched for FSIQ and age (tolerance factors 11 & 0, groups did not differ significantly ( $p > .05$ ), resulting in mean FSIQ=105.66 (SD=13.38)) within ASD and 108.99 (SD=11.97) in TD. Parents completed the Child Behavior Checklist (CBCL), which includes reports of favorite hobbies and time spent on them compared to others of the similar age, as well as assessments of aggressive behavior. Participants were first categorized into video game players and non-players based on their responses to the hobbies questions, and then into 4 groupings based on their frequency of game play (don't play, play less than average, play an average amount, or play more than average). Social functioning was assessed using the Social Responsiveness Scale, Second Edition (SRS-2; parent report questionnaire).

Results:

Results indicated a significant group (ASD/TD) by video game playing status interaction ( $\chi^2(1, n=178) = 8.91$ ,  $p = .003$ ) with the ASD group playing more games. No significant differences were found in CBCL Aggression T-scores or SRS Total T-scores between players and non-players with ASD.

Similarly, significant diagnostic group differences, based on playing frequency, were found (Mantel-Haenszel  $\chi^2(1, n=173) = 20.40$ ,  $p < .0001$ ) (Figure 1). CBCL Aggression T-scores were significantly higher for ASD participants who played "more than

average” compared to those who played video games an “average” amount of time (Figure 2a). In ASD, amount of time spent playing video games was not associated with social impairment/satisfaction measures as measured by the SRS-2 (Figure 2b).

Conclusions:

While adolescents with ASD play more video games than their TD peers, in ASD, overall, video game playing is not associated with increased aggression or social functioning. However, those who play more than average compared to peers of a similar age have a higher Aggression T-score than those who play only an average amount.

**443.053 (Poster)** Visual Scanning Patterns Predicting Theory of Mind Performance

*J. M. Moriuchi<sup>1</sup>, S. Licon<sup>2</sup>, M. Printen<sup>3</sup>, H. Lechniak<sup>4</sup>, E. V. Ocampo<sup>1</sup> and L. Soorya<sup>1</sup>, (1)Department of Psychiatry, Rush University Medical Center, Chicago, IL, (2)Rush University Medical Center, Chicago, IL, (3)Child and Adolescent Psychiatry; Autism Assessment Research and Treatment Center, Rush University Medical Center, Chicago, IL, (4)Child and adolescent psychiatry, Rush University Medical Center, Chicago, IL*

---

**Background:** Impairments in mentalizing represent a key deficit in social cognition for children with autism spectrum disorder (ASD). Explicit mentalizing tasks, such as the Reading the Mind in the Eyes Test, have shown promise as an outcome measure in social intervention studies. However, performance on explicit mentalizing tasks can be variable, even as individuals with ASD continue to struggle with applying mentalizing skills within everyday contexts. One hypothesis is that overall accuracy measures on explicit mentalizing tasks may not fully capture underlying social cognition; children with ASD may be utilizing alternate, compensatory strategies and may be solving mentalizing problems in a different way than typically-developing peers.

**Objectives:** To help clarify the underlying mechanisms of children’s mentalizing performance, we developed a computerized battery of social-cognitive measures co-registered with eye-tracking. By examining visual scanning patterns as participants completed mentalizing tasks, we aimed to measure not just whether children were accurate in their social attributions, but also how they were attempting to make social attributions on a moment-by-moment basis. Because mentalizing impairments tend to be most apparent in everyday contexts, we compared visual scanning patterns predictive of mentalizing performance and social disability across tasks using increasingly naturalistic stimuli, including still images and dynamic facial expressions and gestures.

**Methods:** Participants included 20 verbally-fluent children with ASD (16 male, 4 female) between the ages of 8 and 11 years old who represented a broad range of severity in ASD symptomatology (ADOS-2 Calibrated Severity Score: mean=8.4 [3.4]). Participants were enrolled in a randomized clinical trial of a combination behavioral-pharmacological treatment targeting social cognition and social behavior; the current study focused only on data at baseline, pre-treatment.

Eye-tracking data were collected while participants completed a battery of computerized social cognitive measures, including an adapted version of the child Reading the Mind in the Eyes Test (RMET; Figure 1A-B) and a dynamic emotion recognition test developed from the Geneva Multimodal Emotion Portrayals (GEMEP; Figure 1C-D) database.

**Results:** Accuracy on mentalizing tasks ranged from 25 to 89% correct responses. Visual attention to nonsocial regions was positively correlated across still images and dynamic stimuli ( $r=0.60$ ,  $p<0.05$ ) and higher than attention to social regions ( $t=2.00$ ,  $p=0.05$ ). Children who exhibited higher visual attention to the eyes region of faces tended to have less severe ASD symptomatology ( $r=-0.50$ ,  $p=0.03$ ) and higher mentalizing accuracy ( $r=0.52$ ,  $p=0.02$ ). Ongoing analyses are utilizing more temporally-sensitive measures to identify visual scanning patterns that may mediate the relationship between attention to eyes and mentalizing performance.

**Conclusions:** The computerized social-cognitive battery yielded a broad range of mentalizing performance in our pilot sample of school-age children with ASD and identified consistent visual scanning patterns contributing to mentalizing accuracy. This new approach holds promise as a tool sensitive to change both in mentalizing performance and in underlying social-cognitive processes.

**443.054** (Poster) Watch Your Step! the Link between Coordinated Joint Action and Peer Social Engagement in ASD and TD  
**S. Bar Yehuda<sup>1</sup>, Y. Estrugo<sup>2</sup> and N. B. Bauminger-Zviely<sup>3</sup>,** (1)School of Education, Bar - Ilan University, Ramat - Gan, Israel, (2)School of Education, Bar - Ilan University, Ramat-Gan, Israel, (3)School of Education, Bar Ilan University, Ramat Gan, Israel

---

Background:

Coordinated joint action (CJA) occurs when two confederates accomplish a shared goal by coordinating their social-motoric movement in time and space. Abilities to mirror, complement, and predict the other's actions during CJA requires successful operation of social-motor capabilities. Though social deficits in cognitively able (IQ > 70) youngsters with autism spectrum disorder (CAASD) have been relatively explored, the contribution of CJA to social engagement along development in children and adolescents with CAASD remains underexplored.

Objectives:

This study examined group and age differences in CJA for children and adolescents with CAASD compared to age-matched controls with typical development (TD), as well as CJA's links with social engagement. Findings regarding motor coordination's role for social functioning during development may open new future intervention paths focusing on social-motor coordination in youngsters with CAASD.

Methods:

Participants: Children and adolescents ages 6–16yrs included 80 with CAASD ( $M = 11.1$  yrs,  $IQ = 103.88$ ) and 64 with TD ( $M = 10.73$  yrs,  $IQ = 114.53$ ) in three age-groups: early-childhood (6–8), pre-adolescence (8–12), and early-adolescence (12–16). Group differences on age and IQ were non-significant.

Measures: Four dyadic CJA tasks were executed in peer dyads paired by IQ and chronological age: two imitation or mirroring tasks (side-by-side walking, face-to-face movement) and two completion tasks (virtual-football kick-and-catch, corridor completion during virtual football). CJA performance was coded via *Interact* micro-analyses coding system, providing four major coordinated movement scores for each task. In addition, dyadic construction game performance was observed (using Dyadic Relationships Q-Set) to assess social engagement, yielding total social engagement score (ranging between: 1–7) that was based on the following dyadic peer engagement qualities: positive social orientation, cohesiveness, harmony, responsiveness and coordinated play.

Results:

A series of Group X Age ANOVAs yielded significant group differences (CAASD < TD) for all four CJA tasks and significant age differences (early-adolescence and pre-adolescence > early-childhood) for three CJA tasks, beyond group. For CJA–mirroring, early-adolescence surpassed early-childhood. The Group X Age interaction was significant only for CJA–walking (early-adolescence and pre-adolescence > early-childhood), only in the TD group (see Table 1). All CJA tasks significantly and positively correlated with social engagement (total Q-set), only in the CAASD group. Controlling for age group yielded the same results (see Table 2).

Conclusions:

Findings regarding CJA's developmental trajectory indicated growing CJA competence with age for both groups. The differences in CJA performance found between the CAASD and TD groups, as well as CJA's significant link with social engagement in the CAASD group, provide a novel viewpoint on dyadic motor coordination's contribution to social engagement and on the possible role of joint body movements for understanding the social deficit in ASD. The current results suggest a promising new avenue for approaching the social deficit in ASD via a different, complementary channel – motor functioning and coordination – which may encourage the design of future socio-motoric interventions and further empirical investigations of the links between social and physical communication for this population.

**443.055 (Poster)** What Are the Obstacles Encountered By Autistic Children and Adolescents during the Pandemic in Quebec?  
**A. Ethier<sup>1,2</sup>, I. Soulieres<sup>3</sup> and C. Jacques<sup>1,2</sup>,** (1)University of Quebec in Outaouais, Gatineau, QC, Canada, (2)Autism Research Group, CIUSSS du Nord-de-l'Île-de-Montréal, Montréal, QC, Canada, (3)Département de Psychologie, Université du Québec à Montréal, Montréal, QC, Canada

---

Background: COVID-19 hit all the society, bringing changes on a global scale (Courtenay & Perera, 2020). For about two months in Quebec, schools were closed and the entire province of Quebec was lock downed, depriving most people of social contact. During this period, few opportunities for community support were available (Montreuil et al., 2020). Adaptation was needed to cope with this situation, particularly for children and adolescents with special needs and their families (Eshraghi et al., 2020). Isolation for children in the general population had many consequences (Montreuil et al., 2020), but what about the impact on autistic children and adolescents?

Objectives: To document the obstacles reported by autistic children and adolescents as well as by their parents during the lockdown period in Quebec.

Methods: Through *LimeSurvey*, 109 parents of autistic children completed the new *French Questionnaire on the Needs of Children and Adolescents with Autism and their Families During the COVID-19 Pandemic*. Then, 56 of their autistic children aged 4 to 18 years completed a sub-section of the same questionnaire. Multiple-choice and open-ended questions were included. For each question, descriptive analyses were performed using SPSS software, and barriers were identified through thematic and qualitative analyses of the open-ended answers.

Results: Three main obstacles were reported by the autistic children. The greatest difficulty they encountered was related to not seeing their friends (57% of children), followed by fear of catching the virus (48%) and changes in routines (36%). The parents also emphasized that one of the most harmful factors in their child's adjustment was in the social sphere, more particularly linked to the isolation from their relatives (55%). When asked in open-ended questions what other factors were harmful to their autistic child's adjustment, isolation and lack of socialization were named by 36% of the parents, which is twice the proportion of those who mentioned the lack or difficulty of access to services (18%). In addition, 61% of the parents mentioned that spending time with their family was a facilitating factor in their child's adjustment. Finally, when the children were asked what they would recommend to a stressed friend during the pandemic, 29% of the recommendations were related to the social sphere, which represents the main theme of this qualitative analysis. More precisely, 70% of these recommendations pertained to communication and closeness with their parents, whereas the rest concerned visiting family and talking to trusted adults.

Conclusions: These results highlight a paradoxical aspect of autism: whereas this condition is marked by significant social deficits, the lack of social contact represents the main obstacle reported by autistic children/adolescents as well as by their parents during the lockdown period. It would be relevant to consider the social interactions in autistic children's lives as they seem to play a major role in their well-being and quality of life.

**443.056 (Poster)** With Whom Would You Prefer to Interact?: Investigating Context Dependent Effects of Social Behavior and Special Interests  
**K. M. Stockwell<sup>1</sup>, J. M. Gillis<sup>2</sup> and V. K. Jaswal<sup>1</sup>,** (1)University of Virginia, Charlottesville, VA, (2)Binghamton University, Binghamton, NY

---

Background: Autistic people often differ from non-autistic people in their style of interaction, which can lead non-autistic people to be reluctant to interact with them (Sasson et al., 2017). This manifestation of stigma can negatively impact mental health and reduce opportunities to form relationships (Slavich et al., 2009). Approximately 44% of autistic young adults enroll in college within eight years of completing high school (Newman et al., 2011), making college an important setting in which to understand the stigmatization of autistic students (e.g., Gillespie-Lynch et al., 2020; Stockwell et al., 2020). A better understanding of which kinds of social activities are most likely to result in stigmatization may be helpful in the development of interventions to reduce the stigmatizing beliefs and behaviors of non-autistic people.

Objectives: This study investigated how non-autistic college students' preferences for interacting with autistic and non-autistic peers differed depending on the hypothetical social activity.

Methods: On each of 225 trials, undergraduates ( $N = 324$ ; 70.37% female;  $Mage = 19.09$  years,  $SD = 1.01$ ) selected which of two characters they would prefer to engage in a particular activity with (see Figure 1 for a list of the activities). The characters were described in vignettes as college students who behaved in ways characteristic of autism (or not) and additionally described as having a special interest (SI; or not). Participants also reported their knowledge of autism and relationships with autistic people.

Results: Participants chose to interact with vignette characters differently overall, Friedman test  $\chi^2(5) = 1187, p < 0.001$ , Kendall's  $W = 0.733$ . Participants selected non-autistic characters more than they selected autistic characters. They also chose to interact with vignette characters differently depending on the activity proposed, Friedman test  $\chi^2(77) = 16430, p < 0.001$ , Kendall's  $W = 0.659$ . For example, as Figure 2 shows, when the activity was working on a class project together, participants selected an autistic character with an SI about as often as one without (22.5% vs. 25.2%). But when the activity was going on a date, participants selected an autistic character with an SI significantly less often than one without (17.1% vs. 31.4%). Depending on the activity, participant character preferences were differentially impacted by social behavior and by SI.

Conclusions: While overall measures of stigma can give insight into how a group may be viewed, focusing on the individual items may enhance this insight. Examining how responses to individual level traits (social behavior, presence of an SI) differ depending on which activity participants are presented with can offer insight into areas that may need to be specifically targeted in anti-stigma interventions. Understanding how autistic social behavior and the presence of SIs influence interaction choices in non-autistic people may also assist in the development of these interventions.

## POSTER SESSION — SOCIAL NEUROSCIENCE

### Poster 444 - Social Neuroscience Posters

**444.001** (Poster) A Diminished Neural Response to One's Own Face in Autism, As Shown Using Fast Periodic Visual Stimulation

*A. D. Nijhof<sup>1,2</sup>, C. Catmur<sup>3</sup>, R. Brewer<sup>4</sup>, J. R. Wiersema<sup>5</sup> and G. Bird<sup>6</sup>, (1)Institute of Psychiatry, King's College London, London, United Kingdom, (2)Department of Experimental-Clinical and Health Psychology, Ghent University, Ghent, Belgium, (3)Kings College London, London, United Kingdom, (4)Department of Psychology, Royal Holloway, University of London, Egham, United Kingdom, (5)Department of Experimental Clinical and Health Psychology, Ghent University, Ghent, Belgium, (6)University of Oxford, Oxford, United Kingdom*

#### Background:

Research suggests that self-related processing is altered in individuals with autism. Several recent studies report that individuals with autism show a diminished neural response for their own name and own face (Nijhof & Bird, 2019), making the neural processing of self-related stimuli a promising avenue for further study. Currently however, neuroimaging research, especially in clinical groups, is limited by the fact that data are generally quite noisy. Therefore, stimuli have to be repeated many times, making experiments long and demanding. The use of an EEG approach called Fast Periodic Visual Stimulation (FPVS), makes it possible to obtain a great amount of meaningful data with a high signal-to-noise ratio, in a relatively short time.

#### Objectives:

In this study, we wanted to use FPVS to test the discrimination of one's own face (as compared to a close other's face and a stranger's face) among other faces, in adults with and without autism. The aim was to further test the hypothesis that self-processing, as compared to other-related processing, is diminished at the neural level in autism.

#### Methods:

Neural activity of 20 adults with autism and 24 typically developed adults was recorded using a 64-electrode EEG-system, while they were watching rapidly alternating naturalistic images of faces on a screen. Strangers' faces were presented at a base frequency of 5.77 Hz, in three runs of 82 seconds with order counterbalanced. On each run, every fifth image (oddball frequency: 1.154 Hz) had the same identity. Per run, this was either one of ten photos of the participant, of someone close to the participant, or of a specific stranger.

#### Results:

A collapsed localizer approach indicated the signal-to-noise ratio at the oddball frequency to be highest in a left and right parieto-occipital cluster, as well as a midfrontal cluster. Within each cluster, the same pattern of results was found: the control group showed a significantly greater response to one's own face than for both the close other's and stranger's face, and a greater response for the close other's face than for the stranger's face. In contrast, in the autism group, the own and close other's face showed stronger responses than the stranger's face, but the difference between own and close other's face was not significant. See Figure 1 for the difference topography between own face and close other's face for the two groups.

#### Conclusions:

In a recording of under five minutes, we managed to extend previous findings of a diminished response to seeing one's own face in adults with autism, as compared to adults without autism. These findings provide further evidence for decreased self-other distinction in autism, despite intact familiarity processing. More generally, we want to emphasize that the use of FPVS is promising for studying face recognition in clinical groups.

**444.002 (Poster)** Attention to Novelty Vs. Habituation in Preschoolers with Autism Spectrum Disorders (ASD): An Eye-Tracking Study

**N. Kojovic<sup>1</sup>, L. Ben Hadid<sup>2</sup>, D. Bavelier<sup>3</sup> and M. Schaer<sup>4</sup>,** (1)Developmental Imaging and Psychopathology Lab, UNIGE, Geneva, Switzerland, (2)Department of Psychiatry, University of Geneva, Faculty of Medicine, 1211, Switzerland, (3)Department of Psychology, University of Geneva, Geneva, Switzerland, (4)Developmental Imaging and Psychopathology Lab, University of Geneva, Geneva, Switzerland

---

**Background:** Our prior knowledge on the world is constantly used to predict the incoming information. The incoherence between the two (i.e. prediction error, surprise) is thought to be estimated inflexibly and with high precision in individuals with autism (Lawson et al., 2014; Van de Cruys et al., 2014). Thus the rich inputs from the ever changing world might appear constantly novel and lacking regularity. In coherence with this framework previous studies in ASD reported prolonged habituation to repeated visual stimuli (Vivanti et al., 2018) and decreased attention to novel visual stimuli (Keehn, 2008).

**Objectives:** The goal of the present study was to compare visual habituation and novelty detection patterns between preschoolers with ASD and their age-matched typically developing peers and with regards to two stimuli types (social vs. non-social).

**Methods:**

A custom-designed habituation task with two conditions (social and non-social) was implemented on the Tobii eye-tracking device. In both conditions, two dynamic stimuli were displayed on each trial (videos of human faces vs. shape animations). One of the stimuli remained constant over trials (habituation stimulus) while the other one changed on each of the seven trials (novelty stimulus). Taking into account the findings of diminished attention to social stimuli in ASD (Chita-Tegmark, 2016; Pierce et al., 2011), all videos were framed with a static band containing geometric shapes, to ensure that the attention is captured on the screen. The task was shown to 100 (18F) preschoolers with ASD (aged 3.5±1.1) and 35 (11F) typically developing (TD) preschoolers (aged 3.9±1.7).

**Results:**

In social condition, preschoolers with ASD failed to habituate while the TD group showed less attention to the repeated stimulus over trials ( $p = 0.01$ ). However, both groups presented a similar pattern of habituation in the non-social condition ( $p = 0.99$ ). On the novelty side, the ASD group did not show preference for the novel social stimuli over trials as the TD ( $p > 0.001$ ). In social condition (solely), the ASD group looked more at the static frame containing geometric shapes compared to the TD group ( $p = 0.006$ ). Among children with ASD, we identified a subgroup of children who showed sensitivity to social novelty. These children had less severe (social) symptoms of autism ( $p = 0.13$ ) and better cognitive and adaptive functioning ( $p < 0.001$ ) compared to “novelty insensitive” subgroup. On the other hand, children with ASD who attended a static frame during the social condition presented more severe symptoms of autism ( $p = 0.11$ ), lower cognitive ( $p < 0.001$ ) and adaptive functioning ( $p = 0.002$ ).

**Conclusions:** The preserved pattern of habituation and novelty in geometric condition, as opposed to social condition in the ASD group, can be linked to the higher predictability of this type of stimuli compared to social condition. This finding is coherent with the predictive encoding deficit framework where the supposed high predictive error precision does not necessarily hinder the learning of new contingencies in the context of higher regularity but appears more problematic in less precise contexts such as social exchanges.

**444.003 (Poster)** Combined Frequency-Tagging EEG and Eye-Tracking Measures Provide No Support for the Excess Mouth/Diminished Eye Attention Hypothesis in Autism

**S. Vettori<sup>1</sup>, S. Van der Donck<sup>1</sup>, J. Nys<sup>2</sup>, P. Moors<sup>3</sup>, T. Van Wesemael<sup>4</sup>, J. Steyaert<sup>5</sup>, B. Rossion<sup>6,7</sup>, M. ---

**Background:**

Scanning faces is important for social interactions. Difficulty with the social use of eye contact constitutes one of the clinical symptoms of autism spectrum disorder (ASD). It has been suggested that individuals with ASD look less at the eyes and more at

the mouth than typically developing (TD) individuals, possibly due to gaze aversion or gaze indifference. However, eye tracking evidence for this hypothesis is mixed. While gaze patterns convey information about overt orienting processes, it is unclear how this is manifested at the neural level and how relative covert attention to the eyes and mouth of faces might be affected in ASD.

**Objectives:** We used frequency-tagging EEG in combination with eye tracking to assess the "excess mouth/diminished eye attention" hypothesis in ASD. We modeled temporal scan paths to understand face exploration dynamics in ASD.

**Methods:**

We used frequency-tagging EEG in combination with eye tracking, while participants watched fast flickering faces for 1-minute stimulation sequences. The upper and lower halves of the faces were presented at 6 Hz and 7.5 Hz or vice versa in different stimulation sequences, allowing to objectively disentangle the neural saliency of the eyes versus mouth region of a perceived face. We tested 21 boys with ASD (8-12 years old) and 21 typically developing (TD) control boys, matched for age and IQ.

**Results:**

Both groups looked longer at the eyes than the mouth, without any group difference in relative fixation duration to these features. TD boys looked significantly more to the nose while the ASD boys looked more outside the face. EEG neural saliency data partly followed this pattern: neural responses to the upper or lower face half were not different between groups, but in the TD group, neural responses to the lower face halves were larger than responses to the upper part. Face exploration dynamics showed that TD individuals mostly maintained fixations within the same facial region, whereas individuals with ASD switched more often between the face parts.

**Conclusions:**

Combined eye-tracking and frequency-tagged neural responses show no support for the excess mouth/diminished eye gaze hypothesis in ASD. The more exploratory face scanning style observed in ASD might be related to their increased feature-based face processing style.

**444.004 (Poster)** Comparing fNIRS-Based Cortical Activation during a Dyadic Versus a Triadic Non-Verbal Communication Task in Children with and without Autism Spectrum Disorder

*A. Bhat<sup>1</sup>, W. C. Su<sup>2</sup>, C. Cleff<sup>3</sup> and D. Tsuzuki<sup>4</sup>, (1)Department of Physical Therapy, University of Delaware, Newark, DE, (2)Physical Therapy, University of Delaware, Newark, DE, (3)Physical therapy, University of Delaware, Newark, DE, (4)Department of Language Sciences, Tokyo Metropolitan University, Tokyo, Japan*

---

**Background:**

Children with ASD have difficulties interpreting and communicating various hand and body gestures within a social interaction. Our previous work compared cortical activation patterns of children with and without ASD performing/observing simple dyadic communicative gestures such as waving bye, etc. (Bhat et al., 2019). However, cortical activation associated with simple dyadic communication did not clearly differentiate the two groups. In contrast, children with ASD had lower cortical activation over the Observation-Execution Matching System (OEMS) regions of inferior frontal gyrus (IFG) and superior temporal sulcus (STS) along with increased inferior parietal lobule (IPL) activation when observing and synchronizing triadic (object-related) reaching movements with an adult partner compared to children without ASD (Su et al., 2020).

**Objectives:**

In the present study, we compare triadic and dyadic non-verbal communicative gestures/actions and associated cortical activation between children with and without ASD as they observed partner's actions, performed solo, or copied a partner's reach-clean up actions during a reach-cleanup task or symbolic gestures during an engaging charades game task.

**Methods:**

Sixteen children with ASD and 15 typically developing school-aged children (TD) participated in the study. An fNIRS cap embedded with a 3x11 probe set covering middle frontal gyrus (MFG), IFG, STS, pre- and postcentral gyrus (PCG) and IPL was placed on the children's head to collect cortical activation data. Each child was seated across from an adult partner. In the reach-

cleanup task, children with ASD either observed or performed reach-cleanup actions (solo or in synchrony) based on the picture cards showing the order of cleanup or by following an adult partner's actions. In the charades game task, the child either observed gestures performed by the adult partner, performed gestures shown in a picture card or copied the adult's performed gestures. The reaching/gestural errors and synchrony errors during the solo and synchrony conditions were coded. The fNIRS-related oxy-hemoglobin response (i.e., regional cortical activation) was analyzed to study differences between groups, conditions, hemispheres, and regions.

#### Results:

Our preliminary analysis suggests that even the relatively complex and engaging dyadic task showed no group differences, the triadic task clearly showed lower cortical activation in the children with ASD compared to the children without ASD across all three conditions of Watch, Do, and Together (see representative figure for the synchrony condition). In terms of task-related differences, cortical activation was lower in the dyadic task compared to the triadic task across both groups. We are in the process of scoring video data assessing children's motor and synchrony behaviors and standardized tests and questionnaires to relate brain activation to synchrony errors and ASD-related behaviors.

#### Conclusions:

Our findings elucidate the various synchrony errors in children with ASD and how that might be mediated by poor cortical activation in the various OEMS regions important for motor planning, anticipation, and visuo-motor correspondence during certain synchrony tasks. We will identify multiple fNIRS-based neurobiomarkers that could be used to assess objective neural changes following a prolonged bout of synchrony-based interventions.

#### **444.006 (Poster)** Fixation-Related fMRI: Coregistering Eye-Tracking and MR Scanning to Identify the Neural Correlates of Engagement in ASD

**S. Koirala<sup>1</sup>, J. Pincus<sup>1</sup>, L. Li<sup>2</sup>, A. Klin<sup>3</sup>, W. Jones<sup>3</sup> and S. Shultz<sup>3</sup>, (1)Department of Pediatrics, Emory University School of Medicine, Marcus Autism Center, Atlanta, GA, (2)Marcus Autism Center, Children's Healthcare of Atlanta, Emory University, Atlanta, GA, (3)Marcus Autism Center, Children's Healthcare of Atlanta and Emory University School of Medicine, Atlanta, GA**

#### Background:

The social world is complex and dynamic, yet the study of social interaction/cognition typically uses static and artificial stimuli. Such methods can particularly limit ecological validity in ASD research, in which atypical engagement with the social world is a defining feature of the condition. Recent studies have utilized naturalistic approaches to fMRI work (e.g. movie viewing) to capture the complexity of the real world and examine underlying neural signatures of social perception. However, such naturalistic paradigms present challenges with regard to segregating neural activity in relation to specific onscreen events-of-interest, and thus often require complicated manipulations and/or analytic approaches to isolate and model stimulus properties (such as presence or absence of faces, motion changes etc.).

#### Objectives:

In our study, we explore fixation-related (FIRE) fMRI (Henderson et al., 2015)—a novel method for examining neural correlates during real-world scene viewing—to quantify what is engaging to children with and without ASD and to identify the neural mechanisms that underlie such engagement.

#### Methods:

Simultaneous eye-tracking and fMRI data were obtained while 8- to 12-year-old TD (n = 8) and ASD (n = 12) children viewed videos of naturalistic social scenes. Children were trained in a mock scanner until movement was <3mm for 3 8-minute periods. fMRI data were collected using a T2-weighted EPI sequence (TE=25s, TR=2.15s, flip angle=90°, voxel size=3.5mm x 3.5mm x 3.5mm, 37 axial slices without gap). Blink patterns (Shultz et al., 2011) and visual fixations were used to identify events-of-interest that *viewers themselves* perceived as 'highly engaging' or 'less engaging', and where viewers were looking during those events (e.g. at a face, body, or object), respectively. Nearly 50 events were identified per condition (highly engaging and less engaging), per group, yielding almost twice the number of trials sufficient (from a statistical standpoint) for eliciting an interpretable hemodynamic response. An inter-stimulus-interval of at least 2 seconds was used as the criterion for defining events, thereby maximizing the statistical efficiency of the design.

## Results:

TD and ASD participants had similar numbers of 'events-of-interest' ( $p > .05$ ), indicating that ASD participants are engaged by naturalistic stimuli as often as TD participants. The number of events identified was also comparable between conditions (highly engaging vs. less engaging,  $p > .05$ ), thereby suggesting that viewers are not always highly engaged with what they are looking at, even while looking at socially-relevant stimuli. However, there was only a small amount of overlap (12%) in which events were perceived as engaging by both groups.

## Conclusions:

Our preliminary analyses suggest that TD and ASD participants are differentially engaged while watching the same naturalistic stimuli. Immediate next steps include characterizing the content of participant-defined events-of-interest for each group to examine what stimulus properties are engaging to them, and analyses of fMRI data using such events-of-interest to identify the neural mechanisms underlying engagement in TD and ASD participants. The observed statistical efficiency of this novel methodology indicates a promising potential of this paradigm for gaining insight into the subjective experiences and perspectives of individuals with ASD.

### 444.007 (Poster) Neural Mechanisms of Imitation As a Social Signal in Autism

S. Krishnan-Barman<sup>1</sup>, U. Hakim<sup>1</sup>, M. Smith<sup>1</sup>, P. Pinti<sup>2</sup> and A. Hamilton<sup>1</sup>, (1)University College London, London, United Kingdom, (2)Birkbeck College, London, United Kingdom

---

## Background:

Some people imitate prolifically, even when it is not strictly necessary to do so but children with autism do this less than typically developing children. This might be explained by the social signalling hypothesis: that neurotypicals use imitation as a signal to boost affiliation but autistic people do not. Previous research has found that neurotypical imitation increases when their partner can see them, in line with the social-signalling hypothesis of imitation. Neuroimaging of this task using functional near-infrared spectroscopy (fNIRS) in typical adults found changes in right temporal-parietal junction and the right inferior parietal lobule in relation to viewing unusual actions and being watched.

## Objectives:

We aimed to evaluate spontaneous imitation of irrational actions and the neural correlates of this behaviour in participants with and without autism spectrum condition, using a naturalistic block-moving paradigm.

## Methods:

22 adults with autism and 22 neurotypical adults performed a simple block-moving task. Participants (Followers) were paired with a trained confederate (Leader), and in each trial the Leader demonstrated the order in which three blocks were to be moved from one board to another. Unbeknownst to the Follower, the Leader would move the blocks with either a rational (low) or irrational (high) trajectory (Fig1A). During the Follower's turn, the Leader would either watch them make their move or not. The 16 experimental trials thus followed a 2 x 2 factorial design where the trajectory demonstrated was rational or irrational, and the Follower was Watched or Unwatched. fNIRS signals were obtained from 44 channels over the right and left temporal-parietal junctions.

## Results:

When watching irrational actions, NT participants suppressed activity in the left TPJ relative to both baseline and ASC participants. In contrast, ASD participants showed significant activation in frontal lobe when watching irrational actions. When being watched, NT participants showed suppression in the left inferior parietal lobule (IPL), while ASD participants showed suppression in the right IPL. ASD participants also showed significant activation in the left TPJ where there were also group differences.

Following a trial where the Leader demonstrated an irrational trajectory, there is an implicit demand for irrational action. Here, the behavioural results showed that both NT and ASD participants imitated to the same extent. Despite the similar behavioural pattern, there were group differences in neural activations between NT and ASD participants: NT participants showed

suppression of neural activity in the left TPJ and left IPL while ASD participants showed activations in these regions, but showed a suppression of activity in the primary somatosensory cortex (Fig 1B).

### Conclusions:

Overall, the behavioural patterns of both NT and ASD participants were similar but there were differences in how irrational actions and the feeling of being watched were processed in the brain. In particular, left STS and TPJ were engaged in autistic but not typical adults. This implies that different neural mechanisms may be engaged when autistic participants imitate actions in order to achieve the same behavioural performance as typical participants.

**444.008 (Poster)** Temporal Binding of Body Postures into Movements in Individual Scoring High Versus Low on Autism Symptomatology: An Ssvpe Study

**D. Oomen<sup>1,2</sup>, J. R. Wiersema<sup>1,2</sup> and E. Cracco<sup>2,3</sup>,** (1)Department of Experimental Clinical and Health Psychology, Ghent University, Ghent, Belgium, (2)Research group EXPLORA, Ghent University, Ghent, Belgium, (3)Department of Experimental Psychology, Ghent University, Ghent, Belgium

---

**Background:** Perception of biological motion (BM) is an important social cognitive ability and impairments in this ability may severely impact social functioning. Two processes contribute to BM perception: spatial binding of motion patterns and temporal binding of body postures. So far, most research on BM perception in ASD has focused on the first process, which yielded inconsistent findings. A recent meta-analysis highlights the importance of the temporal dynamics of stimuli in determining BM processing anomalies in ASD (Federici et al. 2020), stressing the importance of investigating temporal binding of body postures in ASD. Recently, a new EEG paradigm was developed in which an apparent motion task was combined with steady-state visually evoked potentials (SSVEPs) to dissociate between the representation of individual body postures and their temporal integration into movements (Cracco et al., 2020).

**Objectives:** To further our understanding of ASD-related social perception difficulties, we investigated whether anomalies of BM perception could be explained by altered integration of body postures into movements in individuals scoring high (versus low) on ASD symptomatology.

**Methods:** Using EEG, we analyzed SSVEPs to fluent and non-fluent body posture sequences (See Figure 1) in adults scoring high versus low on ASD symptomatology ( $m_{low} = 34$ ,  $m_{high} = 35$ ), based on AQ scores. Sequences were symmetrical around the midpoint, leading to 3 SSVEPs: 1 coupled to image presentation (base rate), 1 coupled to the turning point in the sequence (half cycle), and 1 coupled to the repetition of the full body posture sequence (full cycle). Crucially, in fluent sequences, the primary percept is a series of movements, whereas in non-fluent sequences, it is a series of body postures. As movements repeat at half cycle rate and body posture sequences at full cycle rate, half cycle responses capture movement processing and full cycle responses capture body processing.

**Results:** Repeated measures ANOVAs showed that full cycle SSVEPs were stronger for non-fluent sequences, whereas half cycle SSVEPs were stronger for fluent sequences, replicating Cracco et al. (2020). The full cycle fluency effect was greater in the high-scoring group, suggesting enhanced body posture processing. However, contrary to the idea that ASD is associated with diminished integration of body postures into movements, a greater fluency effect in the high-scoring group was also found for half cycle responses.

**Conclusions:** Contrary to our prediction, individuals that scored high on ASD did not show diminished temporal integration of body postures into movements. On the contrary, integration of body postures into movements was enhanced in individuals that scored high, as was body processing. In other words, they showed a stronger response to the salient – more predictable – information of the stimulus (i.e. repeating movements in the fluent condition, repeating bodies in the non-fluent condition), which may reflect a preference for predictable information, in line with predictive coding theories, warranting further investigation.

**444.009 (Poster)** The Neurobiology of Face Processing in ASD: Evidence from a Combined fMRI and Eye-Tracking Study

**E. A. Kaplan-Kahn<sup>1,2</sup>, B. E. Yerys<sup>2</sup>, J. Pandey<sup>2</sup>, R. T. Schultz<sup>2</sup> and J. D. Herrington<sup>2</sup>,** (1)Department of Psychology, Syracuse University, Syracuse, NY, (2)Center for Autism Research, Children's Hospital of Philadelphia, Philadelphia, PA

---

**Background:** Facial information processing differences are typically viewed as central to understanding difficulties experienced by autistic individuals during social interaction. Neurobiological studies of face processing in autism spectrum disorder (ASD) have yielded mixed results: some studies find differences in activity within facial information processing regions (particularly the

“fusiform face area” (FFA), within fusiform gyrus), while others find no differences. Many studies reporting null FFA differences in ASD interpret studies showing decreased FFA activity in terms visual attention – that autistic individuals do not have difficulty with face processing per se, but rather, they attend less to relevant facial information. Implicit in the face processing literature is previously untested assumption that the FFA functions equivalently in autistic and neurotypical (NT) individuals during face processing tasks; here we tested this assumption in one of the largest single fMRI studies on face processing in ASD.

**Objectives:** To test the hypothesis that FFA in ASD is less sensitive to traditional patterns of visual attention towards faces – namely, visual attention toward eyes.

**Methods:** Participants included 48 NT children (ages 6.08 to 18.00,  $M=12.01$ ) and 47 ASD children (ages 7.75 to 18.17,  $M=11.67$ ). Participants completed an identity discrimination task wherein they indicated whether two images (of faces or houses) were the same or different while fMRI and eye-tracking data were collected. For region of interest analyses, parameter estimates were derived from participants’ activation peak within pre-defined anatomical masks of bilateral FFA.

**Results:** As predicted, the faces > houses contrast yielded increased activity in bilateral FFA, in both ASD and NT groups. A RM-ANOVA revealed no significant main effects of group ( $F_{1, 93}=2.25, p=0.14, h^2_G=0.02$ ) nor hemisphere ( $F_{1, 93}=0.19, p=.67, h^2_G<0.01$ ), nor a group\*hemisphere interaction ( $F_{1, 93}=0.57, p=0.45, h^2_G<0.01$ ) in FFA activation. ASD and NT groups also did not differ in time spent looking at the eyes of face stimuli,  $t(91.46)=-1.00, p=0.32, d=0.21$ . Despite comparable group-level results in FFA activation, Pearson correlations revealed a significant relationship between right FFA activation and time spent looking at the eyes of face stimuli for the NT group,  $r=0.32, p=0.03$ , but not for the ASD group,  $r=0.09, p=0.54$ ; however, these group correlations did not differ significantly,  $z=1.11, p=0.27$ .

**Conclusions:** These findings provide novel evidence supporting the selectivity of right FFA for eye-selective visual attention in NT individuals and raise the possibility that this neurobiological relationship is diminished in autistic individuals. Our results did not confirm the hypothesis that time spent fixating on eyes or peak FFA activity was different between the NT and ASD groups. Other measures of visual attention to faces and fusiform activation measurements may reveal different results. Future large-scale studies that afford more statistical power may elucidate the specificity of the FFA in autism; such research has significant implications for how we understand the role of the FFA in contributing to face processing differences in ASD. This finding also has treatment implications, in that it suggests that increasing visual attention to the eyes may not be sufficient to enhance facial information processing in ASD.

## Technological Approaches

### POSTER SESSION — TECHNOLOGICAL APPROACHES

#### Poster 446 - Technological approaches Posters

**446.001** (Poster) A Computational Approach for Analyzing Gait Synchrony and Balance in Neurodevelopmental Disorders  
*A. Ardalan<sup>1</sup>, N. M. Yamane<sup>2</sup> and S. Goldman<sup>2</sup>, (1)Zuckerman Institute, Columbia University, New York, NY, (2)Department of Neurology, Division of Child Neurology, Columbia University Irving Medical Center, New York, NY*

**Background:** Gait is receiving increased attention as a quantifiable phenotype for children with neurodevelopmental disorders (NDD) including autism spectrum disorder (ASD). However, these assessments (a) are often conducted in laboratory settings using costly and cumbersome experiments, and (b) use locomotion parameters (e.g., cadence, stride length) rather than whole-body measures. While studies have used marker-based motion tracking systems to fill this gap, such systems may not be conducive to overcoming sensory hypersensitivities and social anxiety of some children with NDDs. With the advent of computational methods for pose estimation and complex data analysis, it is crucial to assess the applicability and validity of these techniques in order to develop ecological and less biased data collection and analysis methods to study gait in ASD.

**Objectives:** (1) Investigate the feasibility of a computational pipeline using accessible hardware and modern software to quantify whole-body *gait synchrony* (defined as the variance of the dominant oscillation frequencies of arms and legs) and *balance* (defined as the variance of spinal tilt angle) in children with 16p11.2 gene mutation (proband), a NDD with a high ASD prevalence, while increasing ecological relevance and reducing experimental constraints; (2) Apply our computational pipeline to compare gait synchrony and balance measures between children with 16p11.2 mutation and their typically developing (TD) siblings; and (3) Introduce a novel whole-body gait synchrony measure.

**Methods:** Video recordings of 15 probands (mean age: 9.90 years, 7 girls) and 12 TD siblings (mean age: 9.67 years, 4 girls) performing a preferred-pace walking task were analyzed using pose estimation software to track points of interest (POIs) on their bodies over time. The POI coordinates were then cleaned and converted into timeseries which were robust to camera angle and distance to subjects. Finally, these timeseries were transformed into separate gait synchrony and balance measures and compared between groups.

**Results:** Our computational pipeline successfully extracted movement information from video recordings with high accuracy. Analyses revealed that children with NDD had significantly less whole-body gait synchrony and poorer balance compared to their TD siblings (Goldman et al., 2019). Small and/or non-significant correlations between gait synchrony and balance measures with age indicate that group differences were not attributed to delayed motor development. We also reviewed the video recordings of potential outliers, which confirmed that two proband children with higher synchrony scores had near-perfect gait, and two TD children with relatively lower synchrony scores were walking with their arms held stiffly by their sides. No overall group differences in our gait synchrony measure were found across sex, whereas group differences in balance were significant across sex.

**Conclusions:** The quantification of movements during locomotion in children with NDDs poses unique ecological challenges. Our study reports the results using a novel method that offers a cost-effective solution while preserving the validity of its results. This remote approach also allows for easier and broader enrollment of research participants from commonly under-represented communities, further enriching our understanding of motor outcomes across a wider variety of cohorts.

**446.002** (Poster) A Computational Tool for Automatic Analysis of Parent-Child Interaction in Autism Spectrum Disorder  
*D. Y. Isaev<sup>1</sup>, J. M. Di Martino<sup>2</sup>, Z. Chang<sup>3</sup>, R. E. Aiello<sup>3</sup>, K. L. Carpenter<sup>3</sup>, S. Compton<sup>3</sup>, N. O. Davis<sup>4</sup>, L. Franz<sup>5</sup>, S. H. Kollins<sup>6</sup>, M. Spanos<sup>3</sup>, G. Sapiro<sup>3</sup>, M. Sabatos-DeVito<sup>6</sup> and G. Dawson<sup>3</sup>, (1)Department of Biomedical Engineering, Duke University, Durham, NC, (2)Department of Electrical and Computer Engineering, Duke University, Durham, NC, (3)Department of Psychiatry and Behavioral Sciences, Duke Center for Autism and Brain Development, Durham, NC, (4)Department of Psychiatry and Behavioral Sciences, Duke ADHD Program, Duke University Medical Center, Durham, NC, (5)Duke Center for Autism and Brain Development, Department of Psychiatry and Behavioral Sciences, Duke University, Durham, NC, (6)Psychiatry and Behavioral Sciences, Duke Center for Autism and Brain Development, Durham, NC*

Background:

Lab-based, parent-child play interactions (PCI) are a common method of observing behaviors such as joint engagement in young children with autism spectrum disorder (ASD) (Adamson et al., 2009, 2010, 2012). Such tasks traditionally require manual coding of recorded videos to quantify behaviors that can help to characterize and distinguish children with ASD from other developmental disorders and typical development. Additionally, such coding can be used to quantify behaviors before, during, and after behavioral interventions that seek to improve social communication skills. However, manual coding is a time- and labor-intensive process, requiring raters to learn complex coding systems and to be trained to maintain consistency. Manual coding is therefore a challenging approach to measuring behavior across time and in response to treatment, particularly in large-scale trials. Automated analyses of PCI offers the opportunity to measure behavior in a non-intrusive, objective, and scalable manner.

#### Objectives:

To develop a tool for objective measurements of parent-child interaction from video recordings. We aim to provide an assessment of feasibility of this tool based on percentage of valid frames and continuous segments of recordings, as well as exploration of basic behavioral features such as participants' proximity and orientation.

#### Methods:

We developed a tool for visualization and computational analysis of behavior during PCI. The tool is based on the automatic detection of body landmarks for analysis of the videotaped interaction of PCI synchronously recorded from two RGB cameras. The analysis provides time-dependent computational features such as participant's proximity and orientation, which are key features of human interaction. The system also provides a measure of confidence, allowing to perform data quality checks for subsequent automatic analysis (Figure 1). The developed tool consists of a data processing pipeline, which integrates existing tools for body landmarks detection in 2D and reconstruction of 3D body pose from 2D videos, and a web-based visualization tool, allowing for the synchronous inspection of the recorded video together with the extracted features and manual annotations if available.

#### Results:

A subset of 6-minute recordings of 20 children, 56-67 months of age, five from each of the following diagnostic categories, based on gold standard diagnostic methods: Autism spectrum disorder (ASD) only, Attention deficit hyperactivity disorder (ADHD) only, ASD and comorbid ADHD, and typical development (TD) were included in the analysis. We defined 'valid frame' as a frame where both child and parent are detected, and the upper body is detected with high confidence. We computed the total amount of valid frames per participant, and statistics on continuous segments of valid frames (Figure 2). We did not find any differences in the amount of valid data between groups (Figure 2A). We also provide examples of automatically computed proximity and orientation (Figure 1).

#### Conclusions:

We have developed a visualization and computational tool that appears to be feasible for the automatic analysis of some key features of parent-child interaction, namely, proximity and orientation toward the partner. The modular structure will allow for the addition of new features for better objective characterization of interactive behavior.

#### **446.003** (Poster) AI-Based Classification of Autism from Early Ecological Interactions

**G. Alvani<sup>1</sup>, P. Venuti<sup>1</sup> and C. Furlanello<sup>2</sup>, (1)Department of Psychology and Cognitive Science, University of Trento, Rovereto, Italy, (2)HK3 Lab, Milan, Italy**

**Background:** Early detection is a pivotal factor for limiting the impacts of Autism Spectrum Disorder (ASD). Recognizing this condition in the first year of development allows treatment to start when brain plasticity is more pronounced, thus activating a more comprehensive effect of the intervention (Vivanti et al., 2019). Smiling is one of the primary tools that infants exploit to interact with the social environment. Although behaviors are challenging to investigate within the first months of life (Piven et al., 2017), smiling has been suggested as a possible early marker of ASD. Artificial Intelligence (AI) offers novel solutions for systematic analysis and classification of atypical behaviors (Tariq et al., 2018; Bangerter et al., 2020).

**Objectives:** This exploratory study aims to test whether AI-based models are effective in classifying infants with ASD using smile features in early ecological interactions with caregivers.

**Methods:** Home Videos (HV) of early interactions between caregivers and the toddler aged between 6 and 12 months were collected. The sample includes 18 infants with ASD and 15 typically developing infants (TD). Smiling features in HV dataset were analyzed using Openface: an AI-based software able to encode facial micro-movements and estimate Ekman's Action Units (AUs) activation (Baltrusaitis et al., 2018; Ekman & Friesen, 1979). Thus, a vector of intensities was generated for each AU in any frame of the HV sequence. The software output was processed using pyphysio python library (Bizzego et al., 2019) to filter smiling AUs and extract features such as intensity, frequency and duration. A Machine Learning algorithm (Random Forest) was applied to verify the validity of smiling features for ASD classification. In addition, for dimensionality reduction, Principal Component Analysis (PCA) was employed. We randomly split five times the dataset into training and testing, reserving 40% for the test. Cross-validation on the training set was applied to select hyperparameters with a grid search method, based on the resulting Area Under the Curve (AUC). Finally, a Random Forest (RF) classifier was trained on training and validated for the discrimination of ASD and TD, averaging over the five splits.

**Results:** All dependent variables were controlled for IQ and gender in the ASD group. PCA allowed the number of features to be reduced from 7 to 4 (AU12 *non*-social smile intensity, AU12/AU06 social smile intensities, social smile frequency) explaining more than 95% of the variance (Figure 1). On the five splits, the RF classifier performed on test with an average accuracy of 90%(10) and average AUC of 95%(10) in distinguishing infants with ASD and TD (Figure 2).

**Conclusions:** Even accounting for limitations due to the small sample size, the model achieved promising results in discriminating ASD in infants already within the first year of development. Our findings suggest that smiling features may be a relevant signature for the clinical assessment of early ASD symptoms. The implementation of AI-based models offers novel opportunities for the study of atypical behaviors. Future work includes designing AI-tools for supporting clinicians and families in early detection and monitoring of ASD.

**446.004 (Poster)** Assessing Affect and Physiological Responses in a Psychiatric Inpatient Sample of Individuals with Autism Spectrum Disorder (ASD)

*D. C. Cumpanasoiu<sup>1</sup>, J. B. Northrup<sup>2</sup>, C. Peura<sup>3</sup>, J. Vezzoli<sup>4</sup>, J. Montrenes<sup>5</sup>, J. Goltz<sup>6</sup>, S. Lopez-Pintado<sup>1</sup>, K. Quigley<sup>1</sup>, M. Siegel<sup>7</sup>, C. A. Mazefsky<sup>2</sup> and M. S. Goodwin<sup>1</sup>, (1)Northeastern University, Boston, MA, (2)Department of Psychiatry, University of Pittsburgh School of Medicine, Pittsburgh, PA, (3)Spring Harbor Hospital, Westbrook, ME, (4)University of Pittsburgh Medical Center, Pittsburgh, PA, (5)University of Pittsburgh School of Medicine, Pittsburgh, PA, (6)The University of Alabama, Tuscaloosa, AL, (7)Maine Medical Center - Tufts School of Medicine, Westbrook, ME*

**Background:** More than a third of individuals with autism spectrum disorder (ASD) have an intellectual disability or are minimally verbal. Severe ASD symptomatology is associated with a higher prevalence of comorbid psychiatric disorders and emotion dysregulation problems. However, individuals with severe ASD symptoms are often excluded from research.

**Objectives:** This work systematically assesses the relationship between perceived affect ratings and electrodermal activity (EDA) in a sample of psychiatrically hospitalized youth with ASD who participated in a series of standardized, negative affect-inducing tasks. We evaluated three aims: (1) changes in rated affect; (2) differences in physiological responses; and (3) concordance between rated affect and physiological responses.

**Methods:** Sixty-two participants (mean = 12.5yrs, range 6-20yrs; 80.6% male; 7.02% racial or ethnic minority) from the Autism Inpatient Collection were administered a subset of tasks taken from the Laboratory Temperament Assessment Battery (Lab-TAB) designed to elicit negative affect (Tower, Locked Box, End of the Line) that began with and interspersed baseline rest conditions. The wireless wrist-worn Q Sensor (Affectiva, Inc.) was used to record EDA. Resulting data was parameterized within each segment as normalized *mean* skin conductance level, linear *trend* change, and phasic skin conductance response measured by the *coefficient of variation (CV)* and *non-specific skin conductance responses (NSSCRs)*. Valence and intensity of affective reactions were coded in 10-second intervals on a scale of -3 (highly negative) to +3 (highly positive) (12% of randomly selected videos were double coded, ICC = .751). Three multilevel longitudinal models were constructed to assess differences in rated affected/physiology from (1) initial baseline to consecutive baselines; (2) initial baseline to tasks; and (3) tasks to subsequent baselines. Age, sex, severity, and verbal ability were evaluated as covariates in the models. Correlation was used to assess the concordance of affect and physiology.

**Results:** No significant changes in rated affect from initial baseline to subsequent ones were observed; however, there was significantly more negative and positive affect and less neutral affect during tasks than both initial and subsequent baselines (see Fig 1). Significant increases in mean EDA and NSSCRs from initial baseline to subsequent tasks and baselines, and higher CV during tasks compared to initial baseline and subsequent ones, were observed (see Fig 2). Covariate analyses suggested that younger children showed more negative affect, and younger children and minimally verbal individuals had higher physiological reactivity, particularly towards the end of the protocol. Correlations between affect scores and EDA were reasonably low.

Conclusions: This is the first study we are aware of to simultaneously measure rated affect and physiological reactivity during standardized tasks in a psychiatric inpatient sample of individuals with ASD. Despite similar CV and rated affect in Aims 1 and 2, there was no direct association found in Aim 3, suggesting that EDA and rated affect explain differential variance. Evidence for individual differences based on age, sex, and verbal ability indicates the importance of more tailored interventions and the need for a more direct and sensitive assessment of emotion regulation in individuals with ASD who present with more severe symptomatology.

**446.005** (Poster) Autism Navigator® Jumpstart to Coaching in Everyday Activities: An Innovative Method for Training Non-Profit Staff in South Africa and Ghana

*N. Chambers<sup>1</sup>, J. Carter<sup>2</sup>, G. Ayoka<sup>3</sup>, P. J. de Vries<sup>4</sup> and A. M. Wetherby<sup>5</sup>, (1)Centre for Autism Research in Africa, Division for Child and Adolescent Psychiatry, University of Cape Town, Cape Town, South Africa, (2)Autism South Africa, Johannesburg, South Africa, (3)Alexis Miranda Foundation, Accra, Ghana, (4)Centre for Autism Research in Africa, Division of Child & Adolescent Psychiatry, University of Cape Town, Cape Town, South Africa, (5)Florida State University Autism Institute, Tallahassee, FL*

---

**Background:** Autism Navigator® web-based training and virtual support strategies have powerful potential to address the research-to-practice gap in evidence-based services for young children with autism. The Autism Navigator JumpStart to Coaching in Everyday Activities (JCEA) distils the evidence-based Early Social Interaction intervention model into an interactive web-based course designed to equip specialist and non-specialist intervention providers to implement caregiver coaching for young children showing early signs of autism. In the first phase of an ongoing study, we explored whether this web-based training could be implemented by providers in real-world low-resource service settings in South Africa and Ghana, specifically, the autism-specific non-profit sector, when supported by implementation strategies focused on developing stakeholder relationships and training.

**Objectives:** The objective of this study was to determine the feasibility, acceptability, and appropriateness of the Autism Navigator JCEA course with virtual support for training non-profit providers in an evidence-based early intervention for children with autism.

**Methods:** Supported by implementation strategies from two ERIC clusters (Develop stakeholder interrelationships, Train and educate stakeholders), providers in autism-specific non-profit organisations in South Africa and Ghana were invited to complete the JCEA with bi-monthly virtual support from a regional trainer. Staff completed the Evidence-based Practice Attitude Scale (EBPAS-36) prior to completing the training, and Weiner et al.'s (2017) Feasibility, Acceptability, and Appropriateness measures following the training. Aspects of course utilization were examined.

**Results:** Between September 2019 and September 2020, 23 staff from 5 non-profits consented to complete the course. The sample included a substantial minority (44%) who did not speak English as a first language, and nearly half were non-specialists with no university education. Within the year, 11 staff (48%) completed the course in an average of 3.64 months (SD=2.29), 9 providers are still completing the course, and 3 have left the study. Providers generally had positive attitudes about implementing a new evidence-based intervention (EBPAS-36 mean total of 2.82; SD=.76). The Divergence subscale correlated with educational level ( $\rho = .53$ ;  $p < .017$ ), while the Feedback subscale correlated with time taken to complete the course ( $\rho = .63$ ;  $p < .007$ ). Ratings of course appropriateness, acceptability, and feasibility were generally high (means of 3.98, 4.15, and 3.85, respectively). The most rapid course progress took place during hard lockdown conditions in South Africa and Ghana between April and July, 2020. Non-profit leadership identified three implementation strategies as critical to uptake of the training in their organisations: local consensus discussions, ongoing training, and organisational support for the training in the lockdown period.

To date, 9 of the 11 providers who completed the course have recruited eligible families to participate in the second supervised-implementation phase of the study, suggesting buy-in to the intervention approach.

**Conclusions:** The Autism Navigator JCEA course shows promise as being feasible, acceptable, and appropriate for training specialist and non-specialist staff at non-profit organisations in South Africa and Ghana. Thoughtful use of implementation strategies related to stakeholder engagement and training enhanced implementation success. Lockdown conditions due to the COVID-19 pandemic may have contributed to engagement with and completion of the course.

**446.006** (Poster) Community Research during a Pandemic: Pivoting Community-Based Trial of Parent-Mediated Intervention for ASD to a Telehealth Format

*M. Matheis<sup>1</sup>, S. Dufek<sup>2</sup>, S. R. Rieth<sup>3</sup>, J. A. Ko<sup>3</sup> and A. C. Stahmer<sup>4</sup>, (1)Psychiatry and Behavioral Sciences, University of California at Davis MIND Institute, Sacramento, CA, (2)Psychiatry, University of California, Davis, Sacramento, CA, (3)San Diego State University, San Diego, CA, (4)UC Davis MIND Institute, University of California, Davis, Sacramento, CA*

---

#### Background:

Health and safety restrictions due to the COVID-19 pandemic have pushed researchers to think about study design more creatively and flexibly. Project ImPACT for Toddlers (*PI for T*) is a parent-mediated intervention developed to meet the growing need for effective treatment for toddlers with or at high likelihood of having autism spectrum disorder (ASD; Stahmer et al., 2019). In response to the COVID-19 pandemic, and subsequent publicly-funded early intervention service system shift, a current community-based trial of *PI for T* pivoted from an in-person model to a fully telehealth format.

#### Objectives:

This study examines the transition of the *PI for T* community-based trial to a telehealth format. Telehealth adaptations made to child and family assessment, training of community providers in *PI for T*, intervention delivery, and data collection are described. Survey data on the feasibility and acceptability of the telehealth adaptations to provider training are reported.

#### Methods:

The community-based trial utilizes a randomized waitlist control design to examine provider fidelity of implementation (FI) of *PI for T* parent coaching strategies, parent FI of *PI for T* intervention strategies, and child outcomes. It involves training community providers in parent coaching strategies and tracking their use of *PI for T* with families within their clinical services. The initial plan (v. 1.0) for provider training involved weekly in-person workshops over six weeks, while the assessment protocol for child participants involved standardized, direct assessments (see Table 1) conducted in the home or clinic. Following the onset of COVID-19 and subsequent service system shift to telehealth for intervention, the research team removed all in-person contact in an alternative research plan. Telehealth child assessments and community provider training were piloted to examine feasibility and acceptability. Eight providers participated in the pilot telehealth workshop and completed surveys at midpoint (3 weeks) and training completion (6 weeks). Qualitative feedback from assessors informed the final (v. 2.0) assessment battery.

#### Results:

For the v. 2.0 assessment protocol, telehealth delivery of observational and interview measures provided assessors with adequate information to characterize child participants and determine study eligibility. Telehealth administration of direct behavioral assessments, (e.g., Preschool Language Scales, 5<sup>th</sup> edition), proved to be too complicated and burdensome for parents to deliver for the age-range targeted. Direct behavioral measures were replaced with standardized parent report assessments in similar domains. For the v. 2.0 training protocol, mid-point feedback indicated that providers found the telehealth format to be successful, with the majority of participants rating the following aspects as “extremely useful”: breakout room activities, virtual coaching practice with volunteer families, and observing the trainer model with a family (M=3.6 out of 5 each, respectively). Following completion of the workshop, the majority of providers rated their readiness to deliver *PI for T* highly (M=4.1 out of 5).

#### Conclusions:

Preliminary data indicate that training in a parent-mediated intervention can be successfully delivered through a telehealth format. Additionally, suitable telehealth alternatives were identified for the child assessment battery. Further data on the telehealth format, including long-term provider FI, is being collected and will be reported.

#### **446.007 (Poster) Desensitizing Hospitalized Children with Autism to a Wearable Biosensor Device**

**B. J. Taylor<sup>1</sup>, C. Peura<sup>2</sup>, D. C. Cumpansoiu<sup>3</sup>, K. A. Pedersen<sup>4</sup>, C. A. Mazefsky<sup>5</sup>, M. S. Goodwin<sup>3</sup> and M. Siegel<sup>6</sup>,** (1)Center for Psychiatric Research, Maine Medical Center Research Institute, Portland, ME, (2)Spring Harbor Hospital, Westbrook, ME, (3)Northeastern University, Boston, MA, (4)Center for Psychiatric Research, Maine Medical Center, Portland, ME, (5)Department of Psychiatry, University of Pittsburgh School of Medicine, Pittsburgh, PA, (6)Maine Medical Center - Tufts School of Medicine, Westbrook, ME

---

#### Background:

Wearable biosensors may provide information regarding the internal states of severely affected children with autism spectrum disorder (ASD) (i.e., those who are minimally verbal, have intellectual disability, or who have co-morbid psychiatric disorders). However, research utilizing wearable biosensors often excludes the most severely affected children with ASD, potentially due to heightened sensory sensitivities and/or unsafe behaviors that make wearable technology challenging to use. Paradoxically,

severely affected children with ASD are also the population most likely to benefit from wearable biosensor research, as they often experience difficulties communicating emotional dysregulation and physical discomfort.

#### Objectives:

In service of increasing the representation of severely affected youth with ASD in wearable biosensor research, we developed and assessed a desensitization protocol to prepare severely affected and psychiatrically hospitalized children with ASD for wearable device data collection.

#### Methods:

Seventy-seven participants were recruited through the Autism Inpatient Collection (AIC), a multisite study of specialized psychiatric inpatient units. Three sites from the larger AIC study used the desensitization protocol to acclimate severely affected youth with ASD to a wrist-worn biosensor. All participants had a diagnosis of ASD, verified through a research reliable administration of the Autism Diagnostic Observation Schedule (2<sup>nd</sup> Edition) and clinical diagnosis. The protocol involved four categories of support: 1) staff and research assistant (RA) support, 2) wearable accessories to cover the biosensor, 3) behavioral reinforcement, and 4) visual communication supports. Desensitization success was determined subjectively (i.e., the RA reported that the participant was ready for real data collection) and objectively (i.e., the child did not tinker with or remove the device for at least 75% of their real data collection sessions). The utility of each category of support was determined by RAs.

#### Results:

Participants were 89.6% male with a mean age of 12.0 (SD=3.5). Of the 77 participants, 62 (80.5%) were deemed desensitized by an RA after one session, and 6 (7.8%) were deemed desensitized after a second session. The remaining 9 (11.7%) participants could not tolerate the device, despite up to 5 further attempts at desensitization and did not move on to real data collection sessions. Of the 68 participants who did move on to data collection, 11 (16%) continued to experience difficulty with the biosensor, as indicated by tinkering or removing the device for  $\geq 25\%$  of their data collection sessions. As such, the desensitization protocol was successful for 88.3% and 74.0% of participants based on subjective and objective indicators, respectively. Wearable accessories to cover the device were viewed as most helpful during the desensitization process. Neither subjective nor objective indicators of desensitization success differed by age or sex.

#### Conclusions:

The desensitization protocol was successful in helping children with ASD adjust to a wrist-worn wearable biosensor device. However, additional research is needed to better understand how to increase tolerability in the sub-population of children who did not desensitize.

**446.008** (Poster) Differences in Outcomes between in-Person and Distance Coaching in Classroom Pivotal Response Teaching  
**K. Oliver<sup>1</sup>, A. Nahmias<sup>2</sup>, C. Alvarado-Martinez<sup>3</sup>, K. Chavez<sup>3</sup>, I. Le<sup>3</sup> and A. C. Stahmer<sup>4</sup>, (1)Psychiatry and Behavioral Sciences, University of California at Davis MIND Institute, Sacramento, CA, (2)Stony Brook University School of Medicine, Stony Brook, NY, (3)University of California, Davis MIND Institute, Sacramento, CA, (4)UC Davis MIND Institute, University of California, Davis, Sacramento, CA**

---

**Background:** Classroom Pivotal Response Teaching (CPRT) is one research-supported strategy for autistic students. Teachers can learn to implement CPRT with fidelity, leading to more positive student outcomes (Stahmer, et al., 2016; Suhrheinrich, et al., 2019). However, training has been limited by district proximity to a training site. Video-conferencing technology is a well-established treatment delivery model for teaching evidence-based practices to providers in sites with minimal access to training (Fischer et al., 2018). Research directly comparing distance to in-person coaching for autism practices in classrooms is needed to understand how to best scale up evidence-based practices in schools.

**Objectives:** This study examines the effectiveness of CPRT distance coaching in public schools by comparing training outcomes, provider-reported feasibility and acceptability of CPRT, and perceptions of coaching support for in-person and distance training conditions. Teachers in the distance condition also identified barriers to using distance technology.

**Methods:** 191 providers serving autistic students in public schools participated. Based on district proximity to a training site (over a 1-hour drive), 62 providers received distance training and 129 received in-person training. Both groups participated in (1) a seven hour in-person CPRT workshop that included didactics, video examples and group activities; (2) four one-hour group

consultations; and (3) six individual coaching sessions involving a coach observing a CPRT lesson and providing feedback. Teachers in the distance group completed all coaching and consultation via using Zoom, a secure video conferencing technology. Outcome measures include training outcomes (i.e., coach-rated CPRT fidelity, training completion, CPRT certification) and provider report of CPRT feasibility and acceptability, Coach-Teacher Alliance (Johnson et al, 2016), and identified barriers to distance coaching. Multi-level modeling will be used to compare outcomes between training methods (multilevel logistic regression for dichotomous outcomes and hierarchical linear modeling for continuous outcomes) to account for providers nested within districts. These analyses plus analysis of CPRT feasibility and acceptability and Coach-Teacher Alliance will be completed prior to the conference.

Results: Preliminary chi-square analyses for 191 providers (62 distance, 129 in person) indicated that in-person trained providers had better training outcomes than distance-trained providers. A significantly larger percentage of providers trained in person were certified (79.8%) than those that received distance training (54.8%),  $\chi^2(1, N = 129) = 12.9, p < .001$ . A significantly larger percentage of providers trained in person completed training (87.6%) than those that received distance training (61.3%)  $\chi^2(1, N = 129) = 17.5, p < .0001$ . When comparing top scores for coach rated fidelity, teachers trained in person had significantly higher fidelity ( $M = 88.96, SD = 12.04$ ) than those trained using distance training ( $M = 83.57, SD = 17.72$ ),  $F(1, 129) = 5.07, p = .026$ . Provider-reported challenges with technology included uncertainty with using apps, district technology restrictions, and slow or inconsistent Wi-Fi connections.

Conclusions: Preliminary data suggest that fewer providers complete training and reach CPRT certification through coaching via distance technology than in-person. Results indicate a need to understand and address the barriers to distance training to maximize positive outcomes.

**446.009 (Poster)** Effectiveness of Applying Virtual Reality in Job Interview Training for Young Adults with Autism Spectrum Disorder

**Y. L. Chien<sup>1</sup>, Y. L. Tseng<sup>2</sup> and T. R. Huang<sup>3</sup>,** (1)National Taiwan University, Taipei, Taiwan, (2)Department of Electrical Engineering, Fu Jen Catholic University, New Taipei City, Taiwan, (3)Department of Psychology, National Taiwan University, Taipei city, Taiwan

---

Background: Job interview is a major obstacle for adults with autism spectrum disorder (ASD) when seeking for a job. Thanks to the development of virtual reality (VR) technique, studies have applied such technique in training young adults with ASD to get a job. However, the effectiveness of VR job interview training program waits to be examined.

Objectives: This study aims to investigate the effectiveness of VR job interview training in Taiwanese young adults with ASD.

Methods: We recruited 15 young adults (all males) with ASD in the training program. The participants received 6 sessions, focused on three topics including job interview, public presentation, and handling disagreement. After role play practice on the VR platform, feedbacks were provided by the trainer. The participants then practiced the second time after the feedbacks and discussion. During the role play practice on the VR platform, heart rate and Galvanic skin response (GSR) were monitored. We also used Role Play Interview Scale to compare the interview performance before and after the training.

Results: Overall, the participants showed high motivation to learn on the VR platform and were well-tolerated using the head mounted display. The effectiveness of the training was observed on several aspects. After the training, fewer pause, better eye contact, lower anxiety were noted during interview. Speech volume, amount and content were more appropriate. The content became more positive, more solid and relevant, and more organized.

Conclusions: Our findings suggested that VR technique may be a promising method for job interview training in young adults with ASD. More clinical application can be considered in the future.

**446.010 (Poster)** Evaluating Autism Likelihood in the First Year of Life: A Telehealth-Based Approach

**M. R. Talbott<sup>1</sup>, S. Dufek<sup>2</sup>, G. S. Young<sup>3</sup> and S. J. Rogers<sup>4</sup>,** (1)Psychiatry and Behavioral Sciences, University of California at Davis MIND Institute, Sacramento, CA, (2)Psychiatry, University of California, Davis, Sacramento, CA, (3)University of California at Davis, MIND Institute, Sacramento, CA, (4)Psychiatry and Behavioral Sciences, University of California MIND Institute, Sacramento, CA

---

Background: Maximizing the benefits of early intervention for supporting the development of individuals on the autism spectrum (ASD) requires widespread and efficacious early screening and identification practices. Despite decades of effort to identify early behavioral markers of ASD, there remain significant gaps throughout the identification-to-services pipeline. This is in part due to variable and protracted onset, with some infants' behavioral markers emerging between 6 and 12 months, and others not meeting

criteria for a diagnosis until 36 months or later (Ozonoff et al., 2010, 2015; Zwaigenbaum et al., 2015). Parent concerns as early as 6 months have been associated with subsequent ASD diagnoses (Sacrey et al., 2016, 2015). However, families with early concerns typically face long waitlists and often must travel long distances to centers with appropriate expertise. Initial feasibility data suggest telehealth is a promising avenue to addressing this gap (Talbot *et al.*, 2019).

**Objectives:** Expand our initial findings using the Telehealth Evaluation of Development for Infants (TEDI) in a larger group of infants to determine whether infants with significant early ASD behavioral markers can be identified via telehealth.

**Methods:** Infants aged 6-12 months whose parents had concerns about social communication development or ASD were recruited nationally across two cohorts. Infants were assessed using the TEDI protocol, wherein parents are coached through a series of semi-structured interactions via synchronous telehealth. Examiner-coded measures included the Autism Observation Scale for Infants (AOSI; Bryson *et al.*, 2008) and examiners' clinical best estimate of ASD risk. Coders naïve to parent concerns scored the Early Communication Index (ECI; Greenwood et al., 2010). Parents completed Ages and Stages Questionnaires (3<sup>rd</sup> Edition and Social-Emotional 2<sup>nd</sup> Edition), and satisfaction questionnaires.

**Results:** 25 infants ( $n_{\text{cohort 1}} = 11$ ;  $n_{\text{cohort 2}} = 14$ ) enrolled and were evaluated (Mean age = 9.68 months,  $SD=2.32$ ). Most infants' scores fell into the "Refer for Assessment" range on at least one domain of the ASQ-3 (18 infants, 72% of the sample) and the ASQ-SE2 (14/15 infants, 93%). AOSI Total Scores were elevated ( $M = 13.52$ ,  $SD = 6.30$ ) compared to the suggested cut-off risk score of 7. A one-sample Wilcoxon signed rank test comparing mean AOSI Total Score to the cut-off indicates observed scores were significantly higher ( $Z = 304$   $p < .001$ ). Overall CBE ratings indicated significant concern for ASD 20/25 infants. A one-sample Wilcoxon signed rank test comparing Mean Parent Overall Satisfaction Ratings to a neutral rating indicates significant parent satisfaction with the TEDI (Cohort 1:  $Z = 66$ ,  $p = .003$ ; Cohort 2:  $Z = 105$ ,  $p = .001$ ).

**Conclusions:** These findings support the feasibility of conducting an informative developmental assessment via telehealth to detect infants with a high likelihood of ASD in the first year of life. Recruitment and additional behavioral coding of ASD-relevant behaviors (e.g. communication, play) is ongoing, and infants will be followed prospectively until toddlerhood to determine diagnostic and developmental outcomes. Further demonstration of the validity and clinical utility of this telehealth tool has the potential to increase services for underserved infants and their families.

**446.011 (Poster) Feasibility of a Low-Cost Motion Capture and Virtual Reality-Based Motor Intervention for Improving Gross Motor Skills in Youth with Autism Spectrum Disorder**

**A. Ardalan<sup>1</sup>, H. Farhat<sup>2</sup>, R. Lenroot<sup>3</sup> and D. R. Hocking<sup>4</sup>,** (1)Zuckerman Institute, Columbia University, New York, NY, (2)PlayingForward, New York, NY, (3)University of New Mexico, Albuquerque, NM, (4)Psychology & Counselling, Developmental Neuromotor & Cognition Lab, La Trobe University, Melbourne, AUSTRALIA

---

**Background:** Motor impairment is widely acknowledged as a core feature in children with autism spectrum disorder (ASD), which can affect adaptive behavior and increase severity of symptoms. Low-cost, markerless motion capture and virtual reality (VR) game technologies hold a great deal of promise for informing personalized approaches to motor assessment and intervention in ASD.

**Objectives:** (1) Examine feasibility of using the GaitWayXR™ VR-based intervention to improve motor skills in children and adolescents with ASD, by examining compliance, tolerability, and acceptability with parent and child questionnaires and structured feedback; (2) Demonstrate a proof-of-concept for a method of quantifying dynamic whole-body movement from low-cost motion capture in children and adolescents with ASD, by developing a novel framework for objectively assessing motor skill and spatiotemporal features from motion tracking data during VR gameplay.

**Methods:** Ten children and adolescents (10-17 years) completed six, 20-minute VR-based motor training sessions over two weeks while whole-body movement was tracked with a low-cost motion capture system. We developed a methodology to quantify whole-body movement in skill and spatiotemporal categories (synchrony and symmetry) from motion tracking data, and explored associations with standardized measures of motor skill, cognitive flexibility and autism symptom severity.

**Results:** Our results confirmed that the VR intervention is safe and feasible, and parents and children reported high levels of engagement, enjoyment and acceptability. Our quantitative approach to whole-body movement during VR gameplay represented stable measures and corresponded with clinical features of ASD, although there was little evidence of any benefits of the GaitWayXR™ intervention on improving gross motor skills.

Conclusions: The use of custom-designed VR games that personalize the challenge during motor skills training combined with low-cost motion capture appears to be a feasible approach in youth with ASD. This is specially important for keeping this population engaged in physical activities which has been shown to help improving their daily living skills. Our quantification methodology shows promise in exploiting the VR technology to assess, track and potentially improve motor skills in children and adolescents with ASD.

**446.012** (Poster) Novel Digital Outcome Measures: Community Involvement in Research Development

**I. Yorke<sup>1</sup>**, N. Chromik<sup>2</sup>, C. E. Grant<sup>3</sup>, L. Frangou<sup>4</sup>, M. Palmer<sup>1</sup>, R. Holt<sup>1</sup>, J. Man<sup>1</sup>, E. Loth<sup>5</sup>, J. K. Buitelaar<sup>6</sup>, D. Murphy<sup>5</sup> and E. Simonoff<sup>1</sup>, (1)King's College London, Institute of Psychiatry, Psychology and Neuroscience, London, United Kingdom, (2)King's College London, Institute of Psychiatry, Psychology and Neuroscience, London, United Kingdom, (3)University College London, London, United Kingdom, (4)Autism Research Centre, Department of Psychiatry, University of Cambridge, Cambridge, United Kingdom, (5)Department of Forensic and Neurodevelopmental Sciences, Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, United Kingdom, (6)Department of Cognitive Neuroscience, Donders Institute for Brain, Cognition and Behaviour, Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands

---

Background: Primary objectives of the AIMS-2-TRIALS research programme are advancing understanding of the rich inter- and intra-individual variation that characterises autistic people, and developing appropriate intervention for challenges commonly faced by this population. Both these goals depend on measurement that is reliable, valid, precise, and has well-understood association with meaningful outcomes. Innovation in digital technology, e.g. wearable sensors and smartphone applications enabling remote monitoring, provides a new set of tools with which to complement conventional measures that rely on human judgments, e.g. informant or clinical ratings. However, development of such novel instruments requires careful consideration and consultation with the autism community in order to address potential practical and ethical issues.

Objectives: We aimed to open discussion with autism community representatives to jointly explore key barriers and enablers for using digital technologies to measure autism characteristics and commonly co-occurring difficulties (e.g. mood, attention and sleep dysregulation). This work informs an AIMS-2-TRIALS project investigating the acceptability, feasibility, and validity of these candidate measures.

Methods: We approached community representatives through several autism research organisations (AIMS-2-TRIALS A-reps, Autistica's Insight Group, and the Cambridge Autism Research Database) to participate in discussions. We also invited adolescents attending the Service for Complex Autism & Associated Neurodevelopmental Disorders at the Maudsley Hospital. Eleven autistic adults, six parents/carers of autistic individuals and four autistic adolescents were involved. All discussions took place remotely due to the ongoing pandemic, and primarily comprised small focus groups (3-4 community representatives and 1-2 researchers), conducted via Zoom Meetings. Additionally, several advisors preferred a one-to-one discussion and one corresponded via email. Discussions were guided via a document sent prior to the meetings, outlining several candidate technologies and anticipated themes, such as device comfort and data security. Conversations were documented via notetaking and (where all parties agreed) Zoom's recording function.

Results: Discussions revealed positive interest in efforts to broaden the repertoire of measures for autism and related characteristics beyond those based on human judgement. However, preliminary analysis has also identified a number of key concerns relating to ethics, practical implementation, and validity. Given potential intrusiveness of certain remote data collection modalities, ethical concerns included the need for provision of appropriate information during the consent process and demonstrably secure data management systems. Future uses for the technology supporting the measurement methods were highlighted as having potential for benefit, but also misuse. Practical considerations included comfort, accessibility, and usability of the measurement devices. Concerns about validity included the ability of these measures to accurately reflect the experiences of autistic people, and residual potential for subjectivity in ostensibly objective measures.

Conclusions: Representatives recommended that researchers proceed with a sense of responsibility, and that community involvement continue throughout the research project. Therefore, involvement activities continue to guide our research in an iterative manner. For example, advisers' input on comfort and appearance has already informed choice of wearable devices, and next steps will include re-consulting advisers to obtain feedback on proposed remote monitoring procedures.

**446.013** (Poster) Novel Scalable Computational Method Reveals Distinctive Patterns of Eye Gaze in Toddlers with Autism Spectrum Disorder

**Z. Chang<sup>1</sup>**, J. M. Di Martino<sup>1</sup>, R. E. Aiello<sup>2</sup>, K. L. Carpenter<sup>2</sup>, S. Compton<sup>2</sup>, N. O. Davis<sup>3</sup>, S. Espinosa<sup>1</sup>, J. Flowers<sup>2</sup>, A. Harris<sup>4</sup>, J. Howard<sup>3</sup>, S. H. Kollins<sup>3</sup>, P. R. Krishnappa Babu<sup>1</sup>, E. M. Perrin<sup>4</sup>, S. Perochon<sup>1</sup>, M. Spanos<sup>2</sup>, G. Dawson<sup>2</sup> and G. Sapiro<sup>1</sup>, (1)Department of Electrical and Computer Engineering, Duke University, Durham, NC, (2)Department of Psychiatry and Behavioral Sciences, Duke Center for Autism and Brain Development, Durham, NC, (3)Department of Psychiatry and Behavioral Sciences, Duke ADHD Program, Duke University Medical Center, Durham, NC, (4)Boston University, Durham, NC,

Background:

Feasible, reliable quantification of eye gaze has been a goal of behavioral research. Autism spectrum disorder (ASD) is characterized by reduced attention to social information, a feature that emerges during infancy.

Objectives:

Use low-cost, scalable devices to display brief naturalistic movies designed with social stimuli primarily on one side and nonsocial stimuli on the opposite side of the screen, record eye gaze responses, and use computer vision analysis to quantify gaze information relevant to ASD.

Methods:

In a sample of 993 children 17 – 37 months of age, 40 of whom diagnosed with ASD, brief movies were displayed on either an iPad or iPhone. Gaze information was extracted from the video of the child captured with the device's frontal camera while he/she was watching the movies. Features were derived from this gaze information; specifically, percent of frames during which the toddler gaze was on the right versus left side of the screen (percent right) and the time correlation of the gaze with the stimulus events. Side of social stimuli was counterbalanced across movies.

Results:

Figure 1 displays the distributions of the percent right (percent of frames during the movie when the child was gazing at the right side of the screen) for the 'Spinning Pinwheel' (iPhone) and 'Blowing Bubbles' (iPad) movies. Also shown are the results of silhouette analyses, which measured the extent to which the gaze patterns form distinct right versus left clusters (left versus right side of the screen). Analyses of both the percent right and silhouette scores revealed significant differences between the TD and ASD groups, with toddlers with ASD showing reduced attentional preference to the social stimuli ('Spinning pinwheel':  $P < 0.0001$  and effect size=0.51 for percent right,  $P < 0.00005$  and effect size=0.52 for silhouette score; 'Blowing bubbles':  $P < 0.000005$  and effect size=0.47 for percent right,  $P < 0.000001$  and effect size=0.51 for silhouette score).

We analyzed children's attention to speech patterns while watching the 'Fun at the park' movie in which two speakers located on opposite sides of the screen engaged in a conversation, evaluating the degree to which shifts in gaze occurred in conjunction with which person was speaking. We observed significant differences between the ASD and TD groups for the gaze-speech time correlation ( $P < 0.0001$ , effect size=0.42) and left-right clusters silhouette score ( $P < 0.00005$ , effect size=0.45). Figure 2 illustrates the feature distributions for the ASD and TD groups, and shows an example of the temporal gaze pattern for individuals with TD and ASD. Whereas children with TD show a tight correlation between their gaze and the alternating speech of the two adults in conversation, the children with ASD show a more variable pattern, less coordinated with speech.

Conclusions:

We demonstrated that ubiquitous, relatively low-cost, scalable devices can be used to collect and quantify gaze information relevant to ASD. This is a first step toward developing tools for advancing methods for early detection and reducing disparities in access to screening and diagnosis, which open the door to early intervention and improve the outcomes of individuals with ASD.

**446.014** (Poster) Predicting the ADOS-2 Calibrated Severity Score from Video and Audio Analysis

L. Soorya<sup>1</sup>, A. Sarkany<sup>2,3</sup>, K. Kamal<sup>3</sup>, E. F. Dillon<sup>4</sup>, Z. Tóser<sup>5</sup>, A. Wainer<sup>4</sup>, E. V. Ocampo<sup>1</sup> and S. Licon<sup>6</sup>, (1)Department of Psychiatry, Rush University Medical Center, Chicago, IL, (2)Argus Cognitive, Inc., Budapest, Hungary, (3)Eotvos Lorand University, Budapest, Hungary, (4)Center for Autism and Related Disorders, Kennedy Krieger Institute, Baltimore, MD, (5)Argus Cognitive, Inc., Lebanon, NH, (6)Rush University Medical Center, Chicago, IL

---

Background:

Identifying granular behavioral attributes remains central to autism diagnosis, with the ongoing advances in robust non-intrusive methods paving the way for the application of computational behavioral assessments in clinical/research settings. This study presents an automated, multi-modal approach to extracting key social features of autism: gaze, facial movements, and prosody.

#### Objectives:

Our objective is threefold: (1) to utilize a state-of-the-art behavioral analysis pipeline that characterize observed behavior during autism diagnostic evaluations; (2) to filter the measured variables and retain the ones that have predictive power; and (3), to test regression model of biometric data predictive of Autism Diagnostic Observation Schedule-2 (ADOS-2) Calibrated Severity Score (CSS).

#### Methods:

Forty-seven participants with neurodevelopmental disorders, including ASD (mean=±8.7 years, SD=±2.4, F=20, M=27) were recruited. ADOS-2 footage was collected using off-the-shelf 2D cameras and Tobii Pro Glasses 2 worn by the examiner. The footage was then analyzed with the Argus Medical Decision Support (MDS) System, using state-of-the-art machine learning components, which automatically identified patients, analyzed their vocalizations, eye movements, facial expressions, and body pose. The system estimated 143 variables (Table 1). Research-reliable ADOS-2 raters selected 32 of these metrics based on discriminative power between NDD and controls, and/or correlations with clinical measures (Table 1). To ensure models were not overfit to test data with this feature selection (Smialowski et al. 2010), identified variables were verified to show robust correlations across the cross-validation folds used in later steps. To reduce the risk of multicollinearity and spurious correlations even further, we applied an iterative approach to narrow down the set of variables for each regression type (random forest, support vector regressor, k-NN, linear regression), a hill climbing algorithm combined with cross-validation and regression analysis. This step was necessary because due to the limited sample size, the risk of overfitting the training data was higher with more variables. Analyses included analyzing the predictive value of the selected features compared to the participants' IQ, age, and gender data and the model's predictive performance using root mean squared error (RMSE) and mean absolute error (MAE) with leave-one-out cross-validation. Four baseline results were utilized for each regressor type to put our results into perspective: (1) a model that predicts CSS scores randomly, (2) a model that predicts median CSS score (5) in all cases, (3) a regression model that uses just age and gender as independent variables, and (4) a regression model including age, gender, and IQ.

#### Results:

Table 2 shows the predictive performance of the trained models, including the baseline methods, yielded from leave-one-out cross-validation.

#### Conclusions:

The automated Argus MDS System yielded key social behavior metrics: gaze related features, emotional valence, vocal communicative abilities, and linked gaze and emotion metrics. Results suggest introducing biometric social markers increases predictive power and reduces the error rate for estimating ADOS-2 CSS. Further evaluations analyze social behavior metrics with social scores on standardized scales and include biometric data of repetitive behaviors (e.g. sensory, mannerisms) to advance understanding of the role of nonintrusive computer-vision-based behavior analysis in clinical settings.

#### **446.015 (Poster) Quantifying Social Approach in Preschoolers with ASD in Inclusion Classrooms**

**C. Banarjee<sup>1</sup>, Y. Tao<sup>2</sup>, R. M. Fasano<sup>3</sup>, L. Vitale<sup>3</sup>, C. Song<sup>4</sup>, M. L. Shyu<sup>4</sup>, L. K. Perry<sup>3</sup> and D. S. Messinger<sup>1</sup>**, (1)University of Miami, Coral Gables, FL, (2)University of Miami, Miami, FL, (3)Psychology, University of Miami, Coral Gables, FL, (4)Electrical and Computer Engineering, University of Miami, Coral Gables, FL

#### Background:

Children's movement supports the initiation, maintenance, and termination of social interactions, and allows for physical exploration of the environment (Adolph & Franchak, 2016). Children with Autism Spectrum Disorder (ASD), a developmental disorder characterized by atypical social communication and repetitive behaviors, exhibit a range of movement abnormalities, although their centrality to the disorder is unclear (Hilton et al., 2011). Atypicalities in social approach are thought to be characteristic of children with ASD, but few studies have quantified the social movement of children with ASD using objective measures.

#### Objectives:

In the current study, we introduce a new method—computational modeling of radio frequency identification (RFID) child tracking—for studying children with ASD in naturalistic settings. We present the use of RFID measurements to investigate the velocity and social approach of children with ASD and typically developing (TD) children interacting together in preschool inclusion classrooms during repeated multi-hour observations. We examine children's individual movement (i.e., angular and Euclidean velocity) and social approach (social movement to peers and teachers) in the classroom.

#### Methods:

Observations of 30 preschoolers (14 with ASD and 16 TD) in two inclusion classrooms on a total of 10 days yielded approximately 10 hours of data per child. Objective measurements of position and orientation were collected using four corner-mounted radio frequency identification (Ubisense) sensors, which tracked a right and left tag worn by each child (in a vest) and teacher in the classroom. We calculate angular velocity, Euclidean velocity (speed of movement), and social approach, and compare ASD and TD children on these parameters using multilevel statistical models.

#### Results:

Children with ASD did not differ from TD children in angular velocity or velocity of movement in the classroom. Rather, differences were apparent in social movement between peers and teachers. With respect to peer approach, a significant interaction term revealed that pairs of TD children moved toward ( $p_{\text{POS}}=0.001$ ) and away ( $p_{\text{NEG}}=0.001$ ) from each other at higher velocities than pairs of children in which one or both partners had ASD. By contrast, children with ASD approached their teachers ( $p_{\text{POS}} = 0.02$ ,  $p_{\text{NEG}} = 0.009$ ) – and were approached by their teachers ( $p_{\text{POS}} = 0.012$ ,  $p_{\text{NEG}} = 0.027$ ) – more quickly than TD children.

#### Conclusions:

Multi-hour, objective measurements indicated that children with ASD did not move through space or turn at higher velocities than other children. Instead, ASD differences were evident in social approach. Children with ASD were slower in approaching peers but quicker in approaching teachers than were TD children, shedding objective light on the patterning of interaction in preschool inclusion classrooms. More generally, the results suggest the potential of modeling RFID measurements to produce a quantitative understanding of the ASD phenotype in naturalistic social contexts.

**446.016** (Poster) Quantitative Evaluation of Imitation Performance for ASD Subjects Using Social Robot Zeno  
*N. Taghavi<sup>1</sup>, J. M. Berdichevsky<sup>1</sup>, G. M. Kuravackel<sup>2</sup>, R. Pennington<sup>3</sup>, K. Welch<sup>1</sup>, G. Barnes<sup>2</sup> and D. Popa<sup>1</sup>, (1)Louisville Automation & Robotics Research Institute, University of Louisville, Louisville, KY, (2)University of Louisville School of Medicine, Louisville, KY, (3)University of North Carolina, Charlotte, NC*

---

**Background:** The diagnosis of Autism Spectrum Disorder (ASD) in affected children is usually based on social, communication, restricted, and repetitive patterns of behavior and provided by a physician or psychologist. Recent studies show that both motion kinematics and reaction time to visual stimuli in autistic children is quantitatively different in comparison with non-autistic children. While the diagnosis of ASD is based on human observations, robotic technology can assist in quantitatively measuring them and use them as a future tool for autism diagnosis and intervention with robots.

**Objectives:** We developed an algorithm called Online Dynamic Time Warping (ODTW) to measure human reaction time as well as the similarity cost in robot-human gesture imitation in real-time. In this poster, we discuss the implementation of this algorithm on social robot Zeno, and testing results of Zeno's imitation interaction with human subjects.

**Methods:** In our method, socially appropriate motion trajectories of human upper limb gestures such as waving, hand shaking, pointing, etc., are recorded from a physician and sent to the robot as reference trajectories to its motor joints. The subject is then asked to imitate the motion of the robot and their upper limb motion trajectories are recorded using a Kinect® sensor. The OTDW algorithm calculates the similarity between the pre-recorded robot motions and real-time subject motion responses. Furthermore, a measured time index to where the most similar human motion starts is proposed to indicate the subject's reaction time. A metric combining the similarity cost and reaction time was then proposed to estimate the overall imitation performance of the subject.

Results: The metric was validated using off-line interaction data collected from a cohort of 55 subjects interacting with Zeno. It was then used to provide on-line feedback during interaction and to design adaptive human-robot imitation sessions that encourage a subject to perform upper limb imitation motions with higher precision and speed. This second set of experiments was conducted with 13 human subjects. In order to simulate performance impairments during interaction, we asked subjects to follow the robot's arm movements with and without carrying a 15-pound weight. Results show that the algorithm can correctly reveal important features of human movement including the quality of motion and human reaction time to robot stimuli.

Conclusions: Based on our experiments, we validated the ODTW metric to assess imitation performance with social robot Zeno. In the future, this technology will be used to diagnose ASD conditions, or as a basis for evaluating the effect of robotic interventions on children with ASD.

---

Background: Outcome measures currently used in clinical trials for ASD have limitations in terms of reliability, validity, burden and ecological validity (Anagnostou et al., 2014). To address this unmet measurement need we have developed novel digital tools for the remote measurement of ASD signs and symptoms and deployed these into an observational study. By measuring symptoms objectively in the home environment, digital health technology tools could reduce participant burden, improve ecological relevance and be administered more frequently which may increase sensitivity to change.

Expressive communication impairment is one of the core symptoms of ASD. This can manifest through differences with typically developing individuals in conversational, acoustic, prosodic, phonetic or lexical features of speech which may be more pronounced in individuals with lower IQs (Fusaroli, 2016). These differences can be quantified by recording natural conversations in the home environment of a participant and deriving conversational features. To do so audio recordings must be segmented according to the speaker. Whilst segmentation can be done manually, manual labelling is labor intensive when recordings are captured on a weekly basis from a large sample of participants in a clinical trial. Instead one can use an algorithm for automated segmentation, however this is challenging when recordings are captured in the home environment due to the presence of background noise.

Objectives: To investigate the feasibility of segmentation of conversation recordings captured in a natural environment using manual and automatic segmentation, based on known-groups analysis.

Methods: 90 individuals with ASD and 45 typically developing (TD) controls (5-45yrs) were asked to record a conversation with a study partner once per week during the 12-week observational period of a non-drug observational study. Task adherence was observed to be between 40-50% throughout the study leading to conversation recordings every 2-3 weeks on average. Individuals with ASD were categorized as low-functioning ( $IQ \leq 70$ ) or high-functioning ( $IQ > 70$ ). For automated segmentation, a deep-learning based human voice activity detection plus speech diarization pipeline was applied to the conversation recordings. To assess the performance of automated segmentation, one recording per participant from a representative subset of 8 low-functioning and 8 high-functioning participants diagnosed with ASD was manually labeled. Talk Duration (average duration that a participant speaks for within their turn) was then estimated based on both manual labeling and automated segmentation of the recordings.

Results: When using manual labels to estimate Talk Duration, there was a significant difference between low- and high-functioning participants (unpaired left-tailed t-test,  $p = 0.03$ ). When using the predicted labels from the speaker segmentation algorithm, this conversation measure showed a trend towards a significant difference ( $p = 0.08$ ).

Conclusions: Our results show that the expressive communication of individuals with ASD can be assessed in the home environment using natural conversation recordings. Analysis of conversational features can demonstrate known-group differences based on either manual labeling of recordings or through automated segmentation. Automated segmentation would be a key enabler to allow the use of this approach in large clinical trials.

**446.018 (Poster)** Role of Implementation Climate and Training in Predicting Telehealth Implementation of Applied Behavior Analysis Services during the COVID-19 Pandemic

**Background:** Following social distancing guidelines, Telehealth has been utilized to provide Applied Behavior Analysis (ABA) to children with Autism Spectrum Disorder. Telehealth implementation of ABA services (e.g., parent training), has shown to yield positive outcomes and reduce service disparities (Ferguson, 2019). However, previous research has shown that providers underutilize services due to limited training and resources (Ingersoll, Straiton, & Rivera Caquias, 2019). Additionally, telehealth users' attitudes and beliefs play a significant role in service uptake (Tsai et al., 2019). Understanding ABA providers' resources and beliefs will help support successful telehealth implementation during and after the COVID-19 pandemic.

**Objectives:** The present study examined implementation climate and telehealth training as predictors of Board-Certified Behavior Analysts' telehealth usability, acceptability, and future use.

**Methods:** To date, 311 Board-Certified Behavior Analysts working with children with Autism Spectrum Disorder have completed a Qualtrics online survey. Clinicians provided ratings for the Acceptability of Intervention Measure, Telehealth Usability Questionnaire, and Implementation Climate Scale. Acceptability is defined as clinicians' agreeableness or satisfaction with Telehealth, usability as perceptions of ease-of-use, effectiveness, and efficiency, and implementation climate as perceptions of policies and practices that are rewarded by their agency or clinic. A 5-point Likert scale was used to measure clinicians' intentions to use telehealth after COVID-19 restrictions (i.e., future use). Additionally, clinicians reported previous Telehealth training experiences (i.e., workshop, observation, self-guided webinar, and supervision or feedback on the job). Simple linear regressions were used to predict acceptability, usability, and future use from implementation climate and training experiences.

**Results:** Simple linear regressions indicated that implementation climate significantly predicted clinicians' perceptions of telehealth acceptability, usability, and intentions for future use (Table 1). In terms of training, not receiving training for Telehealth significantly predicted lower perceptions of telehealth usability, acceptability, and future use (Table 2). Participating in a Telehealth workshop significantly predicted higher perceptions of acceptability and intentions for future use (Table 2). Receiving feedback and supervision during a practicum or on the job significantly predicted higher perceptions of Telehealth usability (Table 2).

**Conclusions:** Findings suggest that implementation climate predicts clinicians' perceptions about telehealth usability, acceptability, and intentions to use in the future. Clinicians who did not receive any training on Telehealth were less likely to rate it as usable or acceptable, as well as less likely to want to use it in the future. Taken together, these findings highlight the importance of the implementation climate and educational support on clinicians' perceptions of Telehealth to deliver Applied Behavior Analysis. Increasing an agency's focus on Telehealth and Evidence Based Practices in general can help support clinicians' Telehealth use. Findings also suggest that practical feedback and supervision supports clinicians' understanding of Telehealth's usability, as it provides direct and personalized guidance on how to utilize Telehealth services. Additionally, structured and practical education about Telehealth (i.e., workshops) are helpful for increasing clinician's acceptability and usability of telehealth, as workshops provide both practical guidance and overall education about Telehealth use.

---

**Background:** Advances in computation and computer vision technologies open avenues towards the development of scalable behavioral analysis tools that can capture biomarkers related to Autism Spectrum Disorder (ASD). Among the early emerging symptoms of ASD are differences in facial expressions and movements, including differences in facial expression type, range, and complexity.

**Objectives:** Design and deploy scalable computational phenotyping tools for eliciting, recording, and measuring ASD-related behavioral biomarkers using a combination of strategically-designed stimuli consisting of social and non-social components that can potentially evoke variations in facial landmark features, differentiating ASD and typically developing (TD) individuals.

**Methods:** This study is a part of a broad effort to design a scalable, robust, and portable tools for computational behavioral phenotyping. Toddlers in the age of 17-37 months were recruited at four pediatric primary care clinics during the child's well-child visit (ASD: N=33, TD: N=366). While sitting on the caregiver's lap, the participants were shown stimuli that consisted of several short movies, presented on an iPad or iPhone. Stimuli included both social and non-social components (illustrative snapshots are presented in Figure 1). The toddler's face was recorded using the front-facing camera of the device. Computer vision algorithms were used to track and detect the facial landmarks (e.g., the periphery of the mouth and eyebrows). Landmarks' dynamics and affect were analyzed. In this work, we focused on how complex (or predictable) the facial dynamics are; to this end, we exploited multiscale entropy (MSE) ideas.

**Results:** Complexity on the landmarks related to the eyebrows and the mouth regions were explored (Figure 1). The results indicated that 1) the TD group often tend to elicit higher complexity in landmark movements while exposed to the social stimuli ( $p < 0.05$ ); 2) the ASD group demonstrated higher complexity for most of the non-social stimuli ( $p < 0.05$ ); 3) the TD group showed higher complexity ( $p < 0.05$ ) in the eyebrows compared to mouth region for social stimuli, unlike the ASD group. In agreement with existing literature, we observed that the complexity in landmark movements can serve as a biomarker to distinguish ASD and TD groups. A novelty of this work is that this biomarker can be retrieved using ubiquitous devices in a standard clinical setting. Lastly, analysis of the relationship between the complexity and the participants' affective state was non-significant, indicating that the landmarks' movement was not limited to the participants' affective state and it carries information beyond it.

**Conclusions:** We designed and deployed a scalable and portable computational behavioral phenotyping tool usable in pediatric clinics that displayed visual and interactive social and non-social stimuli while recording the participants' evoked responses. The complexity in facial landmark movements were explored, showing its potential for an ASD biomarker with value beyond differences in affective expression.

#### **446.020 (Poster)** Searches for Web Tools to Screen for Autism Produce Few Results

**B. W. Sanders<sup>1,2</sup>, S. Bedrick<sup>1</sup>, S. Broder-Fingert<sup>1</sup>, J. K. Dolata<sup>1</sup>, E. Fombonne<sup>3</sup>, P. Fuch<sup>4</sup>, J. Reeder<sup>5</sup>, L. Rivas Vazquez<sup>6</sup> and K. Zuckerman<sup>9</sup>,** (1)Department of Medical Informatics and Clinical Epidemiology, Oregon Health & Science University, Portland, OR, (2)Pediatrics, Oregon Health & Science University, Portland, OR, (3)Pediatrics, Boston University School of Medicine, Boston, MA, (4)Department of Pediatrics, Oregon Health & Science University, Portland, OR, (5)Department of Psychiatry, Oregon Health & Science University, Portland, OR, (6)Boston University School of Medicine, Boston, MA, (7)Oregon WIC Program, Oregon Health Authority, Salem, OR, (8)Department of Pediatrics (Division of General Pediatrics), Oregon Health & Science University, Portland, OR, (9)Division of General Pediatrics, Oregon Health & Science University, Portland, OR

**Background:** What happens when a parent is worried about a child's risk for Autism Spectrum Disorder (ASD) and he/she searches online for help?

**Objectives:** To simulate and characterize the results of a web search by a parent who is concerned about their child's risk of ASD.

**Methods:** ASD screening tools were defined as a) existing on the internet; b) user inputs data; c) assigning a risk category to a child; d) intended for parental use; e) screening for ASD; f) can stand alone; g) designed for children < 9 years. A set of 42 relevant search terms was developed iteratively from Google Search auto-fill responses. An 18-member parent panel suggested their own terms and then chose their preferred terms out of the set of 42. For a 10-term search set, similar terms among top-ranked parent choices were combined and age-specific terms were added in order to represent all major themes from parent suggestions. Predominant browsers & search engines were identified based on market statistics. Country-specific search results for the United States, United Kingdom, India, Australia, and Canada were accessed using VPN (Virtual Private Network) software. Each of the 5 countries was searched using Google with all 10 terms to total 50 searches. The 3 most productive search terms were used to validate comparability of Bing with an additional 15 searches. The first page of each set of search results were recorded and sites meeting criteria for ASD screening tools were identified.

**Results:** Sixty-five searches yielded 1,475 results (mean 23 per search), 275 (19%) of which were sponsored links. 147 (10%) of search results were websites with content that met criteria for an ASD screening tool. Thirty-six of 65 searches (55%) contained a result with a tool. Sixty-six (45%) of these required more than one click to arrive at the tool from the search result. Sixteen (1%) unique websites containing tools were ultimately identified, three of which were labeled M-CHAT (Modified Checklist for Autism in Toddlers) or M-CHAT-R (M-CHAT Revised). Four terms were most likely to identify any tools (listed with mean tools per search): "autism quiz" (7.8), "autism screening tool" (4.0), "does my child have autism" (3.6), and "autism toddler"

(2.6). Study searches yielded no new tools after these four terms were used in the United States and the United Kingdom. Bing searches were comparable to Google.

Conclusions: This simulated search for ASD screening tools revealed few screening tool websites. Low yield rates illustrate the challenge for parents in finding useful tools online to help them assess their child's risk for an ASD. To help parents connect to needed resources more efficiently, advocates may consider creating curated resources that are optimized for common online search engines.

**446.022** (Poster) Study of Predictive Abilities of ASD Subjects with AI Based Assistive Methods

**S. Gulati<sup>1</sup>, C. Majumdar<sup>2</sup> and T. K. Gandhi<sup>3</sup>,** (1)Centre of Excellence and Advanced Research for Childhood Neurodevelopmental Disorders, Child Neurology Division, Department of Pediatrics, All India Institute of Medical Sciences, New Delhi, India, (2)Department of Electrical Engineering, IIT Delhi, New Delhi, India, (3)Electrical Engineering, Indian Institute of Technology Delhi, New Delhi, India

---

Background: Autism Spectrum Disorder (ASD) encompasses a broad range of behavioral and functional deficiencies, often displaying wide divergence in presentation. Repeated attempts have been made to understand if there is any common underlying causality that can explain this wide presentation. It has been hypothesized that ASD could be a result of disorder in prediction capabilities in human brain. However, it's unclear as to what extent both spatial and temporal predictive abilities are impaired.

Objectives: To determine if basic prediction abilities in simple temporal and spatial domains are impaired in ASD using Machine-Learning based interactive video games. Is it possible to improve the ability through machine learning based AI tools?

Methods: Participants were 11 ASD and 12 age-matched Neurotypical (NT) controls in the age range of 7-15 years. All were healthy individuals with CARS score in mild-moderate ASD range.

Reinforcement-Learning based interactive video games were developed that measure and analyze the responses of the player to determine their prediction abilities. These games analyzed both the temporal and spatial predictions. For example, how long (temporal estimations involved) they need to keep the screen touched in order to achieve a certain length of a stick (spatial estimation involved) to cross a given computed barrier which is dynamically updated using ML-techniques based on prior responses. They were presented to the participants on Android-based Lenovo Tab with 8" screens for clear visibility and had sound effects to increase immersion.

For each participant, there was a 20-minute priming exercise to get comfortable and understand the game. During this priming exercise, their parents and a team of psychologists additionally supported them. Following the familiarization process, they were comfortably seated in a distraction-free room and played the games. Their performance was recorded on remote servers. Based on the subject's response, the next task was dynamically presented on Reinforcement Learning frame work to improve their prediction abilities.

Results: From the results, we observed a definite trend that ability to predict seems to be severely compromised in all subjects, compared to neurotypical subjects.

On average, the mean prediction success rate was just around 20%, whereas NT consistently demonstrated significantly higher success in the ranges of 80% and above. Performance did not correlate with the CARS scores. It seemed that CARS score does not capture the prediction abilities, even though prediction abilities seemed to be markedly impacted in ASD. However, ASD subjects with better eye-contact seemed to fare better in predictive tasks. Current state of Affect (emotions) in-relation to their loved ones such as parents seemed to significantly impact their predictive abilities. The follow up data demonstrated that the proposed AI based reinforcement based learning model helps in improving their spatial and temporal predictive abilities on successive trials.

Conclusions:

This pilot study show presence of a strong correlation between ASD and impairment of prediction abilities. Further studies are needed to better characterize both spatial and temporal predictive abilities, so that the AI based tool can be developed to enable improvement of the predictive abilities.

**446.023** (Poster) Supporting Transition Planning to Prepare Individuals with Autism Find Opportunities for Employment: Technological Design Challenges and Recommendations  
**J. G. Kim**<sup>1</sup>, **G. Abowd**<sup>1</sup> and **C. E. Lee**<sup>2</sup>, (1)Georgia Institute of Technology, Atlanta, GA, (2)Vanderbilt University Medical Center, Nashville, TN

---

Background:

Transition planning is a process to help individuals develop the necessary skills to successfully transition into adulthood. Despite the mandate of transition planning in public schools in the United States, individuals with autism have the lowest employment rate even compared to individuals with other types of disabilities. There are technological interventions proposed to better support transition planning for people with autism. However, most research has focused on using technology to train specific vocational or interview skills. To improve post-school outcomes, people with autism need more comprehensive and organized support especially from their transition planning team for identifying long-term career goals and developing skills that are tailored to the goals. To investigate more effective technological interventions for transition planning, we need a better understanding on how people with autism and their transition team collaborate to develop and achieve long-term employment goals for people with autism.

Objectives:

This work investigates the challenges that people with autism and their transition team face in preparing for employment through transition planning and opportunities of socio-technical systems to support the challenges.

Methods:

We conducted in-depth semi-structured interviews with 21 participants, including three people with autism, ten parents, and eight professionals (e.g., transition coordinator, special education teacher) who have participated in transition planning within the last three years. Semi-structured interviews took between 45 minutes and 1.5 hours through either phone or video conference. Two researchers used open-coding to independently code the transcribed interview data. They met and compared the codes, and developed the code-book with definitions of each code. Using the agreed-upon definitions, the data were re-coded and organized into categories.

Results:

We found the challenges in engaging people with autism and facilitating team collaboration in three major phases of transition planning---identifying interests, goal setting, and progress monitoring (see Figure 1). First, to better understand the interests and preferences of individuals with autism, we found the needs of visual and experience-based communication methods as well as the needs for hearing from team members who know various aspects of the individual. Second, to set realistic goals, it was important to support for collaborative goal setting and also show gaps between reality and dream goals. Finally, we needed effective ways to engage both people with autism and team members in progress monitoring toward the goals.

Conclusions:

We suggest several different technological design recommendations to address the difficulties that people with autism and their transition team face in transition planning. First, we suggest a visual and experience-based communication technology that can help people with autism effectively experience each occupation and discuss their preferences with their team. To help setting realistic goals, we recommend developing the online employment portfolio repository that leverages crowd experience to create both feasible and challenging employment goals and plans. Finally, we suggest collaborative monitoring technology to support progress tracking toward employment goals with the transition team.

**446.025 (Poster)** Using Virtual Reality to Investigate the Effect of Autistic and ADHD Traits on Visual Processing and Executive Function Patterns

**S. Savickaite**<sup>1</sup>, E. Gaillard<sup>1</sup>, N. McDonnell<sup>1</sup> and D. R. Simmons<sup>1</sup>, (1)School of Psychology, University of Glasgow, Glasgow, United Kingdom, (2)School of Philosophy, University of Glasgow, Glasgow, United Kingdom

---

**Background:**

Autism Spectrum Disorder (ASD) and Attention-Deficit Hyperactivity Disorder (ADHD) are neurodevelopmental conditions often characterised by a local bias in visual processing and difficulties with executive functions, such as planning and working memory. These difficulties have previously been experimentally assessed using the Rey-Osterrieth Complex Figure (ROCF) task, an extensively used neuropsychological tool in which drawings of a complex figure (first copied and then re-drawn from memory) are analysed. Several theories have been proposed to explain and challenge the local visual bias in ASD, including, but not limited to, Weak Central Coherence (WCC) and Enhanced Perceptual Function (EPF). Building on our previous pilot work (INSAR, 2020) we investigated visual processing and executive function patterns in a novel Virtual Reality (VR) version of the ROCF task.

**Objectives:**

The aim of this study was to analyse drawing performance in a VR environment using a combination of personality questionnaires and screen captures of participants' viewpoints.

**Methods:**

92 (39 male, 53 female) neurotypical participants (average age 22.5) filled in AQ (Baron-Cohen et al, 2001), ASRS (Kessler et al, 2005) and SQ (Baron-Cohen et al, 2003) questionnaires and then a standard ROCF task (i.e. Copy, Immediate Recall and Delayed Recall) was completed in Virtual Reality. Organisational (Hamby et al, 1993) and perceptual (Booth, 2006) scoring systems were used to quantify emerging visual processing and executive function patterns. These patterns were quantitatively compared to "ideal" stereotypical sequences by calculating the inner product. The order in which elements of the ROCF were completed was visualised and compared to these ideal sequences (Figure 1).

**Results:**

Although significant differences were not found in the drawing tendencies of participants with differing levels of autistic and ADHD traits, drawings scoring higher on the organisational scale were systematically linked with higher performance rates. Higher ROCF organisation predicted better performance for both recall conditions. Matrices illustrating the order of figure completion were compared between the experimental conditions (Figure 2).

**Conclusions:**

Our study offered several innovative ways of visualising and evaluating VR data: matrix plots of drawing sequences and data-driven pattern identification approaches. This new approach supported other empirical findings that organisation is a predictor of performance in the ROCF task. The organisational level is thought to correlate with executive function abilities, but, surprisingly, we did not identify significant performance differences in neurotypical participants with differing levels of autistic ADHD and Systemizing traits. Consequently we have no evidence to confirm that visual processing and executive functioning biases vary with these personality trait levels. However, modification of the task to suit VR better, and recruitment of diagnosed autistic participants are the next steps in identifying what the visual processing and executive function patterns we have identified really mean.

## Technology Demonstration / Devices

### POSTER SESSION — TECHNOLOGY DEMONSTRATION / DEVICES

#### Poster 447 - Technology Demonstration / Devices Posters

**447.002** (Poster) Innervoice: Smart Communication for Autism  
*L. J. Brady, iTherapy, LLC, Martinez, CA*

Background: Autism Spectrum Disorder (ASD) is a leading causes of communication disorders. Acquiring functional language abilities can be difficult depending on the severity of the disorder. Those who are minimally to non-verbal face great challenges when participating in daily communication. Effective communication relies not only on words but on tone of voice and facial expressions. The ability to express emotion through one's tone of voice, or prosody, clarifies the communicative intent behind a spoken message. While there are augmentative and assistive communication (AAC) systems that allow a person to communicate using digitally synthesized speech, these voices are monotone and can be readily identified as computer generated. To be more effective, AAC products must convey emotions through prosody and have the ability to video-model a user's facial expressions to convey happiness, sadness, or anger.

Objectives: As a solution to the current limitations in AAC technology, *InnerVoice*, a therapeutic communication platform that utilizes VSM to express emotional content through an intuitive interface and which incorporates contemporary user experience (UX) elements that help individuals quickly find content and begin to communicate. *InnerVoice* will be the only communication technology on the market to use the highly effective, evidence-based technique of video self-modeling, which can not only speak for nonverbal individuals but also show them how to speak for themselves by demonstrating how the face and mouth move to form words within a conversation. In addition to speech, *InnerVoice* will feature synthesized emotional content that will convey users' feelings, making their messages much clearer and thereby minimizing miscommunication and frustration.

The core of *InnerVoice* is a 3D animated picture of an avatar; a representation of the user, the 3D avatar can be a picture of the user or any other person/character that motivates the user. The avatar displays facial expressions to convey emotional content which is combined with a synthesized voice that incorporates tone of voice. This ability to provide a fuller range of communication using a computer-mediated system will provide three distinct communication outcomes for people with communication disorders:

Methods: Provide the visual designs and the technical specifications for the facial expressions, speech animations, and user interface. Content will be created using core vocabulary and high frequency words that are meant to increase versatility in conversations.

Results: Upon completion of the R&D, we expect to demonstrate that *InnerVoice* will successfully model emotional communication and that usage will teach ASD individuals to learn how to communicate more effectively compared to other leading AAC devices. This application will stimulate interest and engagement, both of which positively impact attention and comprehension, two important foundations of learning.

Conclusions: *InnerVoice* teaches communication using a unique process called Multi-Sensory Semiotics: which pairs sensory stimuli -- anything from movements, touch, or sound -- with auditory symbols (words), visual symbols (text), or gestural symbols (sign language).

Additionally, potential for *InnerVoice* emotional response features and speech animation technology to become part of emerging fields such as virtual reality and gaming, particularly as they apply to the healthcare, education, and science fields.

**447.003 (Poster)** Interactive Elearning Modules to Support Paraprofessionals in Using Evidence-Based Practices with Students with Autism

**A. Sam<sup>1</sup>, J. R. Steinbrenner<sup>2</sup>, S. L. Odom<sup>3</sup> and V. Waters<sup>4</sup>,** (1)Frank Porter Graham Child Development Institute, Carrboro, NC, (2)Frank Porter Graham Child Development Institute, University of North Carolina at Chapel Hill, Chapel Hill, NC, (3)Frank Porter Graham Child Development Institute, University of North Carolina at Chapel Hill, San Diego, CA, (4)Frank Porter Graham Child Development Institute, University of North Carolina at Chapel Hill, Carrboro, NC

---

**Background:**

Paraprofessionals are often the primary providers of instruction to students with autism in schools. Yet, the literature suggests that minimal training is provided to paraprofessionals for implementing evidence-based practices (EBPs) with students with autism. When this training does occur, it is usually in the form of a workshop with very little follow-up from researchers (Walker & Smith, 2015).

The AFIRM team developed a set of interactive, e-learning modules designed specifically for paraprofessionals including an introduction to autism and six modules on specific evidence-based practices (reinforcement, prompting, time delay, visual cues, visual schedules, supporting peer interactions). Four of the modules are currently publicly available and free on the AFIRM website (<https://afirm.fpg.unc.edu/>), with the additional three modules to be released in Winter 2020.

**Objectives:**

1. Examine the change of knowledge gain from pre to post knowledge assessments for each module.
2. Examine the usability, relevance, and quality of the modules through collected survey data.

**Methods:** Users complete the same 10-item knowledge assessment about the content of the modules before and after each module. Additionally, users complete a survey with Likert-type questions on a 4-point scale with 4 being the highest possible rating. The survey addresses the usability, relevance, and quality of each module. Descriptive statistics were used to examine the usability, relevance, and quality of the modules. Paired sample t-tests were used to determine knowledge gain.

**Results:**

Collection of data is ongoing as new modules are released and more users complete modules. Currently, four modules are publicly available. For the Introduction to ASD module (n = 36,026 users), users pre-assessment score was 77.48 out of 100 and post assessment was 84.55. There was a similar pattern of improvement for the reinforcement module (n = 11,094 users, pre-assessment score = 57.03, post assessment score = 66.41), prompting (n = 5,941 users, pre-assessment score = 64.61, post-assessment score = 76.42, and time delay (n=1,194, pre-assessment score = 45.49, post assessment score = 58.12). Significant change from pre-assessment to post-assessment occurred for all modules at the p<0.001 level. The mean effect size was 0.52 across modules and ranged from 0.45-0.60 for individual modules. The quality of the modules were rated highly ranging from a mean of 3.43 to 3.52. Users rated these modules as relevant to the work they do ranging from a mean of 3.42 to 3.54. Users found the modules useful ranging from a mean of 3.40 to 3.50. Data collected through March 2021 will be added to the findings.

**Conclusions:**

Initial findings indicate that AFIRM users find these new modules to be relevant to their work, useful, and the quality of the modules high. Users increased their knowledge on content presented from pre-assessment to post-assessment. The information available through these modules is part of a process for supporting practitioners' use of practices having evidence of efficacy with children and youth with autism. Additional support through coaching and on-the-job feedback may be necessary to move the practice into sustained use with fidelity when working with students with autism.

**447.004 (Poster)** Making Data Collection on Autism Programs Easier and More Motivating: Development of a Novel Data Collection App Incorporating User-Centered Design and Behavioral Economics Insights

**H. J. Nuske, J. Buck, B. Ramesh, E. Becker-Haimes, K. Zentgraf and D. S. Mandell,** Penn Center for Mental Health, University of Pennsylvania, Philadelphia, PA

---

**Background:** Despite the importance of data collection on autism treatment programs for evidence-based programming, many one-to-one behavioral support workers (1:1s) do not systemically collect quantitative data on child behaviors. Two significant barriers limit current data collection practices: 1) use of labor-intensive paper-and-pen data collection methods that do not easily

allow for behavior tracking over time or sharing of data amongst team members, and 2) the solitary nature of one-to-one work, which limits opportunities for timely supervisor feedback. We incorporated principles from behavioral economics to address these two barriers, as well as several user-centered design approaches to ensure a match between the app and the environment through incorporating stakeholder feedback each stage of the design process.

**Objectives:** Our app addresses these barriers by: 1) making it easier to collect data with a server-based digital interface including a smartphone app and web portal, and graphing features for child behaviors, and 2) providing individualized in-session pop-up reminders and between-session tailored feedback via text messages on data collection performance, including comparison charts to agency averages and expectations.

**Methods:** First, we conducted a community-based innovation tournament involving 11 1:1s to gather ideas on solutions to make data collection easier and more motivating. Second, we conducted 7 observations and 9 interviews with 1:1s and 7 interviews with their supervisors to better understand the barriers and facilitators to data collection on autism programs. Third, we integrated behavioral economic principles with community feedback to develop a prototype that we are testing with 1:1s to iteratively improve it (2/4 testing cycles completed so far involving 10 1:1s). See Figure 1 for the app design and current prototype. We will test the app in an RCT in spring, 2021.

**Results:** Participants in the innovation tournament, observations, and interviews all cited the chaotic environment as a primary barrier to data collection and issues with team communication around treatment planning. Many spontaneously (i.e., without knowing about the novel data collection app idea) expressed enthusiasm for a digital data collection system. Our initial data suggest that 1:1s find the app: 1) usable, feasible, acceptable, and appropriate to support data collection, and 2) an improvement on current practices. 1:1s also provided 17 discrete suggestions for improvement; 11 were actionable suggestions, including three new app features (e.g., interval data collection form), seven feature modifications (e.g., numeric type-in option for behavior frequency), and one flow modification (deleting a redundant behavior form submission confirmation). Six other suggestions were not actionable (e.g., were in contrast with the core project's aims to incorporate motivational messages grounded in behavioral economic theory, or were outside the project scope to create an app for 1:1s and not youth).

**Conclusions:** Results support the continued development and testing of the novel app for data collection on autism treatment programs. The presentation will include a technology demonstration of the app whereby attendees will be able to "take data" on a videotaped session of a child with autism using the live app.

**447.005 (Poster) Mobile and VR Technology to Find and Support Individual Needs**

*V. K. Korhonen<sup>1</sup>, S. Merilampi<sup>2</sup>, K. Toivonen<sup>2</sup> and M. Virnes<sup>1</sup>, (1)Autism Foundation Finland, Helsinki, Finland, (2)Satakunta University of Applied Sciences, Pori, Finland*

---

### **Background:**

Since the 1970s research has found a preference for the use of technology by autistic individuals. However, individual presentation of autistic traits and support needs are also prevalent. Hence it is imperative to design different avenues for providing support whether they are based on technology or not.

### **Objectives:**

The objective is to provide alternative designs for supporting autistic individuals with 1) a mobile game called Spiral for self-evaluation of functional status and 2) virtual reality and 360-video production for relaxation, training and structuring environments.

Spiral game was originally developed as a "roll-a-dice-type" board game for group sessions. The idea is to encourage to self-evaluate own functional status and to identify areas of personal development. The game contains question cards covering different aspects of functioning and allow players to evaluate themselves. The question cards' answers are discussed with other players. The first player at the finish line wins.

Mobile Virtual reality (VR) technology has shown potential use in health and social care. VR can be used to provide realistic experiences in a safe environment. It is becoming inexpensive and easy to use. The content creation does not necessarily require programming skills. This creates an opportunity to develop personalized content for relaxation, training and structuring different everyday scenarios.

## Methods:

An iterative, multidisciplinary development process started by technology knowledge transfer. In both cases early-stage-prototypes targeted for other user groups were presented to care professionals to visualise the potential of the used technology. The production of the prototypes was also discussed to boost the ideation. Each development cycle contained demo testing by care professionals or end-users. The feedback was used in development of the next demo version.

## Results:

A single player mobile game was produced that mimics the original game. The forest theme was copied from the board game to keep the brand consistent. The player's avatar is navigated through forest while picking berries as in the original game. Fifteen questions were selected as mobile games are played for a shorter time. The professionals selected the questions to cover all important areas. A slider was used (worst to best options) to evaluate their own status. In the end, the player selects three most important development goals to be further processed with professionals.

For the VR, videos were filmed with 360-camera. The scenarios and video production were first made by the researchers, and in the later development cycle, by care professionals with the users. The scenarios were selected based on the individual need of autistic individuals for relaxation purposes as well as for training and structuring different scenarios.

## Conclusions:

Preliminary experiences are encouraging but the development is still on-going and larger group of users will be involved in testing and further development. Spiral game will be further gamified by leveling and other game features. Further VR-content will be developed with users and care professionals. Next steps also include development of services which utilize the developed technology demos.

**447.006** (Poster) Socialmind- a Digital Trainer for Parents of Children with Autism

**K. Sagiv**<sup>1,2</sup> and **G. Levy**<sup>3</sup>, (1)KerenOr, Carcur, Israel, (2)SocialMind Ltd., carcur, Israel, (3)tzafirim 9, SocialMind Ltd., carcur, Israel

---

Background: In many countries, there is a substantial time gap between the time of autism diagnosis and the time of starting the intervention. This period is critical for development and has great potential for early intervention. Many studies have found that parents of children with autism can learn to implement interventions, and help their children develop. The parents, therefore, if given the tools, can serve as agents of change for their children in this critical gap period. However, there are many challenges in the process of effectively training parents, ranging from a shortage of professionals, high costs, and in these complicated times of COVID-19 also physical accessibility.

### Objectives:

The purpose of this study is to examine the effectiveness of a "digital trainer" in training family members of children with ASD to implement components of evidence-based interventions and promote their child's language and communication skills. The study will utilize a digital trainer developed as part of a project called "SocialMind", aiming to democratize evidence-based treatment and increase its accessibility in the community.

### Methods:

The study will involve a 10 children 12-week case-control study in which we examine the efficacy of evidence parent training through a digital trainer in targeting functional use of communication in young children with ASD.

### Primary Outcomes:

Children's progress will be assessed during a 10-minute structured observation at baseline and week 12. During the structured observation, parents are instructed to try to get the child to communicate as much as possible. Raters will tally the children's frequency of functional utterances, the average length of utterances, and types of utterances (ie, unintelligible, imitative, verbally prompted, nonverbally prompted, or spontaneous), and frequency of responsive and initiative shared attention. In addition, parental fidelity of implementation is assessed and coded.

### Results:

data were collect by a pilot of 11 children through digital training and tele-health

| <b>Attention</b>                          | <b>7.29</b>  | 2.25      | <b>8.52</b>  | 2.44      |
| <b>Number of opportunities/ 10 min</b>    | <b>29.70</b> | 12.54     | <b>44.09</b> | 28.42     |

The data of 10 children that their parents used digital training with no tele-health support will be published in January 2021.

Conclusions:

We should collect more data in a randomized control trial. The pilot study results suggest a promising direction for parent training and children's progress.
